James H. McCall

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, F.L.S., Author of "Alpine Flowers," etc.

"YOU SEE, SWEET MAID, WE MARRY
A GENTLE SCION TO THE WILDEST STOCK;
AND MAKE CONCEIVE A BARK OF BASER KIND
BY BUD OF NOBLER RACE: THIS IS AN ART
WHICH DOES MEND NATURE; CHANGE IT RATHER: BUT
THE ART ITSELF IS NATURE."—Shakespeare.

VOL. XII.—CHRISTMAS, 1877.

v. 12

TO

JAMES McNAB,

Curator of the Royal Botanic Gardens, Edinburgh,

THIS TWELFTH VOLUME OF "THE GARDEN" IS DEDICATED

IN RECOGNITION OF HIS LONG AND FRUITFUL SERVICES

TO HORTICULTURE.

M.

INDEX TO VOLUME XII.

A.

Abelia floridunda, 30
Abies canadensis pendula, 437; Dou-
 glasi, 71; Englemanni, 71, 226;
 Menziesi, 71
Abutilon Lemoinei, 194; roseiflorum, 697
Abutilons, culture of, 133; notes on,
 215
Acacia Farnesiana in perfumery, 308;
 Parasol, 405
Acacias, culture of, 134
Acantholimon glumaceum, 56
Acanthus Candelabrum, 292
Acer dasycarpum, 128, 226
Achillea tomentosa, 417
Achimenes in boxes, 80
Acis autumnalis, 271
Aconite, winter, 298
Aconitum Napellus, 362
Actæa spicata, 362
Adiantum glaucophyllum, 398
Adonis autumnalis, 131
 Adulteration of Seeds Act, the, 529
Aerides crassifolium, 29; odoratum,
 in Covent Garden, 30; virens, 106
Æsculus californica, 204, 226
Agapanthus, the double, 30
Agave americana, 396; Celsiana, 213;
 densiflora, 336; Miradorea, 30;
 Scolymus, 397; Yuccaefolia, 593
Ageratums, Countess of Stair, in winter,
 580; improving, 536
 Agricultural Hall floral decorations, 199
 Air roots on the Vine, 276
 Alder, black, 562
 Alexander Palace Fruit Show, 267;
 Rose Show, 27
 Algeria, flower culture in, 490; the
 Encalyptus in, 313
 Alkali or charcoal, 33
Allamanda Hendersoni, 416
Allamandas, flowerless, 75; in Dorset-
 shire, 103
 Almond, the Dwarf, 273
 Almonds at Santa Rosa, 20
Alnus oregona, 593
Alocasia metallica, 467; Thibautiana, 28
Amarantusea, globe, 419
Amaryllis Ackermanni out-of-doors,
 343
 America, Lee's Prolific Currant in, 118
 America, the Pomegranate in, 255
 American blight, cure for, 457
 American Senna, 399
 American Water Weed, 340
Amorphophallus Rivieri, 374
Ampelopsis Veitchi, 202
Amygdalus nana, 273
Anchusa capensis, 69
Andromeda arborea, 175; floribunda,
 formosa, 424; japonica, 424
Androsace lanuginosa, 399; sarment-
 osa, 488
Anemone appennina, 83; japonica, 295;
 344, 402; ditto, notes on, 215; ditto
 alba, 247, 347; nemorosa, 83; Pula-
 tilla, 83; "Robinsoniana," 545, 670;
 the wood, 83
 Anglesey, plants in bloom in, 534
Angræcums, notes on, 523; bilobum,
 593; sesquipedale, 592

Annuals at Chiswick, 124; August-sown,
 178; notes on, 91
Anomatheca cruenta, 53
Antiaris toxicaria, 407
Antirrhinums, 151, 402; dwarf, 296;
 late blooming, 419; treatment of, 313
 Antrim, frosts in, 364
 Ants, red, 172
Aphelandra fascinator, 560
Aplopappus alatus, 74
 Apple, Cobbett's Fall, 276; Lady
 Henuiker, 440; Small's Admirable,
 124; stone, 33; in Kent, 274; Wor-
 cester Pearman, 344; a few good,
 569; American, 483, 533; best crop-
 ping, 150, 360, 457; Cellini, 124; extra
 growth in, 457; for England, 74;
 gathering, 350; hardy, 176; ditto in
 Rutlandshire, 386; importations of, in
 1773, 393; keeping, 412, 457; storing,
 283, 457; sweet, 359; in Dorsetshire,
 367
 Apple culture in brief, 368
 Apple grub, remedy for, 473
 Apple trees, miniature, 247; Mistletoe
 on, 601
 Apricot, culture of the, 564
 Apricot disease, 231, 601
Aquilegia, the, 3, 283
Aralias, culture of, 133
Araucaria imbricata at Kew, 125
Araucarias, Scotch seedling, 198
 Arboretum, the Edinburgh, 8; Segre-
 ianum, 320; the Arnold, 663
 Arboricultural Society, Scottish, 459
Arbutus Unedo, 511
Aristolochias, the best, 329
 Armenia, mountain flowers in, 1
 Artichoke, the flake, 107, 293; Jerusalem,
 history of the, 48; effects of ditto in
 rheumatism, 36; origin of, 238;
 flowering, 178, 185
 Artillery plant for windows, 193
 Art studies, 256
 Arums, tropical, at Kew, 207
Arundinaria falcata, 65, 269, 405
Arundo conspicua, 533
Asclepias, hardy, 155
 Ash, Mountain, berries, 224; trees,
 splitting, 32
 Ashes, coal, in the garden, 368
 Asparagus, culture of, 12; early with-
 heat, 413; forcing, 248; in rheumatism,
 36;
 Asphalt, poisonous fumes from, 340
Aspidistra lurida variegata, 134
Aspidistras and their fertilization, 257
Aspidium fragrans, 176
Aster ericoides, 439; grandiflora, 570;
 pendulous, 439; Quilled, Novelty,
 314
Asteriscus mauritanicus, 209
 Asters, late flowering, 369; notes on,
 13; Quilled, 339; Tasseled, 296
 Athole, forests of, 343
 Aucubas for market, 497
 Audley End, 56
 August, 198
 Auriculas in pots, winter treatment of,
 492; notes on, 13, 67, 171, 243; show,
 347;

Avenue, Poplar, 561
 Azaleas, English grown, 344, Indian,
 221; new, 488

B.

Baccharis halimifolia, 436
 Balsams, Sardinian, 56
 Bamboo, remarkable growth of, 407
 Bamboos, curious seed bed for, 405;
 hardy, death of, 65; mountain, 476;
 square-stemmed, 203
Bambusa arundinacea, remarkable
 growth of, 490
 Bananas cracking, 75
 Banbury, cultivation of medicinal
 plants at, 4
 Bark, spent, for mulching, 200
 Barnet, Cucumbers at, 198; Grapes at,
 197; Melons at, 198; Nectarines at,
 197; Peaches at, 197; Strawberries at,
 193
 Barometrical flowers, 10
 Basil, the Sacred, 208
 Bathing places, 318
 Battersea Park, 223; bathing in, 318;
 Bean, Flageolet, 391; the Sacred, 103;
 the Tonquin, 232
 Beans, dwarf French, 186; French, for
 forcing, 369; ditto winter, 414; ditto
 late, 163; ditto two, 391; in paraffin,
 dipping, 107; Runner, 186
Beaucarnia longifolia suspended, 443
 Bedding plants, wintering, 519; select
 604
 Bed straw for carpeting, 29
 Beds cocked up, 347
 Beech tree caterpillars, 292
 Bees and fruits, 20
 Beet, storing, 336
 Beetle, Colorado, 392
Begonia Froebelii, 376, 513, 545, 604; Mo-
 narch, 75; Mrs. Charles Scorer, 75;
 natalensis, 451; Octopetala rosea,
 545; Queen of the Whites, 194; Star-
 light, 440;
Begonias at Chiswick, 123; at Pine-
 apple place, 103; hardy, at Chelsea,
 78; in winter, 311; new tuberous
 rooted (1877), 341; three good, 330;
 tuberous-rooted, for bedding pur-
 poses, 202; tuberous-rooted, notes on,
 39; tuberous-rooted, out-of-doors, 202
Belladonna at Hitchin, 410
Belladonna Lily under glass, 318
 Bellow's Dictionary, 337
Berberis vulgaris, 362; Wallichii, 273
Berkheya purpurea, 56
 Berkshire, Musa Ensete in, 177
 Betony, white, at Hampstead, 223
 Beverage, a new, 350
 Biennials and perennials, 38
Bignonia radicans, 327, 349; venusta,
 finely-flowered, 488; tree, a, 190
 Birch, the cut-leaved, 138
 Bird-cherry tree, an old, 47
 Bird destroyers, 36
 Birds, protection of, 196; small, and
 cats, 21
 Bird's nest in a human skull, 133

Birds' nests in hothouses, 58; robbing,
 219
 Birmingham, park for, 534
 Birthworts, the best, 32
 Blackberries, American, 276, 316
Blechnum spicatum trinervium, 319
 Blossoms in Shakespeare, 278
 Blumenthal, flowers at, 22
Bocconia cordata, 203
 Boiler, portable, 133; Wright's flame-
 compact, 21
Bolbophyllum odoratissimum, 593
 Bomarea Carderi, 440
 "Book about Roses," 290
 Borders, floral effects in, 34; herbaceous,
 518
 Botanical Fete, Maida Vale; Regent's
 Park, 1
 Botanic garden, new, at Hull, 103
Bougainvillea glabra in autumn, 421;
 spectabilis, 80
Bouvardia Humboldtii corymbiflora,
 199
 Bouvardias and how to grow them,
 442; for market, 149; in autumn,
 416; planted out, 519
 Box edging, 185
Brabea filamentosa, 63
 Brake, the common, 486; eradicating,
 680
 Bramble, Parsley-leaved, fruit of the,
 255
 Brambles at Cambridge, 419
 "Breeze" as hothouse fuel, 510
 Bridge, a natural, 167
 Brittany, scene in, 333
 Broccoli, Snow's, 391; Veitch's Self-
 protecting Autumn, 107, 127, 555, 579;
 winter, 127; winter and spring, 409
 Brook, a rocky, 7
Browallia alba, 106; elata, 106; Roezli,
 244
 Brugmanias planted out, 11, 380
 Brussels Sprouts, 361; Dalmeny, 530;
 fly on, 192; large, 463; over-grown,
 458
 Buckeye, the Californian, 204, 226
 Buds in Shakespeare, 278
 Buildings, over-decoration of, 439
 Bulbs, depth to plant, 361; hardy,
 planting, 227; potting of, 312; spring,
 255; treatment of, 675
 Burghley, fruit crops at, 56
 Bush fruit in Kent, 357

C.

Cabbage, sowing for spring, 68; St.
 John's-day, 458, 481
 Cabbage beds, old, 163
 Cabbages, culture of, 340; planting,
 315; spring, 244; spring, notes on,
 107
 Cacti in South Africa, 77; Old Men,
 30
 Cactus, Tooth-pick, 501; Turk's-cap,
 443
 Oalanthes and Palms, 493
 Calceolarias, bedding, cuttings of, 349;
 culture of, 239; herbaceous, 13; notes
 on, 114, 216; wintering, 393

- Calla (Richardia) zethiopica in winter, 311
 Callicarpa gracilis, 622
 Callirrhoe macrorrhiza alba, 69
 Caltha palustris, 287
 Calycanthus occidentalis, 438
 Camellia leaves, striking, 184
 Camellias, treatment of, 615
 Campanula flexuosa, 175; macrostyla, 65, 209; pyramidalis, 201; culture of, 265; Vidali, 247
 Campanulas, 492; tall and dwarf, 445
 Canary Creeper and Clematis, 376
 Candytuft, carmine-flowered, 123; Sander's, 204; Tom Thumb, 145
 Canna iridiflora, 126, 199
 Canon Kingsley's garden at Eversley, 498
 Canterbury Bell, 455; notes on, 39
 Capier-plant, the, 181; hardy in England, 193
 Capparis aphylla, 162; spinosa, 181
 Capsicum, the, culture of, 194
 Carica candamarcensis, 104
 Carlisle International Exhibition, 266
 Carlisle, International Show at, 223
 Carnation and Picotee Society, 76
 Carnations, border, 162; from cuttings, 259; in leaden cups, 228; notes on, 114, 166; propagating, 79; select, 400; treatment of, 349; Tree, 233, 618; Tree, in winter, 310; Tree, plauted out, 224
 Carpet bedding, 248, 459
 Carriage crop, the, 424
 Carrot, James's Intermediate, 184
 Carrots, culture of, 111; 213; Early Horn, 35
 Cas Cram, or plough, 553
 Casimiroa edulis in Ireland, 458
 Cassia corymbosa, 66; marylandica, 399
 Cassie, use of in perfumery, 308
 Castilleja indivisa, 61
 Castor-oil leaves and grasshoppers, 409
 Casuarinas, the, 233
 Catalpa, a fine grown, 263; durability of, 23; in October, 367; the golden, 363; the, in London parks, 151
 Caterpillar nest-destroyer, 538
 Cats and small birds, 21
 Cattleya exoniensis, 610; gigas, a winter flowering plant, 468
 Cattleyas at Chelsea, 463; select, 448
 Cauliflower, early Snowball, 414
 Cauliflowers, culture of, 162; frame, 336; notes on, 163; winter, 315
 Caves covered with Ivy, 33
 Celery, blanching in spent tan, 364; culture of, 283; late blanching, 315
 Celosias for chuch decoration, 388
 Centaurea americana, 224
 Centaureas, culture of, 134; propagating, 155, 201, 232
 Cerasus ilicifolia, 123
 Cercis japonica, 263
 Cereus, a large-flowered, 148; candelans, 467
 Celtis occidentalis at home, 232
 Chamaedora Ernest-Angusti in bloom, 610; glaucifolia, 687
 Chamaerops excelsa in Cornwall, 352; Fortunei at Alderley, 36
 Charcoal or alkali, 39; wood for, 459
 Chelidonium, the, from seed, 433
 Chelsea, Barry Begonia at, 73; Lapagerias at, 271; Lilium auratum at, 247; Pitcher-plants at, 271
 Cherry-apples, 668
 Cherry, May Duke, origin of name, 173
 Cherry tree wild in Ireland, 374
 Cherries, culture of, 91; from France, 1; in Kent, 333
 Chestnut, Golden, in Scotland, 223; the Water, 23, 339
 Chestnut trees, mortality of, 206
 Chocory, 543
 Chilianthus californicus, 206
 Chinese Cypress, 561; plants, drawings of, 103; vase, 591
 Chirita sinensis, 519
 Chiswick, flower trials at, 219; fruit trials at, 219; vegetable trials at, 219
 Choisy a ternata, 232
 Christmas dinner-table, 561
 Christmas Rose, large-flowered, 462
 Christmas Roses, 288, 512, 558; culture of, 265; Madagascar, 357; out-of-doors and under cover, 545; protecting, 488
 Christmas trees, 533
 Christmas vegetables, 602
 Chrysanthemum frutescens, 255; Falton, 555; Golden Empresa of India, 555; Précoceité, 559
 Chrysanthemums, a few of the best, 497; at Hackney, 610; at Kingston, 574; at Liverpool, 574; culture of, 113; early, 247; Japanese, 535; grafted, 175; in London, 418; in pots, 243; in winter, 311; notes on, 187; Poinpoue, 488; summer flowering, 516; treatment of, 432; white, 448; ditto, at Christmas, 466
 Church decoration, 364, 461
 Cibotium pruinatum, 565
 Cinerarias, culture of, 239, 575; in winter, 311; notes on, 187
 Cissus porphyrophylla, 441
 Citronella, 495
 Citrons, otto of, 477; in Devonshire, 533
 Citrus, peculiar varieties of, 421
 Clapton, Cape Heaths at, 272; Orchids at, 272
 Clematis and Canary Creeper combined, 376; cirrhosa, as an anti-epileptic, 193; flava, 344
 Clematis, the genus, 400; Vitalba, 83
 Clematisea and Roses mixed, 399; at Kew, 256; groups of, 173; in autumn, 247; on trees, 520
 Clethra alnifolia, 328
 Clitanthus panicus at Edinburgh, 5
 Climbers and rats, 350; hardy, 556
 Cloches, 643
 Clove, Mrs. Matthews, 75
 Cloves, border, 162
 Cochlostema Jacobiana, 223
 Cock's-foot, Yellow, 81
 Cocoa-nut as a medicine, 236
 Cocos australis, 392
 Codling moth, remedy for, 473
 Coffee as an antidote to Strychnium, 307
 Colchicum nudiflorum, 295; speciosum, 295, 344; vallicola, 295
 Colchicums and Crocus speciosus, 417; double, 418, 440; seeding without flowering, 339
 Coleworts, planting, 186
 Collomia grandiflora in Germany, 376
 Colorado Potato Beetle, 78, 104, 223; at Liverpool, 50
 Columbines, the, 8, 288
 Combination, a pretty, 175
 Combretum purpureum, 191
 Comfrey, the, 109; variegated, 65
 Compass-plant, the, 296, 644
 Complaint from a Lady-bird, 170
 Conifera littorea, 198
 Coniferous tree, slow growth and durability of, 497
 Conifers in Somerset, 152; propagating, 31
 Conservatories, sizes of large, 435, 443
 Conservatory, Chatsworth, 435
 Contrast a pretty, 73
 Convolvulus mauritanicus as a basket plant, 490
 Coprosma Baueriana variegata, 134
 Cornwall, Deodars not coming in, 289; Lomaria procera in, 103; trees in, 273
 Coronilla glauca, 592
 Corsican Pine, sowing, 604

J A M E S M c N A B .

JAMES McNAB, the present Curator of the Royal Botanic Gardens, Edinburgh, was born at Richmond, in Surrey, in April, 1810, and was taken to Scotland when five weeks old. For twelve consecutive years before 1834, he served as an apprentice, journeyman, and foreman in the Edinburgh Botanic Gardens with his late father. Besides the general routine of garden work, his early life was much devoted to the preparing of plans of gardens, greenhouses, heating apparatus by steam and hot-water, as well as to the drawing of many of the plants which flowered in the Edinburgh Gardens and Nurseries from the year 1829 and onwards. These were figured in the "Botanical Magazine," Sweet's "British Flower Garden," and other works. The year 1834 was spent in travelling in the United States and Canada, and the records of the more interesting plants obtained in this journey are to be found in a series of papers published in the "Edinburgh Philosophical Journal" for 1835, and in the earlier numbers of the "Transactions of the Edinburgh Botanical Society." In 1835 he was appointed Curator of the Caledonian Horticultural Society's Experimental Garden at Inverleith, where, besides the management of the garden, he had much practice in landscape gardening. This situation he held till 1849, when, on the death of his father in December, 1848, he was appointed Curator of the Royal Botanic Garden. At that time the garden contained only fourteen imperial acres. During 1859 two additional acres were added to its western side, and these were laid out and planted by Mr. McNAB. During 1864, by the annexation of the old experimental garden ground which belonged to the Crown, ten additional acres were added to the Botanic Garden, and re-arranged by the Curator for Conifers and other evergreen trees and shrubs. On the additional ground a rock garden was commenced in the autumn of 1860, in order to utilize the stones of the wall which originally separated the botanic from the experimental garden. This rock garden contains 5442 stone compartments or spaces for the cultivation of Alpine and dwarf herbaceous plants. To this rock garden additions have been made every year since its commencement. At first, all the plant compartments had more or less a northern exposure, but now many portions of the southern Grass slopes have been devoted to the culture of bulbous and other plants that require their roots to be thoroughly ripened for flowering, and the result has been in every way satisfactory. During the present year, twenty-six additional acres have been acquired by the City of Edinburgh, in order to be laid out as a general arboretum. This ground lies immediately to the west of the present garden, and is well adapted for arboretum purposes, being beautifully situated and commanding one of the finest views of Edinburgh from the north, besides affording great protection to the present garden. In addition to the extensive practise of gardening, Mr. McNAB has often been a contributor to horticultural literature, as his writings, not only in THE GARDEN, but also in the transactions of the Botanical Societies of Edinburgh and elsewhere, amply show. He did not, however, confine himself to strictly botanical and horticultural matters; on the contrary, his writings embrace numerous essays on Vegetable Climatology, landscape gardening, and arboriculture, all of which, if gathered together, would form many volumes. He is a corresponding member of several societies, both at home and abroad; also one of the original members of the Edinburgh Botanical Society, established February 8, 1836, to the transactions of which he has been a frequent contributor ever since their commencement.

Among the various features of the Edinburgh Botanic Garden which we owe to Mr. McNAB's skill is the Palm-house, which is most satisfactory from the point of view of design, and still more so from the admirable cultivation and arrangement shown in it by the Curator. If size only is not to guide our judgment, we must pronounce this the best-managed tropical house (both from the point of view of design, arrangement, and culture) of any in the botanic gardens of the United Kingdom.

Not less satisfactory are the collections of hardy herbaceous plants, Alpine flowers, shrubs, and trees in the garden. Mr. McNAB is among the faithful few who never deserted the beautiful hardy flora of our gardens for the famous red and yellow streaks that sometimes disfigure even our great botanic gardens. The Edinburgh Botanic Garden was always a garden, even during the most dismal period of the absence of variety in gardens. Therefore, when the tide began to turn back to pure gardening, Mr. McNAB found his reward in richly-stored collections of the finest hardy plants. His knowledge of these in such a national garden is most precious. It comprises the culture and habits of the plants, in addition to a mere acquaintance with their names and relationships. To enter, however, into the various departments of the garden which owe their riches in great part to long years of unwearyed attention on the part of the Curator, is beyond the scope of the present note. It has been part of our plan to publish a portrait of a horticulturist who has done worthy work for our art with each volume. For this one we could think of none more worthy than JAMES McNAB.

W. R.

THE GARDEN.

VOL. XII.

PIGMY LILIES.—It is not only the tall and stately Lilies which recent years have added to our gardens that give new and valuable materials to the flower gardener—the dwarf races are no less precious. We do not mean by this diminutive Lilies like *L. tenuifolium*, fine as these are, but the much dwarfer forms of *Lilium Thunbergianum*, particularly the variety *alutaceum*. The remarkable value of these arises from the fact that the flowers are as large as the stoutest of the Orange Lilies, and the stems as dwarf as those of Cowslips. There are sheets of those now in Ware's nursery with large and glowing blossoms below the level of some of the dwarf Hairballs near. It is needless to add that these dwarf Lilies are very precious to all who wish to make artistic use of hardy flowers on the rock garden, or in borders or beds.

A SPLENDID ESCHSCHOLTZIA.—From a gardening point of view sometimes a new form may be a greater gain than many new species. A new variety of this old plant now in possession of Messrs. Carter, of Holborn, really deserves the above hackneyed epithet. The flowers, instead of being of the usual colour, are of a most brilliant orange-crimson outside, and deep orange within. The buds are particularly brilliant, but in all stages the colour is wonderfully showy and lustrous.

THE BOTANIC EVENING FETE.—This was very successful on Wednesday, and the gardens looked as beautiful as usual. The various garnishings for tables, &c., were graceful, though perhaps a little too much after one style, and that a painfully tedious one to carry out; we hope few will be led by these displays to worry themselves with elaborate compositions in floral decoration. The best of all are those which anybody can make in a few minutes with a handful of flowers or a few sprays. A list of prizes will be found in our outer sheet.

ROSES ON THEIR OWN ROOTS.—The Rev. Canon Hole spoke as follows on this subject at a meeting of Rosarians which took place in St. James' Hall on Wednesday evening last:—The result of my experience is this, that the seedling Brier is the best stock for Roses, but I have a presentiment that ultimately the Rosarian will discard, not altogether but mainly, stocks of all kinds, and will grow Roses on their own roots.

MOUNTAIN FLOWERS IN ARMENIA.—In the wild and cruel work now going on in Armenia, there is little time to think of botanical subjects; but we occasionally get from correspondents a reminder of the natural wealth of flowers of the land. A writer to the "Times," speaking of the Khargar Bazaar Range, says:—There was still snow remaining on the Herman Dooz. The parts where it had

recently melted were covered with wild flowers of every hue and kind. A delicate Bluebell, such as I have never before seen, drooped gracefully at the very edge of the snow, while within a few yards a more homely-looking Bell and a delicately-tinted pink Anemone were to be seen. A large and very handsome Orchid, with Tulips of every colour, was found on the lower slopes of the mountain, and Sweet Brier, Mint, Thyme, Fennel, and wild Rhubarb were in great profusion.

CHERRIES FROM FRANCE.—Last week an immense quantity of fruit was brought into Newhaven harbour. In two days only no less than 190 tons of Cherries were unloaded at the wharf and despatched at once to London.

SPIREA ARUNCUS AND ITS FORMS.—Mr. Amos Perry calls our attention to the variability of this plant as regards stature, time and character of flowering. Some of the forms where the flowers are white and abundantly produced in beautiful plumes are so valuable that they ought to find a place in even the smallest collection of hardy plants. They are well fitted for planting in an isolated manner on the turf near beds of shrubs.

ORCHIS FOLIOSA.—This lovely early summer-flowering plant, though perfectly hardy, is exceedingly useful in pots for greenhouse or conservatory decoration. In Mr. B. S. Williams's nursery at Holloway, plants of it are grown in 9-in. and 10-in. pots, and when bearing from twenty to thirty strong spikes of rosy-purple blossoms, as one now finds them, they are very effective, especially when associated with either cool Orchidaceous or conservatory decorative plants.

STRAWBERRIES.—These have been gathered about London for the past fortnight. They promise to be plentiful in this year of scarcity as regards hardy fruits generally. The following method of keeping Strawberries fresh is recommended in the "Bulletin de la Société Pratique d'Horticulture du Rhône." The fruit should be gathered early in the morning soon after the dew is off, spread out in shallow layers on screens, sieves, or the bottoms of wicker-work baskets, and lightly covered with Vine leaves. These receptacles are then placed on vessels of fresh water in a cool cellar. Thus treated, the most delicate and perishable kinds of Strawberries will remain fresh for a considerable length of time, even in the hottest weather.

THE POTATO BEETLE DEFEATED.—Mr. E. S. Carman, writing to us from River Edge, Bergen, New Jersey, states that, as regards the Potato beetle, Paris green is so effectual a remedy, and so easily applied,

that after one becomes used to it the beetle is no longer a source of dread. A paper has been printed by the Lords of the Council, Whitehall, with a coloured engraving of the beetle life-size and magnified twice. The paper in question is the memorandum of the Canadian Minister of Agriculture sent last November, which the Lords of the Council think it desirable to reprint and circulate, as intimation has been received from Ontario, Canada, that the country around that town is swarming with beetles. London papers contain alarming statements concerning this beetle—"leaders" appearing on it in all directions. Much of this might, we think, be spared till the enemy shows some sign of threatening us. The beetle is well figured in *THE GARDEN* (see Vol. XI., p. 460).

EDRAIANTHUS DALMATIUS.—This very beautiful Campanulaceous plant is now blooming freely in Mr. Ware's nursery at Tottenham. It seems robust enough to thrive in ordinary borders.

THE WIOAN PARK COMMITTEE have received twenty-one designs for the laying out of the new park, the estimated cost ranging from £2200 to £18,000. Six have been selected for further consideration.—"Architect."

A BOTANICAL FETE AND MUSICAL PROMENADE will be held in Messrs. E. G. Henderson & Sons' conservatory in the Pine-apple Nursery, Maida Vale, on Thursday evening, July 12, in aid of the Fund for the Enlargement and Improvement of St. Mark's Church, Hamilton Terrace, N.W. The conservatory will be illuminated with gas and coloured lights, and embellished with works of art contributed by various artists.

THE TUILERIES GARDEN.—The new Rue des Tuileries, cut through the late private garden of Napoleon III., in front of the charred ruins of the Palace, was opened for traffic on Friday week. The construction of this street—an immense convenience to the Paris population—was voted by a great majority of the Municipal Council in 1875, on the motion of M. Yves Guyot.

SCUTELLARIA MOCINIANA.—This highly ornamental greenhouse plant, a coloured plate of which was given in *THE GARDEN* (see p. 606, Vol. X.), is now finely in bloom at Kew, and for some time past small plants of it may have been seen in the Centre Avenue, Covent Garden. Considering its easy culture and attractive character when in bloom, it is however surprising that it is not grown for market more extensively than it is. Cuttings of the young wood taken off in the autumn, and inserted under a bell-glass, strike readily, and if grown on liberally in a warm pit close to the glass, early in the following summer they make dwarf handsome plants, which, when in flower, are unsurpassed as regards brilliancy of colour by any other plant at this season of the year.

PUBLIC GARDENS IN NEW ENGLAND.—Boston's great scheme for the construction of an elaborate system of public gardens has been favourably reported upon by a majority of the Government Committee. The estimated cost of the proposed Charles River Embankment, the Back Bay Park, and the South Bay Park, is over £1,800,000. The committee urge that the work be begun at once, as land, labour, and materials are unusually cheap.

PRACTICAL ENTOMOLOGY.—A pamphlet has recently been printed and distributed amongst farmers and gardeners, accompanied by ruled sheets, and illustrated, for the purpose of recording monthly observations on certain selected insects, for the most part remarkable for the injury they cause to our common crops. This distribution is somewhat of an experiment, but similar observations taken by the Meteorological Society have not been without benefit, and we hope in this instance it will result in assisting to clear a somewhat vexed question, and help to relieve our agriculturists from one of the heaviest of their losses.

STRAWBERRIES IN NEW YORK.—The "New York Times" of June 1 says:—"The quantities of Strawberries sold in the markets of this city yesterday were the largest ever known. Upwards of 750,000 quarts were shipped to the markets, and all were disposed of. Thirty thousand quarts came from Charleston, while the steamer from Norfolk brought the enormous quantity of 300,000 quarts; 75,000 quarts of this shipment came from one grower. He has upwards of 200 acres in Strawberries, and gives employment to 1000 pickers. The freight bill for yesterday's shipment was over 1000 dols., and the profit from the sale of the fruit will be about 5,000 dols. About 300,000 quarts came from Delaware and Maryland, and a large quantity from New Jersey, and some small shipments were made from points along the Hudson. The prices realised on the fruit were from 5 cents to 12 cents per quart."

Outbreak of the Potato Disease.—The Potato disease has broken out in this locality to a serious extent, the first affected being the American varieties. The following are notes made after inspecting some cottage gardens this morning:—American Early Rose—

spots in leaves noticed first week in June, haulm now nearly destroyed, one-fourth of tubers effected, and very small. American Natives—leaves slightly spotted, a few of the tubers effected. Rector of Woodstock—leaves slightly spotted, no disease in tubers. Improved Ashleaved Kidney—leaves much spotted, tubers affected. Snowflake—leaves spotted, no disease in tubers. Early Red Emperor and Rector of Woodstock on same plot of ground, in rows parallel with these, but not at all affected. Bresee's Peerless—leaves spotted. Perkins' Pink Eye, Lapstone, Wilmott's Black, and Flounders grown in some garden, but not all affected.—ANDREW DONALDSON, *Stoodleigh Court, Tiverton*.

Figs Trained and Untrained.—Some are of opinion that Figs on open walls are more satisfactory left to grow wild than trained. The reason for this is obvious; the training was not suited to the requirements of the subject dealt with. I have myself seen fruit in abundance in exceptionally fine seasons on trees uninterfered with, but the crop was certainly not so regular, fine, or satisfactory as that on trees which were systematically trained so that the maximum of heat and light might reach the useful bearing wood, and the strength of the tree be directed towards its production, instead of being wasted on useless watery growth. My own impression is that no fruit tree better repays a little extra attention than the Fig.—JAMES GROOM, *Henham*.

Covering Early Vinery Borders.—Neither Mr. Baines nor myself are, I trust, actuated by the motives to which he alludes in this discussion, viz., a determination to carry the argument rightly or wrongly. I submit that I have fully stated my side of the question, and in the plainest English, to put it as shortly and concisely as possible, it is simply this, the root temperature necessary for the successful culture of the Vine cannot be sustained by the aid of non-conducting materials alone, where the roots are all outside, and where forcing is carried on throughout the winter and spring. This is the question involved and the point which Mr. Baines has hitherto evaded. I have never known good crops of early Grapes to be produced under such circumstances with any constancy or regularity—I might say, never—and Mr. Baines himself is not able to produce any such instance, for the case which he cites, near London, in which half the roots are inside, and in which there does not appear to have been any particular object in applying the non-conducting materials, cannot reasonably be offered as evidence in support of his case; and besides Mr. Baines keeps the whereabouts, &c., of the experiment a secret, while he does not hesitate to call it evidence sufficient to satisfy any unprejudiced person, and accuses me of not furnishing evidence on my side, whereas I have given him evidence of the most decided kind, the truth of which he may prove to his own satisfaction if he will try and a thermometer inserted in an outside early Vine border protected in the way he recommends will indicate a state of things wholly unnatural and most certainly injurious to Vines. This is the aspect which the question assumes in the mind of anyone who realises the force, as I said at the outset, of Mr. Baines' remarks at page 312. As I am not very anxious to have the last word, I here leave the subject.—J. SIMPSON.

The Fruit Crop in Ireland.—From what has come under our own observation and been gathered from other sources, we ("Farmers' Gazette") cannot help coming to the conclusion that the wail as regards the year's fruit crop need not be quite so despairing as we have heard it; on the contrary, we anticipate that when the wind-up of the season comes, the prophets of evil, who prematurely announced the "total wreck" of the crop, and that we would have "no fruit" this year, will have no great reason to be proud of their vaticinations. It is true that, with the exception of bush fruits, as Gooseberries, Raspberries, and Currants, and also Strawberries, all of which are up to and perhaps over the average, the crop of other out-door fruits will be considerably under it. But neither the Peach crop nor the Pear crop, the Apple, or the Apricot will be, as we were told they would be, blank. It is at all times rash to draw conclusions from particular instances. Situation, soil, shelter, habit of the tree, and other circumstances, modify greatly the results of the season as regards fruit. For instance, we have remarked that the early blooming Pears, as the Jargonelle, pulled through this year rather safely, and are carrying fair crops; so also have Pears on south walls, while later-flowering kinds are nowhere as regards a crop. Peaches will carry a crop quite heavy enough for the trees to ripen, taking into account how the foliage has suffered this year. Plums will, we apprehend, have the worst account to give of any, Pears coming next. Apples will by no means be so scarce as we were led to expect. Of some kinds and in some places the crop is even a heavy one. When we take into account that in ordinary Pears fruit thinning is not practised to one-half the extent it ought to be, we may expect that size and quality will, too, this year go far to make up for quantity.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE thirty-fourth Anniversary Festival of this Institution was held on Wednesday evening last at the "Albion," Aldersgate Street, under the presidency of Sir Trevor Lawrence, Bart., M.P., and there were also present among others Mr. W. E. Brymer, M.P., Serjeant Cox, Lord Alfred Churchill, Major Sandys, Messrs. G. F. Wilson, A. Philbrick, J. S. Bockett, Robert Wrench, H. J. Veitoh, Edward J. Beale, George Deal, John Lee, Charles Lee, John Fraser, and B. S. Williams.

The Chairman, after the usual loyal toasts had been given, proposed the toast of the evening—"The Gardeners' Royal Benevolent Institution, long may it prosper." He said that when four months ago it was proposed to him that he should have the honour of taking the chair at the thirty-fourth Anniversary Festival, he confessed that it was not without very serious misgivings that he consented to do so. He had a sense of considerable fear that owing to the inefficient way he should lay before the company the claims of the Institution, that, owing to his insufficient force in urging its great and just claims—the Institution might in some shape or other suffer. However, they all knew that there was some excuse made for people if they had their hearts in the right place; and he thought he might safely say that his was so as far as the Institution for which he was pleading was concerned. His early recollections were associated with gardening; and he did not think that, from the time that he was able to "toddle" about the room, that he had been long absent from the associations of gardeners and gardening; it would therefore be strange if the man did not grow up as the child was trained. He might say that in his great love for gardening, and for all who belonged to it, he yielded to no one. In his opinion gardening and gardeners had almost as great a claim upon the public as upon those who were especially devoted to the pursuit. He did not believe that there existed in this country even one man or one woman who had not been much influenced and attracted and delighted by the produce of the garden. The real truth of the matter, so far as this country was concerned, was that England was a country of gardens. Recently he had been talking to Mr. Walters, M.P., of the "Times," and that gentleman said that it was almost impossible to describe the delight with which he came, after a long journey amid the endless plains in America, to the beautiful hills and cultivated country of Warwickshire. And there was a somewhat similar to feeling that with travellers when they came back from northern parts of France and passed through Kent, for it was impossible for them to draw comparisons not altogether favourable to the country they had left. He wished to urge that there was no purer, simpler, and healthier taste than the taste and delight which were experienced in gardening. One of the great features of this country were its gardens. He need not ask them to go far to prove how true that was, for those who lived a great deal of their time in London had only to walk into one of the parks of this great Metropolis to see what strides had been made in gardening, so far as certain parts of the Metropolis was concerned. He did not believe that more beautiful gardens of their sort existed than those which the nation had been wise enough to give them in Hyde Park, in Battersea Park, and other parks. Anyone who compared the condition of those parks now with what they were ten years ago, must see that we have among us a great love of flowers, and that leads us to think of those who tended them and to whose skill and care we were indebted. Many of the gardens on the Continent were under the care of English and Scotch gardeners; and we believe that it was a fact that no nation had so successfully devoted itself to the beautiful productions of Nature—the flowers, fruits, vegetables, and trees—as the English, the Scotch, and the Irish. It was very common in this country to hear complaints about the climate—and he was not going to deny that there were certain features about this climate which were not altogether what we should like them to be—but he had had a good deal of experience about climates, and he was certain that if they took the climates of the countries around they would not find a climate nearly as good as that of England. They might pick two or three months in one country, and two or three in another, and out of such a combination they might make a better twelve months than they could get here, but on the whole he preferred the English twelve months. Whilst the gardeners complained that every now and then nature placed great obstacles in their way, it was all the more creditable that their skill was able to triumph over those obstacles. He need hardly remind them that the surface of this country was covered, in a great measure, with plants, fruits, and flowers, which were not strictly indigenous to the soil. They were exotic, and it was only by the care and the great skill of our gardeners that they had been naturalised in this country, by which means they had been adapted to the new conditions under which they had to live. Further than that, as exhibiting

the great skill shown by gardeners in this country, he referred to the beautiful hybrids which were continually being raised. When they came to consider what it was which made a successful gardener, he thought that they would allow that he must possess very considerable natural powers, that he must have used those powers of observation to advantage, that he must have been both careful and industrious, and that he must have employed the early years of his life to the best advantage, and the outcome of such use of his powers was the grand results produced by such persons as those on whose behalf he ventured to ask for support. From a statement which he had had placed in his hands, it appeared that the Gardeners' Royal Benevolent Institution had now been established for a considerable number of years, since 1838, and during that time it had assisted 242 persons—242 gardeners or their wives—at the cost of £21,700. It had now upon its funds 72 pensioners, and with regard to these he would ask them to look at the list, because it afforded a great deal of satisfaction to notice what a healthy man the gardener was, and that he attained to an advanced age, some of them having reached to ninety and ninety-one. £16 per annum was allowed by the Charity to a male, and £12 per annum to a female pensioner; the amount of the funded property of the Institution was £11,000, invested in Three per Cent. Consols, and he had ventured to suggest to the secretary that the money might be so invested as to produce a larger amount, but the reply was that the Act under which the Charity was registered would not allow it to be done. The income of the Charity was mainly depending upon the donations received at the annual dinner, the annual subscriptions, the money received from advertisements, and the dividend on stock, but the first—the donations received at the annual dinner—was the most important. He therefore asked them to drink the toast with all gratitude to those persons with whom they had been connected, perhaps for many years, and to whom they owed many of their purest and most satisfactory pleasures. While asking them to drink the toast with all enthusiasm, he asked them to support it with the best and most kindly intentions.

Mr. Robert Wrench (the treasurer) responded to the toast. He was glad to see Lord Alfred Churchill present; it was an example which it was to be hoped would be followed. There were many gardeners, but they would like to see their employers there. They hoped to have the Prince of Wales to take the chair some day, and when that happy occasion arrived, they might depend upon it it would result beneficially for the Charity.

Mr. Philbrick, Q.C., proposed the health of the Chairman, and referred to his great love of flowers.

The Chairman expressed his desire and willingness at any time and on all occasions to assist both the Institution and those who were engaged in gardening. He expressed his thanks on behalf of the company to those nurserymen who had contributed to the evening's entertainment by the trouble they had gone to in providing beautiful decorations of fruit and flowers and plants.

Serjeant Cox, in proposing "The Horticultural and Botanical Societies of London," said that the toast could not be omitted, for they were honoured by the presence of a vice-president of one of those societies. Those two great societies centred in themselves in this country the science of horticulture, and they showed the importance of bringing together the horticultural knowledge of the country. It was only by so doing that it could have made the progress which it had done of late years. They must all regret that one of those societies was now under a cloud, but he trusted that it would be merely temporary, and that when the cloud had passed away, the society would have before it a long life, and would be able to render even greater services to horticulture than it had done. He could not say much of the Royal Horticultural Society, because they could not conceal from themselves that its object was rather to induce a love of flowers than to give a knowledge of horticulture. Nevertheless, the Society performed a very important work by keeping before the public by its gardens the fact that horticulture was a science. But what would those societies be but for the work of the gardeners on whose behalf they were assembled on that occasion? They could do little but for those men whose power, mind, and muscle were devoted to performing the work of those societies. What would they do without the services of such men as Mr. Alfred Shurtleworth and Mr. Dornay? Those were the working men—whose hands and heads were doing the work that was centred in the proceedings of the societies to which he was referring. Therefore it was most proper when success to those societies was being proposed that they should recognise the claims of the persons whom they were assembled that evening to support. Those persons were entitled to every assistance and support when illness overtook them or when old age came upon them.

Lord Alfred Churchill, in responding, said that he was glad to say that the Society which had been referred to as passing through some difficulty was now showing signs of improvement in its financial

position, and it was now also endeavouring to encourage scientific horticulture. For that purpose the Society had determined to recommence the publication of a journal in which would be published correspondence from scientific societies on the Continent and the results of scientific meetings of the Society. It was also intended to resume the provincial shows, and in the following year to establish a great national show similar to one which took place in 1866. He rendered them his cordial thanks for the support which they had given those societies on all occasions.

After the health of the Secretary had been proposed and responded to, the "Patrons and Lovers of Gardening" was next proposed by the Chairman, and Mr. Philbrick, Q.C., responding, said that to those who lived within the limits of London, it was a great privilege to be able to pursue their favourite amusement and their favourite relaxation, despite the difficulties which the surrounding atmosphere and circumstances entailed upon them. They had to rely upon the constant care, vigilance, and attention of their gardeners; and a more faithful, honest, and respectable body of men than the gardeners of the United Kingdom he thought could not be found. Reference had been made to the ennobling effect which the pursuit of horticulture had upon persons, and he quite agreed with that. Their efforts were now directed by the continual struggle to bring back the primeval paradise, and they got the nearest to it when their gardens were the best. Therefore, the most ancient of all arts, the best of all pursuits, the most ennobling, and of all occupations that which most tended to refine and to give the greatest enjoyment was—gardening!

THE CULTIVATION OF MEDICINAL PLANTS AT BANBURY.

THE principal grower of medicinal plants in the neighbourhood of Banbury is Mr. Usher, of Bodicote, a small village about two miles from the town. At present he has about sixty-five acres under cultivation, twenty of which are devoted to Rhubarb, forty to Henbane, and four or five only to the White Poppy. He has also lately commenced the cultivation of *Rosa gallica*, L., on a small scale. On a recent visit to Banbury much interesting information was kindly given me by Mr. Usher, and as it was the result of observations which had been made by that gentleman during the course of many years, it seems very desirable that it should be placed upon record.

Rhubarb.

The history of the cultivation of this plant in this district has been briefly sketched by Hanbury in "Pharmacographia." In that work he attributes the plant cultivated at Banbury to *Rheum Rhaponticum*, L. It, however, more closely resembles *R. undulatum*, L., differing chiefly from the description of that plant, as given by Meisner, in the upper leaves being distinctly stalked. From *R. Rhaponticum* it differs in all the leaves being longer than broad and minutely ciliate at the margins, and in the petiole being distinctly channelled on its upper surface above the middle, although it becomes flat near the base. The leaves have a few large somewhat triangular teeth near the point and the petioles and stem are slightly furrowed, and the ochreae do not appear to be deciduous as in *R. undulatum*. It would thus appear to be a hybrid between the two, if indeed the two species be really distinct. When in blossom the panicle is at first decidedly spreading, so much so as to present an appearance totally different to that which it offers at a later stage, when its branches become quite erect. Indeed, had I not found the two stages proceeding from the same root, I could hardly have believed that there were not two species growing in the same field. On closer inspection, however, the characters presented by the leaves and leaf-stalks convinced me that only one species was under cultivation. The soil on which the plant is chiefly cultivated is a rich red friable loam, which appears to suit it well, although in some spots where the soil is damp the root decays and the plants gradually disappear. Mr. Usher's experience with regard to this plant is as follows:—Up to three or four years of age the plants flower rather freely, but after that time they rarely produce inflorescence. Singularly enough, for many years past no fruit has been ripened, the little that is formed falling off soon after "setting," so that it would seem as if the plant

had already acquired a tendency to become a root-producing rather than a fruit-yielding form.

The Rhubarb plant does not appear to be much attacked by insects or by fungi. After about eight or nine years the soil becomes exhausted, and a rotation of crops becomes necessary. The exhaustion of the soil is, however, in some degree counterbalanced by the matter returned to it by the leaves, which are allowed to decay on the ground, and even those which are taken up with the root are afterwards returned in the form of manure. The young plants are not obtained from seed, but are always propagated from the lateral shoots of plants about four years old, at which period the shoots are more vigorous and produce finer plants than if obtained from older ones. The petioles are never gathered for food, because it has been found that so doing injures the size and quality of the root. The young plants are set at distances of 3 ft. apart, and the root is not fit for collecting until the plants are about four years old. From that period up to nine or ten years of age the root improves in size and quality. Plants of different ages are of course cultivated in different fields so as to secure a succession of harvests each year. Plants of about four years old yield from $1\frac{1}{2}$ to 2 tons of dried root per acre, but ten-year-old plants will yield about 5 tons per acre. The drying is by no means an easy task. The roots are dug up in hot weather, at any time between July and October, and for the first fortnight are exposed to a current of air on wicker baskets in a covered shed. They are then removed to the drying-room, where they are dried gradually but thoroughly for about six weeks, by means of a current of heated air. This part of the process requires great care, lest their outer portion should be dried too rapidly, while the interior is still moist. The large central portion, or tap root, furnishes the pieces known in trade as "fine large flats" and "fine large rounds." The "small rounds" and the cuttings commonly known as English "stick" Rhubarb are obtained from the side branches of the root. Some of the flat pieces, except for their shrunken exterior, are not unlike the East India Rhubarb of commerce, and being more thoroughly dried right through and harder in the centre seem to meet with a greater demand than the rounds. The raspings obtained in trimming the pieces are ground into powder. The average yield of the dried root every year is from 8 to 10 tons.

Of the *Rheum officinale*, Mr. Usher has now under cultivation in his garden about forty large plants between two and three years old, as well as about 200 seedlings. These plants are truly magnificent, each plant occupying a space from 8 to 12 ft. square, and standing 4 or 5 ft. high. Some of the leaves are nearly 3 ft. broad, and longer than they are broad. It is just suitable as an ornamental plant for lawns, where it would have plenty of room to grow; indeed it is already used in this way in some of the public gardens in Paris. The root of only one plant has as yet been dried, and was obtained from a plant barely two years old. A piece of this root has been presented to the museum of the Pharmaceutical Society, the remainder having been almost all sent to the Philadelphia Exhibition, where it obtained a medal, and was purchased. In colour, the dried root is paler, although the veins are darker, than in the East Indian Rhubarb. Mr. Usher informs me that it nevertheless yields a bright yellow powder. The external markings do not exactly correspond with those of the East Indian Rhubarb, the peculiar reticulated appearance characteristic of that sort not being visible on the two pieces that I have seen. This may, however, be due to the age of the root, which was less than two years old. It yet remains to be seen whether the root differs when older, or whether some portions present a different aspect to others. These points I hope to have an opportunity of investigating a little later on, when Mr. Usher will dig up some larger roots. Towards the close of the year he will probably have sufficient of the dried root of this species to be available for therapeutic purposes, and it will then only remain to ascertain whether its purgative properties are equal to those of the foreign Rhubarb, which after all will be the test of its acceptance by the medical profession. A chemist at Banbury has prepared some simple tincture from the trimmings of the root, in the proportion of two ounces to the pint of proof spirit, and has found it an effectual purgative in ounce doses.

Henbane.

Doubtless many of the readers of this Journal have often wondered at the high price of biennial Henbane. The information which Mr. Usher has kindly furnished will probably throw considerable light upon this point. The biennial plant is the only one cultivated at Banbury, it being found that the presence of the annual plant tends to deteriorate the biennial variety. With regard to the difference between the two plants, Hanbury says there is scarcely any distinctive character, except that the one is annual and the other perennial. There is, however, something very distinctive in habit. The biennial plant grows to the height of 2 or 3 ft., and is abundantly branched, and the stem is often nearly an inch thick at the base. At a distance, a field of biennial Henbane looks like a field full of Thistles, so much so, that Mr. Usher has occasionally heard the remark from farmers passing by. "That is bad farming, look at those Thistles." This curious appearance is owing to the leaves being deeply cut, in fact almost pinnatifid. The chief difference in the leaves of the two varieties is, that in the biennial plant the leaves are about twice as long as in the annual one, and deeply cut, and the terminal lobe of the leaf is long and rather narrow. The leaves of the upper branches, however, resemble when young those of the annual variety, being shorter and having the top of the leaf much broader, and more triangular, not lanceolate as in the stem leaves. The seed of the biennial plant is sown in May or June, and either appears in a few days or not for several years. Mr. Usher informed me that in one field sown with Henbane none of the seed came up, and the field was again sown with other crops, and it was not until nine years afterwards, during which period the field had been several times ploughed, that it yielded a good crop of Henbane, quite unexpectedly, and without any more Henbane seed having been sown. This uncertainty seems to depend upon the weather being dry soon after the seed is sown. If the weather be damp immediately after sowing the seed, it usually comes up at once.

The cultivation of the plant is beset with difficulties. In the first place, it grows very slowly when young, and is soon hidden by weeds of more luxuriant growth, so that it has been found necessary to mix some rapidly growing plant, such as Mustard, with it in order to indicate where it is sown. It also requires shelter when young. This difficulty Mr. Usher has obviated by sowing it in rows between Beans, so that it may be protected in its early stage. As soon as the young leaves are fully formed the Turnip fly attacks them; when the autumn leaves of the first year have decayed, a white slug eats away the central bud; and if it still manage to live, a wire-worm attacks the root during the winter. It will be easily understood, therefore, why the fields of Henbane often present very large bare patches, and why the price of the drug is so high. The plants are collected for drying about the third week in June. The upper leaves are deprived of the midrib, and these as well as the flowering tops are dried, and form the best biennial Henbane of commerce. The lower leaves and stems are used for preparing extract, for which purpose they are crushed under an edge runner, and the juice squeezed out by hydraulic pressure, and then evaporated down to a proper consistence. It is obvious that an extract prepared in this way on the spot by the grower is likely to be better than when prepared from the herb sent to a distance by rail, for these plants become heated in twenty-four hours when packed closely. The leaves and flowering tops are dried in malt-kilns, of which seven are in use at once. The leaves are spread thinly at first and are turned over about three times a day, and as they become somewhat dry are collected closer together into rows or heaps on the kiln floor. As one lot becomes partially dried it is removed to another kiln until quite dry, which usually happens in about three days, and a fresh lot takes its place. There are one or two points with regard to the flower which are rather interesting. The flowers are protogynous, the stigma becoming mature and viscid before the anthers open, and the stigma and nearly half the style are protruded beyond the unopened flower-bud. The corolla is more deeply divided in its lower half than elsewhere, and the stamens and pistil are depressed towards this portion, so that insects visiting the flower for nectar must

pitch upon the stamens and receive the pollen upon their legs or abdomens, and must thus almost of necessity convey it to the protruded stigma of the unopened flower. When the corolla is fully grown it exceeds the stigma, so that the style does not appear to grow in proportion to the corolla. The anthers are furnished with a curious connective of a narrowly triangular form into which the filament tapers. As soon as the anther bursts it becomes bent backwards away from the stigma and towards the ovary, as if to prevent the pollen from falling on the stigma of the same flower. Mr. Usher informs me that the annual variety does not possess a long protruded style, but as he had no plants growing, I was unable to verify this observation. It would be interesting to ascertain if the Henbane be dimorphic, and if the annual plant be the second form. Another interesting point of inquiry is whether the plant possesses the power of digesting the multitude of minute insects which late in the season are caught by the clammy glandular hairs. The frequent occurrence of Henbane on manure heaps or places in which insects are abundant seems almost to point to such a property.

White Poppy.

The culture of this plant is attended with so much trouble and expense that it scarcely repays the labour expended on it. The seed has to be selected very carefully, for singularly enough the Poppy shows a constant tendency to "sport," and if left to itself, the flowers of the White Poppy become coloured in a few generations; the size of the capsule decreases, and the colour of the seeds and of the flowers becomes darker in proportion, until at length the flowers become purplish-black, and the seeds quite black. Mr. Usher accounts for this fact by supposing that insects carry the pollen from the wild Red Poppy (*Papaver Rhæas*) to the white one. In order to get large capsules, only the very whitest seeds are retained and sown. Those Poppies which have dark flowers, he states, produce darker coloured somewhat oblong capsules. The German Poppy seed produces a large capsule much flattened at the top and bottom, and with the carpels strongly convex and prominent so as to have much the appearance of a peeled Orange, or of the capsule of *Papaver hybridum*, L. This variety is not, however, readily accepted in commerce. The seeds of the White Poppy are sown in rows about 20 in. apart. When young the plants require constant weeding. The capsule, when the flower has fallen, is about the size of a Walnut, and is stated by Mr. Usher to grow to the size of an Orange in the short space of ten days, although it takes nearly five weeks to ripen. Each plant bears about two or three capsules. The harvest is collected during the last week in August or the first in September. A waggon-load of the capsules is placed on the floor of each of the kilns and forms a layer about a yard deep, the whole of which becomes dry in about twelve hours, and is then ready for sale.—"Pharmaceutical Journal."

CLIANTHUS PUNICEUS AT EDINBURGH.

At Almore, near Edinburgh, the residence of Mr. Guthrie, this favourite old greenhouse plant has been for some weeks beautifully in bloom. It was planted six years ago in the ordinary soil (a strong loam) in front of the mansion, which faces south-west. It covers 15 ft. by 6 ft. of the wall, and is still one mass of bloom from the ground to the top. It would have occupied double the space, but it is properly kept within certain limits, so as not to interfere with important architectural lines on the building. On the front of the house, which is panelled, grow other plants besides the *Clianthus*—such as *Escallonia macrantha* (a fine wall shrub, both as regards foliage and bloom), *Forsythia viridissima*, *Ceanothus rigidus*, *Gloire de Dijon* Rose, various creepers, and a Black Hamburg Vine, all sufficiently luxuriant to show that their wants are specially studied. The two last, indeed, are in much better condition than that in which they are usually met, and are only surpassed by a *Maréchal Niel* Rose and a Black Hamburg Vine a short distance from here, on the house of the Rev. D. K. Guthrie. This Rose is furnished with 100 expanded blooms, each of which is sufficiently good for an exhibition stand, and the Vine is now in flower. The situation is high and exposed, and success in this case is only the result of constant care and attention. I may add that indoors, where plant cultivation is successfully carried on, I noticed growing on each side of the inner door of the entrance

hall a Kangaroo Vine (*Cissus antarctica*), forming an unbroken arch from floor to ceiling, and in point of luxuriance quite equal to Vines growing outside.

A. McLEOD.

14, Royal Exchange, Edinburgh.

A RARE INSTANCE OF CONING AND SUBSEQUENT DEATH.

IN March 1876 I sent to the Royal Horticultural Society in London two coned sprigs of *Picea religiosa*, the sacred Fir of Mexico, grown at Penrose. Mr. A. Murray, then secretary of the Arboricultural Committee of that Society, believed it to be the first recorded instance of the fructification of this graceful and delicate Conifer in England, a fact which may be worthy of record. I have only two specimens of this *Picea*; one is a seedling raised here from a cone which was brought me from Mexico, planted out in 1859, and now about 20 ft. high; the other, which produced these cones, was bought by my father in 1847, and transplanted by me in 1857 into a sheltered spot in the rich soil of an ancient rookery; here it died back after removal, was cut down to a promising shoot, survived the severe winter of 1860-61, lost its head again in a gale in 1867, was pruned again, and though not, as might be expected after such treatment, a very shapely tree, was fairly vigorous, about 25 ft. high, and 2 ft. 10 in. in girth at 30 in. from the ground. In the autumn of 1875, I observed more than 100 cones had formed upon it; in December, I picked a few, which then had the purple tint of those of *P. Webbiana*, but somewhat smaller. The finest cones, when I gathered the remainder in March, were 4½ in. long. London represents them as only 1½ in. in Mexico: but I have observed a similar increase in the size of cones under favourable treatment of the parent tree in England, in the case of other varieties. The specimen cones were deposited in the Museum of the Royal Botanic Gardens at Kew, and the remainder were carefully sown, some here, some at Mr. Nichol's nursery, Redruth; but no seedlings were produced at either place, the climate of Cornwall being probably not dry enough to mature the seeds. I have now the mortification of reporting that the effort has destroyed the parent. The tree is quite dead.

J. J. ROGERS.

Penrose, near Helston.

The Edinburgh Arboretum.—Twenty-seven acres of ground have been added to the Botanic Garden, which now embraces 54 acres. The first steps for the addition were taken by Prof. Balfour three years ago, with the object of having room for the cultivation of trees suited to the climate of Scotland, and to prevent devoting the ground for building purposes, which would not only have spoiled the amenity of the gardens, but would have been productive of much injury to the plants by the smoke which would have been carried over the gardens by the west winds. Mr. Alexander Beattie was the first with whom he (Prof. Balfour) communicated on the subject, and through him he was enabled to bring the matter under the notice of the Secretary of the Treasury. The First Commissioner of Works, Lord Henry Lennox, approved of his proposal, in which also he was supported by others. His next step was to go to London, and personally bring the matter under the notice of the Treasury. Having laid the case fully before Mr. Smith, shown him the plans of the ground, and urged the importance of making such an addition to the Royal Gardens, he pointed out to him that the Chief Commissioner of Works had seen the ground and considered that it would be a most important and valuable acquisition. Mr. Smith stated that if it were proved to him that the town of Edinburgh would take an interest in the Arboretum by contributing to the acquisition of the ground and handing it over to Government, the Arboretum would be put under regulations similar to those of the London parks, and would be supported in all time coming by an annual grant from Government. On returning to Edinburgh he waited on the Lord Provost, who entered enthusiastically into the plans, and said he would do all he could to further the scheme. Many difficulties presented themselves, but by his energy and tact he overcame them all, and to his lordship the city of Edinburgh was indebted for this important addition to its gardens. The Government was pledged to enclose the grounds and complete the arrangements in two years, and he therefore hoped that immediate steps would be taken to fence the grounds and begin the building of the lodges at the different entrances.

Summer Transplanting.—With care many trees and shrubs may be moved successfully during summer. These consist of Hillies

Rhododendrons, Azaleas, Aucubas, Lantanas, Common and Portugal Laurels, Box, and, indeed, most evergreen subjects, except the Pine tribe, which it is better to leave until autumn or spring. The same advice applies to deciduous subjects, though they are sometimes moved in full leaf. The young growth of summer-transplanted evergreens is almost certain to suffer, but that is not of much importance, and is soon made up again. In summer of course the plants must be lifted with good balls and plenty of roots, and be well and frequently watered and mulched. In looking over some Yews and other trees, a number of which were planted early in March, and the rest in May and up till the end of that month, I find that the earliest-moved trees have suffered worst, the persistent east winds of March and April having scorched them severely, while the later-moved ones—all of them begun to grow at the time—look well. Laburnums from 8 ft. to 9 ft. high were just coming into leaf when lifted, and they are now in flower and growing away famously. They were taken from a thicket of self-sown seedlings, and consequently had no soil whatever to their roots. A quantity of named Rhododendrons, hybrids which were planted some years ago in somewhat heavy loam of an iron character, were found to have rooted in it freely and made good growth, though they were originally transferred direct from the Surrey peat. There is no difficulty in getting all the hardy Rhododendrons to grow and flower freely in good loam that is free from lime. I am acquainted with one large plant, or rather three plants in one—all having been planted together—that are just about 100 paces round, and they are growing in loam; but of course the fallen leaves have been allowed to accumulate on the ground under the branches for years, and no doubt they constitute part of the rooting medium and keep the roots healthy and enriched. In all shrubbery and Rhododendron borders the fallen leaves should be allowed to lie and decay—they are as good a top-dressing as can be provided. Newly-planted shrubs of all kinds should of course be mulched.—*CHEF.*

Early Peas.—I have always until this year gathered my first Peas (outside from seeds sown early in November) from the 28th of May till the 6th of June, but this season the look of my November sowings in January was anything but satisfactory. I therefore sowed 4 doz. boxes of Little Gem in the Cherry-house, which was unheated, and grew them close to the glass. When coming into bloom I top-dressed them with rotten manure, and gathered half a peck from them on May 13th, and I have continued to gather from them twice a week until late in June. The boxes are 3 ft. long, 11 in. wide, and 3 in. deep. This plan I shall continue to practise. I sowed under the protection of a wall on Feb. 13th Laxton's Harbinger, and gathered my first dish from it on June 3rd. This Pea comes into use earlier than any other. Criterion, one of the late Mr. Standish's seedlings, has been in bearing since June 22nd, beating William the First and Little Gem by about a week as regards earliness. It is a green marrow of the very richest flavour, and grows from 5 ft. to 5½ ft. high. This Pea is destined to become a popular one.—*R. GILBERT, Burghley.*

Potato Sprouts for Seed.—It is now upwards of forty years since I tested the use of "Potato shoots for seed," and I continued to do so for some years as an experiment—for at that time my Potato growing was confined to garden produce. I had the buds carefully picked from the tubers, after they had thrown out roots outside the parent bulb—at the same time I had other tubers cut for seed in the usual way. I planted three drills in the garden, side by side—one of cut tubers, one of sprouts, and one of small whole tubers. When at maturity, I daily dug up three stalks from each drill, counted, and weighed the produce of each three, and found that of the sprouts fully equal to any of the others, both in weight and in number. The second year I did the same, taking no pains to dibble the sprouts, but scattered them in the open drills, and covered lightly. I went further, for having found a heap of fine sprouts on the road—thrown over the wall by some sagacious cultivator who had got his seed Potatoes carefully turned and picked, and had thrown away the vigorous shoots—I had some barrowsful gathered up and scattered broadcast on a few ridges prepared for the purpose, and covered them with mould out of the furrows. The result was most satisfactory. The sprouts soon appeared over the ground, and the crop came to maturity much earlier than that from Potatoes planted the same day. It must be obvious to any one who considers the matter, that once the tuber has generated the sprout, it is no longer of use, for on digging the crop the tuber—whole or cut—will frequently be found whole and detached from the roots of the stalk. Why, then, pick off the first vigorous growth and plant the tuber to produce a second, and more puny and sickly one? Sprouts can be planted much later than the tubers, or, if at the same season, they will come to maturity earlier, because they are so much ahead of the tuber which, after being planted, has to throw out a bud or sprout.—*'Toronto, Globe.'*

THE FLOWER GARDEN.

TALL PHLOXES.

THESE unquestionably rank amongst our most beautiful autumn flowers. They are quite hardy, are easily propagated, and they can adapt themselves to any locality or situation. Nothing can be more beautiful for a mixed border, and they are equally useful in pots for the embellishment of the greenhouse. Phloxes are divided into distinct sections, viz., the decussata group, which blooms from July to October, and the suffruticosa section, which flowers during June, July, and August. The kinds belonging to the first section are as a rule the favourites; they form magnificent pyramids of bloom from 18 in. to 3 ft. in height, the colours varying from pure white to the most glowing crimson-red, with many other shades of colour. The varieties of the suffruticosa group are altogether of a different habit; they are dwarfer, and the flowers, which are fragrant, are much more delicate in appearance, and they bloom earlier, too, than the decussata breed. Phloxes are easily propagated. Cuttings of them may be struck in spring and early summer. About the middle or end of March the plants will have made shoots 2 in. or 3 in. high, and then is the best time to take the cuttings. As many as are required should be taken from a plant, and inserted singly in thumb pots. If a very slight hotbed be at work this would be the best place in which to root the cuttings, but they would strike freely in a cold frame under hand-lights, or even in the open air, if shaded from bright sunshine. If under glass, whether on a hotbed or in a cold frame, they will, providing all goes well, be rooted in about three weeks, when they may have more air, and soon after be placed in a position in the open air. If they are intended for pot culture, as soon as the pots are filled with roots they should be shifted into 6-in. pots, in which they may be allowed to bloom. A very excellent compost for Phloxes consists of three parts sandy loam, one part leaf-mould, and one part rotten manure. During the period of growth the pots should be plunged up to the rims in coal ashes in the full blaze of the sun, but sheltered from cutting winds, and they should receive abundant supplies of water, both at the roots and overhead. Occasional supplies of manure water will considerably increase the size of the truss. As the shoots advance in growth they must be carefully staked, and each branch neatly tied. During the first year, if the plants be struck from cuttings only one shoot will be thrown up, but the second year a number of shoots will rise from the base. If the plants be grown for exhibition and the trusses be required very fine, about four shoots should be retained to each plant, and the rest cut clear away. Phloxes make grand ornaments either for planting in separate beds or in mixed borders; but when they are made a special object of culture, they should be grown in beds by themselves. A few plants in a mixed border form a pleasing feature, and afford a marked contrast to other herbaceous plants. It is in the mixed border that we grow our Phloxes, and as all the plants in the same bed are equally

Rocky Brook.

choice, they come in for a fair share of attention. Early in March is the best time to plant them, and the ground should be deeply dug and well enriched with good rotten manure, and throughout the growing season they should be liberally supplied with manure water. Where not offensive to the eye a mulching with half-rotten manure would be highly beneficial. When planted in beds the first year the plants should stand about 15 in. apart, but the following spring they should be replaced, for by this time they will have increased in size, and will require more room. The first year they will begin to bloom towards the middle of August, and continue for six or seven weeks, and the second year they will begin in July, and continue till the end of September. When the plants are in a healthy condition, the second season they will throw up a good number of shoots, when they should be reduced to five or six. When more are allowed to remain the flowers are not so fine. A stout stake should be placed to each plant, and as the shoots keep growing they must be securely tied to it. In exposed situations high winds make terrible havoc with Phloxes when this little duty is neglected. A succession of young plants should be kept up from cuttings. Dividing the old roots with the spade is a rough-and-ready way, but the plants are never so fine either in flowers or foliage as those raised from cuttings. Those who have only a limited knowledge of plant culture cannot do better than grow Phloxes; they do not require half the care of many of our half-hardy bedding plants, which must be wintered where artificial heat can be given. The following are good sorts, and well worth growing, viz.:—Admiral, A. F. Barron, Edith, Gladstone, Larina, aurantiaca superba, Gambetta, Queen of Whites, Madame Bonneau, Madame Hoste, Madame Beust, Mrs. Ware, Mrs. Laing, Triomphe de Parc de Neuilly, Lothair, Mons. Van Houtte, Madame la Comtesse de Turenne, and Walter Ware. There are many more the names of which are well worth recording, but these are some of the brightest and most continuous flowers.

K. R.

Rocky Brook Mouth.—The accompanying sketch shows a successful attempt to ornament the mouth of a streamlet as it joins a piece of water. Here the placing of a few natural rocks gives an interesting diversity to the scene, and allows of the culture of a more striking variety of plants than could be otherwise grown. A small rocky bridge—a kind of stepping-stone bridge—crosses the streamlet a little this side of the rocks, and from this point of view the effect of the rocks, trees, &c., with the lake immediately beyond them is very interesting. The spot affords a home for a variety of water-side plants.

Dracæna australis in Flower.—I have this now in good bloom in the open air. Mr. George Vicary, who gave me the seed, has just called and says it is a very fine plant, and an unusual thing to see such a good blossom outside.—N. F. BARTON, *Corsley House, Warminster*. [I have just seen this plant, which is beautifully in flower; it was planted in the flower garden about ten years ago. Its spike of bloom measures 5 ft. through at the base and 4 ft. 6 in. in length; the plant is about 8 ft. high up to where the bloom-spike shoots out. G. BEERY, *Longleat*]

THE COLUMBINES OR AQUILEGIAS.

THOSE among us whose memories date far back in the present century will recollect how popular these beautiful hardy border flowers were at that time, and with what care they used to be cherished; but since then fashion has changed many things, and the present mode of embellishing both beds and borders is very different from what prevailed when such good old-fashioned plants as the above were more in favour than they now are. Without in any way decrying a system of decoration that has many admirers and which has done a vast amount of good in extending a love for flowers among the multitude who have first been attracted by gaudy colours, I do think it is much to be regretted that many choice hardy perennials and biennials that once had prominent positions, and which were so attractive in shrubbery and mixed borders should now be so seldom seen, for, after all, there is nothing to equal them either in form, colour, or interest; and being of a hardy enduring character, there is not that ever-recurring expense which there is in the case of bedding plants that have to be worked up annually and wintered under glass.

Common as many of the Aquilegias may appear to be from the persistent way in which they seed and propagate themselves, they are in certain situations even more desirable on that account, as, for instance, in semi-wild places, where with Foxgloves, hardy Geraniums, both native and foreign, and many other plants of similar habit and character, quite a wealth of beauty may be enjoyed, and that of a kind far more satisfying than is afforded by long lengths of ribbon border or the most intricately worked patterns which it is possible to devise. All that is required when it is desired to establish them in such places is to dig over a patch of ground and either to sow the seed at once, or raise plants in nursery beds and transplant them in the spring or as soon as they are large enough to be handled; but it should be borne in mind that only the more common and robust kinds will thrive without good cultivation. One or two of the choicest Alpine species of recent introduction only succeed really well in very favoured situations where the conditions under which they grow somewhat resemble those of their native habitat in regard to moisture, shade, and shelter. The Rocky Mountains of California appear to be rich in Columbines, if not in varieties at least in quality, as they have afforded us some of the choicest of the family, and as all seed and cross so freely, there will be no difficulty in raising others of a hardier constitution and possessing some of the characteristics for which these are so highly prized. Indeed, this has been done already, as many new hybrids are now to be had, which, if not equal to some of the Californian species, afford variety, and are therefore desirable on that account. Besides an endeavour to effect a cross with the view of raising new varieties, the aim of cultivators should be to keep pure those which we now have, and which, with such sportive tendencies as is natural to Columbines, can only be done by isolating the plants from which seeds are to be saved.

AQUILEGIA CŒRULEA.—This is by far the most beautiful and perhaps also the most difficult to keep and cultivate; it was introduced by Mr. Thompson, of Ipswich, to whom we are indebted for bringing not only this, but, also many other useful plants into notice. To get strong healthy plants that will flower freely, seeds of this kind should be sown annually, and treated after the manner of Canterbury Bells or other biennials, as it rarely does well after standing the second year, and in many cases dies out altogether at or before that time. The flowers are, however, so lovely and so useful for cutting, that it is deserving of any amount of trouble and attention to have it in good condition, a result which can only be attained by treating it in the manner just indicated. All the Columbines delight in a deep rich sandy soil where they can find plenty of moisture below for the roots, and as they make their growth early, the friendly shelter of shrubs or rock to keep off cold cutting winds and frosts is of great benefit, if not too near to rob them or restrict their root-room. The best way to treat them when they are to be grown in single patches in borders is to dig up the soil to a good depth, and, while doing so, to work in some rotten manures, keeping the same well down in order that the plants

may have it to feed on as they come into flower. If when this is about to take place a slight mulching of leaf-mould be afforded and a soaking of water given, the bloom will be much finer and more lasting than it otherwise would be.

A. CHRYSANTHA.—This stands next in point of merit, and is one that affords a rich contrast as regards colour. It has canary-yellow flowers of the same form, and nearly as large as the foregoing. This by many is considered only a variety of *A. cœrulea*, but although the botanical distinction may not be great, they differ considerably in habit and time of flowering, *A. chrysantha* being at least a month later, and altogether of stronger growth and constitution. Although it has the same spur-like appendages, the flowers are smaller and not nearly so much distended as those in *A. cœrulea*, and these differences taken altogether are sufficient to warrant it being regarded as a distinct kind.

A. CANADENSIS.—This, till within the present century, was the only representative of the New World Columbines, and is, compared with the two kinds just named, a very slender grower, rarely exceeding 12 in. high. Its flowers, too, are much smaller, but what they lack in size is made up in brilliancy of colour, the sepals being scarlet and the petals bright yellow. *A. canadensis lutea*, introduced in 1835, is, as its name implies, a yellow form of *canadensis*, which it in other respects resembles.

A. KANAORIENSIS, a native of the Himalayas, is a delicately beautiful variety, having small flowers with white sepals and petals, the latter of which at the upper part gradually merge into a soft blue, and this deepens in intensity at the end of the spurs, thus giving the blooms a very ornamental character.

A. GLANDULOSA is a charmingly beautiful species, but one which does not succeed well except in favoured, cool, shady situations, where its roots can find plenty of depth and moisture. It is a native of Siberia, where it is found near the margins of mountain streams.

A. CALIFORNICA.—This, the strongest and most robust of all the American species, grows to a height of 3 ft., and bears flowers of a shell-like form, which, from their pendent position, are not seen to advantage unless turned up and examined.

A. VULGARIS, with which most of us are more or less familiar, used at one time to be an occupant of almost every cottage garden, and a more graceful or ornamental plant than it there formed cannot well be imagined. Although it has in most places been lost or eradicated to make room for others of more recent date, it is not yet surpassed either in utility or beauty by its more favoured rivals.

Now that we have these new comers from California, which have brought the Columbines again prominently into notice, no doubt they will ere long take the position which they formerly held. There are many more named kinds, but those enumerated above are the kinds most deserving of cultivation, and by growing them near together and sowing seed, there is no end to the variety of colour and form that may be obtained, especially among our native kinds, which are the most suitable for growing near the margins of drives or woodland walks, where, once fairly established, they would take of themselves. Excepting these, all the others should be looked on as biennials, and, as before observed, raised annually by sowing the seed under glass early in spring, and afterwards pricking the plants out and nursing them on till strong enough to plant out in August, or if sown at that time, to keep them under protection till the following spring; but the first is the best way of treating them, as they have the whole summer for making their growth.

J. SHEPPARD.

Climbing devoniensis Rose.—This is a beautiful Rose for covering a lofty wall, and at this season its flowers are lovely in a cut state. It is often complained of as being a shy bloomer, but it is a rampant grower, and in order to induce it to flower well, the young shoots, which in vigorous specimens are often 10 ft. or 12 ft. long, should be left their full length. The pruning should be confined to thinning out the wood, and removing occasionally an old branch to make room for the young shoots, as it is towards the points

of these that the flowers are chiefly produced; no shortening should be permitted beyond removing a few inches of the soft points.—
E. HOBDAY.

THE MILK THISTLE.

THIS old plant should find a place oftener in our gardens in these days of fine-foliaged plants than it does. It is hardy, easily-grown, biennial, and raised readily from seed. It looks exceedingly well

in the mixed border before the flower-stems spring up. It is, however, most suitable for growing in a semi-wild state on dry banks and similar places.

LOBELIA SPECIOSA AND ITS VARIETIES.

In the open air and in pots the speciosa section of *Lobelia* is one of the largest and the most important; hardly any flower garden is now considered complete without one or more beds or borders being plentifully supplied with this beautiful *Lobelia* or some of its many varieties, such as Lustrous, Blue Stone, Blue King, and the lovely Paxtoniana, a white variety margined with blue. There are also one or two pure white *Lobelias* of the speciosa section with flowers nearly as large as the species. Of the smaller or *pumila* section of *L. speciosa*, *magnifica*, *grandiflora*, and Mrs. Murphy (pure white) are perhaps among the best. The double variety is also magnificent where it succeeds well, but it is very erratic, and hardly to be depended upon in beds or borders, sometimes forming a complete sheet of bloom, and at others the shoots running up through it, as it were, overpowering and preventing it from blooming, presenting the appearance of tufts of Grass. It seems difficult, perhaps impossible to guard against this peculiarity, inasmuch as where the plant is perfect in form and flowering one season, it becomes weedy-looking the next. This double blue is, however, a grand subject for culture, and under the superior climatal conditions that glass affords, it comes with greater certainty, and hardly any plant can equal the richness and beauty of this double *Lobelia* crowned as thickly as possible with its lovely balls of beautiful blue.

The chief points to start with in the successful culture of the *Lobelia* are good soil and well-grown established plants. The soil should be light and rich, and rest on a dry and perfectly drained bottom. The *Lobelia* enjoys abundance of water when in robust and free growth, but nothing is more fatal to its well-doing than stagnant water at the roots—if on a porous bottom it may be plentifully watered during a dry time in summer, without fear of injuring the roots, neither can the roots of *Lobelia* make way nor the plants thrive in a strong adhesive soil composed of clay or heavy loam, or if the compost be heavy, it must be lightened by a plentiful addition of leaf-mould, sand, or peat. The *Lobelia* thrives admirably in equal parts of rather sandy loam and leaf-mould with a fair admixture of sand to keep it open. Charcoal dust and peat also form capital additions to loam for their successful culture; likewise spent manure from Mushroom beds. A slight mulching of one-year-old sifted hotbed manure will be found a capital addition to beds or borders for keeping out the drought from and nourishing the roots of *Lobelias* through a dry season. One of the greatest difficulties, however, in carrying *Lobelias* in full beauty through the season is

the freedom with which they produce seed and the tentative mode in which it is ripened—a pod at a time almost is the order of ripening. But where flowers are the object, this stage of maturity should never be reached. The moment the flowers fade they should be picked off, and so on persistently every week or ten days throughout the season. Of course the labour is great, but so is the reward. Few features in the flower beds or borders are more thoroughly enjoyable and satisfactory than a perfect band or small bed of any of the varieties of *Lobelia speciosa* from the middle of June till the frost clears the garden of its autumnal beauty. Of course this mode of culture prevents the saving of seeds, but this is of little moment, as it is better to purchase them than save them. If, however, any plants of unusual merit, distinctness, or improvement in size, colour, or substance of flower, appear, it is easy to perpetuate such, either by means of cuttings, rooted branches, or by lifting the plant, potting it, and placing it in a gentle bottom-heat until established; after that set it on a light, airy greenhouse or forcing-house shelf, when it may be increased by cuttings and root division to any extent in the spring, planting a stock on a piece of reserve ground for seed. This increase by cuttings, rooted side-shoots, or conservation of the old plants by potting a few of them in the autumn, is also the best method of preserving and increasing the stock of special varieties. The seeds of even the truest types vary considerably from each other, and also from the original, and to this inherent variability we owe the many kinds of *Lobelia speciosa* that add so largely to the enrichment of our flower gardens. It is, nevertheless, mortifying when white or semi-white flowers break forth among the truest strains of Blue King, or tall speciosas revert from the most carefully selected stock of *L. pumila grandiflora*. To avoid the risk of all this strike cuttings, plant rooted layers during the summer, or pot sufficient old plants for stock in the autumn. The *Lobelia* strikes roots freely in a brisk heat in a moist propagating pit or frame in spring. These cuttings should be potted or boxed off, and got into bulk by the end of May in exactly the same way as seedlings sown in heat in September, October, or February. Those who want early *Lobelias* from seed should sow in the autumn, and prick the seedlings off in boxes or pans, or shift them into thumb pots before winter. Store them on shelves near the light exposed to abundance of air, give another shift into small 6-in. pots in March into equal parts of leaf-mould and loam, and such plants will be perfect for planting by the end of May. Spring-sown seedlings may go into smaller-sized pots, and be planted rather more closely, but will not flower so early nor so well. On the whole, therefore, autumnal propagation, either by means of cuttings or seeds, is preferable to the sowing of the seeds in spring. For pot culture these autumn-sown plants are best. They are merely pushed on a little farther till they are large enough to fill a 6-in. or 8-in. pot; the first size is the best, the second as large as any pot should be for a single *Lobelia speciosa*. The taller-growing sections may be stopped a few times during the earlier stages of growth, to cause them to grow horizontally. At the final shift the plants should be kept well up in the pots, so as to allow the shoots to fall over the sides and cover them as they grow and flower. In the case of well-grown plants belonging to the taller sections, such as Paxtoniana, one of the chief merits of pot plants is that of drooping over and wholly hiding the pots. In the *pumila* section the plants are too dwarf to do this, but the rim may be entirely covered by a carpet of blue. The double blue is also of this dense habit, and is inimitable for the decoration of light-coloured marble, glass, or silver vases, or flat baskets. Some of the taller ones are also admirable for the furnishing of small hanging baskets or raised stands. The soil for *Lobelias* in pots should be equal parts leaf-mould and loam, mixed freely with silver sand or charcoal dust. The drainage should be clean and ample, and over it should be put a layer of small pieces of manure about the size of marbles, and almost as hard, such as that of cows at least two years old mixed with a little Cocoa-nut fibre refuse, to ensure a thorough and nourishing drainage. When the plants are in full growth and flower, they enjoy manure-water at least once a week; that made of a slight admixture of guano and soot suits them admirably. Having such a limited root-run, these plants must

never once be allowed to become dry; and if carefully attended to they will continue long in beauty. When done flowering they may be cut down, repotted, and used for flowering again or for stock. With about three lots of *Lobelias* in pots to be brought on in succession, the conservatory, window garden, or sitting room need seldom be without the enlivening and enriching presence of these lovely plants from April to November.

D. T. FISH.

HARDY PLANTS FOR NARROW BEDS.

In the immediate neighbourhood of large mansions or buildings it is sometimes desirable to cover certain places with some permanent living carpet, especially in positions where Grass cannot be got to grow satisfactorily, or where it is difficult to keep it in good condition by means of the mowing machine or scythe. Areas surrounded by stone curbing and its usual adjuncts are difficult to mow, and where the necessary operation of clipping has to be performed with shears, other subjects might be substituted for Grass that would have a good appearance at all seasons, and that would require less labour. We have some narrow borders enclosed with massive stone curbing, and the majority of these are planted with Irish Ivy, pegged down close until well established, when the only attention which it requires is clipping over occasionally, and the beautiful, fresh green groundwork which the young foliage presents can scarcely be surpassed by any plant with which I am acquainted. When the borders are wide enough to admit of its being done, a space is left in the centre for brightly coloured flowers, which the Ivy shows off to great advantage, and in spring a beautiful effect is produced by large masses of Snowdrops peeping through the foliage of the Ivy. These were planted with the Ivy, and have been allowed to remain undisturbed for years. Large specimens of *Hydrangea* and similar plants have an excellent effect plunged in this kind of border during summer, and replaced by *Thuja aurea* or Golden Yews in winter; in fact, any number of variations may be worked out on this simple but effective groundwork. As a good contrast to the above we have planted some panels with Golden Honeysuckle (*Lonicera aurea reticulata*), and treated it in every way like the Ivy. It is a charming subject, and in such positions is better variegated than on pillars or arches, as there is always an abundance of small spray-like shoots with the freshest and most effectively-marked variegation, induced by the frequent pinching and clipping to which it has to be subjected. On some very shallow panels, where the curbing is only 2 in. or 3 in. high, I have found the different varieties of Sedums or Stonecrops most effective as groundwork, as, though only planted thinly at first, they quickly form an even unbroken mass, and they have this advantage, that they will grow in shallow, dry soils where little else will succeed.

Henham.

JAMES GROOM.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Thalia dealbata not Hardy.—In reply to "V" (see p. 523, Vol. xi.) allow me to say that this plant has not proved hardy with me either here or at Bilton. I have tried several well-rooted plants of it, and though a successful grower of hardy aquatics in tubs for more than forty years, *Thalia dealbata* never would succeed with me.—H. T. ELLACOMBE, *Clyst St. George, Devon.*

New Japanese Hollyhock.—This distinct variety was offered last year, I believe for the first time. It differs from the ordinary Hollyhock in its pyramidal form and dwarf growth, growing only about 2 ft. in height. The flowers are semi-double, and of a bright crimson-scarlet; it blooms during the summer months.—PETER HENDERSON.

Barometrical Flowers.—A sympathetic friend sent me a barometrical Hyacinth and Rose from Paris last week to keep me company during an attack of rheumatism. They are quite as clever weather prophets as the little man and woman who are always oscillating between going to market and staying at home. Like the chameleon, my flowers keep changing colour, and their language is interpreted thus:—When "fair" they are dark blue; when "changeable" a pale mauve; and when "rain" they become a bright pink. These curious and interesting effects are produced by some chemical agent into which they have been previously dipped.—"The World."

Heather in Nova Scotia.—Prof. Lawson adds to the localities of *Calluna vulgaris* in America six other stations, and in an interesting paper on the subject gives the following as his conclusions:—*Calluna vulgaris* is an indigenous plant, and still exists as such in very small quantity on the peninsula of Halifax. In Point Pleasant Park, at Dartmouth, and possibly in other places, the stations for the plant are artificial, but the plants are probably native. "The various traditions as to the foreign origin of the Heather are not unlikely to have been suggested by the desire to account for the presence of what was regarded as necessarily a foreign plant rather than by actual historical facts."—"American Naturalist."

PEACE.

"How are the mighty fallen! and the weapons of war perished!"

I.

Sing on, sweet bird, thy thankful psalm of peace,
Sing on, to HIM, Who maketh wars to cease!
Armed men came, trampling down the corn and flowers,
Silenced thy mirth, and scared thee from thy bowers;—
And, where God's Beauty held its ancient reign,
Hate maimed and murdered, and thieves stripped the slain.

II.

Sing on! Once more, by His eternal Love,
Where swooped the vulture, coos the happy dove,—
Where shot-torn banners swayed 'mid battle-cries,
The fruit-trees blossom 'neath the deep blue skies,—
The shepherd whistles where the soldier fell,
Once more 'tis Eden, where it seemed as hell.

III.

Sing to us men, that death shall die, and Life
And Peace prevail, and Victory, after strife.
Sing on, sweet bird, sing to our Faith and Hope,
That they shall conquer, who with sin shall cope.
"Peace at the last"—proclaim it in thy song,
For all who love the right and hate the wrong.

S. REYNOLDS HOLE.

THE FIRST FUCHSIA.

(F. COCCINEA).

THIS well-known but lovely *Fuchsia* associates well with the ordinary occupants of a mixed border, and is so graceful and beautiful both in growth and bloom as to commend itself to the notice of the most casual observer. It readily adapts itself to any locality, provided the soil be not of the wettest and coldest description, and even then a slight covering of coal ashes after the stems have been cut down in autumn will suffice to protect the roots in winter. In favourable situations it often attains a height of 6 ft. From the axils of the leaves, which are of a fine green colour, beautifully tinged or veined with red, the flowers, which before they fully open are not unlike crimson drops, are produced in profusion during the greater part of the summer. In the "Botanical Magazine," vol. iii., t. 97, it is stated that this plant is a native of Chili, and that it was introduced to the Royal Gardens at Kew, in the year 1788, by Captain Firth. It takes the name of *Fuchsia* from Fuchs, a German botanist of great celebrity, author of "Historia Stirpium," in folio, published in 1542, containing woodcut illustrations of 516 plants, which, though merely done in outline, express the objects which they are intended to represent infinitely better than many laboured engravings of more modern times. The *Fuchsia* in question was at that time supposed to require the temperature of a hothouse; consequently we may presume that it was lost to cultivation prior to the ultimate purchase of a plant of it by Mr. Lee, the founder of the well-known nursery at Hammersmith. Of this transaction I find the following account written in an old scrap-book just as I heard it narrated at Knowsley twenty-five years ago. Mr. Lee having heard that in the window of an humble dwelling in Wapping, growing in a pot, was to be seen a beautiful plant with drooping flowers like earrings, his curiosity became excited, and he at once determined to proceed to the locality and see for himself. Once there, he could not disguise his admiration of the plant in question, and soon introduced himself to the owner, whom he found to be the wife of a sailor. After some preliminary conversation, he offered her a golden guinea in exchange for the plant, but this she refused, saying that her "Jack had brought it home from a foreign country, therefore she would not part with it for his sake." After some persuasion, however, and a promise that he would propagate a plant of the same for her, and at the same time placing in her hands all the cash he had about him (about ten guineas), he obtained possession of the plant, which was speedily propagated, and found, as may be imagined, a ready and profitable sale. The fine old *Fuchsia gracilis rubra* and *F. Riccartoni* may also be used for outdoor decoration, being equally hardy; but where a strong-growing, free-blooming kind is required for training against a wall or fence, there is, as yet, nothing to equal the old *F. corallina*, which is a cross between *F. rupestris* (a climbing species) and *F. exoniensis*, this latter being a cross between *F. globosa* and *F. cordifolia*.

R. BULLEN.

FLOWERS AND SONG VICTORIOUS.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Ferns.—Of late years Tree Ferns and other strong-growing kinds have been so much in fashion as to put in the shade the great number of small and more elegant sorts that met with favour when these beautiful plants first came into ordinary cultivation. This is much to be regretted, as amongst the dwarf species are to be found many of the most graceful forms of vegetable life in existence, and which are better suited to the space which numbers of amateurs have at command than the large-growing kinds. The raising of decorative plants of a permanent character from seed is always a pleasing operation to those who are fond of gardening, and one in which amateurs with a little practice will be sure to attain success. The seeds or, more correctly speaking, spores (as these germs from which Ferns increase naturally are not fully-developed seeds), can with little trouble be induced to vegetate in large numbers, but from their peculiar character they require different treatment to that employed with seeds of ordinary plants. The spores in the case of the majority of species are produced in little brown masses on the backs of the fronds; they are extremely small, more like particles of fine dust than living organisms. As they require from the time of sowing to be kept continually moist, and, if watered on the surface in the usual way, they are likely to be carried down too deeply in the soil for them to vegetate (and although young plants are moisture-loving plants, they need the (and although young plants are moisture-loving, they need the treatment:—Procure as many feeders (that is, shallow pans, like those sometimes placed under flower-pots) as the number of kinds of spores to be sown; also an equal number of smaller-sized seed-pans to stand in the feeders; place in the pans one-third of drainage material, covering it with some decayed Sphagnum or a few rotten leaves, filling them up to within $\frac{1}{2}$ in. of the rims with half turfy peat full of finely-sifted vegetable fibre, rubbing the vegetable constituents of the soil with the hand through the riddle along with the earthy matter; to this add one-fourth of rough, gritty sandstone (a portion of it broken fine, the remainder left in bits about as large as marbles), and an equal part of charcoal broken in like manner; mix the whole together, pressing it firmly down with the hand or the bottom of an empty pot; take a fine-rosed can, and give as much water as will thoroughly saturate the whole, again smoothing the surface; and on it immediately sow the spores, scattering them on much thicker than ordinary seeds, as only a moderate percentage will grow; cover each pan with a bell-glass or a sheet of ordinary window glass cut so as to just cover the pan. There is a twofold object in thus covering the pots—to retain the moisture so as to keep the surface continually damp, and to prevent water from accidentally getting to it, which, as already observed, would have the effect of washing the spores too deeply into the soil. The pans must be placed in the feeders, which should be kept with about half-an-inch of water in the bottom, of which the soil will absorb a sufficient quantity to keep itself always moist. They should then be stood in a shady position in a stove or greenhouse, according to the warmth required by the respective species. Even the greenhouse kinds will be none the worse for an intermediate temperature, such as a late Vinery, but the pans should be on a moist bottom of sand or ashes, and not on dry shelves; if placed where the sun will have a direct influence on the glasses, shade them with paper, so as not to darken the surface too much. In the course of eight or ten weeks some kinds will begin to vegetate, but even if longer one need not despair of their appearance ultimately. Their first appearance will be indicated by diminutive green cups not larger than the head of a pin; these will increase in size and ultimately push up from their centres small green fronds. When the seedlings are large enough (which, if the spores be sown shortly after this time, will be in the course of the ensuing spring), they must be pricked off 1 in. apart in pans or pots drained and filled with sifted peat made porous with a mixture of sand and broken charcoal, kept continuously moist and slightly shaded; and, when of sufficient size, place them singly in small pots. Many amateurs are under the impression that if they have not got a stove or house devoted exclusively to the cultivation of Ferns, they can only succeed with a few of the commonest kinds, whereas there is a large number of the most beautiful species that will thrive better in a greenhouse temperature, with a fair amount of air and plenty of light, than if grown in a hotter temperature, for not only are they more robust and healthy under the cooler treatment, but they are much less subject to the attacks of thrips, which insect is the bane of greenhouse Ferns grown in heat; yet in the case of these during the first year after potting it will conduce considerably to their size and strength if they can be accommodated with an intermediate-house temperature, after which the darkest corner in the greenhouse should be selected for them. Not only will this be an advantage in leaving the lightest positions for other plants that

require them, but a shady, somewhat confined situation where there is no necessity for giving air so as to come in direct contact with the Ferns, will be better suited to their requirements; yet here, as in the first stages of their existence, they should not be stood upon dry shelves, but on some moisture-holding material. The following are a selection of the most beautiful small and medium-growing species:—*Adiantum cuneatum*, *A. gracillimum*, *A. hispidulum* (pubescens), *A. formosum*, *Davallia bullata*, *D. elegans*, *D. Novæ Zelandiæ*, *Nephrolepis exaltata*, *Pteris serrulata*, and *P. cretica albo-lineata*. The above are the best and most suitable for cutting to mix with flowers for either bouquets or other floral arrangements; the *Davallias* named are especially useful through the autumn when the fronds are fully matured. The undermentioned are equally handsome, but not so generally used for cutting:—*Adiantum sulphureum*, *A. scabrum*, *A. Capillus-Veneris*, *Asplenium Belangeri*, *A. bulbiferum*, *Cheilanthes dealbata* (one of the most beautiful of silver Ferns), *C. frigida*, *Lomaria canariensis*, *D. dissecta*, *D. chærophylla*, *D. pyxidata*, *Lomaria gibba*, *L. Cycadifolia*, *Lygodium scandens*, *L. palmatum* (the last two are climbing Ferns), *Notholaena nivea*, *N. rufa*, *N. tenera*, *N. Eckloniana*, *Platynerium alciorne*, *P. Stemmaria*, *Pteris scaberrima*, *P. aspericaulis*, *P. serrulata variegata*, and *P. serrulata corymbifera*. The following are equally handsome and deserving of cultivation, but require an intermediate temperature:—*Adiantum curvatum*, *A. Farleyense*, *A. tenerum*, *A. trapeziforme*, *Brainea insignis*, *Asplenium dimorphum*, *Cheilanthes elegans*, *Davallia Mooreana*, *D. scabra*, *Lomaria Zamiaefolia*, *Platynerium grande*, *Polypodium Muscæfolium*, *Pteris tricolor*, *P. palmata*, and *P. rubricaulis*; to these may be added *Gleichenias*—*Speluncæ*, *rupestris*, *flabellata*, and *dichotoma*—free-growing, distinct kinds; they will grow in a greenhouse, but do better continually in a little warmth, always moist at the roots, but with a drier atmosphere than most Ferns like. I have purposely omitted *Gymnogrammas*, the gold and silver varieties of which are much liked, but they require a considerable amount of heat to keep them in good condition through the winter, and they are not of use for cutting.

Peaches.—In this most exceptional season I have found it necessary to refer to the treatment requisite for Peaches on open walls, and though often spoken of I consider it advisable to urge still further upon those who have not had to manage this fruit during a summer so adverse as the present, the production and necessary ripening of the wood for next year's bearing. Owing to cold cutting winds, aphides, and blister, the trees in many places, where not closely attended to, have only within the last few weeks begun to make growth of a character calculated to produce fruit; there is no possibility of this late growth getting fully matured, except by careful attention and keeping it sufficiently thinned out so that every shoot retained may be fully exposed to the sun. I should recommend all the young wood that is thus allowed to remain to be kept tied or laid in to the wall, as there is no question that the heat given off from the bricks helps to ripen the wood much quicker than if it be left growing loose at a considerable distance from the face of the wall: but in doing this it is necessary to remind beginners in Peach culture that a few inches of the points of the shoots should be left at liberty so long as they keep extending, for, if tied in too closely, their growth is frequently stopped, in which case some of the lower eyes would break instead of forming bloom-buds. Use the syringe regularly to keep down red spider, which at this time generally makes its appearance, and unless more precautions than usual are taken with the trees, there is every probability that next summer's crop of fruit will not exceed the scanty supply of the present season.

Strawberries.—Late varieties of these, such as British Queen and Elton Pine, will be greatly benefited by liberal waterings. With this fruit, as with other things, mere sprinklings are worse than useless; where the time at command or the supply is insufficient to water further upon those amateurs who have not had to manage this fruit during a summer so adverse as the present, the necessary berries last formed and the last to ripen will keep on growing to a larger size; this watering will also greatly assist the production of runners required for planting shortly, which otherwise promise to be very late.

Asparagus. like all other things this year, has been more than usually late in springing, and through the scarcity of other vegetables, many will have been tempted to continue cutting longer than the welfare of the plants would warrant; where this has been the case, it is well to assist the growth as far as possible with liquid stimulants, the advantage of which to Asparagus is that they act so much quicker than solid manure, giving strength to the plants immediately they reach the roots; it is immaterial what is used to enrich the water thus given—horse or fowl manure, or guano—and as Asparagus is a marine plant, some salt added will be an advantage, in the proportion of a

small handful to 3 gallons of the water; one copious soaking to the beds given early in the present month will generally be found sufficient, except in extraordinarily dry seasons. All weeds should now be removed by hand, for if allowed to remain, the liberal amount of manure given to Asparagus accelerates their growth apace.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

July 9.—Potting *Celosias*, *Primulas*, and herbaceous *Calceolarias*. Shifting *Amarantus salicifolius*, and potting off young *Balsams*. Sowing Bath Cos Lettuce, Digswell Prize, and dwarf green Curled Endive and Spinach. Placing pot Vines in house where they are to fruit, syringing and keeping them in a temperature of 70° at night. Earthing up Cucumbers and French Beans. Planting out Sunflowers.

July 10.—Potting *Bonvardias*. Basketing *Aërides quinquevulnerum* and repotting *Odontoglossum Phalaenopsis* in Moss, top-dressing with peat. Sowing Nonpareil and Advancer Peas, Cabbages, and Early Horn Carrots. Putting in *Pelargonium* cuttings. Clipping shrubs, and giving Peach trees in pots a top-dressing of manure. Hoeing among fruit bushes and putting *Epacris* in cold pits.

July 11.—Putting freshly-imported plants of *Cattleya superba* on blocks, and placing *Dendrobium McCarthiae* in a bare basket. Sowing Six-week Turnips, Long-podded Negro, and Sir Joseph Paxton French Beans; also a late crop of Broad Beans. Putting in cuttings of *Crassula coccinea*. Watering and mulching Peach trees and training conservatory creepers. Placing *Camellias* in Peach-house where they can be shaded a little. Staking Peas.

July 12.—Potting *Cypripedium Lowi* in peat, Moss, and sand. Sowing Ne Plus Ultra Peas. Planting Ten-week Stocks. Salting Asparagus and Carrot beds. Nailing up Tomatoes and outdoor Figs and Vines, and watering Scarlet Runners with guano water.

July 13.—Shifting *Odontoglossum Andersoni*, and sowing a border of Early Horn Carrots and a box of Intermediate Stocks. Planting Asters. Putting in cuttings of *Poinsettias*. Clearing land of Early Peas, and digging it for late Cauliflowers; also preparing land on which to plant Endive. Watering French Beans with guano. Leaving night air on Vineries and Peach-houses in which fruit is ripening.

July 14.—Potting off seedling Musk plants, *Colens* cuttings, and White Pinks. Sowing *Mignonette* in pots for autumn flowering, also Prickly Spinach, and Radishes. Planting Cauliflowers for late supply, and pricking out Wallflowers, clipping hedges and cutting Laurels. Pinching and pegging down plants in flower garden, and picking off all decayed flowers and leaves. Sowing Turnips, having previously watered the drills into which a little guano has been placed. Planting Neapolitan Cabbage Lettuce, Sweet Basil, and Marjoram. Putting in cuttings of *Kalosanthes*, clipping *Arabis* and *Cerastium* edgings, and digging land for late French Beans.

Hardy Flowers.

AURICULAS.—Plants which were re-potted at the proper time are now busily engaged in putting forth new roots into the fresh soil, and, as a consequence, the outer leaves, put forth with so much vigour in early spring, are dying away and giving the plants an unhealthy appearance. There is, however, no cause for alarm; the plants may bear soft showers, but heavy drenching rains should be avoided. As the outside leaves decay they should be removed, and the surface soil should be stirred occasionally.

ASTERS.—Every effort should be made to induce these to make a strong uninterrupted growth by means of watering, mulching with manure, and sprinkling overhead in dry weather. As soon as the buds begin to form, a little weak manure-water will be found of great assistance.

HOLLYHOCKS.—These are already in many instances diseased. It fastens on the lower leaves and eats them quite away, eventually destroying the flower-stalks also. Some assert that moisture at the roots will prevent the spread of the fungus, but this of itself, I fear, will not prove sufficient to stay its progress. It is stated that Mr. Worthington Smith's remedy for the Potato disease—a preparation to which he has given the name of *Salus*—has been applied to the Hollyhock disease with considerable advantage. In the case of this

pest it is best used in solution; the plants should be well drenched overhead with it, and the undersides of the leaves washed also. A healthy growth is soon the result, and if the disease again appear, a second application will soon subdue it. A mulching with manure, and copious root waterings will greatly assist the *Salus*.

PELARGONIUMS.—As early blooming varieties of the show class go out of flower, they should be placed out-of-doors and kept a little dry. After a few days they may be cut down, and it is always well to allow the soil to become quite dry about the roots for two or three days before this is done, as the wound made by cutting away the branches will heal all the sooner. Then, when the cuts begin to heal over, the plants may be placed in a close frame to induce the branches to break vigorously. As soon as the shoots are 1 in. long, water should be withheld for a day or two, the plants turned out of their pots, the whole of the soil shaken out, and the main roots cut away to within 3 in. of the main stem, leaving some fibrous roots about them. The plants should then be re-potted in 5-in. or 6-in. pots, according to their size, in a soil consisting of good yellow loam, sand, leaf-mould, and a little well-decomposed manure, dry enough when used to crumble to pieces in the hand. After potting, the plants need to be kept close for a time to induce them to put forth roots, when they can have more air as the growth lengthens. The branches cut away make good cuttings, and if six or eight be put into a well-drained 4½-in. pot they will soon root and make excellent plants for potting in autumn to bloom in spring.

PYRETHRUMS.—A surprising improvement is taking place in the double varieties of the perennial *Pyrethrum*. I have just received a box of blooms of some new seedling varieties that are large in size, richly coloured, and singularly double—the centre being densely filled with quilled florets, and then surrounded with a double row of broad guard-petals. They have more than rivalled the Quilled German Aster, and they are much more satisfactory plants to grow. Let me describe a few of these flowers: Captain Boyton is cherry-red, large, and full; Captain Nares, magenta; Galopin, deep magenta, shaded with maroon; Krenmhilda, pale pink, large, and full; Queen Mary, blush, flushed with pink, a charming variety; Ceres, bright pink, deepening to rose on the outer florets, large, and fine; Achille, rosy-pink, large and full, and fine in outline; Amethyst, amethyst-pink, brightening to violet, large and full; Cleopatra, pure white; and Duchess of Edinburgh, pale pink, tinted with violet and margined with silver. There are now a great number of varieties of double *Pyrethrums* in cultivation, and they take high rank as border flowers. Some of the brightly-coloured single varieties are very effective also, but generally they have a loose and more branching habit of growth, which is thought objectionable.

RHODANTHES.—In the exhibition of annals in Regent's Park, these form a conspicuous feature. There is the old *Rhodanthe Manglesi*, and then come the more recent introductions, *maculata*, *maculata alba*, and *atro-sanguinea*. These are just now so full of flower that I give them the highest place among annals suitable for pot culture and decorative purposes. *Rhodanthes*, too, are so lasting in character, and, even when the blooms are cut, they are of great service for winter decoration.

VIOLAS.—A *Viola* that will succeed well in the London parks is one that can scarcely fail to be invaluable for bedding purposes. Such an one is *Princess Teck*, a pale mauve-coloured variety, which is now very fine in Battersea Park, and strongly recommended by Mr. Roger, the superintendent.

D.

WELL-GROWN HERBACEOUS CALCEOLARIAS.

CALCEOLARIAS may be said to consist of two distinct sections the shrubby and herbaceous, which do not readily blend with each other. The shrubby sorts are well known as useful decorative plants for the flower garden during summer, although they are now less favourably regarded as bedding plants than they have been in times gone by, a circumstance due in a great measure to a difficulty which has in many localities been experienced with respect to their culture. The herbaceous section are seldom used as bedding plants, but are found to be exceedingly useful in greenhouses, conservatories, and even in sitting rooms, in all of which with attention they will continue to be highly ornamental for a period of not less than three or four months. Herbaceous *Calceolarias* may be readily increased by division, or cuttings inserted in light soil or sand, and placed in a close pit or frame, an operation which should be effected soon after the plants have ceased flowering; but unless it be with the view of increasing unusually meritorious kinds, propagation by this method is seldom

resorted to at the present time, as herbaceous Calceolarias can now be raised from seed, and the plants so obtained will be found to possess every good quality that can be desired or expected. Mr. Barratt, of Bury St. Edmunds, has for years devoted attention to this section of Calceolarias, and his plants have this season been greatly in advance of those of former years. This result has been secured by a judicious system of selection, having reference to the habit of growth, form, texture, and healthy colour of the foliage, as well as the form, colour, size, and markings of the blooms. This season the foliage has been clean and healthy, the flower-stalks stout and robust, carrying abundance of large, well-formed blooms, the markings of which are of the most diversified character, and the colours vary from a straw-white or pale primrose-yellow to the richest crimson-magenta and deep maroon. So distinctly diversified, indeed, are the markings of the flowers, that out of a very extensive collection, it was found to be difficult to select two plants whose blooms were in all respects alike.

Mr. Barratt sows the seed about the middle of July, and the plants generally commence flowering about the end of April. He flowers them in pots 7 in. or 8 in. in diameter, and when large specimens are desired he uses pots of larger dimensions. The seeds of the Calceolarias being exceedingly small, a little care is necessary in sowing as well as in the treatment of the plants during the early stages of development. It is advisable to use for the purpose small seed-pans, or pots some 6 in. in diameter. These should be well drained, and filled with light rich soil, which should be pressed moderately firm, placing the rougher portions upon the Moss which should cover the crocks forming the drainage. The surface of the soil should be made perfectly smooth and level, and should then be well watered with a fine-rosed watering-pot. When this has been absorbed, the seeds should be sown upon the wet surface slightly pressed down; and they may have a slight portion of light soil or silver sand dusted upon them. Some growers, however, do not cover with soil at all, but merely cover the surface of the pot with a piece of glass which the rim will prevent from pressing upon the soil. The pot or pan should then be placed in a pit or frame, or under a hand-glass, so that it can be shaded from the sun, or the pot, with its glass covering, may be placed on the north side of a wall, where the seeds will speedily germinate. As soon as the plants are large enough to handle they should be pricked into pans of similar soil, and shaded from intense sunshine; afterwards they should be potted singly into 3-in. pots, from which they may in due time be transferred into pots of some 6 in. or 8 in. in diameter, in which, unless in cases where large specimens are desired, they may be flowered. They should be wintered in a light pit, or on a shelf in a greenhouse as close to the glass as possible; and as Calceolarias are very liable to the attacks of aphides, the structure containing them should be fumigated with Tobacco or good Tobacco paper, whenever these pests make their appearance.

The soil used for the final shift may be composed of about two parts turfy loam, and one part well-rotted hotbed manure or leaf-soil, with the addition of a portion of silver or other sharp sand, should the loam be of a heavy or tenacious charac-

ter; and as soon as the plants begin to throw up flower-stems they will be materially assisted by the use of clear soot-water, applied about twice a week, more particularly in cases where it is intended to flower the plants in comparatively small pots. As soon, however, as the blooms begin to be fully developed the use of soot or manure water of any kind should be discontinued, as it is possible that a persistence in its use might prove prejudicial to the exquisite markings of the flowers.

P. GRIEVE.

Culford.

PLATE LXXXI.

THE WINTER-SWEET.

(*TOXICOPHLEA SPECTABILIS*).

Drawn by Mas. DUFFIELD.

THIS handsome Cape plant bears, as will be seen by the coloured plate, compact clusters of white blossoms, which in the case of

Brugmansia planted out.

well-grown plants, are produced freely. As a winter and spring-flowering greenhouse plant it well deserves attention, its blossoms, which are sweet-scented, being produced in succession for many weeks at a time when really good white flowers are scarce. Years ago it used to be grown in a few establishments, but became somehow lost to cultivation. Mr. B. S. Williams, of Holloway, however, recently re-introduced it, and brought it into notice by exhibiting finely-bloomed plants of it at South Kensington and elsewhere. In habit of growth and general appearance it bears some resemblance to a *Posoqueria*. The soil best suited to its growth is a mixture of equal parts of loam, peat, and leaf-mould, to which a little sharp sand should be added. It may be easily increased either by means of seeds or cuttings. Seedling plants, however, are never satisfactory, on account of the rampant habit which they assume previous to flowering. Healthy cuttings of half-ripened wood taken off in autumn and

inserted in sharp sandy soil under a bell-glass, will, under favourable circumstances, make bushy, flowering plants the following spring.

The White Brugmansia Planted out.—All who aim at making the greenhouse or conservatory beautiful and picturesque with the smallest amount of trouble have a valuable aid in this well-known plant. Planted out in a bed or border of any kind, and without any special culture beyond allowing it plenty of root-room and water it quickly becomes a handsome bush. It is also generally so healthy and vigorous that year after year it is a source of pleasure. The long and fine white fragrant trumpets are produced plentifully, and are seen to advantage among the soft and ample fresh green leaves. They last a long time in flower, often appearing till nearly the end of the year. It is fitted for walls in certain positions as well as for beds and wide borders, and it is particularly valuable in large cool houses where more natural verdant effects are sought than are obtainable by means of plants in pots.

Pinus omorika.—A new European Conifer, to which the name of *Pinus omorika* is given, has been discovered by Dr. Panic in the mountain regions of South-western Servia. It is said to attain a large size, and to be closely allied to *P. orientalis*.

THE WINTER SWEET (*TOXICOPHLÆA* *SPECTABILIS*)

THE WILSON RAFT.

I HAVE sent you a sectional illustration of the raft which in a tank in our garden at the cottage has proved so useful in the cultivation of bog and water plants. For more than a year I have tried experiments, and can now report perfect success. It will be readily admitted that in ordinary gardens growing marsh and water plants requires much care, and is by no means easy, and that many of even our native bog plants are of very great beauty, for example, the Buck Bean (*Menyanthes trifoliata*), and Grass of Parnassus (*Parnassia palustris*). I will now proceed to show what we have done, in the full hope that others will take up the idea and work it out more fully. Our first raft was very rough and small; it consisted of two pieces of Fir tree, connected by narrow boards; this had not much floating power, but the plants in the few pans which it carried gave good promise. We next made the present raft; this is 8 ft. square, and consists of nine planks, connected underneath by cross pieces, and having about 2 in. open spaces between; this was sunk by the weight of the pots and pans—until sufficiently weighted by pieces of rock—to 2 in. or 3 in. under the surface. On the raft bog plants in pots and water plants in pans were placed, with the result that, with no attention, they flourish as well as in their natural homes. After a time, when the wood had become saturated with water, and its floating power thus lessened, we nailed large pieces of Cork underneath the raft; this enabled it to carry a heavy load. The plants now growing on the raft number twenty, and were

The Wilson Raft for Water Plants.

chosen as representative plants. There are the North American Pitcher-plant (*Sarracenia purpurea*), with three flowers out; *Saxifraga palmata*, Buck Beans (these were sent from America in ignorance of their flowering in this country), Bog Violets (*Pinguicula vulgaris*), Grass of Parnassus, several sorts of *Mimulus*—the Spotted *Mimulus* overgrows its pan, and with floating roots in the water is most beautiful—*Lobelia cardinalis*, Bog Myrtle, a large variety of Yellow Iris, and North American Lady's-slipper (*Cypripedium spectabile*). It is obvious that, while the raft floats between 2 in. and 3 in. under water, each pan or pot may be adjusted according to the requirement of its inhabitant; thus a water-plant is sunk to the full depth, while a plant requiring only moist soil is raised up by a piece of wood placed under its pot. Hitherto I have confined the experiments to simple cultivation; the next aim should be to add ornamental arrangement. Of course the weight of the pots and pans wastes much of the floating power of the raft: I propose superseding these by wood and Cork boxes, the diminished weight will allow the raft to be covered with plants, and to have the effect of a floating island; but probably a still more ornamental form would be a round raft of wood with Cork or wood fastened with copper nails to form sides, the bottom to have only small holes all over to admit the water; there might be cross divisions for different mixtures of soil suitable for the various plants, made not deep enough to show above the surface; in this case the whole raft would be covered with soil, and all woodwork, except the sides, hidden. In any garden with a pond this floating island might be moored to the bank or anchored. As I believe this raft to be a good idea, and that it will prove a real boon to the gardening world, I should like my name to be associated with it, and therefore propose to name it the "Wilson Raft."

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 552, Vol. XI.).

Pomegranate.

- (1) *Lafau*. Go to, sir, you were beaten in Italy for picking a kernel out of a Pomegranate.
All's Well That Ends Well, act ii., sc. 3.
- (2) *Juliet*. It is the nightingale, and not the lark,
That pierced the fearful hollow of thine ear;
Nightly she sings on yon Pomegranate tree.
Romeo and Juliet, act iii., sc. 5.
- (3) *Francis*. Anon, anon, sir; look down into the Pomegranate, Ralph.
1st Henry IV., act ii., sc. 4.

There are few trees that surpass the Pomegranate in interest and beauty combined. "Whoever has seen the Pomegranate in a favourable soil and climate, whether as a single shrub or grouped many together, has seen one of the most beautiful of green trees; its spiry shape and thick-tufted foliage of vigorous green, each growing shoot shaded into tenderer verdure and bordered with crimson and adorned with the loveliest flowers; filmy petals of scarlet lustre are put forth from the solid crimson cup, and the ripe fruit of richest hue and most admirable shape" (*Lady Calcott's "Scripture Herbal."*) A simpler but more valued testimony to the beauty of the Pomegranate is borne in its selection for the choicest ornaments on the Ark of the Tabernacle, on the priest's vestments, and on the rich capitals of the pillars in the Temple of Solomon.

The native home of the Pomegranate is not very certainly known, but the evidence chiefly points to the north of Africa. It was very early cultivated in Egypt, and was one of the Egyptian delicacies so fondly remembered by the Israelites in their desert wanderings, and is frequently met with in Egyptian sculpture. It was abundant in Palestine, and is often mentioned in the Bible, and always as an object of beauty and desire. It was highly appreciated by the Greeks and Romans, but it was probably not introduced into Italy in very early times, as Pliny is the first author that certainly mentions it, though some critics have supposed that the *aurea mala* and *aurea pomæ* of Virgil and Ovid were Pomegranates. From Italy the tree soon spread into other parts of Europe, taking with it its Roman name of *Punica Malus*, or *pomum granatum*. *Punica* showed the country from which the Romans derived it, while *granatum* (full of grains) marked the special characteristic of the fruit that distinguished it from all other so-called Apples. Gerarde takes advantage of the name to give a queer instance of local etymology:—"Pomegranates grow in hot countries, towards the south in Italy, Spaine, and chiefly in the kingdom of Granada, which is thought to be so named of the great multitude of Pomegranates, which be commonly called *Granata*." This derivation, however, may be matched by the derivation of Yucatan, from the quantity of Yuccas growing there. The Pomegranate lives and flowers well in England, but when it was first introduced is not recorded. I do not find it in the old vocabularies, but Chaucer gives it a prominent place in "that gardeyn, wele wrought," "the garden that so lyked me."

There were, and that I wote fulle well,
Of Pomgranettys a fulle gret delle,
That is a fruit fulle welles to lyke,
Namely to folk whaune they ben sike.

Romance of the Rose.

Gerarde had it in 1596, but from his description it seems that it was a recent acquisition. "I have recovered," he says, "divers young trees hereof, by sowing of the seed or grains of the height of three or four cubits, attending God's leisure for floures and fruit." Three years later, in 1599, it is noticed for its flowers in Batte's "Dry Dinner" (as quoted by Brand), where it is asserted that "if one eate three small Pomegranate flowers (they say) for a whole yeaere he shall be safe from all manner of eyesore;" and Gerarde speaks of the "wine which is pressed forth of the Pomegranate berries named Rhoitas or wine of Pomegranates," but this may have been imported. But, when introduced, it at once took kindly to its new home, so that Parkinson was able to describe its flowers and fruits from personal observation. In all the southern parts of England it grows very well, and is one of the very best trees we

have to cover a south wall; it also grows well in towns, as may be seen at Bath, where a great many very fine specimens have been planted in the areas in front of the houses, and have grown to a considerable height. When thus planted and properly pruned the tree will bear its beautiful flowers from May all through the summer; but generally the tree is so pruned that it cannot flower. It should be pruned like a Banksian Rose, and other plants that bear their flowers on last year's shoots, *i.e.*, simply thinned, but not cut back or spurred. With this treatment the branches may be allowed to grow in their natural way without being nailed in, and if the single-blossomed species be grown, the flowers in good summers will bear fruit. Last year (1876) I counted on a tree in Bath more than sixty fruit; the fruits will perhaps seldom be worth eating, but they are curious and handsome. The sorts usually grown are the pure scarlet (double and single), and a very double variety with the flowers somewhat variegated. These are the most desirable, but there are a few other species and varieties, including a very beautiful dwarf one from the East Indies, that is too tender for our climate out-of-doors, but is largely grown on the Continent as a window plant.

Pomewater (see Apple).

Popering (see Pear).

Poppy.

Iago.

Not Poppy or Mandragora,
Nor all the drowsy syrups of the world
Shall ever medicine thee to that sweet sleep
Which thou own'dst yesterday.

Othello, act iii., sc. 3.

The Poppy had of old a few other names, such as Corn-rose and Cheese-bowls (a very old name for the flower), and being "of great beautie, although of evil smell, our gentlewomen doe call it Jone Silverpin." This name is difficult of explanation, even with Parkinson's help, who says it means "faire without and foule within," but it probably alludes to its gaudy colour and worthlessness. But these names are scarcely the common names of the plant, but rather nicknames; the usual name is and always has been Poppy, which is an easily-traced corruption for the Latin *papaver*, the Saxon and early English names being variously spelt *popig* and *papig*, *popi* and *papy*; so that the Poppy is another instance of a very common and conspicuous English plant known only or chiefly by its Latin name anglicised.

Our common English Poppy "being of a beautiful and gallant red colour," is certainly one of the handsomest of our wild flowers, and a Wheat field with a rich undergrowth of scarlet Poppies is a sight very dear to the artist, while the weed is not supposed to do much harm to the farmer. But this is not the Poppy mentioned by *Iago*, for its narcotic qualities are very small; the Poppy that he alludes to is the Opium Poppy (*P. somniferum*). This Poppy was well known and cultivated in England long before Shakespeare's day, but only as a garden ornament; the opium was then, as now, imported from the East. Its deadly qualities were well known. Spenser speaks of the plant as the "dull Poppy," and describing the Garden of Mammon, he says:—

There mournful Cypress grew in greatest store,
And trees of bitter gall, and Heben sad,
Dead-sleeping Poppy, and black Hellebore,
Cold Coloquintida.

And Drayton similarly describes it—

Here Henbane, Poppy, Hemlock here,
Procuring deadly sleeping.

The name of opium does not seem to have been in general use, except among the apothecaries, and I believe that Milton is the first writer of eminence that uses it.

Which no cooling herb
Or medicinal liquor can assuage,
Nor breath of vernal air from snowy Alp;
Sleep hath forsok and given me o'er
To death's bennuming opium as my only cure.

Samson Agonistes.

Many of the Poppies are very ornamental garden plants. The pretty yellow Welsh Poppy (*Meconopsis cambrica*),

abundant at Cheddar Cliffs, is an excellent plant for the rock-work, where, when once established, it will grow freely and sow itself; and for the same place the little *Papaver alpinum*, with its varieties, is equally well suited. For the open border the larger Poppies are very suitable, especially the great Oriental Poppy (*P. orientale*) and the grand scarlet Siberian Poppy (*P. bracteatum*), perhaps the most gorgeous of hardy plants, while among the rarer species of the tribe we must reckon the *Meconopses* of the Himalayas (*M. Wallichii* and *M. nepalensis*), plants of singular beauty and elegance, but very difficult to grow and still more difficult to keep, even if once established. Within the last three years they have been successfully grown at Kew and in a few other places, and have been proved to be perfectly hardy, for they have been grown in wonderful beauty in Mr. Elwes' garden at Miserden, one of the coldest villages on the Cotswold, but whether they can be permanently preserved, time only can show. Besides these Poppies, the large double garden Poppies are very showy and of great variety in colour, but they are only annuals.

Potato.

(1) *Thersites*. How the devil Luxury, with his fat rump and Potato-finger, tickles these together.

Troilus and Cressida, act v., sc. 2.

(2) *Falstaff*. Let the sky rain Potatoes; let it thunder to the tune of green sleeves, hail kissing comforts, and snow Eringoes.

Merry Wives of Windsor, act v., sc. 5.

The chief interest in these two passages is that they contain almost the earliest notice of Potatoes after their introduction into England. The generally received account is that they were introduced into Ireland in 1584 by Sir Walter Raleigh, and from thence brought into England; but the year of their first planting in England is not recorded. They are not mentioned by Lyte in 1586. Gerarde grew them in 1597, but only as curiosities, under the name of Virginian Potatoes (*Battata Virginianorum* and *Pappas*), to distinguish them from the Spanish Potato, or *Convolvulus Battatas*, which had been long grown in Europe. They seem to have grown into favour very slowly, for half a century after their introduction, Waller still spoke of them as one of the tropical luxuries of the Bermudas.

With candy'd Plantains and the juicy Pine,
On choicest Melons and sweet Grapes they dine,
And with Potatoes fat their wanton swine.

The Battel of the Summer Islands.

Potato is a corruption of *Batatas* or *Patatas*.

As soon as the Potato arrived in England, it was at once invested with wonderful restorative powers, and in a long, exhaustive note in Steevens' *Shakespeare*, Mr. Collins has given all the passages in the early writers in which the Potato is mentioned, and in every case they have reference to these supposed virtues. These passages, which are chiefly from the old dramatists, are curious and interesting in the early history of the Potato, and as throwing light on the manners of our ancestors; but as in every instance they are all more or less indelicate, I, of course, refrain from quoting them here.

As a garden plant, we now restrict the Potato to the kitchen garden and the field, but it belongs to a very large family, the Solanaceæ or Nightshades, of which many members are very ornamental, though as they chiefly come from the tropical regions, there are very few that can be treated as entirely hardy plants. One, however, is a very beautiful climber—the *Solanum jasminoides* from South America, and quite hardy in the South of England. Trained against a wall it will soon cover it, and when once established will bear its handsome trusses of white flowers with yellow anthers in great profusion during the whole summer. A better known member of the family is the *Petunia*, very handsome, but little better than an annual. The pretty Winter Cherry (*Physalis Alkekengi*), is another member of the family, and so is the Mandrake (see *Mandrake*). The whole tribe is poisonous, or at least to be suspected, yet it contains a large number of most useful plants, as the Potato, Tomato, Tobacco, Datura, and Cayenne Pepper.

Primrose.

- (1) *Queen.* The Violets, Cowslips, and Primroses
Bear to my closet.
Cymbeline, act v., sc. 2.
- (2) *Queen Mary.* I would be blind with weeping, sick with groans,
Look Pale as Primrose, with blood-drinking sighs,
And all to have the noble duke alive.
2nd Henry VI., act iii., sc. 2.
- (3) *Arviragus.* Thou shalt not lack
The flower that's like thy face—pale Primrose.
Cymbeline, act iv., sc. 2.
- (4) *Hermia.* In the wood where often you and I
Upon faint Primrose-beds were wont to lie.
Midsummer Night's Dream, act i., sc. 1.
- (5) *Perdita.* Pale Primroses
That die unmarried ere they can behold
Bold Phoebus in his strength.
Winter's Tale, act iv., sc. 3.
- (6) *Ophelia.* Like a puffed and reckless libertine,
Himself the Primrose path of dalliance treads
And reck's not his own rede.
Hamlet, act i., sc. 3.
- (7) *Porter.* I had thought to have let in some of all professions that go the
Primrose way to everlasting fire.
Macbeth, act ii., sc. 3.
- (8) Witness this Primrose bank where on I lie.
Venus and Adonis.

Whenever we speak of spring flowers, the first that comes into our minds is the Primrose. Both for its simple beauty and for its early arrival among us we give it the first place over

Whatsoever other flowre of worth
And whatso other hearb of lovely hew,
The joyous Spring out of the ground brings forth
To cloath herself in colours fresh and new.

It is a plant equally dear to children and their elders, so that I cannot believe that there is any one (except Peter Bell) to whom

A Primrose by the river's hrin
A yellow Primrose is to him—
And it is nothing more.

—rather I should believe that W. Browne's "Wayfaring Man" is a type of most English countrymen in their simple admiration of the common flower—

As some wayfaring man passing a wood,
Whose waving top hath long a sea-mark stood,
Goes jogging on and in his mind nought hath,
But how the Primrose finely strews the path,
Or sweetest Violets lay down their heads
At some tree's roots or mossy feather beds—
Britannia's Pastorals—(Contemporary with Shakespeare).

It is the first flower, except perhaps the Daisy, of which a child learns the familiar name; and yet it is a plant of un-failing interest to the botanical student, while its name is one of the greatest puzzles to the etymologist. The common and easy explanation of the name is that it means the first Rose of the year—but like so many explanations that are derived only from the sound and modern appearance of a name, this is not the true account. The full history of the name is too long to give here, but the short account is this—"The old name was Prime Rolles—or primerole. Primerole is an abbreviation of Fr., *primeverole*: It, *primaverola*, diminutive of *prima vera* from *flor di prima vera*, the first spring flower. *Prime-rolle*, as an outlandish unintelligible word, was soon familiarized into *primerolles*, and this into *primrose*"—(Dr. Prior). Yet though the name Primrose was not applied to the flower, it was an old English word, used to show excellence.

A fairer nymph yet never saw mine eie,
She is the pride and Primrose of the rest—
Spenser—(Colin Clout).

Was not I (the Briar) planted of thine own hande
To bee the Primrose of all thy lande,
With flow'ring blossomes to furnish the prime
And scarlet berries in summer time—
Spenser—(Shepherd's Calendar, February).

It was also a flower name, but not of our present Primrose, but of a very different plant. Thus in a homale of the 15th century we have "hoc ligustrum, a Primerose," and in a Pictorial Vocabulary of the same date we have "hoc bigus-

trum, A^{ca} a Prymrose"—and this name for the Privet lasted with a slight alteration into Shakespeare's time. In Tusser's "Husbandry" we have "set Privey or Prim" (September Abstract), and

Now set ye may
The Box and Bay
Hawthorn and Prim
For clothe's trim—(January's Abstract).

And so it is described by Gerard as the Privet or Prim Print (*i.e.* primé printemps), and even in the 17th century, Cole says of ligustrum "This herbe is called Primrose." When the name was fixed to our present plant, I cannot say, but certainly before Shakespeare's time, though probably not long before. It is rather remarkable that the flower, which we now so much admire, seems to have been very much overlooked by the writers before Shakespeare. In the very old vocabularies it does not at all appear by its present Latin name, *Primula veris*, but that is perhaps not to be wondered at, as nearly all the old botanists applied that name to the Daisy. But neither is it so much noticed by its English name. I can only find it in two of the vocabularies. In an English Vocabulary of the 14th century is "Hæc pimpinella, A^e primerolle—but it is very doubtful if this can be our Primrose, as the Pimpernel of old writers was the Burnet. But in the treatise of Walter de Bibbesworth (13th century) is

Primerole et primeveyre (cousloppe)
Sur tere aperunt en tens de veyre.

I should think there is no doubt this is our Primrose. Then we have Chaucer's description of a fine lady—

Hire shoon were laced on her legges hie
She was a Primerole, a piggenie,
For any lord to ligen in his bedde,
Or yet for any good yeman to wedde.

Canterbury Tales, i., 3267.

I have dwelt longer than usual on the name of this flower, because it gives us an excellent proof of how much literary interest may be found even in the names of our common English plants.

But it is time to come from the name to the flower. The English Primrose is one of a large family of more than fifty species, represented in England by the Primrose, the Oxlip, the Cowslip, and the Bird's-eye Primrose of the north of England and Scotland. All the members of the family, whether British or exotic, are noted for the simple beauty of their flowers, but in this special character there is none that surpasses our own. "It is the very flower of delicacy and refinement; not that it shrinks from our notice, for few plants are more easily seen, coming as it does when there is a dearth of flowers, when the first birds are singing, and the first bees humming, and the earliest green putting forth in the March and April woods; and it is one of those plants which dislikes to be looking cheerless, but keeps up a smouldering fire of blossom from the very opening of the year, if the weather will permit" (Forbes Watson). It is this character of cheerfulness that so much endears the flower to us; as it brightens up our hedgerows after the dulness of winter, the harbinger of many brighter perhaps, but not more acceptable beauties to come, it is the very emblem of cheerfulness. Yet it is very curious to note what entirely different ideas it suggested to our forefathers. To them the Primrose seems always to have brought associations of sadness, or even worse than sadness, for the "Primrose path" and "Primrose ways" of Nos. 6 and 7 are meant to be suggestive of pleasures, but sinful pleasures.

Spenser associates it with death in some beautiful lines in which a husband laments the loss of a young and beautiful wife—

Mine was the Primerose in the lowly shade!

Oh! that so fair a flower so soon should fade,
And through untimely tempest fade away.

And in another place his only epithet for it is "green," which quite ignores its brightness—

And Primroses greene
Embellish the sweete Violet.

Shakespeare has no more beautiful epithets for our favourite flower than "pale," "faint," "that die unmarried;" and Milton follows in the same strain, yet sadder. Once, indeed, he speaks

of youth as "Brisk as the April buds in Primrose season" ("Comus,") but only in three passages does he speak of the Primrose itself, and in two of these he connects it with death—

Bring the rather Primrose that forsaken dies.

And every flower that sad embroidery wears.

Lycidas.

O fairest flower, no sooner blown but blasted,
Soft silken Primrose fading timelessly;
Summer's chief honour if thou hadst outlasted
Bleak winter's force that made thy blossoms drie.

On the Death of a Fair Infant.

His third account is a little more joyous—

Now the bright morning star, day's harbinger,
Comes dancing from the East, and leading with her
The flowery May, who from her green lap throws
The yellow Cowslip and the pale Primrose.

On May Morning.

And nearly all the poets of that time spoke in the same strain, with the single exception of Ben Jonson and the two Fletchers. Jonson spoke of it as "The glory of the spring." Giles Fletcher says—

Every bush lays deeply perfumed
With Violets; the wood's late wintry head,
Wide flaming Primroses set all on fire.

And Phiucas Fletcher—

The Primrose lighted new her flame displays,
And frights the neighbour hedge with fiery rays.

And here and there sweet Primrose scattered.

Nature seemed work'd by Art, so lively true
A little heaven or earth in narrow space she drew.

I can only refer very shortly to the botanical interest of the Primula, and that only to direct attention to Mr. Darwin's paper in the "Journal of the Linnean Society," 1862, in which he records his very curious and painstaking inquiries into the dimorphism of the Primula, a peculiarity in the Primula that gardeners had long recognised in their arrangement of Primroses as "pin-eyed" and "thrum-eyed." It is perhaps owing to this dimorphism that the family is able to show a very large number of natural hybrids. These have been carefully studied by Professor Kerner, of Innsbruck, and it seems not unlikely that a further study will show that all the European so-called species are natural hybrids from a very few parents.

Yet a few words on the Primrose as a garden plant. If the Primrose be taken from the hedges in November, and planted in beds thickly in the garden, they make a beautiful and true display of flowers and foliage from February till the beds are required for the summer flowers; and there are few of our wild flowers that run into so many varieties in their wild state. In Pembrokeshire and Cardiganshire I have seen the wild Primrose of nearly all shades of colour, from the purest white to an almost bright red, and these can all be brought into the garden with a certainty of success and a certainty of rapid increase. There are also many double varieties, but all of these are more often seen in cottage gardens than elsewhere; yet no gardener need despise them.

One other British Primrose, the Bird's-eye Primrose, almost defies garden cultivation, though in its native habitats in the north it grows in most ungenial places. I have seen places in the neighbourhood of the bleak hills of Ingleborough, where it almost forms the turf; yet away from its native habitat it is difficult to keep, except in a greenhouse. For the cultivation of the other non-English species, I cannot do better than refer to an excellent paper by Mr. Niven in THE GARDEN for January 29, 1876, in which he gives an exhaustive account of them.

I am not aware that Primroses are of any use in medicine or cookery, yet Tusser names the Primrose among "seeds and herbs for the kitchen," and Lyte says "the Cowslips, Primroses, and Oxlips are now used daily amongst other pot herbes, but in physicke there is no great account made of them."

Prunes (See Plums).

H. N. ELLACOMBE.

(To be continued).

THE KITCHEN GARDEN.

SOWING TURNIPS IN DRY WEATHER.

It often happens at this season, when the main crop of Turnips for the winter's supply requires to be sown, that the land is in a dry, rough, harsh condition, totally unfit for the germination of small seeds. Some may say, wait for rain, and this I have sometimes done; but I have never been altogether satisfied that I have acted rightly in doing this, for not only are delays dangerous, but frequently at this season if we have a passing shower, it is of no real benefit in the case of our porous soil. I find it to be a better plan to sow about the right time, and if the land be dry and no immediate prospect of rain, to break down the soil so that the drills can be drawn, and, before sowing the seeds, well water with liquid manure, made with guano and salt, about 2 lb. of each to 40 gallons of water, covering the seeds with a mixture of fine soil and ashes or burnt earth, saved for such a purpose when the rubbish-heaps are cleared up. This moistening of the soil in the drills and for some distance down with liquid manure has a wonderful effect on the vigour of the plants all through the season. Of course, at the time it involves a little extra trouble, but then reliance may be placed upon having a crop, and it is worth something to feel free from anxiety on that head—especially in a place where the Turnip-fly is troublesome if the plants be weakly. I am rather partial to this mixture of guano and salt for many things on our soil. Lettuce, Spinach, and many other crops of which a succession is required to be kept up are greatly benefited by having the drills soaked with liquid manure at the time of sowing; it enables them to make a start, and when rain does come they have the full benefit of it. Waiting for rain is, in most cases I think, a mistake; even in planting out Broccoli or Winter Greens two or three good waterings will usually be sufficient to establish them, drawing a little dry earth round the stems after the last watering to check evaporation; and everyone knows how much cleaner and pleasanter the work can be done when the surface is dry. Although I have only mentioned guano and salt, nothing that has any value as a manure need come amiss. Soot in a liquid form, applied in the drills with the seeds, is very beneficial, as the crop at once appreciates its presence.

E. HOBDAY.

CULTURE OF HORSERADISH.

HORSERADISH succeeds best in a deep, rich, sandy soil. The finest Horseradish which I ever saw was grown in mud thrown out from the River Lea; by the side of the river was a large bed of Horseradish that had been growing there for a number of years, the digging of it up, when wanted, being generally done haphazard wherever there were likely to be the best sticks. It became necessary to clean out the river, and mud was thrown over the bed of Horseradish to a depth of from 2 ft. to 3 ft. Next year the Horseradish came up through the mud in the shape of clean, straight sticks, from 2 ft. to 3 ft. in length, and in every way excellent. The general way, however, of growing Horseradish is to trench a piece of ground 2 ft. deep, adding plenty of rotten manure, and in the spring to plant crowns with 2 in. or 3 in. of straight root attached to them, or, in the event of not having sufficient crowns, to use pieces of straight root 4 in. or 5 in. long. The best way is to plant in rows 12 in. or 15 in. apart, the sets being 8 in. or 9 in. asunder in the rows; holes may be made with a stout stick or crowbar 15 in. or so deep, and the set dropped in and covered with a little fine soil. Some prefer a ridge similar to that between Celery trenches, planting small, long roots, 14 in. or 15 in. long, in three rows, and as the sticks are dug up for use the ridge is made up and planted again, therefore a succession of good Horseradish can always be obtained. By the following method of growing Horseradish sticks that measure from 5 in. to 8 in. in circumference may, it is said, be produced in ten months. During February take small, straight pieces of the roots about the size of, or somewhat smaller than, the little finger; from these remove all the side-shoots and roots, and form them into straight sets from 8 in. to 14 in. long. Prepare a piece of ground by deeply digging and well manuring

it, and plant the sets in it in rows 3 ft. apart, and from 12 in. in the rows; the sets must be planted in a slanting position, and must not be more than 2 in. beneath the surface. The ground at all times must be kept free from weeds, and should be well watered in very dry weather. Planting the set at an angle—in fact, in nearly a horizontal position—is, no doubt, the great secret of success, for, being placed so near the surface, it has the full benefit of the sun's heat, which, as a matter of course, induces it to make rapid growth long before that which is planted according to the ordinary method—*i.e.*, from 18 in. to 20 in. deep, and in a perpendicular position—reaches the surface.

One cultivator with whom I am acquainted inserts a common round drain-tile a couple of inches in the ground, fills it with fine earth, and plants a set near the top of the tile and 10 in. above the surface, a plan by which digging for the product is saved, and a fine clean stem is the result. Another

easily grown as Horseradish should be sufficiently remunerative to pay for importation, whilst in London market gardens comparatively little of it is grown. The reason for this may probably be that there is only a demand of any importance at certain seasons of the year, December being the principal month in which it is required. It might perhaps, therefore, scarcely do for market gardeners near London, who have to pay such high rents to occupy a very large portion of their ground with such crops as Horseradish, that will not admit of other crops being grown amongst it, and for which the sale is somewhat uncertain. Indeed, only a few salesmen who do business with hotels and similar places can dispose of it in any quantity; and Horseradish being a root that will keep good for a considerable length of time, they can afford to import large quantities of it at a time, and by so doing buy at a much cheaper rate than would remunerate English growers. S.

Mushroom Cave.

says that by placing leaves or litter on the tops of Horseradish crowns 2 ft. or so thick, the plants grow through them in the course of the summer, making small white roots the thickness of one's finger, which are as tender as spring Radishes. During the winter months, a supply of Horseradish should always be at hand, stored away in sheds, &c., and covered with dry soil, or sand, in the same way as Carrots, &c. The salesmen in Covent Garden Market have a large demand for Horseradish, judging by the immense quantities of it which are imported from Holland. Huge heaps of it may be seen on market mornings about Christmas time, consisting of bundles containing from twenty to twenty-five sticks each, of first-rate quality, tied up with small but strong withies. These bundles arrive packed firmly in large barrels, and in many cases the heads are found to have made a considerable amount of growth on their way, which, of course, is blanched as white as Seakale. The sticks are not washed before being packed, but are placed in the barrels apparently as they are dug from the ground with a quantity of soil adhering to them. It is somewhat remarkable that a crop so

Mushroom Cave.—The accompanying view of one of the Parisian Mushroom Caves was drawn by M. De Bar during the present year. As we have before fully explained this curious and profitable mode of Mushroom culture, it is needless to say more on the subject. We, however, think that so striking a view by one of the best artists in black and white, and so well engraved, can hardly fail to interest our readers.

A Friend in Need.—Nobody can read the following extract without feeling the great need of knowing the habits of the insect creatures that haunt our gardens:—"One of the most troublesome of all garden pests in the way of raising Cabbages is the white Cabbage butterfly (Pieris Rapae) and its caterpillars, or "green Cabbage worms" as sometimes called. This enemy of the Cabbage was imported from Europe to America nearly twenty years ago, and appeared near Montreal. Its principal enemy which has held it in check in Europe for hundreds of years was left behind, and it was unopposed in its ravages in this country for half-a-dozen years, during which it spread over New England and the Middle States, and has now reached Nevada in the west. After a time, however, its insect enemy, a minute fly (Pteromalna puparum), found its way over the ocean and commenced its attacks on its old enemy in the New World. The female fly deposits her eggs in the body of the caterpillar just under the skin, sometimes to the number of twenty, which hatch there and feed upon the fat of the caterpillar. These grubs continue to feed upon the caterpillars until they cause their death, which is before they become transformed into butterflies."

THE FRUIT GARDEN.

SUMMER-PRUNING GOOSEBERRIES.

"J. M. D." (see p. 542, Vol. XI.) asks for the opinion of Gooseberry growers as to the merits of summer-pruning; and in giving a short outline of the system of pruning and culture practised here, I by no means wish to imply that as good results may not be obtained by other means, but simply that the produce is so satisfactory that no change is desirable. We have at present an unusually heavy crop, and, although the fruit has been thinned several times for tarts and bottling in a green state, what is left increases in weight so rapidly that the majority of the outer branches rest on the ground when not supported by temporary forked stakes or other supports. We have a new plantation, made only eighteen months ago, prepared in the following manner:—The ground was deeply trenched in the previous autumn; a quantity of old hotbed manure was worked into the bottom of the trenches, and in February last year, a number of healthy young bushes that had been closely headed down the previous year were planted in rows running north and south, 6 ft. apart each way, and as soon as they commenced to grow a good mulching of old spent tan and leaf-mould was spread over the roots, and a row of Strawberry plants, from which to procure pot runners was planted half-way between each row. Although the summer was hot and dry, the bushes grew amazingly, and each produced a few fruits; they were all headed back, and the branches were thinned out as soon as the buds began to burst, and now every piece of wood is literally lined with fruit, averaging from 3 to 4 quarts per tree. There is therefore no necessity for keeping old worn-out, sucker-producing bushes, for fear of being without fruit for years. I may add that all our bushes are on single stems, and they are never summer pruned, because the weight of crop keeps them from requiring it, and there are no suckers. Our spring pruning exactly coincides with "J. M. D.'s" practice, viz., to keep the centre of the bushes open and the branches thin and evenly balanced; side shoots where not required for filling vacancies are cut in close, and if the trees be kept free from the attacks of birds the main shoots will be well furnished with fruit buds; although our bushes look thin after pruning, they are so full of fruit and foliage during the gathering season as to leave just sufficient room for getting amongst them. Of bushes left entirely unpruned we have examples in those that are to be destroyed the following year: but for bushes intended to stand several years there can be no question as to the propriety of judicious pruning.

J. GROOM.

Henham.

VARIETIES OF STRAWBERRIES.

THIS season is teaching us, somewhat roughly, the great value that ought to be placed upon the Strawberry as a fruit both for dessert and preserving, even under not too favourable circumstances. Whilst so many of our hardy fruits are thin as regards a crop, and in some cases absolutely barren, the Strawberry has done remarkably well—a great point in favour of this fruit. Perhaps of all hardy fruits the Strawberry and the Raspberry are the most certain to produce regular crops; neither are, however, keeping fruits. They must therefore be largely preserved, and for that purpose I certainly expect to find the Strawberry more largely grown in private gardens in future than it now is. A few weeks ago I alluded to some few varieties that I was growing here this season in larger quantity than usual. The selection comprises a dozen of the best kinds; the soil in which they grow is a stiff, clayey loam, and in it, in spite of drought and the soil baked to the hardness of brick, the plants have done remarkably well, and for yearlings have borne a good crop. Strawberries, like other fruits and many vegetables, are apt to change character on diverse soils, but that a stiff loam is the very soil in which these plants succeed best, I am constrained to believe. I have found each variety displaying its true merits or demerits, as the case may be. Not only earliest but best of the earliest kinds is Vicomtesse Héricart de Thury, a variety of the old Keen's Seedling type, having that broad,

robust foliage so peculiar to that section. It is a first early cropper, and bears medium-sized fruit of a rich deep colour in profusion. Next in order of ripening comes La Grosse Sucrée, a French kind, having broad foliage, robust growth, and an average cropper. The fruit, which is medium-sized, is pale red, pointed, and of brisk flavour, but it is only a second-rate variety. Sir J. Paxton possesses considerable excellence, and is much in favour for market purposes. Premier proved to be the best in the collection: at the blooming time it exhibits more flowers than any of the others, and its fruit is the finest; it is an early second early, and is evidently a superior variety; its foliage is broad, robust, and handsome; the fruit is large, broad, solid, richly coloured, and of a pleasant brisk flavour; it is a first-rate market variety. President is almost too well known to need description; it is a capital kind for forcing, and in some soils is a valuable outdoor variety, but with me it was not particularly good; it is, however, a useful sort, and finds a place in all good collections. Dr. Hogg is perhaps the very best, and also the earliest of all the British Queen section; its fruit is large, generally well coloured, but at times apt to show a green point; this, however, detracts more from its personal appearance than from its value, as it is a luscious variety and a good cropper. Empress Eugénie has narrow foliage, but a strong, robust habit, and it is a heavy cropper; its fruit is large, somewhat pointed, rich in colour, and excellent in flavour; it is a valuable variety as a general cropper. Lucas is a particularly fine, robust, third early variety with a broad, umbrageous foliage that serves so well to protect the flowers from frost and the fruit from bright sunshine; it is an abundant cropper, the fruit being rather long and pointed, richly coloured, and good in flavour. James Veitch has foliage like that of the British Queen; its fruit is moderately large, and of good colour, but not first-rate in flavour; some growers have, however, written favourably of this kind. The Rev. W. F. Radclyffe is another variety of the British Queen type, but rather later; it is a good cropper, and the fruit is large and delicious in flavour; with many growers this is an exceedingly popular kind. Amateur belongs to the Pine family, and has peculiar foliage that renders it more distinct; it is a robust grower, and a heavy cropper; its fruit is somewhat sharp in taste, but it is one of the most useful kinds to cultivate for preserving purposes. Last of all is that most excellent and popular variety, the Frogmore Late Pine; this, in soil that suits it, produces most delicious fruit of the true Pine flavour late in the season; it is a robust variety, and one which should be grown in all gardens where late Strawberries are in request. If I could grow only six kinds, I should select Héricart de Thury, Sir Joseph Paxton, Premier, Dr. Hogg, Lucas, and Frogmore Late Pine; and for three varieties only, Héricart de Thury, Premier, and Lucas.

Bedfont.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Bees and Fruits.—A correspondent of the "Société Centrale d'Apiculture et d'Insectologie" in France denies the accusation that bees injure fruits. He states, and from our experience correctly, that the bee does not attack sound fruit; that it only sucks injured fruit, or such as has been punctured by the sparrow or earwig, or that the rain has caused to split open.

Screens for Fruit Trees.—Mr. P. Barry stated, at the horticultural meeting at Rochester, that winds often have a drying effect, and often injure the blossom-buds or blossoms. He had known fruit to succeed in the city and fail in the country. Mr. Moody had known Peaches killed on the windward side of trees and escape on the other side. Mr. Adams, of Michigan, said that screens as wind-breaks were the best protection for the tops, and mulching for the roots. Mr. Moody said that wind-breaks also prevented the snow blowing off, and thus saved the trees from exposure.

Peach Trees Killed by Paraffin.—My Peach trees were well formed and healthy, and bore crops equal to any in the county. Scale having appeared on them, I was strongly recommended to brush them over with paraffin oil, which I did on December 21. It not only destroyed the scale, but the trees also. There were no signs of harm done until the fruit was set, when gradually branch after branch showed signs of decay, and now they are more like firewood than growing trees. I also know others in this neighbourhood who have suffered through using paraffin, and would therefore, like "R. W.," recommend your readers to consider before using it on trees or Peas. I have also tried an experiment on a plant of Prickly Comfrey, which it destroyed in two days.—S. LAIRD, Dunninald Castle, by Montrose, N.B., in "Gardener's Chronicle."

Frost and Low Ground.—It appears from the "California Horticultural," that the planters of Almonds at Santa Rosa are avoiding the valleys and planting on hills. No failure of the Almonds is recorded when growing on the higher grounds, but the crop is sometimes lost lower down.

WRIGHTS ENDLESS FLAME-IMPACT BOILER.

THIS boiler, which is constructed on a somewhat novel principle, has lately attracted a good deal of attention. I had an opportunity of seeing it at work at two different places during the last month, viz., at the Grange near Chester, and at Clovenfords vineyard, where Mr. Thomson intends to replace all the old boilers with it, feeling confident, as he told me, that it would effect a great saving in fuel—a very serious item of the expenditure at Clovenfords, where none of the numerous long ranges of Vineries are under 200 ft. in length, while they are nearly all span-roofed and 24 ft. wide and nearly as high, and consequently expose a vast area of radiating surface to the air, fully taxing the dozen or more long rows of 4-in. piping in each house. The merits of Wright's boiler, scientific and otherwise, are fully set forth in the advertisements, and it is not my intention to say much about them here. What gardeners and others want to know most in such cases is what the boiler can do, and on this point I shall only record what I saw. It is necessary to explain first, however, that the boiler is constructed in sections which are cast separately in one piece, and afterwards put together by india-rubber joints at the corners in what appears to be an excellent and secure manner. Thus more power can be added to the boiler when necessary by simply putting on additional sections, and the whole process is very simple. Unlike the saddle boiler, or other sectional boilers, the flame does not travel horizontally but vertically, and without any doubt at all in Wright's boiler is secured that direct action of the fire upon the boiler surfaces which, as the late Mr. Robert Thompson observes in his "Gardener's Assistant," is the great point that should be aimed at in the construction of hot-water boilers. In short, Mr. Wright boils the kettle from the bottom and trusts as little as possible to side or auxiliary surfaces. The flame from the furnace first hits the bottom section along its whole length, then splits, hits the side sections, meets again, and again splits and meets, and so on till the draught escapes into the chimney by the hole in the centre of the top section. Here, however, recent experience has suggested an improvement which is, we believe, to be adopted in future. The top of the boiler may be compared to a table with a hole in the centre of it; this hole is the flue-way, and, being in the centre, it was found to control the direction of the draught to some extent. To prevent this, and make the flame travel equally over all the surfaces, this central hole has been done away with, and instead four holes, one at each corner of the table, has been substituted, which is found to produce the necessary divergence, thereby enveloping the whole of the sections in flame when the fire is going well. Other and recent improvements, which are introduced for the first time at Clovenfords, consist in a contrivance for warming the air before it passes into the furnace, either through the top or bottom doors. As regards the circulation of the water in most boilers, as is well known, the water is left pretty much to find its own way, and consequently there is often a good deal of churning after the lighting of the fire before a regular circulation is established, but in Wright's boiler this cannot take place, for owing to the way the boiler is cast and put together, the water is compelled to flow in the channels provided for it, which is over the entire surfaces of the boiler from base to summit, and in the direction of the draught. And now as to the way the boiler does its work. I had intimated to Mr. Thomson that I desired to do the stoking myself, or at least to superintend it, and he had obligingly complied with my wish, for I found the boiler and pipes quite cold on arrival, and the fire ready for lighting. The boiler—the first of several that will be required to heat the whole of the premises at Clovenfords—is not much bigger than a good-sized tea-chest, if the depth of the furnace be excluded, and it is intended to heat 2600 ft. of 4-in. piping, or two long houses, each 270 ft. long, one of which is just finished, and contains 1300 ft. This amount of piping the boiler heated up to a tolerably high degree in two hours and a half, the water all being cold to begin with, and at a distance of 300 ft. from the boiler the pipes were just as hot as they were near the furnace. I had no means of testing the temperature of the water in the pipes, but the heat was just such as the hand could easily bear—a heat which gardeners do not care to exceed in their hot-

houses if they can help it, and to effect this but a very small quantity of coal was consumed. In addition to the few spade-fuels used to start it, the fire was mended twice, a few shovelfuls being added each time, and by five o'clock the fire had burnt quite out, having been lit a little after twelve o'clock. I am particular in stating these facts, for they furnish data for those who are accustomed to judge in such matters. My own opinion was that it was the quickest example of heating by hot water I had ever seen, and I left with a very favourable impression of the boiler's merits. I witnessed similar results with the same boiler at The Grange, near Chester, only the boiler there, which was 4 ft. by 3 ft., and 2 ft. wide over all, including furnace room, was much in excess of its work. It had at the time of my visit 1547 ft. of piping to heat, and all of it throughout the entire range was so hot that the hand could not bear it; the temperature of the water could not be under 190° and at the time about 100 ft. of the piping was exposed to the open air and the rain. At the first trial, Mr. Edge (the gardener) informed me he had heated the above amount of piping up to 180° in 2½ hours with cinders from the gasworks, the pipes having been just filled with water from the pump. Mr. Edge, like Mr. Thomson, expressed a very favourable opinion of the boiler, laying particular stress on the saving of fuel which it effected and its quick action. A feature of the piping arrangements at the Grange gardens is that the top of the boiler is above the level of the pipes 6 in., the flow-pipe dropping down with an elbow as soon as it enters the hot-houses; yet, and as indicating the force with which the water is driven through the boiler, this descent in the piping does not appear to impede the circulation in the least. During the cold weather, the fire was made up every night at nine o'clock, and left till seven o'clock next morning without any reduction of temperature in the houses. J. S. W.

MOUNT VERNON.

I WENT down the Potomac to see the old home of George Washington and his garden and trees. The Potomac hereabouts is a wide and beautiful river, its banks frequently wooded to the edge and rising in varied folds till they present a well-wooded line against the sky. Over it occasionally tosses a little boat on its way to Washington laden with Water Melons, the oarsman having just space to work between the piles of large fruit. Here and there nets are seen from which the sturgeons that plough about the muddy banks like so many great river pigs are taken almost as easily as so many sheep when once in the net. Mount Vernon is interesting even now, showing the first president's love for trees, gardens, and country life, and a sunk fence and other objects rarely seen in America show that he designed it after old-country models. Many trees of his planting are still here, and among them a greater number of the true Service tree than I have seen in England. The Box edgings in the old kitchen and flower garden have grown into large shrubs. Specimens of the Allspice tree (*Calycanthus floridus*) presented by Jefferson to Washington, huge Paper Mulberries, and a good many interesting trees are here. The old gardens are being saved from the neglect into which they had fallen; the orchard is to be replanted, and means will be taken to preserve the old place in as interesting and uninjured a condition as possible. From the little lawn in front of the old house the most beautiful scenes at Mount Vernon are enjoyed. Three openings through the woods that fringe the little lawn show the wide expanse of the Potomac, and in consequence of the configuration of the ground and river at this spot, the effect is as if one were looking on a broad and noble lake with large wooded islands. I have rarely seen a more lovely site for a garden; with trifling expense and a little judicious clearing and opening up of more views here and there, it could be made a very charming spot. H.

Cats and Small Birds.—The note of "E. C." on this subject merits attention; my experience has been similar as to the unceasing destruction of small birds by cats. One marauder, however, who tried to destroy a nest of tits in the pedestal of a large vase, got into trouble thereby. Not being able to reach the nest through the drainage hole of the vase into the pedestal below, it placed itself on the pedestal to watch the birds, but in doing so managed to overturn the vase and get caught beneath it, the young birds remaining safe in the pedestal.—O.

Flowering of the Sweet Potato.—The "New York Tribune" gives the statement of a Florida correspondent that the Sweet Potato blooms in that southern region, the flowers resembling those of the Morning Glory, to which, as is well known, the plant is nearly allied. They are pink and pale lilac in colour, and remain open only in the morning.

(*Potentilla atro-sanguinea var. hybrida*).Spotted Sun-rose (*Helianthemum guttatum*).Virginian Poke (*Phytolacca decandra*).Large Indian Cress (*Tropaeolum majus*).Variously-coloured Lupine (*Lupinus mutabilis*).Sweet-scented Bramble (*Rubus odoratus*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

LILIES of the candidum, Thunbergianum, and Martagon sections now rank amongst the most attractive occupants of our gardens. Delphiniums, too, are more beautiful at present than they have been all the season, and now that so many improved kinds, all of which are hardy, have been raised by different cultivators, the effect of groups of them planted in small isolated beds on the lawn or in front of shrubbery borders is better than can be obtained by even the most showy

Butterfly Schizanthus (papilionaceus).

bedding plants. The white Gladiolus Colvilli, now very attractive, is being brought in a cut state to the London markets, and the purple-crimson G. byzantinus is also finely in flower. Hemerocallis fulva and H. Thunbergi are likewise very showy. The double Dropwort (Spiræa Filipendula fl.-pl.) is flowering remarkably well this year; it is frequently used as edgings to borders, but that is a position in which its real worth can by no means be appreciated. Foxgloves, which are just

Double-flowered Meadow Sweet
(Spiræa Ulmaria fl.-pl.)

Cut-leaved Meadow Sweet
(Spiræa lobata).

now at their best, are shown off to good advantage when dotted here and there among ornamental trees and shrubs. When planted in formal masses—beautiful as are some of the seedling kinds now in cultivation—they lose much of their effect. The scarlet Invincible Sweet Pea, when properly used, is very attractive, and affords abundance of flowers for cutting purposes. Irises of the Xiphion and Kämpferi sections are still finely in flower, as are also Potentillas of various shades of colour. Different kinds of Yucca are throwing up flower-spikes, and the noblest of them all

viz., Y. gloriosa, is in many places in full flower. Of Enotheras, all of which are showy plants, one of the best for shrubby work is E. Youngi, which grows about 2 ft. high, and bears great quantities of rich golden-yellow blossoms. The Bell-flowers (Campanula grandis and pyramidalis) are very attractive. The white Water Lily, too, is now flowering freely, and affords abundance of blossoms for use in large vases, in which, associated with Club Mosses, they have a cool and striking appearance. Ornithogalum pyramidale is very pretty just now, as is also the crimson-purple Tritoleia Murrayana. Ixias and Sparaxis, planted in warm soil, are very showy, and the Pæonias still yield abundance of large gorgeous blossoms. Calochorti in variety may still be met with in good condition, and some of the kinds are peculiarly interesting as well as attractive. Hardy annuals of many kinds are beginning to flower, and, where skilfully arranged, add greatly to the beauty of gardens in which they are grown. S.

SELF-FERTILIZATION AND CROSS-FERTILIZATION OF FLOWERS.

By T. MEEHAN.

At our last meeting I inquired whether insects are any material aid to plants as regards fertilization. After another year of observation I desire to answer my own question in the negative. Insects sometimes fertilize flowers and cross-fertilize them, but I believe these cases are less frequent than they are supposed to be, and that when they do occur, they have no bearing on the general welfare of the race. In other words, such fertilization is of no material aid to plants in the progress of the species. I may repeat the argument of those who differ from me. All plants with brilliant colours, with fragrance, or with honeyed secretions, have these attractions for the purpose of enticing insects, which unconsciously bring pollen at the same time, and thus cross-fertilize the flower. The proof of this is thought to be chiefly in the fact that many plants do not perfect their stamens and pistils at the same time, are placed in relative positions which make it seem difficult or even impossible that they should have any influence on each other, or in some other way present apparent obstacles to sexual union. From this it has been assumed, and not from any actual experiment of which I am aware, that plants abhor close breeding. That plants abhor close breeding is an idea borrowed from a supposed experience in the higher animals; but the comparison is not fair. In the higher animals the idea of sex is essential to the perpetuity of existence, but it is not so in plants. They reproduce themselves by bulbs, tubers, suckers, offsets, buds, and in the lowest organisms by simple cell division. Propagation, as an idea, is entirely independent of sex in plants. True, many of our forest trees have none of these accessories, even the skilful horticulturist can scarcely graft some of them, and then there are annuals which depends wholly on seeds—a product of the sexes—for perpetual existence; but there is not one that I know of that a horticulturist would say could not be reproduced indefinitely without the aid of seeds. The Red Dutch Currant is an individual plant which has been reproduced by cuttings from long anterior to modern history, and I believe the Canada Thistle, Couch Grass, Horseradish, and numerous other plants could be continued for countless ages by their running roots alone. Now this is a closer kind of breeding than anything that could come through the operation of separate sexes, and with which no analogy can be drawn from any experience in the higher forms of animal life. We can see that seeds in plants favour the distribution of species, and enable them to maintain existence for a longer period than mere plants could. Sex in plants may be a factor in the evolution of form; but those who have kept pace with botanical knowledge, and are familiar with what is known as bud variation, will not lay much stress on the absolute necessity of sex to this end in vegetable nature. I believe I am safe in saying that there is nothing whatever known to prove that there is any physiological benefit to plant races by the establishment of the sexes. Some have thought that the varieties of Apples as sexual products wear out in time; but even this is being argued on both sides by the most distinguished horticulturists;

and I may say that I have seen at the recent Centennial Exhibition, as fine Golden Pippin Apples (the kind used to illustrate the theory), as ever Mr. T. A. Knight thought were only seen in his younger days. We must then lay aside all considerations of the benefits of cross-breeding from analogy or inference, even though we should find that all plants discarded their own pollen. There may be some other reasons quite independent of any sexual consideration; and it is because I believe there are other reasons in dioecious, monœcious, and other cases, that I adhere to my statement.

We may note, in the first place, that insects visit some anemophilous plants as freely as they do others. They, for instance, abound on the male flowers of the Willow, especially *Salix caprea*, which have abundant honeyed secretions; but they avoid the female plants. If honeyed secretions be for the purpose of enticing insects for cross-fertilizing purposes, how is the object attained here? Later in the season we see the same thing in *Rhus*. *R. glabra* and *R. copallina* are in effect dioecious. The male flowers have a honeyed secretion peculiarly attractive to innumerable insects. A paucity of these flowers is a wonderful entomological cabinet. I know of nothing like their visits here in the whole floral world. I have six plants of *Rhus copallina* within twelve paces of each other. Five are males and one is a female. I have never seen one insect on the female plant, neither does it seed, neither wind nor insect serves it. Here are two species with colour and honeyed secretions on which insects abound inordinately; and yet the insects aid fertilization in no degree whatever. I ask you whether I may not say most decisively that whatever may be the purposes of colour, fragrance, or honeyed secretions, they are not for the purpose of attracting insects in the interests of cross-fertilization. Then there is *Yucca*, about which so much has been made. In my grounds, *Yucca filamentosa* abounds. It opens its flowers about the 25th of June. In 1875 a plant of *Yucca angustifolia* blossomed on the 5th of June. Though closely watched, I found no *Pronubas* about them. They produced no seed. The *Y. filamentosa* had numbers, and seed abounded. About the 5th of June this year, the *Y. angustifolia* again opened its flowers. On the 12th I noticed the *Pronuba* to abound, and I hoped for seed. There were from one to five in each flower. On the 19th, I noticed that the flowers had almost all fallen fruitless. I then placed some pollen on four of the flowers, each pollen from its own flower, and these four capsules which I exhibit are the results. They are the only seeds the plant produced. Even when fertilized at all by insects, I am sure the fertilization is from the pollen of the same flower. My experiment shows its own pollen is acceptable to it. It is true it is difficult to understand why the plant seems unable to fertilize its own self without extraneous aid; but it is clear that it is not from any abhorrence of its own pollen, or an especial desire for insect aid, especially the aid of an insect whose chief mission seems to be to prey on the fertilized seed!

The chief arguments for the necessity for insect fertilization are drawn from structure and not from fact. For instance, we are told that *Iris*, *Campanula*, *Dandelion*, *Ox-eyed Daisy*, the *Garden Pea*, *Lobelia*, *Clover*, and many others are so arranged that they cannot fertilize themselves without insect aid. I have enclosed flowers of all these named in fine gauze bags, and they produced seeds just as well as those exposed. I was somewhat surprised at the two first, *Iris virginica* and *Campanula*, producing seeds under these circumstances, as they are common illustrations of the necessity of insect fertilization. In short, in all the cases I have tested in this way, seeds were produced as well under the gauze as without, except in one instance—*Baptisia australis*. In most *Papilionaceæ* plants that I examined, in spite of the suggestions of my friends, I thought the arrangements favoured self-fertilization—not only by the position of the organs, but from the fact that the moment anything touched the flower so as to liberate the pistil or stamens, a mass of pollen floated around like a little cloud; a dispersion of pollen, which, by the way, in view of prevailing theories, the class of flowers with “fragrance, colour, or honeyed secretions,” ought not to make. *Genista scoparia* will give an excellent illustration of this. But in *Baptisia* I did not notice this little

cloud; and it did seem in the actual act of collecting honey, the humble bee's pollen-covered abdomen pressed itself closely down on the stigma. I covered a spike of a dozen unopened flowers with a gauze bag, and had only one seed-vessel, though in the exposed spikes nearly every one perfected. This fact may go for what it is worth; for be it remembered, I am far from denying that flowers are sometimes fertilized by the aid of insects. It is the extent of these facts, and the theories to be deduced from them, that I have to deal. Independently of trials by gauze bags, I have experimented with single flowers of some species. I take plants of which there are no others in the vicinity, and pick off all but a solitary flower, not permitting another to open until the other has faded, and if they seed, it must be only by their own pollen. I was led to try this from noticing a few first flowers of *Oenothera serrata* (which open about noon and die in a few hours) seed when I was almost sure no insects had visited them. In watching for this purpose *Talinum teretifolium*, I found that it opened always a few minutes before one p.m., began closing at three, and by half-past three had wholly closed. No insect visited them in that time, but every flower seeded, as did subsequent experiments with single flowers. An ally, the common Purslane, remains expaused only from eight to nine a.m., and is, I think, an undoubted self-fertilizer, and yet on what theory of the advantages of cross-fertilization could a plant make better headway through the world?

It is, of course, well known that some flowers are opening and closing at almost all hours of the day and night, many remaining open but a very short time. Can this varying and limited time have anything to do with insect fertilization? Would not fertilization by insect aid be more certain if at least a whole day were given for the chance? In my district the little florets of the *Chicory* are all fertilized before eight o'clock, and by nine have faded away. This species is an excellent one for noting how self-fertilization is effected in Composite plants, as the pistils are blue, and the pure white pollen is easily seen. Soon after daylight, the corolla lengthens. After a little while it rests, but the stamens and pistil go on. Then the stamens cease to grow, but the pistil continues to lengthen, carrying an immense quantity of pollen with it. Here is the difficulty which those who differ from my experience. The pistil has to cleave, and only on the interior of the clefts seem to be the stigmatic surface; the pollen then must, it is said, rest of necessity only on the exterior, where it cannot operate; but if any one will get up early and spend a couple of hours in watching the development of the flower, driving away an occasional sand-wasp that would like to gather the pollen, he will find there is not a cloven pistil that has not some pollen on the interior stigmatic surfaces. Of what avail are “must be's” against positive facts like these? But if he watch closely, he will see that this pollen falls into the chasm made by the opening stigmas. In the language of my friends, it is a “beautiful arrangement” for ensuring self-fertilization. If, further, we allow the sand-wasps to work at pollen gathering, we find that while clearing the pistils of pollen, they push quantities into the clefts, and are, therefore, agents in self-fertilization instead of the reverse. I have observed the same in *Dandelion* and the *Ox-eyed Daisy* (*Chrysanthemum leucanthemum*), as well as I am sure that thousands flower and perfect seeds that no insect visits. There seems to be something yet inexplicable as to how some flowers become fertilized. In *Cirsium Pitcheri* and many others of that section, what in others is a bifid stigma, is nearly entire, the stigmatic surfaces being almost, or perhaps in some cases wholly, united together. *C. Pitcheri* has very long pistils; the honey-bee seems very fond of the flowers; it works between the pistils. I have never detected a grain of pollen on the almost entire apex, though the sides are covered as in other composites; but it seeds abundantly.

I think the peculiar closings of flowers are as much designs for effecting self-fertilization as for anything else. It does effect it in *Ranunculus*, *Claytonia*, most likely in the *Iris* enclosed in the gauze bag, and perhaps many plants with flowers that close and twist up in fading. In *Ranunculus*, on the first day's opening of the flower, the outer of the numerous rows of pistils throw their pollen on the glazed petals; these close at night, and the pollen is dropped in over the hollow in which

are the mass of perfect pistils. I refer to *R. bulbosus*. In *Claytonia virginica* the same thing occurs with the early flowers, so far as drawing the stamens up to the pistils is concerned. In the later flowers the anthers recurve more, and in the closing at night are drawn under the pistils, and hence we find seed here only from the earliest flowers. These illustrations are not uncommon. Even in wind fertilizing flowers, the times of opening and closing of certain parts of the flowers may be worth a study. I find *Luzula campestris*—the wood form—bursts its anthers about nine o'clock a.m.; by ten, the pollen is committed to the atmosphere. As its own pistil has dried up by this time, having expanded two days before, it cannot fertilize its own pistil. There is no evidence that it would not be just as well if it could. This precision and uniformity as to time shows that there are other considerations involved in the acts connected with fertilization besides those usually suspected.

This brings us to the question of dichogamy as an agent in this question. Much stress is laid on the fact that in many flowers the pistil is mature before or after the stamens, and this is interpreted as an especial arrangement for cross-fertilization. I pointed out last year that this difference in time varied with the season in many species, but the difference is striking in some closely allied species. *Barbarea præcox* and *B. vulgaris*, two Cruciferous plants, are so nearly related that the difference can scarcely be defined. The former, however, has its pistil of about equal length with the stamens, all included in the petals. The stigma certainly receives its own pollen simultaneously with the expansion of the petals; but in *B. vulgaris* the pistil protrudes beyond the closed petals, and in perfect condition to be fertilized by extraneous pollen before it can be served by its own: both species make their way equally well through the world. I think no better illustration could be offered of the fact that a dichogamous plant has no advantage in the struggle for life. This fact may, however, be illustrated in various ways. Supposing the *Iris* could not self-fertilize, its next of kin (*Sisyrinchium*) is certainly a self-fertilizer, and who will say that it has not made its way proudly? *Iris virginica* is comparatively local, but any student can get a specimen of *Sisyrinchium bermudianum* on a few hours' notice. You can find flowers which seem to forbid self-fertilization, it is true, but let us not close our eyes to those so constructed as to render insect aid impossible. There are some Scrophulariaceous plants which have the pistil arranged above the stamens so as to seem placed there, in order that a visiting insect may rub its pollen-covered back against the pistil on entering; but many Pentstemons (*P. grandiflorus*, *P. Cobææ*) incline the pistil downwards, impossible for any such insect-fertilization, yet every flower perfects seeds. *Browallia elata* has a hairy cap over the stamens, and an insect would only aid in self-fertilization; but when the *Browallia* is not visited by insects it yet seeds abundantly, and it might be argued because it has no fragrance; but there are some garden Verbenas which have fragrance as well as colour. No insect visits them on my grounds as far as I can find, but both kinds seed equally well. In fact, this idea that colour and fragrance are necessary to attract insects, and are given to plants for that purpose, does not accord with the fact that flowers with neither are thronged with insect patrons; but I have taken especial pains to note *Rubus occidentalis*, our native Black-cap Raspberry. It has not the faintest trace of odour. Its small, greenish-white petals are so inconspicuous that it might as well be apetalous; but nothing can exceed the fondness of the honey-bee for it. They abound in my vicinity, and from sunrise to far into the twilight of evening, the honey-bee crowds on them. They neglect every flower, even White Clover, for them as long as they last. Surely, there should be a necessity for insect-fertilization in cases where insects are so assiduous! I have had this point suggested to me. A cluster of flowers had a gauze bag thrown over them, and yet there was a perfect fruit to every blossom, as also had all the neglected Clover flowers as well.

As to Clover flowers, I will refer you to what I said of them last year. Since then, so great is the faith in the necessity for insect-fertilization, that humble bees have been sent from England to New Zealand to help the Clover along. Since last season I have discovered that our humble bees do not enter

the mouth of the Red Clover, care nothing for the elaborate arrangements for cross-fertilization, but slit the tube and get at the honey from the outside! And yet the Clover seeds abundantly. So far as I could see, every flower in the field where I saw the bees behaving so outrageously, bore its seed. Many flowers are served in this way, and unless one looks closely he may be deceived. In the Persian Lilac, if we follow the course of our friends of the insect-fertilization school, we see the stamens arranged above the pistil, and as the pollen bursts simultaneously with the opening of the corolla, it ought to fall on the pistil, and the entrance of an insect would only aid its self-fertilization; but with us it never yields a solitary seed, and we may be asked to behold the results of self-pollinization! But we see exactly the same arrangement in the common Lilac, and that seeds abundantly. In both cases the humble bee slits the tube, and the honey-bee follows in the slits made by its stronger friend, or else makes slits for itself—a point I was unable positively to determine. Indeed one of the points I wish to insist on most strongly is, that the facts in the question have been but imperfectly observed, and then erroneously construed, and of this I will offer but one more illustration. It relates to dimorphous flowers, those with the pistils long in some flowers, and short in others, as in *Epigæa*, *Mitchella*, *Houstonia*, and others. When we look at the allies of these plants, we notice that this behaviour is exceptional. It may be assumed that they have wandered from a condition when the separate sexual organs were nearer to a perfectly hermaphrodite condition, and it is assumed that this wandering is in order to derive some benefit from cross-fertilization through insect agency. I have endeavoured to test this assumption in *Houstonia cœrulea*. I selected a number of plants of both forms, and marked them when in flower. In some clusters aggregating about fifty flowers of the short-styled plants, and which, I have no doubt, were self-fertilized, forty-two perfected seed. Of fifty with long styles, and which would necessarily have more difficulty of availing themselves of their own pollen, only five matured seed. Thus we see that the self-fertilizer has at least the advantage of numbers, and, in the battle for life or for any purpose, that is surely an advantage of no mean importance. I believe I have shown that the facts are not wholly as represented, and that the facts, even when they may exist as represented, do not produce results according to the deductions drawn from them.

Let me now show the danger of attempts to read the purposes of Nature from her direct acts. If we examine swamp vegetation, we find *Magnolias*, *Willows*, *White Cedars*, *Red Maples*, *Cypresses*, and numerous others growing therein. We at once conclude that they grow there because those trees prefer the wet to the drier land; but a wider acquaintance with trees will show that all of them do better when, as we often find them, growing in drier places. A suspicion then arises that there is something wrong with our reasoning, and we find at last that Nature has a deeper purpose than merely an individual regard for these trees. Their seeds will only grow in wet soil, and of necessity, and not for individual benefit, have these trees to remain there. Again, I think there is nothing more certain than that effects will continue long after the causes which produced them have ceased to exist; so that actions which you see may be associated with degradation instead of evolution, may be the last flickering of a dying light, and not an Aurora indicating the birth of a new day. In the present question, our reason will tell us that the phenomena we see may bear this interpretation as well as those given to them by our friends. In Europe, for instance, the common Strawberry is almost universally hermaphrodite; but in this country the tendency to dioecism is well known. We know also that those parts of the world in which dioecism prevails is not so favourable to the existence of the Strawberry as the other, and we may safely conclude that dioecism—a form of dimorphism—has no relation to any advantage to be derived through the sexes, but is an actual result of degrading conditions. Then, physiologically, what good can result? It is asserted by those who differ from me that probably most of the large Order of Composites are cross-fertilized; the flower in one head receiving the pollen of another flower in the same head, by the aid of insects. This they contend after an

examination of the structure. After noting the behaviour of the parts, and in the absence of insects, I contend that they are self-fertilizers. But supposing they were all that is asked for them; compare one with an ordinary polypetalous flower—say *Ranunculus*—and where is the gain? The floral parts are all on the same common peduncle in both cases, and the stamens and pistils are more widely separated in a *Ranunculus* than in a Dandelion. Practically there is a wider separation of the sexes in the *Ranunculus* than in the Dandelion, granting even all or more than is asked for as cross-fertilization in Composites. Physiological disturbances that aid the vital principle in the pistils, and interfere with that of the stamens, of course weaken the vital power of the pollen. In such cases foreign pollen—pollen from flowers free from these disturbances, or where the disturbances favour the stamens instead of the pistils, would have more potency. It is therefore not surprising that some cases should occur proving foreign pollen better than their own pollen. It would be more surprising if there were none; for in every direction we find Nature with overflowing abundance, pushing beyond what we regard as the necessary mark. As the boy, who to jump across the stream first goes back, and when he lands on the other side goes farther than he wants; so does Nature in all things, or I have not read her story rightly. I can refer, in a brief paper like this, to but a few observations I have made, nor do I think it necessary. I will now submit these propositions:—1st. That cross-fertilization by insect agency does not exist to near the extent claimed for it. 2nd. Where it does exist there is no evidence that it is of any material benefit to the race—on the contrary. 3rd. Difficulties in self-fertilization result from physiological disturbances that have no relation to the general welfare of plants as species.—“Proceedings of the American Academy of Sciences.”

SOCIETIES AND EXHIBITIONS.

THE NATIONAL ROSE SHOW.

THIS, considered simply as a Rose show, gave satisfaction to good judges, considering the lateness of the season and the fact that the northern growers were at a disadvantage from this cause; but from the point of view of the public, and all who look at the Rose from anything more than the exhibitor's standpoint, we regret to say that the arrangements were far from what one would like to see those of a great National Rose show. In the first place, St. James's Hall is a most unsuitable place in which to hold any kind of flower show, particularly during hot weather. If any building were desirable, it should have been a more commodious one. The fact is, Londoners accustomed to the charms of Grass and trees and fresh air in connection with our flower shows, do not care to face St. James's Hall in July, even for Roses. Thus it happened that a most extensive and beautiful display of Roses, forming undoubtedly the most charming sight in London on the 4th of July, was left mainly to the contemplation of those who staged them. We never expected any better result from holding it in St. James's Hall. There may be good reasons why Rosarians keep their show away from the great societies, but not that it should be held under such disagreeable conditions as on Wednesday last. There are the Floral Hall and the Albert Hall, where much better arrangements could be made both for the convenience of the public and for the effect of the flowers. At St. James's Hall, in the centre the light was too strong, at the sides too obscure. At one end, under the wide gallery, a fine display of Roses was almost hidden away in dismal obscurity. In judging, the boxes had in many cases to be carried from where they were placed into a better light to enable the judges to see them. We do not hesitate to speak plainly in the matter, seeing the importance of the interests concerned. A National Rose Society should meet with sympathy from all who care for our gardens, and it ought on such an occasion to make a display of the most admired of all flowers which would be an attraction to all London. As it was arranged, there was positively not standing room for one-fourth the number of persons who attend a good London flower show. This trouble was, however, got over by the public not coming. If Rosarians merely seek to please themselves and their friends the recent show may be all very well, but a National Rose Show should be arranged on a very different plan.

As regards the exhibitions in the nurserymen's class for seventy. no single trusses, there were six competitors, all of whom produced

blooms much better than might have been expected considering the season, which, on the whole, has been anything but favourable to the proper development of the Rose. The best stands came from Messrs. G. Paul & Sons, The Old Nurseries, Chesham, in whose collection we remarked magnificent examples of Antoine Ducher, the brilliant crimson maroon-centred Jean Liabaud, the rich rose magenta-petalled Star of Waltham, very large and highly-coloured flowers of La France, the satiny-white Madame Lacharme and Maréchal Niel set off to advantage amid brilliant scarlets such as Louis Van Houtte, and others; the same collection also contained Baroness Rothschild and exquisitely-formed François Michelon. Mr. Cant, Colchester, who produced blooms scarcely inferior to those just named, had good examples of Captain Christy, Annie Disbach, Exposition de Brie, Duke of Wellington, and Sénateur Vaisse, still one of the best of Roses for exhibition purposes. With these were associated Antoine Mouton, the lovely Souvenir d'Elise, and the brilliant Sir Garnet Wolseley, each bloom being surrounded by abundance of foliage and unexpanded buds.

In the class for forty-eight varieties, three trusses each, there were five exhibitors, all of whom had fine blooms tastefully arranged both as regards colour and position. The best collection came from Messrs. George Paul & Sons; it contained magnificent examples of Madams Jamain, supported by highly-coloured blooms of François Michelon, the dark crimson Xavier Olibo, and the beautiful lively flesh-coloured Madame Eugène Verdier. Associated with these were also blooms of the deep magenta-coloured Comtesse d'Oxford, Louis Van Houtte, and the dark-flowered La Rosière. The next best group came from Mr. Charles Turner, who showed amongst others good blooms of Madame La Baronne de Rothschild, Ferdinand de Lesseps, Comte de Nanteuil, the dark maroon-crimson Lord Macaulay, and grand examples of François Michelon, a Rose which throughout the show held a prominent position in nearly every collection. The next best group, which came from Mr. Cant, contained fine examples of Souvenir d'un Ami, the cream-coloured, Tea-scented kind called Rubens, the bright rosy Sir Garnet Wolseley, and François Michelon. Amongst other collections in this class were beautiful blooms of La Baronne de Haussmann, Madame Nachury, and Louis Van Houtte. In the class for forty-eight single trusses, seven exhibitors staged blooms, of which the best came from Messrs. Cranston & Co.; amongst them were magnificent examples of Marguerite de St. Amand, Duke of Edinburgh, the dark crimson Baron de Boustetten, Madame Chas. Wood, and the rosy-salmon Madame Thérèse Levet. Associated with these were also well-formed blooms of Madame Lacharme, Madame Vidot, Niphotos, and the rich salmon-pink-coloured Mlle. Marie Coindet.

In the class for twenty-four varieties of Hybrid Perpetuals, three trusses of each, there were six exhibitors, the most successful one again being Messrs. Cranston & Co., Hereford, who had effectively-arranged blooms of Baroness Rothschild, Lord Macaulay, the deep rosy Annie Laxton Xavier Olibo, and the beautiful satiny-white pink-fleshed Marquise de Mortemarte. Some good Roses also came from Messrs. Paul & Son, who showed Duke of Edinburgh, Marquise de Castellane, and Maurice Bernardin, in unusually good condition. In the class for twenty-four trusses there were nine exhibitors, and taken as a whole, the blooms individually were perhaps better than those in the larger classes. The best came from Messrs. Curtis, Sanford, & Co., Devon Rose Nursery, Torquay; amongst these were the dark velvety-crimson Prince Camille de Rohan, the pink Princess Beatrice, fine examples of Paul Neron, and a beautiful creamy-white kind.

In the class for twelve Tea-scented or Noisette Roses, distinct trusses, Mr. Cant showed a fine stand, in which were good blooms of Madame Bravy, Vicomtesse de Cazes, and finely-shaped examples of Souvenir d'Elise, and La Boule d'Or. Messrs. Mitchell & Son, Pitt. down, was a close second with magnificent blooms of the creamy-white, pink-edged Duc de Magenta, Souvenir d'un Ami, and excellent examples of Marie Ducher. The premier prize in the amateurs classes was awarded to Mr. Jowitt, The Old Weir, near Hereford, who furnished splendid blossoms of Captain Christy, Madame Hippolyte Jsmain, the dark velvety crimson Prince Camille de Rohan, and the largest blossom of François Michelon we have seen this season. Next to these came a stand of beautiful blooms from Mr. R. N. G. Baker, Heavitree, near Exeter; amongst them were Captain Christy, Marie Baumann, Madame La Baronne de Rothschild, and Prince Camille de Rohan, all in fine condition.

In the amateurs' class for thirty-six single trusses, the exhibits were so numerous that they occupied one whole side of a long table. The best blooms in this class came from Mr. Baker, who had exquisite examples of La France, Duke of Wellington, Edward Morren, Dr. André, the beautiful pink Rose called Miss Hassard, and pure white, satiny blooms of Marquise de Mortemarte. The next best, from Mr. J. Brown, Reigate, contained good blooms of similar kinds.

In the class for twenty-four Hybrid Perpetuals, Mr. Atkinson, Brentwood, showed excellent blooms of Edward Morren, Duke of Edinburgh, and Marie Baumann. Associated with these were also the salmon-tinted Baroness Rothschild, Dr. André, and Countess of Oxford. Mr. Baker also showed in this class good examples of Marguerite de St. Amand, Victor Verdier, and Baroness Rothschild. In other classes provided for amateurs, the best examples came from Mr. Baker, Mr. J. Ridout, Woodhatch Lodge, Reigate, Mr. T. Lakin, Chipping Norton, and Mr. Smallbones, Chatteris. Amongst these we noted remarkably fine blooms of Ferdinand de Lesseps, Elegant, Xavier Olibo, Sir Garnet Wolseley, Duc de Rohan, very large blooms of Maréchal Niel, Louis Van Houtte, and unusually good trusses of Duke of Edinburgh. In the amateurs' class for twelve distinct trusses, there were staged some remarkably fine blooms; indeed in these collections might have been seen blooms superior to those in any of the other classes. Of Tea-scented and Noisette Roses, some fine blooms came from Mr. J. Brown, Reigate, who had amongst others Anna Olivier, Souvenir d'Elisé, Niphetos, alba rosea, and Souvenir de Paul Neron. Mr. Chard, Salisbury, contributed good examples of devoniensis, the flesh-tinted Catherine Mermet, and finely-coloured blooms of Cloth of Gold.

In the class for twelve trusses of English-raised Roses, the best came from Messrs. Paul & Sons, Cheshunt, who had examples of Reynolds Hole, Marchioness of Exeter, Duke of Connaught, Annie Laxton, and Duke of Edinburgh, all in excellent condition. The same firm showed John Bright as the best new seedling Rose, and it obtained, as it well deserved, the first prize in that class. Messrs. Paul & Sons also exhibited several other kinds of new Roses, amongst which we noticed Robert Marnock, a finely-formed bloom with dark maroon petals edged with scarlet. Mr. Turner furnished a kind named Penelope Mayo, which, when well established, will probably be a first-class Rose.

In the class for twelve blooms of La France, Mr. Baker showed a stand of magnificent blooms, and in competition for the prize offered by Messrs. Fisher Holmes & Co., Sheffield, for twelve blooms of Fisher Holmes, Mr. Baker was first. In the class for the best stand of François Michelin, Messrs. Curtis, Sanford, & Co., showed splendid examples of that fine Rose, a coloured illustration of which was given in THE GARDEN (see p. 356, Vol. XI.). The best stand of Marie Baumann came from Mr. Cant, who had even, well-formed, and richly-coloured examples of that fine variety, and Messrs. Paul & Sons had lovely blooms of Alfred Colomb. Of Reynolds Hole, a kind also figured in THE GARDEN (see p. 356, Vol. XI.), Messrs. Paul & Son, showed twelve charming blooms; and of Maréchal Niel the exhibitions were numerous and in every case excellent; the best of them came from Mr. Turner. Mr. William Corp, High Street, Oxford showed a collection of Tea Rose-buds gathered from plants budded on seedling Briars; though small, this collection afforded an excellent opportunity for judging which were the best kinds to grow for market purposes, as, of course, for bouquet making, small buds are at all times preferable to fully-expanded blossoms.

In the evening there was a dinner, well attended by Rosarians—though probably less so than it would have been had it not have been for the counter-attraction of the Gardeners' Royal Benevolent Institution dinner taking place on the same evening. The Rev. Canon Hole, who was in the chair, in proposing the health of the Queen said:—Rosarians, I will not ask you to remember the Queen of Bourbons, nor the Queen of Denmark, nor Frederic the Second, nor Leopold the First, nor Roi des Belges, nor Empereur de Maroc, nor the Sultan of Zanzibar, nor Rivers's George the Fourth; but my toast shall be La Reine, Paul's Victoria, and everybody's Victoria—our Perpetual Rose! *Esto perpetua!* May she live for ever, and you and I be there to see. And let us add to our Souvenir de la Reine d'Angleterre, the rest of the Royal Family. The Duke of Edinburgh, the Duke of Connaught, and Prince Arthur have been a good deal tried by the heat; but Princess Mary of Cambridge and Princess Beatrice have bloomed in royal beauty. But where, my loyal Rosarians, where are our Prince and Princess? The Prince of Wales, sent out by Laxton (alas, my brother, misereatur Deus!), is not a success, and we have as yet no Rose of Denmark. All honour to the man who shall supply the vacancies with Roses raised on English ground! Gentlemen, I give you the Queen and the rest of the Royal Family.

The Chairman then said:—We do not propose to prolong our floralia this evening—some would return to the Roses, and others to home, sweet home—and I will therefore express at once another sentiment, which must be uppermost in all our hearts—Success to the National Rose Society. I may not dwell upon the privileges which such an institution brings to us—the communion of kindred spirits, the brotherly friendships, the extended and more careful culture of the most beautiful of all flowers, and therefore the greater and purer happiness of men (for where have we such fresh, innocent, and

enduring happiness as in our gardens?). I may not dwell on these things, because it was my good fortune to suggest, some twenty years ago, a society of this kind, and with the help of earnest brothers, to establish the first National Rose Show, and I might seem, therefore, to be imitating the conceit of John Hopper—I beg your pardon—I mean John Horner, who “put in his thumb and pulled out a Plum, and said what a good boy am I.” And again, if I say too much about the present revival and development, if I express my feelings of deep gratitude to my old and dear friend, D'Ombain, for his successful efforts, I shall seem, perhaps, to flatter, and some may say, that, though they don't dislike anchovy toast with coffee, they don't like buttered toast with wine. Well, let the National Rose Show speak for the National Rose Society. There has been a good deal written about the “language of flowers,” and I certainly seem to hear these Roses speak, and what they say is this: Whatever difficulties may oppose you at first—however coldly jealousy and apathy shall say you nay—even though your coffers may not overflow upon your opening day—though your space be insufficient—with such an exhibition as this, you must, you shall, succeed. Just let me add one word more on the title of our Society. If it is to be really National, we must have two annual exhibitions, for this simple reason, that the Roses of the nation do not bloom simultaneously. We should have a Rose Show in London towards the end of June, and, some ten days later, a Rose Show in the midland and northern districts. I should have so little apprehension as to the success of the latter, that I would take upon myself, because I rely on the sure support of the brethren, the hazard of a first experiment. I am sure that in Nottingham, Liverpool, Manchester, Scarborough, Hull, York, and many other places, an exhibition of Roses, under the auspices of the National Rose Society, would be appreciated and supported by them, who believe that

Old England's emblem is the Rose,
There is no other flower,
With half the graces that adorn
This beauty of the bower.

ALEXANDRA PALACE ROSE SHOW, JUNE 30.

THIS Show may fairly be pronounced to have been a success both as regards quality and quantity of exhibits and the numbers of visitors. In all the classes, of which there were twenty-five—there were numerous entries, and the exhibits in all were so good that in many cases extra prizes had to be awarded. Cut Roses, of which the Show was chiefly composed, were arranged in boxes which occupied five long tables, between which was allowed plenty of room for visitors to pass and repass. The premier prize was awarded to Messrs. Paul & Sons, Cheshunt, for seventy-two distinct trusses; among them were specially noticeable fine forms of the amaranth-crimson La Rosiere, very large blooms of François Michelin, the beautiful semi-double velvety-black Xavier Obilo, Charles Lefebvre, and Wilson Saunders; these were effectively relieved by the bright golden blossoms of Maréchal Niel, finely-shaped blooms of Madame Lacharme, and the white rose-tinted flowers of Duchesse de Valombrosa. In the same class Mr. Cant, Colchester, exhibited capital examples of La France, the dark crimson Louis Van Houtte, and Comtesse d'Oxford. In the class for forty-eight trusses of three blooms each Messrs. Paul and Mr. Turner, Slough, had effective groups, conspicuous in which were Monsieur Boncenne, Exposition de Brie, Baron de Bonstetten, and Etienne Levett, and associated with these were fine examples of Madame Lacharme Maréchal Niel, and Duke of Wellington. From Mr. Keynes, Salisbury, came Louis Van Houtte, the blush-centred, white-petalled Captain Christy, and Alfred Colomb in capital condition. Tea-scented and Noisette Roses were well represented by Mr. Turner and Mr. Keynes, the most prominent in both collections being Ferdinand de Lesseps, Madame Lacharme, alba rosea, Countess of Oxford, Dean of Windsor, and François Michelin. The best collection in the amateur's class came from Mr. R. N. Baker, Heavitree, near Exeter, who had excellent blooms of Duke of Edinburgh, Sultan of Zanzibar, François Michelin, the dark crimson Louis Van Houtte, the bright rose-coloured Louisa Wood, and the velvety crimson Prince Camille de Rohan. Mr. Thomas Jowitt was second with good examples of Horace Vernet, La France, and an excellent bloom of *amœna*. The best Tea-scented and Noisette kinds came from Mr. Pemberton, who had good examples of Lyonnoise and Madame Bravy; and Mr. Davis, Aynhoe, Banbury, had fine blooms of Marie Van Houtte, President, Souvenir d'un Ami, and Perle des Jardins. In the open classes for twelve Roses of 1875, 1876, or 1877, Mr. Turner was awarded the first prize for excellent blooms of Miss Hassard (one of the best pink Roses in cultivation for exhibition purposes), Rev. J. B. M. Camm (a large, globular-shaped, rosy-pink kind, exquisitely scented), Alex. McKenzie, and Monseigneur Fournier, a kind with very large flowers of a reddish-rose colour, and finely imbricated in form. Messrs. Paul & Sons showed in the same class magnificent blooms of Duchesse de Valombrosa and Marchioness of Exeter, a kind raised by Mr. Laxton, and admirably adapted for exhibition. In the class of English-raised Roses in commerce, Messrs. Paul & Sons and Mr. Turner were the chief

competitors, both producing fine blooms of Duke of Edinburgh, Emily Laxton, Reynolds Hole, Marquis of Salisbury, Sir Garnet Wolseley, and Oxonian. In the class of twelve blooms of specified kinds, that best of all white Roses, Madame Lacharme, was shown in unusually good condition by Mr. Cant and Mr. Turner. The best blooms of Princess Beatrice came from Mr. Cant and Messrs. George Paul & Sons; and Maréchal Niel, large and fine, was shown by Mr. Turner and Mr. Davis. La France was furnished in good condition by Messrs. Paul and Messrs. Cranston; and the best box of Marie Baumann came from Mr. Cant. Mr. William Paul, Waltham Cross, showed a miscellaneous collection of cut Roses beautifully fresh and fragrant. The best vase of cut Roses came from Mr. Turner, who, in addition to having good blooms, had them tastefully arranged. Palms, Ferns, and other fine-foliaged plants were arranged in such a way throughout the show as to set the Roses off to advantage, a point of much importance as regards effect in the case of such exhibitions as that in question.

ROYAL HORTICULTURAL SOCIETY'S SHOW.

JULY 3.

THIS meeting, though perhaps the smallest that has taken place this year at South Kensington, was not without interest, Mr. Cannell showing some good Verbenas, and Mr. Turner cut blooms of Pelargoniums; there was also a number of new plants.

First-class Certificates.—These were awarded to the following new and rare plants:—

Aerides crassifolium (Veitch).—A dwarf-habited plant, bearing drooping spikes, furnished with large flowers, having rich purple-tipped petals, and ivory white throat.

Alocasia Thibautiana (Veitch).—A vigorous-habited kind, with large, heart-shaped, deep green leaves, having, very prominent, fleshy greenish white ribs, and white cobweb-like veins.

Cypripedium albo-purpureum (Veitch).—A twin-flowered variety—a cross between C. Schlimi and C. Dominyi. The leaves of this plant, which are of a lively green colour, assume a gracefully drooping habit, and measure about 18 in. in length. The flowers, which are of a dullish-brown crimson, have a beautifully-spotted throat, and long twisted rosy-pink tails on each side, rendering it one of the most distinct and useful of Lady's Slippers.

Rhododendron Countess of Derby (Veitch).—A compact-habited greenhouse shrub, with glossy green leaves and an abundance of long tubular-shaped flowers of a bright pink colour suffused with orange-scarlet, and having conspicuous bright scarlet, black-tipped anthers.

Rose, Marc'ness of Exeter (George Paul & Sons).—A large, well-formed, conical-shaped flower, very double, and of a clear rose colour, some of the petals being flushed with cherry-rose. One of the best English-raised Roses, of which we have already several fine kinds.

Rose, May Quennell (William Paul).—A fine Hybrid Perpetual Rose, with well-formed, stiff petals of a deep rose colour suffused with bright magenta.

Iris Kämpferi alba grandissima (Barr & Sugden).—A large broad-petalled flower of good substance, pure white, with bright greenish-yellow throat, and well worth a place in every collection.

Iris Kämpferi, Mrs. Barr (Barr & Sugden).—A kind with petals having a lilac ground, conspicuously marked with bluish-purple veins.

Iris Kämpferi, Robert Parker (Barr & Sugden).—Flowers round-petalled and of good form, the centre being rich dark purple, and the petals, are of a lilac colour strikingly marked with deep purple and wine-coloured stripes.

Eschscholtzia crocea, Mandarin (Carter & Co.).—A floriferous kind to which allusion is made in "Notes of the Week" (see p. 1).

Eschscholtzia crocea fl. pl. (Carter & Co).—A semi-double variety having a rich orange-colour, and probably the beginning of a race of double-flowered Eschscholtzias.

Lilium elegans, Mawi (Maw).—A variety resembling the type but with larger flowers, orange in colour profusely spotted with dark purplish crimson.

Lilium croceum, Chaixi (Maw).—A roundish-petalled flower of a rich orange colour, and having short, stiff, reddish-brown anthers.

Miscellaneous Subjects.—From Messrs. Veitch & Sons came a collection of new plants, consisting of Cypripedium, Masdevallias, Vandas, two Rhododendrons, and other interesting genera. Mr. W. Paul, Waltham Cross, showed a box of Roses containing several kinds of a meritorious character, and Messrs. Paul & Sons showed three new Roses, viz., Marchioness of Exeter, Duke of Teck, a kind with brilliant crimson well-formed flowers, the outer petals of which are of a dark velvety maroon, and John Bright, a kind with remarkably bright crimson-coloured flowers, and ample green foliage. Mr. H. J. Elwes contributed an interesting group of bulbous plants, consisting of varieties of Calochortus, a white variety of Gladiolus Colvilli, Lilium parvum, a spike of Hyacinthus candicans bearing drooping bell-shaped blossoms, and a fine variety of Lilium auratum called Wittei. In the same collection

were also some fine varieties of Alstroemeria, Lilium Washingtonianum purpureum, and several choice kinds of Irises and Ixias. Lilium Thunbergianum came from Mr. Maw, Benthall Hall, Broseley, who also sent L. Chaixi, and L. canadense; to this group a label of commendation was awarded. Mr. G. F. Wilson, Weybridge, showed several varieties of Lilies, including Lilium Kramerii, the small bright scarlet-flowered L. callosum, and L. columbianum; Eurya latifolia variegata was also shown in flower by Mr. Wilson. From Messrs. Barr & Sugden came a collection of cut blooms of Lilies, comprising all the best kinds now to be found in flower. From the same firm also came a collection of new varieties of Iris Kämpferi, to which allusion is made elsewhere. Amongst Mr. Turner's Pelargoniums we noted a pure white-flowered kind with purple anthers, admirably adapted for bouquet making. A bright-flowered kind named Challenger is also worthy of notice; its lower petals are bright crimson, the upper ones being blotched with dark velvet. Amongst others, too, the semi-double, Regal kinds were conspicuous. From the Society's gardens at Chiswick came a collection of cut blooms of Antirrhinums and Sweet Williams, which, being intermixed with Ferns, constituted an interesting feature of the show. From the same source also came a well-grown panful of Mimulus moschatus Harrisoni. A collection of Sweet Peas and other hardy annuals came from Messrs. Carter & Co. A Tree Carnation, named Lady Avevel, from Mr. Turner was admired on account of its large pure white, waxy-looking, sweet-scented blooms, which are produced in great profusion. Messrs. F. & A. Smith, Dulwich, sent plants of show Pelargoniums and double-flowered Petunias. From Mr. Parker, Tooting, came branches of Fremontia californica, bearing numerous large yellow flowers, cut from a bush grown for many years in the Tooting Nurseries, where it has had no protection even during the severest winters. A vase of cut flowers of Andromeda cassinifolia came from Mr. Ollerhead, gardener to Sir H. Peel, Bart., and the same exhibitor also showed two well-grown Queen Pine Apples. A collection of Strawberries from the Society's gardens at Chiswick consisted of most of the varieties in cultivation; amongst them, the best as regards appearance were Lucas, Royalty, Vicomtesse Héricart de Thury, and Keen's Seedling. Mr. Wm. Bull showed a brace of Cucumbers named Excelsior, and Messrs. Veitch & Son exhibited a new Pea named Criterion, evidently a heavy cropper, and otherwise an excellent variety.

NOTES AND QUESTIONS—VARIOUS.

Durability of the Catalpa.—Prof. Barrill, of the Illinois Industrial University, furnishes the "Prairie Farmer" with a number of statements to prove the great durability of the Catalpa. One of these would draw hard on the credulity of some persons—a tree lying on the ground about a century was found to be sound, and was sawn up into good boards.

Weeds.—The best time to kill a weed is as soon as it has germinated, before you can see it. When it is just ready to break through the ground, the least disturbance of the soil disarranges its connections and it dies in the sun; but if it grows until it makes roots it is not so easy to disturb it, it has a hold upon the soil and it sometimes lives on in spite of one.—T.

The Georgia Pine Lands.—Across the State of Georgia, from east to west, extends a broad belt of primitive Pine forest. Its width is about 75 miles and the surface of the country is almost a dead level. No underbrush grows, and no other tree besides the tall, spindling, long-leaved Pine. The ground is carpeted with a green growth of weeds, and so open is the forest that were it not for the fallen trunks of dead trees, one might ride through it at a gallop. Streams are rare. There is a melancholy monotony in the endless vistas of tall, brown columns roofed with green, that becomes oppressive after hours of travel through this sombre region.—Correspondent of "Tribune." [This, we presume, refers to Pinus palustris, rarely seen in cultivation in this country.]

Tall Border Flowers.—Can you furnish me with the names of a few hardy plants of this description which would look well in front of shrubberies, or at the back of mixed borders?—DELTA.—Aconitum Sterkianum, A. variegatum; Delphinium, tall varieties; Baptisia exaltata; Lathyrus latifolius, L. latifolius albus, L. grandiflorus; Oenothera Lamarckiana; Epilobium angustifolium, Lythrum Salicaria rosea; Echinosops exaltatus, E. rubenicus; Galega officinalis, Aster Novae-Angliae, A. Novi-Belgii, A. elegans, A. ericoides, and many others; Achillea Eupatorium; Campanula pyramidalis; Asclepias Cornuti; Verbascum Chaixii; Phlox, taller kinds; Tritoma Uvaria grandiflora; Dracopis speciosum; Lilium in variety; Polygonum cuspidatum; Arundo Donax, Pampas Grass; Anchusa italica; Arundo consanguinea; Eupatorium ageratoides; E. purpureum; Helianthus scaberrimus, H. multiflorus flore pleno; Hollyhocks; Dahlias; Pyrethrum uliginosum; Crambe cordifolia; Phytolacca decandra; Lupinus polyphyllus; and Macleaya cordata.]

Richmond Park.—The following letter has been sent by Mr. De Morgan to his Royal Highness the Duke of Cambridge, Ranger of Richmond Park:—"Commons Protection League, June 29.—Sir,—My attention has been called to your illegal enclosures of portions of Richmond Park, and to various illegal practices you have resorted to since you were appointed Ranger. I have to inform you that I have been appointed by request and public meeting to assert the right of the people to enjoy Richmond Park, and I have concluded to put in force every legal means to maintain that right. As I do not wish to do anything unlawful, I will thank your Royal Highness to cause to be forwarded to me copies of any Act of Parliament or other authority under which you have made the said enclosures. I have sent a copy of this letter to Her Majesty's First Commissioner of Works.—Your obedient servant, JOHN DE MORGAN." The following reply has since been received from the Duke's private secretary:—"July 2.—Sir,—I am directed by his Royal Highness the Ranger of Richmond Park to acknowledge the receipt of your letter, which has been referred to Her Majesty's First Commissioner of Works and Public Buildings, under whose authority all enclosures and plantations are placed, and by whose orders all works in the park are executed."—"Times."

No. 295.]

SATURDAY, JULY 14, 1877.

[Vol. XII.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE VALLEY OF FLOWERS.

ABOUT half an hour's walk north-west of the Hotel des Alpes at Mürren, lies a broad valley known as the Blumenthal, and well it deserves its name. It is about three-quarters of a mile broad and about a mile and a half long, surrounded on three sides by walls of green grass sloping steeply up rocky cliffs which rise at the upper end to a height of some 2000 ft., and are part of the first slopes of the Schilthorn, which is hidden by them. Up this valley I lately took a botanical ramble, and though I returned drenched to the skin, I thought myself amply repaid by the rich harvest of plants which I brought home. My way lay through the picturesque châteaux of Mürren, and up a steep path of stone steps between fields of uncut hay, which now look like brilliant flower-beds with half-a-dozen different sorts of Campanulas, Pink Polygonum, Orchis, Phyteumas, Ranunculuses of different kinds, and here and there a grey rock peeping out encrusted with Saxifrage, Sempervivum, the exquisite dark blue Veronica saxatilis, and every crack full of Ferns—Polypodium Dryopteris, Cystopteris fragilis, and Asplenium septentrionale being among the commonest. After passing the last châteaux, where later in the afternoon the whole village congregate to meet their goats as they return from pasture, we found ourselves fairly in the Blumenthal, the Almendhubel rising green and fir-crowned to our right, the precipitous rocks of the Schiltgrat to our left, and down the middle of the valley from the snows of the farthest wall rushed the beautiful Mürrenbach between high rocks which broke it into scores of tiny waterfalls. The hay was white with Ranunculus, and blue with Forget-me-nots; but my object was thoroughly to search a mass of high rocks at the upper end of the valley, lying just below some large patches of unmelted snow, and for these I made with as little delay as possible. The first thing that attracted attention was a bed of Anemone narcissiflora just coming into full bloom, the unopened buds pink like a bunch of Crab blossom, and beside them in every sheltered damp hole between the rocks grew Thalictrum aquilegiæfolium, with heads of pinkish-purple flowers. The short damp turf was studded with Primula farinosa, here in full bloom, while below at Mürren nothing but seed-vessels are to be found. The large blue Gentian, the smaller G. bavarica with its almost sky-blue blossoms, Pinguicula alpina, P. vulgaris, and the grand golden flowers of Geum montanum, each as large as a penny-piece, were to be found here. On the rocks themselves grew sheets of the exquisite Dryas octopetala, Saxifraga aizoon in full flower, Primula viscosa with a few blooms still left on it, and last but not least, P. Auricula, though with nothing but seed-vessels to be seen. This last formed the special object of my search, and I had vowed that if it were to be found in flower I would find it; so after half-filling my baskets with roots from the rocks, I pressed on towards the great sheets of snow which lay above me. As I neared them, I found myriads of delicate white Crocuses springing up through the burnt brown Grass mingled with the small purple parasols of Soldanella alpina, and around each heap of stones a fringe of a little and richly-scented Oxlip. At last, on the top of a heap of stones, I espied the treasure for which I was looking—a splendid plant of Primula Auricula in full bloom. Around grew thousands of the splendid white Anemone alpina and A. sulphurea; at this height their petals were all a purplish-grey outside, and the plants were somewhat dwarfer than below, where they were rapidly passing out of flower, and were either pure white or sulphur-coloured. They grow here in such immense quantities that I am surprised they are not more commonly found in English gardens, for certainly it would be hard to find two more beautiful plants, or plants more useful for the garden or for indoor decoration, as they last many days in water. And now having gone so far, I determined to go still farther, and to try and reach a col on the wall of the valley between the

Schwarzthorn and the Schiltgrat. A smooth green slope, broken here and there by piles of stone or a solitary rock, led up to this col, and on I went. Never was green slope more cruelly deceptive. I am afraid to say at what angle it lay; I only know that with nailed boots and strong alpenstock I could hardly keep my feet as I toiled sideways up it, for in reality it was a mass of the finest slate detritus covered with vegetation, which the rain had made as slippery as so much ice. Once on it return was impossible, so with great difficulty I managed to get to a large boulder, which gave me a firm foothold, and to my great delight I found it covered with pink cushions, which proved to be Silene acaulis in full bloom. While resting here and waiting for my companion, who was laden with the plant-basket, I heard a roar and a rattle, and to my horror saw a couple of big boulders bounding down from the upper cliffs. They passed within half-a-dozen yards of where she stood, and plunging on buried themselves in the snow below us. This was an unpleasant warning, so we hurried forwards, and at last reached a small path, which led us in a few yards to the summit of the col. Here a magnificent view greeted us, but as it was getting late, and the rain-clouds were rolling up from the valley, we hardly stayed to look, but followed the path along a knife edge of shaly rock to the highest point of the Schiltgrat, 6970 ft. above the sea, and 1643 ft. above Mürren. Here we stayed for a moment to get breath, and to get some roots of Anemone sulphurea, which was here in great beauty; large blue Gentian, Primula farinosa, a small Ranunculus, Hedysarum obscurum, Botrychium Lunaria, and to gather some Alpen-rose (Rhododendron ferrugineum) which clothed the precipitous cliffs to our left into the Blumenthal. We were now on a high and dry green Alp, and finding a good path we set off for home, reaching the hotel in forty-five minutes, wet through but triumphant.

ROSE G. KINGSLEY.

Mürren.

BUYING "COMMON" PLANTS FOR KEW.

SIR JOSEPH HOOKER suggests in his recently-issued report on Kew, that it would be well to purchase from suburban nurserymen the commoner kinds of plants for the embellishment of a certain house at Kew. Considering the appliances, the cost, and the able staff at Kew, this will scarcely be thought a desirable innovation. There is certainly glass enough at Kew to provide for all its wants. But we believe with the director that it would be well to "devote attention to the rarer sorts alone." It would be greatly to the gain of our horticulture if the director would courageously throw over the practice of growing tender plants that may be seen on every hawker's barrow and in every garden we pass by. The aim of the garden should be to lift us out of our meanness and poverty of garden embellishment. We have, for example, always held that one of the things that ought to be done well at Kew would be the hundreds of fine hardy plants now worth a place in the best parts of our gardens. Instead of healthy aim in that way, however, it for years past has merely tried to rival the big bedding-out places. We could well spare many "common" plants at Kew. But how much remains to be done in making uncommon ones known to us! We can allow for the many cares of such an establishment, but with bedding-out and "common" plants on one side and fine hardy plants and rare ones on the other—there should be no hesitation as to the right course.

SUMMER PRUNING FRUIT TREES.

IN nearly all districts fruit this year is thin, and there will probably be a tendency to produce too much wood, especially late in summer. This scarcity of fruit may perhaps in some cases beget an indifference about giving the trees the necessary attention, a course which would be most unwise, as it is only by close attention now that a crop next year can be secured. It is true we cannot control the seasons; nor is it possible in all cases to carry out our ideas in the matter of glass or other protectors, but the trees themselves at this season are, or should be, under control, and can be so arranged by thinning and training as to expose the future bearing wood to the full influence of air and sunshine, and the thorough maturation which such treatment ensures. In the case of trained trees, it is

important to secure well-developed foliage and buds—the one cannot be had without the other—close to the base of the spurs, and this can only be obtained by keeping the young wood thin. If the shoots be allowed to unduly extend themselves before pruning begins, the bottom leaves will lack substance, and the buds will be weak and probably imperfectly ripened. At the same time, very close pruning or pinching is not desirable, for if the young shoots be cut in closer than four or five leaves, the back eyes may start into growth instead of forming fruit buds. Trees of a rather weakly habit, or that have in previous years borne heavy crops, should be allowed a little more freedom of growth, as, provided a gross habit be not contracted, and the young wood not crowded, the stimulus imparted by a greater breadth of foliage will infuse new life into any tree that lacks vigour, and enable it to go on again for a series of years in a fruitful condition.

E. HOBDAY.

NOTES OF THE WEEK.

A BEAUTIFUL SHRUB.—We once figured (see Vol. X., p. 58) a most beautiful *Abelia* (*A. triflora*) that forms large bushes in the Botanic Gardens at Glasnevin, and this week we are indebted to Dr. Moore, the director of the Gardens in question, for specimens of a more showy species, wreathed with large tubular flowers of a fine rose, viz., *Abelia floribunda*.

DESFONTAINEA SPINOSA IN SCOTLAND.—At the Marquis of Tweeddale's fine old gardens at Yester, in Haddingtonshire, I noticed a noble plant of this in flower in the open air, though in a pot. It was about 4 ft. high and nearly as much through, and bore numerous flowers. It is set out in the open air in summer, and no doubt protected in winter in a cool house. In this way this brilliant plant is well worth growing where it does not thrive out-of-doors, as in Wales and the south of England and Ireland. I also noticed here a plant of the old *Venus Victrix Fuchsia*, now so seldom seen, and which is said to be the first white *Fuchsia* ever raised.—D. S.

FINELY-FLOWERED ORCHIDS.—We have at present a plant of *Oncidium Vexillarium roseum* bearing on four strong spikes fifty-two expanded flowers. The sepals and petals are of a very dark pink colour, and the tip nearly blood-red, and measuring 3 in. across. It is one of the best varieties I have seen. We have also a fine specimen of *Oncidium macranthum* bearing 156 flowers; its longest spike is 12 ft. 3 in. *Masdevallia chimera* is showing twelve spikes; and *M. Harryana sanguinea* is producing eighty-four flowers.—A. FALCONER, *The Poplars, Leyton*.

MOSS ROSES IN THE MARKET.—Notwithstanding the unfavourable season which we have had, Moss Roses seem this year even more plentiful than usual in London, for at the corners of nearly every street may be seen huge baskets of them, whilst in Covent Garden and other markets early in the morning they may be seen by the cartload. They are made into "button-holes" and sold for 1d. each. There are white, red, and pink ones, but the latter are most abundant. Of all under crops in market gardens Moss Roses are the most profitable, and about Ealing, Kew, and Hammersmith many acres of land are devoted to them. They are grown chiefly under orchard trees, and therefore the young buds are protected in spring from late frosts by the overhanging boughs, which of course are not then sufficiently leafy to injure the Roses by their shade.—S.

CYPRIPEDIUM SPECTABILE.—A large mass of this Lady's-slipper may now be seen in Messrs. Rollisson's nursery at Tooting. It grows near a wall belonging to one of the plant-houses, where it is somewhat sheltered, and thus situated, it flowers freely. If a few weeks previous to the blooms expanding the plants be taken up and potted, they make excellent subjects for conservatory, greenhouse, or room decoration. As a pot plant this Lady's-slipper is, however, a little too leafy in proportion to the flowers which it produces; but if it were possible to hybridize this with such kinds as *C. insigne* or *C. barbatum*, this objection might probably be obviated, and a good hardy, free-flowering greenhouse variety be obtained.—C. S.

CARLISLE INTERNATIONAL HORTICULTURAL EXHIBITION.—The Executive Committee have nearly completed their arrangements for this great show, which is to take place on September 6, 7, and 8, next. The fruits, plants, flowers, and vegetables, will be exhibited in large marquees, and the accommodation will be on a more extensive and convenient scale than that provided for the Dundee International Show last year. There will be a large central pavilion 100 ft. in diameter, from which will diverge marquees from 40 ft. to 50 ft. wide and 1000 ft. in length. The exhibition will take place on The Saucerias, a beautiful meadow close to Carlisle, extending from the ancient walls of the castle to the River Eden, which will be the northern boundary of the show ground. The principal entrance is a

few yards from the roadway in Dacre Street. The interior arrangements and general management of the show have been entrusted to Mr. William Thomson, of Clovenfords, who will be assisted by an Executive Committee experienced in all matters relating to gardening. In the meadows outside the marquees will be an exhibition of horticultural buildings and other appliances connected therewith.

AGAVE MIRADORENSIS.—A large plant of this at Sudbury House, Hammersmith, is throwing up a flower-spike which has grown 10 ft. in three weeks. It belongs to the American *Aloe* class.—J. C.

IMPORTED OLD MEN CACTI (*Pilocereus senilis*).—Of a quantity of these which have been imported, some only 2 in. high have hairs 3 in. and 4 in. in length, giving them quite as old a look as if they were 100 years of age.—J. CROUCHER, 75, South Row, Kensal New Town.

CLIMBING BESSIE JOHNSON ROSE.—This is the name given to a new Rose now in flower in Messrs. Paul & Sons' nurseries, Cheshunt. It has flowers resembling those of Bessie Johnson, but it is a climber, a great advantage, considering the few good free-blooming, light-coloured climbing Roses which we possess.—F.

ROSE BEAUTY OF GLAZENWOOD.—We regret to see that the "Journal des Roses" reproduces the monstrous exaggeration which was figured in an English publication under the above name. We have seen specimens of the said Rose, and wonder by what imaginative process the drawing of the plate in question was obtained.

IXORA COLEI.—Fine specimens of this white-flowered *Ixora* may now be seen in flower in several of the London nurseries. In habit it is compact and dwarf, and quite as floriferous as other kinds, single plants bearing in some instances from fifty to sixty clusters of flowers of snowy whiteness.—S.

PEACHES FROM FRANCE.—These are arriving in the London markets in large quantities, and some of them are very large in size, resembling in form *Grosse Mignonne*, but very inferior to that kind in flavour. Royal George, from the same source may, however, be had in excellent condition, many fruits of it being very large and beautifully coloured.

ÆRIDES ODORATUM IN COVENT GARDEN.—Fine spikes of this Orchid may have been seen for some time past in the florists' shops in Covent Garden. Such spikes are, of course, too large for use in ordinary floral decorations, but the individual, sweet-scented, white purple-tipped flowers, when stripped from the stalks and wired, are valuable in small bouquets, in which, associated with Rosebuds and scarlet *Bouvardias*, they have a charming appearance.

THE NEW ZEALAND FLAX IN THE SOUTH OF IRELAND.—Dr. Moore writes to us from Glasnevin:—"I have again had the rare treat of seeing, at Lismore, the *Phormium* in all its beauty, with thousands of wasps feeding on the nectar which fills the tubes of the perianth; it is truly magnificent. The stems rise from 10 ft. to 15 ft. The double purple *Dentzia* is also a fine plant, as it grows there, in the midst of Myrtles and other shrubs."

THE DOUBLE AGAPANTHUS.—This form of a well-known decorative plant will doubtless, when plentiful, be largely grown for furnishing cent blooms for market. For bouquets or button-holes, its double deep blue flowers are admirably adapted, and form a pleasing contrast to white Rosebuds, Jasmines, or Gardenias. Really good blue bouquet-flowers are generally scarce, the kind chiefly used for that purpose now being the Cornflower, to which the *Agapanthus* might be made to form a good succession. Flowering plants of it may now be seen in the Victoria Nurseries, Holloway.

SWEET PEAS IN COVENT GARDEN.—Of these the pure white-flowered forms and the Scarlet *Invincible* are the kinds liked best on account of their decided colours. They are the produce of seeds sown in November, a time when many sow their first crops of culinary Peas. As soon as they are above ground they are earthed up and staked. As the weather gets warmer the plants grow apace, and in June they yield a good supply of bloom, which is kept regularly out three times a week, and the better this is attended to the longer the plants continue to grow and yield blossoms. For later supplies seeds are sown in succession during the spring months, and in dry seasons they are given copious supplies of water.—S.

NATIONAL CARNATION AND PICOTEE EXHIBITION.—This is to take place in the Westminster Aquarium on the 18th and 19th inst., when the number and value of the prizes offered will doubtless induce keen competition. The prizes are open to all exhibitors, whether they are subscribers to the Society or not. Notice of entry should be given to Mr. E. S. Dodwell, 11, Larkhall Terrace, Clapham Rise, not later than the 13th inst. Prizes offered for Roses by the Royal Aquarium Company will be competed for on the same occasion. Entries in the Rose classes must be sent to Mr. E. Bennett, at the Aquarium, not later than the 14th inst.

PROPAGATING CONIFERS.

CONIFEROUS trees and shrubs are propagated by means of seeds, cuttings, and grafting, the latter process being reserved for those kinds which either do not strike readily from cuttings, or from which seeds are not easily procured. Grafting now, too, takes the place of layering, which was formerly extensively practised, but is now, owing to a better knowledge of grafting, but seldom resorted to. There are two methods by which seedling Conifers may be raised: they may be either sown in pans or boxes, and placed under glass, or they may be sown in the open air. In the case of rare kinds, or where but a limited quantity of seed is intended to be sown, the former is preferable, as, owing to the seeds being protected from accidents and variations of temperature and moisture, there is a greater certainty of the seed germinating properly. The pans or shallow boxes in which the seed is sown should be well drained. The soil used should be a mixture of loam and leaf-mould, with the addition of about one-third of sand. The pans or boxes should be filled about three-fourths full, the soil made firm, and then watered; this to be done the day previous to sowing, as it is necessary that the bulk of the soil should thoroughly settle into its place before the seed is sown. On this another layer of fine sandy soil must be put and firmly pressed down. On this the seed should be sown, making the surface firm, and giving a moderate watering. If they be placed where not exposed to drying air and sun, there will be no occasion for subsequent heavy waterings. The consolidation of the soil is an important point as regards this description of seed, at the same time it must not be rendered in any way hard, or impervious to the young rootlets. If, however, the compost be not of too tenacious a nature and have been carefully prepared, there will not be much to be feared upon this score. Especial care must be exercised not to over-water just as the seedlings are pushing through, as a little indiscretion in that respect at that period often proves disastrous. As soon as they are fairly up they should be placed where air has free admission, or whole panfuls of young plants will go off in a few days, if a free circulation of air be not kept up among them. If it be intended to plant them out in open ground a bed should be prepared for them, say 4 ft. in width, which will allow of their being easily watered and cleaned when necessary. In planting out it is extremely important that the young fibres do not in any way go dry. The contents of each pans should be carefully knocked out, and all the roots retained. The best way to plant them is to cut out a small trench several inches in depth, against the side of which each plant should be firmly but gently pressed, allowing the roots to extend downwards to their full length, covering them immediately with soil. In this way fresh roots will be made in a few days, which will at once strike deeply into the ground. The difference which these few precautions and extra care makes in the growth of the young plants is surprising, for although Conifers are as a rule hardy in character, yet if subjected to careless manipulation they do not fail to show the effects of it in the shape of stunted growth. If once they get into bad condition it is difficult to induce them to start freely again into growth. Water must be given them when required, and if cleanliness be observed a satisfactory growth will be the result. If sown in the open ground 4 ft. beds should be prepared, and the soil well pulverized, and according to its consistency it must be made more or less firm for the reception of the seed. The latter may either be sown broadcast or in drills, and the thickness of soil used in covering it will have to be regulated by the size of the seed. When sown it is as well to lay some boughs over the beds until the young plants begin to germinate, as they protect the seeds from birds and hot sun. Branches of the White Spruce answer well for this purpose, but failing them any evergreen will do. The ensuing season they may be pricked out in beds in the manner just mentioned.

Cuttings.

There are several ways of propagating Conifers by means of cuttings; one of the best is to take strong shoots in August with some 2 in. of ripened wood attached to them. These should be inserted firmly in 4-in. or 6-in. pots, in a light, sandy compost, and placed in frames situated, if possible, in a

north aspect. Here the greatest amount of air and light possible must be admitted to them, only shutting up and shading lightly during the hottest part of the day. On fine, still nights the lights should be entirely removed, in order that they may enjoy to the full extent the refreshing dews which generally fall about that season. In September a mild hotbed should be made up either of tan or leaves and manure; if the latter be used, then it must be surfaced with about 1 ft. of tan or sawdust, in which the pots should be plunged. Thus treated, the cuttings, after being callused, speedily emit roots, and on no account must they be allowed to suffer from want of moisture. By the end of October they will be well rooted, when they may be removed to a cool house or frame, there to pass the winter; in spring they may be potted off or planted out. In the case of kinds which it is desirable to push into quick growth, or of which there is only a limited stock, great advantage will be gained by potting them off early in February, and plunging them in a gentle bottom-heat. This will induce the formation of an extra amount of rootlets, by means of which the plants will be benefited when placed in the open ground. The method just described can only be employed where there is plenty of strong plants from which to take cuttings; where the stock is limited, and it is desired to make the most of it, it will be necessary to proceed differently. The cuttings must be taken in a smaller state from the green wood, and put into pots or pans, which should be surfaced with 2 in. of silver sand. In autumn they will have to be placed in a close house, where they may enjoy a warm, equable temperature during the winter; if a little bottom-heat can be afforded them they will be all the better for it, and will have made good root by the spring, when they may be either potted off or planted out. There is another way by which many of the Coniferous tribe may be propagated with a fair amount of success, and which possess the merit of simplicity. Take strong shoots early in September, and put them firmly in sandy soil in a north border, or where they are effectually screened from direct sunshine and drying air in the early summer months. The cuttings should have quite 3 in. of the ripe wood inserted in the soil, and in dry weather should be kept well watered. In this way many of the Thujas, Cypressess, &c., will strike fairly well.

Grafting.

Grafting may be performed either early in spring or about the month of August. For this purpose two-year-old stocks are preferable, as it is desirable that the stock and scion should be as near of a size as possible. They should be established in 3-in. pots, and if it be intended to use them early in the spring they should be kept during the winter in cold frames. There are several methods of grafting Conifers, but ordinary side-grafting is in most cases the best. This operation consists in making a clean cut in the stem downwards about an inch in length, then at its termination making a transverse cut, thus removing a piece of the bark-wood clean away from the side of the stock. The scion should be cut off clean and square at the end, and a piece of the wood should be shaved off about equal in length to the cut on the stock. The butt-end of the scion should then be placed upon the notch cut in the stock, taking care that the bark on one side meets exactly the whole length of the cut. The great aim in this operation is so to cut the scion and stock that the former when fitted on nearly replaces the piece removed. The scion being thus fitted must be held firmly in its place by the thumb of the left hand and tied on with bast or wool so that it does not afterwards shift. When the scion is very small, or the stock much out of proportion to it, another method may be practised. This consists in simply making an incision obliquely in the stock, the scion being so cut that one side of it forms a sharp edge, in order that it may be easily inserted therein, the bark of the scion thus coming level with that of the stock. This is a neat and expeditious method, as when united it is difficult to perceive the union. The cuts must be cleanly made with a sharp knife, and the incision in the stock and the cut on the scion should correspond in length as nearly as possible. This latter method scarcely needs tying, as if properly done the scion will not easily move, and it quickly unites to the stock. In neither of the methods just described is clay or grafting-wax

necessary, and the stock is not headed down but merely shortened by cutting a portion of the top away, leaving sufficient foliage to ensure a free flow of the sap. The plants should be placed as soon as worked in close frames or cases. If in early spring, the latter should be in a house where a regular temperate heat of about 55° is maintained; and if in the summer, they may be placed in any ordinary glass structure where shade can be easily given them. After the first few days air must be admitted every morning and increased in amount when the graft begins to unite to the stock, which is easily perceived by a white callus being formed at the union of the bark. As soon as the graft appears to have fairly taken the sashes may be entirely removed, and in the course of a week or ten days the plants may be placed in a cool frame, where it is, however, advisable to shade them from the hot sunshine. The regular daily admission of air is the most important point to be observed, as, if neglected, the grafts are apt to become yellow and fall off, and much to the surprise and disgust of the operator this will often happen, even after the plants are turned out to all appearance in good vigorous health.

Byfleet.

JOHN CORNHILL.

Evergreen and Deciduous.—Than this no division is better understood. He would be a bold man who ventures to throw a doubt on the fact that trees and shrubs are either evergreen or deciduous; but it may have escaped the notice even of naturalists that the division is not quite perfect, and for this reason that, although no deciduous tree (as generally understood) is evergreen, yet some evergreens are deciduous. Indeed, by far the greater number of them shed their old leaves as the new ones take their places, as any one may observe at this time of year by looking at the ground under a Holly, an evergreen Oak, or most of the Pine trees. This rule is so general, that it need not be remarked on if it were not for the fact that some evergreens are not deciduous. My attention was first drawn to this fact by observing the *Arancaria imbricata*, whose spikes never drop off, but appear to be gradually absorbed into the stem, and if they be forcibly removed Nature does not replace them. I have gone on to observe that the same rule applies to *Wellingtonia* and to all the *Arbor-vitæ* tribe, and, as far as I can see, also to other Conifers, such as *Picea nobilis*, but I would request some better-informed observer to give us the benefit of his knowledge on the subject.—I. T.

Large Walnut Trees.—There is a Walnut tree here which measures as follows:—16 ft. girth, not measuring the roots, and the branches cover 297 ft. circumference. I am under-estimating the amount of timber by putting it at 223 ft. Is this unusually large? Where are the largest Walnut trees on record in Britain?—H. M. RIDLEY, *Downland House, Liphook, Hants.* [This must be an exceptionally fine specimen, and, if so, it is of considerable value. The great spread of branches and curious contents are particularly remarkable. It is probably one of the largest examples of the Walnut tree in Britain. There is a fine Walnut tree at Rufford Abbey, Notts. The girth of its butt, which is only 4 ft. long, is 21 ft. 10 in. at 2 ft. above the ground. The stem divides into huge limbs at 4 ft. up, forming a not particularly handsome head.]

Ash Trees Splitting.—On a property in Ireland a large number of Ash trees used to grow. A certain number are still there, and unusually large in size; but when they reach about the age of thirty-three years they begin to split down the trunks, and thus in time they die. Can any of your readers explain the cause of this?—H. M. R. [It is not easy to account for the splitting of the Ash trees in question with any degree of certainty without knowing more particulars, or personal inspection. Probably the soil and subsoil are not favourable to the healthy growth of Ash. Ash timber is often grown where the soil is light, thin, and poor, and although the trees seem to thrive and grow rapidly for some years, and to outward appearance the timber looks clean and of good quality, it is generally the reverse, being short in the grain, brittle, and inferior. Where plantations have not been regularly and judiciously thinned when young, and the trees allowed to get thick and drawn up, and then subjected to a severe thinning, the sudden exposure to rough and prevailing winds will cause many to be blown over, and in the case of Ash, most probably many will be split from the fork downwards. Ash trees should be planted in loams and clay soils, to become valuable timber and of first quality.—Eo.]

Siamese Twin Trees.—An example of this kind of abnormal growth may be seen in Windsor Park, near the Bishopsgate entrance lodge, Englefield Green, very near the water tower in Baron Schroeder's grounds, on the outskirts of the park. Two very large centeearian Beech trees, springing apparently from the same root, are united at about 14 ft. up. A hundred yards or so farther on may be seen, through a forest vista serving as a frame to the picture, perhaps the most charming miniature view of Windsor Castle to be seen in the vicinity.—Tom SMITH, *Glenty House, Egham.*

—I was induced this morning to make a sketch of two Oak trees, standing about 5 ft. distant from one another, which trees apparently started in life quite independent of each other, but, after growing in this unfriendly state for many years, they must have determined to live together; one, therefore, took a header into the other, and this being received in a friendly spirit by his neighbour, they have grown up as one tree some 35 ft. or 40 ft. high, quite healthy, and vigorous. The junction is made some 10 ft. or 12 ft. from the ground, and makes a picturesque arch seen from a footpath close by. My woodkeeper, who has been on the estate with me for many years, says he has met with several instances of "Siamese twin trees;" but they have generally been rather higher up the trunk of the tree than in the sketch sent by Captain Morris.—H. M. HAWLEY, *Tumby Lawn, Boston, in "Field."*

FLORAL ARRANGEMENTS AT REGENT'S PARK.

In addition to the exhibits which one is accustomed to see at the evening fêtes held by the Royal Botanic Society, several new classes were added, some for flowers arranged for a head-dress, garlands for personal adornment, wreaths of flowers or leaves, set of six specimen glasses for a dinner-table, &c. The specimens staged in several of these classes were so good that many equal awards had to be made. As a rule the sprays arranged for the hair had a tendency to be overdone, and too many flowers were employed. In the lightest-looking and best made one, the exhibitor had not gummed the *Pelargoniums*, and therefore if touched it would have fallen to pieces; arrangements of this kind require to be made as light-looking as possible, the flowers selected of varieties that last best, and if of a description that requires preparing, let the preparation be well done. In the class for garlands for dresses, those staged were one and all very pretty; the same may be said in reference to the class for six specimen glasses; all were made like button-hole bouquets, save those to which the first prize was awarded, and they were made all round in the form of table bouquets, and were composed of light-looking and light-coloured flowers, and wild Grasses. The entries in the class for a centre table decoration were much above the usual number, and there was not one badly-arranged stand staged. The table decorations were much about the same as usual, except that in one class the tables had to be furnished as well as florally decorated, and, as a rule, the exhibitors were not evidently so much at home in the furnishing as in arranging the flowers. An extra prize was awarded to one table arranged quite in the old style; as far as the arranging of the flowers went, they were heavy and packed, but a very fine effect was made by the colouring of the stands, glasses, plates, &c.—all were well blended, and a rich effect produced, which would have been further enhanced had they been on a handsome table without a cloth. In the miscellaneous class some pretty crosses were shown, suited for church decoration, as well as other purposes. Amongst the tables I noted one on which the flowers employed for decoration were nearly all white, with the exception of a few crimson Rosebuds; they were charming, but, from being nearly all white, a dead effect was produced, but had there been mats of crimson cloth or velvet under the stands the general effect would have been improved. On the whole, the Royal Botanic Society are to be congratulated on their exhibition, which was the largest and best I ever remember seeing in the Regent's Park.

ANNIE HASSARD.

WILD FLOWERS ON THE SEA-COAST OF WIGTOWNSHIRE.

THESE are in great profusion this year, and I was so much struck by the variety and quantity that, as I walked along the high road lately, I jotted down the names of those that were most abundant and gay. The list includes some interesting species:—

<i>Anthyllis vulneraria</i>	<i>Lonicera Periclymenum</i>	<i>Rosa canina</i>
<i>Armeria vulgaris</i>	<i>Lotus corniculatus</i>	<i>Scutellaria galericulata</i>
<i>Asplenium marinum</i>	<i>Lychnis Flos-oculi</i>	<i>Sedum Telephium</i>
<i>Astragalus glycyphyllos</i>	<i>Lysimachia nemorum</i>	" <i>acre</i>
<i>Cerastium Soidanella</i>	<i>Malva sylvestris</i>	" <i>anglicum</i>
<i>Digitalis purpurea</i>	<i>Mertensia maritima</i>	<i>Silene maritima</i>
<i>Eryngium maritimum</i>	<i>Myosotis palustris</i>	<i>Thymus Serpyllum</i>
<i>Geranium sanguineum</i>	<i>Ononis arvensis</i>	<i>Verbascum Thapsus</i>
<i>Glancium luteum</i>	<i>Orchis maculata</i>	<i>Veronica Buccabunga</i>
<i>Glaux maritima</i>	<i>Oxytropis ulrensis</i>	" <i>Chamaeiryza</i>
<i>Hypericum Androsæmum</i>	<i>Polygala vulgaris</i>	<i>Vicia tetrasperma</i>
" <i>Elodes</i>	<i>Rhinanthus Crista-galli</i>	" <i>ayratica</i>
<i>Iris pseudoacorns</i>	<i>Rosa pimpinellifolia</i>	" <i>sapium</i>
<i>Jasione montana</i>	" <i>rubiginosa</i>	

SALMONICEPS.

Thinning Fruit.—We have frequently pointed out the great advantages of thinning fruit on the trees while yet small. Many of our readers know that for marketing, well-grown specimens that have had plenty of room to develop size and quality, will sell at much higher prices than poor and crowded fruit. In one experiment, recorded in the "Country Gentleman," after two-thirds of the fruit on trees of Louise Bonne of Jersey had been taken off, the crop was not diminished in quantity; it would have been better if three-fourths had been removed. The objection that additional labour is required for thinning is not valid, as it is much easier to pick off the young fruit when no care is necessary to prevent bruising, than to hand-pick the same specimens after they are fully grown, and then to assort them carefully by rejecting all the poor ones. Well-thinned crops need little assorting. In thinning Apples and Pears, throw off the small, imperfect, and wormy specimens, and leave the largest and smoothest. In this way the insects are early destroyed, and the trees will not be exhausted by bearing a surplus of worthless fruit. The earlier the work is done in summer, the better for both tree and crop. It is worth experimenting definitely to ascertain what distances are most profitable for the remaining fruit after thinning.

HYDRANGEA PANICULATA GRANDIFLORA.

Of this hardy, robust-growing, deciduous shrub, a coloured plate of which appeared in THE GARDEN (see p. 264, Vol. X.), I have a good specimen in the nursery fully 6 ft. high and as much through, which has been a mass of bloom during the past month or five weeks; I should think almost every bud on last year's wood has pushed forth a flower-spike. The buds are set opposite and in pairs along the drooping branches, and when they burst into blossom the latter present a pretty wreath-like appearance, all the branches arching one over the other from the base to the top. The flowers are palish when first opened, afterwards changing to pink and rose, somewhat resembling *Weigela rosea* in both foliage and flower, but it is a much stronger grower and the flowers are larger. My plant of *Hydrangea*, when not in leaf, might easily be mistaken for a *Deutzia scabra* or *Philadelphus coronarius*, on account of its strong woody growth. As a proof of how quickly a large bush may be grown, I bought it in a 4-in. pot six years ago, it being evidently a cutting-struck plant the previous year; it would have been much larger, only I kept it in the nursery for a stock plant, and I have taken some scores of cuttings from

it; they strike as freely as any common shrub in the open ground. Many that were put in last winter are now in bloom, the flower-spikes being much larger than the actual plants or cuttings. This plant is, I think, a real acquisition amongst the many beautiful deciduous flowering shrubs. It should have plenty of good soil, as I find it, as well as most other shrubs, will well repay for liberal treatment. A good thick layer of manure laid over its roots in autumn or spring is the sort of stimulant in which it delights. Many trees and shrubs are nearly starved to death when planted out for want of a little extra attention to encourage them to start into vigorous growth at once. They are often planted

in small holes with nothing but the original poor soil covering the roots, and then left to take care of themselves—the result, of course, is failure.—G. B.

Rocky Caves covered with Ivy.

ROCKY CAVES COVERED WITH IVY.

CONSPICUOUS common-looking buildings in gardens have been among the most effective means of neutralising any good effects therein, as, for example, the wooden structures in the centre of various London gardens. The accompanying illustration shows a successful attempt to hide with graceful vegetation (Irish Ivy) some caves for storing tools, and also, in part, serving as a shelter to passers-by in case of showers. These caves are almost completely covered with a mantle of Irish Ivy, which also spreads into the bushes and Grass around. Where the rocky masses forming the grottoes are seen, the effect is good, owing to the rock being well formed. The caves occur in a sloping bank backed with trees. It will be seen from this and from other examples that where such structures are necessary in gardens, it is easy to make them ornaments and not eyesores in the landscape.

BEST TIME FOR MANURING ROSES.

Roses require feeding. The more food the richer the colours, the larger the size, the more solid the texture, and more marvellous still, the sweeter the fragrance. There is, however, a proper time for manuring Roses. Many give it too late in the season; they seem to imagine that when the strain is heaviest on Roses or other plants, that is the time to assist them with stimulants, and so it would be could the stimulants get at them, but it takes a long while for solid dressings applied at the root to reach Rose leaves or flowers. Even liquid manure, of which we are accustomed to speak and write as if it acted at once, takes days, weeks, and even in some cases months, to reach the points where it is most needed in our Rose trees; while as for solids, they have to undergo no one knows how many processes of comminution and chemical decomposition, and perhaps recombination, before one particle of their strength can go to support the Rose either in its efforts at growing or flowering; hence the best time to manure Roses is, probably, November. Winds, rains, frosts, snows, sunshine and showers, heat and cold, all these prepare the manure for the plants and assist the roots to absorb it. The roots, too, are

also abnormally active during winter; they never cease absorbing unless when frozen, and then during the winter and early the manure may be turned in or out, or tossed about, in any way best suited for the Roses, without creating much or any annoyance to any one.

Under such circumstances, Roses feed at their leisure all the winter, and are well furnished for their work before their flowering season in June. On the same principle, even manure-water should be applied early. March and April are much better months for saturating Rose-beds with sewage and other manure-water than May or June. Water is no doubt quickly absorbed, but it is exceedingly doubtful if

the manure can be appropriated by the plants in anything like the same time; or whether, in fact, it does not really take a long time to convert any of the strength of the manure into Roses. Besides, it is of the utmost importance for the proper enjoyment of a Rose garden that it should be kept sweet and clean throughout the flowering months. What are called surface-mulchings might also generally be dispensed with. They are mostly composed of some loose, unsightly material of slow-conducting powers, to keep the moisture in and the heat out. But a loose surface of the soil itself would answer either purpose as well or better, and prove at the same time neat and sweet. Roses are also often rendered disagreeable through the application of insect remedies of various sorts—such, for instance, as Tobacco-water, sulphur, and Scotch snuff. All such dressings should be forbidden. Only three remedies against insect-pests are at once effective, cleanly, or pleasant. These are the finger-and-thumb cure in the early days of the grub or aphides, heavy washings with clean water from a powerful garden-engine, or doses of carbonate of ammonia, or smelling-salts, applied with a sponge or a small squirt. This last destroys the insects, adds a new perfume to the Roses, and seems to invigorate their growth and enhance their beauty.

D. T. FISH.

A Green Rose.—Dr. Wakley has shown us blooms of a green Rose, which he states were produced on bushes of very large size, and which have borne similar blooms for several years past. It is understood to have originated in America, from a sport from the old China Rose. Concerning this Rose, the late Prof. Lindley wrote, in 1860, as follows:—"There is to be found in French Rose catalogues a certain *R. Bengale verte*, which we seek in vain in those of England. In the "Prix Courant" for 1857, of Guillot Père & Clement, of Lyons, mention is made of a certain *Rosa viridiflora*, first introduced into the world in the autumn of 1856. Some thought this an apocryphal announcement, most believers formed an opinion of the new comer by no means complimentary, a very few resolved to judge for themselves. At last the *Rose* appeared in various places between Ross-shire and London, and very strange it proves to be. Conceive a China Rose with every part bright green, deep on the outside, pallid in the middle; the calyx wholly unchanged; the five natural petals transformed into five, small, broad, green leaves, and all the rest of the centre consisting of pale green straps of various degrees of narrowness, spreading evenly round the middle and forming a green star with innumerable points. Such is the *Rose Bengale verte*. Scent it has none, nor does it show the feeblest indication to exchange its verdure for a rosy hue. It is, however, quite regular in its form and greenness, no change having been remarked in it since the year of its birth. It is now a well-established five-year old, with a fixed habit." Mr. Brown, of the Exotic Nurseries, Tooting, where a plant of this Rose may now be seen growing, informs us that he has known the plant twenty-two years, and that it has experienced no change during that time.

Garden Design.—The teachings on landscape gardening that are more or less applicable to all grounds, may, I think, be briefly summed up as follows:—1st. Grounds must be sufficiently graded—or, if not, a system of underdraining must be resorted to. 2nd. Lay out paths and drive wherever needed and only there. Let them curve as if of necessity, and as much as possible so that this appearance be preserved. 3rd. Then plant fruit trees—deciduous and evergreen ornamental trees as closely as possible so that each may develop the form that belongs to it in its finest maturity, and so that liberal areas be left for carpets of velvety Grass—the choicest gem of all. If we be willing to transplant or remove them, as in later years they begin to interfere with one another—then we may prefer to set them so closely together that a year or two will suffice to obliterate that new, naked look so painfully conspicuous in newly-laid out grounds that, under the old plan, would require double the time. 4th. Arrange the shrubs and trees so as to conform, in a measure, to the paths and so to create secluded, shady, cosy nooks and openings through which the eye may range as far as the grounds permit and rest only upon verdure. 5th. Plant only low shrubs immediately about the house. 6th. Let the size of the trees in maturity be adapted, so far as may be, to the extent of the grounds. 7th. Give to each, as far as practicable, the soil and situation best adapted to its needs. 8th. So intermingling evergreen and deciduous trees that the evergreens may have proper winter distribution. Do not confine them to the N. S. E. or W.—but ever bear in mind that evergreens are "friends in deed," since they cheer up when all else is naked and shivering, and we have only them to depend upon for the bright relief of our winter grounds.—E. S. CARMAN.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dracæna australis in Flower in Devonshire.—There is now at Gorway, the residence of Mr. Whidborne, a splendid specimen of *Dracæna australis* in full bloom in the open air. It was planted about five years ago, and is now 10 ft. high to where the flower-spike is showing. This spike is 4 ft. high, and 3 ft. through at the base, and is a perfect mass of white bloom. It is situated high above the sea, and has received no protection of any kind.—J. D. N.

Roses on their Own Roots.—Mr. George Paul, at a meeting of Rosarians which took place the other evening in St. James's Hall, objected to these. He preferred to bud low and plant deeply, by which he maintained there was received—first, the impetus derived from the roots of the stock, and then the further support and permanency to be derived from the natural roots afterwards produced from the budded portion.

Floral Effects in Borders.—For a spring and early summer border, a pretty effect can be produced by mixing *Myosotis dissitiflora* with *Silene pendula compacta*, using either for the edging of the other. Some bedding *Pelargoniums* can be reserved at the planting-out season to take the places of the *Silene* and *Myosotis* when required. Sow now for next year, and plant the seedlings in their places when the *Pelargoniums* are removed.—B. S.

A Dahlia Catalogue.—It puts us in mind of some thirty years ago, to see a beautifully got up catalogue wholly on Dahlias! It is from Mr. Max Deegan, junior, and from Kostitz in Thuringia, and we really think the Dahlia deserves more than the cool treatment it has had of late years. Mr. Deegan grows only Dahlias, having given up all other branches of the floral business for them. Such devotion deserves reward.—"Gardeners' Monthly."

THE KITCHEN GARDEN.

LETTUCES AND THEIR CULTURE.

LETTUCES appear to have been in cultivation ever since the time of the ancient Greeks and Romans. They form, when properly grown, a remunerative crop, inasmuch as a large quantity of them may be grown in a little space, and being quickly off the ground they may be cultivated in many vacant places that could not be otherwise properly utilised, such as between rows of Celery, close under walls, between fruit bushes, &c. Lettuces are mostly placed on the table whole, or at least the leaves are not cut, but they are also used cut up in salads with other ingredients, and of late years it has been a custom even to boil Lettuces in the same manner as Cabbages. In order to have a good supply of Lettuces at all seasons of the year, glass structures of some kind are indispensable. The French use cloches, (i.e., large bell-glasses), for salad growing with marvellous success, and they might be tried here. One of the greatest aids to good Lettuce culture is a deep, rich soil, and it is far easier to make it deep and rich enough in the first instance than to struggle on through a hot, dry summer on a poor, hungry soil, harassed by the necessity for incessant watering to keep the plants from bolting. The first requisite in Lettuce culture is a well-manured, deeply-cultivated soil—all other things are, in a sense, subordinate to this—and the next is frequent sowing and planting.

Sowing, Planting, and Mulching.

Where the demand is regular and constant, a small sowing of two or three sorts once a fortnight from March till September will ensure a supply, and save a good deal of annoyance. The first spring sowing should be made in February, in a gentle hotbed if possible, or if the hotbed cannot be spared, then a box or two may be sown and placed near the glass anywhere, to be gradually hardened off, and finally planted out in April. It will succeed the last sowing made in September, and very frequently the finest Lettuces of the season will be produced from this February sowing. Towards the end of June and through July, sow on the north side of a wall, and thin the plants out according to the size of the kinds grown; 8 in. apart will be sufficient for Tom Thumb Cabbage Lettuce, whilst the larger kinds of Cos and Cabbage will require 10 in. or 12 in. Sow in drills, as it gives facilities for frequently stirring the soil with the hoe. The thinnings, if desired, may be planted elsewhere; but if the season be hot and dry, those that have not been transplanted will probably be most satisfactory. When hot and dry weather sets in, mulch with rotten manure, if possible, between the rows, laying it nearly up to the plants. A very great thickness will not be necessary; 2 in. or 3 in. at the most will be sufficient. This mulching saves a deal of labour in watering in dry summer. In fact, without mulching, on some soils watering is worse than useless; it encourages, during the time the effect of the water remains, the production of fibres near the surface, and if the water be neglected for even a short time these fibres perish. Far better will it be on hot soils, if mulching cannot be resorted to, to deepen the soil in every possible way, keep the surface loose by constant hoeing, and discontinue watering altogether, unless a regular and constant supply can be given. But when plants are mulched, a watering once a week or so washes the soluble portions of the manure down to the roots, and pushes on the plants rapidly. The last autumn sowing should be made about the middle of September, on a warm south border, to stand in the seed-bed over the winter, as it frequently happens small plants survive a severe winter when larger ones perish.

Blanching.

This process is probably the most vital point in Lettuce culture, for to have badly blanched Lettuces, no matter how ever fine they may be in other respects, they are wanting in crispness, flavour, and appearance. There are now so many kinds of Lettuces that naturally turn in and blanch themselves, that these are probably the most likely to give satisfaction to most people. Where, however, those kinds are grown that do not naturally turn in, tying must be resorted to. This

operation should at all times be performed on dry days, for if tied up while the leaves are wet, losses from rot will be the result. Tying should be done when the plants have nearly attained their full dimensions, and two ties to a plant are better than one if time can be spared for it. If, however, Lettuces be wanted before they have time to grow to their proper size, they must be tied up at least a week previous to use.

Varieties.

Varieties of Lettuce, like those of most other vegetables, are known under so many different names that it is almost impossible to ascertain the true name of any of them. Perhaps to answer all purposes there is no Lettuce to equal the Black-seeded Brown Cos, whose chief faults are its wanting tying in order to have it properly blanched, and its brown colour. If, however, it be well tied, the inner leaves may be had of a pure white with purple ribs. Among the varieties of Cos Lettuce we may mention Alexandra (white), which grows to a large size, and is crisp and finely flavoured. The Paris White and Green Cos are too well known to need much comment; for summer use, as every one knows, there are few to equal them, blanching themselves as they do in the most perfect manner, and thus obviating the tedious task of tying. Williams' Victoria, too, is a fine dwarf kind, and excellent for winter use. The best kind of Cabbage Lettuce is probably Hammersmith Hardy for winter, and All-the-Year-Round for summer; the old Neapolitan, however, still keeps in the front rank. Wheeler's Tom Thumb, Lee's Hardy Green, and White Dutch, are all good kinds. Commodore Nutt is a Cabbage Lettuce of the All-the-Year-Round type, but it proved to be still dwarfer than that variety. It is nearly all heart, does not run to seed so soon as some of the larger kinds, and is a great acquisition, owing to its taking up so little room in beds or rows. Sutton's Gem is another Cabbage Lettuce of a large size, and one which forms good hearts, which are crisp and well-flavoured. One market gardener, writing on the varieties of Lettuce, remarks that, after careful trials of many sorts of Cos and Cabbage Lettuces for several years, it has been proved that most of the so-called new kinds of white Cos are, after all, but mere selections from the old Paris white Cos. The two best strains are Waite's Alexandra and Dimmick's Victoria, the first being exceedingly even, true, and slow to run to seed; the latter also inherits most of these qualities, and is specially to be commended for its great size and usefulness for exhibition. Of winter Cos Lettuces the largest and best are Acme, White Cos, a very fine hardy variety, and Sugarloaf, Brown Cos, a strain of the Black-seeded Bath Cos. Neither of these require tying, and they are without exception first-rate. Among Cabbage Lettuces, the best is Leyden White Dutch for the earliest. If sown with the summer White Cos kinds, it will be ready for cutting a fortnight before them; and with it also sow Victoria Cabbage Lettuce, a fine solid kind, but several days later, and one which stands well. For winter work sow in the end of July and beginning of August Stanstead Park Brown Cabbage Lettuce, the finest grown, and with it Fearnought Cabbage Lettuce, which is made like the last, but stands longer. Than these no better selections can be made.

S.

PARSLEY AND EARLY HORN CARROTS.

A good breadth of these sown now will prove to be exceedingly useful, but no time should be lost in getting them in. A south or sheltered border will be the best site for them; it should be dressed with a sprinkling of guano or some other artificial manure, or, if more convenient, the drills may have a good soaking of liquid manure just previous to sowing the seeds. The drills for the Carrot may be 8 in. apart, and as soon as the young plants are up thin them out to 6 in. apart in the rows; this will be sufficient, as the largest may be drawn for use when about the size of one's thumb, and the operation of drawing them fresh from the ground should be continued all through the autumn and winter, merely protecting with a thin covering of dry litter when severe weather sets in. The Parsley drills should be 1 ft. apart, and the young plants should be thinned out to 5 in. or 6 in. asunder. I have a bed that was sown about this time last year that is far superior to any sown in the spring, in fact, without it in a backward season like this I do not know how we should manage; not

a dozen plants have shown any symptoms of running to seed, and they will not do so before next year. With a good breadth sown now, and some efficient means of protecting during severe weather, there need be no scarcity of good Parsley.—E. HOBDAV.

Early Peas in Pots.—I have practised growing early Peas in pots with success for the last ten years, and in backward springs like the past they are most useful in furnishing early dishes. They are grown in pits built on purpose, so as to have them near the glass, and the dwarf early varieties only are grown, such as Little Gem, Multum-in-Parvo, and Blue Peter. This year I have tried The Shah, one of Mr. Laxton's new early kinds, which grows rather taller than the sorts just named, but it is a good cropper, excellent in flavour, and is likely to prove one of the best early market varieties when it gets into general cultivation. The pits here, after the Peas have been all gathered in May, are useful for growing Tomatoes, Capsicums, and Vegetable Marrows in, and being heated with one row of 4-in. piping all round, severe frosts late in autumn or winter are prevented from injuring the plants grown in them. The Multum-in-Parvo Pea, gathered in the end of April or early in May has as fine a marrow flavour as that of Ne Plus Ultra or Dr. McLean in summer.—WILLIAM TILLERY, Welbeck.

Testacella haliotoidea.—We lately had occasion to speak of this slug—which one of our correspondents blamed for eating the roots of his plants. We explained that the Testacella was carni-

Testacella haliotoidea.
1. Extended. 2. Contracted. 3. Under side of shell. 4. Eggs.

vorous, and therefore must have been unjustly charged with the supposed mischief. We now give illustrations representing it extended and contracted, in which the characteristic shell is well seen.—M.

PARAFFIN OIL AND SEEDS.

THERE seems to be considerable diversity of opinion as to the safety of using paraffin oil in preventing seeds from being destroyed by vermin. We have formerly suffered very much in this way from rats, mice, and game, especially from pheasants and rats, so that we were obliged to cover all such things as Peas, Beans, &c., with wire netting; the netting kept the pheasants at bay, but of course was ineffectual as regards rats. In order to beat off rats I used to damp such things as Peas, Beans, &c., and then dust them over with crushed fiddler's rosin and arsenic, until they were coated over with the mixture. This had the effect of keeping them off for a time, but as soon as they burst the husk and began to grow, then the rats began at them as badly as ever. I have lost three sowings of Peas in succession by rats. This season I began to use paraffin oil as a preventive, and I must say with perfect success, so that I have not made use of any other protection whatever. The way I use it is this—I put what Peas or Beans I mean to sow into a biscuit-box, and pour on top of them some paraffin oil (one glass is sufficient for four quarts of Peas), and shake them about till they all get well moistened, and then sow immediately. It has not, in any case, prevented germination in the slightest degree; indeed, from the luxuriant way the Peas are all growing, I rather incline to think it has acted as a stimulant to vegetation. Though the vermin above-named are as numerous here as ever they were, they have hardly ever attempted to touch them. At first both rats and pheasants scraped up some and tasted them, and then they seem to have turned tail on them in disgust, and now they never even attempt to scratch them up. I sowed a lot of Broad Beans without putting oil on them, and all have been eaten up. I

have also tried it with success in keeping sparrows from eating the haulm of young Peas, by syringing them with a mixture of one glass of oil to 2 gallons of water. It requires to be repeated occasionally. Except in the case of Turnips, I have not tried it on any small seeds. After well moistening the Turnip seed with oil, I put a handful of dry sand among the seeds, and rubbed all through each other, as it would not be possible to sow it without something dry mixed among it: and neither in this case has it injuriously affected germination. In one instance it has done harm with me—in the case of some young Peach trees which had got very much affected with black fly. As fumigating with Tobacco had no effect on the fly, I tried paraffin, in the proportion of two glasses to a gallon of water, and bent the shoots down, shaking them about in the mixture for a few seconds. It did kill the fly, and every leaf it came in contact with as well, even the tips of the shoots. Probably the mixture was too strong, but I should hesitate in using it at all on any tender foliage. A farmer in this neighbourhood informs me that he steeped Peas twenty-four hours in pure paraffin, and then sowed them, and he thinks almost every Pea grew, though they were swelled up ready to burst when sown. This is not at all necessary, however, to attain the object in view, and I consider the risk too great. The same person also poured it in a highly dilated form along his rows of Carrots about the time they are generally attacked by the maggot, and he had a fine crop of clean Carrots, whereas he formerly could not get any free from disease. I mean to try this myself this season.—JOHN GARRETT, *Whittingham, in "The Gardener."*

Bird Destroyers.—The paragraph in *THE GARDEN* (see p. 21) reminds me of a circumstance which I lately witnessed. Passing through the garden of a friend in this neighbourhood, I saw five sparrows which had been shot by his gardener, hanging on a string over what should have been a row of Peas. The poor birds had been shot for pecking off the young Peas, the fact being that they had been engaged in the destruction of the real culprits, the Pea weevils; and the gardener lamented that although he had destroyed "ever so many sparrows" the evil had not been stayed. It is almost possible to fancy the Pea weevils, while luxuriating on the few remaining Peas, also enjoying the fate of their arch enemies—the sparrows; it was much as though in a neighbourhood noted for burglaries, a few policemen on the look-out for the culprits should have been impaled as a warning to the burglars. The ignorance of cultivators whose occupations it might be supposed would teach them the habits of birds and of insects is almost beyond belief. Is there any book on birds, and also on entomology, which (in a concise form) would enlighten not only them but also their employers?—J. RENNIE, *Milford.*

THE GREAT FLOWER PAINTERS.

DANIEL SEGHERS—BORN 1590, DIED 1661.

AMONG the flower painters of the Flemish school, Daniel Seghers, the Jesuit, was distinguished for his large, free, and partially idealistic method of painting, founded partly on his own individual taste, and influenced, no doubt, by the broad and dashing manner which the masterly brush of Rubens had communicated, not only to painters of his own walk in the higher branches of historical painting, but more or less to other styles of pictorial art, even to the animal and the flower painters. There is a freedom and breadth of touch in the flower painting of Seghers, which the great painter of the "Descent from the Cross" and the "Life of Marie de Medicis," by his fascinating and magnificent facility of execution, communicated even to the sister arts of sculpture and engraving. Seghers not only became imbued with that dashing manner, but even in some respects went beyond it, in the direction of a reckless disregard of the relative proportions of his floral models, and often in the characteristic individuality of the foliage proper to each flower. His groups, grand and attractive at a glance to every spectator, and always so to one unacquainted with the botanical character of popular flowers, will seldom bear a careful analysis.

His Jesuitical dogmatism followed him into his painting—"So shall be my Rose," he seems to have said, "and so my Lily." This kind of pictorial despotism is strikingly illustrated in a well-composed group of flowers preserved in the Museum of Lyons, of which the large engraving is an excellent reproduction. It will be seen that the White Lily (*Lilium candidum*), at the top of his composition, is almost entirely evolved out of his own impressions and recollections, rather than from a conscientious study of the plant itself, and yet the masterly treatment of the Lily buds, in a few happy touches, renders the identity unmistakable—though the expanded flowers have but little of the peculiar elegance of their well-known character—but the mass of white does its duty well, which is all that he intended, and

Works of the Great Flower Painters: Group of Flowers by Seghers.

forms an excellent apex to the composition. In immediate juxtaposition with his Lily, he required a contrast both of form and colour, and has apparently taken one of the many kinds of Chrysanthemum as his model, making the flowers larger than those of the Lily, to suit his special purpose; while immediately below, to the left, is a stem of Hollyhock, which, happening to be on the external edge of the entire group, he feared to make too heavy, and therefore without hesitation reduced the size of the flowers to something less than that of the Chrysanthemums. The sprays of the Orange variety of the "Prince's Feather" are well treated, and, as it suited him to give them their proper proportion in relation to the other plants, he has, in this instance, adhered more closely to Nature. His Roses, on the other hand, are unnaturally small, indeed, insignificant in size—an arbitrary departure from the grand characteristics of the flower which was no doubt intentional. He required, for carrying out the theory upon which the composition of his group was founded, several distinct shades of pink paling to blush, and blanching into white, and with that intention, one or two grand Roses alone would not have enabled him to carry out the idea. He therefore introduced many instead of two or three, each one exhibiting an individual tint of its own—a proceeding which is of the highest value in forming that useful artistic device, a mass of distinct yet closely allied tones. A plant, with

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Tomato Farms.—Much as our readers know of the general use of Tomatoes, we doubt whether they have any idea of how extensive their culture for preserving is. There is a Tomato-growing company in King William's Co., Virginia, that plant this year 700 acres. The seeds were started under six hundred hot-bed sashes. The yield is about a peck to the hill. These farms are mainly for the canned Tomatoes now beginning to be so well known in London.

Asparagus.—The advantages of Asparagus are not sufficiently appreciated. It is said that those who suffer from rheumatism are cured in a few days by feeding on this delicious esculent, while more chronic cases are much relieved, especially if the patient avoid all acids. The Jerusalem Artichoke affords a similar relief. [This is one of the notes—and varied notes—of the "Court Journal," which appears to be unsupported by any proof. No doubt it is as useful as any other wholesome vegetable.]

Charcoal or Alkali.—Charcoal as an ingredient in soil has been highly recommended by some plant growers, and decried by others, but the gist of the matter seems to be that pure wood charcoal or vegetable carbon is mostly beneficial, and never hurtful to the tenderest plant. On the other hand, much of the so-called charcoal used in some gardens is picked from the rubbish-heap fire, and contains as much alkali as carbon, and this latter is very hurtful to the roots of most plants, as is shown by the deserts near Salt Lake City, Utah, where hundreds of acres of land are uncultivable and totally barren.—B.

Campanula-like flowers—probably a stem of *Campanula pyramidalis*—is thrown out at the side of the general mass in a drooping manner, regardless of its naturally erect habit; and many other objects in the composition are made to play arbitrary parts in such an exceedingly dogmatic fashion that it would be difficult to assign to them any specific name. Even the branch of *Viburnum* with its balls of white, the florets of which are well indicated, is made to play the part of a drooping spray—as he required such to straggle over and break the horizontal lines and mouldings of his marble slab, and to light up the deep mass of shadow over which the depending branch is made to stray. In the midst of all this defiance of accurate

treatment of any special plant, the group, taken as a whole, represents the beauty and profusion of a luxuriant mass of flowers, with a truth and general effect which is charming, while scarcely a single flower, in its individual treatment, is truly painted; yet, with wonderful skill, the “modesty of Nature” is scarcely overstept, and Seghers, in a flower region of his own creation, charms the eye, even of the botanist, who, through the fascinations of art, refrains from any scientific criticism of a thing of beauty, which, taken from the point of view of its producer, possesses merits of invention and exquisite devices of pictorial skill, which he at once admits, admires, and enjoys. In the smaller specimen, from another work of this audaciously clever flower painter, there are still more reckless departures from his models, whether physically present or only existing ideally in the form of more or less imperfect reminiscences. There are for instance, sprays

of an old spring favourite, Solomon's Seal, in which the typical elegance of the plant is happily caught, and yet the specific details are all but entirely absent, or incorrectly treated. Sprays of Clematis of two species, of a single white kind and of the double purple, are, for once in a way, botanically correct, or nearly so, because their natural characteristics happened precisely to suit his purpose in the position of his picture which they are made to occupy. The Roses, also, double and semi-double, are in some respects very fairly truthful, and yet a striking white ball of florets, which might be a *Viburnum*, or almost anything else, has had to submit to the idealistic and arbitrary treatment peculiar to the painter. Seghers received his earliest instructions in painting from his father, but subsequently studied under the celebrated Breughel, who was not

only a delightful landscape painter, but also the greatest of Flemish flower painters of that day. At twenty-four years of age Seghers became an ardent and even fanatical student of theology, and in 1614 was admitted a member of the Company of Jesuits. He still, however, pursued his art, and soon became known beyond the boundaries of his native Flanders, and even in sterily Protestant Holland the talent of the young Jesuit was admired and actively sought after by enthusiastic amateurs. The Prince of Orange himself, deputing the Court painter, Willebouts, to obtain from Seghers one of his best works at any price, Seghers sent the Prince a magnificent group of flowers as a present from the Order of Jesuits,

declining any kind of money payment. But the Prince, not to be outdone in generosity, sent to the Order a noble casket of jewels in return for the exquisite work in question. The Princess of Orange, in her turn, having succeeded in obtaining a grand work of the painter, who still refused to accept any payment, presented him with a pallet and maulstick of solid gold. His greatest works were, however, executed in and for the charities of Antwerp. In the Jesuits' church, the portal of which was designed by Rubens, he painted many of the finely-carved panels of Oak with wreaths, festoons, and garlands of flowers, the striking and yet harmonious colouring of which was deemed in every way remarkable. Like his master, Breughel, he was often employed to enclose the Madonnas and other works of Rubens and his contemporaries with borderings of flowers, which not unfrequently found as many admirers as the greater works, which they not only framed but adorned.

One of the favourite artistic devices of Seghers was that of painting his flowers on a black ground, which, while it aids the definition of his always graceful outlines, produces at the same time an occasional hardness which has been severely criticised. Our smaller specimen is an example of this practice of the artist.

H. N. H.

Works of the Great Flower Painters: Group of Flowers by Seghers.

The Manchester Flower Mission.—The first year's work of the society bearing this title has just been concluded, and the committee have issued an interesting report containing information which will, no doubt, tend to assist them in the future. When the Mission was instituted only twenty-two bouquets could be distributed. The workers of the Mission have since met every Thursday morning, in the Association Rooms, Peter Street, and during the twelve months under review they have distributed 17,118 bouquets in weekly numbers varying from 22 to 798.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Verbenas, Lobelias, and Heliotropes for Bedding.—Carpet bedding has in some measure supplanted many of our best flowering plants, amongst which in particular may be named *Verbenas*, than which, when suitable varieties for outdoor culture are selected, there are few more desirable plants. To secure a stock from which to propagate next spring, some should now be placed in pots large enough to enable their attaining size and strength to furnish plenty of cuttings at the desired time; this will be found much better than depending upon autumn-struck plants, which frequently do not winter well without more care than is necessary with those that have been longer established in the pots. Use 8-in. pots and drain them sufficiently; in each place a spring-struck plant, which will generally be found to grow more freely than if struck in the autumn; put them in ordinary loam, to which add one-fifth of manure and a little sand. Out of the many varieties, by far the greater number are totally unsuited for bedding, for however fine the individual flowers may be, unless produced in quantity, and the plants possess a close habit of growth, they are worthless for outdoor culture; neither is it advisable to grow many kinds; the best representatives of the most decided colours will be found much more satisfactory than greater numbers. Amongst whites, *White-as-Snow* and *Snowflake* are the best; in reds, *Basilisk* and *Ganymede* (scarlet); *Crimson King* (crimson); and *Purple King* (purple), will all be found good. If these be well attended to with water through the summer and kept clear from insects and mildew, they will furnish abundance of cuttings in the spring. *Lobelias* should be similarly treated, as there is no dependence to be placed upon seed, for even when saved from the best-selected plants, it usually produces flowers of many different shades. Amongst the blue varieties *Elbor* is a splendid kind—for intensity of colour I have seen nothing to equal it; it is a most profuse flowerer, with a beautiful habit of growth, intermediate betwixt the compact *pumila* and *speciosa* sections. *Lady Macdonald*, white, edged with blue, is a fine variety. As a dwarf sort for edging small beds, *pumila grandiflora* may be selected; a few plants of these placed singly in 6-in. or 7-in. pots will furnish an almost unlimited quantity of cuttings in the spring. Some plants of *Heliotrope* potted on in like manner will be found equally useful to afford cuttings for either bedding or pots. *Cheshire Hero* (violet), *oculata* (violet with white centre), and *Heloise Delesalle* (lavender) are good kinds for beds or pot cultivation; 7-in. or 8-in. pots will be suitable for them. The above plants should if possible occupy a cold frame with abundance of air night and day, and be stood on a few inches of ashes to keep out worms.

Tricolor Pelargoniums are much more difficult to propagate than the green-leaved varieties, and, unless they are struck early in the season, many of the cuttings will damp off, and those that do succeed are not easy to keep through the winter, unless placed where they receive continuously a little warmth. Any plants of these to spare after the beds were filled should now be encouraged to make all the growth possible, in order to furnish a crop of cuttings by the middle of next month. Their requirements as to manure, either in a liquid or solid state, are very different to the green-leaved kinds, which latter, if too liberally treated in this respect, grow coarse and strong, whereas the *Tricolors* will bear a large amount of stimulating, either in pots or when planted out. Those that are intended to produce cuttings will be much assisted in making growth by being constantly supplied with manure-water, and when sufficient are thus grown to supply stock for increase, it obviates the necessity of taking cuttings from such as are bedded, with which there is usually a reluctance to interfere until late on in the season. The *Silver Tricolors* are not generally so much used for bedding purposes as the *Golden* varieties, but some of them are very beautiful.

Biennials and Perennials.—Sufficient space in the reserve ground should be now prepared for the reception of the different kinds of biennials and perennials sown some time ago. These, as soon as they are large enough to handle, ought always to be pricked out from 4 in. to 6 in. apart in nursery beds, where they can remain through the winter until spring, at which time they should be finally planted where they are to remain. It is a very common occurrence to see the plants left standing in the seed-bed until they are so weakened by overcrowding as to be of little value. If the soil in which they are to be planted be of a heavy adhesive nature it must be made lighter by the addition of sand and decomposed vegetable matter, so that the plants when removed in spring will have an abundance of roots, a condition not possible where the ground is close and impervious, but it should not be made rich by the application of manure, as the object is not to induce rank, succulent growth, but rather that of a compact character, such as will enable the plants to pass

unscathed through the winter, and to suffer little or nothing whatever from the effects of their subsequent removal.

Flower Garden.—Where any of the large-leaved sub-tropical plants are used for bedding out, it is essential that they are never allowed to suffer in the least degree for want of water, which, from their strong free-growing habit, they need much more than subjects of smaller growth, and if ever allowed to get too dry, their lower leaves lose colour and have to be cut away, in which condition the plants have an unsightly appearance.

Roses.—Hybrid *Perpetuals* should be sufficiently syringed overhead to keep them clear from aphides, so as to encourage the production of second growth for flowering later on. The limited number of plants that amateurs usually grow admits of their being thus attended to, and the labour will be well repaid by the extra quantity of flowers they will bear throughout autumn. When the ground is at all dry, a good soaking of water at the roots will still further assist them in this way. Amongst the large number of fine free-growing *Roses* now in cultivation many will be found to succeed better in some localities than others, which knowledge can only be attained by individual experience. I should recommend amateurs in all parts of the country to take notes of the kinds that succeed the best in their own gardens and those of their neighbours, and for general decorative purposes to confine themselves to such sorts as grow and flower well. Half the magnificent *Roses* seen on the exhibition stages throughout the country are all but useless for growing, except where soil and situation are especially adapted to their respective requirements.

Kitchen Garden.—The rains which have recently fallen in many parts of the country will have a most beneficial effect on crops of all kinds. Advantage should now be taken of getting in the whole of the remaining crops of *Broccoli*, *Kale*, and *Savoy*s, for winter and spring use. Where a portion of the plants, as recommended early in the year, were transferred to nursery beds, and another portion left thinned out in the seed-bed, the advantage of the former treatment will now be fully apparent, as on removal the plants that have been so pricked out will each be found to possess a dense mass of compact root-fibres, whereas those that have never been moved from the seed-bed will have extended much further, but not in such abundance, a circumstance which causes the plants in this condition to receive a much greater check in their future growth. If the soil be not sufficiently moistened by rain, the plants, before being taken up, should be thoroughly soaked; this is of much more consequence than giving water after planting, as when well moistened beforehand the roots will take up with little breakage. Any *Celery* remaining to plant should at once be put out. All crops, such as the earliest *Peas*, *Broad Beans*, and *Spinach*, that are exhausted, should immediately be cleared off and the ground dug for the reception of the foregoing plants, as upon thus carefully husbanding the resources a continuous and sufficient supply of seasonable vegetables through the winter and spring will depend.

Turnips.—Of these more should now be sown, and means be taken to preserve the plants when they germinate from being destroyed by birds and the *Turnip-fly*, as it is upon success with the present sowing that the autumn supply will mainly depend. Slight and repeated sprinklings with soot early in the mornings, whilst the dew is on the plants, I have found the most effectual means of saving *Turnips* from the fly, which, in dry districts where the land is not well adapted for the summer cultivation of this vegetable, is destructive to such an extent as to render its growth very difficult until the advent of cooler autumn weather.

Lettuce, Endive, &c.—Sow more *Lettuce* of both *Cos* and *Cabbage* kinds, as also *Radishes*, *Mustard* and *Cress*, where these latter are continually required; a little *Green Curled* and the *Plain-leaved* or *Batavian Endive* should likewise be put in. Spring-sown herbs, such as *Marjoram* and *Thyme*, especially the latter, should in dry weather be well supplied with water, otherwise from the late season it will have little time to reach maturity. Herb beds collectively, as well as *Onions*, and all crops where there is not much room to use the hoe, should be frequently hand-weeded. A few years' careful attention in never allowing any weeds to seed very soon diminishes their production to such an extent as to enable their being kept down without difficulty, and this is not the only advantage, for, where they are permitted to grow under the impression that they are not doing much harm unless they absolutely interfere with the growth of the crops, they impoverish the land to a far greater extent than any crop in cultivation, and necessitate the labour and expense of much more frequent and heavier applications of manure. Any advancing crop that shows by its want of vigour that the soil is deficient in manurial elements, can always be assisted by manure-water, but it is in the early stages of growth that this has the most effect; for instance, if

given to Peas, French Beans, Lettuce, Cabbage, Cauliflowers, or anything of a similar nature before they have more than half arrived at maturity, its effect in increasing the quantity of produce will be much greater than if applied when growth has further advanced, although there is no question that even when thus given in the latter stages it assists development.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

July 16.—Potting Tree Carnations in stiff soil, pressing them in firmly. Potting off seedling Musk plants and *Coleus* cuttings, and shifting *Lælia purpurata*. Sowing a row of Mignonette for supplying cut blooms; also another crop of Endive. Planting Cauliflowers and Paris Cos Lettuce. Clipping hedges and cutting Laurels. Pricking dead flowers and leaves off flower beds, and pegging down such plants as require that attention. Thinning Turnips and drawing drills in which to sow Spinach.

July 17.—Potting old winter Carnations and staking them neatly. Shaking out and repotting old plants of Poinsettias. Blocking *Epidendrum bicornutum*. Pulling up Shallots and laying them in the sun to ripen. Watering Cauliflowers, seed-beds, Radishes, Vegetable Marrows, and Celery. Tying Lettuces. Netting Currant, Cherry, and Gooseberry trees. Plunging Chrysanthemums and Cherry trees in pots out-of-doors.

July 18.—Repotting *Lycaste Skinneri*, *Epidendrum Frederici Guelmi*. Planting a border with Endive. Hoeing among all vegetable crops. Earthing up Savoys. Taking up Strawberry runners. Plunging all Roses in open ground, and placing Azaleas out-of-doors to ripen their wood and clear them of thrips. Storing away Shallots and Garlic on floor of cool loft, and shading Peaches that are ripe, in order to keep them back.

July 19.—Potting Roses in a mixture of loam, manure, bones, charcoal, and sand. Planting May-sown Veitch's Autumn Giant Cauliflowers on land lately cleared of Peas. Leaving the lights of Peach-houses open day and night where the fruit has all been gathered; also giving abundance of air to all Vines where the Grapes have commenced to colour. Nailing in leading shoots of Apricot, Peach, and Plum trees.

July 20.—Potting Strawberry runners; also *Coleus* and Balsams. Sowing Cucumbers for late crops; also Turnips, Radish, and Chervil. Tying Peach trees, and planting Green Cos, Bath Cos, and Neapolitan Cabbage Lettuces; also late Celery. Putting in cuttings of Hydrangeas, scarlet Pelargoniums, Cytisus, and *Coleus*. Hoeing among Raspberry plants; also all vegetable crops, and digging land for more Spinach.

July 21.—Potting Mrs. Marshall and Rose of Castile *Fuchsias*; also Abutilons, Clerodendrons, and Keen's Seedling Strawberries, and repotting young Cyclamens in loam, leaf-soil, and sand, afterwards placing them in a cold pit and shading them until well established. Sowing Batavian and Green-curbed Endive, Hill's Incomparable, and Early Market Cabbage; also Cucumbers for winter supply. Digging land in which to plant Wallflowers, and earthing up Cauliflowers and Winter Greens.

Hardy Flowers.

TUBEROUS-ROOTED BEGONIAS.—When planted out in a light rich soil, on a sunny, warm border, these do well, and flower profusely, and their blossoms prove more durable than when the plants are in pots in the heated atmosphere of a greenhouse. It is an interesting process to raise a few of these Begonias from seed. It is easy to get a good strain of seed from any seedsman, and it should be sown in a pan or box of light sandy soil, and then placed in a gentle bottom-heat with a piece of glass over it. As soon as the seedlings are large enough to handle, they should be pricked off into pots and grown on as fast as possible. Tuberous-rooted Begonias make good exhibition plants, but they require to be conveyed with much care to the place of show or they will shed their flowers. It may not be generally known that *B. Weltoniensis* makes an excellent town plant, growing well and flowering freely in confined places where other plants will fail.

CANTERBURY BELLS.—Some beautiful forms of these have appeared this year, the flowers of which are very large, and in many cases double. They vary in colour from pure white to bluish, lilac, pink, rosy-purple, violet, and blue. They rank amongst the most attractive of border flowers, because they bloom so freely and so con-

tinuously. Then there is the form known as *C. Medium Calycanthema*, in which the calyx is coloured and of large size—in the form of a disc. In this section we get white, cream, delicate mauve, and blue flowers. They are very attractive, but one could wish they were a little less lanky in growth. In this respect the new strain of Canterbury Bells decidedly gets the best of it. It is best to sow the seed in March and April, in order to get the plants strong before planting-out time, but some may be sown at once if the plants be pushed on into growth as soon as possible.

ESCHSCHOLTZIA.—The beautiful new forms of this glowing annual, which we have recently seen, are indeed great acquisitions; the rich reddish-orange of Mandarin, and the unique form of the double crocea, are accessions of real value, and with crocea, alba, and the orange aurantiaca, give us a batch of most attractive flowers. What is known as *E. rosea* is decidedly pretty, but is so apt to revert to the white form from which it sprang. Some jagged-edged sports, named *dentata*, are really not worth growing, and have become almost lost. Eschscholtzias are very effective when treated as biennials, the seed being sown in well-prepared ground in September to bloom early in spring; the plants get well established, and send their roots readily into the soil during winter, and then bloom with dazzling splendour in May.

PHLOX DRUMMONDI.—Here is what is known as a tender annual, that is, for all practical purposes, a hardy bedding plant, and a most effective one, too; its great requirement is a fine soil into which its roots can make a free growth. I have recently seen a bed the soil in which was made up of loam, manure, leaf-mould, and a quantity of finely-sifted mortar-rubbish. During dry weather the plants were watered freely, and they now cover the bed completely, and are throwing up remarkably fine trusses of flowers, double the size usually seen. This Phlox must be in rich soil to produce fine flowers, and it is a mistake to have it in poor soil; a good mixture of kinds is essential, that is, the bed should contain plants having flowers of varying and, let us add, striking colours. I saw a bed a few days ago in which the prevailing colour was a pale, indistinct lilac, with scarcely a dash of any brightness to break the monotony. Phlox Drummondii is much to be preferred to the Verbena as a bedding plant, and the rich blood-crimson *P. grandiflora splendens* is most effective. This variety especially should be used for bedding and border purposes.

ROSES.—Roses have given amateur gardeners much trouble this season; they did not break into a kindly growth, and the shoots got sadly infested with blight. I have a select few on the seedling Brier, and seeing them thus affected I mulched them with manure and then sprinkled them heavily with hot soap-suds; this was done for two or three weeks, and a great improvement has been the result, a vigorous, clean growth is being followed by fine flowers. The blooms are somewhat late, but they are so fine as to be doubly welcome. Some growers speak of the rich-coloured Louis Van Houtte as a "miffy Rose" and a "delicate grower," but on the seedling Brier and in a stiff loam it grows vigorously, flowers freely, and such flowers, too! large, full, and superbly brilliant.

TULIPS.—A leading grower of these, writing to me a few days ago, said:—"Tulips are taking up beautifully." He meant by that that they were coming up clean and bright, and large and plump. It is best to take them up as soon as they have ripened, that is, when the foliage has quite died down. Growers have drawers prepared with small compartments, and each bulb is put into a compartment with a little fine sandy soil adhering to the roots, and the drawers are put away in a cabinet in a cool place. Those growing choice Tulips should put each sort in a paper bag, and place the bags in a cool, dry place till October, when the bulbs may be looked over, cleansed of the old shell or skin, and will then be ready for planting out again early in November.—D.

Frost in Valleys.—It was thirty-eight years ago that we made and published some marked observations and experiments on the destruction of Peach-buds by frost in warm valleys, and their escape on elevations, which was the result of more rank growth in the rich soil below, greater stillness of the air, and the settling of the colder and heavier air at the bottom. We have frequently recorded the reported observations of others in later years as additional confirmation of this fact. A late number of the "American Farmer" contains a statement, the substance of which is as follows:—A Peach orchard was placed on the slope of a hill, 49 ft. above the Creek Valley, and the crop escaped the frost, which destroyed the fruit below. The past winter being severe, the tops of the highest trees this spring were the only parts that blossomed, and trees on ground 21 ft. higher up escaped, being 70 ft. above the bottom of the valley. In moderate winters, the cold lake of air was shallower or nearer the bottom; in colder winters, it filled the valley to a greater depth. When orchards cover a slope, the exact line of the fatally cold air may be seen on a level along the inclination, varying in height in different years with the varying intensity of the cold of the winter. These observations have been so many times made and repeated, that the principle is now well understood by most fruit-growers throughout the country.—"Country Gentleman."

HILL GARDENS.

We have often, in speaking of terrace gardens, alluded to the kind of position in which they were originally made, and for which they are only really fitted. The accompanying illustration shows the kind of situation referred to; where the small town spread around the chateau or villa, the slopes were occasionally terraced for ornamental as well as useful culture. In such ground and in ground much less disadvantageous no culture at all is possible without the terrace, therefore the walls of ten thousand valleys in Europe are terraced into steps or stairs. In many parts of Italy and in the Maritime Alps, towns may be seen perched on the hills, just as is the castle in the accompanying cut. In such places when men began to form gardens the terrace was necessary, and it was natural that it should be made ornamental in the hands of the wealthy. The

PLATE LXXXII.

PETRÆA VOLUBILIS.

ONE amongst the many objects in which THE GARDEN is helpful is in rescuing from unmerited oblivion long-introduced but now little-known plants of sterling merit, and such is the beautiful climber now figured. Although introduced from Vera Cruz more than a century ago, *Petræa volubilis* is at the present day scarcely known to modern plant growers, and is rarely, if at all, to be met with outside botanical collections. Yet, where even among the glowingly depicted modern introductions, can we find a more worthy subject for the plantsman to take in hand than this, possessing, as it does, wealth of bloom, exquisite delicacy and contrast of colour, and a grace and elegance probably unequalled amongst indoor

Château de St. Suzanne.

rude stone wall of the cultivator soon became in the hands of artist architects the stately terrace, necessary to secure water, soil, and standing ground for flowers and trees, and also for those who tended them. We are convinced that one of the most hideous errors running through the whole practice and history of landscape gardening is the carrying out of the same style and the various modifications of it in the level meadows of Europe and Britain.

Flowers for Perfuming Tea.—A Chinese "Materia Medica" affords some information regarding the flowers used for perfuming Tea. The principal ones appear to be those of *Gardenia radicans*, *Jasminum Sambac*, *Aglaia odorata*, *Ternstroemia japonica*, *Camellia Sassanqua*, and *Olea fragrans*; those of the last-named shrub being especially esteemed for the purpose. The leaves of *Salix alba*, and many other species of Willow, are employed in making a kind of Tien-cha, and are said to be openly mixed with the Tea intended for exportation at the Chinese ports.

climbers? The genus *Petræa* is a very small one, comprising only a very few species, amongst which the one now figured and *P. Stapelsiæ* are both twining stove shrubs, the stems of each being woody, somewhat rough, and of a brownish colour. The leaves are oblong, blunt, and of a rather hard leathery texture. The flowers are borne in marvellous profusion on elongated light airy thyrses. The calyx of each individual flower is divided into five radiating narrow strap-shaped segments of a very pale mauve, and are almost twice the length of the divisions of the corolla, which is bluish-purple, presenting a pretty and pleasing contrast to the paler tints of the conspicuous calyx. The corolla is rather fugacious, the calyx, on the other hand, being remarkably persistent; consequently, when some of the flowers part company with the latter, they leave behind pale lingering stars, a circumstance which makes the casual observer imagine that the plant pro-

ch
east,
on
ed

TWining PETRÆA (F VOLUBILIS).

duces two distinct kinds of flowers. The appearance of the scattered stars in a cloud of azure is singularly pretty. In the flowers of *Petræa* we have a colour unique perhaps among stove climbers, and one calculated to afford a pleasing variety in the plant-house and still more so on the exhibition stage. Its most congenial quarter is no doubt a warm conservatory, where, planted out, its roots and stems may have free play. It is not quite so amenable to pot culture; but taken in hand by a skilful plant grower there is little doubt that it could be turned to good account. Be that as it may, however, there is no more beautiful object to be met with in the stove than this, when, in April or early in May, from roof or pillar it throws out in rich profusion its pendent thyrses of starry flowerets. It grows freely in a compost of light fibry loam to which a little sandy peat or heath-mould has been added, with a portion of charcoal, taking care that the drainage is good. Cuttings strike freely in sand, plunged in heat, and covered with a bell-glass. When growing, it likes a moist heat, and should then be watered freely; but during the resting season it should be kept rather dry than otherwise.

AMBROSE BALFE.

CUTTING-POTS.

THOSE, who find their *Pelargoniums* and other cuttings to suffer from damp, should try the method indicated in the accompanying illustration. The damping off of cuttings usu-

Section of a pot containing *Pelargonium* Cuttings.

ally results from applying water by pouring it on the surface of the soil, and allowing it to percolate through. But if a small pot be sunk in the middle to receive it, moisture will be supplied where it is of most use; the quantity can always be regulated, and the cuttings are not so likely to suffer so much from an occasional overdose as they otherwise would. The best pots for *Pelargonium* cuttings are those whose width exceeds their height. The section, which is taken vertically through the middle of the pot, shows the cuttings, two only of which appear; the mould in which they are planted should contain plenty of silver sand, a thin layer of that material resting on a layer of Cocoa-nut fibre, and below that a quantity of corks or washed cinders to ensure perfect drainage.

B. S.

SHADING, DAMPING, AND AIRING.

THESE are as ticklish duties as can devolve upon any one in charge of hothouses, and this season, so far, has probably been as trying to the patience of cultivators as any they can remember. The long spells of dull weather which we have experienced have told upon the well-being of the inmates of both plant and fruit houses. Throughout the whole of the spring the weather was cold, with a constantly overcast sky, which prevented free ventilation; and the foliage of Vines and other subjects has a pale flabby look, which does not bode well for the successful finishing of the crops. Peaches, as a rule, always flag and droop considerably under such circumstances; but they never scorch, and they recover when shut up in the afternoon with a little moisture, and in a few days are sufficiently hardened to be out of danger; but Vines, and particularly the woody-leaved sorts, do not escape so easily, and with the greatest care they are usually singed more or less.

It is not so much the bright sunshine which does the mischief as the freer circulation of dry air that one is necessarily compelled to admit in order to keep down high temperatures. Forethought in such cases is necessary; and the great point is to reduce the necessity of giving so much air by checking the fires early in the morning, and in damping the floors and paths frequently during the day. Vapour has a great capacity for heat, which it kills, or neutralises, so to speak, and by raising a vapour under and about the trees in hot days the atmosphere is cooled while the air is moistened, thus lessening the evaporation from the foliage in two ways, and preventing injury. But the syringe is too slow an implement for damping at such times. A good-sized pitcher with a large and free-running rose, should be used and all inside surfaces should be sprinkled before the thermometer indicates a rise, and then the ventilation should afterwards be regulated. If these precautions be attended to in good time, it is rare that much injury is done by scorching, though the plants may droop for a few days. Such precautions are more necessary in the case of Vineries and other fruit-houses, because it is seldom that provision is made for shading them; nor is it advisable to shade fruit trees under glass. I never use shades, nor afford opportunities for their being used, as they are apt to be employed on any occasion as a mere convenience; and frequent shading is as bad as a dull sky, and simply aggravates the evil it is intended to prevent. With many kinds of plants it is quite different, and a word of caution is particularly necessary in the case of *Camellias*, which cannot stand bright sunshine under glass at any time, let alone after dull weather; but they do not object to plenty of subdued light. In their case the danger is that those in charge will not use the shading in time, and a few minutes' neglect will sometimes half ruin a collection of *Camellia* plants. The safest plan is to paint the glass on the outside with whiting mixed with a little turpentine or milk, or anything else to make it stick, but it should be put on as thinly as possible; the merest streak of the brush will break the sun's rays, and that is quite enough. Such adhesive mixtures come off easily in autumn if the glass be first wetted with a strong solution of soft soap. In the case of plant-houses containing subjects that need shade—such as Ferns, *Caladiums*, *Orchids*, &c., placed perhaps with others that require most light—a compromise must be made by using a movable shading that can be rolled up and down as occasion requires. All that our shade-loving plants object to is fierce sunlight, which some other subjects often necessarily occupying the same house enjoy; but the latter will not suffer from being shaded during the hottest part of the day, while the former will be saved. The shading should not remain on the roof a moment longer than is necessary, however. In span-roofed houses, exposing one side of the roof to the east, and the other to the west, the shading should be let down on the respective sides before the sun gathers power, and pulled up again when its influence is on the wane in the afternoon: there is never so much danger after the house has been damped down, even though the sun is shining upon it. Lean-to houses, which receive the direct rays when they are most powerful, require more watching; and the most dangerous period of the day is between ten o'clock in the morning and four in the afternoon, and between these hours the shading should be done on hot days. Connected with the subject of airing must be mentioned that peculiar accumulation of moisture which gathers upon the leaves during the night under certain conditions, and which is most frequently noticeable in the case of Vines, the leaves of which are often laden with dewdrops in the morning. As a rule, this is a welcome sign, for it is often associated with good health, and shows the Vines to be gorged to repletion, and that the night temperature is not too high. Vines and other plants will show dewdrops in this way when the house is shut up after a fine day and left all night without fire-heat. There is danger, however, at such time; for, unless air be given early in the morning to dissipate the moisture, scorching of the leaves and scalding of the berries will occur, through the rapid evaporation produced by the sudden and free admission of air, should the morning prove bright. A chink of air left on all night, and a slight increase by six or seven o'clock in the morning will generally prevent any mischief.

CHEF.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 18).

Pumpion.

Mrs. Ford. Go to, then. We'll use this unwholesome humidity—this gross watery Pumpion.

Merry Wives of Windsor, act iii., sc. 3.

Pumpion, Pompion, and Pumpkin were general terms including all the Cucurbitaceæ, such as Melons, Gourds, Cucumbers, and Vegetable Marrows. All were largely grown in Shakespeare's days, but I should think the reference here must be to one of the large useless Gourds, for Mrs. Ford's comparison is to Falstaff, and Gourds were grown large enough to bear out even that comparison. "The Gourd groweth into any forme or fashion you would have it . . . being suffered to clime upon an arbour where the fruit may hang; it hath bene seene to be nine foot long." And the little value placed upon the whole tribe helped to hear out the comparison. They were chiefly good to "cure copper faces, red and shining fierce noses (as red as red Roses), with pimples, pumples, rubies, and such-like precious faces." This was Gerarde's account of the Cucumber, while of the Cucumber Pompion, which was evidently our Vegetable Marrow, and of which he has described and figured the variety which we now call the Custard Marrow, he says, "it maketh a man apt and ready to fall into the disease called the cholericke passion, and of some the felonie."

Mrs. Ford's comparison of a big, loutish man to an overgrown Gourd has not been lost in the English language, for "bumpkin" is only another form of "Pumpkin," and Mr. Fox Talbot, in his "English Etymologies," has a very curious account of the antiquity of the nickname. "The Greeks," he says, "called a very weak and soft-headed person a Pumpion, whence the proverb *πεπονος μαλακωτερος*, softer than a Pumpion; and even one of Homer's heroes, incensed at the timidity of his soldiers, exclaims *ω πεπονης*, you Pumpions! So also *cornichon* (Cucumber) is a term of derision in French."

Yet the Pumpion or Gourd had its uses, moral uses. Modern critics have decided that Jonah's Gourd, "which came up in a night and perished in a night," was not a Gourd, but the Palma Christi, or Castor-oil tree. But our forefathers called it a Gourd, and believing that it was so they used the Gourd to point many a moral and illustrate many a religious emblem. Thus viewed it was the standing emblem of the rapid growth and quick decay of evil-doers and their evil deeds. "Cito nata, cito pereunt," was the history of the evil deeds, while the doers of them could only say—

Quasi solstitialis herba fui,
Repete exortus sum, repente occidi.

Plautus.

Quince.

Nurse. They called for Dates and Quinces in the pastry.

Romeo and Juliet, act iv., sc. 4.

Quince is also the name of one of the "homespun actors" in "Midsummer Night's Dream," and is no doubt there used as a ludicrous name. The name was anciently spelt "coynes."

And many homly trees ther were
That Peches, Coynes, and Apples beere,
Medlers, Plowmes, Perys, Chesteyns,
Cherys, of which many oon fayne is.

Chaucer ("Romaunt of the Rose").

The same name occurs in the old English vocabularies, as in a nominale of the fifteenth century, "hæc cocianus, a coven-tre;" in an English vocabulary of the fourteenth century, "Hoc coccinum, a quoyne," and in the treatise of Walter de Bibbesworth, in the thirteenth century—

Issi trovezet en ce verger
Estang un sek Coigner (a Coyn-tre, Quince-tre).

And there is little doubt that "Quince" is a corruption of "coynes," which again is a corruption, not difficult to trace, of Cydonia, one of the most ancient cities of Crete, where the Quince tree is indigenous, and whence it derived its name of Pyrus Cydonia, or simply Cydonia. If not indigenous elsewhere, in the East it was very soon cultivated, and especially in Palestine. It is not yet a settled point, and probably never will be, but there is a strong consensus of most of the best

commentators, that the *Tappuach* of Scripture, always translated Apple, was the Quince. It is supposed to be the fruit alluded to in the Canticles, "As the Apple tree among the trees of the wood, so is my beloved among the sons; I sat down under his shadow with great delight, and his fruit was sweet to my taste;" and in Proverbs, "A word fitly spoken is like Apples of gold in pictures of silver;" and to have given its name to various places in Palestine, as Tappuach, Beth-Tappuach, and Aen-Tappuach.

By the Greeks and Romans the Quince was held in honour as the fruit especially sacred to Venus, who is often represented as holding a Quince in her right hand, the gift which she received from Paris. In other sculptures "the amorous deities pull Quinces in gardens and play with them. For persons to send Quinces in presents, to throw them at each other, to eat them together, were all tokens of love; to dream of Quinces was a sign of successful love" (Rosemaller). The custom was handed down to mediæval times. It was at a wedding feast that "they called for Dates and Quinces in the pastry;" and Brand quotes a curious passage from the "Praise of Musick," 1586 ("Romeo and Juliet" was published in 1596):—"I come to marriages, wherein as our ancestors did fondly, and with a kind of doting, maintaine many rites and ceremonies, some whereof were either shadowes or abodements of a pleasant life to come, as the eating of a Quince Peare to be a preparative of sweet and delightful dayes between the married persons."

To understand this high repute in which the Quince was held, we must remember that the Quince of hot countries differs somewhat from the English Quince. With us the fruit is of a fine, handsome shape, and of a rich golden colour when fully ripe, and of a strong scent, which is very agreeable to many, though too heavy and overpowering to others. But the rind is rough and woolly, and the flesh is harsh and unpalatable, and only fit to be eaten when cooked. In hotter countries the woolly rind is said to disappear, and the fruit can be eaten raw; and this is the case not only in Eastern countries, but also in the parts of Tropical America to which the tree has been introduced from Europe.

In England the Quince is probably less grown now than it was in Shakespeare's time—yet it may well be grown as an ornamental shrub even by those who do not appreciate its fruit. It forms a thick bush, with large white flowers, followed in the autumn by its handsome fruit, and requires no care. "They love shadowy, moist places"—"It delighteth to grow on plaine and even ground and somewhat moist withall." This was Lyte's and Gerarde's experience, and I have never seen handsomer bushes or finer fruit than I once saw on some neglected bushes that skirted a horsepond on a farm in Kent; the trees were evidently revelling in their state of moisture and neglect. The tree has a horticultural value as giving an excellent stock for Pear-trees, on which it has a very remarkable effect, for "Cabanis asserts that when certain Pears are grafted on the Quince, their seeds yield more varieties than do the seeds of the same variety of Pear when grafted on the wild Pear" (Darwin). Its economic value is considered to be but small, being chiefly used for Marmalade, but in Parkinson's time it was in higher repute, for "there is no fruit growing in the land," he says, "that is of so many excellent uses as this, serving as well to make many dishes of meat for the table, as for banquets, and much more for their physical virtues, whereof to write at large is neither convenient for me nor for this work."

Radish.

(1) *Falstaff*. When he was naked, he was for all the world like a forked Radish.

2nd Henry IV., act iii., sc. 2.

(2) *Falstaff*. If I fought not with fifty of them, I'm a bunch of Radish.

1st Henry IV., act ii., sc. 4.

There can be no doubt that the Radish was so named because it was considered by the Romans, for some reason unknown to us, the root par excellence. It was used by them, as by us, "as a stimulus before meat, giving an appetite thereunto"—

"acria circum
Rapula, lactuca, radices, qualia lassum
Pervellunt stomachum."—*Horace*.

but it was cultivated, or allowed to grow, to a much larger size than we now think desirable. Pliny speaks of Radishes weighing 40 lb. each, and others speak even of 60 lb. and 100 lb. But in Shakespeare's time the Radish was very much what it is now, a pleasant salad vegetable, but of no great value. We read, however, of Radishes being put to strange uses. Lupton, a writer of Shakespeare's day, says: "If you would kill snakes and adders strike them with a large Radish—and to handle adders and snakes without harm, wash your hands in the juice of Radishes and you may do without harm."—"Notable Things," 1586.

We read also of great attempts being made to procure oil from the seed, but to no great effect. Hakluyt, in describing the sufficiency of the English soil to produce everything necessary in the manufacture of cloth, says—"So as there wanteth, if colours might be brought in and made natural, but onely oile; the want whereof if any man could devise to supply at the full with anything that might become naturall in this realme, he, whatsoever he were that might bring it about, might deserve immortal fame in this our Commonwealth, and such a devise was offered to Parliament and refused, because they denied to allow him a certain liberty, some others having obtained the same before that practised to work that effect by Radish seed, which onely made a trial of small quantity, and that went no further to make that oile in plenty, and now he that offered this devise was a merchant, and is dead, and withal the devise is dead with him."—"Voiages," vol. 2.

The Radish is not a native of Britain, but was probably introduced by the Romans, and was well known to the Anglo-Saxon gardener under its present name, but with a closer approach to the Latin, being called *Radic*.

A curious testimony to the former high reputation of the Radish survives in the "Annual Radish Feast at Levens Hall," a custom dating from time immemorial, and supposed by some to be a relic of feudal times, held on May 12th at Levens Hall, the seat of the Hon. Mrs. Howard, and adjoining the high road about midway between Kendal and Milnthorpe. Tradition hath it that the Radish feast arose out of a rivalry between the families of Levens Hall and Dallam Tower, as to which should entertain the Corporation with their friends and followers, and in which Levens Hall eventually carried the palm. The feast is provided on the bowling green in front of the Hall, where several long tables are plentifully spread with Radishes and brown bread and butter, the tables being repeatedly furnished with guests.—"Gardeners' Chronicle."

Raisins.

Clown. Four pounds of Prunes and as many Raisins of the sun.

Winter's Tale, act iv., sc. 2.

Bearing in mind that Raisin is a corruption of *racemus*, a bunch of Grapes, we can understand that the word was not always applied, as it is now, to the dried fruit, but was sometimes applied to the bunch of Grapes as it hung ripe on the tree. So Chaucer uses it:—

For no man at the firste stroke
He may not felle down an Oke;
Nor of the Reinsins have the wyne
Till Grapes be ripe and welles afyne.

Romaunt of the Rose.

The dried fruit were Raisins of the sun, *i.e.*, dried in the sun, to distinguish them from those which were dried in ovens. They were, of course, foreign fruit, and were largely imported. The process of drying in the sun is still the method in use, at least, with "the finer kinds, such as Muscatels, which are distinguished as much by the mode of drying as by the variety and soil in which they are grown, the finest being dried on the Vines before gathering, the stalk being partly cut through when the fruits are ripe, and the leaves being removed from near the clusters, so as to allow the full effect of the sun in ripening."

The Grape thus becomes a Raisin, but it is still further transformed when it reaches the cook; it then becomes a Plum, for Plum pudding has, as we all know, Raisins for its chief ingredient and certainly no Plums; and the Christmas pie into which Jack Horner put in his thumb and pulled out a Plum must have been a mince-pie, also made of Raisins; but how a

cooked Raisin came to be called a Plum is not recorded. In Devonshire it undergoes a further transformation, for there Raisins are called Figs, and a Plum pudding is called a Fig pudding.

Reeds.

(1) *2nd Servant.* I had as lief have a Reed that will do me no service, as a partisan I could not heave.

Antony and Cleopatra, act ii., sc. 7.

(2) *Arrivagus.* Fear no more the frown o' the great,
Thou art past the tyrant's stroke;
Care no more to clothe and eat,
To thee the Reed is as the Oak;
The sceptre, learning, physick, must
All follow this and come to dust.

Cymbeline, act iv., sc. 2.

(3) *Ariel.* His tears run down his beard like winter's drops
From eaves of Reeds.

Tempest, act v., sc. 1.

(4) *Ariel.* With hair up-staring—then like Reeds, not hair—

Ibid., act i., sc. 2.

(5) *Hotspur.* Swift Severn's flood,
Who then, affrighted with their bloody looks,
Ran fearfully among the trembling Reeds.

1st Henry IV., act i., sc. 3.

(6) *Portia.* And speak between the change of man and boy
With a Reed voice.

Merchant of Venice, act iii., sc. 4.

Reed is a general term of almost any water-loving, grassy plant, and so it is used by Shakespeare. In the Bible it is perhaps possible to identify some of the Reeds mentioned with the Sugar Cane in some places, with the *Papyrus* in others, and with the *Arundo Donax*. As a Biblical plant it has a special interest, not only as giving the emblem of the tenderest mercy that will be careful even of "the bruised Reed," but also as entering largely into the mockery of the Crucifixion. "They put a Reed in His right hand," and "they filled a sponge full of vinegar, and put it upon a Reed and gave Him to drink." The Reed in these passages was probably the *Arundo Donax*, a very elegant Reed, which was used for many purposes in Palestine, and is a most graceful plant for English gardens, being perfectly hardy, and growing every year from 12 ft. to 14 ft. in height, but very seldom flowering.

But in Shakespeare, as in most writers, the Reed is simply the emblem of weakness, tossed about by and bending to a superior force, and of little or no use—"a Reed that will do me no service" (No. 1). It is also the emblem of the blessedness of submission, and of the power that lies in humility to outlast its oppressor.

Like as in tempest great,
Where wind doth bear the stroke,
Much safer stands the bowing Reed
Than doth the stubborn Oak.

Shakespeare mentions two uses to which the Reed was applied, the thatching of houses (No. 3), and the making of Pan or shepherd's pipes (No. 6). Nor has he anything to say of its beauty, yet the Reeds of our riversides (*Arundo Phragmites*) are most graceful plants, especially when they have their dark plumes of flowers, and this Milton seems to have felt—

Forth flourish't thick the clustering Vine, forth crept
The smelling Gourd, up stood the Cornie Reed,
Embattled in her field.

Paradise Lost, book vii.

Rhubarb.

Macbeth. What Rhubarb, Senna, or what purgative drug
Would scour these English hence?

Macbeth, act v., sc. 3.

Shakespeare could only have known the imported drug, for the Rheum was first imported by Parkinson, though it had been described in an uncertain way both by Lyte and Gerarde. Lyte said—"Rha, as it is thought, hath great broad leaves;" and then he says—"We have found here in the gardens of certaine diligent herboristes that strange plant which is thought by some to be Rha or Rhubarb;" but from the figure it is very certain that the plant was not a Rheum. After the time of Parkinson, it was largely grown for the sake of producing the drug, though it is still doubtful whether any of the species now grown in England are the true species that

have so long produced Turkey Rhubarb.* The plant is now grown most extensively as a spring vegetable, though I cannot find when it first began to be so used. Parkinson evidently tried it and thought well of it. "The leaves have a fine acid taste; a syrup, therefore, made with the juice and sugar cannot but be very effectual in dejected appetites." Yet even in 1807 Professor Martyn, the editor of "Miller's Dictionary," in a long article on the Rhubarb, makes no mention of its culinary qualities, but in 1822 Phillips speaks of it as largely cultivated for spring tarts, and forced for the London markets, "medical men recommending it as one of the most cooling and wholesome tarts sent to table."

As a garden plant the Rhubarb is highly ornamental, though it is seldom seen out of the kitchen garden, but where room can be given to it, *Rheum palmatum* will always be admired as one of the handsomest of foliage plants. The finest species of the family is the Himalayan *Rheum nobile*, but it is exceedingly difficult to grow. Botanically the Rhubarb is allied to the Dock and Sorrel, and all the species are herbaceous.

Rice.

Clown. Let me see. What am I to buy for our sheep-shearing feast? Three pound of sugar, five pound of Currants, Rice. What will this sister of mine do with Rice?

Winter's Tale, act iv., sc. 2.

Shakespeare may have had no more acquaintance with Rice than his knowledge of the imported grain, which seems to have been long ago introduced into England, for in a nominale of the fifteenth century, we have "*Hoc risi, indeclinabile, ryse.*" Yet he may have seen the plant, for Gerard grew it in his London garden, though "the floure did not show itselfe by reason of the injurie of our unseasonable yeare 1596." It is a native of Africa, and was soon transferred to Europe as a nourishing and wholesome grain, especially for invalids—"sume hoc ptisanarium oryzae," says the doctor to his patient in Horace. It has been occasionally grown in England as a curiosity, but seldom comes to any degree of perfection out-of-doors, as it requires a mixture of moisture and heat that we cannot easily give it. There are said to be species in the north of China growing in dry places, which would perhaps be hardy in England and easier of cultivation, but I am not aware that they have ever been introduced.

H. N. ELLACOMBE.

(To be continued).

Effects of the Winter of 1860-61 on Shrubs at Penrose.

—August, 1860, was cloudy and wet (21 days' rain), and summer shoots of shrubs were not ripened properly. Winter began early, and half-hardy shrubs, whose young branches were still full of sap, suffered severely in Cornwall, whilst the same kinds survived the winter in the suburbs of London.

SHRUBS KILLED AT PENROSE.

Abutilon vitifolium (some).
Acacia lophantha (all).
Araucaria brasiliensis (all).
Arundo Donax.
Benthamia fragifera (some).
Cineraria arborea.
Cedrus Deodara (some).
Daphne purpurea.
Juniperus flaccida.
Mesembryanthemums (all).
Olive.
Paulownia imperialis (all but one).
Physianthus albidiflorus.
Piptanthus.
Pittosporum.
Thuja Dooneyana.
Veronica picta (all).

DIED BACK, BUT RECOVERED SINCE.
Acacia dealbata.
Deciduous Cypress.

Humea.
Rosa Macartneyana.
Viburnum suspensum.

INJURED.

Azalea (various).
Benthamia fragifera (all, and some killed).
Cedrus Deodara.
Hydrangea.
Hydrangea japonica.
Liquidambar.
Rhododendrons (some).

UNINJURED.

Araucaria imbricata (all).
Camellia japonica.
Juniperus (various, except *flaccida*).
Phygelia capensis.
Pomegranate.
Rhododendron ponticum.
Thuja nepalensis.

Injury to trees was not generally registered, but *Pinus austriaca* suffered much more than *Pinaster*. *Pinus insignis* suffered from snow.—JOHN JOPE ROGERS.

* When writing the above, I was not aware that the *Rheum officinale*, and other species, are largely grown in England solely for their medical uses, and that very good Rhubarb is produced. But in THE GARDEN for July 7, I find a very interesting account of the growth of Rhubarb by Mr. Usher, near Banbury.—H. N. E.

HARDY FLOWERS IN LONDON GARDENS.

THE rains which we have lately had have greatly altered the appearance of gardens in and around London for the better, and some plants have become wonderfully improved; but no amount of fine weather can wholly obliterate the effects of the disastrous easterly winds and frosts experienced late in the spring. Lilies have suffered severely, especially the south European red Lilies, *Humboldti*, *Washingtonianum*, *superbum*, *canadense*, and the early flowering forms of *colchicum*. The later-flowering ones look well, and from them we may

Gilia liniflora.

safely expect a good display. The finest Lily at present in flower is *L. Szovitzianum*, which is one of the best of all Lilies; it grows from 4 ft. to 5 ft. in height, and bears from four to ten sweet-scented flowers on a stem, the colours varying from creamy-white to deep golden yellow; of these there are some thousands in flower in the north of London. *L. elegans* and its numerous varieties also afford a blaze of colour just now, some kinds having from three to five large

Godetia rubicunda.

Lilium Szovitzianum.

flowers on stems not more than 6 in. above the ground. *L. tenuifolium*, also in flower, is vivid scarlet; and *L. philadelphicum*, on a warm sunny border, is likewise in fine condition, as is also *L. Washingtonianum* and its purple variety. Most of the Californian section, indeed, will prove grand additions to our list of hardy plants, as they appear to grow almost anywhere, and they are not injured in the slightest by the late spring. *L. canadense*, which is very showy, varies considerably in colour; the most beautiful is the Californian variety called *parvum*. *L. longiflorum* and *L. Browni* are just opening; *L. excelsum* and *L. candidum* and its varieties are also

Slender Loosestrife (*Lythrum virgatum*).

Large Evening Primrose (*Oenothera grandiflora*).

Nolana atriplicifolia.

Calandrinia discolor.

Gilia tricolor.

Mountain Sheep Scabious (*Jasione montana*).

Phlomis Herba-venti.

Devil-in-a-bush (*Nigella damascena*).

Gilia laciniata.

Bird's-foot Stonecrop (*Sedum pulchellum*).

Royal Fern (*Osmunda regalis*, var.).

Common Banberry (*Actaea spicata*).

coming finely into flower. Of Martagons, the most beautiful is the white, and all the varieties of bulbiferum and croceum are likewise pretty. These constitute the best of this family now in bloom. English Irises still form an attractive group, and some of the late-flowering Ixias, especially *I. longiflora*, are in perfection in some of the London establishments. *Brodiaea coccinea*, a perfect gem, should be grown by every one; it has been in flower a month and is now as fresh as ever. *B. grandiflora*, *congesta*, and *capitata*, are likewise pretty, and the curious climbing *B. volubilis* is worthy the attention of all lovers of hardy plants. *Alstroemerias* are just in perfection, as are also some of the *Bomarea*s; *B. oculata*, a handsome climbing plant, has dark olive-green foliage and numerous heads of deep crimson flowers. *Triteleia laxa*, and *Allium acuminatum*, are at their best; both are perfectly hardy and exceedingly ornamental. *Tropaeolum polyphyllum* is now a mass of golden-yellow—a lovely plant, and yet almost unknown; it succeeds in nearly any position, is easily propagated, quite hardy, and attractive from the moment it starts growing in spring until it has done flowering. *Sparaxis pulcherrima* is still showy, although now past its best. *Amaryllis longifolia* and the white variety are very conspicuous: their stately heads of long, tubular flowers entitle them to a place in every garden. *Freesia odorata*, and the variety *Leichtlini*, are just expanding in the open ground, but they are better adapted for pot culture indoors; as pot plants (six in a 5-in. pot) they are superb. In the bulb grounds there are at least thirty varieties of *Gladioli* now in full bloom, principally varieties of *G. ramosus*, *trimaculatus*, *Colvilli*, and *sagittalis*; among the best may be mentioned *G. Colvilli* var. *The Bride*, pure white, a most useful plant for cutting from; *Queen Victoria*, *Princess Mathilde*, *insignis*, *Lavinia*, *Little Beauty*, *emicans*, and *Rosa mundi*, are also beautiful and invaluable in a cut state. They will grow in any moderately light soil, and may be allowed to remain undisturbed for years. Among perennials, *Cypripedium spectabile* is now in perfection, some of the strongest plants bearing three and even four flowers. For this *Lady-slipper Orchis foliosa* makes a good companion, both growing freely in peaty soil in a quiet shady nook. *Phlox ovata* makes a fine deep rose-coloured border plant about 1 ft. or so high. *Onosma tauricum* (deep yellow) and *O. echioides* (creamy white and very fragrant) are also two good plants for the front row of a herbaceous border. *Symphyantra Wanneri*, a charming little Alpine closely allied to the *Campanula*, forms a pyramid of purple flowers; *Lysimachia lupinoides*, a Japanese species, I believe, and probably not very hardy, bears abundance of white flowers; and among the *Campanulas* the most noteworthy are the varieties of *C. turbinata*, *pusilla*, *pumila*, *garganica*, *muralis*, *carpatica*, *lactiflora*, and numerous forms of the old Peach-leaved Bell-flower *C. persicifolia*. *Actaea racemosa* is a stout-growing border plant which bears drooping spikes of white flowers. *Spiraea Aruncus*, when furnished with feathery plumes of white flowers, is a good plant for the margins of shrubby borders. *Wyethia amzonica* is a showy Californian Composite, which bears bright yellow flowers 4 in. in diameter; and *Linum viscosum* is one of the best perennial Flaxes, and is easily grown. The Cape Forget-me-not (*Anchusa capensis*) although not hardy is well worth growing, treated as an annual; its flowers are deep gentian blue, and they last until late in the autumn; *Edraianthus dalmaticus*, with numerous purple flowers and a dwarf prostrate habit, is at present very attractive; and *Sedum pulchellum*, one of the most beautiful of the Stonecrops, is very floriferous on rock-work, the flowers being of a light rose colour. A. P.

The Australian Pitbury.—Baron Mueller has given, in an Australian medical journal, an account of his examination of the leaves of the Pitbury, said to be of marvellous power as a stimulant, and to be found growing in desert acacias from the Darling River and Barcoo to West Australia. He is of opinion that it is derived from the *Duboisia Hopwoodii*, described by him in 1861, the leaves of which are chewed by the natives of Central Australia to invigorate themselves during long foot journeys through deserts. The blacks, he says, use the *Duboisia* to excite their courage in warfare; a large dose infuriates them. The "Sydney Herald" is informed also that some dry leaves and small stems, said to come from far beyond the Barcoo country, and called "pitchevine," are used by the aboriginals as we use Tobacco, for both chewing and smoking, and it is stated that a small quantity causes agreeable exhilaration, prolonged use resulting in intense excitement.

HISTORY OF THE JERUSALEM ARTICHOKE.

By J. H. TRUMBULL AND ASA GRAY.

LINNEUS, in "Species Plantarum," gave to the Jerusalem Artichoke (*Helianthus tuberosus*) the habitat in Brasilia. In his earlier "Hortus Cliffertianus" the habitat assigned was Canada. M. Alphonse De Candolle, in his "Géographie Botanique," ii., 824 (1855), refers to this as "decidedly an error, at least as to Canada properly so called," assigns good reasons for the opinion that it did not come from Brazil, nor from Peru (to which the name under which it appeared in cultivation in the Farnese garden seemed to refer), but in all probability from Mexico or the United States. He adds that Humboldt did not meet with it in any of the Spanish colonies. About this time I received from my friend and correspondent, the late Dr. Short, of Kentucky, some long and narrow tubers of *Helianthus doricoides*, with the statement that he and some of the neighbours found them good food for hogs, and, if I rightly remember, had planted them for that purpose. They were planted in the Cambridge Botanic Garden; after two or three years it was found that some of the tubers produced were thicker and shorter; some of these were cooked along with Jerusalem Artichokes, and found to resemble them in flavour, although coarser. Consequently, in the second edition of my "Manual of the Botany of the Northern United States" (1856), it is stated that *H. doricoides* is most probably the original of *H. tuberosus*. This opinion was strengthened year after year by the behaviour of the tubers, and by the close similarity of the herbage and flowers of the two plants, as they grew side by side; indeed, as the two patches were allowed to run together in a waste or neglected place, they have become in a measure confounded. Wishing to obtain an unmixed stock, I applied last autumn to Prof. J. M. Coulter, of Hanover, Indiana, and received from him a good number of tubers from wild plants of the neighbourhood, which will now be grown. Some of these were slender, some thicker and shorter, and a few were to all appearance identical with Jerusalem Artichokes. If they were really all from one stock, as there is reason to believe, the question of the origin of *Helianthus tuberosus* is well-nigh settled. We were now interested to know whether our Indians—at least these of the Mississippi Valley, where *H. doricoides* belongs—were known to cultivate these tubers or to use them for food. Recently a note in the "American Agriculturist" called attention to a sentence in Dr. Palfrey's History of New England, i., 27, stating that the Indians of that region raised, among other articles of food, "a species of Sunflower, whose esculent tuberosus root resembled the Artichoke in taste." The venerable historian found himself at the moment unable to refer me to the sources of this statement; but, as it was now certain that some record of the kind existed, I applied to Mr. Trumbull, who obligingly and promptly supplied the information required, and placed it at my disposal in the following letter:—

Hartford, Conn., March 26, 1877.

MY DEAR PROF. GRAY:—I cannot refer you to the authority for Dr. Palfrey's statement that the Indians of New England cultivated "a species of Sunflower whose esculent tuberosus root resembled the Artichoke in taste," but there can be, I think, little doubt of the fact. The historical evidence that "artischoki sub terra" were cultivated in Canada and in some parts of New England before the coming of Europeans, is tolerably clear. The only question, if there be any, is as to species, and this does not appear to have been raised for more than half a century after the Jerusalem Artichoke was known to English and Continental botanists. I can discover no authority whatever, before 1700, for ascribing to the *Helianthus tuberosus* either a Brazilian or a Mexican origin, except—and the exception is unimportant—in C. Bauhin's identification (in his "Pinax," 277) with *Helianthemum indicum tuberosum* (*H. tuberosus*), of a plant that he had described in his earlier "Prodromus" (ed. 1671, p. 70) as *Chrysanthemon latifolium Brasilianum*, from a dry specimen sent to him "eo nomine" from the garden of Contarini. The first trace I find of this species in Europe, is in the second part (cap. 6) of Fabio Colonna's "Ephrasia minus cognitarum stirpium," published at Rome in 1616. He described it from a plant growing in the garden of Cardinal Farnese. The Sunflower was already well known to European botanists, and had been described and figured by Dodoeus (1563) and Lobel (1576) as *Chrysanthemon peruvianum* and *Flos solis peruvianus*. With reference to these descriptions, probably Colonna gave the new species the name of *Aster peruanus tuberosa radice*, otherwise *Solis flos Farnesianus*. (He gave a more particular description of the plant in his annotations to Recchi's Hernandez, Plant. Mexic. Hist., 1651, pp. 878, 881, as *Peruanus Solis flos ex Indiis tuberosus*). The author of the "Descriptio variorum plantarum, in Horto Farnesiano," published under the name of Tobias Aldinus (Rome, 1625), gave some account of the roots, which he calls *Tubera indica*, of the "*Solis Flos tuberosus, seu Flos Farnesianus Fabii Columnæ*" (p. 91). It

may be observed that several of the rarer plants in the Farnese garden at this time were from Canada and Virginia. The Passion-flower (admirably figured by Aldinus) is described under its Virginian name, Maracot (the Maracocks of John Smith and Strachey); and a *Campanula americana* is otherwise named *Campanula virginiana*, seu ex Virginia insulis. C. Bauhin, in his "Pinax" (first published in 1623), ed. 1671, p. 276, notes that the *Helianthemum indicum tuberosum* is called *Chrysanthomum à Canada*, quibusdam. Canada et Artischoki sub terrâ, aliis. Gigantea, Burgundia. P. Laurenberg, Appar. Plant. (Rostock, 1632), names the species *Adenes canadensis* or *Flos solis glandulosus*. Ant. Vallot, "Hortus Regis Paris," 1665 (as cited by Bauhin) gives the names Canada and Artischoki sub terrâ, and Canadas, and describes also *Helemum canadense altissimum*, Vosacan dictum, which Tournefort distinguishes as *Corona Solis rapunculæ radice* (Inst. Herb., 490), and which became *H. strumosus*. Vosacan, by the way, is a French fashion of writing the Algonkin word *wassakone* or *wassakwan*, which means a "bright yellow flower." The modern Chippeways give this name to the flowers of the Pumpkin and Squash. Under whatever name the Jerusalem Artichoke was described, there seems to have been a general agreement among European botanists that it came from Canada. F. Schnyl, Catal. Horti Lugd. Bat. (Heidelberg, 1672), varies the specific name to *Chrysanthemum canadense arumsum*. P. Amman, Charac. Plant. Nat. (1676), has *Helemum canadense*. It was introduced to England about 1617. In that year, Mr. John Goodyer, of Maple Durham, Hampshire, "received two roots thereof from Mr. Franquerville, of London," which were planted and enabled him, before 1621, to "store Hampshire." He wrote an account of the plant, under date of October 17, 1621, for T. Johnson—who printed it in his edition of Gerard, 1636 (p. 753). Before this species had been figured and described by J. Parkinson, in "Paradisus Terrestris" (London, 1629), as *Battatas de Canada*, and in his "Theater of Plants," 1640 (p. 1383) he has the figure—a good one—without the description, under the names *Battatas de Canada*, the French *Battatas*, or Jerusalem Artichoke. Johnson in Gerard (p. 753), refers to Parkinson's description, and gives the name as *Flos Solis pyramidalis*, Jerusalem Artichoke. It already grew well and plentifully in many parts of England.

The notices by early voyagers, of Ground-nuts eaten by the Indians, are generally so brief and so vague, that it is not easy to distinguish the three or four species mentioned under that name or its equivalents. The *Solanum tuberosum*, *Apios tuberosa*, *Aralia trifolia*, and a *Cyperus* (*articularis*?) were all Ground-nuts, or Earth-nuts. We find, however, in a few instances, unmistakable mention of the roots already known in Europe as Canadian. Brereton, in his account of Gosnold's voyage to New England in 1602, notes the "great store of Ground-nuts found on all the Elizabeth Islands." They grow "forty together on a string, some of them being as large as a hen's egg" (Purchas, iv., 1651). These doubtless were the roots of *Apios tuberosa*; but when Champlain, a few years later (1605-06) was in the same region, he very frequently observed that the Algonquian Indians near Point Mallebarre (Nauaset Harbour, probably), had "force des racines qu'ils cultivent, lesquelles ont le goût d'artichaut" (Voyages, ed. 1632, p. 84). And it is to these roots, evidently, that Lescarbot alludes in "Histoire de la Nouv. France," 1612 (p. 840): Here is in the country of the Armouchiquois, (*i. e.*, New England, west and south of Maine,) a certain kind of roots "grosses comme naveaux, très excellentes à manger, ayans un goût retirant aux cardes, mais plus agréable, lesquelles plantées multiplient en telle façon que c'est merveille;" and he thinks these must be the *Afroditides* described by Pliny. Sagard-Theodat, Hist. du Canada, p. 785 (1636), mentions the cultivation of the Sunflower by the Hurons—who extracted oil from its seeds—and names also the "roots that we [the French] call Canadiennes or Pommes de Canada, and that the Hurons call Orasqueinta, which are not very common in their country. They eat them raw, as well as cooked, as they eat another sort of root resembling Parsnip [*Sium lineare*?], which they call Sondhratates and which are much better; but they seldom gave us these, and only when they received some present from us or when we visited them in their cabins." He goes on to speak of "patates, fort grosses et très excellentes," some of which he had obtained from an English vessel captured by the French; but none of these were to be found in the Huron country, nor could the Indians tell him the name of them; and he regretted that he had not brought some with him for planting, since "this root, being cut in pieces and planted, quickly grows and multiplies, it is said, like the pommes de Canada" (pp. 781, 782). It is plain that the Huron roots first mentioned were, or that Sagard believed them to be, Jerusalem Artichokes—already known as Canadian. I find no mention of the Artichoke in Virginia, or the Southern Colonies, before it was cultivated by Anglo-Americans. The author of "A Perfect Description of Virginia," printed in 1649,

says that the English planters have (*inter alia*) "roots of several kinds, Potatoes, Sparagne, Carrots, . . . and Hartichokes." Beverly, ("Hist. of Virginia," 1722, p. 254), mentions *Batatas Canadensis*, or Jerusalem Artichoke, as planted by some of the English, for brewing beer. Yet the name of one of the esculent roots mentioned by Hariot ("Brief and True Report," &c., 1585) ought to belong to some species of Sunflower—and if to any, to *H. tuberosus*. Hariot names three tuberous roots found in Virginia:—"Openank, a kind of roots of round form, some of the bignes of Walnuts, some far greater, which are found in moist and marish grounds growing many together one by another in ropes, or as though they were fastened with a string. Being boiled or sodden, they are very good meate." [C. Bauhin ("Prodromus," 89) identifies these with *Solanum tuberosum esculentum*—and has been followed by later writers. The description seems to me to indicate *Apios tuberosa*.] "Kaishucpenauk, a white kind of roots about the bignes of hen eggs and nere of that forme: their taste was not so good to our seeming as of the other, and therefore their place and manner of growing not so much cared for by vs; the inhabitants notwithstanding used to boile and eat many." These may be Virginia Potatoes, but their name, if Hariot recorded it correctly, means Sun-tubers. The etymology is perfectly clear. The other roots described by Hariot, Okepenank are also of round shape, found in dry grounds: some are of the bignes of a man's head," &c. These must be the *Tubera terræ maxima*, of Clayton, *vulgo* Tuckahoo, which Gronovius (Fl. Virgin., 205) refers to *Lycoperdon solidum*, and for which Rafinesque (Med. Pl. ii., 270) proposed a new genus, *Tucahus*. Kalm describes them ("Travels," i., 225) as Truffles. Fries (El. Fung. ii., 39) assigns them to his *Pachyma Cocos*.

Writing in haste and with frequent interruptions, it has been possible to do little more than copy, without condensing or arranging, such notes as I had before me. They have extended to such a length that I must not add even an apology for the superfluous matter.

J. H. TRUMBULL.

It would be interesting to know whence came the French name of these *Helianthus* tubers, *Topinambour*, it being the only thing in the case which, as Mr. Trumbull remarks, "looks to a Brazilian origin, as it seems to be derived (and so Littré gives it) from the *Topinamboux* Indians of Brazil." The English name Jerusalem Artichoke, comes, as is well known, from the Italian *Girasola*, *i. e.*, Sunflower. As to the annual Sunflower, or *Helianthus annuus*, said by Linnæus to come from Peru and Mexico, I have for some years been convinced that its original is the *H. lenticularis* of Douglas, which again is probably only a larger form of *H. petiolaris* of Nuttall, natives of the western part of the Mississippi Valley and of the plains to and beyond the Rocky Mountains. It is an interesting confirmation of this opinion, that Sagard (as mentioned in the above communication) and Champlain found this Sunflower in cultivation by the Huron Indians, for the sake of the oil of its seeds, which they used for hair oil.—"American Journal of Science and Art."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Early Victoria Peach.—This appears to be a capital variety for early forcing, and not so commonly met with as its merits deserve. It is a good average-sized Peach, of excellent flavour, and a capital cropper, and it has a hardy constitution. I have a tree which has produced very heavy crops of fine fruit during the past four seasons without showing any signs of weakness, &c. The house in which it is growing has never been forced before this season, and yet the fruit was ripe on Early Victoria on June 12, quite three weeks before the other tree in the same house, which is a Bellegarde.—H. I. C.

Vines and Potash.—As the result of some experiments made by M. Andoynaud, Professor in the School of Agriculture of Montpellier, on the influence of manures containing potash on the growth of the Vine, recorded in the "Annales Agronomiques," it is stated (1) that sulphate of potash and chloride of potassium have a marked influence on the development of the Vine, and nitrate of potash still more so, while carbonate of potash is less efficient. 2. That weak plants of Vines appear to appropriate as much manure as strong ones. 3. An excess of nitrogenous manure is more hurtful than useful. 4. Potash should enter into the composition of manures for the Vine, that which exists already in the soil being usually not in a fit condition to be readily absorbed. The absorption of the potash seems to be associated with that of the other fertilizing principles. 5. The potash from the root passes to the stem, to the leaves, then to the shoots, and ultimately to the fruit. 6. Only a part of the potash taken up by the root is used up, since after the ripening of the fruit a considerable reserve store is found in the wood. It will be seen that M. Andoynaud's researches are quite in conformity with the plan advocated by Mr. Wildsmith of employing wood ashes as a manure for Vine borders.—"Gardeners' Chronicle."

Old Bird-cherry Tree.—The following are the dimensions of an old Bird-cherry tree (*Prunus Padus*) growing in Eccleshall churchyard. Close to the ground its circumference is 3 ft. at 1 ft. up, 2 ft. 6 in.; at 4 ft. up, 2 ft. 5 in.; at 4 ft. it branches into two parts, the diameter of the branches when in bloom is 28 ft., and the height 26 ft. I cannot form any idea of its age, but an old person of thirty-five years' residence says it seems to have altered but little during that time: there was another tree of similar size, but it was blown down a few years ago.—T. L. BAILY, *Holt House, Abbeydale, Sheffield.*

TREES AND SHRUBS.

THE SILVER FIR.

(PICEA PECTINATA).

THIS Fir, which is a native of Central Europe, Asia, and other temperate regions, was introduced into this country as far back as 1603. Its leaves are dark, glossy above and silvery beneath, and the branches grow in regular whorls round the stem, which is erect and not very tapering. The cones, in contradistinction to those of the Spruce Fir, are upright, while the

cones of the latter are pendent and hang on the tree for a longer period. The Silver Fir is, I believe, up to the present time, the loftiest-growing Conifer which we have in Britain. It is a majestic tree either singly or in a clump, and when planted sufficiently apart to allow its branches full development, it becomes feathered to the ground. Its habit is symmetrical, pyramidal, and very formal, particularly when young; when old it presents a greater variety of form and exhibits many picturesque features. The liability of this tree when young to start into growth very early in spring and lose its leading shoots from the effects of frost, has often proved disappointing to nurserymen and planters; probably on this account it has not been so extensively planted as the Larch and the Scotch and Spruce Firs, neither has it ever been so cheap and plentiful in the market as the two latter, owing no doubt to its being so difficult to rear when young; when older and fairly established in its permanent quarters it will withstand the severest winters and will thrive on the most exposed sites. In many localities it is a tree but seldom seen, indeed, in some parts of the country

it will not succeed, and again in others it is the most prominent tree, towering high above its compeers and breaking the level outline of wooded hills. The timber of this tree is less valuable than the Larch; under ordinary circumstances it sells at about the same price as the Scotch and Spruce Firs, and is used for similar purposes. A few years ago its timber was in some request for making suites of bedroom furniture, but I do not think it is now in so much demand, apparently having been superseded by the Pitch Pine for that

purpose. The Silver Fir thrives well on a variety of soils and subsoils; where lime and chalk abound, perhaps it succeeds the worst, but as a rule it flourishes best in rich loams and clays. At Longleat there are some remarkable noble clumps of this tree growing on directly opposite conditions of soils. The oldest and tallest specimens (probably the largest in England) are growing in a clump in the park; the soil in which they are growing is a rich hazel loam and Kimmeridge clay subsoil; the clump consists of nine trees, and they vary from 105 ft. to 141 ft. high, and girth at 5 ft. above the ground from 10 ft. to 15 ft. 2 in.; they are quite matured, indeed, some

of them are becoming decayed, and one or two have withered tops and a great many dead branches. I am unable to give the contents, as it would be dangerous to attempt to climb up amongst the decayed limbs; it is said the highest tree in the clump (its top is now dead and some portion of it broken off) was 150 ft. high about twenty years ago. The clump stands in an open, exposed situation on an elevated level piece of ground on the confines of the grove; it forms an apex to the latter famous collection of fine old timber, and stands out in bold relief as a landmark so far as the eye can reach from prominent heights in the surrounding country. Viewing this clump, too, in the evening at sunset with a brilliant and various coloured horizon as a background, it presents a pleasing feature in the landscape, the withered and broken tops add picturesque touches to the clump. Another clump of magnificent trees is growing in an Oak coppice adjoining the park; the soil is a stiff loam on the Oxford clay. Six of the largest trees in this clump measure from 116 ft. to 129 ft. high, and girth at 5 ft. up from 13 ft. to 15 ft.: at 30 ft. up they girth from 10 ft. 7 in. to

12 ft. 3 in.; and at 60 ft. up girth from 7 ft. 3 in. to 8 ft. 5 in. The average cubical contents of six trees is 465 ft.; the largest tree contains 517 ft. The whole of these trees are beautiful, healthy specimens, full of vigour and growth, and are branched quite near the ground. The next clump I will mention is growing in a thin poor soil on the greensand, it was planted probably about the same time as the last-mentioned clump. Twenty of the largest trees in this clump measure from 95 ft. to 114 ft. high, they girth at 5 ft. up from 9 ft. 10 in. to 14 ft.

Masson's Silver Fir (*Picea pectinata* Massoni).(a) Branch of *P. pectinata*. (b) Branch of *P. pectinata* Massoni.

3 in., and the contents of each tree vary from 240 ft. to 345 ft. These are all healthy trees and well furnished with branches near to the ground, forming a large, bold, and effective clump, situated on the verge of an open valley with hanging woods on either side, and when viewed from the summit of hills in the vicinity, form a striking feature in this wild ornamental portion of the estate. At Strathfieldsaye there are some fine specimens of the Silver Fir upwards of 140 ft. high, and girthing at 5 ft. up from 11 ft. to 13 ft. 6 in. At Springkell, in Dumfriesshire, there are also some remarkable Silver Firs, twelve of the largest trees measure from 80 ft. to 115 ft. high, and girth at 5 ft. up from 10 ft. 8 in. to 13 ft. 9 in.; their cubical contents vary from 180 ft. to 520 ft. In many other parts of Britain fine specimens may be seen, but I hardly think there are any to be found that will exceed the measurements of those I have given. Although the Silver Fir cannot be classed amongst the most useful and profitable timber trees, it is, however, one of the quickest and tallest-growing Conifers for giving shelter and ornamental effect. It is a most valuable tree for game cover—in fact, I do not know a better tree to plant for filling up blanks in old woods for game shelter, thriving so well as it does in the densest shade, and close under the drip of overhanging trees.

Loughead.

GEORGE BERRY.

EXCRESCENCES ON TREE TRUNKS.

MR. THOMAS MEEHAN stated that on many trees were peculiar excrescences, which, up to a few years ago, had been referred primarily to insect origin. Cutting these through lengthwise there was no appearance of this agency. There were layers of wood of annual growth, just as in the normal parts of the tree. Examining some Oak knots of this character, and finding pulverulent fungoid matter abundant on the surface, he said he had introduced some of these to the Academy a few years ago, and suggested this as a substitute for the insect theory; but subsequently Professor Farlow had kindly examined them critically and found no trace whatever of fungoid matter in their structure. This left us wholly in the dark as to the exact origin of these structures. It was worth noting that these excrescences were often of a uniform character in each species of tree. In many cases, no matter how large or how old they were, they would separate from the parent stem easily by a short sudden blow. He had made collections of these and in most cases found great uniformity. In *Quercus obtusiloba* they were depressed globose; in *Fagus sylvatica* (American Beech) they were convex and oval, with the narrow ends crosswise with the trunk; in the *Acer rubrum* (Red Maple) they were oval, but drawn out lengthwise; in the common Weeping Willow they varied very much in size, sometimes being as large as a bushel measure, but always knocking out easily as in all named before; in the common Cherry (*Cerasus Avium*) and the Paper Mulberry (*Broussonetia papyrifera*) the excrescences were also very irregular in form, and seemed to have a stronger attachment to the parent stem than the others. The Apple had very small and numerous ones in some species; and it was from an examination of these, he said, that he had derived the key to the whole subject. On the bark of some kinds of Apple trees numerous small Pea-like projections would exist on the bark within a space of a few inches. On cutting open, these were found to be not vesicular, but to be filled with hard and perfect wood. A careful examination showed that these woody masses took their rise seemingly from the liber, to which, in the newly formed cases, they would be found still attached by a small thread-like vessel. In order to understand the formation, it was necessary to understand

How Wood is made.

In many trees the annual layer was so regular, and seemed to be placed so nicely, that one not a botanist might be pardoned for believing that the sap was changed to wood matter in the leaves, and the new formed matter sent down, sliding over the old layer like the sections of a telescope; but though the food was prepared by the leaves in a great measure, the actual growth was made by the germination of some of the cells along the whole outside wall of last year's wood beneath the

inner bark. In his own observations of this process he had taken the common Cherry for his experiments. The germination of the cells takes place here about the middle of June. He takes a healthy Cherry tree and strips it entirely of its bark to any length desired. At that season a viscid liquid will be found covering the woody surface in abundance. The stripped part is covered with a cloth to prevent evaporation, and in a few days numerous dots, like needle points, will be seen about the sixteenth of an inch apart all over the surface. These are the young cells which have germinated from those of last year. They continue germinating, one from the other, until they meet, when they unite and form a complete surface. In the autumn a layer of wood will be found just as thick as in the part of the tree not disbarked, and a single layer of liber, with its outer coat of cellular matter—perfect bark—will have been formed over the whole. The entire formation of wood and bark can thus be seen by the ordinary observer, without the necessity of any nice microscopical work. Other people have tried the experiment with other trees. He has seen large Apple trees that have had their bark peeled wholly off from their trunks, at the season named, make an entire new layer of bark and wood, not only with no injury to the tree, but to its manifest enjoyment; but his own experiments were confined exclusively to the Cherry. By this experiment we learn that there is no difference primarily in any part of the annual covering. The same cell may become permanent tissue or generating tissue—and from the generative tissue may come before the season of growth closes every form of structure known to anatomists, from pure wood to the outermost cuticle of the bark. How these cells become differentiated may be passed over here. We know that cell-growth is not always uniform in its operations. The law that changes the outermost series of newly made cells into liber need not necessarily operate so exactly as to make them perfect to this end—a few may be thrown off into the liber as generative tissue—and, granting this possibility, we see how the woody granules in the Apple bark are formed. How cells usually of one character may be made to assume others is shown in the

Formation of Adventitious Buds.

Sachs ("Text Book," Eng. ed., p. 563) thinks that few dicotyledons produce adventitious buds. The shoots that often spring from the bark of the older stems of trees, he says, are probably from dormant buds which have retained vitality, though buried from the first growth of the stem. This sort of growth is true. In *Gymnocladus* the buds formed the first year in the axil of the leaves are in a linear series of three or more, of which but one is generally seen above the surface; but after many years, if the bark be gently shaved, these will be found just beneath the surface as they were the first year, having kept along their hidden growth all that time. In some *Magnolias* (*M. acuminata* and *M. tripetala*), besides the axillary bud, one forms exactly horizontal to it, on the side opposite to the direction of the spiral growth. This bud is rarely seen above the surface, and has not been before made known to botanists, as I believe, but may always be found beneath the surface of the stronger shoots when the bark is gently shaved, no matter how great may be the age, unless, as sometimes happens, some accident should favour its development to a perfect branch. These are the sort of buds referred to by Prof. Sachs, and of course make up their share of new branches when time comes to favour them. He knew of no dicotyledonous tree that could not be made to throw out numerous adventitious buds from any part of its surface by sawing off. In our common street Maples this was everyday experience. A few inches below the cut generally died back from evaporation of the juices; but when the shoots pushed out they came by the dozen in the space of a few inches. Now in the original shoot—the first year's growth—there would be found in a vigorous specimen seldom more than six buds in a length of 6 in.; but in a strong six-year-old branch of Maple (*Acer dasycarpum*) cut back he had seen as many as fifty shoots in that space. He exhibited a one-year shoot of *Catalpa*, where the normal buds were 10 in. from each other. In old branches cut back in early winter, so that the surface may harden a little before spring, and thus the tree lose little of its juices by

evaporation, shoots will come out numerously from any part of the foot space between these original buds. It was interesting, however, to note that in no case that he knew of would adventitious buds be produced between the nodes from a one-year-old branch. Such a branch cut beneath the node invariably died to the next. It would seem as if the demand on the nutritive powers of the plants for the axial elongation had left the generative tissue with less power than in subsequent years they may possess. How cells which under some circumstances become permanent tissue, or at best generative tissue, may become the parents of adventitious buds and shoots was well shown in cutting down Horse Chestnuts, some Poplars, and some Birches. As before said, during the season following the first year, no adventitious buds will form between the nodes, when the branch is shortened; but in the older trees, the new cells from the generative tissue all along the exposed part or surface of the stump form adventitious buds and branches. The whole circle between last year's wood and the bark produces a forest of branches. He had seen this also, he said, in cotedledons and other succulents under greenhouse culture. From these considerations there was no reason why cells, predestined, under ordinary circumstances, to be merely bark cells in their change from wood cells, should not occasionally retain enough of growth force to carry on a feeble wood-constructing system of their own. We thus come naturally to the

Origin of Woody Excrecences.

Imperfectly formed liber cells, still retaining their generative power, would make a growth the next season, forming a layer of wood, and making its own cortical layer simultaneously with the normal wood growth of the tree, assimilating from the same store of reserve material that the normal growth does. The proof of all this lies in the cutting through longitudinally of one of these excrecences when it will be found to have made one more annual layer from the point of its origin than the tree itself, showing that the origin dated from a double set of germinating cells in that one year. Where, as in the Weeping Willow and Cherry, the excrecences are protruded much beyond the normal diameter of the tree, the annual layers of wood are on the average thicker, through having assimilated a greater share of food, as is generally the case with cells situated above an obstruction; for instance, as when a wire fastened around a branch, a ring of bark taken off, or other means employed to interfere with the connection between root and foliage. Mr. Meehan further said that explanation of growth in connection with these excrecences, explained also much that was usually inexplicable in the various eccentricities of growth. He exhibited a specimen of a trunk of a *Bauhinia*, presented to the Academy by the Brazilian Centennial Commission, in which the wood seemed a mere fasciculus of many separate stems, forming a sort of ligneous mosaic work. The trunk was about 6 in. in one direction and two in the other. The first year's growth round the small pith was circular; the subsequent ones irregular, through the varying powers of growth in the germinating tissue. Very often, but a very small section of the previous year's circle of wood would germinate, in which case the whole growth would be made from that point pressing round and over with great luxuriance, and enveloping the bark as well as wood of the previous year. Mr. Meehan thought it quite likely that the cases of *Wistaria* with bark between some of the annual layers of wood, might be explained in a similar way. M. Licopoli, of Naples, has suggested that the appearance of bark mixed with the wood of *Wistaria* is due to the formation of woody matter by the bark, which wood then continues to grow, and leaves the bark, as it were, behind the wood, instead of being pushed steadily before, as in normal wood growth. Although sure that my facts were as I detailed them, it is pleasant to have the confirmation of my views of these abnormal wood growths in this independent way. The subject of the

Eccentricity of the Annual Layers of Wood in Trees

could also be understood, keeping in mind the generating tissue, and its varying powers of life and transformation. Anything which favoured nutrition in one part of the mass of cells more than in another, would increase their power of

growth, and induce thicker layers at that point than in others. A very hot sun on one side, or in one season on one side, or on particular spots on one side, inducing an inordinate evaporation from those parts, would weaken the vital power of the cell just there. The germination would be weak, and the woody layer thin. Cold winds on one side in very cold weather would have the same effect in some cases. The continual blowing of trees always in one direction might favour assimilation by the cells on one side more than on the other, or even the closer proximity of some cells to healthy foliage or vigorous roots, would give them a greater advantage over others, and the layer would thicken. In some plants there was pretty equally divided power. The whole mass of tissue seemed equally and regularly vitalized, and the generative tissue formed a new layer of wood of about equal thickness all round. But in other trees some masses of cells seemed to easily draw from the others more than their share, and the latter were correspondingly weakened. This was beautifully illustrated in the Hornbeam (*Carpinus americana*). Here the irregularities in the thickness of the annual layers defied all system. They might be very thick at one point, and yet an inch or two above or below the same layer, be very thin. The Red Cedar (*Juniperus virginiana*) exhibited similar characters, except that the loss of generative power in some of the cells was more uniformly in a direction lengthwise with the stem. In a section he had recently examined the annual layers were tolerably regular for fifteen years. A young tree of the same species had then grown up close to it on one side, and the annual layers became thinner, finally ceasing there. The other sides grew on as before, the layers tapering, with the weakened vitality, to where the tissue was wholly at rest. So in various parts of the outline could be noted the time when various parts of the generative tissue lost vital power. In one part of the section, in a direct line from the centre, there was a continuous and nearly regular annual layer for over fifty years; but, in many directions, by counting the rings or layers, the time could be traced when the tissue ceased to be generative or nearly so, fifteen, eighteen, twenty-eight, and so on. All the cases of peculiar eccentricities, *Hedera*, *Toxicodendron*, *Ampelopsis*, and the peculiar cases of ordinary timber trees, could be explained by this, so far as to note that the immediate law was a loss of generative power in the cells of the annual layer. Of course, the indirect causes leading to this would be very numerous, and left room for much more investigation. The remarks were made as much as possible in language divested of botanical technicalities for the benefit of those interested in the many other branches of science present; but those who would pursue the subject of wood growth, as described here and applied to the explanation of excrecences and eccentricities, are referred to Sachs's "Text Book of Botany." Mr. Martindale inquired if Mr. Meehan had noted the square growth of a Coniferous trunk from the Pacific coast, on exhibition at the recent Centennial, and if that growth could be accounted for on his explanations? Mr. Meehan replied that he had examined that trunk. It was square only at the lower end. It was of *Picea amabilis*. At the four corners the annual layers were thicker than at the sides. He had no doubt that in that case, and in similar ones if repeated, four strong roots had grown out at nearly equal distances, and the mass of cells nearest to these roots had an advantage in nutrition. We saw this in the trees of our own forests. Just in proportion to the vigour of the roots below was the thickness and irregularity of the trunk for a considerable distance above. If these trees had but four main roots of equal strength at equal distances, a portion of the trunk would be about square. Mr. J. H. Redfield inquired whether Mr. Meehan would class Cypress knees among the excrecences he had described? Mr. Meehan replied: No, as they were an outgrowth from the normal woody system of the roots of the tree, while the excrecences originated in the liber, or the tissue very closely allied thereto.—"Proceedings of the Philadelphia Academy of Sciences."

Philesia buxifolia.—A handsome plant of this is now blooming freely in M. De Smet's nursery at Ghent. Its flowers resemble those of the *Lapageria* in substance and colour, but are smaller. M. De Smet informs me that it flowers from June till August, and lasts for three weeks in great perfection.—F. H.

GARDEN PLAN.

THE plan published at p. 508, Vol. XI., and there attributed to M. André, was not designed by that gentleman, but by one of the pupils of the late M. Barillet. We have now the pleasure of publishing a plan of a small garden by M. André, which can hardly fail to interest those forming small gardens. It is a small rectangular place at Neuilly, simply designed and agreeably undulated. After (A) the house, (B) the summer-house, (C) gymnasium, and (D) seat in shade, the first interesting reference is (E) a circular place on top of a mound, with rocks disposed in a picturesque manner, and treated according to the style of the calcareous stratification; in the centre is a table, with garden seats. From this point three views are obtainable, one to the house, the second to the summer-pavilion (B), the third to the principal entrance (I). Some Weeping Willows afford a shade to the spot, and the rocks, abruptly disposed above the water, are intermixed with Alpine and rock plants. (F) Two rustic bridges; (G) source of the stream, which disappears under

Castilleja indivisa.—The genus *Castilleja* is probably but little known to the present generation of horticulturists, though to many of the older ones the name at least of *C. coccinea*, a species that was temporarily under cultivation about thirty-five years ago, may perhaps be familiar. The true explanation of its rarity in European gardens is probably due to the fact that most of the perennial species, at least, are root parasites, and their cultivation is therefore hopeless. There is, however, good reason to believe that the annual species are more amenable to treatment, and they are too ornamental to be relinquished without a fair trial. Their attractions are due, as in the case of some other interesting plants, less to the beauty of the flowers, properly so called, than to the highly-coloured bracts or floral leaves accompanying them, and in *C. indivisa* these bracts are of so bright a scarlet as to render the plant most effective. It grows from 1 ft. to 1½ ft. high, with stems sparingly branched and having deeply pinnatifid foliage, with linear acute lobes, the specific name *indivisa* having reference to the floral leaves or bracts, which are mostly entire. The flowers are arranged in a dense, terminal spike,

Plan of a Small Garden at Neuilly by E. André.

the ground at (D). Rocks covered with Alpine, climbing, and creeping herbaceous plants. (E) is raised about 10 ft. above the level of the surrounding walks. (H) Shady seat behind a deep belt of evergreens, forming the background of this part of the garden, and affording a quiet cover, with grateful shade. (I) Two principal entrances for carriages, with view of the rockery and the house. (J) Entrance to the kitchen garden. The whole ground is gradually undulating towards the central point occupied by the pond, which is about 3 ft. below the platform fronting the house. Both the lateral pavilions of this building are furnished outside with a bed of Rhododendrons. Several flower beds, all elliptic or circular, are placed on the verge of the Grass, and raised 1 ft. above the average level of the walk. The scattered trees are shown on the plan by a round mark; the stellate ones mean the Conifers or hardy and beautiful-foliaged plants. The plantations are planned on the mixed principle, deciduous and evergreens, standard trees and shrubs, flowering and foliated plants. The walls are well concealed in every direction.

the corolla being somewhat tubular, scarcely exceeding the calyx in length, and of a yellowish-white colour. Each flower is accompanied by a large ovate bract, the lower half of which is of an agreeable green colour, the rest of the leaf being of a brilliant red. It is to this feature that several of the species owe their popular name of Painted Cup. The seed should be treated like that of half-hardy annuals, sowing in a frame with gentle heat, and employing a light vegetable soil.—W. THOMPSON, Ipswich.

Wearied Plants.—"There go those wretched old plants again," said a young friend of mine the other day as we passed together by a house in which a ball was imminent; "I have seen those Palms everywhere for the last month, and as for that Pitcher-plant, I stuffed a cigarette into one of its jaws at Lady Y—'s and smoked that same at Lady Z—'s." It is certainly disenchanted to suspect that the very flowers in a London ball-room are undergoing a course of dissipation similar to that which fades the cheeks of human "wall-flowers." Roses and Geraniums should, at all events, be fresh, since unsullied bloom is their *raison d'être*.—"Truth."

SOCIETIES AND EXHIBITIONS.

WEST OF ENGLAND ROSE SHOW.

THE eleventh annual exhibition of the West of England Rose Show was held at Hereford, on July 6, and was a great success in spite of many drawbacks. The weather for some days previously was very unfavourable, and the day itself was rainy, to which must probably be attributed the fact that the attendance was far short of what might reasonably have been expected. The absence, too, of so many of the principal nurserymen and amateurs was to be regretted, Mr. Cant of the nurserymen, and Rev. R. G. Baker, Heavitree, of the amateurs, being the only representatives from a distance. But whatever the show lacked in quantity was quite atoned for in quality, being fully equal in that respect to the show at St. James's Hall, with the further advantage of a much better light. The schedule comprised a full and liberal list of prizes, beginning with Class A 1, nurserymen, open to the United Kingdom.—Here Messrs. Cranston and Co. had it all their own way with as splendid a lot of Roses as any one could desire, and were first with 72, 36 (three trusses), and 24. In form, colour, substance, and (of course) staging they left nothing to be desired, the most noticeable of their blooms, if selection could be made, being—Reynolds Hole, Lælia, Horace Vernet, Auguste Rigotard, Monsieur Boncenne, Victor Verdier, La Rosière, Abel Gaud, François Michelon, Louis Van Houtte, Marguerite de St. Amand, Duke of Edinburgh, Thomas Mills, Annie Wood, Mademoiselle Eugénie Verdier, Etienne Levet, Xavier Olibo, Maurice Bernardin, Madame Lacharme, Prince Camille de Rohan, Hardy Frères, Baroness Rothschild, Madame Charles Wood, Mademoiselle Marie Cointet, Rushton Ratcliff, Ferdinand de Lesseps, Madame Caillat, General Jacqueminot (maintaining well his old reputation throughout the show), Annie Laxton, Dr. Andry, Centifolia rosea, Duc de Wellington, Edward Morren, Sir Garnet Wolseley, and Belle Lyonnaise. In the 72 and 36 Messrs. Davison, the White Cross Nurseries, were a good second to Messrs. Cranston & Co., their best blooms, in addition to several of the above, being Marie Baumann, Mlle. Prosper Langier, Beauty of Thame (rather thin), Julie Tonvais, Mme. Haussmann, Marquise de Castellane, Countess of Oxford, Alexander, Leopold II., Black Prince, Duchesse d'Aoste, and Auguste Neumann. In 36, the third prize fell to Mr. Grove, Tapsley; and in 24, in which only two prizes were given, the second was awarded to Mr. Griffiths, Tillington, a special prize in this class being given to Mr. W. Lee, Lyonsball. In Class A 2, open to nurserymen not residing in Herefordshire, Mr. Cant was the only competitor, but well deserved the first prize of £20 awarded him for a glorious display of 72, chief among which may be mentioned—Madame Moreau, Abel Grand, Fisher Holmes, Capt. Christy, Monsieur E. Levet, Victor Verdier, Mrs. Baker, Marie Baumann, Exposition de Brie, Star of Waltham, Louis Van Houtte, Monsieur F. Michelon, Madlle. Marie Rady, Maurice Bernardin, Black Prince, Sir G. Wolseley, Alfred Colomb, Madame Hippolyte Jamin, Thomas Mills, Camille Bernardin, Horace Vernet, Monsieur Woolfield, Niphetos, Ferdinand de Lesseps, Auguste Neumann, and Madame M. Cole. In class B, amateurs, open to the United Kingdom, nothing could exceed the beauty of the collection shown by the Rev. R. G. Baker, Heavitree, Exeter, who was first for 36, 24, 18 (three trusses), and 12. He thus turned the tables on Mr. Jowitt, Old Weir, who beat him at St. James's Hall, winning Messrs. Cranston & Co.'s fifty-guinea Challenge Cup. The fifteen-guinea Challenge Cup given in this class by the same enterprising firm fell, of course, to Mr. Baker. Mr. Jowitt was a very close second to Mr. Baker in 36 and 24; Mr. J. H. Arkwright, Hampton Court, being third; and Rev. C. H. Bulmer, Credenhill, commended. In 18, the Rev. C. H. Bulmer was second; Mr. Arkwright, third. In 12, the Rev. C. H. Bulmer was again second; Mr. J. L. Wight, Tedstone Court, third. For twelve blooms, single trusses of the same Rose, Mr. Arkwright was first with a box of magnificent Maréchal Niel; Mr. Jowitt second, with Monsieur F. Michelon; and the Rev. R. G. Baker third, with Baroness Rothschild. In Class C, open to amateurs residing in Herefordshire, and not exhibiting in class B, the display all through was exceedingly good, especially the Roses of Miss Bulmer, Broadlands, near Hereford, who was easily first for 24, 12 (three trusses), and 12 (singles). In Class D, open to the United Kingdom, for a collection of twelve new Roses, sent out by English nurserymen in the spring of 1875, 1876, and 1877, Messrs. Cranston & Co. were first with Souvenir d'Arthur de Sansal, President Leon de St. Jean, Comtesse de Serenye, Avocat Duvivier, Duchess of Edinburgh (H.P.), Mousieur Alexis Lepere, Henry Bennett, La Rosière, Gustave Revilliod, Abel Carrière, Monsieur E. Y. Teas, and the Rev. J. B. M. Camm. Messrs. Davison & Co. were second, with Comtesse de Serenye, Madame Prosper Langier, La Rosière, Gustave Revilliod, Abel Carrière, Duchess de Valombrosa, Duc de Montpensier, Mrs. Baker, Jean Dalmais, Oxonian, Jean Ducher, and Hippolyte Jamin. For twelve trusses of any new Rose, sent out by English nurserymen in the spring of 1875, 1876, and 1877, Messrs. Cranston & Co. were first with Sir G. Wolseley; Messrs. Davison & Co. second, with Comtesse de Serenye; and Mr. Cant third, with Duchess de Valombrosa. For twelve trusses of Tea or Noisette Roses, Mr. Cant was first, Messrs. Davison & Co. second, and the Rev. C. H. Bulmer third. For twenty-four blooms of any one Rose, Messrs. Davison & Co. were first (François Michelon); Mr. Jowitt second (Marie Baumann); Messrs. (Cranston & Co. third (La France). For special prize, given by J. H. Arkwright, Esq., for twelve varieties carrying bloom and buds in various stages, after the manner of Rose portraits as sent out by growers, Messrs. Davison & Co. were the only competitors. Prizes were also given for dinner-table and drawing-room decorations, also for opera, bridal, and hand bouquets, and the displays in all cases were very beautiful.

A City Flower Show.—On Tuesday last an exhibition of window plants and flowers grown within the City was held in the small but pretty gardens of Finsbury Circus. Some hundreds of specimens were exhibited, and the prizes were divided into thirty classes of three prizes each, the majority being open to all except *bona fide* gardeners. Special prizes were given by the Royal Horticultural Society, by Mrs. Smee, and others. The flowers and plants exhibited included Pelargoniums, Fuchsias, Musk, Creeping Jenny, Ferns, Ivy, and Myrtle. Many of the winners were little girls and boys, whose delight at the success of their pet flowers can be well imagined. In the course of the evening the Rev. William Rogers proposed in appropriate terms a vote of thanks to Her Grace the Duchess of Westminster (who distributed the prizes), specially alluding to her efforts and those of her husband to improve the condition of the humbler classes in the City, in which they were so largely interested. The Duke of Westminster said that only within the last few years has it been possible to grow and rear plants in the City, owing to the smoky and impure condition of the atmosphere; but he hoped the time was not far distant when not only the pretty specimens they had seen, but even Roses might be grown. He expressed a hope that the old and disused burial grounds of the City might be utilized, where practicable, as flower-gardens, and that the squares and enclosures of London might be made more generally available for innocent recreation.

Scottish Horticultural Association.—At a meeting of this Association held on Tuesday evening last, Mr. Hugh Fraser gave an account of a visit which he paid to the Dublin Botanic Garden the day previous to the meeting. After complimenting Dr. Moore on the way in which the Garden is being conducted, he made some interesting remarks on the mildness of the climate of Dublin. Shrubs which we consider only half hardy, or at best growing with the aid of walls, were, Mr. Fraser said, in glorious perfection in the open border. *Fabiana imbricata*, *Eurybia Gunni*, various species of greenhouse Acacias, *Chamarops chinensis*, and numerous others were flowering in perfection. Mr. McLeod, superintendent of public gardens in Edinburgh, described a plant which he had seen the other day of *Chianthus panicus* growing on the gable of a house at Liberton, and of which an account appeared in THE GARDEN last week (see p. 5). Mr. Carson, of Melbourne, gave an amusing account of the way in which he began to grow Oranges in Australia. Mr. Dunn, the president, furnished a very interesting account of a ten years' experience in growing various half-hardy plants in Ireland. —R. M. A.

Horticultural Exhibition at Oporto.—At this exhibition Mr. B. S. Williams was placed first in the following classes:—New plants, gold medal (the only one awarded); Orchids, silver medal; and new Dracenas, silver medal. A first prize was also awarded to him for works on Orchids, Ferns, stove plants, &c. The premier prize, a handsome silver cup presented by the Municipality, was unanimously awarded to Mr. Williams, who was considered to have contributed the finest collection of plants in the show. The group in question included Pitcher-plants, Dracenas, over twenty Orchids, and many other new and rare plants, all of which arrived at Oporto in excellent condition.

NOTES AND QUESTIONS—VARIOUS.

Stapelias.—As I fail to grow these satisfactorily, I should be greatly obliged by a few hints as to the best mode of managing them.—A. B. [They flower best when placed on a shelf in a greenhouse, and fully exposed to direct sunshine, allowing them to have a good roasting. If shaded or over-moist they grow, but do not flower.—J. GORDON.]

Splitting of Peach Stones.—Can any of your correspondents give me any clue to the cause and cure of this disaster? We have two trees in our second and late peach-houses respectively, the fruit-stones of which have split somewhat considerably during the past two years. In the past winter I lifted the roots of one, and re-planted them in fresh soil, thinking that might be a preventive. I find, however, that there are a number of the fruits again with split stones. The roots of both trees are partially inside and partially out, and have not suffered from want of water at any time.—C. J. H.

The First Fuchsia.—Allow me to remind Mr. Bullen (see p. 10) that *Fuchsia coccinea* is not the plant which he has described. Few have seen the true *F. coccinea*: I never yet met with it, nor am I aware that it is in commerce. The *Fuchsia* to which Mr. Bullen alludes is, I believe, *F. virgata*. The true *F. coccinea* was discovered by accident in the Botanic Garden at Oxford, by some botanist (whose name I forget), and is a totally different plant from the one described by Mr. Bullen.—THOS. WILLIAMS, *Ormskirck*.

Dendrochilum filiforme.—This graceful Orchid is now unusually good condition in Messrs. Rolisson's nursery at Tooting. Plants of it in 6-in. pots bear from twenty to thirty long pendent spikes of greenish-yellow blossoms; associated with these are also some plants of it equally floriferous, growing in wooden baskets suspended from the roof.—S.

Tabernaemontana camassa.—Growers of flowers for market should cultivate a house of this plant alone. It is a newly-introduced evergreen stove shrub of a neat, compact, dwarf habit, with glossy bright Laurel-like leaves, and racemes of double white flowers of Gardenia-like outline and fragrance, which are produced on the point of every shoot. From the Gardenia it differs in its easier growth, and in requiring a much less stimulating atmosphere to produce its bloom; the usual temperature of a hothouse with less humidity will produce blooms more freely and longer in succession. The petals of the flowers are lighter and more elegantly arranged than the Gardenia, and not quite so large: small plants in 3-in. pots will produce flowers freely.—JOHN SAUL.

SATURDAY, JULY 21, 1877.

[Vol. XII.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SHAKESPEARE'S ROSES.

- (1) *Titania.* Some to kill cankers in the Musk Rosebuds.
Midsummer Night's Dream, act ii., sc. 3.
Titania. And stick Musk Roses in thy sleek, smooth head.
Ibid., act iv., sc. 1.
- (2) *Julia.* The air hath starved the Roses in her cheeks.
Two Gentlemen of Verona, act iv., sc. 4.
- (3) *Song.* There will we make our beds of Roses
And a thousand fragrant posies.
Merry Wives of Windsor, act iii., sc. 1.
- (4) *Autolycus.* Flowers as sweet as Damask Roses.
Winter's Tale, act iv., sc. 3.
- (5) *Olivia.* Casario, by the Roses of the spring,
By manhood, honour, truth, and everything,
I love thee so.
Twelfth Night, act iii., sc. 1.
- (6) *Diana.* When you have our Roses,
You barely leave us thorns to prick ourselves,
And mock us with our bareness.
All's Well That Ends Well, act iv., sc. 2.
- (7) *Lord.* Let one attend him with a silver basin
Full of Rose water and bestrewn with flowers.
Taming of the Shrew (Introduction).
- (8) *Petruchio.* I'll say she looks as clear
As morning Roses newly washed with dew.
Ibid., act ii., sc. 1.
- (9) *Tyrrell.* Their lips were four red Roses on a stalk,
Which in their summer beauty kissed each other.
Richard III., act iv., sc. 3.
- (10) *Gower.* Even her art sisters the natural Roses.
Pericles, act v., chorus (see Cherry, No. 5).
- (11) *Friar.* The Roses in thy lips and cheeks shall fade
To paly ashes.
Romeo and Juliet, act iv., sc. 1.
- (12) *Romeo.* Remnants of packthread in old cakes of Roses
Were thinly scattered to make up a show.
Ibid., act v., sc. 1.
- (13) *Hamlet.* With two Provincial Roses on my razed shoes.
Hamlet, act iii., sc. 2.
- (14) *Laertes.* O, Rose of May,
Dear maid, kind sister, sweet Ophelia.
Ibid., act iv., sc. 5.
- (15) *Duke.* For women are as Roses whose fair flower,
Being once displayed, doth fall that very hour.
Twelfth Night, act ii., sc. 4.
- (16) *Constance.* Of Nature's gifts, thou may'st with Lilies boast,
And with the half-blown Rose.
King John, act iii., sc. 1.
- (17) *Queen.* But soft, but see—or rather do not see—
My fair Rose wither.
Richard II., act v., sc. 1.
- (18) *Hotspur.* To put down Richard, that sweet lovely Rose,
And plant this Thorn, this canker, Bolingbroke.
1st Henry IV., act i., sc. 3.
- (19) *Hostess.* Your colour, I warrant you, is red as any Rose.
2nd Henry IV., act ii., sc. 4.
- (20) *York.* Then will I raise aloft the milk-white Rose,
With whose sweet smell the air shall be perfumed.
Ibid., act i., sc. 1.
- (21) *Don John.* I had rather be a canker in a hedge than a Rose in his
grace.
Much Ado About Nothing, act i., sc. 3.
- (22) *Theseus.* But earthlier happy is the Rose distilled
Than that which, withering on the virgin Thorn,
Grows, lives, and dies in single blessedness.
Midsummer Night's Dream, act i., sc. 1.
- (23) *Lysander.* How now, my love? Why is your cheek so pale?
How chance the Roses there do fade so fast?
Ibid.
- (24) *Titania.* The seasons alter: hoary-headed frosts
Fall on the fresh lap of the crimson Rose.
Ibid., act ii., sc. 2.
- (25) *Thisbe.* Of colour like the red Rose on triumphant Briar.
Ibid., act iii., sc. 1.
- (26) *Biron.* At Christmas I no more desire a Rose
Than wish a snow in May's new-fangled shows,
But like of each thing that in season grows.
Love's Labour's Lost, act i., sc. 1.
- (27) *King.* So sweet a kiss the golden sun gives not
To those fresh morning drops upon the Rose.
Ibid., act iv., sc. 3.
- (28) *Boyet.* Blow like sweet Roses in the summer air.
Princess. How blow? how blow? Speak to be understood.
Boyet. Fair ladies masked are Roses in their buds,
Dismasked, their damask sweet commixture shewn,
Are angels veiling clouds, or Roses blown.
Ibid., act v., sc. 2.
- (29) *Touchstone.* He that sweetest Rose will find,
Must find Love's prick and Rosalind.
As You Like It, act iii., sc. 2.
- (30) *Countess.* This thorn
Doth to our Rose of youth rightly belong.
All's Well That Ends Well, act i., sc. 3.
- (31) *Bastard.* My face so thin,
That in mine ear I durst not stick a Rose.
King John, act i., sc. 1.
- (32) *Antony.* Tell him he wears the Rose
Of youth upon him.
Antony and Cleopatra, act iii., sc. 11.
- (33) *Cleopatra.* Against the blown Rose may they stop them more
That kneeled unto the buds.
Ibid.
- (34) *Boult.* For flesh and blood, sir, white and red, you shall see a Rose
and she were a Rose indeed!
Pericles, act iv., sc. 6.
- (35) *Juliet.* What's in a name? That which we call a Rose
By any other name would smell as sweet.
Romeo and Juliet, act ii., sc. 2.
- (36) *Ophelia.* The expectancy and Rose of this fair state.
Hamlet, act iii., sc. 1.
- (37) *Hamlet.* Such an act . . . takes off the Rose
From the fair forehead of an innocent love,
And sets a blister there.
Ibid., act iii., sc. 4.
- (38) *Othello.* When I have plucked the Rose,
I cannot give it vital growth again,
It needs must wither. I'll smell it on the tree.
Othello, act v., sc. 2.
- (39) *Timon.* Rose-cheeked youth.
Timon of Athens, act iv., sc. 3.
- (40) *Othello.* Thou young and Rose-lipped cherubim.
Othello, act iv., sc. 2.
- (41) Roses have thorns and silver fountains mud,
And loathsome canker lives in sweetest bud.
Sonnet 35.
- (42) The Rose looks fair, but fairer we it deem
For that sweet odour that doth in it live
The canker blooms have full as deep a dye
As the perfumed tincture of the Roses,
but they
Die to themselves—Sweet Roses do not so;
Of their sweet deaths are sweetest odours made. *Ibid.* 54.
- (43) Why should poor beauty indirectly seek
Roses of shadow, since his Rose is true? *Ibid.* 67.
- (44) Shame, like a canker in the fragrant Rose,
Doth stop the beauty of thy budding name. *Ibid.* 95.
- (45) Nor did I wonder at the Lilies white
Nor praise the deep vermilion of the Rose. *Ibid.* 98.
- (46) The Roses fearfully in thorns did stand,
One blushing shame, another white despair,
A third, nor red nor white, had stolen of both
And to his robbery had annexed thy breath. *Ibid.* 99.
- (47) I have seen Roses damasked, red and white,
But no such Roses see I in her cheeks. *Ibid.* 130.
- (48) More white and red than doves and Roses are.
Venus and Adonis.
- (49) What though the Rose has prickles? yet 'tis plucked. *Ibid.*
- (50) Who, when he lived, his breath and beauty set
Gloss on the Rose, smell to the Violet. *Ibid.*
- (51) This silent war of Lilies and of Roses.
Rape of Lucrece.
- (52) O how her fear did make her colour rise,
First red as Roses that on lawn we lay,
Then white as lawn, the Roses took away. *Ibid.*
- (53) That even for anger makes the Lily pale,
And the red Rose blush at her own disgrace. *Ibid.*
- (54) I know what thorns the growing Rose defends. *Ibid.*
- (55) Sweet Rose, fair flower, untimely plucked, soon vaded,
Pluck'd in the bud, and vaded in the spring.
The Passionate Pilgrim.

In addition to these many passages, there are perhaps thirty more in which the Rose is mentioned, but all having reference only to the Red and White Roses of the houses of York and Lancaster. To quote these it would be necessary to extract the entire Act, which is very graphic, but too long. I must, therefore, content myself with the beginning and the end of

the chief scene, and refer the reader who desires to see it *in extenso* to "1st Henry VI.," act ii., sc. 4. The scene is in the Temple Gardens, and Plantagenet and Somerset thus begin the fatal quarrel.

Plantagenet. Let him that is a true-born gentleman,
And stands upon the honour of his birth,
If he suppose that I have pleaded truth,
From off this Brier pluck a White Rose with me.

Somerset. Let him that is no coward, nor no flatterer,
But dare maintain the party of the truth,
Pluck a Red Rose from off this thorn with me.

And Warwick's wise conclusion on the whole matter is—

This brawl to-day,
Grown to this faction in the Temple Garden,
Shall send, between the Red Rose and the White,
A thousand souls to death and deadly night.

There are further allusions to the same Red and White Roses in "3rd Henry VI.," act i., sc. 2, "3rd Henry VI.," act ii., sc. 5, "1st Henry VI.," act 4, sc. 1, and "Richard III.," act v., sc. 4.

There is no flower so often mentioned by Shakespeare as the Rose, and he would probably consider it the queen of flowers, for it was so deemed in his time. "The Rose doth deserve the cheefest and most principall place among all flowers whatsoever, being not only esteemed for his beautie, vertues, and his fragrant and odoriferous smell, but also because it is the honore and ornament of our English Scepter" (Gerarde). Yet the kingdom of the Rose even then was not undisputed; the Lily was always its rival (see Lily), for thus sang Walter de Bibbesworth in the thirteenth century—

En go verger troverouns les flurs
Des quens issunt les douz odours (swote smel)
Les herbes ansi pur medicine
La flur de Rose, la flur de liz (lilie)
Liz vaut pur royne, Rose pur piz.

But a little later the great Scotch poet Dunbar, who lived from 1460 to 1520, that is, a century before Shakespeare asserted the dignity of the Rose as even superior to the Thistle of Scotland.

Nor hold none other flower in sic dainty
As the fresh Rose of colour red and white;
For if thou dost, hurt is thine honesty,
Considering that no flower is so perfite,
So full of virtue, pleassance, and delight,
So full of blissfull angelic beauty,
Imperial birth, honour, and dignity.

Volumes have been written, and many more may still be written, on the delights of the Rose, but my present business is only with the Roses of Shakespeare. In many of the above passages the Rose is simply the emblem of all that is loveliest, and brightest, and most beautiful upon earth, yet always with the underlying sentiment that even the brightest has its dark side, as the Rose has its thorns, that the worthiest objects of our earthly love are at the very best but short-lived, that the most beautiful has on it the doom of decay and death. These were the lessons that even the heathen writers learned from their favourite Roses, and which Christian writers of all ages loved to learn also, not from the heathen writers, but from the beautiful flowers themselves. "The Rose is a beautiful flower," said S. Basil, "but it always fills me with sorrow by reminding me of my sins, for which the earth was doomed to bear thorns." And it would be easy to fill a volume, and it would not be a cheerless volume, with beautiful and expressive passages from poets, preachers, and other authors, who have taken the Rose to point the moral of the fleeting nature of all earthly things. Herrick in four lines tells the whole:—

Gather ye Roses while ye may,
Old time is still a-flying,
And the same flower that smiles to-day,
To-morrow will be dying.

But Shakespeare's notices of the Rose are not all emblematical and allegorical. He mentions these distinct sorts of Roses—the Red Rose, the White Rose, the Musk Rose, the Provençal Rose, the Damask Rose, the Variegated Rose, and the Canker Rose. The Canker Rose is the wild Dog Rose, and the name is sometimes applied to the common Red Poppy. The Red Rose and the Provençal Rose (No. 13) are no doubt

the same, and are what we now call *R. centifolia*, or the Cabbage Rose, a Rose that has been supposed to be a native of the south of Europe, but Dr. Lindley preferred "to place its native country in Asia, because it has been found wild by Bieberstein with double flowers, on the eastern side of Mount Caucasus, whither it is not likely to have escaped from a garden." We do not know when it was introduced into England, but it was familiar to Chaucer—

The savour of the Roses swote
Me smote right to the herte rote,
As I hadde alle embawmed be.

Of Roses there were grete wone,
So faire wexe never in Rone.

i.e., in Provence, at the mouth of the Rhone. For beauty in shape and exquisite fragrance, I consider this Rose to be still unrivalled, but it is not a fashionable Rose, and is usually found in cottage gardens, or perhaps in some neglected part of gardens of more pretensions. I believe it is considered too loose in shape to satisfy the floral critics of exhibition flowers, and it is only a summer Rose, and so contrasts unfavourably with the Hybrid Perpetuals. Still, it is a delightful Rose, delightful to the eye, delightful for its fragrance, and most delightful from its associations.

The White Rose of York (No. 20) has never been satisfactorily identified. It was clearly a cultivated Rose, and by some is supposed to have been only the wild White Rose (*R. arvensis*) grown in a garden. But it is very likely to have been the *Rosa alba*, which was a favourite in English gardens in Shakespeare's time, and was very probably introduced long before his time, for it is the double variety of the wild White Rose, and Gerarde says of it:—"The double White Rose doth grow wilde in many hedges of Lancashire in great abundance, even as Briars do with us in these southerly parts, especially in a place of the countrey called Leyland, and in a place called Roughford, not far from Latham." It was, therefore, not a new gardener's plant in his time, as has been often stated. I have little doubt that this is the White Rose of York; it is not the *R. alba* of Dr. Lindley's monograph, but the double variety of the British *R. arvensis*.

The White Rose has a very ancient interest for Englishmen, for "long before the brawl in the Temple Gardens, the flower had been connected with one of the most ancient names of our Island. The elder Pliny, in discussing the etymology of the word Albion, suggests that the land may have been so named from the White Roses which abounded in it—"Albion" *insula sic dicta ab albis rupibus quas mare aluit, vel ob rosas albas quibus abundat.* Whatever we may think of the etymological skill displayed in the suggestion . . . we look with almost a new pleasure on the Roses of our own hedgerows, when regarding them as descended in a straight line from the 'rosas albas' of those far-off summers." Qu. R., vol. 114.

The Damask Rose (No. 4) remains to us under the same name, telling its own history. There can be little doubt that the Rose came from Damascus, probably introduced into Europe by the Crusaders or some of the early travellers in the East, who speak in glowing terms of the beauties of the gardens of Damascus. So Sir John Mandeville describes the city—"In that Cytee of Damasce, ther is gret plentee of Welles, and with in the Cytee and with oute, ben many fayre Gardynes and of dyverse frutes. Non other Cytee is not lyche in comparisoun to it, of faire Gardynes, and of faire desportes." (Voiage and Travaile, cap. 11). And in our own day the author of Eothen described the same gardens as he saw them:—"High, high above your head, and on every side all down to the ground, the thicket is hemmed in and choked up by the interlacing boughs that droop with the weight of Roses, and load the slow air with their damask breath. There are no other flowers. The Rose trees which I saw were all of the kind we call 'damask'; they grow to an immense height and size." ("Eothen," ch. 27). It was not till long after the Crusade that the Damask Rose was introduced into England, for Hakluyt in 1582 says:—"In time of memory many things have been brought in that were not here before, as the Damaske Rose by Doctour Linaker, King Henry the Seventh and King Henrie the Eighth's Physician."—"Voiaiges," vol. 2).

As an ornamental Rose the Damask Rose is still a favourite, though probably the real typical *Rosa damascena* is very seldom seen—but it has been the parent of a large number of Hybrid Roses, which the most critical Rosarian does not reject. The whole family are very sweet-scented, so that "sweet as Damask Roses" was a proverb, and Gerarde describes the common Damaske as "in other respects like the White Rose; the especiale difference consisteth in the colour and smell of the floures, for these are of a pale red colour and of a more pleasant smell, and fitter for meate or medicine."

The Musk Roses (No. 1) were great favourites with our forefathers. The Rose (*R. moschata*) is a native of the north of Africa and of Spain, and has been also found in Nepaul. Hakluyt gives the exact date of its introduction. "The turkey cocks and hennes," he says, "were brought about fifty yeres past, the Artichowe in time of King Henry the Eight, and of later times was procured out of Italy the Muske Rose plant, the Plumme called the Perdigwena, and two kindes more by the Lord Cromwell after his travel."—"Voiaiges," vol. 2. It is a long straggling Rose, bearing bunches of single flowers, and is very seldom seen except against the walls of some old houses. "You remember the great bush at the corner of the south wall just by the blue drawing-room windows; that is the old Musk-rose, Shakespeare's Musk-rose, which is dying out through the kingdom now."—"My Lady Ludlow," by Mrs. Gaskell).—But wherever it is grown it is highly prized, not so much for the beauty as for the delicate scent of its flowers. The scent is unlike the scent of any other Rose, or of any other flower, but it is very pleasant, and not overpowering; and the plant has the peculiarity that, like the Sweet Briar, but unlike other Roses, it gives out its scent of its own accord and unsought, and chiefly in the evening, so that if the window of a bedroom near which this Rose is trained be left open, the scent will soon be perceived in the room. This peculiarity did not escape the notice of Lord Bacon. "Because the breath of flowers," he says, "is far sweeter in the air (when it comes and goes like the warbling of music) than in the hand, therefore nothing is more fit for that delight than to know what be the flowers and plants that do best perfume the air. Roses, damask and red, are fast flowers of their smells, so that you may walk by a whole row of them, and find nothing of their sweetness, yea, though it be in a morning's dew. Bays, likewise, yield no smell as they grow, Rosemary little, nor Sweet Marjoram; that which above all others yields the sweetest smell in the air is the Violet, especially the white double Violet which comes twice a year, about the middle of April, and about Bartholomew-tide—next to that is the Musk-rose."—"Essay of Gardens."

The Roses mentioned in Nos. 34, 46, and 47 as a mixture of red and white must have been the mottled or variegated Roses, commonly called the York and Lancaster Roses; these are old Roses, and very probably quite as old as the sixteenth century. There are two varieties: in one each petal is blotched with white and pink; this is the *R. versicolor* of Parkinson, and is a variety of *R. damascena*; in the other most of the petals are white but with a mixture of pink petals; this is the *Rosa Mundi* or *Gloria Mundi*, and is a variety of *R. gallica*.

These, with the addition of the Eglantine and Sweet Briar, are the only Roses mentioned by their names by Shakespeare, and they were the chief sorts grown in his time, but not the only sorts; and to what extent Roses were cultivated in Shakespeare's time, we have a curious proof in the account of the grant of Ely Place, in Holborn, the property of the Bishops of Ely. "The tenant was Sir Christopher Hatton (Queen Elizabeth's handsome Lord Chancellor), to whom the greater portion of the house was let in 1576 for the term of twenty-one years. The rent was a Red Rose, ten loads of hay, and ten pounds per annum; Bishop Cox, on whom this hard bargain was forced by the Queen, reserving to himself and his successors the right of walking in the gardens, and gathering twenty bushels of Roses yearly."—Cunningham.

My space forbids me to enter more largely into any account of these old species, or to say much of the many very interesting points in the history of the Rose, but two or three points connected with Shakespeare's Roses must not be passed over. First, its name. He says through Juliet (No. 35) that the

Rose by any other name would smell as sweet. But the whole world is against him. Rose was its old Latin name corrupted from its older Greek name, and the same name, with slight and easily-traced differences, has clung to it in almost all European countries.

Shakespeare also mentions its uses in Rose-water and Rose-cakes, and it was only natural to suppose that a flower so beautiful and so sweet was meant by Nature to be of great use to man. Accordingly we find that wonderful virtues were attributed to it, and an especial virtue was attributed to the dewdrops that settled on the full-blown Rose. Shakespeare alludes to these in Nos. 22 and 27; and from these were made cosmetics only suited to the most extravagant.

The water that did spring from ground
She would not touch at all,
But washt her hands with dew of Heaven
That on sweet Roses fall.

The Lamentable Fall of Queen Elinor—"Roxburgh Ballads."

And as with their uses, so it was also with their history. Such a flower must have a high origin, and what better origin than the pretty mediæval legend told to us by Sir John Mandeville?—"At Bethleim is the Felde *Floridus*, that is to seyne, the *Feld florished*; for als moche as a fayre mayden was blamed with wrong and sclaudred, for whiche cause sche was demed to the Dethe, and to be brennt in that place, to the whiche she was ladd; and as the Fyre began to bren aboute hire, sche made hire preyeres to oure Lord, that als wissely as sche was not gylyt of that Synne, that He wolde helpe hire and make it to be knowen to alle men, of his mercyfulle grace. And when sche hadde thus seyd, sche entred into the Fuyr; and auon was the Fuyr quenched and oute; and the Broudes that weren brennyng becomen red Roseres, and the Brondes that weren not kyndled becomen white Roseres, full of Rosers. And these weren the first Roseres and Rosers, both white and rede, that evere ony man saughe" ("Voiaige and Travaile," cap. 6.)

With this pretty legend I may well conclude the account of Shakespeare's Roses, commending, however, M. Biron's sensible remarks on unseasonable flowers (No. 26) to those who estimate the beauty of a flower or anything else in proportion to its being produced out of its natural season.

H. N. ELLACOMBE.

A VALUABLE NEW TREE.

WE have received from Mr. John Luscombe, of Combe Royal, South Devon, a very beautiful specimen of a tree which is likely to prove a very desirable addition to our gardens. This is *Idesia polycarpa*, a Japanese tree, which was not known to science until 1866, when it was described by the Russian botanist Maximowicz, who met with it in cultivation at Nipon and Yedo, in Japan, and ascertained that it was a native of the island Kiusiu, at the foot of a mountain called Hikosan. Mr. Luscombe describes it as a handsome tree-like spreading shrub, with fine foliage, but according to Professor Maximowicz it attained in Japan the dimensions of a large tree. The leaves in the specimen before us are irregularly serrate, acuminate, very slightly cordate at the base, the larger ones about 6 in. across, bright green above, whitish or almost glaucous beneath, with five prominent branching nerves, which are reddish towards the base: the leaves are borne on red petioles about their own length. The flowers are dioecious; the males, which Mr. Luscombe has sent us, have from four to six yellowish-green spreading sepals, and an indefinite number of pale green filaments with orange anthers. Each blossom is about $\frac{1}{2}$ in. across; they form long, gracefully-drooping, branched racemes, springing from the axils of the upper leaves. The female flowers are similar in appearance, but are succeeded by very numerous orange berries, which appear, from dried specimens communicated by the discoverer to the British Museum Herbarium, to be about as large as a small Cherry. The flowers are deliciously fragrant, their odour resembling that of a Vanda; and, although their colouring is not brilliant, their effect, combined with the red leaf-stalks, the varying green of the leaves, and their elegant drooping habit is extremely pleasing. The tree belongs to the Order Bixineæ (or Flacourtiaceæ), to which our gardens have not hitherto been largely indebted. It was named by M. Maximowicz in commemoration of a Dutch traveller named Ides, who was sent to China by Peter the Great at the beginning of the last century, and who subsequently published an account of his travels.

NOTES OF THE WEEK.

PLANTS TIED INTO BUNDLES.—Among the various practices which waste the time of gardeners, and tend to make our gardens ugly, may be named that of tying beautiful plants into besoms. Wherever possible staking should be avoided. One of the loveliest fringes of blossom we have ever seen in garden or in wild has been afforded lately by a line of Everlasting Peas in Mr. Parker's Nursery at Tooting, not staked at all, but wandering about in all sorts of graceful ways. Treated so Everlasting Peas become one of the most effective materials in the hands of the artistic gardener. The brilliant crimson variety of the old Everlasting Pea, which may be seen in great beauty in this nursery is likely in time to supplant the old variety. The white, the striped, and this fine form associated together are among the most beautiful of all things that may be grown in any soil or situation.

JARGONELLES FROM FRANCE.—The first consignment of Jargonelle Pears to Covent Garden market from the south of France arrived last week. They are somewhat small individually, but of fair quality, and we are told that in a few weeks very large consignments of better fruit may be expected.

YORK AND LANCASTER ROSE.—I saw a group of this at Mr. Parker's at Tooting the other day, and was struck with the size and the handsome markings of its blooms. It is, I think, the finest of all striped hardy flowers, and well deserves culture. Such subjects have often been lost, and still more often weakened by planting among mixed shrubs and in borders. This would be best grouped with other interesting old Roses, or even in a small bed by itself.—R.

FLORA IN THE MUSIC HALL.—The Carnation and Picotee Show at the Westminster Aquarium the other day brought together a great number of beautiful flowers, which, however, could not be enjoyed, owing to the jingling music that accompanied the various music hall entertainments to which this place is devoted. We, of course, have nothing to say against daylight theatricals and music hall performances, but we may ask the promoters of this society whether it is wise to bring their beautiful flowers to a place where they may not be enjoyed except under the influences of the distractions above alluded to? The majority of Londoners who care for flowers answer this question unmistakably—by not going!

THE PRICKLY THRIFTS.—Few would seem to have any idea of how much is lost by many of our herbaceous and Alpine plants in pots. Many of them are never seen in fair health in these, and often perish when planted out of them. The public should be able to obtain strong plants grown in the open ground, and sent in Moss instead of a pot. Many persons are disheartened, owing to the wretched mites of plants that are often sent out. I have so often seen the Prickly Thrifts starved in small pots that I was pleased to see last week one of them (*Acantholimon glumaceum*) a rosy cushion of flowers more than 1 ft. through. It is on a hot border at the foot of the house wall in the Exotic Nursery, Tooting. The heat or drought did not seem to have the least effect on its abundant flowers.—V.

SARDINIAN BALSAMS AND ZINNIAS.—Messrs. Stuart & Co., of Tavistock Row, Covent Garden, have shown us some lovely blooms of Balsams and Zinnias, the produce of plants raised in their seed-grounds at Nice. The Balsams consisted of white, purple, scarlet, and carnation-striped kinds, large and double; and amongst the Zinnias were scarlet and reds of different shades, white, purple, and sulphur-coloured varieties, some of which measured more than 3 in. across, and they were as double as any of the best forms of *Chrysanthemum*. Along with them, too, were miniature Zinnias, quite as perfect in form as the larger kinds.

SMALL FRUITS IN KENT.—Although complaints are being made on all sides of the failure of the fruit crop this season, the enormous quantities of small fruits which can now be made into preserves will go far to compensate for the loss of other kinds. In Kent, Strawberries are this year wonderfully abundant though rather small; and some idea of the quantity grown in the neighbourhood of Swanley may be gleaned from the fact that Mr. Cannell has informed us that a neighbour of his on one day last week sent to London 2500 pecks of Strawberries. This, reckoning 14 lb. to the peck, would amount to nearly 16 tons. One grower in Kent, we were informed the other day, sold last year 125 tons of Strawberries. Raspberries are in great demand; one buyer last week wanted to purchase 100 tons for preserving, and one grower had contracted to supply 10 tons of that quantity. Of Gooseberries, one cultivator sent 120 bushels to Sunderland, and a similar quantity was being gathered for Manchester. It will thus be seen that great as i

our foreign trade in fruits, a large amount of our small fruits is still supplied by English growers.

AUDLEY END.—The illustration of Audley End published this week was from a photograph by Mr. Vernon Heath, and for which we are indebted to that gentleman.

ROYAL BOTANIC SOCIETY.—At a meeting of the Council of this Society, held on June 14th, a special gold medal was awarded to Messrs. Carter & Co., of High Holborn, for their collection of fine-foliaged plants and annuals grown in pots from seed, and exhibited in the gardens of the Society during the month of June.

EFFECTS OF THE WEATHER IN DORSETSHIRE.—Mr. Pragnell, of Sherborne, informs us that the hot days and cold windy nights which have lately been experienced in that part of Dorsetshire have had a disastrous effect upon vegetation, which has suffered severely this season, even in that favoured district. The Potato disease, too, has made its appearance, and is rapidly increasing.

LABELS.—Messrs. Bradley & Sons, Halam Nursery, near Southwell, Notts, have sent us specimens of wooden labels in which both names and numbers which are printed are slightly sunk in the wood and blackened, the result being a very legible label. Some are varnished and some are not: but possibly the varnished ones may prove the most durable. The wood itself consists of Oak, Beech, and Red Deal steeped in oil; one of the labels sent, made of horn, is light and transparent, the lettering being impressed on it as in the case of the wood. Labels of this kind may eventually prove to be the best, and they can be made of almost any form desired.

ANNUALS AT READING.—The display of annuals in Messrs. Sutton's seed-grounds about a mile from Reading continues to attract attention, the kinds being not only numerous but well varied in colour. Among the most effective are Red Virginian Stock, White Candytuft, *Clarkia pulchella*, *Silene pendula compacta*, *Lupinus nanus*, *Crimson Candytuft*, *Saponaria calabrica*, tall dark *Nasturtium*, *Viscaria oculata*, new dark *Convolvulus*, yellow *Tom Thumb Nasturtium*, dwarf *Rocket*, *Larkepur*, *Bartonia aurea*, dark *Sweet William*, *Malope grandiflora*, *Kaulfussia amelloides*, *Sweet Peas*, *Marigolds*, *Chrysanthemums*, and other interesting kinds. At the meeting of the Prince Consort's Royal Association, which took place the other day at Windsor, Messrs. Sutton exhibited upwards of two hundred varieties of annuals, cut from the grounds just alluded to, and which attracted much attention.

STATE OF THE FRUIT CROPS AT BURGHLEY.—On Apples there was a great deal of bloom, but it was light-coloured and weak; still we have a sprinkling. Our best varieties are Wellington, King of Pippins, Ribston Pippin, and Dutch Mignonne. Pears, both standards and wall trees, are a failure. The best sorts here are—*Passe Colmar*, *Beurré d'Arenberg*, *Fondante d'Automne*, and *Glou Morcean*. Plums are quite a failure. *Green Gage*, *Princess of Wales*, *Victoria*, and *Prune Damsons*, which have for nine seasons past given us full crops, are this year barren. *Apricots* are a good half crop; these have all been protected with nets. *Peaches* and *Nectarines* are also a good half crop on south walls, but on west walls there is not a fruit. The following *Peaches* are generally good, viz., *Galande*, *Royal George*, and *Princess of Wales*. The best *Nectarines* are *Albert Victor*, *Eldrige*, and *Victoria*. *Gooseberries* are a first-class crop. The best sorts are *Warrington*, *Whitesmith's*, *Crown Bob*, and the small *Champagne*, for preserving. *Currants* of all three sorts are a good crop, and the same may be said of *Nuts* of all kinds. *Strawberries* have been really good: the best are *Charles Napier*, *Amateur*, *President*, and *Sir Joseph Paxton*. So prolific is *Amateur* that plants of it nine months old bear 170 fine fruit. *Laxton's new Strawberry*, *Premier*, promises to be good; it is exquisite in flavour, firm-fleshed, and particularly hardy. *Raspberries* are a good crop, both white and red; *Prince of Wales* is one of the very best both for dessert and preserving. Of *Cherries* we have none outside, but in a cold house they are all that could be wished.—R. GILBERT.

Large *Photinia serrulata*.—In Vol. XI. (p. 326) a specimen of this tree is alluded to. We have one here, a standard, 19 ft. in height and 23 ft. 6 in. in diameter. It has bloomed well this season; the late frost has injured the young shoots, but they are now recovering. It is the largest tree I have seen. Have any of your correspondents a larger one?—JOHN D. NAUCAWEN, *Whiteley*.

Berkheya (*Stobæa*) *purpurea*.—This Cape Thistle is now in flower at Tooting, where it has been watched with considerable care, being still somewhat rare; the different kinds sometimes vary in colour from white to deep purple, but the variety now in bloom at Messrs. Rollison's is very light purple. It is quite hardy, and will doubtless become a favourite both for rock-work and border decoration.—J. T. R.

AUDLEY END.

AUDLEY END, the principal residence of Lord Braybrook, apart from its many objects of interest for the archaeologist, the naturalist, and the student of history, is also well worth the notice of the horticulturist and the landscape gardener. The mansion itself, built by Thomas Howard, Earl of Suffolk, in 1816, stands on the site of a priory, founded by Geoffery de Mandeville, the first Earl of Essex, in 1136, and suppressed when an abbey by Henry VIII., and although even now of considerable dimensions and palatial in appearance, it is but a small portion of the original building, which is stated to have occupied a period of thirteen years in its erection, at a cost of £190,000, and in extent and splendour to have rivalled Hampton Court, which it also resembles in the character of its architecture.

In passing from the chief entrance to the mansion, many fine pictorial effects are observable, one of the best being the

of it can be obtained excepting from the picture gallery, or the upper rooms. It ought to have been sunk to have done it full justice, and so viewed from a terrace; but in consequence of the low position of the house that idea was no doubt found to be impracticable. Some of the beds are furnished with a fine selection of hardy herbaceous plants, and the remainder with the choicer bedding kinds, and being bounded on the outskirts by irregularly-formed masses of evergreens enlivened by bright-foliaged deciduous shrubs such as the Variegated Negundo, &c., the effect produced will be rich, and free from that tawdry glare of colours usually the result of the ordinary system of bedding out.

Around the mansion the grounds are beautifully diversified by hill and dale, richly clad with picturesque groups and masses of noble timber, &c., enlivened also by the waters of the Cam and one of its tributaries, which unite in the park, presenting in numerous directions charming studies for the

Audley End.

Lion Lodge and its accessories, situated south-west of the mansion. Near the east end of what is called the Joshua Bridge, and by which the Saffron Walden road crosses the Cam, is a remarkably fine specimen of the cut-leaved Alder, probably the largest of the kind in the kingdom; at a short distance from the western extremity of the same structure is also a grand mass, composed of groups of round-headed trees, chiefly Elms.

The west view of the mansion, as shown in our illustration, is very imposing, but owing to the naked and stiffly-defined edges of the river, and the barrenness of the widely-extended lawn (it is said to occupy a space of about 8 acres), a certain air of coldness prevails. On the south side the trees and shrubs have been made to produce agreeable effects, and a grand old Cedar of Lebanon is especially effective, whether viewed from the house or as seen with the house from the lawn at various points. On the east side is a very extensive geometric flower garden, arranged in excellent keeping with the style of the house, but unfortunately no really good view

painter, and necessarily also subjects for the consideration of the landscape gardener. Prominent in the view eastward is a Grecian temple, erected to commemorate the restoration to health of George III. after his long illness. Of itself it may no doubt be esteemed a fine work of art, but considered in relation to the mansion and the thoroughly English character of the scene in which it stands, the effect of its presence is certainly incongruous. The same remarks are also equally applicable to the Joshua Bridge and the handsome Roman temple on the summit of Ring Hill, though perhaps in a less degree in the last instance, seeing that it occupies the site of an ancient Roman encampment. Ring Hill is the western boundary of the demesne, and from its summit is obtained a magnificent panoramic view of the mansion and its surroundings, also of the ancient and interesting town of Saffron Walden; and in the dense wood on the east side of the hill are some fine vistas.

The English Elm, of which there are many fine and distinct seminal varieties produced on the estate, is in great

luxuriance. The Beech, Oak, Ash, Horse Chestnut, Lime, &c., are well represented, though they are not so numerous. Of the Western or what is commonly called the London Plane, there are some fine specimens, and regarding them it is deserving of remark that they are generally on swampy ground, and in two or three instances where they are close to the river, their roots protrude into the water after the fashion of those of the Willow. In the park there appears to be a paucity of evergreen trees, and the introduction of a few Conifers, such as the Corsican Pine, &c., planted judiciously in large masses and groups would undoubtedly produce an excellent result, especially in winter. Evergreen shrubs are also comparatively rare, and limited as to variety; of the choicer kinds of the Holly hardly an example is to be seen, nor, indeed, of the ordinary green form, owing, I presume, to the character of the soil being unfavourable for their development. Of the English Yew and the Tree Box there is, however, an abundance in the neighbourhood of the mansion; and, indeed, they are the only two evergreen shrubs that appear to have escaped unhurt the effects of the frosts of 1860.

A specimen of a Black Hamburgh Vine, reported to be 100 years old, was particularly noteworthy in the early house, from its healthy, vigorous condition, and its finely-developed bunches; and certainly if it could be done, it would be well worth while devoting a house entirely for its accommodation, after the fashion of the treatment of that grand old Vine in the gardens of Eastnor Castle; I was also much pleased to witness in a late Vinery some good bunches of an old favourite—Oldaker's West's St. Peter's—which is deserving of more consideration than is usually accorded to it by Grape-growers, for when well grown it is one of the best of late-keeping varieties. In the Peach-houses at Audley End the trees were succeeding satisfactorily, and one variety, the Early York, was producing an abundant crop of well-developed fruit.

In the stoves and greenhouses are many fine specimens of fashionable plants, both for table and general decorative purposes, and ample provision is also made for the supply of cut flowers. What is called the fish-pond garden came next under notice, and upon its walls appeared, among many other suitable wall shrubs and climbers, a specimen of a fine old evergreen Rose (Maria Leonida), now rarely seen; and in one of the ponds or basins are thriving examples of *Richardia æthiopica* and *Aponogeton distachyon*. The chief feature, however, in this department is a piece of artificial rockwork by Pulham, which, although it may not harmonise happily with its surroundings, nor yet, as an imitation, meet the requirements of a geologist, produces a pleasing effect; the blocks, from long exposure, are weather-stained and mossy, and the crevices are filled with the true Shamrock (*Oxalis Acetosella*), *Cotyledon umbilicus*, and the smaller-growing Ferns, &c. Overhanging are wide-spreading branches of the English Yew, and the recesses and various of the more salient points are occupied by fine specimens of hardy Ferns and shrubs, such as *Berberis Darwini*, &c., arranged and planted by some one who evidently had studied natural, or, in other words, true artistic effects.

The kitchen garden, despite the damage inflicted by the frosts of last spring, especially the one of May 4, when the thermometer registered 14°, is well cropped; but fruit here as well as elsewhere is a failure, with the exception of the following Pears, which promise to yield a fair average crop:—*Ne Plus Meuris*, *Beurré Rose*, *Beurré Rance*, *Bergamotte d'Espérance*, and *Glou Morceau*. Of Apples, there is just a slight scattering, but of Filberts the crop will be plentiful. Plums are a total failure, and of bush fruits the supply will be limited. Peaches, Nectarines, and Apricots on the walls are in this, as they have been in many former seasons, more or less a failure, and unless recourse be had to some radical measure—for example, the entire removal of the Peach walls to a higher part of the ground where there is a soil of a better quality and an atmosphere less influenced by late spring and early autumn frosts—the young trees now in course of preparation to replace them will suffer a similar fate. The site of the principal kitchen garden is low and perhaps for successful cultural purposes little more than sufficiently above the natural level of the Cam or Granta which runs close by, and the soil is of a light description, resting upon a gravelly substratum. It would appear that the celebrated Brown, or a close imi-

tator of his style, to produce an improvement in the landscape on the west side of the house, raised the river 7 ft. or 8 ft. above its natural level by means of a dam; and although it may be a moot point whether the result is in an artistic sense an improvement or otherwise, it certainly, so far as the garden is concerned, has proved the opposite of a benefit; and further, it is questionable if the sanitary conditions of the locality have not also thereby been of some extent injuriously affected. The wall occupied by the Peach trees just alluded to seems to have been built in 1811, and is furnished with flues which for very many years have been disused. Instances of flued walls seldom now occur, but heated walls without glass might, I think, be re-introduced with advantage into many places, for I well remember an old decayed garden in the north of England surrounded by flued walls; and I recollect also reading in the "Transactions of the Horticultural Society," when Andrew Knight was president, of first-class prizes being won by Peaches and Nectarines grown on these walls and exhibited at the Society's shows; and further I can call to mind being told by contemporaries of the grower of those fruits that by the end of October the wood of the trees was generally well ripened and the leaves fallen—a result not often witnessed now-a-days on similar trees on the open wall.

G. T.

Green Roses.—These are not such rarities as they are supposed to be. I have had a green Rose tree for nearly thirty years, and I fancy there must be more than one kind of green Rose—mine is certainly a monstrous form of the old China or Monthly Rose, in which the stamens, pistils, and petals seem to have a peculiar tendency to revert to the bracts or divisions of the calyx. The sport or reversion is, however, fixed, as I have never known it to vary. A green Rose has a strange sound, but the possession of it creates more wonder than satisfaction. I have also a very old Rose called *Celestial*, the blooms of which are delicate pink with a bright rosy centre, and very sweet-scented. It is of an arborescent habit, a prodigious bloomer, and the buds are simply beautiful.—THOMAS WILLIAMS, *Ormskirk*.

Anomatheca cruenta.—Allow me to say a word on behalf of this pretty little plant. A few years ago I purchased a few bulbs of it for a pot, and after they had flowered I turned them out into a London back garden which gets no sun for six months in the year, and where all but the hardiest subjects succumb to the damp and cold of winter. The *Anomatheca* seems, however, to be proof against all such adverse influences, for it has come up and flowered each succeeding year in increasing quantity, and seems likely to spread to an indefinite extent if permitted to do so. Should it be unknown to any of your readers, I may add that it is a small Cape Irid, which throws up slender spikes of flowers from 9 in. to 1 ft. in height, each flower consisting of a slender tube, and flat limb of six oval rosy or salmon-red segments, the three lower of which are marked at the base with a deep blood-red spot, which gives the flower a very distinct appearance.—R. C., *Kensington*.

Birds' Nests in Hothouses.—A similar case to that recorded in THE GARDEN (see p. 498, Vol. XI.), has come under my notice. In the spring of 1876 a robin found access to our plant stove, and there built its nest in a specimen Fern (*Nephrolepis exaltata*); eggs were laid, and in due time young birds hatched. In March last the same robin again entered the stove, but on this occasion a higher position was chosen for its nest, which was built in a suspended basket planted with Maiden-hair Fern; here were hatched three young robins, which remained in the house three or four days after leaving the nest, when they escaped from their glass cage either by the ventilators or through the small hole by which the parents found access. I saw no more of my companions until the latter part of May, when the industrious parents again returned to the stove, and built another nest in the same basket, and succeeded in rearing another brood, which are now (July 10) flying about the stove, as if waiting for a change of weather before leaving the hot climate. The two empty nests still remain in the basket.—J. F. HART, *Birt Castle, Parsonstown, Ireland*.

A Raft for Water Plants.—We have floating in the water here a mass of *Myosotis palustris* upon a raft about 16 ft. in circumference. The *Myosotis* has been in flower for the last six weeks, and is likely to last six more. The board rises and falls with the water. The Forget-Me-Not is quite established, seeding year after year, and improving each year in its growth. Why should it not be called the "Rollison Raft?"—W. ROLLISON & SON, *Tooting*.

HEATED PLANT-CASES.

By BOVERTON REDWOOD, F.C.S.

THERE are few domestic occupations for the leisure hour more deserving of encouragement than the cultivation of plants in the dwelling house, and there is probably no one who has so much contributed to the successful prosecution of this pursuit as the late Mr. N. B. Ward, F.R.S. The Wardian Case has, in fact, long since become a common article of furniture, and it may safely be asserted that as much real pleasure and instruction are often afforded by these miniature greenhouses as by vastly more ambitious structures. The number of plants which may be satisfactorily grown in an ordinary closed case is far from small; but the enthusiast will certainly wish to add to his collection some of the very beautiful forms of vegetable life to be found among the tropical Ferns, Orchids, and so-called fine-foliaged plants. The gratification of this desire will render it necessary that some arrangement be provided for warming the little greenhouse and transforming it into a small stove or hothouse. Hitherto heated plant-cases have not been largely

made and sold, though various forms have been from time to time devised; but there can be no question that their use will be much extended as the advantages they offer in the cultivation even of such plants as are now grown in the ordinary Wardian Case become more appreciated. At the present time the choice of ready-made plant-cases with heating apparatus is limited, and the critical in such matters will probably prefer to construct their own, in order to consult their individual tastes on various points of detail. It is with a view of assisting those who have reached this conclusion that the following description has been penned. The arrangement set forth has been practically tested by the writer with most satisfactory results, and a strict adherence to the dimensions given may, on this ground, be recommended: but it will be obvious that in these and many other particulars deviations may be made to suit individual circumstances, without necessarily impairing in any way the efficiency of the whole.

Fig. 2 (A) represents a rectangular box, 3 ft. 5 in. in length, 2 ft. in breadth, and 2 ft. 5 in. in depth—all external dimensions. This box, which should be of 1-in. well-seasoned deal, strongly dovetailed together, is provided with a false bottom (b) securely fixed, so that its upper surface is 9½ in. from the top of the box. In what may be termed the front of the box, two doorways are cut, as shown in the figure, each 15½ in. high and 12½ in. wide. The doors for these openings are provided with two projecting studs fitting into corresponding depressions where hinges would ordinarily be placed; the

reason for which arrangement will presently be obvious. Between the true and false bottoms of the box two partitions (c c) are fixed, as shown by the dotted lines, at 12 in. and 13½ in. respectively from the front and left-hand (as the reader looks at the figure) end of the box, thus forming a chamber of these dimensions as to depth and breadth, and of 17 in. in height. This chamber is for the reception of the heating apparatus, and it is essential that air-communication between it and the rest of the box be entirely prevented by caulking all the joints and angles with a mixture of red and white lead with linseed oil, and by screwing over them slips of wood with

Fig. 2.—Box, with heating apparatus and false bottom.

the interposition of felt smeared with the same compound. Two holes (d d), 2½ in. in diameter, are bored through the left-hand end of the box at the top and bottom of the apparatus chamber, so as to provide for the ingress and egress of air to and from the source of heat. At the opposite end of the box a circular orifice, 9 in. in diameter, is cut, equidistant from the sides and bottoms, and is provided with a circular zinc ventilator of the ordinary form, having a button in the centre, by means

of which the openings in the outer plate may be wholly or partially covered by the under plate. A number of 1½ in. holes are bored through the false bottom, say 2 in. apart, omitting that portion which forms the roof of the heating apparatus chamber. At a distance of ½ in. from the front, back, and sides of the box, a continuous strip of wood, ½ in. in thickness, is screwed to the upper surface of the false bottom, with the interposition of stout flannel or felt smeared with the red and white lead mixture, so as to form a watertight channel or gutter (f); and in this channel two holes are bored through the false bottom, into which pieces of ¾-in. composition tubing (g g) are fitted, so as to convey any water from the channel into a pan to be placed in that portion of the box communicated with by the right-hand door. These holes may be at the back and front of the box and midway between the ends, and the composition pipes

Fig 2 (h).—Receptacle for the soil.

may be bent as shown by the dotted lines so as both to deliver into the same pan. Fig. 2 (h) represents the receptacle for the soil, consisting of a trough or deep tray 3 ft. 1 in. in length by 1 ft. 8 in. in width (both outside measurements at the top), and 9 in. in depth (outside), the sides tapering somewhat towards the bottom. This trough should be strongly made of ¾-in. deal, lined with thin sheet lead or stout zinc, and the bottom should be perforated to receive a piece of 1-in. lead pipe (i), which passes through the false bottom of the box when the trough is placed in its position, and delivers into the pan already mentioned. Over the inlet of this pipe an inverted saucer of perforated

zinc is placed to act as a drainer. Across the bottom of the trough outside, several strips of wood, $\frac{1}{2}$ in. in thickness, are nailed, so as to form a bearing and to admit of air freely passing under the trough from the orifices in the false bottom of the box. The trough is not shown *in situ*, in order to simplify the figure; but it will be obvious from a consideration of its dimensions that when resting upon the false bottom of the box there will be a space surrounding it 1 in. wide at the top (the space increasing towards the bottom in consequence of the tapering of the sides) through which the heated air from the hotwater pipes, presently to be described, can freely ascend. This air-space being in communication, through the perforations in the false bottom, with the larger chamber on the right-hand side of the box, it follows that the ventilator already mentioned affords a means of regulating the air current passing over the pipes. For the sake of appearance a strip of perforated zinc with large apertures may be fixed over the space between the trough and the sides of the box.

The heating apparatus should now receive attention. Fig. 3 represents the boiler, which is of stout sheet copper, $4\frac{1}{2}$ in. in diameter by 5 in. in height, and provided with a flue (a) tapering from about 2 in. in diameter at the lower end to about 1 in. at the upper. The boiler is fitted with two unions (b c) at the top, one of which (c) carries a piece of 1-in. pipe (d) passing nearly to the bottom, and a small tap (e) is placed at the lowest point to draw off the water when required. A copper strap (f f), soldered to the boiler, serves to fix it to the side, or preferably in the angle of the apparatus chamber, and it should be placed as close to the roof as is convenient, in

Fig. 3.—Section of Boiler.

order to leave as much room as possible beneath for the lamp. The boiler may advantageously be provided with a well-fitting felt jacket to check the radiation of heat from its surface. In fixing the boiler, the orifice of the flue should be turned towards the upper hole in the end of the box, so that an elbow may be fitted on, if desired, to convey away the products of combustion. From the union (b) a piece of 1-in. lead pipe passes through the false bottom, along the left-hand end and so round the case, as shown in fig. 2, until it reaches the left-hand side of the front, gradually rising as it goes until it is 3 in. or 4 in. from the top. Here it is doubly bent and it passes back beneath the first coil, finally re-entering the apparatus chamber, and being connected with the union (c). Thus is provided a flow and return pipe altogether about 19 ft. in length, and having between 4 and 5 square ft. of heating surface. The openings through which the coil passes through the false bottom must be carefully caulked to make them airtight, and in attaching the coil to the sides of the box thin strips of wood should be interposed to keep the pipes from contact with the sides. Into the highest point of the coil one end of a short piece of $\frac{1}{4}$ -in. composition tube is soldered, the other end being similarly attached to the bottom of the small water-tank (k), which is fixed to the side of the box so that the tops are flush. This tank may be 8 in. long by 1 in. wide, and $2\frac{1}{2}$ in. in depth.

As a source of heat the writer would recommend gas, where it is laid on, and in many cases the supply pipe may be conveniently brought through the floor of the room, and directly through the bottom of the case to the burner. In the selec-

tion of the burner something will depend upon the locality as influencing the general temperature of the apartment, and upon the extent to which the room is used. In a cold room, that is to say, a room where there is seldom a fire, and in a cold locality it will be best to have a ring burner, 2 in. in diameter, pierced with a dozen holes. This, placed at a distance of 1 in. from the bottom of the boiler, will give abundance of heat in the coldest weather. Of course where little heat is wanted the ring burner may still be used and the gas supply checked to the necessary extent, but in such cases it will be found that an ordinary steatite fish-tail or bat's-wing burner turned down low is more convenient. And here we come to the consideration of a most important question. Shall we make the regulation of the gas, and consequently of the heat of the case, automatic, or not? Some there are who are ready to affirm that it is quite useless to attempt the heating of so small a structure unless an automatic regulator be provided, and they confidently predict the freezing or frying of the contents as a necessary conse-

Fig. 4.—Automatic Heat-regulator.

quence. The experience of the writer is, however, entirely opposed to this view. With the heating apparatus already described he has found no difficulty in regulating the temperature without the use of any automatic apparatus, even when the case has been left for days unattended to. Of course violent fluctuations in the temperature out-of-doors will produce alterations within the plant-case, but not nearly to the same extent as if the case were in the open air; and if anything like daily attention can be given, even for a couple of minutes, these fluctuations can be easily counteracted after a little experience. Besides which it is not as if the temperature were the only point requiring attention; the ventilation of the case is an equally important matter, and inasmuch as the rate of passage of the heated air through the openings provided depends upon the difference of the temperatures of the air inside and outside the case, it follows that whenever the heat is increased under the boiler the ventilator openings should be decreased, unless one desires to expedite the ventilation, as for instance in damp weather or in winter, when the case is required to be kept freer from moisture. The only kind of regulator

which the writer would recommend is Sugg's Governor, which is useful in keeping the pressure of gas uniform. This little apparatus is now commonly attached to the street lamps, and may be procured for a few shillings. The pattern selected should be that which admits of adjustment for any desired rate of consumption of gas, however small. The governor screws on to the cast-iron pedestal of the lamp beneath the burner. In case, however, the reader should prefer to have an automatic heat-regulator, the following description of a suitable arrangement is given. Fig. 4 (*a*) is a water-tight box of thin sheet zinc, 6 in. long by 4 in. deep and 1 in. wide. Into the top of this box is soldered a brass tube (*b*), about $\frac{1}{2}$ in. in internal diameter, bent at right angles at about 6 in. or 7 in. from the box, and terminating at (*c*), where it is connected by a piece of india-rubber tubing with a glass tube (*c c*) of the same diameter and bent as shown in the figure. Over the tube (*c c*) is fitted by means of a cork a larger tube (*d*), about 1 in. in diameter and 5 in. or 6 in. in length, and through the same cork is passed a tube (*e*) bent once at a right angle. The upper end of the large tube is also closed by a cork which carries a glass tube (*f*), bent once at a right angle, and sufficiently small to pass loosely into the tube (*c c*). The metal box and tube are filled with water (boiled to expel air), and the upper part of the tube (*c c*) is similarly filled. The lower part of the tube (*c c*) is filled with mercury, care being taken that there is no air between the mercury and the water, and no water above the mercury in that limb of (*c c*) into which the tube (*f*) passes. The apparatus is placed in the plant-case at the temperature which it is desired to maintain, and left there until the water ceases to expand under the influence of the heat, and drive the mercury forward. The tube (*f*) is then adjusted

so that its orifice is only just closed by the mercury. The apparatus may stand upon the hot-water pipes at the end of the case, where it will be less unsightly than elsewhere, but under these circumstances it will maintain a uniform heat in the pipes rather than in the atmosphere of the case. For use with this regulator the gas burner will require to have two small tubes soldered into the supply pipe, one on each side of a small tap as shown in fig. 4. These tubes are to be connected with the tubes (*e*) and (*f*) of the regulator, and for this purpose it will be convenient to fix, air-tight in the roof of the apparatus chamber, two small tubes close to the end of the case, the connections with these being made with india-rubber tubing. The action of the apparatus will now be seen. The tap of the gas burner between the two small tubes should be turned on only so much as to give a supply insufficient to provide enough heat, and indeed the only use of this "by-pass" is to prevent the extinguishing of the gas by the action of the regulator. As the temperature of the air in the case falls, the water in the metal box contracts, the mercury recedes, the orifice of the tube (*f*) is uncovered, and gas passes through it, up the annular space between (*f*) and (*c c*), into the large tube (*d*), through the tube (*e*), and so to the burner,

which it continues to supply until the increased size of the flame has so much raised the temperature of the case that the expansion of the water in the box has again, through the medium of the mercury, closed the orifice of the tube (*f*), and stopped its passage. Where gas cannot be used for heating, the best substitute is a mineral oil lamp, with a flat wick $\frac{5}{8}$ in. in width, provided with a chimney of metal and talc, and having a shallow oil reservoir of large diameter. The lamp should be fed with "water-white petroleum oil."

The decoration of the case should now be proceeded with, in order that the inelegant deal box depicted in fig. 2 may be converted into the handsome pedestal represented in fig. 1. Three mouldings should be provided. The upper one may be about 1 in. in width, and should be put on so that its edge is about $\frac{1}{2}$ in. above the top of the box, and it will be well for the top of the box itself to be slightly bevelled, so that its inner edge is somewhat the lower. This will prevent any accumulation of the water which may be condensed on the glass. The middle moulding may be about 2 in. in width, and it should be about 2 in. in thickness at its lower edge, which should be

7 in. from the top of the box. The lower moulding at the bottom of the box should be somewhat bolder than the middle one. The surface of the box, including the doors, comprised between the middle and the lower moulding, should be covered with virgin cork, broken into small pieces for convenience of fitting, and fastened on with French nails. Upon the care which is expended in this operation the appearance of the case when finished will largely depend, and whatever else is entrusted to the workman, the writer would recommend this being done by the amateur. It is more a question of patience than of skill, though a prolonged study of the Chinese puzzles

Fig. 1.—Heated Plant-case (open).

of our infancy would be a fit preparation for the task. A $\frac{1}{2}$ -cwt. bale of the cork will be more than enough, and will permit of the rejection of the less suitable pieces. It will now be seen why the doors of the pedestal are not hung on hinges, for of course, if they were, being covered with cork, they would not open unless an unsightly blank were left. By the method of fitting recommended, the joint may be made so neatly that the doors are almost invisible, and they require no fastening to keep them shut. The cork surface should be sized and well varnished, and the woodwork may be painted a dark olive-green and bronzed or ebonised and the mouldings gilt.

The quondam plain deal box will now present the appearance of a receptacle for the soil, resting on a handsome solid pedestal, and is ready to receive the glass superstructure. This part should be made by a specialist accustomed to the work, and there is some room for difference of opinion as to its form. The arrangement shown in fig. 1 is convenient, the two doors in front affording easy access to the contents; but a simple sheet of glass for the front and back, with the ends to open as doors may be considered by some to have a better appearance. Whether the doors are at the ends or in front,

they must fit well. The curved top, though more costly, is worth the extra price. On the summit is the ventilator, consisting of two strips of glass sliding in a groove 1 in. in width and slightly overlapping in the centre when the ventilator is closed. By sliding them over each other to a greater or less extent, corresponding openings for the escape of the heated air are left at the ends of the groove. The glass case should have a strong wire passing from end to end beneath the ventilator for the support of hanging baskets, and another wire should be stretched across each end on a level with the tops of the doors. The following dimensions will be found suitable, and a structure of this size, made of stout glass and strong zinc angle bar (which should be painted to match the pedestal) will not be too heavy to be easily lifted on and off by two persons:—Length, 3 ft. 4 in.; breadth, 1 ft. 11 in.; height to top of doors, 2 ft.: total height, 2 ft. 11 in.

The selection of a suitable position for the case will probably have been made before its construction was commenced. As to aspect, much will depend upon the character of the plants to be cultivated. Plants with brilliantly coloured foliage and most flowers, cannot, it is well known, be grown to advantage without strong light; and, on the other hand, Ferns will not thrive if exposed to sunshine. A sunny spot may, of course, be shaded, but this precaution may on some occasion be neglected, to the injury of the occupants of the case, and it will therefore probably be the wisest course to choose a northern aspect where possible. It has been already mentioned that the orifice of the flue of the boiler should be turned to the opening in the end of the box so that an elbow may be applied to carry off the products of combustion. This is not a necessity, but where convenient it would certainly be well to adopt it, and the elbow should preferably pass through the wall or window-frame and terminate in the open air.

The construction of the plant-case having been completed, and the little boiler with its circulating pipes filled with water, heat may be applied, and the bed of soil prepared for the reception of the plants. Covering the bottom of the trough should be a layer of potsherds at least 2 in. deep, the largest fragments at the bottom, and with these may be advantageously mixed some pieces of charcoal; over this layer should be placed a stratum of dried Moss to prevent the earth from passing into and choking the drainage; and lastly, the trough should be filled to within 1 in. of the top with the compost, which may consist of good fibrous peat mixed with plenty of silver sand, to which may be added loam when planting those subjects which require it. The surface of the soil may be diversified by the formation of slight hills and dales, and by placing here and there, half-embedded, a few fragments of porous stone. The earth should then be thoroughly saturated with boiling water, which will destroy any animal or vegetable life present in it, and next day the case will be ready for the plants.

On the subject of stocking the case, the writer proposes to suggest little beyond giving the names of various plants which he has practically found to succeed well. In planting a case, as in laying out a garden, written descriptions are of little use, and almost everything must be left to the taste of the operator. Nevertheless, a few general hints may be of service. It is well to line, as it were, the ends and back of the case with tall-growing Ferns, so as to form a good dense background of verdure, but uniformity of height in the plants thus arranged must be avoided, so as not to produce anything approaching to a straight line. In the rest of the case, marked contrasts as to height and form should be aimed at, and a few distinct plants springing from a carpet of dwarf plants will be more effective than a number nearer alike in character. Above all things, a crowd of plants should be avoided, and room should be given to each to develop and display its beauties of form—all large-growing plants being thus necessarily excluded from a case of the dimensions given, unless one is prepared to keep them only so long as they remain in a small state. Again, no supporting or training of the plants is admissible, for it is essential that they should appear to be growing quite naturally. Passing from generalities, the following arrangement is given as one which will be found to afford satisfaction. As a background *Pteris serrulata cristata*, *P. s. angustata*, and *Adiantum affine*. In the centre of the case a well-grown Palm

—say *Areca lutescens*. At the ends of the case, *A. assimile*, *A. cuneatum*, *A. concinnum latum*, *A. Sanctæ Catherinæ*, and *Cheilanthes elegans*. Difficulty is sometimes experienced in the management of some of the large-fronded *Adiantums*, especially in the winter, but the writer has found *A. Sanctæ Catherinæ* to thrive well in the heated case. The very beautiful *A. macrophyllum* cannot, unfortunately, be recommended for the purpose, though it may be preserved in good condition through the summer. Towards the front of the case may be planted the graceful *Asplenium viviparum*; right and left of the Palm, *Maranta rosea picta*, *M. Makoyana*, *M. chimboracensis*, and a small plant of *Alocasia metallica*, the splendid foliage of the *Marantas* and *Alocasias* contrasting well with the Ferns. *A. metallica* will soon grow too large, but not before it has well paid for the trouble of its removal. Space should be preserved for a plant of *Anthurium Scherzerianum*, which will thrive and produce its brilliant spathes with a little care. A specimen may also be added of the New Holland Pitcher-plant (*Cephalotus follicularis*), and of the interesting little *Venus' Fly-trap* (*Diourea muscipula*), though the writer has found it impossible to preserve the latter in an active condition—probably in consequence of its receiving insufficient light. If possible, room should be found for at least one species of *Cypripedium*, say *C. insigne*, *C. barbatum*, or *C. niveum*. The pretty little *Fittonia argyroneura*, *F. Pearcei*, and *F. Verschaffelti* are also useful for filling nooks. All vacant spaces should be carpeted with the common *Selaginella*, the beautiful blue *S. cæsia*, and the compact *S. apoda*, and a small plant or two of *Tradescantia zebrina* and *Cyrtodeira fulgida* may be added. From the top and sides of the case should be hung a few Orchids in baskets, which will succeed well without more care and attention than they require in the Orchid-house. It will be found in all cases that the cooler-growing *Oncids* do remarkably well, and, in fact, the writer has had blossoms of *Oncidium flexuosum* as good as could be wished for produced in the plant-case. A further selection may be made from the various species of *Lycaste* and *Odontoglossum*, and those who admire its blossoms may add a plant of *Sophranitis grandiflora*, which is best grown on a small block. In addition to the Orchids (which may be advantageously planted in home-made baskets of virgin cork), plants of *Æschynanthus fulgens*, *Panicum variegatum*, and *Tradescantia zebrina* may be suspended from the upper part of the case. *Isoplepis gracilis* cannot be recommended for this purpose, as it is difficult to keep it sufficiently well watered. The arrangement thus sketched out may of course be modified in all cases by the substitution of many other Ferns for those named, as for instance, *Phlebodium aureum* (selecting a small specimen), *Pteris cretica albo-lineata*, *Gymnogramma chrysophylla*, &c., and by replacing the *Marantas* by *Caladiums* or by variegated-foliaged *Begonias*; but although such *Caladiums* as *C. Chantini* and *C. argyrites* brighten up the case wonderfully, they possess the great objection that their places are necessarily blank during the winter, and, in fact, no deciduous plants can be altogether recommended as suitable for the case. Again, the *Areca lutescens* may be replaced by a *Dracæna* or by a different species of Palm, and by none better than *Cocos Weddelliana*, if expense be no consideration.

Those who have had no experience in the indoor cultivation of plants may be glad of a few suggestions as to the management of the case. The temperature at which it is kept may, for such a collection as that described, be, during the summer, about 70° Fahr. in the day, and somewhat less at night—the gas remaining at the same height, the decrease in temperature of the room will do all that is needed in diminishing the heat. It may be objected that the most fitting temperature for the cultivation of the *Marantas*, *Caladiums*, and other fine-foliaged plants enumerated is somewhat higher than that which would be recommended for some of the Ferns with which they are associated; this, however, is an evil inseparable from every mixed collection, whether in a house or case, and it will be found that the intermediate temperature specified will sufficiently meet the requirements of both classes of plants. During the early part of the summer, when the plants are making new growth, ventilation should be carefully attended to, so that the atmosphere may not become unduly dry; and it

will be found advantageous to have two or three small water-tanks, made of sheet zinc, about 4 in. long by 1 in. wide, and of such depth that when resting on the hot-water pipes their tops are level with the top of the trough containing the soil. These tanks are to be filled with water, which by its evaporation will keep the atmosphere of the case charged with moisture. In addition to a dry-bulb thermometer hanging in the case to indicate the temperature it will be well to have a wet bulb thermometer in the same frame, the two constituting a hygrometer, and in the summer there should not be at any time a difference of more than 2° , or at most 3° , between the readings of the two thermometers, while the nearer the indications are the better. While striving to maintain a sufficiently humid atmosphere, the operator must see that enough ventilation takes place at the same time, or the Orchids and some of the other plants will suffer. This is regulated, as already described, by the revolving ventilator at the end of the base or pedestal, and by the glass slides on the top of the case. There is, however, more danger with a heated case of having too much ventilation than too little, and in fact it will sometimes be found necessary to cover the glass slides with a strip of felt to further check the escape of air through the crevices. The condition of the glass will afford some criterion as to the state of the air; the surface should not be quite dry, but need not be allowed to become so much bedewed with moisture as to obscure the contents of the case. The watering of the plants (with the exception of those in baskets) will not require to be very frequently attended to, in consequence of the large bulk of the soil; once a week will usually be as often as it is required (though some of the plants will enjoy a more frequent dose if the drainage be good), except round the edge, where the contiguity of the pipes causes more rapid desiccation. Of course the supply of water to the little tank of the hot-water apparatus must not be neglected, and it will be well to have a slip of glass to act as a cover and check evaporation, when the tank will not require filling so frequently. In winter the temperature of the case may be allowed to fall to 50° or 60° Fahr., and the atmosphere, as well as the soil, should be kept drier by somewhat freer ventilation and less frequent watering.

Keeping Out Flowers Fresh.—With regard to the length of time during which cut blooms will remain fresh, much depends on the manner and at what time they are collected. Flowers should, if possible, never be cut during the heat of the day, but of all things avoid doing so in sunshine, as they droop almost at once, and even if they regain their freshness when placed in water, it lasts but a short time. Flowers should always be cut with a sharp knife, not with a pair of scissors, and the stems should be severed in a slanting direction; the advantage of doing so is that when the little vessels of the stem are cleanly cut, they draw up moisture freely, which keeps the flowers fresh; but if bruised, absorption is stopped, or at least impeded. The water in which flowers are arranged should be changed every alternate day, if not daily, and the stems of the flowers should be cut afresh.—ANNIE HASSARD.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Brahea filamentosa.—Amongst recently-introduced Palms, few surpass in usefulness and attractiveness this *Brahea*. Its leaves, which are palmatifid, are thickly beset with whitish filaments which enhance their beauty. It succeeds well in a greenhouse, and cannot fail, when better known, to find favour with cultivators of ornamental-foliaged plants.—S.

Hemlock Leaves and their Uses.—Permit me to direct attention to the usefulness of the leaves of Hemlock for decorative purposes; small leaves of this plant have a pretty light Fern-like appearance when interspersed amongst flowers in a vase. The foliage of this plant when growing in dry sunny spots assumes a crimson-brown tint, which for the decoration of light-coloured fruits is very effective.—A. HASSARD.

Panicum variegatum.—Where indoor decoration has to be provided, plants of a trailing or pendulous habit of growth are necessary for furnishing the edges of jardinettes or stands, and this is an invaluable plant for the purpose, its habit of growth and beautiful variegation being in every way perfect. I insert three cuttings in a small pot, and, as soon as they get a few inches long, peg them down close on the soil, when they throw out a number of side shoots and form excellent plants without any further training.—J. GROOM, *Henham*:

THE FRUIT GARDEN.

FRUIT TREE BORDERS AND WALLS.

WITH regard to fruit tree borders, very much must be allowed for climate and situation in considering such matters as soil, depth of border, manures, &c. It is comparatively easy to find a soil in which the trees will grow freely enough, but getting them to ripen their wood sufficiently is another matter. In some parts of the south of England—in Gloucestershire, for example—I could name gardens where all the fruit trees, both on the walls and open borders, are growing in pure loam of a strong texture. The loam was carted from the fields and chopped up, and the borders were made with as much care as is usually bestowed upon Vine borders. The trees did well; they were planted more than twenty years ago, and they are now fine specimens, and have always borne famous crops; but was it the soil that accomplished this? Certainly not altogether. It was the climate more than anything else, as was evidenced in every orchard in the district, though the well-prepared borders and the culture got, perhaps, the largest share of credit in the matter. No doubt a good deal was due to good management; but neither that nor the soil would have accomplished the same results in the more northern parts of the kingdom, or in any late and cold locality. I have seen quite as much pains taken in the formation of borders—a fertile soil used, and everything done that skill could suggest; but the experiment was carried out some 500 miles further north, and in a damp climate, and the results were very different. The trees grew and flourished in the well-prepared borders, or rather they grew too much; but, having neither the temperature nor the light that favours the southern counties of England, they did not mature their wood, and were consequently but indifferently productive. If you have a good fruit-producing climate, any ordinarily good garden soil of which the staple is a fair loam will produce fine fruit of Apples, Pears, or stone fruits, and the richer the soil is the better after the trees acquire age; but the same treatment will not do when the climate is unfavourable. In wet and late districts it is neither advisable to make the borders deep nor rich. Where growth does not begin till near May, or the middle of that month, and is apt to be prolonged till November, it must be clear, I think, that shallow and not over-rich borders, comparatively, and particularly for stone fruits, are best. Shallow borders answer quickly to the sun's heat, and, if not too rich, they produce moderately strong wood that ripens in good time. I am satisfied that strong wood, such even as some people would call gross, produces the largest fruit and the greatest weight of it, but only when it is matured to the core, which cannot be accomplished in the north as a rule. No general advice can be offered, therefore, on the subject of fruit tree borders that would be applicable everywhere in this country. In late, and particularly in wet districts, 2 ft. of soil is enough for Apples and Pears; and for Plums, Peaches, and Apricots, 18 in. will be ample; while in the south, where it is dry and warm, from 3 ft. to 4 ft. is not too much, but this is possibly the limit anywhere in this country. Everyone, therefore, who contemplates planting fruit trees, should be guided by these considerations. As regards soil, the Apple and Pear will thrive in very different soils; but they prefer a good loam, and if marly or calcareous all the better. It is not necessary to pave the bottoms of the borders, for it hardly pays; but when the subsoil is soft and clayey it must be thoroughly well rammed with a heavy wooden rammer, which will prevent the roots getting down. In renovating old fruit tree borders which are poor and exhausted, the ground should be trenched and enriched with fresh loam and rotten cow manure; the first alone, if used in sufficient quantity, is best, and the ramming of the bottom should be done at every trench as the work proceeds, and the work should be done early in autumn, to permit planting in November. For the Peach, Apricot, and Plum—in fact, for all the stone fruits—a strong but not in the least tenacious soil, of a rather calcareous texture, is the most suitable; but I must say I never knew any of the species to fail in a soil that produced general good crops of vegetables, provided the trees were intelligently trained and cared for, and the climate

suited them. Under all circumstances, however, the bottom of the border should be paved or well rammed and rendered impenetrable to the roots, for stone fruits are soon rendered unfruitful, and sometimes ruined, by the roots getting into the moist subsoil, causing gumming and all its attendant evils. In preparing the border, the soil should be trenched and enriched in the usual way with good fresh loam if needful, but afterwards it may be allowed to settle down into a hard mass that will bear treading on with the feet. There is no doubt about stone fruits preferring a hard soil to all others; but it is necessary that such borders be mulched during the summer, for the trees are as easily ruined by drought at the roots as anything else. Almost the only point that can be urged about walls is that they should be high enough—much higher than they are usually built; and this advice is particularly offered to villa gardeners and those who have small gardens with low walls. I doubt if many good examples of culture from low walls—that is, walls under 12 ft. in height—could be furnished. According to my experience, the trees are at the top of such low structures in no time, and then they have to be kept within bounds by a continual system of mutilation both at the root and top, and bareness is the consequence. I am aware it is not always practicable to have the walls as high as they should be; but it is very little use building walls at all if they cannot be made high enough. Height is of most importance in the case of stone fruits, which cannot be successfully trained on any other than the fan system. Pears and Apples may be trained on low walls on the horizontal system, and pretty successfully, provided the trees are prevented from running to growth at their tops by timely pinching and disbudding; but stone fruits, and particularly the Peach, like a long stretch for their branches, and a fan-like spread, to insure a good development and a fruitful habit. For such subjects I should prefer the gable end or side of the dwelling-house to low garden walls, which could be devoted to other things. Where expense of building is a consideration, walls may be heightened by a boarding at little cost. Rough, unplanned Pine boards are good enough, and they may afterwards be painted with pitch to preserve them. Nearly all kinds of fruits usually cultivated against walls will cover an immense extent of wall surface if they have room, and in a very short time too, if they be trained on the extension system, which is superseding every other plan. I have seen Peach trees in Scotland that covered a wall 25 ft. high, and which spread out twice that distance laterally, and bore great crops; and as for Apples, Pears, Plums, &c., they grow even more vigorously than the Peach.

CHEF.

Vines and Potash.—A paragraph having reference to this subject has been going the rounds of the horticultural papers, from which it would seem that the idea of potash being a good manure for Vines is considered as new, whereas it is nothing of the kind. I am not sure if there be any kind of plants that potash would not benefit, but it has long ago been particularly recommended for Vines. In Lindley's "Theory and Practice," published more than twenty years ago, potash, in the form of wood ashes or otherwise, is especially recommended for the Vine, and to be used in large proportions in making up borders (see pp. 145, 146, and 554). Thomson also recommends wood ashes in his "Treatise on the Vine," p. 17, and I remember reading years ago—ten years perhaps—that potash markedly influenced the colouring of the berries. For these reasons I have repeatedly burned all the rubbish on the place here since 1865 for the sake of getting the ashes for the Vine-borders, and the proportions used have only been limited by the quantities which we could procure by these means.—J. SIMPSON, *Wortley*.

Variation in Peach Ripening.—The "Southern Cultivator" gives some curious facts showing the wide variation in the ripening of Peaches, effected by locality and external influences in South Carolina. The first specimens of the Alexander ripened June 19; Hale, July 7. This is probably about the usual difference in time between these two sorts; frequently they ripen nearer together. Tillotson is commonly a week later than Hale, but last year it was several days earlier. A Tillotson ripened its fruit from the 20th to the 24th of June; much earlier than the average. In one year, Serrate, Early York, and Mott's Early Red, ripened with Hale; in another, Hale was greatly in the advance. These facts show the importance of trying new sorts for several years, and in different places, before fixing their proper time of maturity.

PLATE LXXXIII.

GLADIOLUS SAUNDERSII.

Drawn by H. HYDE.

This fine species was sent to me a few years ago from South Africa by Mr. Thomas Cooper, who was then acting for me as a collector of plants. The bulbs, when they reached this country, were in a very distressed condition, having been long out of the ground, and I could not get them to flower until I had grown them for one or two seasons. The first that flowered satisfactorily was planted in the ground under a movable glass covering running along the east wall of a stove, and protected from too much rain and frost. Here it flowered well. My experience of the plant is not great, but I see no reason to believe that its constitution differs from that of other South African species of *Gladiolus*, and if treated as good cultivators grow the fine hybrid *Gladioli* of the present day, it will succeed perfectly. For the specific characters of *G. Saundersii* given below and for notes on the species I am indebted to my friend Mr. J. G. Baker, of the Royal Herbarium, Kew, whose knowledge of the Iridaceæ and whose minute acquaintance with the species of *Gladiolus* make him at present the best authority on this very interesting set of plants. Few bulbs are so worthy of cultivation as those of the genus *Gladiolus*, and looking to the beauty and elegance of their blossoms, they must long hold a place in the estimation of all interested in the cultivation of flowers. Much has already been done in producing a number of very fine hybrid varieties, but there is yet a very wide field for further improvement by means of hybridization, particularly where new and distinct species can be brought into action, such as the species now under consideration, and others of a good showy character and constitution. The latter quality should be particularly attended to, for we want hybrids that will bear our climate in the south of England during the summer, and not suffer from the violent changes which so much affect the growth of plants in our gardens. Many species of *Gladiolus* do well with me here, planted in rich, light, loamy soil about 1 ft. from the bottom of a warm south wall; when so treated, the bulbs seem to gain strength yearly and flower freely. I should observe that our winters are mild here, and under a south wall the frost would scarcely ever penetrate more than 2 in. or 3 in. into the ground.

W. WILSON SAUNDERS.

Raystead, Worthing.

The following is Mr. Baker's description above alluded to:—

GLADIOLUS SAUNDERSII (Bot. Mag., t. 5873).—Bulb globose, with brown tunics; leaves five to six in a distichous, basal rosette, ensiform, 12 in. long, and 1 in. broad when the plant is cultivated, narrowed to the point, with moderately strong, raised veins; stem, including the spike, about 2 ft. high, bracteated by one or two reduced leaves between the inflorescence and basal rosette; spike very lax, secund, 6 in. long when well developed under cultivation, composed of from five to six flowers; spathe-valves lanceolate, acuminate, green at the flowering time, the outer one from 1½ in. to 2 in. long; ovary oblong, ½ in. long; tube slender, curved, not more than 1 in. long; limb bright scarlet, 2 in. long in wild, and from 2½ in. to 3 in. long in cultivated specimens, the three upper segments uniform in size, oblong spatulate, entirely scarlet down to the base, 1 in. broad, the top one standing forward and permanently convex on the back, the side ones reflexing from low down; the three lower segments rather smaller, reflexing from low down when expanded, furnished with a large, pure white patch at the throat, with a few scarlet dots; stamens arching inside, the upper permanently concave, perianth-segment, and reaching to its tip; filaments scarlet; anthers ½ in. long; style reaching to the top of the perianth and stamens, its arms ½ in. long, falcate, with the oblong-cuneate stigmas at the tip. The above description is taken mainly from a plant that flowered in the Kew collection in July, 1872. The only wild specimen that I have seen that I can refer to here with full confidence was gathered on the Krans Kop in Natal, by the late Mr. McKen. I believe Mr. Cooper's plant from the Albert district, spoken of in the "Botanical Magazine," to be not *Saundersii*, but a form of *psittacinus* and the same with Burke's from the Fat River. The general habit is quite that of *psittacinus*, but the leaves are rather thinner and more grassy in texture; the spathe-valves are thinner, more membranous and more acuminate; the shape and colouring of the flower are very different, bright scarlet with a pure white throat, continuous in colour, not at all mottled with yellow. In *psittacinus*, the tube is as long as the segments, the tube being longer than in *Saundersii* and segments shorter, and in *psittacinus* the three lower segments are not only smaller absolutely, but in proportion to the three upper, being generally only about 1 in. long and ½ in. broad, so that the expansion of the limb is

SAUNDERS' GLADIOLUS (G. SAUNDERSI-BAKER).

much greater in *Saundersii* than in *psittacinus*, and this, taken with the purer, brighter colour, gives the newer species a much finer decorative effect.

The annexed illustration was prepared from a plant which flowered in Messrs. E. G. Henderson's Nursery, about this time last year.

SNOWY-LIPPED LADY'S-SLIPPER.

(*CYPRIPEDIUM OCCIDENTALE*).

The annexed illustration represents a pretty little plant which was exhibited in May last at South Kensington by Mr. H. J.

Cypripedium occidentale.

Elwes, in whose garden at Cirencester these hardy Lady's-slippers seem to attain a luxuriance unheard of elsewhere. It is a graceful little species, attaining 10 in. or 12 in. in height, and generally bearing a couple of flowers at the top of its leafy stems. In general habit, size, and form of its flowers, it closely resembles *C. Calceolus*, but is readily distinguished from all other hardy *Cypripediums* by its egg-shaped lip being of a pure white colour. It is undoubtedly a desirable plant,

superior in size and beauty to *C. candidum*, of the type of which, however, it may prove to be a more showy form. Lindley describes a similar plant under the name of *C. cordigerum* as being found scattered through Europe, Dahuria, and, according to Thunberg, also in Japan, adding that its characters are those of our native *C. Calceolus*, except that the lip is pure white. For a long time neither cultivators nor botanists recognised the vagaries in size, form, and colour which are now apparent in tropical and epiphytal Orchids, and the immense variety observable in the hardy, exotic, terrestrial species is just beginning to be apparent. That the hardy Lady's-slippers, however, do vary quite as much as their tropical congeners was shown in a luxuriant batch of the rosy-lipped *C. acaule* (*C. humile*), recently exhibited by Mr. Elwes, among which we noted three forms so distinct in size and colour of the flower and in breadth of the leaf that only a few years they would undoubtedly have been described as new species. Only last year we were astonished at the immense variety in size of flower, breadth of petal, and colouring, as exhibited among perhaps 500 individual clumps of the rosy-lipped *C. spectabile* in Messrs. Rollisson's nursery at Tooting, where, in some individuals the flowers were almost pure white, while in others they were decidedly flesh-coloured, with rosy-crimson, boldly-rounded lips. This variety in the way of colour, is not, however, confined to Orchids; it is equally well exemplified in Irises and many other genera.

F. W. B.

Death of Hardy Bamboos.—The simultaneous death in Great Britain and Ireland of *Arundinaria falcata* is much to be deplored, as large plants of it were strikingly ornamental. At Combe Royal there were fifteen or sixteen huge clumps of it in the grounds, which were greatly admired; one of them—the largest—in a somewhat damp situation, after many canes having from time to time been cut, was found on examination to consist of quite 550 stems, from 15 ft. to 18 ft. high. Perfect seed was produced last summer, from which plants have been raised, but of course many years must elapse ere they rival their progenitors.—JOHN LUSCOMBE, *Combe Royal, Kingsbridge, South Devon*.

Campanula macrostyla.—You may like to see the enclosed flowers of *Campanula macrostyla* (if that be its right name; I had it before as *macrocalyx*). You sent me seeds from Paris, but these are not from your seeds, but from self-sown seeds of a plant that flowered two years ago; but there was no appearance of anything last year.—H. N. ELLACOMBE, *Bitton*. [This is a novel-looking plant with very large flowers, with blue netted veins on a white ground getting purple at the edges, and having a huge stigma. It is wholly distinct from any of the *Campanulas* hitherto in our gardens, and well deserves culture. It is an annual plant, indigenous to Anatolia, and said to be as hardy as Venn's Looking-glass.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Double British Spiræas.—These are admirable garden plants—the Double Dropwort (*S. Filipendula* fl.-pl.) being as graceful in its foliage as pretty in flower. It is used with very good effect as an edging to quarters in Mr. Parker's nursery at Tooting. It is valuable for the mixed border also.

Hardy Lady's-slipper.—*Cypripedium spectabile* has yielded me some sixty flowers in the open ground, and *C. parvidorum* has also bloomed finely, whilst *C. occidentale* flowered without protection a week before the latter, and a fortnight before the former.—H. B.

Burghley Yellow Rose.—A correspondent of the "Journal of Horticulture" states that he has "known this Yellow Rose for the last forty years. It is the double yellow Provence. It was brought originally to Burghley House, the seat of the Marquis of Exeter, by a French cook. I have also seen it growing in a semi-wild state at Bologna. It is a most difficult Rose to bloom, but of great beauty when the buds will open. I know no such yellow. Mr. George Paul, of Cheshunt, informs me they are unable to grow it there. I have several times budded it on the Briar. It is known in Lincolnshire, and is grown at this time in great perfection at Enham Place, near Andover.

Variegated Comfrey.—"T. M." in "The Gardener" says:—*Symphytum officinale variegatum*, a variegated kind of the well-known Comfrey, is strikingly beautiful. Its large lanceolate leaves are broadly and distinctly margined with creamy white. It is a very effective plant for planting in mixed borders, and is no less so in lines in ribbon borders; indeed, it is one of our very best plants for this purpose, far surpassing the variegated Coltsfoot that was recommended so strongly some years since. Our own opinion is that the leaves become shabby too early in the season to make it worth much in the flower garden.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Large-flowered Pelargoniums, if not already placed out-of-doors, should be fully exposed to the sun for two or three weeks in order that the shoots may be ripened before cutting back, a condition that it is invariably necessary to secure, otherwise they do not break properly, for if headed down whilst the wood is in a green, immature state, it often happens that not more than a single eye will break from each shoot so cut back instead of several; when sufficiently matured the bark of the shoots should assume a brown colour for a considerable length above the point where cut back to last year; to assist this maturing process give no more water than will just prevent the leaves flagging, and should the weather be showery, or there be an appearance of thunderstorms, the plants should be laid down on their sides. In the case of specimens that are as large as required, when cut in the shoots should be shortened to within two or three eyes of where cut back to the preceding year; with smaller plants that it is desirable to increase in size, four or five eyes may be left to every shoot. When well managed these Pelargoniums will last a long time: I have had them for a dozen or fifteen years, at the expiration of which time they grew and flowered every year just as freely as when younger. The Fancy kinds may be likewise turned out, they have been grown in houses where they have received insufficient light, and the growth has been correspondingly weakened, otherwise it is not necessary to place them out-of-doors as from their naturally close habit of growth the hardening process is not so essential; they must not be cut so closely as the large-flowered kinds, not being able to break and grow from the hard wood in the same way; if the current season's shoots be shortened to one-half their length, it will be sufficient. Whilst the plants are out-of-doors it is necessary to take care that the soil is not too wet, as the roots are more impatient of any excess of moisture than the large-flowered varieties.

Fuchsias, &c.—Some cuttings should now be put in to keep on growing slowly through the winter; these will give much more satisfaction than old plants, which, as generally managed, are thin and scraggy, showing too much of the old wood, whereas a well-grown Fuchsia should be profusely furnished with young shoots covered with flowers and healthy foliage. Fuchsias, Petanias, and Zonal Pelargoniums that are intended to flower through the autumn should receive all requisite attention, and be kept in a blooming condition so long as there is sufficient atmospheric heat and light, as from this time forward there are comparatively few greenhouse plants to maintain a display.

Cassia corymbosa and Plumbago capensis.—There are not many plants better adapted for autumn blooming than the yellow-flowered Cassia corymbosa; it blooms for a considerable time, is easily grown, and with ordinary care will last for many years; and, as it requires to be cut back moderately after flowering, it need not occupy much space through the winter. Plumbago capensis will now be coming into flower, and if encouraged with manure water, it will both increase the strength of the blooms and cause the plants to keep on flowering longer.

Strawberries.—Amateurs who intend to grow Strawberries in pots should at once make preparation for them. The most satisfactory way is to lay the runners in small pots, allowing them to root therein, after which they can be severed from the parent plants and subsequently moved into the larger pots in which they are to be grown and fruited. This will be found a much better plan than taking runners that have first been left to root into the open ground and then potting them, as by the former process the plants do not receive the check which is inseparable from the latter method, and which, in a season like the present, when the runners in most places are so unusually late, it is necessary to avoid; for upon the time which the plants have to make plump, well-ripened crowns, depends their ability to fruit, always bearing in mind that in the pot culture of Strawberries, unless the plants are thoroughly matured before the autumn advances, it is impossible to ensure a satisfactory crop. Procure a number of 3-in. pots, and place at the bottom two or three pebbles or pieces of crock with some dry, shaly manure, to prevent the soil clogging up the drainage; on this dust a little soot to stop the ingress of worms, fill up the pots to within $\frac{1}{2}$ in. of the rims with ordinary garden soil, to which has been added a little manure, pressing it firmly in; make holes with a planting trowel, and plunge the pots between the plants from which the runners are to be taken; then lay each runner at a joint singly on the pots, securing each with a small stone until rooted. The soil in the pots must be kept regularly watered—in the first instance to encourage the production of roots, and after these are formed to support the plants. This watering is important if the weather be dry, as upon attention or neglect

in this matter depends the successful development of the plants; in hot weather it should be given every day. The runners will need nothing further until well rooted in the pots. It is now also time to prepare ground for planting Strawberries, and with these, as with the plants for pots, during a season like this, it is essential that no time should be lost, otherwise but a small quantity of fruit may be expected from them next year. Strawberries succeed best in strong, heavy land, frequently doing well in soil of a clayey nature, provided it be sufficiently drained, for if there be stagnant water in it, the plants will die off in quantity through the winter. Where marl can be had, from its naturally rich constituents, I should give it the preference over clay, but so far as the mechanical influence which clay exerts upon the soil in enabling these plants to grow and fruit well, it is but slightly inferior, and there are few localities in which clay is not obtainable at little cost. Land that has been previously cropped with any culinary vegetable will suit the Strawberry, or still better if broken up from Grass; in the latter case it should be dug 12 in. or 15 in. deep, putting the sward in the bottom, digging in (as the work progresses) a moderate dressing of manure; where the ground has been previously cropped, dig it over, or if there be a sufficient depth of good soil, trench it 15 in. deep, adding manure more or less as required. As soon as the ground is so far prepared, where the soil is too light 3 in. of marl or clay should be laid on the top, breaking it very small, as the finer it is reduced in this way the shorter time it will require for the air and sun to dry it thoroughly, without which it cannot be properly disintegrated. If the weather be hot, ten days will suffice to dry the lumps right through, which upon being moistened with rain or watered by hand will crumble down, and should be forked into the soil, mixing it regularly with about 6 in. of the surface, after which tread the ground solid and plant as soon as the runners are ready—a distance of 2 ft. between the rows and 18 in. from plant to plant in the rows will suffice, immediately giving a good watering, and if the weather continue dry, lay some Pea-sticks over the plants, on which spread bast mats, old blinds, or any material that will shade them for a few days until they get hold of the soil; where sufficient material of this sort is not available, any flat branches of Evergreens, such as those of the Spruce or Yew, stuck horizontally in the ground to protect them from the sun, will answer the purpose; continue to water as required. For the limited extent which amateurs generally plant, it is worth while taking some trouble to give requisite shade, which will not be needed more than ten days or a fortnight, after which the plants will be sufficiently strong to support themselves during the ensuing winter. Where the space to be planted is greater than can be kept shaded and watered as above, there is no other way but to wait for showery, dull weather, in which case it is often advisable, as soon as the runners are ready, to plant them in nursery beds 5 in. or 6 in. apart, which will admit of a considerable number being shaded and watered with little trouble afterwards; when the weather gets cooler with more rain, they can be transferred to where they are to be permanently grown. There is such a difference betwixt the quantity of fruit produced by Strawberries where all possible attention is given to assist them, and where but moderate care is bestowed upon them, that it is worth while, if only a limited breadth be grown, and the situation naturally not over favourable for their cultivation, to take the trouble of layering the runners in small pots for planting-out, similarly to the way described for those intended to be fruited in pots, more especially in such seasons as this, when the runners are late. In the case of Strawberries, as of other plants, it is, no doubt, desirable to study change or rotation of crop. Potatoes prepare the ground as well as anything, but it often happens, especially in gardens of a limited size, that it is more desirable to continue growing some particular plant, such as Strawberries, in the same place; where this is the case, and the ground is occupied by plants that are becoming exhausted, they may be cleared off or dug in with a good dressing of manure, adding marl or clay where required, re-stocking the ground with young plants which will go on bearing as if growing in fresh land. I am acquainted with places where Strawberries have been continuously cultivated for fifteen or sixteen years, and this by men who grow for market, and who most certainly would not keep them on the same ground longer than they would answer.

Cabbage.—Some seed should immediately be put in, but in determining the time of sowing for the spring supply, it is necessary to discriminate betwixt the kinds grown, and also to make some allowance for different parts of the country. If early sorts such as the Early York be sown from the 20th to the 25th of this month in the southern parts of the kingdom, I have generally found them liable to run to seed the following spring; whereas if the somewhat later and larger varieties (of which Enfield Market may be taken as a representative) be sown, I have not seen them so affected; consequently

where the earliest kinds are grown, it is better not to sow until quite the end of the month. To those who have not had much experience in the cultivation of vegetables, it may appear strange that the short interval of a week or ten days should have an influence in the matter, but nevertheless it has, and where sowing is delayed beyond the proper time in some seasons, it will affect the time of the crop being ready in spring more than the few days' difference of sowing, as so much depends upon the plants getting strong before the winter sets in.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

July 23.—Potting late Tuberoses and stove plants. Shifting Daphnes into a mixture of loam, peat, charcoal, bones, and sand; also Amarantus and Dracenas, and put them in warm house. Digging up Rivers' Early Ashleaf Potatoes, watering Vine borders, also Peas, and afterwards mulching them with manure. Thinning Mignonette in pots, and clipping *Cerastium* edging, and preparing borders in which to put *Pelargonium* cuttings.

July 24.—Shifting and re-surfacing some of the *Masdevallias*, and *Odontoglossum vexillarium*. Drying off *Dendrobium Cambridgeanum*. Watering permanent Peach Trees, also the plunging material between Fig trees in pots. Layering Strawberry runners with which to make new plantations. Digging land for Turnips, cutting Lavender, weeding and thinning Chicory, and earthing-up Cucumbers.

July 25.—Potting *Abutilon Boule de Neige*; also *Primulas*, and afterwards placing them in a close shady frame until well rooted. Planting Coleworts on early and dug Pea land, making the holes with a crowbar, and afterwards watering the roots well in. Putting in more cuttings of *Poinsettias*. Staking *Petunias* and *Rhodanthes*; watering Celery. Dressing Apple Trees with Paraffin to kill American blight.

July 26.—Potting Sir Harry Strawberries for forcing. Putting in cuttings of Lady Plymouth *Pelargoniums* for pot culture. Watering Herb beds and Pear trees. Filling pits with fermenting material in which to plant Cucumbers. Digging land for main crop of Spinach.

July 27.—Potting Pinks and winter-flowering Carnations. Sowing Sir Joseph Paxton French Beans under the protection of a wall. Earthing-up Cauliflowers. Planting some *Perilla* amongst *Pyrethrum*, and also planting Paris Cos Lettuce. Putting guano down in Orchid-houses, and cleaning all Orchids that are infested with any kind of insects.

July 28.—Potting *Caladiums* and young *Begonias*. Sowing *Nemophilas* for pot culture; also Ten-week Stocks, *Phlox Drummondii*, *Lobelias*, *Rhodanthes*, *Schizanthus*, and *Clintonia pulchella*; also sowing more Lettuce, American Cress, French Beans, and Spinach. Watering *Rhododendrons* likely to suffer from drought. Putting in cuttings of *Centaurea* and *Artemisia*. Tying-up dried Basil and putting it in paper. Digging land for July-sown Lettuce.

Hardy Flowers.

AURICULAS.—The cool moist weather which we are now having is just suited to newly-potted Auriculas. They should now be screened from heavy rains, but a soft gentle shower may be allowed to fall upon them occasionally. When the frames are on a north aspect only a slight shading is required; but if the position of the frame containing the plants is such that the sun can strike it during a portion of the midday when it is at its hottest, some shading is necessary. If aphides gather about the crowns of the plants, they should be brushed off, and the surface-soil unceasingly stirred, and kept free from weeds.

FUCHSIAS.—There are some Fuchsias which possess an individuality of character both in leaf and flower that renders them valuable as decorative plants. The fine old *F. fulgens* may appropriately head the list, with its long orange, red, and brilliant carmine flowers: it is a very free-flowering plant, and one which lasts long in perfection. A variety called *F. rubra splendens* has the same flowers in every respect, but the leaves are smaller, and blotched with claret. Then there are the fine old *Fuchsia corymbiflora* and its light variety, *F. virginialis*, of which I have a fine plant in full bloom, and very charming it is. In addition I have *F. microphylla*, the most minute of all Fuchsias, *pumila*, *globosa*, *Riccartoni*, *Dominiana* and *spectabilis*, all as varied

in character as they are interesting. They are all the more attractive when mingled with some of the leading modern varieties, and of these I can confidently recommend *Sedan*, *Germania*, *albo-coccinea*, *Noblesse*, *Lustre*, and *marginata*; and for their handsome foliage, *Avalanche* and *Wave of Life*. Some of these are so distinct from ordinary Fuchsias as to be doubly valuable on that account. *F. Riccartoni* is now flowering freely on a west wall in a somewhat cool and shady place in the open air, where it had no protection for the past three years.

GLADIOLUS.—As these are now throwing up their flower-stems, care must be taken to tie them securely to stakes, so that they may not be broken off by the wind. Cases of failure are reported, probably owing to the excessive moisture of the ground and the coldness of the weather at the time of planting. I had some valuable seedlings which I kept out of the ground till they appeared almost shrivelled to nothing, but they have made an excellent growth, and appear to be doing well. In the case of such a spring as the last it is, perhaps, the least risk to plant late rather than early. Beds of *Gladioli* should have the surface soil stirred and freed from weeds. A mulching with decayed cow-manure will be found of great service, but as it is very apt to be infested with grubs and other insects likely to be injurious to the plants, it is well to thoroughly scald it by pouring boiling water over it, allowing it to soak for a few minutes, when it will readily crumble to pieces. The water should be poured about the roots as soon as it is cool enough, before the mulching is put on.

PANSIES.—The late rains are greatly helping Pansies, which are now throwing up young growths from the roots. These may be taken off for cuttings as soon as large enough, and put into a well-prepared bed under a shaded north wall. Such a bed as this is of great value at this season of the year for striking cuttings of such plants as choice *Antirrhinums* and *Pentstemons*, Pansies and *Violas*, *Cheiranthus*, *Rockets*, &c. I have such a bed as this, which is raised about 9 in. above the ground level. At the bottom is a layer of brick-rubbish, and over this another of coarse cinder-ashes, and above that some pieces of green turf, with the Grass downwards. This was trodden down firmly, and then filled up with prepared soil to the depth of 4 in., made up of fine sifted loam and leaf-mould, a little rough Bedfordshire sand and some finely-sifted cinder-ashes. This is well mixed together, and the whole placed in the bed and firmly pressed down; then I add a thin layer of very fine cinder-ashes on the top. In such a compost cuttings of the plants I have named strike freely, and the cinder-ashes seem to keep the soil open, and slugs and other vermin at bay. Cuttings of *Violas* may be similarly treated. A little top-dressing greatly helps the production of strong young wood, from which cuttings can be made.

PETUNIAS.—Beds and ribbon lines of these are now very effective. For decorative purposes the small, finely-formed, striped section is to be preferred; the growth is dwarf, compact, and somewhat spare, while the flowers are produced with great freedom. There is a section with a more robust growth, which produces large but looser flowers than the foregoing, flowers that hang their petals and have a flabby appearance; this section does not bloom so freely as the foregoing. Sometimes persons who grow Petunias are apt to be disappointed because the flowers come self-coloured; this is frequently the case in regard to their early blossoms, but the later ones invariably break into the correct striped form, and then all sense of disappointment is lost in the contemplation of so much beauty. During dull, wet weather, the flowers will come self-coloured, but let a hot sunny day follow, and then the striped character flashes forth again with charming effect. Petunias, both double and single, make fine exhibition plants; they succeed uncommonly well in the west of England, especially the single varieties, where plants can be seen having from fifty to one hundred flowers—and very fine flowers, too. There is nothing like them to be seen round London.—D.

Fairmount Park.—The authorities in charge of Fairmount Park, Philadelphia, have decided to use a portion of that domain for educational purposes, and have asked the co-operation of the Pennsylvania Horticultural Society. It is proposed to begin with the hardy perennial and Alpine plants, and form as complete a collection as is possible. Every character of soil and location is readily obtained, even for the aquatic plants; so that we may anticipate a rich treat for the student of botany when rambling through these grounds in future years. Rockeries are in anticipation for such species as prefer this peculiar treatment, and the many shady nooks and corners will certainly cause our choice natives to feel at home.

Crataegus Hosti.—The "Revue Horticole" figures *Aria Hosti*, a species allied to our common Whitebeam, but with corymbs of rusy flowers. It is the *Sorbus Aria* var. *sudetica* of Linnaeus, and has other synonyms. It is grown by MM. Simon-Louis, of Nancy, under the name of *Crataegus Hosti*.

MILLETS.

FROM whatever point of view the members of the large Order Gramineæ may be regarded, whether as ornamental or useful plants, they always claim a large amount of attention. From the common Meadow Grasses, many of which are of the most delicate and beautiful forms, to the stately Bamboos of the tropical jungles, all have something to recommend them, either for artistic grouping, for their individual grandeur, or for their importance as food plants. Under the general name of Millet we find collected together numerous Grasses of varied habit, but all more or less beautiful in form, of wide geographical range, and moreover of great value in an economic point of view. In many countries Millets under their several genera and species form the staple food crops of the people. With us, however, the grain is comparatively little known, and the name itself is oftener applied to *Panicum miliaceum* or *Setaria italica*, both of which are represented in the accompanying figures, than to anything else. That Millet may claim an equally ancient history with Wheat and other well-known cereals—though not of equal importance—seems probable, from the fact of its being mentioned along with Wheat, Barley, Beans, and Lentils in the book of the prophet Ezekiel; and Virgil says—

Sow Beans and Cinquefoil in a mellow soil,
And Millet, springing from your annual toil.

What the plants were that furnished the ancients with Millet is a question not of easy solution. At the present time the following genera may be roughly charged with producing Millet in some of its varied forms. Taking those, as stated above, that are best known in this country as Millet, we find that the genus *Panicum*, which is typical of the tribe Paniceæ, includes a vast number of species which, though widely distributed, have their head-quarters in tropical and sub-tropical countries. *Panicum spectabile*, in Brazil, grows to a height of 6 ft. or 8 ft., and on the Amazon some other species are quite as luxuriant. *Panicum miliaceum* is one of the kinds largely cultivated in India. It has a loose, nodding panicle, and long, broad, slightly-hairy leaves. The seeds are ovate, somewhat pointed at each end, measuring when ripe about an eighth of an inch in length, smooth and shining. Several varieties of this Millet are known, distinguished chiefly by the colour of the seed—thus in the common kind the seeds are yellow, in one variety grey, in another white, and in one, more distinct perhaps than any other, the seeds are almost black, and the panicle itself has a blackish-green colour. Under the name of Millet Rice, *Panicum miliare* is also cultivated in India. Its panicle is somewhat similar to that of the last, but perhaps even more graceful, bending down as it does with the weight of its ripened grain. *P. frumentaceum* is also frequently cultivated in India, the produce on a dry soil being, it is said, about forty-fold. The seeds are very largely used as food both by man and for cattle. This species is distinguished by having an erect instead of a drooping panicle.

The other species of Millet shown in the annexed illustration is that generally known as the Italian Millet (*Setaria italica*). Its seeds, as will be seen, are borne in much more compact spikes than in the last genus, the hairy or bristle-like appendage of the involucre being also a distinct character. This plant grows to a height of from 3 ft. to 5 ft., the leaves sheathing, and the spikes curved or bending with the weight of the numerous seeds which are small and light-coloured, and when ripe are easily shaken out of the husk. They are largely used in Italy for the preparation of a kind of flour which is made into bread. In India it is also cultivated on light, dry soils yielding two crops in the course of nine or ten months, the first being harvested in June or July, and the second between the months of September and February. The seeds are very largely used when finely pulverised for pastry or for making light foods for invalids. Under the name of German Millet, described as *Setaria germanica*, is cultivated in Moravia, South Hungary, and Lombardy, a plant of a dwarfer habit than the preceding with a shorter, more compact, and more upright spike, the seeds, however, being similar in size and shape. It is known as "Moha" by the Germans, and the seeds are used for making bread as well as for boiling in soup and in milk, and they are also used for feeding domestic animals.

In the genus *Sorghum*, the seeds of which, like those of the preceding genera, are known as Millet, the most important is *Sorghum vulgare*. This is also well known as the Guinea Corn, and some of its varieties grow to a height of 6 ft. or 7 ft. The panicles in some forms are very dense, in others more loose and spreading, but never absolutely drooping

Panicum miliaceum.

when fully ripe and the spikelets open or expanded, the panicle has a very graceful appearance. The seeds are large, nearly oval, and very variable in colour in the different varieties, some being white, others yellow, and others again reddish or black. In one or other of these forms the species is largely cultivated in Italy, Spain, and other parts of Southern Europe, and also in Egypt, Asia Minor, Arabia, India, where it is called Dhurra, and in West, and even Central Africa. In India it is very extensively cultivated and used as food, the flour of the white variety being of a good colour and, when properly prepared, equal in appearance and value to that from Indian Corn or Maize. The produce upon good soil in India is said to be upwards of a hundredfold. In the Gulf of Guinea, and on the Gold Coast, the seeds are mostly used for making a coarse kind of bread, and many tribes subsist almost entirely on this kind of food. By many it is very roughly prepared, the seeds being simply cleansed of the husk, washed in water, and then boiled, and in this form they are eaten either with meat or cured fish, and sometimes mixed with other esculents. Besides their use as food, from these seeds is prepared a fermented beverage of different degrees

of strength, known under different names, according to the greater or lesser degrees of fermentation to which it has been subjected. In some of the French provinces *Sorghum vulgare* is grown chiefly for the purpose of feeding poultry. Though often grown in botanical collections in this country, the *Sorghums* have been proved unsuitable for general cultivation with us, requiring more heat and dryness than our climate affords. A very good collection of panicles of several varieties of *Sorghum* is contained in the Kew Museum. From the panicles of a large variety of this Grass, after being denuded of its seeds, excellent brooms and brushes are made, generally known in commerce as Whisk.

Sorghum saccharatum is generally known under the name of the Sugar Millet, or sometimes by that of the Chinese Sugarcane. In America a good deal of attention has been paid to the cultivation of this plant and to the manufacture of sugar from the stalks, a full account of which may be found at p. 649 of Porcher's "Resources of the Southern Fields and Forests," new edition, Charlestown, 1869. The stalks of these *Sorghums* are much valued for cattle food on account of the quantity of sugar which they contain. Under the name of "Gero," the round grains of *Penicillaria spicata* are in daily household use by the natives on the rivers Niger and Gambia. Though it is cultivated at the present time to a great extent, it is said to

Setaria italica.

be not so generally used among some tribes as formerly. From what has been gathered by travellers from some native tribes, it seems clear that this grain "constituted the most ancient kind of food adopted by their primitive forefathers, and on this account was especially dedicated to the celebration of the more august feasts and religious ceremonies." The plant has long, sheathing leaves, and a terminal, cylindrical, erect spike about 1 in. in diameter, and from 1½ ft. to 2 ft. long. The seeds are somewhat obovate, smooth, and of a

yellowish colour. For convenience of transit among the tribes of the Niger, a large number of these long grain-bearing spikes are frequently joined together by a system of plaiting of the stalks, the spikes standing out at right angles from each other; in this way they are easily rolled up together, and when wanted for use a few spikes are detached or cut off, and the grains beaten out. A fine illustration of this kind of packing is shown in the No. 2 museum at Kew. The seeds are mostly used in the preparation of a coarse kind of bread. On the Gambia a favourite dish is made by pounding the seeds with the husks in a mortar, and after sufficient pounding pouring the contents from one calabash to another, and allowing the wind to blow away the chaff; this is done till the whole of the husky particles are removed. The cleansed grain is then replaced in the mortar, and beaten to a very fine flour; water is added and the mass made into a kind of stiff paste, the vessel containing the mass being continually shaken by a peculiar rotatory motion, so that the contents gradually resolve themselves into very small granular particles, similar to Sago. It is now put into a large earthenware cooking pot, pierced through the lower portion by numerous small holes; through these holes the steam ascends from another vessel beneath filled with water, into which meat or fish, vegetables, and condiments, are put: the vapour arising from this permeates and softens the whole mass above. Amongst the poorer tribes in some parts of Africa this grain is simply eaten when freshly gathered and in its raw state, or dried or parched in the sun. Brnised and then soaked in water, it forms a kind of stock food, convenient in travelling for the use of pilgrims and soldiers; over and above its use as food, the grains of this species of Millet are used for making several kinds of beverages of a nature more or less intoxicating. In parts of Western Africa where the cultivation of this corn prevails, and at the period of the ripening of the grain, the fields are visited by immense flocks of small birds, which have to be closely watched in order to keep them from eating the grain. From the few examples of the cultivated species of Millet just alluded to, it will be seen that these small-grained Grasses are almost as important in some parts of the world as are Wheat, Barley, or Oats, in our more northern clime, besides which they have much to recommend them, if only for their natural beauties. J.

Gallirrhoe macrorrhiza alba.—No white form of any species of this favourite genus of Malvaceous plants has hitherto been discovered; the present introduction has therefore some claim to notice on the score of novelty, apart from its intrinsic merits, which are considerable. It is of very neat habit of growth, producing from a tap root, which ultimately attains some size, an erect stem from 1½ ft. to 2½ ft. high, which bears a corymbose raceme of pure white flowers, on long, naked foot-stalks, articulated near the summit, the corolla being rather more than an inch across, and the calyx without the involucre leaflets, which occur in some other species of this genus. The foliage, mostly radical, is cordate in form, with crenate margins and long-stalked. The plant appears to occur in several shades of colour, varying from rosy-purple to pale rose and white. Sown early, it will bloom the first year. It is a native of the South-western States of North America.—W. THOMPSON, Ipswich.

Anchusa capensis.—Although this has been introduced since the beginning of the present century, it may still be considered almost a stranger in our gardens, but for what reason it is difficult to imagine. Everybody admires its congener, *A. italica*, which is inferior in colour to *A. capensis*, although the flowers of *A. italica* are larger. Those of *A. capensis* surpass the blooms of *Myosotis azorica* in brightness, and, appearing as they do after those of *A. italica*, they form a desirable succession. It succeeds in such positions as are suited to *A. italica*.—J. T. R.

Effects of Sea Water on Land.—Mr. Reinders, from one of the German agricultural experimental stations, says:—Land that has been submerged by sea water generally proves sterile for some time, in some cases for ten to fifteen years. This can be traced to the co-operation of the three following chemical causes, in addition to the mechanical injuries produced by the inundation:—1. To the introduction of too great a proportion of chlorine salts. 2. To the hygroscopic property communicated to it, preventing it from drying properly. 3. From the formation of green vitriol or sulphate of iron, which is known to exert a very prejudicial effect upon plant growth. Land which has thus been damaged should be drained as quickly as possible, and sown with Grass and Clover and allowed to rest. Experience shows that it recovers its fertility sooner if treated in this way than if cultivated all the year round as arable land.

TREES AND SHRUBS.

HARDY FLOWERING TREES AND SHRUBS.

At a recent meeting of the Central Horticultural Society of France, M. Alphonse Lavallée, the Secretary-general, showed flowering specimens of six varieties of rare trees from his Arboretum at the Château de Segrez, with respect to which he made the following interesting statements:—Firstly, there are two varieties of *Aria*—*A. latifolia*, and another as yet undescribed variety closely resembling this, to which he gives the name of *Aria majestica*: this new variety is a tree remarkable for its fine foliage and its large, white, sweet-scented blossoms, to which succeed red fruits, which produce the effect of those of the ordinary Service tree or *Sorbus aucuparia*. This tree has an exceptionally fine appearance, from its large and ample top, which justifies the appellation of *majestica*; the origin of this fine variety is unknown. It may be occasionally found in nurseries under the name of the Nettle tree of Nepal, a name under which M. Lavallée met with it in the nursery of M. Conlombier, at Vitry. These trees are usually slow in their growth, but this variety is vigorous and grows rapidly. The next variety was *Halesia parviflora*, which forms a graceful tree, the general aspect of which is somewhat like that of a *Fuchsia* with white flowers. Unhappily this variety is capricious in its vegetation, and shows itself too apt to lose its branches; it is therefore not much to be recommended. Four varieties of *Viburnum* were then shown in flower, consisting of *V. pyriforme*, *V. Oxycoccoides*, *V. macrocephalum*, and *V. Fortunei* or *himalayense*. The first-named is a little-known variety which forms a vigorous and free-flowering hush with red fruits, but against which must be cited the drawback of the smallness of its foliage, which gives it a bare appearance when the flowering is over. The second-named is a very ornamental shrub, owing to its handsome foliage, pyramidal habit, and red fruits with which it is covered, and which it holds during the entire winter, and till the time of flowering comes round again. M. Lavallée strongly recommends this variety, and offers cuttings of it to any lover of shrub who likes to apply to him for them at the proper season. The *V. macrocephalum* is well known to all growers of hardy shrubs in this country as an exceedingly fine variety which should be in every collection: it was first introduced by Fortune from the North of China, which accounts for its extreme hardness, the severest frost having no effect on it whatever. It is sometimes called *V. Fortunei*, but M. Lavallée has decided that this name more correctly belongs to another variety, of which he submitted specimens in proof of his assertion. W. E. G.

NOTES ON GARDEN VEGETATION FOR JUNE.*

By JAMES M'NAB.

THE weather during June has, upon the whole, been pleasant, but by no means warm. The lowest temperatures experienced were during the nights of the 7th, 12th, 13th, 16th, 17th, and 24th, when 43°, 39°, 41°, 37°, 41°, and 40°, were indicated; while the highest night temperatures were on the 4th, 10th, 21st, 26th, 27th, and 29th, when 52°, 53°, 52°, 58°, 55°, and 55°, were indicated. At this time (June 30) vegetation is still very backward; last season was considered a late one, but this year many trees are still later, both as regards leaf and flower. A few instances may be quoted to show the difference, the same plant or tree being fixed on each year for the purpose. The flowering Ash (*Fraxinus Ornus*) was in perfection this year on June 28; in 1876 it was so on the 15th, and in 1875 on the 7th. The common Elder (*Sambucus nigra*) did not show its first open flower this year till June 27; in 1876 it was as forward on the 16th, and in 1875 on the 5th. The Portugal Laurel had no flowers expanded on June 30, while in 1875 it was in full flower at that date; during the same year the *Cratægus tanacetifolia* was recorded as being in full bloom on June 25, while this year no flowers are yet to be seen open. The ordinary Thorns have been very full of bloom, particularly the single white and red, both being in perfection on the 25th. In the case of the Lime tree (*Tilia europæa*), although covered with blossom-buds, no flowers are expanded. The following trees were observed to be in a free-flowering condition on June 30, viz., double Laburnums, some white Hawthorns, scarlet-flowering Horse Chestnuts, flowering Ash, and many varieties of *Sorbus*, while

the common Horse Chestnut, although it showed its first open flowers on June 20, they were exceedingly poor, and have been so throughout, scarcely a tree, except in sheltered situations, having perfect leaves. The large *Sorbus domestica* in this garden, which has been occasionally noticed for its peculiarity of flowering, has this year the west half covered with bloom, while last year it was the east half; this alternation of flowering has been observed on the same tree for several years; the tree has two main branches proceeding from a stem 7 ft. high and 5 ft. in circumference. In my report for May I stated that a peculiar yellow tint was observed on the young foliage of many trees, particularly when late in coming out. It is somewhat remarkable that the older trees of what is known as the Corstorphine Sycamores, celebrated for their early yellow foliage, which afterwards becomes green, have this year been late in coming into leaf, and were deficient both as regards colour and duration in their coloured condition. The American Oaks, more particularly the species known as the *Quercus rubra*, has this year been late in coming out, all the leaves having a peculiar yellow tint. Subjoined is a list of trees whose foliage is still behind on June 30, viz., Sugar Maple, Scarlet American Oak, Weeping Ash, small-leaved English Elm, Walnuts, Turkey Oak, Hornbeam, *Celtis occidentalis*, *Ostrya virginica*, *Juglans alba*, Tulip tree, *Ptelea trifoliata*, *Robinias*, *Catalpa* tree, *Platanus*, and *Taxodium*. Besides trees, perennial, herbaceous, and annual plants are very backward.* On the rock garden 336 species and varieties were counted in flower on June 30, while last year, at the same date, the number was 452 species and varieties.

List of some of the more Conspicuous Plants in Flower on the Rock Garden.

<i>Arenaria balearica</i>	<i>Menziesia polifolia variegata</i>
" <i>graudiflora</i>	<i>Onosma echioides</i>
<i>Aster alpinus albus</i>	<i>Orchis foliosa</i>
<i>Astragalus alpinus</i>	" <i>maculata superba</i>
" <i>leontinus</i>	<i>Oxytropis cœruleus</i>
" <i>vaginalis</i>	" <i>Lapponicus</i>
<i>Arum Palestinum</i>	<i>Papaver alpinum</i>
<i>Aubrietia grandiflora major</i>	" <i>aurantiacum</i>
" <i>Hendersoni</i>	<i>Phlox Nelsoni</i>
<i>Brodiaea coccinea</i>	" <i>violacea</i>
<i>Campanula turbinate</i>	<i>Potentilla peduncularis</i>
" <i>alba</i>	<i>Pentstemon humilis</i>
<i>Chamaebatia foliolosa</i>	" <i>Menziesi</i>
<i>Chrysobactron Hookeri</i>	<i>Pernettya candida</i>
<i>Cyclobotria cœrulea</i>	<i>Polemonium pulchellum</i>
" <i>pulchella</i>	<i>Primula scotica</i>
<i>Delphinium cashmerianum nudicaule</i>	" <i>sikkimensis</i>
<i>Dianthus alpinus</i>	<i>Rhododendron ferrugineum</i>
" <i>nitidus</i>	" <i>hirsutum album</i>
<i>Erodium Manesavi</i>	<i>Rosa pyrenaica</i>
<i>Epilobium latifolium nanum</i>	<i>Rubus arcticus</i>
<i>Erigeron Roylei</i>	<i>Saponaria ocyroides major</i>
<i>Eriogonum aureum</i>	<i>Saxifraga nuntata</i>
" <i>subumbellatum</i>	" <i>pyramidalis</i> —and others
<i>Erysimum helveticum</i>	<i>Salvia carduacea</i>
<i>Fragaria lucida</i>	<i>Sedum spatulatum</i>
<i>Genista pilosa</i>	<i>Silene alpestris</i>
<i>Hæmanthus, sp. Natal</i>	" <i>maritima rosea</i>
<i>Helianthemum</i> of sorts, single and double	<i>Symphyaundra Wanneri</i>
<i>Hutchinsia alpina</i>	<i>Trifolium alpinum</i>
<i>Linnaea borealis</i> , Scotch	" <i>uniflorum</i>
" <i>American</i>	<i>Vaccinium Morteniana</i>
<i>Lithospermum prostratum</i>	<i>Veronica Guthriana</i>
<i>Meconopsis nepalensis</i>	" <i>rupestris</i>
	" <i>pinguifolia</i>

On the table were placed about eighty species of rare and interesting plants, cultivated in pots; amongst them were:—

<i>Androsace lanuginosa</i>	<i>Lilium columbianum</i>
<i>Arnebia echioides</i>	<i>Myosotis alpestris vera</i>
<i>Astragalus alpinus</i>	<i>Nigritella angustifolia</i>
<i>Brodiaea coccinea</i>	<i>Papaver alpinum</i>
<i>Cyclobotria alba</i>	" <i>aurantiacum</i>
" <i>pulchella</i>	<i>Pentstemon glaber</i>
<i>Cyrtanthus Macowai</i>	<i>Primula scotica</i>
<i>Delphinium cashmerianum</i>	" <i>sikkimensis</i>
<i>Dianthus alpinus</i>	<i>Salvia carduacea</i>
" <i>Henryanus</i>	<i>Saponaria caespitosa</i>
" <i>neglectus</i>	<i>Saxifraga flagellaris</i>
<i>Draba violacea</i>	<i>Sedum californicum</i>
<i>Epilobium oboordatum</i>	<i>Spraguea umbellata</i>
<i>Gentiana ornata</i>	<i>Triteleia laxa</i>
<i>Houstonia cœrulea</i>	" <i>Murrayana</i>
<i>Iris filifolia</i>	" <i>violacea</i>

* On July 13 it was impossible to procure in the fields on this side of Edinburgh specimens of Wheat, Oats, and Barley, in a state for examination at the botanical class, a circumstance of rare occurrence at this particular date.

* Read before the Botanical Society of Edinburgh, July 12, 1877.

THE COLORADO SPRUCES.

By PROF. C. S. SARGENT, Director of the Arnold Arboretum.

THE three Spruces of the Rocky Mountains, Douglas', Menzies', and Englemann's, botanically known as *Abies Douglasi*, *A. Menziesi*, and *A. Englemanni*, seem destined to take such an important position in the northern portions of the United States and Europe that some account of them at the present time will be interesting and will, I hope, help to make them better known to nurserymen and planters generally. *Abies Douglasi* and *A. Menziesi* have been in cultivation for half a century, having been introduced into England from seed collected in California and Oregon, by David Douglas, a celebrated Scotch botanical traveler, whose labours and untimely death in the pursuit of his profession, the Douglas Spruce will always recall to botanists and lovers of Coniferous trees. Although these two trees grew well, and soon became popular in England, all efforts to introduce them into our extreme Northern States failed, or practically failed, as after a few years, more or less, some unusually severe winter had killed all that had been planted, and it seemed settled that our plantations must be made without reference to these really fine trees. But in 1862 Dr. C. C. Parry, to whose indefatigable journeyings and researches are due the solution of so many of the botanical problems of the Western Territories, visited the Rocky Mountains of Colorado, and sent from there seeds of these two trees to the Botanic Garden of Harvard University. From this seed a large number of plants were raised, which, with a view of testing their hardiness, have been widely distributed through several of the Northern States, where they have stood the trial of the last dozen years, and many of them, too, very trying years to plant-life, without, so far as I have heard, a single one, whether planted on the most exposed situations of the New England coast, or in heavy clay soils in Pennsylvania, having been injured in the slightest degree. As a plant is generally more susceptible to injury from cold or drought during the early years of its life, and as our plants have passed through these first years so successfully, their perfect hardiness and adaptability to the soil and climate of the Eastern States must, I think, now be conceded. But why, it will be asked, are these Colorado trees hardy, when the same species had, up to a dozen years ago, proved so unsuited to our climate? The reason for this apparent anomaly is obvious, if we take into consideration the fact that individuals of the same species vary to a remarkable degree in their power to adapt themselves to various conditions of temperature, and that the power of an individual to withstand cold, increases in proportion to the distance at which its seed-bearing parent is situated, either from the Equator, or above the sea-level; or, in other words, our two Spruces are perfectly hardy in New England, the seeds from which they were raised having been collected at an elevation of some 8000 ft. while plants of the same species, raised from seed collected at comparatively low elevations near the Pacific coast, have almost without exception proved too tender for the climate.

THE DOUGLAS SPRUCE, which botanically is closely allied to the Hemlock of the Eastern States, and which, though coarser and less graceful, it somewhat resembles, extends through California and Oregon, as far north as Sitka, and in the Rocky Mountains from New Mexico northward, growing to an enormous size on the Pacific coast, where, in favourable situations, it often attains a height of from 200 ft. to 300 ft., with a diameter of trunk of from 10 ft. to 15 ft. In the Rocky Mountains, however, its average height is hardly above 80 ft., and its growth there is slower and less productive of valuable timber. But it is as an ornamental, and not as a timber tree, that we are now considering this species; as such, few Coniferous trees surpass or even equal it, for it has thus far retained in cultivation (and some of the first trees planted in England are now over 100 ft. high), its lower branches, and close, dense, pyramidal habit; and in this it contrasts most favourably with such trees as the Norway Spruce, and many of the Spruces and Silver Firs of the Old and New World, which, however beautiful and thrifty in their young state, become either naked and unsightly skeletons, or destitute of lower branches, long before they have reached half their full deve-

lopment. For this reason the Douglas Spruce should be selected in preference to any other tree of which, in cultivation, I have any adequate knowledge, where it is desirable to plant a tree of pyramidal habit, which not only is beautiful in its young state, but will improve for generations.

MENZIES' SPRUCE.—The second of our species, *Abies Menziesi*, in favourable situations attains a height of 100 ft., and has nearly the same geographical range in North America as *Abies Douglasi*. It also, under various names, extends through Kamchatka and the Amoor country to Japan. In the Rocky Mountains this tree is found at an elevation of from 6000 ft. to 9000 ft., and never forming extensive forests, as do many Coniferous trees, but scattered widely here and there, and always in low, wet situations, generally along streams at the water's edge, where its roots are constantly kept cool and moist by the mountain torrents. This natural selection of a cool, moist soil indicates under what conditions this tree can be most successfully cultivated. According to Dr. Parry, *Abies Menziesi* is, in the Rocky Mountains, a tree of rather an oval outline, pointing upwards with a rapidly tapering trunk. It has a thick, grey, rough bark, and its leaves are remarkably broad, stout, and very sharp-pointed; indeed, so harsh are they that it is painful to grasp one of the branchlets with the naked hand, and by this peculiarity the species can be most readily distinguished while young from several other Spruces, which in their early years have certain points of resemblance. The young plants, although of rapid growth, are remarkably compact and beautiful, especially those of them (about 20 per cent. in our seedlings) which are of a bright bluish-grey tint. In fact, these young "Blue Spruces," as cultivators are beginning to call them, are the most beautiful and valuable hardy Conifers for this climate that I know. Still, it is only in its young state probably that this species will make a desirable ornamental tree, as it has been observed that when growing naturally, the bluish tint disappears from trees over 30 ft. high, while, long before its full development is reached, loose, unsightly branches, nearly destitute of foliage, take the place of its early compact habit. This comparatively early fading of beauty is less objectionable perhaps in an ornamental tree in this country than in almost any other, and is quite compensated for, in this case, by the superlative beauty which graces its early years. As a hedge plant for this climate, *Abies Menziesi* presents qualities possessed by no other plant, and when it becomes, as it should before long, as common and cheap in our nurseries as the Norway Spruce, it will be used for this purpose in preference to that or any other evergreen.

ENGLEMANN'S SPRUCE.—*Abies Englemanni*, the third of the Colorado Spruces, is the most Alpine in character, forming in the southern Rocky Mountains vast forests above 8000 ft., and reaching even 11,500 ft. above the sea-level. This tree forms a shapely, tapering spire, from 60 ft. to 80 ft. high, with a trunk slender for its height, and which is covered with a thin, scaly, reddish-gray bark. In general appearance *A. Englemanni* resembles the Black Spruce of Eastern America, for which it was mistaken by all botanical travellers in the Rocky Mountains, until Dr. Parry detected its specific distinctions, and dedicated it to the distinguished botanist whose name it bears. Of its merits as an ornamental tree, I cannot as yet speak with so much confidence as of the two trees already mentioned, as material for a satisfactory trial has not been available. But, probably, its resemblance to one of the common trees of the East will work against its general popularity, while its Alpine character, and consequent habit of starting to grow in very early spring, will render it unfit for cultivation, save in the extreme Northern States. In St. Petersburg, as I am informed on the best authority, *Abies Englemanni* succeeds perfectly, in spite of the extreme cold of the Russian winters, and as heretofore the only Conifers available for planting in northern Russia have been the Scotch Pine and the Siberian Spruce, its general introduction there is considered of the greatest value and importance. By far the most valuable of the Colorado Spruces, as a timber tree, and the equal in this respect to the Black Spruce, it is not improbable that Englemann's Spruce will some day form an important element in the formation of artificial forests in Northern Europe.—"American Agriculturist."

Flowering Rush (*Butomus umbellatus*).Trailing Gaultheria (*G. procumbens*).Black Hellebore (*Veratrum nigrum*).*Gilia capitata*.*Datura esatocaula*.Large-flowered Purslane (*Portulaca grandiflora*).Fortune's Lily (*Lilium Fortunei*).Blue Day-lily (*Hemerocallis caerulea*).*Isotoma axillaris*.Common Everlasting (*Antennaria margaritacea*, var.).Yellow Horn Poppy (*Glaucium luteum*).Thready Yucca (*Y. filamentosa*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

YUCCAS rank amongst the most conspicuous flowering plants now to be seen in the London parks and gardens. *Y. filamentosa* blooms freely even in the shape of small plants; indeed, all the hardy Yuccas deserve more extensive cultivation than they generally receive, for where there is a good collection of them,

Giant Lily (*Lilium giganteum*).

some are sure to be in flower all through the summer. Of *Y. recurvata*, one of the most graceful of them, there are remarkably fine healthy plants in Victoria Park. *Y. gloriosa*, everywhere to be met with in suburban gardens, seems to bid defiance to both dust and smoke. Yuccas may be rendered very effective even when not in bloom, by surrounding the

Flame-flower (*Tritoma Uvaria*).

bases of their stems with dwarf flowering plants, such as some of the Campanulas, which are now in great abundance. *Nierembergia rivularis* is one of the best plants which we possess at this season of the year for growing in patches on raised borders or rockwork; large beds of it in Mr. Cannell's nursery at Swanley are literally masses of bloom, and no matter how dry the weather may be, they continue to grow

freely and to flower abundantly. The White *Sedum anomalum* grown in thick masses is now very beautiful. The Everlasting Pea (*Lathyrus latifolius*) is now finely in bloom, and when allowed to run loosely over old tree stumps or rock, it is much more beautiful than when trained on a wall as it often is. Irises of the Kämpferi section are still very showy, and the Californian Lilies are also most beautiful. The *Alstroemerias*—where grown under favourable circumstances, viz., in well-drained, warm, sandy soil—are now very attractive, their

China Aster (*A. sinensis*).

orange and coral tints being so distinct from anything else with which they are associated. S.

BEST TIME FOR MANURING ROSES.

I AM not disposed to agree with Mr. Fish who says (see p. 33) that November is the best time for manuring Roses, that it "takes weeks and even months for manure or manure-water at the roots of Roses to reach their leaves or flowers." My experience is to the contrary, and I have been a successful Rose-grower for several years. I have seen weakly Roses in the course of a few days gratefully acknowledge the stimulant of soot and guano-water. Mr. Fish would manure in November, because he says "the roots are abnormally active during winter." My idea has always been that the Rose required a short season of rest during winter. I have been accustomed to protect the surface of my Rose-beds with rough litter from December to March, and about the time of pruning to fork the surface over with a strong and liberal supply of wholesome farmyard manure. When the first bloom has exhausted the trees, then a judicious and even administration of liquid manure restores vigour to promote an autumn bloom; and I have frequently had Roses in the autumn surpassing in form, colour, and quality those of June. I do not know that I am disposed to any particular sentimentality, but I have now and then wondered in what fervour of poetic enthusiasm William Wordsworth would have moralized over the Roses which have gladdened our eyes since his day. Unhappy man! he "should have died hereafter." If "a Primrose by a river's brim," a "yellow Primrose" could in him raise "thoughts that lie too deep for tears," what would have been his emotion at the sight of perfect blooms of *Marie Baumann* or *La France* in late September? But to return to manure and mulching. I differ from Mr. Fish on the subject of his objection to surface-mulching. A mulch of litter is certainly unsightly, and to be avoided on our Rose-beds if possible; but in some of our hot, dry summers, when the sky is like heated brass all day, and week after week no rain falls, nothing but a surface-mulching will keep moisture in the ground. A frequent thin sprinkling of lawn mowings is sufficient, if spread over the surface before that ground becomes baked and cracked. When the ground is in that condition, a sudden supply of water requires considerable caution and consideration. A friend of mine on one occasion, a week before the local Horticultural Show, being in utter despair, purchased 500 ft. or 600 ft. of gutta-percha hose and deluged his parched Roses with cold reservoir water, and the result was he had not a bloom for the Show. Mr. Fish recommends a solution of carbonate of ammonia as an aphid wash. He says that syringing with this fluid "adds a new perfume to the Roses, invigorates their growth, and enhances their beauty." Certainly as

a wash nothing could be cleaner or more convenient. Will he kindly say how much of the ammonia to the gallon of water may be safely used?

C. W.

Boston.

Aplopappus ciliatus.—At first glance this plant would be taken for a *Grindelia*, of which genus it has the habit and the large flower-heads, but it is entirely free from the glutinous exudation which is so marked a characteristic of most of the species of *Grindelia*. It is a robust-growing annual, with stems from 3 ft. to 4 ft. high, branching in its upper half, the stem and branches clothed with elliptical, smooth, blunt foliage, stem-clasping and serrated, the teeth all pointed with bristles. The flower-heads are more than 2 in. across, both disc and ray being bright yellow, and very effective. It blooms throughout the autumn months, commencing in July. It is undoubtedly a desirable addition to the taller Composites, and may be treated either as a biennial, in which case the seed should be sown about August, or as a half-hardy annual, the seeds being sown under glass as early as means and appliances permit. It is a native of Arkansas.—W. THOMPSON, *Ipswich*.

The Virginian Creeper at Home.—I notice (see page 495, Vol. XI.), your comment upon the Virginian Creeper, concerning which you state that "there is no reason why old, dead trees in Britain should not be made as beautiful as those in the Missouri Bottoms." No doubt it will grow just as well in England as in America, but you will not have the blaze of brilliant colour from base to topmost twig which we have. I am pleased to know that this splendid climber is so well appreciated, for I made the remark in a paper (Vol. VIII., p. 233) which I sent you, "that the Virginian Creeper, overtopping the tallest trees in Southern Illinois, crimsoning the whole summit as with a glow of fire in an October sunset, is a sight never to be forgotten." The very spot where I saw it was within a few miles of the Mississippi River. This creeper is a native of New England, and grows wild in our own grounds, but brilliant as it usually is here, its colour is not to be compared for intensity with that on the Southern Illinois or Missouri Bottoms. The soil or climate, and probably both combined, give a crimson glow to the foliage which it rarely attains in our more northern clime; therefore beautiful though it no doubt is even in the climate of Britain, you must not expect to see it with the fiery brilliancy of plants of it in the Missouri Bottoms.—C. M. HOVEY.

Triteleia uniflora as a Pot Plant.—Many may not be aware how well adapted this pretty little spring-flowering bulb is for pot culture. About a dozen good-sized bulbs should be placed in an 8-in. pot, using a compost of leaf-mould and turfy loam, to which may be added a portion of well-decomposed manure; pot firmly, and give a good watering to settle the soil, and then plunge the pots in a cool frame or at the back of a north wall up to their rims. During September and October place them where they may enjoy full exposure to sun and air; they may be wintered in a cold frame, where they can be fully protected from hard frosts, taking care to keep them sufficiently moist at the roots to prevent the foliage from becoming yellow, which it is apt to do if they be allowed to remain dry. When the buds begin to appear they may be removed to the conservatory or sitting-room. There is one peculiarity in the growth of this plant which adds much to its beauty when thus grown, viz., the leaves turning downwards and completely clothing the sides of the pot; in order therefore to see it to full advantage, it should be placed in a somewhat elevated position. For those who have no convenience for forcing flowers, the *Triteleia* thus treated is invaluable, as the slight protection alone which it receives suffices to bring it into full bloom some weeks earlier than those in the open border.—JOHN CORNHILL, *Blyth*.

A Good Early Potato.—Among fifty varieties of Potatoes growing here this season, I find Alpha to be the earliest of them all. It is also an excellent cropper.—R. GILBERT, *Burghley*.

Erigeron glaucus.—What can surpass in point of beauty this plant at the present time? and yet, singular to say, it is seldom met with in gardens. It thrives well in the open border without much attention, and when once established it may be propagated either by division or seed.—J. T. R.

Apples for England.—So late as the 4th of May, the "Indiana," of the American line of steamers from Philadelphia to Liverpool, took to England 1,500 barrels of Apples. Some of these were of the celebrated Pennsylvania variety, "Smoke House," which is said to be highly appreciated in England. In past time they seem to have known nothing of American Apples except "Newtown Pippin," and seem to have been astonished at the superiority of other kinds.—"Gardener's Monthly." [The writer ought to know the value of the different varieties, but it is only fair to say that nothing as yet sent approaches in flavour to the finest Newtowns.]

SEASONABLE NOTES.

A cold, backward spring and a late summer are often followed by a mild, growing autumn, a circumstance to which due weight should be given when making arrangements for sowing Cabbages and other crops, to which attention must soon be paid. It is well not to be in too great a hurry, however, or the plants may "bolt."

Watering.—The common-sense way of doing this in the open air is to pour it on the land between the crops in the evening only, giving sufficient to moisten the soil to the extremities of the roots, and the next morning scattering an inch or so of short manure, rough leaf-mould, old tan, or dry soil over the surface, having previously just loosened it up with the hoe. Where such precautionary measures for lessening evaporation are taken, once a week will be sufficient to water all crops. If watered frequently, liquid manure should be given occasionally, to compensate for the waste of manurial matters in the soil from so much water being so rapidly passed through the upper stratum, to be as rapidly evaporated again by the hot sun the following day. Never use hard pump-water until it has been well exposed to the sun and air, and hoe up the surface two or three times a week. Few seem to realize the benefit derivable from a frequent stirring of the earth's surface in dry weather as a means of retaining moisture in the land and keeping the root-run cool.

Planting-out Broccoli.—The main crop of Broccoli should have been planted out and established in some open situation, and have space enough allowed it to induce a dwarf, sturdy growth, keeping in mind the average growth which each kind usually makes. The *Leamington* and *Eclipse* are two excellent late kinds, that will not disappoint if obtained true; they come in in succession as I have set them down. There is yet time to plant them out for a late spring crop; *Eclipse* will quite meet the earliest Cauliflowers at the end of May or beginning of June, but it should be got out at once to obtain good heads. Early planting usually leads to firm growth, with its consequent immunity from frost in winter. That indispensable kind, *Veitch's Autumn Self-protecting*, should be planted on rich land, as should also the *Autumn Giant Cauliflower*.

Planting Celery in the Trenches from the Seed-bed.—It is not customary to do this, but in certain places it is not a bad plan; of course where it is done the seeds should either be sown thinly or the plants thinned out to 2 in. apart in good time before they crowd each other. No doubt transplanting increases the numbers of fibres or feeding roots, and keeps them nearer home, so to speak, than if otherwise treated, and on good land where the food supply—both liquid and solid—is ample, it has a beneficial tendency; but in places where water is scarce and difficult to apply, keeping the roots near the surface is not an unmixed good. We cannot transplant anything without checking its growth, and there are places and seasons when the fewer checks given the better.

Sowing Lettuces for Winter.—From the middle of July to the 25th is a good time to sow a good breadth of *Brown Cos*, *Hick's Hardy Green Cos*, *Hammersmith*, and *Tom Thumb Cabbage Lettuces* for winter. Select an open situation, where the land is in good heart; if the weather be dry, soak the bed with water before sowing the seeds, and cover with dry soil.

Radishes.—These, at this season, are often difficult to obtain crisp and good, and as the space occupied by them in comparison with other crops is small, we find it best to make up special beds for them, with rich, light soil, on a cool border. The waste soil from the potting-shed comes in well for this and similar purposes, and where many bedding plants are grown the temporary sheltering places used for them may be employed for this purpose; under such treatment they grow rapidly, and are mild in flavour. The *French Breakfast Radish* is the best variety for sowing in summer.

Potato Disease.—This has made its appearance in several gardens in this district. Everything now, so far as regards the future crop, depends upon the weather. If we have heavy rains and the usual close, heavy, oppressive atmosphere that generally accompanies wet weather at this season, the disease will, I fear, be more than usually destructive in consequence of the lateness of the growth of the crop. In all cases where the crop is fully grown, early lifting will be desirable. E. HOBDAY.

A DELICATE TOMATO SALAD.—Many who like Tomatoes prefer them most of all in a raw state, as salad, served with various combinations of vinegar, oil, and mustard—some using only a little vinegar, others using no vinegar, but a combination of oil and mustard. A great improvement on any of these is made by using the juice of a Lemon only; in this way good Tomatoes, skinned by potting them in scalding water for a minute, allowed to cool, cut into slices, and a good Lemon squeezed over them, form one of the most grateful and wholesome dishes obtainable in summer. Those who know and

appreciate the Tomato in this and similar ways, will be prepared for the statement that no vegetable product ever introduced to garden culture is likely to prove more useful to mankind. In countries where it is well known and grown, it is already far more important than the Potato; therefore all who have the opportunity would do well to help forward its culture in various simple ways.

PROPAGATING ROSES FROM CUTTINGS.

PERHAPS the easiest and at the same time the most successful method of propagating Hybrid Perpetual and other Roses from the old wood is this:—As soon as the leaves fall out the slips into pieces of about four or five eyes each, using of course a sharp knife, so as to make a clean cut—not a pair of shears, which bruises the end of the slip. It does not matter where the cut is made, provided it is a clean cut. The slips may then be planted pretty closely in boxes 3 in. or 4 in. deep, leaving one or two good eyes above the surface, in a soil composed principally of good clean sand free from salt, to which a small quantity, say one-fourth, of loam and leaf-mould may be added. Water well to settle the soil close round the base of the slip, and the boxes may then be placed in a cold frame for the winter. Frost must be rigidly excluded as well as any undue excitement by sun-heat—a temperature as nearly 40° as possible during the winter will answer. If any commence to grow before the base of the slip has formed a good callus, farewell to all hope of its ever making a plant; it may grow as long as the sap stored in the slip keeps it alive, but will then die. Towards spring any material used to keep out frost may be removed, and light and heat gradually admitted until good growth is secured, when the slips should be carefully taken up and either placed separately in small pots in a good rich soil, or about 2 in. apart in boxes, and the frame kept close and moist for a few days to prevent their wilting. After being gradually hardened off they may be planted out at any time after the middle of April, will give a few blooms the first season, and will make plants double the size in the autumn of those propagated in winter or spring from the young or green wood and raised in the greenhouse. If the amateur wish to increase his stock of a new Rose, of which he can only spare a few slips or eyes, root-grafting may be resorted to. A few good strong roots of any free-growing Rose being secured and cut into about 4 in. lengths, a single eye of the Rose to be propagated should be inserted near the top of the root, as in side-grafting, or if the root-stock is large enough as in cleft-grafting, the junction covered with grafting-wax, and the whole then treated as recommended for slips. The amateur need not get discouraged if success do not attend his efforts the first time—we have seen 99 per cent. grow one year, while not over 25 per cent. would reward our efforts at another; but the cause was traceable to neglect, not to the system.—“Forest and Stream.”

QUESTIONS AND ANSWERS.

Harvesting Ornamental Grasses.—I have a collection of ornamental Grasses, and wish to prepare them for making pretty ornaments for the house in winter. Will you kindly tell me when to gather them, and how to dry and prepare them for the purpose just named?—T. G. H. [Gather them just before the flowers are fully open, and dry them in an airy loft or shed.]

Peach Stones Splitting.—Allow me to say in answer to “C. J. H.” (see p. 52) that my impression is that the splitting of Peach stones arises from too much water at the roots rather than too little, as he appears to surmise. Peach trees should always be well supplied with water while the fruit is swelling, but if given when it is ripening, or just previous to ripeness commencing, I have invariably observed that the stones split.—W. H.

Flowerless Allamandas.—On the roof of an Orchid-house we have some Allamandas which we cannot induce to flower; we cut them back and repotted them last spring, and they have made growth fully 4 ft. long, but no appearance of bloom. Can it be the shading on the roof requisite for the Orchids which prevents their blooming?—A GARDENER. [In order to flower Allamandas successfully, they should be removed when growth is completed to a somewhat cooler and more airy house to ripen their wood.]

Bananas Cracking.—I have under my charge a house of Bananas, a plant of which showed flower last autumn; it kept swelling its fruits slowly all winter and spring, and lately some of the pips have begun to crack and decay, a circumstance which has induced me to cut the fruit and hang it up in ainery where the atmosphere is kept pretty dry. Shall I be able to ripen it? and how can I prevent the fruits of the others from cracking in order that I may be able to ripen them on the plants?—A GARDENER. [Bananas will ripen and acquire good flavour hung up in any warm dry place: As soon as the fruit shows signs of changing colour the house should be kept as dry as is consistent with the health of the plants, maintaining at the same time a free circulation of air. Excess of atmospheric moisture, especially at nights, and a confined atmosphere, cause cracking.]

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY'S SHOW.

JULY 17.

THIS meeting was held in the Council Room, which is a much more appropriate place for small exhibitions than the Conservatory. On this occasion the principal feature was a collection of Pot Vines, shown by Messrs. Lane & Sons, Great Berkhamsted, and consisted of six plants, each bearing from seven to ten large bunches, which were acknowledged by the Fruit Committee to be the best ever exhibited. Several bunches of Black Hamburgh in this collection weighed no less than 4 lb. Foster's Seedling was shown in capital condition, the berries in this case being of a transparent amber colour: to these a silver medal was awarded. A bank of Balsams as grown for market, shown by Mr. John Reeves, Acton, was much admired on account of the dwarf compact habit of the plants, and the remarkably large and well-formed blossoms which they bore. Messrs. Veitch & Sons showed a group of Begonias, in which the plants were unusually well grown, and profusely flowered; they consisted of such kinds as Stella, the large and brilliant orange-scarlet-flowered Aene, Monarch, and Charles Scorer; the dwarf-growing B. Davis was shown in good condition, the flowers being of a most brilliant scarlet.

First-class Certificates.—These were awarded to the following new and rare plants:—

Begonia, Charles Scorer (Veitch).—A dwarf-habited kind with large deep-green leaves of good substance, thickly beset with stiff wiry hairs. The flowers, which are produced in abundance on stont fleshy stalks from 6 in. to 8 in. long, are of a dark rich crimson colour.

Begonia, Monarch (Veitch).—A robust-habited kind with large glossy green leaves, and flowers with stiff, waxy, vermilion petals, and conspicuous golden-coloured stamens.

Hydrangea, Thomas Hogg (Veitch).—A pure white-flowered kind, on several occasions alluded to in THE GARDEN.

Odontoglossum miniatum (Mills).—A kind with stiff, deep green foliage. Small plants bearing very large strong flower-spikes, thickly beset with crisp, five-petalled blossoms, the colour of which closely resembles that of *Oncidium crispum*.

Croton, Queen Victoria (Williams).—The result of a cross between C. Weismanni and C. interruptum. It is of medium growth and free-branching habit; the leaves are from 9 in. to 12 in. long, and about 2 in. broad, the ground colour being golden-yellow, beautifully mottled with green; the margin of the leaf is unevenly banded with carmine. A very desirable kind.

Clove Carnation, Mrs. Matthews (Turner).—A free-growing kind which bears beautiful white, waxy-petalled, Gardenia-like flowers of exquisite fragrance.

Lathyrus latifolius magnificus (Parker).—A kind which bears large trusses of rosy-purple flowers.

Echinocactus grandicornis (Croucher).—A large spiny Cactus, which, on account of its singular appearance, cannot fail to be a favourite with all lovers of this tribe of plants.

Miscellaneous Subjects.—Messrs. Veitch & Sons showed a basket of small plants of the now rarely seen *Lisianthus Russellianus*, bearing abundance of large flowers, well adapted for conservatory or greenhouse decoration; the same firm also showed *Crinum erubescens* in flower, and a basket of *Eulalia japonica zebrina* in good condition. An excellent group of plants came from Mr. B. S. Williams, Holloway, amongst which were fine examples of the Crested Woodwardia (*W. radicans cristata*) and *Adiantum palmatum* and *Sarracenia purpurea major*. An exquisitely coloured specimen of *Croton Queen Victoria* also came from the same exhibitor, and was greatly admired, as was also *Lobelia Lilac Queen*, a compact-growing kind, forming a carpet of neat lilac-coloured flowers. Mr. Selwood, gardener to the Duke of Westminster, Eaton Hall, Chester, showed a remarkably healthy specimen of *Dendrochilum filiforme*, bearing nearly one hundred drooping spikes of greenish-yellow blossoms. Sir Trevor Lawrence furnished an unusually well-flowered plant of *Lælia Brysiana*, and a specimen of *Brassava Digbyana* bore seven large, peculiar, greenish-white fringed flowers. Mr. Noble, Sunningdale, showed trusses of *Rose Queen of Bedders*. Mr. Turner sent a *Rose* named *Penelope Mayo*, a kind like *Marie Baumann*, with very distinct deep green leaves. A small group of tuberous-rooted Begonias came from Mr. Pithers, Munster House, Fulham, amongst which were noticeable finely-flowered plants of *B. Illuminator* and *refulgens*. Messrs. Wm. Paul & Sons contributed a collection of new English seedling Roses, not yet in commerce, amongst which were noticeable several very distinct and desirable kinds: amongst them *Red Dragon* was much admired on account of its brilliant reddish-crimson blossoms which are freely produced on climbing branches clothed with large green leaves. May Quennell, of which we have before made mention, was also in good condition. From the same firm also came a collection of Roses, raised at or sent out from the Waltham Nurseries. Amongst them were very fine examples of *Prince Christian*, *Lord Macaulay*, and *Glory of Waltham*. Mr. Wilson, Weybridge, sent a collection of Lilies in good condition and a group of cut blooms of English Irises came from Messrs. Barr & Sugden. A group of Old Man Cactus came from Mr. Croucher. Mr. Barr showed a collection of Lilies, amongst which were some remarkably well-coloured flowers of all the species at present in bloom. A group of well-grown decorative plants came from Mr. James Puttick, Acton, which considerably enhanced the gaiety of the exhibition. Mr. Caunell, Swanley, sent a collection of *Mimuli* and *Sweet Williams*

which were of great merit. A vote of thanks was also awarded to the same exhibitor for boxes of cut flowers of very fine Zonal and Double Pelargoniums; amongst these were kinds entirely distinct from any we have before seen, having very large flowers of the brightest colours. Messrs. Downie & Laird, Edinburgh, sent a stand of seedling Pansies, amongst which were many well-formed flowers. Mr. Dean sent a basket of mauve Beauty Stock, a dwarf variety of branching habit, the flowers of which are of a lively mauve colour, and borne thickly on stout pyramidal stalks. Both for garden and pot culture this Stock is well worth attention.

Fruit and Vegetables.—Very fine examples of Belle de Choisy and Bigarreau Napoleon Cherries came from Mr. Miles, gardener to Lord Carington, Wycombe Abbey; and Mr. Burnett, The Deepdene, Dorking, sent good dishes of Peaches. A Queen Pine weighing from 5 lb. to 6 lb. came from Mr. Ollerhead, Wimbledon House. Messrs. Carter & Co., Holborn, sent plants of Little Wonder Pea heavily laden with pods, each containing seven or eight very large Peas; for field and garden growth this is one of the best Peas which we have seen for a long time. Examples of a new Pea named Sequel came from Mr. J. Hardy, Bures, Essex. Mr. Myatt, Deptford, showed two dishes of French Bean Sir J. Paxton. Mr. Bull, Chelsea, sent a brace of Cucumber Excelsior, a kind with symmetrically-shaped fruit 24 in. long, and well adapted to exhibition purposes.

NATIONAL CARNATION AND PICOTEE SOCIETY.

JULY 18 AND 19.

THIS exhibition, which opened on Wednesday last in the Royal Aquarium, Westminster, was a very attractive one, the cut blooms of both Carnations and Picotees, as well as a display of Roses, being neatly arranged on tables surrounding the fountains at each end of the building—positions well adapted for the purpose. The stands of brightly-coloured Verbenas shown by Mr. Cannell and Mr. Turner were very effective, as was also a table occupied by Tea Roses. In the class for twenty-four Carnations there were five exhibitors. The best blooms came from Mr. Turner, Slough, and Mr. Douglas, Loxford; the latter exhibitor had magnificent specimens of the creamy-white and crimson-petalled Clipper, the rose and white-flaked Sarah Payne, and the well-formed Lovely Ann, a beautiful magenta-petalled flower striped with white. These were associated with the purple and white Premier, and a variety named Dreadnought, the petals of which are equally striped with scarlet-maroon and creamy-white. Mr. Turner had a well-arranged stand containing compact blooms of the bright rose and white-flaked Sybil, and the white and purple-spotted Florence Nightingale. In this stand we also noticed a very conspicuous bright scarlet and white-flowered kind named Sportsman, and well-shaped blooms of Ajax, a deep mauve and purple-petalled kind marked with white stripes and spots. In the class for twelve blooms Mr. Douglas had the best stand, in which were good examples of True Briton, Rifleman, and the kind named Premier; with these were associated good blooms of similar kinds to those mentioned in the other class. Mr. E. S. Dodwell also showed good blooms of James Merryweather and John Kent, together with the deep rose-flaked J. D. Haxtall, and others. Amongst other exhibits in this class were noticeable fine examples of a kind named Snepb, a round bloom, with scarlet and white-striped petals, Samuel Moorman, and a few excellent seedling kinds as yet unnamed. A very large bloom of James Douglas was much admired on account of its large stiff petals, which were slightly striped, and edged with deep mauve. Mr. Ware, Tottenham, sent a stand of yellow-ground Picotees, amongst which Goldfinch, a light yellow-petalled kind, very slightly edged with scarlet, was very conspicuous, as were also the elegantly-marked examples of Falkirk and Seraph. In the class for twenty-four Picotees, Mr. Douglas again held the first place. Amongst his blooms were beautiful examples of Ann Lord, an ivory-white-petalled kind, delicately edged with pink; Lord Valencia, a pure white well-formed flower, regularly edged with scarlet. Other noticeable kinds were Miss Small, and an elegant light pink-edged kind, named Edith Dombrain. Mr. Turner, Slough, had likewise remarkably chaste blooms of Peeress, a seedling of his own, with well-formed stiff white petals, heavily edged with deep chocolate. Leonidas also was a good sort, with a beautiful edge of clear purple. Miss Wood, a magenta-edged kind, might be used with advantage in bouquets, as might also Alice, Frances, and Isabella. Mr. Dodwell and Mr. Ware showed in this class admirable examples of kinds suitable for pot or border culture. In other classes for smaller quantities, blooms of equal excellence were shown. The centre of the table containing the stands just alluded to was furnished with a row of Carnations and Picotees in pots from Mr. Charles Turner. Amongst these we noticed The Bride, a very large pure white kind with fimbriated petals; a deep rosy-pink variety named Flora's Garland; and Elysian Beauty, a kind with well-formed flowers of a most beautiful pink colour. From the same exhibitor also came fine plants of Liliun auratum, some of the single stems of which bore from twelve to twenty large and finely coloured blossoms, which added greatly to the effect of the Show. Mr. Turner likewise showed well-flowered plants of his new Clove Carnation, Mrs. Matthews, a description of which will be found in our report of the Royal Horticultural Society's Meeting. In the class for Selfs and Fancies, Mr. Turner had the best twenty-four blooms, amongst which were several seedlings, as well as new named sorts. Amongst the former we noticed a large flower with broad deep scarlet petals, which set off to advantage the large pure white blooms of The Bride, the bright mauve Cremorne, and the delicate pink Flora's Garland. Mr. Ware, Tottenham, had a good stand, consisting of well-formed self-coloured kinds, amongst which were a very bright scarlet fringed-edged

kind named Glory, a fine yellow variety named Mr. J. Reeve, and a very dark kind called Hindoo, admirably adapted for bouquets. In the same class Mr. Douglas showed fine blooms. In the class for twelve Mr. Turner had excellent blooms, amongst which were noticeable good examples of the deep mauve Ajax, the pink Elysian Beauty, and other attractive kinds. Mr. Dodwell had also a capital stand, in which was a remarkable dark velvety-maroon kind unnamed. Mr. Ware, Tottenham, sent stands containing eighty-four bunches of Carnations and Picotees, both of which were much admired. The prize for the premier Picotee in the Show was awarded to Mr. Douglas for a large and finely-formed bloom of John Smith, a smooth, broad-petalled kind, conspicuously edged with dark chocolate. Of single specimens, which were numerous, the best came from Mr. Turner and Mr. Douglas.

Cut Roses.—These were fairly well represented, many of the blooms being of unusual excellence. The best stand came from Messrs. Cranston & Co., who had a fine display of brightly-coloured, fresh-looking blossoms, effectively surrounded by abundance of deep green leaves. Amongst the most conspicuous were good examples of the deep maroon velvety-petalled Jean Liabaud, the pink-coloured Miss Hassard, very large blooms of the rosy-purple Mme. Chas. Wood. These were effectively associated with Duke of Edinburgh, well-coloured blooms of Francois Michelin, and Souvenir de la Malmaison. Mr. Cant, Colchester, had good blooms of Countess of Oxford, and the golden yellow Madame Hippolyte Jamain, noble blooms of Alfred Colomb (still one of the best of its class for exhibition purposes), and highly-coloured flowers of Baroness Rothschild. Messrs. George Paul & Son, Cheshunt, likewise showed fine blooms. In the class for twenty-four varieties, three trusses of each, there were six exhibitors, among which Messrs. Cranston were again foremost, with beautiful blooms of similar sort to those already mentioned. Mr. Turner, Slough, showed examples of Sir Garnet Wolsley, the brilliant scarlet Duke of Edinburgh, and Chas. Lefebvre—these were supported by fine examples of that most useful of all white Roses, Niphetos, the golden-yellow Belle Lyonnaise, and the blush Mme. la Baronne de Rothschild. The best stand of twenty-four single trusses came from Mr. Corp, Oxford, who showed Captain Christy and Louis Van Houtte. In the same class ten more exhibitors also staged remarkably fine blooms, considering the wet weather to which they have lately been subjected; amongst them were good examples of Princess Beatrice, Marie Van Houtte (a beautiful creamy-yellow, the outer petals of which are delicately marked with pink), and Madame Charles Wood, the latter better shown than we have seen it before this season. An extra prize was deservedly awarded to Mr. William Corp for a collection of Rosebuds grown on the seedling Brier; for button-hole or other bouquets these are unsurpassed, and this exhibition afforded an excellent opportunity of noting the most suitable kind for such purposes. Ma Capucine had well-formed buds of an orange-scarlet colour, and Madame Falcot still retained its position as a button-hole Rose. Clara Salvan is a good white kind; and the best blush was David Pradel. In the amateurs' classes, the best box of twenty-four blooms came from the Rev. N. Pochin, Leicester, who had very fine specimens of Maréchal Niel, Mdle. Marie Finger, well-coloured examples of Monsieur E. Levet, La France, and Reine de Midi. An excellent collection also came from Mr. Jowitt, who had beautiful examples of Louis Van Houtte, Francois Michelin, and the buff-coloured Catherine Mermet. In a stand shown by Mr. Pemberton Romford, we noted remarkably bright-coloured blooms of Reynolds Hole and Duke of Edinburgh. The best blooms of Marquis de Castellane and Madlle. Marie Rady came from Mr. R. N. G. Baker, Heavitree. In the classes devoted to Tea Roses, the best stand of twelve blooms came from Mr. Cant, who had beautifully-formed, half-expanded buds of Madame Villermoz, Souvenir d'un Ami, and others. The finest and best-coloured examples of Maréchal Niel which we have seen anywhere this season came from Mr. J. Tranter, and grand examples of Souvenir d'un Ami were furnished by Mr. Turner. Mr. Cant showed blooms of Alfred Colomb, richly-coloured, and fine in form, each surrounded by its own foliage. From George Paul & Sons came very perfect blooms of the dark, velvety, brilliant crimson-tipped Horace Vernet, Duke of Edinburgh, and Marie Baumann, the last in excellent condition.

Miscellaneous Subjects.—Amongst Mr. Cannell's Verbenas were Blue Boy, a large-flowered, deep blue sort of good substance; a kind named Star of Erin, with flowers as large as those of a Phlox, of a delicate blush colour; and a brilliant scarlet variety named Basilisk, the last very attractive; Mr. Turner, Slough, also furnished stands of Verbenas, amongst which were some brilliantly coloured kinds. Messrs. Lane & Son, Berkhamsted, exhibited six pot Vines, which are fully noticed in our report of the Royal Horticultural Society.

Pine-Apple Nursery Fete, in Aid of St. Mark's Church Enlargement Fund.—This, which took place the other evening in the conservatory and grounds of the Pine-apple Nursery, Maida Vale, was highly successful, the entertainment being of an unusually comprehensive yet select character. The scene on entering the conservatory was singularly picturesque. Coloured lamps led the eye down long vistas, amid fine-foliaged plants of large size. Above and around were quaint-looking Orchids, the curious scarlet Flamingo-plant, and many others. Beautiful and imposing, however, as was the plant display; other departments were not less interesting. A large tent was devoted to table and other decorations. In the trumpets of the March stands we observed Wild Teasel, with its thorny hooks, and the commoner Grasses, too, were much used, and with good effect. These and other varied attractions kept a brilliant assemblage fully entertained until a late hour.

No. 297.]

SATURDAY, JULY 28, 1877.

[Vol. XII.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

PASSIFLORA EDULIS AS A DESSERT FRUIT.

THERE are times and seasons when a few dishes of tropical fruits greatly help the dessert. The Banana, Guava, Cape Gooseberry, and the Edible Passion fruit are all easily grown; they produce fruit freely, and with great regularity, and foremost among them for real usefulness is the *Passiflora edulis*. I have grown this Passion-flower in a cool house, but, although it grew and fruited freely enough, the fruit had a very thick rind, and was faulty in other respects. Planted out in a pit in a house where the night temperature does not fall much below 60°, and where the roots can enjoy a little bottom-heat, I have always obtained the best results. The main branches should be trained thinly under the roof near the glass, and on the back wall if in a light position, and the young fruit-bearing shoots may be trained less rigidly or be allowed to hang down loosely if space permit. A very large border is unnecessary; a brick-built partition about 2 ft. square will in most cases be ample. Turfy loam and peat or leaf-mould in equal proportions, and a good sprinkling of charcoal will suit it well. The latter will be useful in maintaining the necessary porosity in the soil, as, during the growing and fruiting seasons, a liberal application of water will be necessary, and occasional applications of soot-water, or some other form of liquid manure, will be beneficial, especially when the plants are heavily laden with fruit. When quite ripe the fruit has a dark purple colour and makes a very handsome dish, and if it be gathered before it is quite ripe and preserved whole in sugar it is delicious, and may be had for winter use when the ripe fruit is not in season. Unlike the Granadilla, this Passion-flower sets freely without artificial fertilization—at least, I have never found it necessary to resort to that in order to secure a good crop. E. HOBDAY.

NOTES FROM KEW.

DURING a recent visit to Kew, we noted a few plants particularly interesting, either on account of their beauty or rarity. They are here mentioned in the order in which we met with them. In No. 4 (the house for which the Director proposed to buy common plants), there is nothing worthy of special notice, except perhaps a plant of *Mandevilla suaveolens* on one of the rafters, and a good example of *Sollya heterophylla* on one of the pillars. The first compartment of the new range is gay with tuberous-rooted Begonias. In the third division we found *Spigelia splendens*, the fine, dark red spikes of which make it welcome in any collection. Its native country is unknown. A good idea of its size and habit may be obtained by consulting the coloured figure of *S. marilandica*, published in THE GARDEN for March 3, 1877. *Juanelloa parasitica*, a Peruvian, epiphytal, Solanaceous plant (which, however, does well in soil), is very showy, on account of its large, rich, orange-coloured calyxes. *Tinnea æthiopica* is well worth growing; it is a shrubby labiate, with dark maroon flowers with the odour of a Violet. We owe its introduction to this country to the ill-fated Mlle. Tinné. On one of the rafters of the Victoria House there is a splendid Brazilian Bignonaceous climber in fine condition; its large, chrome-yellow flowers are produced on long racemes, and resemble some species of *Allamanda*. The old Lily-house contains several good things. *Cyperus pseudogiganteus*, a recent introduction from tropical America, is worthy of extended cultivation; it may be called a small edition of the Paper-reed (*Papyrus antiquorum*); it is nearly 5 ft. high, but the numerous branches of the loose, mop-like head are erect or ascending, not deflexed or pendulous as in that plant; it is a beautiful and graceful species. *Monochoria vaginalis*, an Indian aquatic, with lanceolate, cordate leaves and hollow foot-stalks, is attractive both on account of its leaves and flowers. The latter are of a warm blue tint, in umbel-like heads of from ten to twenty; the individual flowers measure nearly 1 in. across. It is also interesting on account of the many virtues with which the plant has been credited. The natives say that it is a certain remedy for liver and stomachic complaints, toothache, &c., and when young it is eaten as a salad. The Rose-apple of the Malays (*Jambosa malaccensis*) is now in flower in the Palm-house; its very numerous blood-coloured filaments render

the otherwise somewhat inconspicuous flowers very attractive. *Goethea strictiflora* is too pretty to be overlooked; the flowers have deep red bracts, and are produced in abundance on the stems; the plant flowers in a young state, and apart from the associations connected with its name, is well worth having on its own account. The large plant of *Ptychosperma Cunninghamii* (a Palm much better known under the name of *Scaforthia elegans*) is in fruit; the infructescence springs from below the leaves, about 30 ft. from the ground, and the coral-like fruits contrast well with the drooping, whitish branches on which they are seated. The winter garden possesses a fine specimen of the Pepino of Valdivia—*Philesia buxifolia*; at the time of our visit there were about 100 of its handsome *Lapageria*-like flowers expanded; it is planted out on the rockwork behind the large Australian Royal Fern (*Todea barbara*), and the conditions altogether seem to suit it admirably. In the herbaceous department there are several very handsome *Erigerons* and *Inulas*. *Asteriscus aquaticus* ought to be more generally known; it is a charming yellow Composite, from 1½ ft. to 2 ft. high, and very floriferous. The South European *Senecio Doria* is a magnificent species of this enormous genus; it figures here more than 7 ft. high, and its large, glossy leaves, afford a fine contrast to its fine yellow flowers. *S. sarracenicus*, too, ought to be more generally known; it is little more than half the size of the preceding, yet it is a fine species, and ought to be seen in gardens much more frequently than it is. In conclusion we may observe that the nomenclature in this department leaves much to be desired.

Cacti at Port Elizabeth, South Africa.—I have seen your notes on Cacti (p. 285, Vol. xi.), and particularly observe that your date climate is more injurious to them than the cold. Even in this dry hot climate we find such subjects as the *Epiphyllums* and the Rat's-tail *Cereus* very apt to damp off on their own roots. But any of the family grafted on the large night-flowering *Cereus* grow amazingly fast, and can take any quantity of water, provided they are well drained. I have now a plant of *Epiphyllum truncatum violaceum*, from which I removed a couple of weeks ago over 100 faded blooms, leaving some still expanded. It was grafted on the night-flowering *Cereus* about two-and-a-half years ago. Rat's-tail *Cactus* in three years' time, if grafted on this stock, will produce a regular mop of tails 4 ft. or 5 ft. long and twice as thick as on its own roots, yielding two crops of flowers in the summer, the principal crop lasting several weeks and producing a perfect blaze of colour. The operation of grafting is very simple; a slit in the point of the stock, the scion pared into a wedge and inserted, and a thorn to keep it in its place are all that is needed. The culture, too, is very easy. Plenty of root-room and good soil well drained, and then you may water or neglect the plant without hurting it. I have found by experience that the top of the stock must not be cut off square before grafting.—W. C. E.

Liliputian Rhododendron Plants.—At the Horticultural Exhibition at the Palais de l'Industrie last May, the public had an opportunity of witnessing the results of the method which we do not hesitate to call "new," although assisted by an old one. Up to the present it is quite exceptional, still there is every reason to believe that it will become general and popular, being both simple and inexpensive. M. Moser, of Versailles, was the first to exhibit *Rhododendrons* cultivated in this way. Compared with the usual *Rhododendrons*, they are Liliputians of a decidedly new kind, of which the whole body disappears under one enormous head of flowers. These plants were cultivated in small pots, the stems measuring about 5 in. in height and terminating in an enormous display of flowers. As the varieties were very good and numerous, they presented a magnificent *coup d'œil*, forming as it were a carpet of dazzling brilliancy. The following is the mode of culture:—During autumn when the buds are well formed, good varieties of *Rhododendrons* are chosen; then some branches bearing strong buds are taken from the older plants, grafted on small stocks, and worked in the usual manner. When this is effected, the plants are placed in a cool greenhouse, the temperature of which is kept just above zero. They are left in this state until the following spring, when, as if dealing with mature plants, they are treated according as the use for which they are destined may demand. They are left to flower naturally, unless required early, when they must be forced. An advantage of this method is that the plants can be employed for the decoration of small apartments, such as boudoirs, where only vases of small size can be placed. This style of cultivation is still in its infancy, and is no doubt capable of much improvement. Early kinds grown in this way would be very welcome as forced plants.

Fuchsia coccinea.—Mr. Williams (see p. 52) will find the history of this *Fuchsia* fully given at p. 284, Vol. IX. of THE GARDEN.—H.

NOTES OF THE WEEK.

THE FRUIT CROPS.—From the reports on this subject obligingly furnished by our correspondents, and printed in detail in the present number of *THE GARDEN*, it will be seen that most kinds of hardy fruits are this year a failure. Apples are in some few places a fair crop, but they are thin generally. Pears and Plums appear almost everywhere to be a failure. Wall fruits are also unsatisfactory, but in some districts there is an average crop of Peaches and Nectarines. The cause of failure in our fruit crops this year is by many attributed not wholly to the unfavourable spring which we have experienced, but in a great measure to the sunless autumn of last year, which was unfavourable to the perfect ripening of the wood. Small fruits of all kinds appear to be everywhere abundant, though in some cases inferior in quality. Apples are, however, the fruits which most concern us, and although immense quantities may be expected from America, the prices will probably be very high. The reports we print will be of great value to fruit-tree planters, showing as they do the kinds that succeed in good and bad seasons alike, and under different conditions and situations. Our Irish, Scotch, and English returns received too late for publication this week will appear in our next issue.

TOMATOES FOR PROFIT.—Since Tomatoes have become so popular English growers have paid more attention to their culture, with the view of getting them into the market early, but notwithstanding their efforts in that direction, both from America and from the Continent come large supplies of good Tomatoes, quite as early, or even earlier, than English cultivators can supply them. This has of course the effect of lowering the prices considerably, and we learn that during this month good samples of English-grown fruit have only realised about 1s. 6d. per dozen, and smaller ones 6d. per lb. This, however, does not seem to have greatly affected prices in the retail trade, for good Tomatoes cannot be had in the market for less than 4d. each, and very small ones fetch 2s. per lb. These prices are of course beyond the reach of the majority of people, who, we fear, will never be supplied with either good fruit or vegetables at reasonable prices until a more direct communication exists between buyer and grower. Considering that Tomatoes can be preserved in various ways, we see no reason why such high prices should be asked for them in the market, for the same provision against loss to the salesman exists in the case of Tomatoes as in that of Mushrooms, which latter are made into catsup immediately they are found to be unsalable, and the former could be made into sauce, and with a profitable result.—S.

HARDY BEGONIAS AT CHELSEA.—The usefulness of tuberous-rooted Begonias for pot culture is already fully recognised, but as border plants our experience of them is but limited. Now, however, when improved kinds have become numerous, it is not difficult to select varieties wherewith to adorn our flower gardens during the summer and autumn months. Messrs. Veitch & Sons have now in their nursery a collection of Begonias which have withstood the past winter uninjured, and which now present a very attractive appearance. Such kinds as Monarch, Vesuvius, Acme, and Emperor, are strong-growing, compact kinds, well suited for large beds or borders; then there are *B. roseiflora*, *intermedia*, *Sedeni*, and others of a dwarf character, possessing distinct colours, and the dwarf *B. Davisii*, a Continental species, rather later in flowering out-of-doors, which would make an excellent edging plant, or it could be effectively used in carpet bedding. Of this latter kind a batch of plants in 4-in. pots, under glass in the nursery in question, is just now very effective, many of them bearing, as they do, six or seven spikes of brilliant scarlet blossoms. As town plants Begonias are more suitable than Pelargoniums, and when once established they require less attention. All that is required in this respect is to thoroughly prepare the ground before planting, and each autumn when the foliage has died down to cover the beds with a few inches of Cocoa-nut fibre to exclude frost. If spring-flowering bulbs be planted between the Begonias this covering will also greatly assist them, and on the same beds without any trouble may be had a profusion of flowers from early in spring till the end of October. Several seedling plants of *Begonia* Emperor, growing near a wall of one of the houses in the Chelsea nursery have withstood the cold of the last two or three winters without injury, and are now fine specimens loaded with blossom.—S.

TWO GOOD LOBELIAS.—Varieties of this useful decorative plant are now so abundant that unless one has an opportunity of inspecting a collection of them, it is difficult to judge which are really the best. Mr. Cannell's nursery at Swanley contains nearly every kind in cultivation, and amongst them the best blue sort for all purposes appeared to be one named Ebor, a kind compact in habit and a remarkably free bloomer, the flowers being very dark

and rich, and, either in pots or beds, very effective. The *Bride* is another admirable kind, of similar habit of growth; it has large, pure white flowers, and is well adapted either for pot or border culture. These two kinds also look well in baskets, and as they may be had in flower at nearly all seasons of the year, they should be largely grown for use in the conservatory or greenhouse. They are best obtained from cuttings, which strike readily at any time; seedlings seldom come true to character.—C. S.

A PRECIOUS ROSE.—*Niphetos* is the Rose which is mainly instrumental in supplying Covent Garden with pretty buds of Tea Roses from New Year's Day to New Year's Day. Mr. Philip Ladds, of Bexley Heath, has now 40,000 plants of it in 9-in. pots.

COLORADO POTATO BEETLE.—We have received from M. Louis Stollwerck, 145, Cannon Street, models of this Beetle in all its six stages of growth. They are in a small box with a glass top, and are prepared by order of the German Government. We may add that they are much more like the Beetle than some of the coloured illustrations of it that we have seen.

STUARTIA VIRGINICA.—Mr. Woodbridge, gardener to the Duke of Northumberland at Syon House, has sent us some flowering sprays of *Stuartia virginica*, a beautiful North American shrub, with large, white flowers resembling those of a white Clematis. It is one of the most distinct and beautiful hardy shrubs we have ever seen.

NOTES FROM THE FULHAM NURSERIES.—*Tournefortia heliotropioides* is well established here on a border in front of one of the houses, and in that position is a good perennial; it is a pretty, *Heliotropium*-like plant without the odour. *Leptospermum lanigerum*, a pretty white-flowering shrub is in good bloom against a wall. *Magnolia Thompsoniana* is in fine bloom, and has been so for the past two months: this is very fragrant and handsome.—J. F.

THE OLD WHITE PINK.—London florists still appreciate the value of the small fringed-edged flowers of the old White Pink for bouquet-making, but in private establishments its culture has very much decreased of late years. At one time it was largely used for forcing, a purpose for which it is better adapted than any other kind; and when grown under favourable conditions in 5-in. pots, we have often seen plants of it in spring bearing upwards of fifty flowers. Cuttings of it strike readily in spring or summer if placed under a bell glass in a warm house or pit, and soon make flowering plants which, for furnishing cut flowers, or for conservatory or room decoration, are invaluable.—S. C.

MIMULUS MOSCHATUS HARRISONI.—This new hybrid Musk has found its way to Covent Garden, and plant growers for market regard it with especial favour. It is as easily grown as the common Musk, and its flowers are quite as odoriferous; and being very large and of a rich yellow colour, sometimes blotched with brown, they are very showy and admirably adapted for window decoration. For baskets, too, this is a valuable plant, and if kept well supplied with water it will continue in bloom for many weeks in succession.—S.

A PRETTY CONTRAST.—At the Exotic Nursery, Tooting, in front of a row of Copper Beech, is planted a line of the old double Meadow Sweet (*Spiraea Ulmaria* fl.-pl.). The latter is smothered with large heads of creamy-white flowers, which, viewed against the dark foliage of the Beech, have a very effective appearance. A little further on is a row of *Acer Negundo variegatum*, having for a companion a row of sky-blue *Delphinium Belladonna*, the flowers of which shine out conspicuously against the charming foliage of the *Acer*. Combinations and contrasts of this kind are worthy of notice, as hardy plants as a rule are planted anywhere, without regard to soil or suitable surroundings, and in nine cases out of ten the effect of good plants is lost from want of a little judgment in the selection of a proper site for them.—A. P.

FREESIA ODORATA.—This is now in flower at the Hale Farm Nurseries, Tottenham, and is well worth the attention of all lovers of half-hardy bulbs. I must call it half-hardy, although I believe it is quite as hardy as *Sparaxis pulcherrima*, which is found growing with it at the Cape, and the latter has proved hardy in this country; I cannot, however, speak with confidence until I have proved it. The flowers of this species are smaller than those of the variety called *Leichtlini*, but they are more powerfully scented and are sulphur-coloured, having a deep orange blotch on the three lower petals. *Freesia odorata* *Leichtlini* is a pure waxy white, slightly tinged with orange on the lower petal only. In the open ground plants of this are not more than 6 in. high, but that may be owing to late planting, the bulbs having been out of the ground till April. Those potted in January, six in a 6-in. pot, and brought on gradually in a temperate house, made good specimens 1 ft. high, with at least fifty flowers in each pot, filling the house with a delightful fragrance; they were in flower for six weeks, and are now ripening abundance of seed. When better known, these plants will be grown as extensively as the Hyacinth, and I would strongly recommend all who require abundance of out blooms during May to grow them.—A.

PROPAGATING PINKS, CARNATIONS, AND PICOTEES.

Those who prefer layering these to striking cuttings of them should now set about that work, if it has not been already done. Some layer the shoots in the ground, but a much better plan is to fill 4-in. pots with sandy soil composed of loam, leaf-mould, and peat, sifted through a rather fine-meshed sieve, and plunge them in the ground up to their rims round plants in open borders. Where good young growths exist, by bending them down and splitting the stem from one joint to the other, as seen in fig. 1 (which incision should be well buried in the soil and firmly pegged down), plants may, if the soil be kept moist, be soon obtained, and, being in pots, these when full of

Fig. 1. Layers.

roots can be readily removed with the roots intact; whereas, when rooted in the ground the plants often suffer severely from transplantation. In this way most of our nurserymen get their stocks of Carnations, &c., but they do it of course so that the plants in pots can be sent away in better condition than when rooted in the open ground. Some, however, prefer cuttings to layers. Plants can be propagated quite as quickly in that way, but where choice sorts exist people are often afraid to trust to cuttings. They should be taken off early in spring, made as represented by fig. 2, inserted in good sharp sandy soil, and placed in a

Fig. 2. Cuttings.

gentle heat. Cultivators for market put them in 6-in. pots in which a 3-in. one has been inverted to form drainage; they are then plunged in bottom-heat, and in about a fortnight, if well attended to, they are fit for potting off. C. S.

Cutting Pots.—"B. S.'s" pots (see p. 41) may do for amateurs; but not for those who require cuttings to be struck in quantity. Allow me, therefore, to set before your readers a system by which, if thoroughly carried out, success is certain. In the first place, I should recommend 5-in. pots to be crocked with broken pots (or any other accessible drainage) about one-third full, then a layer of the siftings of leaf-mould, or anything not too coarse, but of sufficient roughness to prevent the soil from stopping the drainage. The soil should be composed of one-third leaf-mould or good light

peat, one-third good turfy loam, and one-third silver sand, to be sifted through a $\frac{1}{4}$ -in. sieve, and well incorporated. The pots should be filled with the prepared soil, pressed as solid with the thumbs as it is possible to make it; then take a portion of dry silver sand and put it round the outside of the pot where the cuttings should be inserted. As to quality and size of cuttings, they should be selected from good strong growths, after the wood is partly ripened, and each cutting should contain three or four eyes, cut at a joint with a good sharp knife, so as to prevent bruising and splitting. Insert them in the prepared pots, care being taken not to dibble the holes deeper than the cuttings are intended to be put in, making all very firm, which is half the battle. Afterwards well water them, and set them in a dry house slightly shaded. Great care should be taken in after watering; they must never be watered until dry at the top, which will vary according to the temperature; and, should the weather permit, a free circulation of air, night and day, must be given. If your readers will adopt the above directions, I feel sure that the damping off spoken of by "B. S." will not occur.—C. L. T.

Roumanian Wild Flowers.—A war correspondent of "The Standard" finds time to say something about plants. The commonest field blossoms which he sees in Roumania are Monk's-hood, Cornflower, Canterbury Bell, Bedstraw, Iris, and that red spike which Ophelia calls "Love in Idleness." These make a sheet of varied colour beside the railway; but most beautiful is a species of Dog Rose, which springs a few inches high among the Grass, and throws up its garlands of large flowers in a cluster. In the far East the same effect of colour and grouping can be seen on a marsh overrun with pink Lotus.

Roses in Nottingham.—In one of the tents at the late exhibition here, Roses formed the chief attraction. Here were Roses in every form—on the tree, in the bouquet, and as single specimens. Mr. Cranston, Hereford, was fairly beaten by Canon Hole, who was able to put forward some magnificent flowers. Mr. Cranston could not well have gone to a better place to have his Roses tried on their merits, for, from a Rosarian's point of view, the show was certainly excellent. The weather being of a character to throw the plants back, and the fact that Notts grows some of the finest Roses, alike tended to bring about this gratifying state of things. Canon Hole swept away by far the largest share of the honours.

Cucumber Disease.—A disease, for which no cause has as yet been definitely assigned, and for which no cure has yet been discovered, has committed sad havoc in the Cucumber-houses of some of our largest growers. Whole sets of plants in full bearing, and which would have furnished thousands of Cucumbers, have been obliged to be cleared out and replaced by young ones. Let us hope that the latter may not share the same fate, for, in addition to the loss which such failures incur to the growers, the prices of Cucumbers will also be affected thereby. We have not heard of this disease as yet making its appearance in frame or outdoor Cucumbers, but unless it can be traced to the soil or faulty cultivation, it is to be feared that sooner or later it will prove equally destructive in private gardens.—S.

Provincial Museums, Parks, and Gardens.—In the House of Commons recently, Mr. Chamberlain drew attention to the fact that the public expenditure for the promotion of science and art was exclusively confined to London, Edinburgh, and Dublin. The amount of the estimate this year, he said, for museums, art galleries, and parks in the metropolis amounted to nearly £400,000, and that for Edinburgh and Dublin to nearly £50,000. To those sums the provinces had to contribute twice over. Birmingham contributed about £4000, and had to find about £8000 a year besides for her own local art institutions. It might be said with truth that a national collection should be placed in the metropolis at the expense of the nation. But that argument did not apply to the expenditure on the public parks, and still less to that which the Bethnal Green Museum involved. It will be well for horticulture and arboriculture if the present expenditure be more fairly distributed. If in general collections it is unwise to gather everything into one enormous focus in London, much more so is it in these two branches. In these branches of knowledge the work must be done on the spot to be of any use to the locality, while horticulture generally benefits more from a variety of collections grown in a variety of soils and situations than from a huge collection in one place. For example, the gardens at Dublin are of the greatest importance to Ireland in showing what may be depended on to succeed in that country. Again, for example, it would be greatly to the advantage of the south and west of England if there were a garden there in which similar experience might be gained. So far as trees and gardens are concerned there are indeed good reasons why something very different from the present system is desirable in the true interests of horticulture.

SWEET PEAS.

At a recent meeting of the Royal Horticultural Society (on at which there was a fine horticultural display, but few to witness it), bunches of flowers of all the cultivated Sweet Peas were exhibited by Messrs. Carter & Co. The group was one of peculiar interest, because Sweet Peas are so seldom shown. The brightest of all in colour was the Scarlet Invincible, a truly beautiful Sweet Pea, with its purple crest and clear bright scarlet wings. Purple Invincible is also a fine selection, the crest being maroon and the wings rich purple, while the flowers are large and bold. The Scarlet Sweet Pea has a purple crest and bright rose-coloured wings, and is very pretty, but lacks the size and brilliancy of Scarlet Invincible. Painted Lady is a pretty variety, the crest of which is pale purple, and the wings pink and white. The Invincible Striped gives us the Scarlet Invincible, with the wings flaked with white, on a scarlet ground. The blue-edged Painted Lady is a novel and charming variety, in which the pink and white wings become suffused with blue as the flowers age, imparting to it a very distinct appearance. The Scarlet-striped is simply the Scarlet Sweet Pea with the wings flaked with white, but is quite distinct as a variety. The Purple Sweet Pea is a pleasing, brightly-coloured variety, the crest of which is maroon and the wings bright purple. The Purple-striped has bright purple wings flaked and pencilled with white. Crown Princess of Prussia has a pale salmon-pink crest with dashes of rosy-purple, the wings being pale pink. A new variety named heterosperma is very pretty and distinct; it is a selection from the Invincible Scarlet: it has a delicate rose crest flushed with scarlet, and purple and white wings. Lastly comes an attractive new variety named Violet Queen; it was not exhibited with the foregoing, but I have since seen it growing at St. Osyth. It has a bright lilac crest and blue-violet wings, and can scarcely fail to be a favourite. There yet remains the white, with its small white flowers, very good as a variety and as affording a contrast to the dark-coloured varieties. It will thus be seen that there is quite a wealth of Sweet Peas, and, whether grown in patches of separate varieties or mixed together, they make charming garden plants both for decorative purposes and for affording cut flowers. D.

New and Old Vegetables.—As this is the usual time for sowing Cabbage seed for planting-out in the autumn, I can recommend a new variety, named the Heartwell Early Marrow (Carter & Co.), which with me has been excellent since the middle of May, and it does not run to seed like Esfield Market and some others in the spring. It is of a good size and nearly all heart, and the flavour for a Cabbage is delicious; an older variety named Cattell's Reliance, is likewise an excellent early variety, and one which seldom runs to seed in the spring. The late Mr. Pearson, of Chilwell, sent out an early variety of Cabbage named Conqueror, which was of the type of Reliance as regards coming in early and not running to seed. With the above three varieties of Cabbage a selection is made that will not fail to give satisfaction to every grower. I have lately fruited a new Cucumber sent me for trial by Carter & Co. It is named Model, and it well deserves the name on account of its great length, shape, and excellence for table use.—WILLIAM TILLEY, Welbeck.

Ferns and Achimenes in Boxes.—A neighbour of mine has the most luxuriant growth of Ferns I have ever seen. They are grown in large boxes on a south verandah, and therefore away from our hot South African sun, and scorching north winds, and they are given plenty of stable or cowshed manure, which is dug in between the Ferns every few months. These Ferns keep their beauty all the year round, but in summer they appear as if they were thickly studded with the flowers of a large blue Achimenes. Naturally one would suppose that these were in pots sunk amongst the Ferns, but no, they are in the same soil all the year round, partaking of all the water and manure which the Ferns get, and take their chance of being dug out with the trowel during the season of rest. Of course in digging in manure at that time the tubers sometimes get turned out, and my neighbour can spare some of them for friends, but enough remain amongst the Fern roots to produce the most lovely effect in summer. This seems to agree with the new light recently given on bulbs needing moisture during their resting season.—W. C. E., Port Elizabeth.

Bougainvillea spectabilis not Flowering.—Can you give me any information as to how to treat this plant so as to make it flower?—J. S. [Failure may arise from various causes, such for instance as the plant being too vigorous through having unlimited root-room, or from being in a house too much shaded, in either of which cases it is impossible to get the wood ripened. Bougainvilleas must have full exposure to all the sun and light it is possible to give them, and at the same time exuberant growth should be checked by

only allowing a limited quantity of soil on which to feed. If "J. S.'s" specimen be planted out and trained under the roof, the best thing that can be done with it now is to cut out all the gross shoots, and give no more water from now till next spring than is just sufficient to keep it from shedding its leaves. By doing this and restricting the roots so as to secure thorough maturation of each season's growth, every shoot will become clothed with flowers almost its entire length. On trellises, Bougainvilleas never get sufficient sun and light, but trained up close to the glass they are easily managed and always bloom freely.—S. J.]

Vegetation and Man.—"The earth at its surface, which human beings look upon and deal with, ministers to them through a veil of strange intermediate being, which breathes, but has no voice; moves, but cannot change its place; passes through life without consciousness, to death without bitterness; wears the beauty of youth without its passion, and declines to the weakness of age without its regrets. And in this mystery of intermediate being entirely subordinate to us, with which we can deal as we choose, having just the greater power as we have the less responsibility for our treatment of the unsuffering creatures, most of the pleasures which we need from the external world are gathered, and most of the lessons we need are written. All kinds of precious grace and teaching being united in this link between the earth and man. . . . Fragility or force, softness and strength in all degrees and aspects; unerring uprightness as of temple pillars, or divided wanderings of feeble tendrils on the ground, mighty resistance of rigid arm and limb to the storms of ages, or wavings to and fro with faintest pulse of summer streamlet. Roots cleaving the strength of rock, or biding the transience of the sand; crests basking in sunshine of the desert, or hiding by dripping spring or lightless cave; foliage far tossing in entangled fields beneath every wave of ocean—clothing with variegated, everlasting films the peaks of the trackless mountains, or ministering by cottage doors to every gentlest passion and simplest joy of humanity."—"Modern Painters," vol. v.

QUESTIONS AND ANSWERS.

St. Peter's Spem.—About a year ago I observed a shrub growing in Jersey and Guernsey which at first sight I mistook for the common evergreen *Eucalyptus*. It had a flower the scent of which was very like that of Orange flowers. A gardener told me it was called "St. Peter's Spem." I should be much obliged if you would kindly inform me of the name and history of it.—J. Y. [The shrub meant is probably *Pittosporum Tobira*, a valuable evergreen for sea-shore and mild districts.]

White Scale on Pine-apples.—It may interest your correspondent, "J.S.W." to know that the advice (see vol. ix., p. 204) which I got through THE GARDEN, how to destroy white scale on Pines, turned out a complete success. I applied it at the end of February, under circumstances not at all favourable, my plants, having been imported in the autumn, not being well established; however, they stood it very well, except a few black Jamaicas.—CHR. L. JOHANNSEN, Hardenberg, Sackjobing, Denmark.

Salus and the Potato Disease.—I notice in a contemporary that the disease has appeared on the Potatoes at Chiswick. Can you inform me whether it has attacked that portion of the crop to which the "Salus" was applied at planting time, under the superintendence of Mr. Worthington Smith, and if the plants are as badly affected as the others? Your contemporary furnishes the most meagre information on this point, and as it is now about time to apply the second dressing of "Salus," the public would now doubt be glad to hear the result of the experiment at Chiswick so far.—A POTATO GROWER. [The Potatoes at Chiswick are affected in a similar manner to those of two years ago, on which Mr. Worthington Smith found the rest-spores of the *Peronospora*. Whether the evil is, as was then stated, an earlier stage of the disease or not, we cannot tell, but it is very different from the well-known form, of which there are no traces apparent yet. Those Potatoes which have been dressed with Salus are affected quite as much as others not so treated. In the disease which is now attacking the plants at Chiswick, a plant here and there becomes affected, the leaves spot and wither up, and gradually dwindle away entirely, without any infection or spreading. Some are of opinion that this new form of disease is due to some extraneous cause.]

Lentils.—(1) Are there different qualities of Lentils used in this country? If so, would Lentils about 2½s. per bushel, containing a large proportion of dirt in small lumps, be considered an inferior quality? (2) What are inferior qualities used for?—A. X. A. [(1) As is the case with other things there are good and bad samples of Lentils, and the price (2½s. per bushel) is the value of a good sample. (2) Inferior samples are used for pig feeding, and they are also ground up and used in certain condiments for poultry feeding.—C. H. S.]

Garden Seats and Wire Netting.—Mr. Thomas, Edgware Road, exhibited at a recent meeting at South Kensington some examples of garden seats and wire netting, which were reported, by mistake, to have been shown by Mr. Hatchman.

CITY AVENUE GARDENS.

THE beauty of which avenue gardening is capable, even in cities, is fairly shown in the accompanying illustration. The effect is from various points of view very free and graceful, there being considerable variety in the vegetation and ample room in the well-formed footways and roads. There is also considerable breadth—a notable fact in days when large gardens have none; indeed, the most pleasing feature to anyone caring about garden design is the ample lawns that form a carpet for the groups and masses of shrubs. Most large cities have opportunities for the formation of avenue gardens which have hitherto seldom been taken advantage of; and in the future improvement of the Metropolis, the mode of proceeding most satisfactory would be the cutting of roomy avenues through many crowded parts of the town, now with closely packed and mean houses of little value and incapable of accommodating many persons. Indeed, such avenues or

TREES AND SHRUBS.

SALIX LAURIFOLIA.

IN several of our nurserymen's catalogues is mentioned a tree which they call *Salix laurifolia*. The specific name is not authorised, and I have not found it even as a synonym in any works to which I have had access. *S. pentandra* is the nearest, from which, in several respects, it is yet notably different. Be this as it may, the tree, though but a Willow, is such a gem among Willows, that one admires it without charging upon it the blemishes of its family. I have been educated to a full appreciation of this medium-sized tree by slow degrees. No other in our grounds has excited from visitors the same amount of praise; in truth it at first annoyed me, that friends would pass by costly novelties, with polite expressions of approval, to pour out upon this words of real admiration; and so at

A City Avenue Garden.

open roads, or whatever they may be called, are a greater need in very large cities than parks, because they give means of ready circulation as well as free air, and also greatly improve the value of property in each part of the town which they traverse.

New White Martagon Lily.—None of the new Lilies equal in beauty the old White, but there is a really good form of the White Martagon in the hands of Mr. Parker: it is likely to be a valuable garden plant. He also has the double Martagon—more curious than beautiful. Good forms of this Lily are desirable from its free growth in our climate even in woods.

The Yellow Variegated Cock's-foot.—This is a new form of a well-known native Grass, which is likely to be as popular or more so than the old well-known variegated form of this plant. The variegation is a soft yellow, regular, and the growth free. The plant is one of the many precious varieties of our native plants discovered by our correspondent Mr. Elliot, who has done more than any other man in discovering and securing beautiful variegated and other interesting forms of British plants. The present form is being distributed by Messrs. E. G. Henderson, of Pine Apple Place.

length it happened that I saw this tree not as a Willow at all, with a malarial atmosphere of swamps about it, but as one of remarkable beauty, none the worse for its lowly connections.

That it should be one of the first to unfold its leaves in the spring, and one of the last to lose them in the autumn, is a characteristic of Willows generally, though possessed by this species in an unusual degree; while that it should thrive in extremely dry situations, as well as in those of medium and excessive moisture is, as far as I am aware, peculiar to this species. We have one specimen growing beside a lake, upon a bank less than 1 ft. above its level, so that its roots are perpetually in the water. Another specimen is placed in a situation that is neither dry nor moist; another grows upon high, dry ground, within 3 ft. of a wing of our dwelling, and still another in a situation so sandy and dry, that we have been obliged, after repeated failures with other plants, to use such salamanders as Pines, Locusts, Privets, Matrimony Vines (*Lycium barbarum*), and the like, to secure something of an ornamental appearance to this half arid belt.

Between the above specimens—growing in soils and situations so widely different—there is little difference in growth or thrift, and this little is in favour of the specimen growing near the dwelling.

The Weeping Willow (*S. babylonica*) is in England a far handsomer tree than it is with us—at least in the middle and northern States. It is not quite hardy in this climate (New York)—not perhaps owing to the severity and extremes of weather alone, but because it is often weakened by various insects or their larvæ, that infest and sometimes girdle the stem. Thus, if not killed outright, it is often so injured by the frosts of winter as to present anything but a pleasing appearance the following summer. Hence we seldom see it in its full size and beauty; besides, it is not, like the *S. laurifolia*, at home in sandy, dry situations. In view of this, as also of the fact that I have never known the stems of *S. laurifolia* to be injured by insects, I attempted last summer to bud the one upon the other. The bud of *S. laurifolia* upon the *S. babylonica* lived, and is now growing vigorously; the bud of the *S. babylonica* upon the *S. laurifolia* perished. Doubtless, however, the rule would work both ways, and thus the insect and drought-resisting *S. laurifolia* could be made the stock of the Weeping Willow, which cannot so well endure drought, and is so often at the mercy of insect depredations.

As to the identity of *S. laurifolia* and *S. pentandra*, the leaves of the former (as you may see by those enclosed) are longer, averaging at this time (June 27) 4 in.; they are also more finely crenate, more acuminate, and provided with reniform stipules. The tree is of more rapid growth, and attains to a somewhat greater height than *S. pentandra*, which, according to Loudon, is from 18 ft. to 20 ft. *S. Meyeriana*, which Linnaeus calls *S. pentandra*, more nearly corresponds with the form and size of the leaf, but the branches cannot be called "brownish," and the stipules do not "soon fall off." One of our oldest nurserymen, Mr. S. B. Parsons, imported it from Augers in 1860, under the name of *S. laurifolia*, which, had it been either *S. pentandra* or *S. Meyeriana*, would have been quite unnecessary.

In the above respects there may be a difference between the male and female trees. I speak only of the female, never having seen any other; but of it I may say with enthusiasm that, on account of its incomparably glossy leaves that reflect the slightest light, its tall, smooth branches that sway in the wind as if they would surely be torn into shreds, and, withal, its elasticity, freshness, and shapeliness, it is worthy to fill not only those out-of-the-way places which are deemed unworthy of the finer plants, but of an imposing position upon the lawn, where, by the free use of the pruning-knife, it may be made to assume a round, spreading head, or, if left to itself, a fastigate form, more glossy than, and as darkly green as, *Magnolia grandiflora*, and as compact and symmetrical as need be desired.

I should be glad if you could determine the name of this Willow.

E. S. CARMAN.

River Edge, Bergen Co., New Jersey.

[The Willow leaf which Mr. Carman has sent is, according to Mr. Gordon, that of *Salix lucida* of Michaux, and *Salix Forbesi* of Sweet's "Hortus Britannicus" for 1830.]

WIER'S CUT-LEAVED MAPLE.

SEVERAL years ago, in August, I was walking between two rows of Silver-leaved Maple seedlings (*Acer dasycarpum*) or the common Soft Maple of our river bottoms. My attention was attracted by one with very peculiar foliage. A careful observation of it convinced me that it was not only very peculiar but very beautiful. Its leaves were finely divided, almost grass-like, clear, bright green above, with the midribs a bright crimson, silvery-white beneath. The twigs were slender, of nearly the same size throughout, and gracefully pendulous. The tree was then of three years' growth from seed, and had been once transplanted, one little tree among many thousands. It was carefully marked, and a number of its finest leaves taken home and pressed; these were shown to neighbours, but most of them considered a Maple tree a Maple tree and nothing more. Samples of the leaves, and a description of the tree were sent to Messrs. Ellwanger & Barry, Rochester. They were at once

interested in it, and wrote me that if I would send them a plant of it they would hold it subject to my order, and if it came up to my commendation they would pay me a reasonable consideration for the privilege of being the first to introduce it. After growing it one season, they offered me a very satisfactory price for this privilege. I sent the stock to them, and it has been one of the attractions in the way of new plants in their catalogues for several years, and may now be seen in many of the finest plantations in the country. The autumn after I found the original tree it was taken up and replanted in a place of safety. At that time it had a little scion growing from its collar, the next season this took root, and it and the scion were sent to Ellwanger & Barry. In the spring of 1870 it became necessary to transplant the original tree again. This was an exceedingly dry season, and I nearly lost it. Wier's Cut-leaved Silver Maple, says Mr. G. Ellwanger, though of recent introduction and therefore but little known, is one of the most beautiful and remarkable trees with cut or dissected foliage yet introduced. Its growth is rapid, shoots slender and drooping, giving it a habit almost as graceful as the Cut-leaved Birch. The foliage is abundant, silvery underneath, and on the young wood especially, deeply and delicately cut. The leaf-stalks are long and tinted with red on the upper surface. We believe it will rank at once among the most interesting and attractive of lawn trees, and may be easily adapted to small places by an occasional cutting back, which it will bear to any degree necessary, as well as a Willow. It will doubtless eventually become vastly more popular than the Birch, owing to the ease with which it may be propagated. It grafts or buds readily on seedlings of the Soft Maple. My favourite way of working it is to bud or graft it at standard height on the strongest-growing seedlings: this plan adds greatly to its pendulous habit.—D. B. WIER, *Lacon, Marshall Co., Ill.*, in "Prairie Farmer."

New Magnolias.—We have received flowers of *Magnolia Lenné*, *M. Thunbergi*, and *M. Halleana* from Messrs. R. B. Parsons & Son. These are varieties—the first of purpurea and the other two of the Chinese. The *Lenné* differs from the *M. purpurea* in having very broad petals. *Halleana* has numerous narrow, white petals—is, in fact, semi-double, and *Thunbergi* is a fine-petaled variety, more cream-coloured. In reference to these we have the following note:—"I sent you by mail a box containing flowers of *Magnolia Thunbergi*, as we named it long ago. Since sending it, Mr. T. Hogg tells us he is under the impression that he bloomed it some time ago under the name of *M. stellata*. We have grown it about twelve years, and these are the first flowers we have had. It is good as a variety, but not equal to *Magnolia Halleana*, which, with its dwarf habit, small flowers, and fragrance, is a great acquisition. This *M. Halleana* we have bloomed a number of years. These Magnolias, with *Retinosporas* and other things, we received from Dr. Hall, who was then in business in Japan, and very fond of plants. I hope you will be able to form some idea of the character of the flower."—"Gardeners' Monthly."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Hardiness of *Fremontia californica*.—This precious shrub, hitherto supposed to require a wall, has this year bloomed freely in the open ground in Mr. Parker's nursery at Tooting. Therefore we may assume that at least on warm or well-drained soils we have in this a hardy shrub of the highest promise for our lawns and choice groups of shrubs and low trees.

Siamese Twin Trees.—Within a mile of where I live there are two trees grown together—an Oak and a Beech. The Beech measures 110 in. round, the Oak 78 in. They are about 50 ft. high, and joined by one limb, which shows no signs as to whether it grew from the Beech or the Oak; but as the Oak faces the field and light, and the Beech is directly behind it, I should think it more likely to have originally sprung from the Beech.—H. M. R.

Large Silver Firs (see p. 48).—There are some very fine specimens of the Silver Fir in the grounds at Herriard Park and Hackwood Park, both in Hampshire. Several of them measure 12 ft. and upwards in circumference at 3 ft. from the ground, and are fairly healthy. I do not know their exact heights, but judging by the way in which they overtop other large trees growing round them, I should say that they are quite 130 ft. in height. At the former place these stand on high ground, and are a landmark for miles around. The soil is a stiff calcareous loam, resting on chalk. A Spruce growing near the Silver Fir in Hackwood Park measured nearly 17 ft. in circumference at 4 ft. from the ground five years ago.—H. J. C., *Grimston*.

THE GARDEN OF BRITISH WILD FLOWERS.

"A MASS of weeds and Briers run wild; the sooner they are cleared away the better!" Such might be the opinion of too many a gardener of the old school on the wild garden. It is hoped, however, that some change is gradually coming over our national taste, and a love for the hardy wildings of Nature—the old-fashioned plants of our forefathers—reviving. We want to see them restored not to trim avenue and made border, but growing in a truly natural garden as if at home in their native haunts. There are many of our British wild flowers which are eminently entitled to garden honours by their beauties of form as well as of colour, and far more suited for true landscape gardening than the stiff beds in which fashion places the favoured foreigners. Without wishing to detract in the least from the merits of the said foreigners, many of which are most useful in the wild garden, it is the object of the present series of papers to pass under review our British flora, calling attention to those features of the various plants which make them desirable in the transcript of Nature that we wish to effect by their groupings.

CLEMATIS VITALBA.—First in the order of the botanist, and among the first in loveliness comes Traveller's Joy, Old Man's Beard, Virgin's Bower of dear old Gerarde, Honesty of the Gloucestershire hills, and Clematis Vitalba (the "tendrill-like White Vine"), as the scientific term it. Strange as it may seem to the uninitiated, this plant is ranked with Anemones, Larkspurs, Columbines, and Monk's-hood, in the natural Order Ranunculaceæ—the Buttercup or Crow-foot tribe—but its woody stem and leaves in opposite pairs are exceptional characters in the group. Its clambering stems and bright green leaves in old quarries or hedge-rows on our chalk downs, the limestone of the Cotswolds, or more sparingly in other situations, are familiar objects in spring; but only the more observant will have remarked its mode of climbing; how it twines the stalks of its leaves around the other plants in its vicinage, thus showing a transition towards those climbers in which the leaves have become modified into tendrils. When we examine its bright, clustered flowers, which are often nearly 1 in. in diameter, we find a resemblance to the Anemone and Marsh Marigold, in that there is no green calyx, the four white sepals alike covering the bud and appearing as petals. In several genera in this Order the corolla is thus absent. The numerous pale creamy stamens add another charm to the beauty of the individual blossoms, while after flowering the plant remains attractive through the summer from the shortly-tufted, woolly tails or awns of the small dry fruitlets or achenes, which, when the leaves are shed, remain considerably lengthened, and give the plant its name of Old Man's Beard. As we have mentioned, the Clematis loves a light, dry, calcareous soil, but it by no means refuses to grow elsewhere, and will flourish in a tolerably stiff garden loam. We have seen its stem 5 in. or 6 in. in diameter, but no doubt, if desired, it might, like its well-known foreign allies, be trained over the wall or porch of a house. It is not a native of Scotland or Ireland, and occurs on the Continent from Holland southwards, in Western Asia, and Northern Africa. Though its blossoms are scented and of good size, it is rather *en masse* that this plant claims our attention, and we would suggest that where it cannot be placed on a steep, rocky bank, or quarry, it may form with the double Pink Bramble, the White Bryony, and the Sweet Brier, or some other wild Rose, a graceful clump of mingling sprays of leaf, blossom, and fruit, such as we have seen on many a Surrey common, clustering round an old Thorn, or under the branches of a fine Elder. Our woodlands afford few more brilliant autumn combinations than the red hips of the Rose, the berries of the Bryony, the large clusters of the black-purple of the Elder, the luscious Blackberries, and the white crests of Clematis.

THE ANEMONE.—Three very distinct species of this genus are ranked among British plants, viz., the Pasque-flower (*A. Pulsatilla*), the Wood Anemone (*A. nemorosa*), and the Apennine Anemone (*A. apennina*); of these the last can hardly be considered wild. The genus is characterised by the absence of petals, the function of which is performed by the overlapping or imbricate sepals, by the lobed or divided leaves springing directly from the ground, and by the three leaf-like bracts,

which form a whorl or involucre on the flower-stalk. Our idea of a trimly-shaven lawn may have had its origin in those natural lawns formed of Moss in woods or of stunted Grass on our limestone downs, and it may be well to have some part of our wild garden similarly free from domineeringly luxuriant Grass, and better still for the variety of gay-flowering, prostrate plants with which we can cover it, if such a space be on calcareous soil. It is on such lawns, on the chalk and limestone from Yorkshire to Gloucestershire, Berkshire, and Suffolk, that the glorious purple blossoms of the Pasque-flower display

The Pasque-flower (*Anemone Pulsatilla*).

their Easter splendour. It was from the Paschal-tide of its flowering that Gerarde gave it its popular name. Last year, growing side by side, the Wood and Apennine Anemones blossomed on the 5th, and the Pasque-flower on the 8th of April. This plant never attains any considerable height, and its white, silky, much-cut leaves, do not fully develop themselves until after the flowering of the plant; the purple, drooping bud appears on a short stalk, but soon turns upwards and opens its bright violet bell, nearly 2 in. deep, exhibiting the mass of golden anthers; the sepals are six in number, and silky on the outside. A single plant will produce over a dozen flowers. After flowering, the flower-stalk, crowded with a bunch of silky awns, lengthens considerably; like the Columbine, the flower sometimes varies to a maroon-red, and Sir William Guise informed me that in Anvergne he found this colour only. Besides the above-mentioned counties, this plant is recorded

Wood Anemone (*A. nemorosa*).Apennine Anemone (*A. apennina*).

from Hertfordshire, Cambridge, Huntingdon, Bedford, Northampton, and Lincoln, the nearest localities to the metropolis being Ashley, in Hertford, and Streatley, in Berkshire. The Wood Anemone (*A. nemorosa*) is so universal in its distribution, and so well known as to need no description. Its white, pink or rosy flowers are among the greatest ornaments of our copses and wood glens from March to May. The flowers are rendered strikingly conspicuous by the dark green of their smooth leaves. The plant derives much of its beauty from the graceful drooping of the flowers, and the large masses in which it grows, especially in clearings in the woods. Besides the above-mentioned colours the recently introduced blue form (*A. nemorosa* Robinsoniana) and that with double flowers are especially noticeable as suited for planting under the trees of

the wild garden. The Wood Anemone extends into Arctic Europe and North America, and reaches altitudes of nearly 3000 ft.

Similar situations in the garden are suited to the Apennine and Yellow Anemones (*A. apennina* and *A. ranunculoides*), neither of which are truly natives of the British Isles. The violet flowers of the former have more numerous and narrower sepals than the Wood Anemone and are more spreading, whilst the latter is a most desirable plant, owing to its bright yellow blossoms, which succeed those of the Winter Aconite (*Eranthis hyemalis*). The Apennine species is naturalized in many plantations, especially at Cullen in Banffshire and at Wimbleton Park, Surrey. The yellow species occurs in parks in several counties, among others at Abbot's Langley, Hertfordshire, Worksop in Nottinghamshire, and in Kent.

MEADOW-RUES.—Another group in the Crowfoot tribe is that of the Meadow-rues (*Thalictrum*), so called on account of the small wedge-shaped leaflets into which the compound leaves (which they possess in common with so many members of the tribe) are divided, which resemble very closely those of

Yellow Meadow Rue (*Thalictrum flavum*).

the true Rue (*Ruta*) and of the well-known Wall-rue Fern (*Asplenium Ruta-muraria*). Like the Clematis, the Meadow-rues have no petals, but the sepals are small and overlap one another in the bud, an important character for diagnosis, which is expressed by the term "imbricate." The individual flowers of the Meadow-rues are neither brightly-coloured nor beautiful; but they are grouped into extremely graceful inflorescences, which feature, in combination with their Fern-like foliage, renders them desirable for the garden. They are variously arranged by botanists, but we would especially direct attention to the Alpine Meadow-rue (*Thalictrum alpinum*), and the Lesser Meadow-rue (*T. minus*), as the other forms are somewhat coarse in their growth. The Alpine Meadow-rue has very minute leaflets and an unbranched inflorescence of few, drooping, purplish flowers. It inhabits Alpine and sub-Alpine bogs, ranging from the Himalayas, across northern Asia and Europe to America, and extending into Arctic latitudes. It grows, as might be expected, also at a considerable altitude, reaching 4000 feet above the sea. The plant ranges in size only from 4 in. to 10 in., but has a close habit of growth, so as sometimes to resemble very remarkably one of the *Adiantums*; thus it is obviously well worthy of cultivation. I recently saw some flourishing examples of the group at Messrs. Henderson's, Wellington Nursery, along with the Lesser Meadow-rue, a plant with similarly graceful foliage and a loosely-branched flower-spike of yellowish blossoms, which ranges in height from 6 in. to 18 in., and is most desirable for the rock garden, since, though having a geographical range similar to that of the Alpine species, it frequents dry places in the wild state, and does not grow at altitudes over 1800 ft.

G. S. BOULGER.

OLD ROSES.

"WITHOUT at all denying the great beauty of many of the Hybrid Roses," writes Mr. Ellacombe, "I am sure that growers of hardy flowering shrubs do not know what they lose in so entirely ignoring old Roses as they do." We entirely agree with our correspondent, and think that one function of the Rose Society should be to extend the knowledge and promote the cultivation of these lovely flowers. As a means to this end we asked Mr. Ellacombe to be kind enough to select from the multitude grown by him those species most remarkable or interesting as garden plants. In reply he has sent us the following list, but in view of the confusion of the nomenclature, he simply gives the names as he finds them, without accepting responsibility for their correctness:

CARRAGE ROSE.—Unsurpassed for scent, the "Provencal Rose" of Hamlet.

MOSS ROSE.

DAMASK.

SCOTCH.—Forms most beautiful bushes, which are loaded with flowers in their season.

BANKSIAN, white and yellow.—Is the single form in cultivation?

BRACEATA OR **MACARTNEY.**—A grand single Rose with bright foliage. The double form is very inferior, as it wants the golden centre.

VILLOSA.—The old Apple Rose. Very effective as a lawn shrub both in flower and fruit.

GREEN ROSE, R. VERTE.—More curious than pretty.

MICROPHYLLA.—A charming Rose when well grown, and very distinct; very double, beautiful foliage, unlike any other plant, and with a curious prickly calyx.

ALBA.—One of the oldest English garden Roses, and most excellent, but seldom seen out of cottage gardens; pure white, double, but not very fully; probably a variety of *R. avensis*, and almost beating the white Rose of York.

RUBRIFOLIA.—Curious for the colour of the stems and leaves, and handsome both in flower and fruit; single.

MOSCHATA.—The old Musk; a long rambling Rose, but very sweet, with clusters of pure white flowers.

YORK AND LANCASTER.—Very distinct.

ALPINA.—The Rose without a thorn.

ANEMONIFLORA.—Fortune's name for a very distinct form of *R. indica*, a small double cluster Rose.

MULTIFLORA.—The Bramble-flowered Rose. A pretty Rose, very like the double Bramble.

DE MEAUX.—An excellent old Rose.

R. RUBIGINOSA.—Double and single Sweet Brier.

AUSTRIAN BRIER.—Distinguished by its different colour on the outside and inside of the petals.

FAIRY ROSE.—Very dwarf, so that edgings may well be made of it. The new white one, Little Pet, is especially pretty.

MONTHLY CHINA.—Too much neglected. I know of no flowering shrub that can show such a succession of flowers as this. Does any one?

R. CINNAMOMEA.—A rambling bush, but the flowers very bright, and the long fruit very handsome.

Has any one got *R. Hardi*, *simplicifolia*, *sulphurea* single, and *myriacantha*?—"Gardeners' Chronicle."

The Wilson Raft for Water Plants.—Having been told that Messrs. Rollisson had done something in this way, I called on the 19th inst. on Mr. Rollisson, who seemed rather amused at what they had done having been made into a rival of the Wilson Raft, and took me down to see it. I found near the side of a pond where there seemed much mud and little water, a fine clump of *Myosotis*, which Mr. Rollisson told me had been supported by a piece of wood. From the present stationary appearance, I should suppose that the roots have long since reached through the few inches of water to the mud at the bottom of the pond. My journey was, however, not wasted, as Mr. Rollisson, on hearing my ideas explained to him, warmly adopted them, and as with his series of ponds he has every facility for the purpose, and has now all the particulars I can furnish, I feel sure that we shall have the uses of the raft most fully and successfully developed. I must add that after seeing so much pond space, with some Water Lilies already growing, and with one part which never freezes, I felt surprised that such a simple contrivance as the Wilson Raft had not been thought of.—GEORGE F. WILSON, *Heatherbank, Weybridge*.

Lilium superbum in Ohio.—In moist localities through the woods here just now, this fine Lily is in perfection—its flower-spikes rising up to a height of 6 ft. or more, producing twelve and fifteen flowers on a single spike. The buds, before they open, are very pretty, being bright orange-scarlet, the inside spotted with dark purple. Lifted in autumn, and planted in a well-enriched flower-bed, they do remarkably well, and form a very attractive addition to the flower garden. A bed in the flower garden here just now, planted with it, is the prettiest one we have.—M. MILTON, *Cleveland, Ohio*, in "Country Gentleman."

THE MOCCASIN FLOWER IN ENGLAND.

AMONG the many evidences of the growth in favour of the finer classes of hardy plants, are the numerous specimens of this that have been seen in flower round London during the past two seasons. The plant thrives freely in moist peat or bog earth, or rich loam with plenty of leaf-soil. It loves a somewhat shady situation, in the south at least. Messrs. Jas. Dickson, of Chester, have lately sent us some forms of this with the lip very dark and rich in colour—a

Cypripedium spectabile.

variation which may sometimes be noticed where large numbers of the flower are growing.

Japanese Note Paper.—Messrs. Goodall have brought out specimens of Japanese note paper and envelopes which possess novelty and tasteful design. The branching and blossoming of the spring-flowering trees, truthfully represented in Japanese paintings and ornaments, are here reproduced with very good effect in green, blue, pink, silver, and golden hues. The Bamboo stem and foliage is also used with a graceful effect in silvery printing; but the same design in black is far from pretty, and this may be said of all the "mourning" patterns. The Japanese are said to be a happy and joyous people, whose art is in many ways worthy of our best attention, and we should never suspect them of printing hideous black patches on their paper—no matter how sad the occasion. The use of black-bordered paper is indeed dying out in this country in many families. The other papers, however, are most tastefully designed and printed, and worthy of the repute of the Messrs. Goodall for tasteful colour-printing.

Trees in Shropshire.—The "Annual Register" for 1760 says:—"We hear from Shropshire that an Oak was lately felled near Ludlow, in that county, the contents of which were as follow, viz. 1—36 tons of timber, 42 cords of wood, 200 park pales, and 4½ cords of brackets. A bough broke off before the tree was felled which weighed 7½ tons. Two men were employed a month in stacking it. The tree was valued at £132."

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 55).

Rosemary.

- (1) *Perdita*. Reverend sir,
For you there's Rosemary and Rue; these keep
Seeming and savour all the winter long.
Winter's Tale, act iv., sc. 3.
- (2) *Baud.* Marry come up, my dish of chastity, with Rosemary and Bays.
Pericles, act iv., sc. 6.
- (3) *Edgar*. Bedlam beggars, who, with roaring voices,
Strike in their numbed and mortified bare arms
Pins, wooden pricks, nails, sprigs of Rosemary.
Learn, act ii., sc. 3.
- (4) *Ophelia*. There's Rosemary, that's for remembrance; pray you,
love, remember.
Hamlet, act iv., sc. 5.
- (5) *Nurse*. Doth not Rosemary and Romeo begin both with a letter?
Romeo. Ay, nurse; what of that? both with an R.
Nurse. Ah, mocker! that's the dog's name; R is for the dog. No; I
know it begins with some other letter:—and she hath the pret-
tiest sententious of it, of you and Rosemary, that it would do
you good to hear it.
Romeo and Juliet, act ii., sc. 4.
- (6) *Friar*. Dry up your tears, and stick your Rosemary
On this fair corpse.
Ibid., act iv., sc. 5.

The Rosemary is not a native of Britain, but of the sea-coast of the south of Europe, where it is very abundant. It was very early introduced into England, and is mentioned in an Anglo-Saxon Herbarium under its Latin name of *Ros marinus*, and is there translated by bothen, *i.e.*, Thyme; also in an Anglo-Saxon vocabulary of the eleventh century, where it is translated *Feld-madder* and *Sun-dew*. In these places our present plant may or not be meant, but there is no doubt that it is the one referred to in an ancient English poem on the virtues of the Rosemary, published in Wright and Halliwell's "*Reliquiæ Antiquæ*."

We can now scarcely understand the high favour in which Rosemary was formerly held; we are accustomed to see it neglected, only tolerated in some corner of the kitchen garden, and not often tolerated there. But it was very different in Shakespeare's time, when it was in high favour for its evergreen leaves and fine aromatic scent, remaining a long time after picking, so long, indeed, that both leaves and scent were almost considered everlasting. This was its great charm, and so Spenser spoke of it as "the cheerful Rosemarie," and good Sir Thomas More had a great affection for it. "As for Rosemarie," he said, "I lett it run alle over my garden walls, not onlie because my bees love it, but because tis the herb sacred to remembrance, and therefore to friendship; whence a sprig of it hath a dumb language that maketh it the chosen emblem at our funeral wakes and in our buriall grounds." And Parkinson gives a similar account of its popularity as a garden plant:—"Being in every woman's garden, it were sufficient but to name it as an ornament among other sweet herbs and flowers in our gardens. In this our land, where it hath been planted in noblemen's and great men's gardens against brick walls, and there continued long, it riseth up in time unto a very great height, with a great and woody stem of that compasse that, being cloven out into thin boards, it hath served to make lutes or such like instruments, and here with us carpenters' rules and to divers other purposes." It was the favourite evergreen wherever the occasion required an emblem of constancy and perpetual remembrance, such especially as weddings and funerals, at both of which it was largely used; and so says Herrick of "The Rosemarie Branch"—

Grow for two ends, it matters not at all,
Be't for my bridall or my buriall.

Its use at funerals was very widespread, for Laurebergius records a pretty custom in use in his day, 1631, at Frankfort:—"Is mos apud nos retinetur, dum cupressu humile, vel rore marino, non solum coronamus funera jamjam ducenda, sed et iis appendimus ex iisdem herbis litteras collectas, significatrices nominis ejus quæ defuncta est. Nam in pnelarum funeribus hæc fere fieri solent" ("*Horticulturæ*," cap. vj.)

Its use at weddings is pleasantly told in the old ballad of "The Bride's Good-morrow"—

The house is drest and garnisht for your sake
With flowers gallant and green;
A solemn feast your comely cooks do ready make,
Where all your friends will be seen:
Young men and maids do ready stand
With sweet Rosemary in their hand—
A perfect token of your virgin's life.
To wait upon you they intend
Unto the church to make an end:
And God make thee a joyfull wedded wife.

Roxburgh Ballads, vol. 1.

It probably is one of the most lasting of evergreens after being gathered, though we can scarcely credit the statement recorded by Phillips that "it is the custom in France to put a branch of Rosemary in the hands of the dead when in the coffin, and we are told by Valmont Bomare, in his 'Histoire Naturelle,' that when the coffins have been opened after several years, the plant has been found to have vegetated so much that the leaves have covered the corpse." These were the general and popular uses of the Rosemary, but it was of high repute as a medicine, and still holds a place, though not so high as formerly, in the "Pharmacopœia." "Rosemary," says Parkinson, "is almost of as great use as Bayes, both for inward and outward remedies, and as well for civil as physical purposes—inwardly for the head and heart, outwardly for the sinews and joints; for civile uses, as all do know, at weddings funerals, &c., to bestow among friends; and the physical are so many that you might as well be tyred in the reading as I in the writing, if I should set down all that might be said of it."

With this high character we may well leave this good, old-fashioned plant, merely noting that the name is popularly but erroneously supposed to mean the Rose of Mary. It has no connection with either Rose or Mary, but is the *Ros marianus*, the plant that delights in the sea-spray. It was also sometimes called Guardrobe, being "put into chests and presses among clothes, to preserve them from moths and other vermine."

Rue.

- (1) *Perdita*. For you there's Rosemary and Rue.
Winter's Tale, act iv., sc. 3. (See Rosemary No. 1).
- (2) *Gardener*. Here did she fall a tear; here in this place
I'll set a bank of Rue, sour Herb of Grace:
Rue, even for ruth, here shortly shall be seen,
In the remembrance of a weeping queen.
Richard II., act iii., sc. 4.
- (3) *Ophelia*. There's Rue for you; and here's some for me: we may call
it Herb-grace o' Sundays: O, you must wear your Rue with a
difference.
Hamlet, act iv., sc. 5.
- (4) *Clown*. Indeed, sir, she was the Sweet Marjoram of the salad, or
rather the Herb of Grace.
Lafew. They are not salad-herbs, you knave, they are nose-herbs.
All's Well That Ends Well, act iv., sc. 5.

Here are two names for the same plant, Rue and Herb of Grace, and though at first sight there seems to be little or no connection between the two names, yet really they are so closely connected that the one name was derived from or rather suggested by the other. Rue is the English form of the Greek and Latin *ruta*, a word which has never been explained, and in its earlier English form of *rude* came still nearer to the Latin original. But *ruth* was the English word for sorrow and remorse, and *to rue* was to be sorry for anything; we still say a man will rue a particular action, *i.e.*, be sorry for it; and so it was a natural thing to say that a plant which was so bitter, and had always borne the name *Rue* or *Ruth*, must be connected with repentance. It was, therefore, the Herb of Repentance, and this was soon transformed into the Herb of Grace (in 1838 London said, "it is to this day called Ave Grace in Sussex"), repentance being the chief sign for Grace; and it is not unlikely that this idea was strengthened by the connection of Rue with the bitter herbs of the Bible, though it is only once mentioned, and then with no special remark, except as a titiable garden herb, together with Anise and Cummin.

The Rue, like Lavender and Rosemary, is a native of the more barren parts of the coasts of the Mediterranean, and has been found on Mount Tabor, but it was one of the earliest occupants of the English Herb garden. It is very frequently mentioned in the Saxon Leech books, and entered so largely into their prescriptions that it must have been very extensively grown. Its strong aromatic smell, and bitter taste, with the blistering quality of the leaves, soon established its character as almost an heal-all.

Rew bitter a worthy gres (herb)
Mekyl of myth and vertu is.

Stockholm MS. 1305.

Even beasts were supposed to have discovered its virtues, so that weasels were gravely said, and this by such men as Pliny, to eat Rue when they were preparing themselves for a fight with rats and serpents. Its especial virtue was an eye-salve, a use which Milton did not overlook—

To nobler sights
Michael from Adam's eyes the filme removed
Which that false fruit which promised clearer sight
Had bred; then purged with Euphrasie and Rue,
The visual nerve—for he had much to see.

Paradise Lost, B. 11.

and which was more fully stated in the old lines of the Schola Salerni—

Nobilis est Ruta quia lumina reddit acuta;
Auxilio rutæ, vir lippe, videbis acute;
Cruda comesto recens oculos Caligine purgat;
Ruta facit castam, dat lumen, et cogent astum;
Cocta facit Ruta et de pollicibus loca tuta.

After reading this high moral and physical character of the herb, it is rather startling to find that "it is believed that if stolen from a neighbour's garden, it would prosper better." As other medicines were introduced the Rue declined in favour, so that Parkinson spoke of it with qualified praise—"Without doubt it is a most wholesome herb, although bitter and strong. Some do rip up a head-rows of the virtues of Rue . . . but beware of the too frequent or overmuch use thereof." And Dr. Daubeny says of it, "it is a powerful stimulant and narcotic, but not much used in modern practise."

As a garden plant, the Rue forms a pretty shrub for a rock-work, if somewhat attended to, so as to prevent its becoming straggling and untidy. The delicate green and peculiar shape of the leaves give it a distinctive character, which forms a good contrast to other plants.

Rush.

- (1) *Rosalind*. He taught me how to know a man in love, in which cago
of Rushes I am sure you are not prisoner.
As You Like It, act iii., sc. 2.
- (2) *Phæbe*. Lean but on a Rush,
The cicatrice and capable impressure
Thy palm some moment keeps.
Ibid., act iii., sc. 5.
- (3) *Clown*. As fit as Tib's Rush for Tom's fore-finger.
All's Well That Ends Well, act ii., sc. 2.
- (4) *Romeo*. Let wantons light of heart
Tickle the senseless Rushes with their heels.
Romeo and Juliet, act i., sc. 4.
- (5) *Dromio*. Some devils ask but the parings of one's nails,
A Rush, a hair, a drop of blood, a pin,
A Nut, a Cherry-stone.
Comedy of Errors, act iv., sc. 3.
- (6) *Bastard*. A Rush will be a beam
To hang thee on.
King John, act iv., sc. 3.
- (7) *1st Groom*. More Rushes, more Rushes.
2nd Henry IV., act v., sc. 5.
- (8) *Eros*. He's walking in the garden—thus; and spurns
The Rush that lies before him.
Antony and Cleopatra, act iii., sc. 5.
- (9) *Othello*. Man but a Rush against Othello's breast,
And he retires.
Othello, act v., sc. 2.

- (10) *Grumio*. Is supper ready? the house trimmed, Rushes strewed, cobwebs swept?

Taming of the Shrew, act iv., sc. 1.

- (11) *Katherine*. Be it moon or sun, or what you please,
And if you please to call it a Rush candle,
Henceforth I vow it shall be so for me.

Ibid., act iv., sc. 5.

- (12) *Glendower*. She bids you on the wanton Rushes lay you down
And rest your gentle head upon her lap.

1st Henry IV., act iii., sc. 1.

- (13) *Marcus*. He that depends
Upon your favours swims with fins of lead
And hews down Oaks with Rushes.

Coriolanus, act i., sc. 1.

- (14) *Iachimo*. Our Tarquin thus
Did softly press the Rushes.

Cymbeline, act ii., sc. 2.

- (15) *Senator*. Our gates
Which yet seem shut, we have but pinned with Rushes;
They'll open of themselves.

Coriolanus, act i., sc. 4.

- (16) And being lighted, by the light he spies
Lucretia's glove, wherein her needle sticks:
He takes it from the Rushes where it lies.

Rape of Lucrece.

- (17) *Cæsar*. This common body,
Like to a vagabond Flag upon the stream,
Goes to and back, lackeying the varying tide,
To rot itself with motion.

Antony and Cleopatra, act i., sc. 4.

I place the Flag (No. 17) among the Rushes with some hesitation. We now commonly call the Iris a Flag, and in Shakespeare's time the Iris pseudo-acorus was called the Water Flag, and so the passage might, perhaps, have been placed under Flower-de-Luce. But I do not think that the Flower-de-Luce proper was ever called a Flag at that time, whereas we know that many plants, especially the Reeds and Bulrushes, were called in a general way Flags. This is the case throughout the Bible, the language of which is always a safe guide in the interpretation of any cotemporary literature. The mother of Moses having placed the infant in the ark of Bulrushes "laid it in the flags by the river's brink." Job and Isaiah also mention the Flag as a water plant, and it is certain that in none of these places is the Water Iris referred to. I conclude, therefore, that when Shakespeare named the Flag he meant any long-leaved waterside plant that is swayed to and fro by the stream, and that, therefore, the proper place for his Flag is among the Rushes. For, like the Reed, the Rush often stands generally for any water-loving, grassy plant, and, like the Reed, it was the emblem of yielding weakness, and of uselessness. The three principal Rushes referred to by Shakespeare are the Common Rush (*Juncus communis*), the Bulrush (*Scirpus lacustris*), and the Sweet Rush (*Acorus Calamus*).

The common Rush, though the mark of badly cultivated ground, and the emblem of uselessness, was not without its uses, some of which are referred to in Nos. 1, 3, and 11. In No. 3, reference is made to the Rush-ring, a ring, no doubt, originally meant and used for the purposes of honest betrothal, but afterwards so vilely used for the purposes of mock marriages, that even as early as 1217, Richard Bishop of Salisbury had to issue his edict against the use of "annulum de junco." But the uses of the Rush were not all bad. Newton, in 1587, said of the Rush—"it is a round smooth shoote without joints or knots, having within it a white substance or pith, which being drawn forth, sheweth like long white soft geatte and round thread, and serveth for many purposes. Heerewith be made manie pretie imagined devises for Bride-ales and other solemnities, as little baskets, hampers, frames, pitchers, dishes, combs, brushes, stooles, chaires, purses with strings, girdles, and manie such other pretie and curious and artificiall conceits, which at such times many do take the paines to make and hang up in their houses, as tokens of good will to the new married Bride; and after the solemnities ended, to bestow abroad for Bride-gifts or presents." It was this "white substance or pith" from which the Rush candle (No. 11) was and still is made: a candle which in early days was probably the universal candle, which, till within a few years, was the night candle of every sick chamber—in which most of us can recollect it as a

most ghastly object as it used to stand, "stationed in a basin on the floor, where it glimmered away like a gigantic light-house in a particularly small piece of water" ("Pickwick")—till expelled by the night-lights, and which is still made by Welsh labourers, and, I suppose, in Shakespeare's time was the only candle used by the poor.

If your influence be quite damm'd up
With black usurping mists, some gentle taper,
Though a Rush-candle from the wicker hole
Of some clay habitation, visit us
With thy long level'd rule of streaming light.

Comus.

But the chief use of Rushes in those days was to strew the floors of houses and churches (Nos. 4, 7, 10, 12, and 14). This custom seems to have been universal in all houses of any pretence. "William the son of William of Alesbury holds three roods of land of the Lord the King in Alesbury in Coun. Buck by the service of finding straw for the bed of the Lord the King, and to strew his chamber, and also of finding for the King when he comes to Alesbury straw for his bed, and besides this Grass or Rushes to make his chamber pleasant."—"Blunt's Tenures." The custom went on even to our own day in Norwich Cathedral, and the "picturesque custom still lingers in the West of strewing the floors of the churches on Whit Sunday with Rushes freshly pulled from the meadows. This custom attains its highest perfection in the church of St. Mary Redcliffe at Bristol. On 'Rush Sunday' the floor is strewn with Rushes. All the merchants throw open their conservatories for the vicar to take his choice of their flowers, and the pulpit, the lectern, the choir, and the communion rails and table present a scene of great beauty."—THE GARDEN, May, 1877.

For this purpose the Sweet-scented Rush was always used where it could be procured, and when first laid down it must have made a pleasant carpet; but it was a sadly dirty arrangement, and gives us a very poor idea of the cleanliness of even the best houses, though it probably was not the custom all through the year, as Newton says, speaking of Sedges, but evidently confusing the Sedge with the sweet-scented Rush, "with the which many in this countrie do use in sommer time to straw their parlours, and churches, as well for coolness as for pleasaut smell." This Rush (*Acorus Calamus*) is a British plant, with broad leaves, which have a strong Cinnamon-like smell. Another (so-called) Rush, the Flowering Rush (*Butomus umbellatus*) is one of the very handsomest of the British plants. On a long straight stem it bears a large umbel of very handsome pink flowers, so sweet-scented that the old Saxon name of the whole plant was Beewort. Wherever there is a pond in a garden, these fine Rushes should have a place, though they may be grown in the open border where the ground is not too dry.

There is a story told by Sir John Mandeville in connection with Rushes which is not easy to understand. According to his account, our Saviour's crown of thorns was made of Rushes! "And zif alle it be so that men seyn that this Croune is of Thornes, zee shall undirstande that it was of Jonkes of the See, that is to sey, Rushes of the See, that prykken als scharpely as Thornes. For I have seen and beholden many times that of Parys and that of Constantynoble; for thei were bothe on, made of Russches of the See. But men have departed hem in two Parties, of the which o part is at Parys, and the other part is at Constantynoble—and I have on of the precyouse Thornes, that semethe licke a white Thorn, and that was zoven to me for great speyaltee. . . . The Jewes setten him in a chayere and clad him in a mantelle, and then made thei the Croune of Jonkes of the See."—"Voiage and Travaile," c. 2.

I have no certainty to what Rush the pleasant old traveller can here refer. I can only guess that as Rushes and Sedges were almost interchangeable names, he may have meant the Sea Holly, formerly called the Holly-sedge, of which there is a very appropriate account given in an old Saxon runelay thus translated by Cockayne—"Hollysedge hath its dwelling oftenest in a marsh, it waxeth in water, woundeth fearfully, burneth with blood (i.e. draws blood and pains) every one of men who to it offers any handling."

H. N. ELLACOMBE.

(To be continued).

PLATE LXXXIV.

THE ZEPHYR FLOWERS

(WITH COLOURED FIGURES OF ZEPHYRANTHES ROSEA AND TUBISPATHA).

Drawn by H. NOEL HUMPHREYS.

THIS beautiful genus, which has not inaptly been termed the Crocns of America, includes about fourteen species, the geographical range of which extends from the meadows of Virginia through Mexico, the West Indies, Peru, Chili, and Buenos Ayres, those growing nearest the equatorial line occurring relatively at the greatest elevation. They are low-growing, bulbous plants, with linear leaves which appear in spring with or before the blossoms, and solitary (or occasionally two) white or rosy pink Crocus-like six-petalled flowers, which are often large and handsome. By some botanists, *Zephyranthes* is regarded as a section of *Amaryllis*, from which it differs in the one-flowered scape and in one or two technical details. Several species are in cultivation, of the best of which we give a description. They require rest during the winter, and at that season are best kept dry, being planted out in the full sun in spring in very sandy soil. They also do well in the greenhouse, planted four or six in a pot. They are increased by means of offsets. Botanists place them in two sections, in the first of which the germen is stalked, while in the second it is sessile.

Section A.—Germen stalked.

***Zephyranthes Atamasco* (Atamasco Lily).**—This handsome plant, which is an old inmate of our gardens (having been cultivated in England in 1690 by Mr. Charles Hatton) is a native of North America (Pennsylvania, Carolina, Virginia, Florida, &c.), where it is a conspicuous ornament of damp places in woods and fields, presenting, when in flower, a very beautiful appearance. It has linear, strap-shaped, glossy leaves, which appear at the same time as the blossoms, which they slightly exceed in height; the blossoms are about 3 in. long, borne singly upon a scape 6 in. high; they are white within, the three outer segments of the perianth being striped with rose-colour. This species flowers from May to July, usually during the last named month. It grows well in the open border, and increases rapidly by offsets, which should be removed and divided in the spring of every third or fourth year.

***Z. carinata*.**—This pretty species has linear, channeled, keeled leaves, which are reddish at the base. The scape, which is 6 in. high, bears a delicate rosy flower 2 in. or 3 in. in length, with obovate, oblong, pointed segments. It blossoms freely in the greenhouse if kept dry in winter, and should be grown in a light sandy loam. This species is widely distributed in South America, from Mexico to Brazil, occurring also in Jamaica. The offsets diverge obliquely, so that their leaves pierce the ground at some distance from the parent, forming, as Herbert observes, "a circle of satellites round it, as if the plant were stoloniferous (which is not, however, the case) instead of making a close tuft like *striata*, *tubispatha*, &c."

***Z. tubispatha*.**—This species has few linear green (sometimes rather glaucous) channeled leaves, about as long as the spathe and as thick as a quill; the scape has a bifid spathe, half as long as the pedicel, bearing a white, slightly fragrant flower, from 2 in. to 3 in. long, with lanceolate subequal segments, which are greenish below; the tube is very short, somewhat rounded within by the bending of the filaments. It is a native of Antigua and of the Blue Mountains of Jamaica, and is properly a stove plant, requiring a sandy soil, rest in winter, and plenty of water in summer. A pretty pink hybrid was obtained by Herbert from this species crossed by *Z. carinata*; this is sometimes met with in cultivation under the name of *Z. Spofforthiana*.

***Z. rosea*.**—This beautiful species has bright green, narrow, recumbent leaves longer than the one-flowered scape; the flowers are of a bright rose-colour, erect, regular, and funnel-shaped. It is a native of the mountains of Cuba. A variety, described as having only two leaves (and hence called *bifolia*) and a more robust scape, is found in the woods of St. Domingo and Cayenne.

Section B.—Germen sessile.

***Z. candida*.**—This very beautiful plant has, like the first, the advantage of being perfectly hardy; at least, so we learn from Dean Herbert, its original describer, who speaks with surprise of the fact that a plant which thrives in the hot valley of Lima should have stood with him out-of-doors unprotected for nine or ten years with-

out ever entirely losing its leaves. It resists, he says, "the severest frosts of our usual winters, and has ripened its seeds with me after snow had lain upon them for three weeks. I have seen the quicksilver 15° below freezing point (Fahr.) without its losing more than the ends of its leaves." *Z. candida* has linear, fleshy, quite smooth, semi-cylindrical, Rush-like leaves, more than double the length of the scape; the scape is about 4 in. high, sloping towards the sun, with a purplish spathe and handsome, brilliant white flowers, which are greenish at the base, and spread out widely in the sunshine, usually lasting only a day. It produces flowers in quick succession during August, September, and the beginning of October. Herbert says he has had seventy blossoms expanded at once on a small patch of the plants. This species is a native of Buenos Ayres, where it is stated that the banks of the River La Plata are so covered with it that it is understood that the river took its name (which means silver) from the profusion of these white flowers upon its shores. It is abundant in old gardens in the valley of Lima, where its blossoms attain a large size. Herbert mentions a variety from Buenos Ayres which has flowers externally suffused with red, and also a larger form from the same district, in which the blossoms are fully 3 in. across. This species increases rapidly by offsets, and should be extensively cultivated. Herbert says there is "a little mystery" as to the expansion of its flowers. He had seen them open quite flat in warm sunshine, but nevertheless, in very cold, gloomy weather with a north wind, its blossoms were seen standing about three-quarters expanded at night; a few days after, when the wind was south-west and warmer, the flowers were not nearly so open even in the day, as if its expansion depended on the dryness of the atmosphere. It grows especially well in a warm sheltered border at the bottom of a south wall.

Another species of this section (*Z. sessilis*) is sometimes met with in cultivation. Two varieties have been described (*Z. verecunda* and *Z. striata*) having slender leaves and white flowers more or less tinged with red on the outside. B. J.

DISTINGUISHING HEMLOCK.

THE HEMLOCK (*Conium maculatum*), will be in perfection in a week or two, and is already being gathered for making extract. This plant is very similar in appearance to many other umbelliferae, but is easily distinguished by certain characters. Although the smooth spotted stem is very characteristic, yet the spots are often present only on the lower portion of the stem. The plant which most closely resembles it in appearance is Fool's Parsley (*Æthusa Cynapium*), which may be distinguished as follows:—Underneath each partial umbel there are three long pendent bracts, but there is no general involucre. The fruit has vittæ, two of which form very distinct lines on the flat surface of the half fruits, and the ridges on the fruit are not crenated. The leaves also have brownish points to every segment, and are minutely serrated below each point. The serrated character is easily seen with a lens. In *Conium* each partial umbel has three, or rarely four, short bracts, which do not surround the stalk, but are placed on the outer side of it. The fruit has no vittæ whatever, and the ridges of the fruit are minutely crenate, and the leaves have minute white points to every segment, which are quite entire below the points. The only fruit with which that of *Conium* could be well confounded is the Russian Aniseed, which is very similar in shape, size, and colour, but is seen by the aid of a lens to be covered with minute white hairs. Two other plants are known in this country under the name of Water Hemlock, which must not be confounded with the true Hemlock. One of these (*Eranthe crocata*), is not uncommon in ditches and damp places in woods. It may be recognised by the somewhat cylindrical fruit, which has two long erect styles, by the wedge-shaped segments of the leaves, and by the roots consisting of five large fusiform tubercles. It is properly called Hemlock Water Dropwort, but is often confounded with the true Water Hemlock (*Cicuta virosa*), a much rarer plant, found here and there in the midland counties, but rarely seen in the south of England. The leaves have narrowly lanceolate, serrate segments, and the fruit is spherical, like that of Coriander, but rather smaller. Both plants are extremely poisonous, and fatal accidents have frequently happened through persons eating the root of *Eranthe crocata*, which has a not unpleasant taste, death usually resulting in two hours after partaking of it, and sometimes even in so short a space as half-an-hour. Most cases of poisoning reported as owing to Water Hemlock are probably caused by the Hemlock Water Dropwort, the *Cicuta virosa* being comparatively rare, and having a simple non-tubercular root, which is not very likely to be eaten.—"Pharmaceutical Journal."

A gentleman has undertaken to supply fruit trees for planting 5 out of the 20 acres of land in Worcestershire belonging to the St. George's Company.

THE SINGLE KERRIA.

DOUBLE flowers have hitherto been so much sought after that the single form, from which they arose, is sometimes lost to cultivation. The single Banksian Rose, for example, is a rarity, though we can say, from seeing it in the south of France in flower, that it is a charming bush. It is the same with the Kerria, of which the common form is the double one—a well-known old favourite; but the single form is the most beautiful of the two. Those who wish

Single-flowered Kerria japonica.

to add a really elegant shrub to their hardy collections should try and secure it.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE admirable manner in which the Chairman at the Thirty-fourth Anniversary Festival urged the claims of necessitous gardeners, causes regret that such well-meant endeavours should fail to enlist the active support of those for whose benefit the Institution was founded; for even the most favourable view that can be taken of the extent of its operations, contrasted with the wide field that exists for such an Institution, must convince the most sceptical that, as far as the majority of gardeners is concerned, the Institution is practically a failure. It awakens no feeling of security amongst those who, to the best of their ability, endeavour to provide for age and infirmity, accident or disease, for although gardeners, as a rule, are temperate and therefore healthy men, they enjoy no special advantages as regards immunity from the ills that "flesh is heir to." Indeed, some of their work in forcing-houses, where high, moist atmospheres are maintained, and the great and sudden variations of temperature to which they are exposed, have a weakening and enervating effect upon them, as many know to their cost. But it is urged—Why do not these young men join the Gardeners' Royal Benevolent Institution? From my own observation and experience, I should say for the following reason:—Gardeners, if really so in anything but name, are led by the nature of their calling and everyday experience to look for "practical results" as the criterion of worth in reference to every operation which they undertake, and although there are no lack of visionary schemes inaugurated under the name of gardening, the great bulk of the order are only found practising and employing

those means that rest on the solid basis of past experience, as affording a reasonable hope of success in the future. Now I can truly say that "The Gardeners' Royal Benevolent" is about the last Institution to which young gardeners look as affording a reasonable hope of support in their time of need. For the benefits which it offers are not only entirely inadequate to meet the most urgent wants of bare existence, but there is nothing definite as to when these slender means of support will be obtainable. For those in the most urgent need of pecuniary support would, as a rule, be equally in need of "friends" to give the necessary votes, and would in all probability have the mortification of seeing more favoured candidates placed on the list, while they went empty away. It is perhaps ungracious to even question the acts of a charity that receives such generous support both from Royalty and the aristocracy generally, but the glossing over or altogether withholding the reasons that keep the rank and file of gardeners from actively supporting an Institution intended for their benefit will never increase its popularity. "Gilding a hive will not make the working bees take to it." The Gardeners' Royal Benevolent Institution labours under the great disadvantage of being partially composed of benefit members, and yet it draws its principal revenue from those who subscribe through purely benevolent motives. The largest item of revenue is derived from donations after the annual anniversary festival dinner—a very precarious source, and, of course, greatly influenced by the pleading, good or otherwise, of the chairman, whose kindly expressions of sympathy and regard for necessitous members of the craft are highly valued by those who have no wish to share in the pecuniary benefits of the Institution. For I should say that by far the greater proportion of gardeners that subscribe do so from purely benevolent motives, in order to assist their less fortunate brethren, and I believe that still more would subscribe if the charity were purely benevolent, as I never yet found gardeners slow to alleviate any real case of distress. But the weak point of the charity is that which affects benefit members, and, unfortunately, gardeners can seldom afford to be anything else. In their young days the majority of them become members of some well-established society that will guarantee the means of existence when incapacitated from following their usual occupation, or they become entitled to an annuity on arriving at a fixed age—not as a charity or by the precarious means of voting papers, but as a right; and gardeners, as well as other men, like to eat the bread of their own industry, in preference to becoming a burden to the generous donors of this or any other society, who, as a rule, have many and urgent calls upon their support. As a gardener myself, and closely associated with improvers, foremen, and even head gardeners I can confidently say that all would welcome and support a society composed exclusively of gardeners, and for their benefit. But if such a society is to flourish, its aim and purposes must be clear and definite, or so practical a class of men will continue to do, as they do now, viz., stand aloof. They do not begrudge thanks to those who, from philanthropic motives and a pure love of gardening, subscribe freely to the only Institution that exists for the benefit of those who are left in needy circumstances while engaged in some of the varied departments of horticulture. But those who would join as ultimate benefit members need think it no disgrace that they are compelled by circumstances to invest the small surplus at disposal, with perhaps more than ordinary care, for self-preservation comes by instinct and overpowers the higher motives of benevolence. While yielding to no one in love for my calling, I cannot disguise the fact that many who enter on its apparently rosy paths with high expectations in youth, too often find them thorny in the autumn of life. All honour therefore to those who from their abundance endeavour to solace the declining years of those who are vanquished in the fight. But let it not be thought that gardeners are negligent of one of the first duties of a citizen, if they do not, as at present constituted, support "The Gardeners' Royal Benevolent Institution."

JAMES GROOM.

Henham.

Rustic Gates.—It is a great fault of much of the rustic work now made, in the minor articles of baskets, chairs, and seats, as well as in the more important structures of gates, pavilions, summer-houses, &c., that they not only do not look permanent, but are really slightly put together and frail. More thought appears to be given to the ingenious fitting of crooked sticks, than to the enduring character of the structure. There is scarcely anything about a place that gives more trouble by getting out of order, than a much-used entrance-gate. Even when constructed with all the care that can be given to straight timber, and braced and bolted in the most approved manner, it often requires repairing. When it comes to the irregular forms used in rustic work, the difficulty of making a durable article greatly increases, and we have not seen a gate of this kind that did not soon become a nuisance. If one feels that he must build a rustic gate, then let it be put together in every part with bolts, and extra care be taken in the bracing, even to some sacrifice of "rusticity."

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vineries.—Amateurs who started their Vines with a little warmth about the beginning of March, will have the fruit now commencing to colour; as soon as this is observable, gradually withhold moisture from the atmosphere and leave on about half-an-inch of air back and front during the night. Where the fruit is desired ripe early, the house should be closed in the afternoon whilst the sun is on the glass, so as to allow the temperature to rise considerably for two or three hours, after which a little air as already recommended should be admitted. Where plants are grown with late Vines overhead the plants should be placed in frames or out-of-doors for some weeks to come, as unless the Vines are pushed on by closing the house early in the afternoons, the crop, which this year is unusually late excepting where fire-heat has been employed in the spring, will not ripen before the autumn is too far advanced; the night temperature, consequent upon this shutting-in of sun-heat with the accompanying moist condition of the atmosphere necessary to exist with it, would be very injurious to the plants, unless in the case of late-flowered Camellias, and Azaleas that have not yet completed their growth, which will be exactly suited by it; but where Azaleas are grown under Vines they should be carefully examined every fortnight or three weeks to see that they are clear from thrips, on the appearance of which the plants should be immediately dipped in or syringed with Tobacco water; which operation will prevent these pests from attacking the Vines. Air must still be given in the mornings as soon as, or before, the sun comes upon the glass, but the house should be shut up by three or four o'clock, according to the state of the weather. With a view to keeping the Vines clear from red spider, a fine-rosed syringe should be used at the time of shutting up the house until the fruit begins to colour, for although the bloom that adds so much to the appearance of the fruit will be somewhat reduced by the application of water, yet this is of much less consequence than keeping the foliage free from this troublesome little insect; the whole of the under side of the leaves should be wetted, at the same time care should be taken not to wet the bunches more than can be avoided. Those who have not had much experience in Grape-growing should look over the leaves of their Vines once a week, to see that they are free from this insect; its presence is easily detected by a little discoloration in the leaves, as it very soon gives them a slightly brown tinge observable when looking through them with the light above; it most usually makes its appearance about the base of the Vines, and when confined to comparatively few leaves it may be kept from spreading by the careful use of a soft sponge and clean water applied to both the under and upper surfaces of the leaves. Nothing should be left undone to keep the foliage free from it, as where it once obtains any ascendancy, it is impossible to colour Grapes properly; although so diminutive, it punctures and sucks the sap from the leaves to an extent that quickly renders them incapable of performing their allotted functions, and the mischief does not end with the defects in the fruit of the present season, but the Vines are rendered weaker for the future. Where any portion of the roots is inside the house, the border must be well supplied with water, any deficiency in this matter whilst the fruit is swelling being fatal to its well-being. If the Vines be at all deficient in strength, or carry a heavy crop, the roots both inside and outside should be well soaked with manure-water; but this must not be applied later than within two or three weeks of the crop beginning to colour, otherwise the flavour may be affected. Keep the laterals stopped more or less closely proportionately with the amount of foliage that exists, remembering that the more healthy leaves the Vines carry, the better they will succeed. When kept closely stopped in to such an extent as is frequently practised, Vines do not long remain in a satisfactory state.

Peaches.—Where Peaches have been gathered, to keep the leaves free from red spider and in a healthy condition the trees should have a copious washing with clean water: the garden engine is the best means of applying it, failing it the syringe. This operation must not be confined to merely sprinkling the leaves, but the whole of both their upper and under surfaces as well as the wood, should have a thorough washing. Admit plenty of air night and day and see that the roots receive enough moisture, for any deficiency in that respect will cause a premature stagnation in the development of the fruit-buds for another year.

Roses.—Amateurs who grow Roses will derive additional pleasure in the cultivation of their plants if they bud them themselves. A few stocks procured every autumn and planted 1 ft. apart in a row in any spare ground in the garden will be in a condition for budding the following summer. Growth with these as with most things has this season been late, consequently neither the shoots of the stocks nor the buds to be inserted have been in a condition for operating upon as in ordinary years; but they may be budded now.

Dahlias and Hollyhocks, where they require it, must be secured with sticks; it is not necessary to use very tall ones for Hollyhocks (as is sometimes supposed), unless the plants are in an exposed situation, which they ought not to be; but the sticks should be strong and inserted in the ground to a considerable depth, in which case if they stand 4 ft. above the surface they will be found to be a sufficient support. The practice of tying Dahlias to one or two single sticks with all the shoots drawn together in the shape of a broom should never be followed; it gives them a most unnatural and unsightly appearance, and seriously injures them through the non-admission of light and air to the foliage; use from three to six sticks so as to tie the shoots out. These being gross-feeding plants with a great portion of their roots lying in a horizontal position just under the surface of the soil, 2 in. of rotten manure should be applied. In gardens where high-class culture is carried out, and where a neat appearance of the beds is looked for, manure when applied as a mulching to these or any other plants should be sufficiently decomposed so that it will crumble to a fine condition, and if thinly covered with a little sifted leaf-mould, the requisite protection can be afforded to the roots of the plants without any objectionable appearance. All late summer and autumn flowering perennials that require any support must have the sticks put to them immediately, always remembering that the less to be seen of the sticks and ties so used the better. Any one possessing good strains of Delphiniums, Sweet Williams, or any similar plants, should secure the seeds as they become ripe, selecting them from the best marked flowers, otherwise they are apt to degenerate. The beautiful Auricula-eyed Sweet Williams that some years ago were to be met with appear now to be all but lost, and have given place to a race of muddy-coloured flowers that have nothing to recommend them: this is much to be deplored, as even for ordinary decorative purposes, a well-marked flower of any description with the colours properly defined will always be more attractive to the general observer.

Pinks.—Amongst hardy plants, there are few more deserving of cultivation than Pinks; they require little room, and are especially adapted for amateurs, their deliciously-scented and beautifully-marked flowers rendering them suitable for cut purposes of all kinds: two or three blooms will fill a room with their agreeable perfume. It is now time to put in the cuttings, or pipings as they are usually called; these should be made from the young shoots that spring from the bottom of the plants, and in a condition neither too hard nor too soft; put them in fine sifted soil, to which has been added some leaf-mould and sand, inserting them 1 in. apart, and covering with a hand-light or bell-glass. The shady side of a Currant bush, or any position where they will be screened from the rays of the sun is suitable for them; all the attention they need is keeping them sufficiently moist, and occasionally examining them, removing any that have damped off and are mouldy. When well rooted in the autumn, they may be planted out three or four together at intervals in the borders, or still better, in a small bed of prepared soil, allowing them to remain through the winter, and flower the ensuing spring.

Pears on walls, espaliers, and trained pyramids, will in most places now be in a condition to have their summer growth removed. There are two methods of carrying out this necessary operation, one of which used to be much more common than it is at the present time:—This consists of breaking the shoots about two-thirds through at 4 in. or 5 in. above the base of whence they spring, leaving them hanging with the remaining portion of the wood and bark for a few weeks, removing them afterwards; this has the effect of checking further growth in the shoots, and directs the energies of the trees to the formation and development of the fruit-buds. The shoots are in this manner operated upon a little before their growth is complete; it entails more labour, but in some cases, with vigorous trees, it is better calculated to induce a fruitful condition than the more ordinary practice of allowing the shoots to remain untouched until their growth is complete, when they are cut off altogether at about 1 in. above the base; but where this course is followed, on no account should they be taken off till their growth is quite completed, which is easily discernible by the terminal leaf at the point of the shoot having attained something approaching its full size, and exhibiting a bud at the base. If the shoots be taken off whilst the points are soft and in a growing state, some of the buds below (that should ultimately produce fruit) will at once break into growth, a circumstance by all means to be avoided. Apples that are trained or grown bush-fashion, and are required to be kept within certain limits as to size, should have their summer growth similarly dealt with, but in all cases the operator ought to bear in mind that with trees whose heads are thus confined within certain limits, if the root-power of the individual tree be in excess of branch development, nothing which can be done by shoot-pruning will bring them into a fruitful state, but generally the reverse. In the case of trees that by their excess

sive vigour evinces too great a preponderance of root-power, means should be taken to curtail this a little later on.

Cherries on walls ought also to have their summer shoots similarly removed, as also Plums; it is not advisable to keep the latter too closely cut in, as they generally bear better when permitted to extend a little.

Raspberries.—It will be well to go over these again and remove any suckers that may have sprung up since the first thinning.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

July 30.—Sowing Wheeler's Imperial and Carter's Heartwell Early Marrow Cabbage, also Fraser's Broad-leaved and Green Curled Endive on border previously well watered. Planting out the last rows of Celery in trenches, in which has been put a good supply of well-rotted manure to which had previously been added soot and salt at the rate of 25 lb. of the former and 1 bushel of the latter to the load. Preparing three-light frames and planting them with Cucumbers. Putting Jargonelle Pears in gauze bags to protect them from wasps, &c. Nailing and tying-in leading shoots of Peaches and Nectarines. Tying-out and picking blooms off Fuchsias intended for exhibition at the end of August. Picking over borders of carpet bedding. Taking lights off early Peach house, and well watering the borders. Laying Strawberry runners in pieces of turf, 4 in. square, which have previously been soaked in manure-water. Fruit in use for dessert:—Pines, Melons, Grapes, Peaches, Nectarines, Apricots, Figs, Plums, Gooseberries, and Currants.

July 31.—Sowing Black-seeded Brown Cos and All the Year Round Lettuce, Red and White Turnip Radish, also a large border of Early Horn Carrots for autumn use. Potting a large batch of Primulas and Cinerarias for supplying out flowers. Taking up and stowing away Shallots and Garlic in a cool shed. Earthing-up Celery whilst it is perfectly dry. Turning a large heap of manure for Mushroom bed. Stopping laterals through all Vineries where the fruit is ripening. Hoeing, cleaning, and watering amongst late Peas. Taking up a border of Early Ashleaf Kidney Potatoes and laying them in the sun to get green for seed. Watering Celery and Cauli-flowers. Commenced summer pruning of Apples and Pears.

August 1.—Sowing Turnips. Putting in a few Pelargonium cuttings. Staking Chrysanthemums. Tying out Tricolor Pelargoniums for exhibition. Pruning and nailing Plum trees. Clearing off a large piece of Peas, and digging the ground for other crops. Pulling up pickling Onions and laying them out to dry. Stopping and nailing the shoots of Tomatoes on walls. Giving the late Vineries a good soaking of guano-water. Watering the Pines all through; also Celery, Broccoli, Lettuce, and Endive.

Aug. 2.—Sowing Mignonette in pots; also Telegraph Cucumber. Planting two three-light pits with Parsley for winter use. Renovating linings round all Melon and Cucumber frames. Digging large piece of ground (previously occupied by Peas) for Cabbages. Gathering Apricots and Gooseberries for preserving. Earthing-up Cardoons and Celery. Dutch-hoeing amongst Gooseberries and Currants. Giving carpet bedding and other borders a good soaking of water.

Aug. 3.—Sowing large piece of Spinach; also in a pit Osborn's Early Forcing Bean to succeed the outdoor crops. Planting-out Wheeler's Imperial and Carter's Heartwell Early Marrow Cabbage, on ground previously occupied by Peas, and well watering them. Re-potting batch of Ferns and Dracaenas for dinner table. Cutting last few bunches of Black Hamburg Grapes, and putting their stalks in bottles of water so that the house may be thrown open in order to ripen the wood. Spawning Mushroom bed at a declining temperature of 80°. Earthing-up Leeks, thinning Turnips and Spinach, gathering Tomatoes from plants grown in pots in Pine-houses. Watering out-door Tomatoes, late-planted Celery, Carrots, and Radishes.

Aug. 4.—Sowing a bed of Early White Naples Onions for use in spring. Pulling up one portion of spring-sown Onions to dry. Weeding and cleaning Box edging in kitchen garden. Rolling gravel walks after rain. Gathering Gherkins, Cucumbers, Cauliflower, Onions, &c., for mixed Pickles. Clearing off large piece of Raspberry canes; also a piece of Broad and Dwarf Beans. Putting together six cartloads of manure, adding 20 lb. of salt, and one bushel of soot to the load, and giving the whole a good turning for Celery trenches. Watering Peach-house; also Cabbage plants, Lettuce, Endive, and Scarlet Runner Beans.

Hardy Flowers.

ANNUALS.—It is in the flower fields at Dedham and St. Osyth that one can see annuals in perfection; the land is well suited to them, and it is thoroughly and richly tilled; it is kept clean and clear from weeds, and every attention is paid to secure a fine head of bloom and an abundant harvest of seed. What marvellous patches of colour are seen bordering the valley of the Stour at Dedham! Take, for instance, Dunnett's extra dwarf crimson Caudytuft, which is of a rich reddish-purple hue when in full bloom, and one of the finest selections found in this group; or the glowing carmine-red of *Clarkia integrifolia pulcherrima*; the deep crimson of *Viscaria cardinalis*; the golden radiance of *Eschscholtzia crocea*; the brilliant orange-scarlet of *Nasturtium Tom Thumb Scarlet*; the striking vermilion hue of *Nasturtium King of Tom Thumbs*; the soft snow-white of *Leptosiphon densiflorus albus*; the azure-blue *Nemophila insignis*, and the charming rosy-pink of the Red *Lavatera*. These might be multiplied indefinitely, but those named give the most effective groups to be met with. These are all brilliantly-coloured annuals, and their remarkable prolificacy of flower is not one of the least of the recommendations attaching to them.

DAHLIAS.—The prevailing rains are greatly helping the growth of Dahlias, but warm weather is sadly needed to give that fine development which the cultivator notes with so much approval. The soil about the plants should be kept clear of weeds, and be stirred occasionally to keep it open. The side-shoots require to be tied out to stakes as soon as they are long enough, so as to keep the centre stem as fully exposed as possible. When hot, dry weather prevails, the plants are greatly benefited by being watered overhead in the evenings through a fine-rosed watering pot.

DIANTHUS.—The annual varieties are now getting into full bloom. There is the well-known Indian Pink (*Dianthus chinensis*) and its double form; both are now in flower, and they contain very charming varieties, especially those having fringed edges. I have recently seen some selections from the Indian Pink with brilliant red and white flowers that had an unusual vividness of character, and which were of great value for cutting from. Then there is the pretty dwarf *Dianthus Heddewigii* and its fringed variety, *laciniatus*, both large and rich in colour. The best soil for these annual *Dianthus* is one of a light sandy nature. The seeds can be sown in the open ground, and the plants thinned out to a requisite distance when the seedlings are large enough to be handled.

TROPEOLUMS.—One of the most distinct of the dwarf varieties is Carter's Ruby Queen, the colour of which is remarkably distinct and good, being of a ruby-red hue, which stands well, and the flowers are produced with remarkable freedom. Another is *Lustrous*, that has vivid dark crimson flowers of remarkably fine shape and freely produced; a variety named *carminatum* has rosy-cerise flowers, and is very effective in a mass. The best yellow is one called *New Golden*; this has golden-yellow flowers with maroon spots, and is very free and effective. These dwarf *Tropeolums* make capital bedding plants, but in order that they should be dwarf and free-blooming, a selection of two or three of the most suitable plants should be made in summer, and be increased in the autumn by means of cuttings. Plants obtained in this way rarely seed, which is of material assistance in prolonging the head of bloom. If a few cuttings be struck in autumn they can be made to furnish a number of plants in spring if placed in heat and forced into growth.

VIOLETS.—Well-established plants of Violets are now throwing out strong runners, and if a stone be placed on each so as to press them to the soil, good strong plants can soon be obtained. As soon as they have begun to root into the soil the runners should be lifted and planted out in a piece of well-prepared ground in the form of a bed, and they will yield fine flowers early in autumn and winter, if the weather be at all open and warm. The state of the weather has much to do with the production of flowers.—D.

Daring Declaration of the Plan of Creation.—An assertion as daring as any with which we are painfully familiar amongst the eccentricities of the pulpit, occurs in the "Gardeners' Chronicle" for July 7, 1877. Referring to a plant of *Pelargonium tricolor* at Dropmore, the writer says:—"The object of the diversity in colour in the wild flower is to serve as a signpost to insects, which are by its guidance induced to visit the flower where they can best get the honey, and where at the same time their aid is most efficient in fertilizing the flower—a wonderful contrivance, the whole significance of which is lost by the average florist." We would ask, what is "the object" of the Creator in the case of a *Pelargonium*, the flowers of which have no "diversity in colour?" But we prefer not to tempt the man to sin again. Besides, the "average florist," who is evidently regarded by the writer as a fool, should always avoid questioning the average botanist, who is such a very superior creature.—"Gardeners' Magazine."

HARDY FLOWERS OF THE WEEK.

THE cool weather during the past week has improved vegetation wonderfully; all plants are making a rapid growth, and many are flowering luxuriantly, some, too, of the early flowering plants are making a second growth, and will flower again later on. At the trial grounds of Mr. Barr at Tooting there is a fine display of annuals, grown with the idea of testing their respective merits; among them I noticed *Leptosiphon roseus* (reminding one of a strong-growing *Androsace*), *Clarkias* in every shade of colour (both single and double), *Tropæolums*, *Collinsias*, *Nemophilas*, and a host of other fine plants. Lilies are abundant (especially the Californian and elegans sections); the *tigrinum* and *speciosum* groups look well and promise a fine display. *Oxalis lasiandra* is very attractive, certainly one of the best of the genus, growing 1 ft. in height with numerous purplish rose flowers; *O. lupinifolia* is also very good, being distinct in both foliage and flower. *Triteleia laxa* and *Murrayana*, when better known, will be found in every garden, being hardy, easily grown, rapid of increase, and producing an abundance of Tyrian purple flowers, on stems 1 ft. in height; there is a fine companion for these, *Calliprora lutea*, with large heads of yellow flowers, equally showy, and well worth cultivation. *Allium acuminatum* is a pretty dwarf species with rosy purple flowers; and *A. descendens*, 3 ft. high, has close spherical heads of a deep purple colour. Many of the Japanese Irises are in flower still; *Iris Kampferi* forms a grand group of border plants, bearing flowers of every shade of colour, and of immense size, looking more like Clematises than Irises. *Coreopsis tenuifolia* is a pretty species with deep yellow flowers on slender stems 2 ft. high; *Sisyrinchium odoratissimum* is a rare species, the flowers before expansion being striped like a barber's pole, the inside of a creamy-white, and the perfume very fragrant. At Parker's, there is a good display, and I noticed many good plants, especially his new Pea, which was justly certificated last week; it is similar in every respect to the old Everlasting Pea, but with deep crimson flowers which shine out conspicuously from the other varieties near which it is planted. *Cyananthus lobatus*, a rare Himalayan plant, of prostrate habit, light green foliage, and large Vinca-like blossoms of a light blue, is an old plant, but one rarely met with. *Omphalodes Luciliæ* is a very fine plant, being 1 ft. or more across, and covered with azure blue flowers. *Spigelia Marylandica* with long tubular crimson green-tipped flowers on stems 1 ft. high, is one of the finest of our North American plants; and beside it I noticed (although not yet in flower) *Rhexia virginica*, which a month or so later will form handsome bushes covered with large rosy purple flowers: this and the preceding like a cool shady spot in peat or leaf-mould. *Scolymus grandiflorus*, both here and at Tottenham, forms a very attractive plant, smothered as it is with golden yellow flowers; although a Thistle, it is a good plant and will repay careful cultivation. *Hypericum tomentosum*, a woolly-leaved species, is very distinct and pretty, and so is the old *Nierembergia rivularis*, which is flowering freely in pots, its large salver-like flowers on stems 2 in. in height completely covering the pots. Many of the Campanulas are flowering freely, and form very showy masses; they are excellent edging plants. One of the most conspicuous border perennials is *Lythrum roseum superbum*, which, if well known, would be in great request; and if planted against a row of *Acer Negundo variegatum*, has a very pleasing effect, the crimson spikes standing out in bold relief against the delicate fringe of the *Acer*. *Delphiniums* are in grand condition, exhibiting every shade of blue, from the sky blue of *D. formosum* *Belladonna* to the ultramarine blue of the old *D. grandiflorum*. At the Hale Farm perennials are looking well, and as this class of plants is grown to a great extent the masses of some of the bright colours form a very imposing sight. Fancy a bed of 500 plants of the double scarlet *Lychnis* in full bloom, and every head of very double flowers 3 in. across; the double white is also in flower, but not so attractive as the scarlet. *Hypericum olympicum* cannot be too highly recommended, it will grow anywhere, and is without doubt one of the finest of the genus; *Oxalis floribunda* is another fine plant of which too much cannot be said, it would make a fine bedding plant as it is in flower for four or five months, producing during that time myriads of bright rose-coloured flowers. These perpetual-flowering perennials are

invaluable, and everyone should make a point of selecting those which remain the longest in bloom; there are several other varieties with lilac, white and crimson flowers. *Dianthus Atkinsi* (flowers as large as a shilling of a fiery crimson colour blooming four months), is the best of the perpetual-flowering *Dianthus*. *Callirhoe involucrata* and *Modiola geranioides* are two

Showy Tiger Lily (*Lilium tigrinum splendens*).

pretty Malvaceous plants, the flowers of both being large and high coloured, invaluable for the front row of the border or on rockwork; both kinds thrive in a sunny spot on sandy soil. *Aquilegia Bertoloni* is the only Columbine in flower, about 1 ft. in height, with deep indigo-purple blossoms and yellow anthers. *Enothera montana* is a new species, with the habit of *E. acaulis*, and yellow flowers larger than *E. macrocarpa*; the latter is flowering freely. *Epilobium obcordatum* (the Rocky Mountain Willow Herb) is flowering more freely than usual, and is certainly a desirable plant; the flowers are large, of rosy-purple colour. *Campanula cenisia*, growing near, with numerous light blue flowers, is a fine companion for it. The scarlet-flowered Iceland Poppy (*Papaver nudicaule minimum*) is very attractive, slender stem 18 in. high, with moderate-sized scarlet flowers; it blooms abundantly, when well established, for at least two months; the white variety is also very

Globe Thistle (*Rehynops Ritro*).

Xeranthemum annuum.

showy. Several of the American Phloxes—*P. ovata* and *P. divaricata*—are still very gay; both are first-class plants. *Agrostemma flos-Jovis* is a dwarf perennial plant, with pink flowers. *Diplopappus chrysophyllus* is a conspicuous shrub, stem and under surface of the foliage of a peculiar golden-yellow colour, each branch terminating with clusters of white flowers. *Rosa rugosa* and the white variety are flowering freely, the dark green abundant foliage forming a good background for the flowers. *Silene fimbriata*, many of the herbaceous Clematis, *Adenophoras*, *Campanulas*, *Epilobiums*, and *Cimicifugas* are striving their utmost to outvie their neighbours in brilliancy and number of flowers, but these are completely eclipsed by the Mexican Dahlias, which are just expanding their bright-coloured blossoms.

THE FRUIT CROPS.

METROPOLITAN AND SOUTH-EASTERN DIVISION.

Middlesex.—Uxbridge District.—Apples in orchards are a failure; on trained trees a good crop; with me, Hawthornden is the best this year. Of Pears we have almost none, and what few we have are all more or less cracked and blackened by frost. Peaches and Nectarines are middling, about half a crop. Of Plums we have none in orchards, and but few on walls, on which the best is Victoria. Apricots are a partial crop. Figs good. Strawberries good in some places, in others middling; Sir Charles Napier and President are the two best with us this season. Of Gooseberries we have a good crop, and the same may be said of Raspberries and Currants. Filberts are a heavy crop everywhere, and Walnuts are also good. I may add that Potato crops look promising in and around this neighbourhood, no disease being as yet apparent.—G. BRUSH.

Royal Horticultural Gardens, Chiswick.—The state of the fruit crops in this district is very deplorable. Those who recommend so enthusiastically the great extension of fruit cultivation in this country, and talk of the immense profits to be derived therefrom, require only the experience of a few such seasons as this to teach them that fruit-growing in England is a very precarious occupation—one crop in seven being about a safe calculation. Commencing with the smaller fruits, Strawberries, Gooseberries, Currants, &c., are a full average crop and excellent in quality. Pears are very scarce; hundreds of trees—standards, dwarfs, cordons of all kinds and in all situations not bearing a single fruit. The only variety bearing a full crop is Aston Town, large standard trees of which are heavily laden. The Hessele, which is almost always to be depended upon, has about half a crop. There are also a few Jargonelles, and one vertical cordon tree of Prince Imperial on a sheltered part of a wall is yielding a very fine crop. Apples are more abundant, but far under the average, with the exception of certain varieties, such as Hawthornden, Stirling Castle, a useful sort; Small's Admirable (which is bearing a heavy crop), Lord Suffield, Cox's Orange Pippin, and some varieties of Nonpareil. Plums are an entire blank. Peaches and Nectarines on walls and in unheated houses are about one-fourth of a crop. Cherries (with the exception of Morellos) are entirely wanting. Figs, good crop. Filberts, a very heavy crop. Blossom was abundant; and the actual frost was not severe. The loss I attribute to the long-continued cold and the absence of sunshine during the flowering and setting period.—A. F. B.

Kent.—Eridge Castle, Tonbridge Wells.—Of Apricots we have none this season, and Peaches only occur where they are well sheltered. Pears on walls are good, and on standards half a crop. Apples are an excellent crop. Figs are good, and Nuts very plentiful. Currants, Raspberries, Gooseberries, and Strawberries plentiful, but the last are small. Cherries are a good crop; but of Plums we have none. We are 400 ft. above the sea, and escape to a great extent spring frosts.—J. RUST.

—**Tunstall, near Sittingbourne.**—The Cherries in Kent have again been a short crop, and not much unlike last year as to produce: the early sorts were all more or less much out. The sorts that stood our need best are the Bigarreau, English, and Florence; Governor Wood (a sort not much yet tried) promises to be a hardy and good cropper in an adverse season. Plums are the worst crop known for years. Pears again a bad crop, the commoner sorts having the advantage. Apples are diversified: at places a fair crop, others only a sprinkling. I doubt if there be half a crop anywhere. In sheltered places Cobnuts will be plentiful, and Walnuts are a very fair crop. Gooseberries have been fine, and a fair although not a heavy crop. Black Currants a moderate crop at most places, but they do not grow out much. Red Currants are better. On walls the crop of Peaches, Nectarines, &c., is probably the worst known for years. The trees also are much injured from the cold spring. Figs promise to be an abundant and good crop.—G. W.

—**Wierton, Maidstone.**—In the garden here we have a fair crop of Peaches and Nectarines. Plums are a light crop; the best are Prince of Wales and Diamond. Cherries are not a full crop. Figs are a heavier crop than I have seen for some years past. Apples are a light crop, the best being King of Pippins, Ribston Pippin, Cellini, Margil, and Winter Hawthornden. Strawberries are not a full crop, as much of the bloom was imperfect and small. Raspberries are a fine crop. Gooseberries of most kinds are a heavy crop, and the same may be said of Currants of all kinds. Pears are a very light crop, with the exception of Knight's Monarch, which always bears well. In orchards and fruit plantations the Apple crop is equally light as in gardens. The best croppers are King of Pippins, Ribston Pippin, Graham's Pile Russet (a good keeping, useful variety), and Stone's Apple, a kind not so well known as it deserves to

be, as it always bears well, and is a large kitchen Apple, fit for use as soon as it is large enough to gather; it is a good market Apple, and one which keeps sound till Christmas. It was raised by a farmer named Stone in this neighbourhood. Common Pears are plentiful. Cherries have produced a better crop than was expected, the kinds being Bigarreau, Kentish, and Flemish. Gooseberries are a heavy crop and fine; these receive high cultivation which answers well, as some growers produce from 2000 to 3000 bushels in one season. Currants of all kinds are a heavy crop; comparing Lee's Prolific Black the other day, with Black Naples I could see no difference between the two; they are in all respects alike. Nuts are a good crop, Cobs being the principal sort; there are still a few Filberts, but these are not so much grown as in former years; they do not succeed so well under trees as in an open situation.—W. DIVERS.

Surrey.—Combe Lane, Kingston-on-Thames.—Apples on orchard trees throughout this neighbourhood are a fair crop, but on pruned trees in gardens there are but few. Apricots are a total failure both on walls and in orchard-houses. Cherries are a thin crop, but of some sorts, such as Florence and Morello, there is a fair supply. Currants, both Red and White, are a very heavy crop, while Black Currants are rather light. Gooseberries are a good crop, and the same may be said of Mulberries. Of Pears, there are none on standards, and they are very thin generally, in some places none at all, even on walls; in pots they are no better, although they had the benefit of artificial protection. Peaches are a thin crop, in most places none at all, and the trees are only just getting over the effects of the late cold spring. Of Plums we have none whatever, either on standards or on walls. Raspberries are a fair crop. Strawberries a heavy and good crop. Figs plentiful where loosely trained on walls. Filberts are an exceedingly heavy crop. Walnuts are a good crop in some places.—WILLIAM DENNING.

Sussex.—Petworth Park.—Apples are an average crop; in some orchards plentiful. Pears very thin. Plums quite a failure, with the exception of Damsons, of which there are a few. Cherries are a fair crop in some places, none on many trees; the late rains have so spoiled the greater part that they have not been gathered, especially Bigarraus. Apricots are a failure, except under glass coverings. Peaches and Nectarines are the same. Figs promise an abundant crop; also Mulberries, Quinces, and Medlars. Nuts and Filberts are everywhere plentiful. Outdoor Grapes look very promising for a heavy crop. Strawberries were plentiful for a short time only, on account of the hot, dry weather then experienced; I have, however, plenty yet on young plants that were well watered; in five weeks only $\frac{1}{2}$ in. of rain fell, while during the past few days we have had over 3 in. Gooseberries and Currants—Black, White, and Red—are abundant. Raspberries are poor in some places, but abundant and fine in a few gardens. Apples, Pears, Cherries, and most kinds of other good fruits grown in this locality are excellent, and they consist of many good old varieties.—GEORGE BREESE.

Hampshire.—Heckfield, Winchfield.—There was as bright a promise for a good fruit harvest at blossoming time as I ever remember to have seen, and certainly I have never known a more complete failure of fruit crops generally than we have this year, the sharp frost which occurred during the month of May being almost the sole cause of their failure. Peaches and Nectarines, though well protected, did not open their blossoms kindly; I therefore think the wet autumn and consequent immature state of the wood had something to do with their failure, which is quite complete. Apples hereabouts are half a crop; the following kinds are fruiting freely, viz., Keswick Codlin, Golden Noble, Blenheim Pippin, Deux Ans, Lord Suffield, Nelson's Glory, and Hawthornden. Apricots are about a third of a crop, Moor Park being the best. Cherries (Morellos), a full crop; others very scarce. Pears are a good crop on walls of all aspects, but on standards and pyramids there are none. Of the following we have heavy crops on walls:—Hacon's Incomparable, Seckle, Marie Louise, Beurré Rance, Passe Colmar, Easter Beurré, Beurré Diel, Louise Bonne of Jersey, Beurré de Capiaumont, and Williams' Bon Chrétien. Plums are very scarce generally; the following kinds on a west wall are, however good, viz., Purple Gage, Belgian Purple, Pond's Seedling, and Magnum Bonum. All small fruits are abundant, and remarkably free from blight or aphides. Strawberries have been extra good. The following are our best kinds:—President, Vicomtesse Héricart de Thury, La Grosse Sucrée, Sir Charles Napier, and Frogmore Late Pine. Potatoes are as yet free from disease.—W. WILDSMITH.

Berkshire.—Royal Gardens, Frogmore.—Although we had 10° of frost on the morning of the 5th of May, that was not alone the cause of failure as regards many kinds of fruit, as at that time the trees were well protected with foliage. The loss of the crop of stone fruit, such as that of Apricots, Peaches, and Plums, must be attributed to a continuation of cold, sunless weather after

the fruit was set. Apples in this locality are generally below the average; Rosemary Russet, Pomona, Frogmore Prolific, and Blenheim are, however, carrying heavy crops. Pears on walls are very thin and on standards are a partial failure. Plums are a total failure. Peaches and Apricots very thin, Nuts plentiful, and Walnuts thin, with the exception of a few places where there is a good crop. Gooseberries, Currants, and Raspberries are good average crops. Strawberries were late but plentiful, and of fair quality; the best were Fairy Queen, Cockcomb, Mr. Radclyffe, La Grosse Sucrée, Sir J. Paxton, J. Powell, and Aromatic.—J. POWELL.

— **Welford Park, Newbury.**—Apricots, Peaches, Nectarines, and Plums, including Damsons, are an entire failure here this year. Of Cherries we have an average crop of May Duke and Elton; other sorts are very scarce; Morellos set an average crop, but fully half of them have dropped off. Figs are good, and look well at present. We have but few Pears: the best are Beurré Rance, Passe Colmar, and Glon Morceau, all on walls. Of Apples we have an average crop on Northern Greening, Keswick Codlin, Eclinville Seedling, Broad-eyed Pippin, and Cox's Orange Pippin; and nearly an average of Alfriston, Blenheim Orange, Cellini, Cockle Pippin, Dutch Codlin, Summer Golden Pippin, Waltham Abbey Seedling, Mannington's Pearmain, and Cornish Aromatic. The Northern Greening has only failed once in eighteen years; it is by far the most useful culinary variety which we possess, being in use from the beginning of October till the middle of June. Strawberries are an average crop. Red and White Currants a full average. Black Currants under an average, but very fine in quality. Raspberries about an average.—CHARLES ROSS.

— **Cottage Farm, Sulhampstead.**—I possess some forty varieties of the Plum tribe, and one half-pint of fruit is the fullest measure of my crop, and this is the usual complement hereabouts. Of Pears we have none upon open standards, but upon walls a fair crop is proffered. I have some two acres of orcharding, and it is said that I am better off for Apples than most people; I have a good half crop, and the limit in this neighbourhood will not reach to half a crop, as by far the majority of the trees that have come within my ken are without fruit. A dozen fair-sized Walnut trees will produce me about a bushel, and Walnuts are a meagre crop generally; but of Filberts, Cob, and common Nuts, the yield is quite an average one. Cherries are scarcely anywhere to be seen. Strawberries may be considered a good crop, and Gooseberries, Currants, and Raspberries are abundant. Odds and ends, such as Figs, Mulberries, and Grapes upon open walls, promise well. Peaches, Apricots, and Nectarines are a complete failure.—ROBERT FENN.

— **Bearwood.**—Peaches and Nectarines are a very thin crop in this neighbourhood, the trees having suffered greatly during the trying winter and spring months. Peach blight has never been so bad as it is this year, and mildew following has made sad havoc with the trees. The same remarks apply to Apricots, many trees of which are killed. Of Plums we have none on walls or standards. Pears on walls are a very fair crop, but on standards they are thin. Apples are a fair average crop, and Cherries on walls are good. Filberts too are fine. Of Strawberries many were killed through the winter; the recent rains have, however, much improved the crop, which is a fair average one. Bush fruits are very good, I may add that our Potato crops are all that can be wished for; early sorts have been good, and later kinds are very promising, and quite free from disease, although I hear of its being in the vicinity.—JAMES TEGG.

SOUTH MIDLAND DIVISION.

— **Huntingdonshire.—Ramsey Abbey.**—I do not remember to have seen Pears and Plums so complete a failure as they are this year, and the same may almost be said of Apricots. Peaches are better; in fact, Royal George, Grosse Mignonne, and one or two others are carrying good crops. Apples generally are thin. Cherries, with the exception of Morellos, are a failure. Figs are heavily laden, especially the Brown Turkey. We have an abundant crop of Currants, Gooseberries, and Raspberries, and the fruit is very fine, although later in ripening than usual. Strawberries are hardly so good, and are much later than in ordinary seasons. Open-air Grapes are very late, and unless the autumn be fine and warm they will not ripen. Nuts of all kinds are thin; indeed, in some places there are scarcely any. In my opinion, the main cause of the failure of the fruit crops this season may be traced to the short but sharp period of drought last summer, followed as it was by an exceptionally wet autumn. The heat and drought arrested the growth prematurely, whilst the damp, sunless autumn caused unusual activity too late in the season, and, as a consequence, bloom, though plentiful, was weak and imperfect. No doubt if the spring had been genial some fruit would have set, but I do not think under any circumstance, with the

wood in such an immature condition, that a good crop would have been gathered.—E. HOBDAY.

— **Buckinghamshire.—Wycombe Abbey.**—Apples are abundant here and in some other places in this locality. Of Apricots we have but few. Cherries are about a fourth of a crop. Of Peaches and Nectarines we have scarcely any. Of Plums we have none here, a few exceptions elsewhere. Pears are not a fourth of a crop. Currants both kinds plentiful and good. Raspberries a good crop. Gooseberries an average crop. Strawberries very good, but late. Nuts plentiful. Walnuts a very light crop. Taken as a whole fruit crops in this vicinity will fall much below an ordinary average, and as regards Plums, Peaches, Nectarines, Pears, and Apricots, they may be considered to be almost a total failure, a circumstance chiefly attributable to the effect of the severe frosts in the early part of May. Apart from this cause, however, it is questionable as to whether the Pear crop would have been otherwise, owing to the superabundant quantity of blossom there was on the trees, a circumstance which oftentimes results quite contrary to what is anticipated.—GEO. THOS. MILES.

— **Northamptonshire.—Castle Ashby.**—Fruit crops in this neighbourhood are, with few exceptions, very inferior, all having been destroyed by the late spring frost, which in some cases not only destroyed the fruit-bloom, but seriously injured the trees; although well covered, in many instances it totally killed the young growth, and in some cases the two and three-year wood of the Plum and Apricot trees; the same applies to the Walnut, Chestnut, and many other early-growing trees. All promised well for a good and plentiful fruit season until the spring frost did its work of destruction. Of Apricots we have none; Apples, very few; Pears, Cherries, and Plums, none; Peaches and Nectarines, a few; of Strawberries we have abundance, and very fine; Red Currants in every way excellent; Black Currants half a crop, but fine in quality; Gooseberries, a medium crop; Raspberries, a few; all kinds of Hazel Nuts plentiful, but of Walnuts we have only a few.—GEORGE BEECH.

— **Oxon.—Blenheim Park.**—I have little to report on the state of our fruit crops beyond disasters, and these, too, of a severe character. Apricots, covered and uncovered alike, are quite a failure; the severe frosts of May 4, 5, and 6 (9°, 11°, and 8° respectively), quite shrivelled up such as escaped the 14° and 16° of Feb. 28 and March 1, when they were in full flower. Where the trees have not died back they are now making a quantity of soft, watery wood, which in the natural course of things will be difficult to ripen; hence there is not a very promising prospect for next season, and this, too, in the very home of the Apricot. The failure in question is a serious loss to the cottagers, who often are enabled to pay their yearly rent from the products of their Apricot trees alone. Apples are about half a crop, such kinds as Hawthornden, Keswick and other Codlins, Stirling Castle, Blenheim Pippin, King of Pippins, and Dumelow's Seedling being about the best. Cherries are scarce; black and green fly have been most troublesome, seeming quite to disregard the usual remedies, with the season so evidently in their favour. Pears and Plums are very thin, although the trees presented perfect sheets of bloom. Nuts, both Filberts and Cobs, are a heavy crop. Strawberries have been abundant and of good quality; President, Sir Joseph Paxton, and Sir Charles Napier being found good trustworthy sorts. Raspberries and Gooseberries are a fair crop, especially the former. Currants, both Black and Red, are also a fair crop, and excellent in quality.—W. CRUMP.

WEST MIDLAND DIVISION.

— **Gloucestershire.—Ashton Court, Bristol.**—In this locality the Apple crop is much under the average, and a very partial one; in the cider orchards there will, however, be fair crops on late flowering kinds. In gardens the following are good exceptions to the general failure:—Hawthornden, Alfriston, Cellini, Kedleston Pippin, Lord Burghley, Dutch Mignonne, and Boston Russet. The continued east winds in April and May, combined with occasional sharp frosts, completely destroyed the Pear bloom, consequently, that crop may be set down as almost a complete failure, a remark that applies in fact to all stone fruits. Strawberries have been a good crop, the best being Keen's Seedling, Black Prince, Sir Charles Napier, President, John Powell, Amateur, and Eleanor. Of bush fruits, all are good with the exception of Raspberries. Figs, Medlars, and Mulberries promise to be good average crops. Common Nuts in the woods are very plentiful. Walnuts are about an average. Fruit trees and vegetation generally have been much benefited by the late rains, and are making rapid growth. I may add that the Potato crop promises to be a good one; up to the present time I have seen no symptoms of disease, and the haulm is particularly strong and healthy.—JOHN AUSTEN.

Herefordshire.—Stoke Edith Park.—Of Apricots we have a tolerably good crop, and the trees, which for some time looked very disconsolate, have begun to grow strongly, so much so that I have given them a good summer pruning (leaving less for winter pruning, much of which in the case of the Apricot is a mistake). I have had a great number of fruits fall, even after stoning, a circumstance that never occurred with me before, and which I presume to be the result of the non-ripening of the wood last autumn, and the arrest of the sap in this immature wood, owing to the frosts which occurred in May; I cover with Britain's garden netting, and it is of great benefit to the Apricot while setting its fruit to give a good soaking of water at the root, mulching immediately afterwards with good stable litter 1 ft. deep. Peaches are nearly a total failure, but I shall be able to ripen some few—perhaps 200; I have never known Peach blister to be so bad as it is this season; there is no remedy for it but stripping off the affected leaves and burning them, afterwards washing the trees well with a good engine, and giving a good soaking of water at the roots; the soil, too, should be broken up to aerate the border, thus getting the trees into active growth. Royal George, Belle Bauce, Noblesse, and Prince of Wales, are the sorts on which I have fruit; the show of bloom was very fine upon all the trees, which were as well covered as the Apricots. Plums—standards, pyramids, and wall trees—are a total failure; I took pains to have Green Gages on walls covered with double 1-in. mesh netting, but it proved useless. Of Damsons we have none. Pears are nearly a total failure, all the earliest-flowering sorts are quite gone; the frost on May 5 destroyed the embryo fruit; on that morning we registered 10°, and then we had a succession of starving east winds. The sorts of Pears which I have been able to save are Joséphine de Malines, Benrre Diel, Leon Le Clerc (Van Mons), all on a south wall. Apples are almost a failure; I would recommend Lord Suffield and Stirling Castle as two of the best Apples—they never fail; and I find that Northern Greening, Warner's King, and Tower of Glamis (in culinary Apples), have been able to resist the general destruction. In our neighbourhood we have a local Apple named Seek-no-Farther, which originated in these gardens, and I hear that it is carrying very good crops. Early cider and perry fruits are not good, but late cider fruit will be an average crop. Of Cherries I have had a very fine crop of the Kentish preserving kind, and I have also an average crop of Morellos, both on a north wall and on bushes—bushes or pyramids should be more extensively used for general culture; May Dukes I do not yet grow; Governor Wood is very good on a north wall, and so is Royal Duke or Late Duke, but on espaliers it has failed. Figs promise to be a good crop if we have warm weather to ripen it. Raspberries are very good and the fruit fine, and I have a good show of the Perpetual or autumn-fruited Raspberry, which always succeeds well here, and comes in usefully for Currant tarts and dessert. Currants, both Red and White, are a good average crop of good fruit, and Black Currants are also very fine. Gooseberries are a good average crop. Strawberries have been good and plentiful; nothing is so helpful to them as a good soaking of water at the roots when the fruit is setting. For our soil and situation Sir Joseph Paxton is the best; Marguerite, second; Oxonian, third. I have tried all others, but these do well in all seasons. Keen's Seedling also succeeds with us; it is the only sort used here for preserving; I do not use it for dessert. Sir J. Paxton and the other two are good travellers, bearing a long journey without injury.—W. WARD.

Shrewsbury.—Downton Castle, Ludlow.—Of Peaches, Nectarines, Apricots, early Pears, Plums, and dessert Cherries we have not more than one-fourth of a crop. The bloom was all that could be desired, but owing to late frosts and north-east winds fruit trees of most kinds have proved a failure. Of early sorts of Apples we have about half a crop, and of very late kinds, such as Bittersweets or cider fruit, a fair crop. Blenheim Orange and King of the Pippins are the varieties most grown in this district. Of Morello Cherries I have a good crop; Red, White, and Black Currants a fine crop; and of Strawberries, Gooseberries, Raspberries, and Mulberries the same may be said. Nuts, both Filberts and Walnuts, are good.—WM. LONDON.

Staffordshire.—Drayton Manor, Tamworth.—Fruit in this district is almost a total failure. Pears on pyramids and bushes are an entire failure; on espaliers they are little better, and on walls about a quarter of a crop. Glou Morcean, Benrre Rance, Ne Plus Meuris, and Bishop's Thumb are the best. Apples are but a sorry crop, especially dessert varieties; of these the best are Ribston Pippin and Blenheim Orange. Kitchen varieties are rather better, but still these are much under average. The different kinds of Codlin and Northern Greening are the best. Plums and Damsons are an entire failure. Apricots are under average, and the same may be said of Cherries and Black Currants. Strawberries are a good crop; my best varieties are President, Sir Charles Napier, and

Vicomtesse Héricart de Thury. Raspberries are a good crop, as are also Gooseberries, and Red and White Currants. The failure of the Pear, Plum, and Damson crops I attribute entirely to the severe frosts which we had on May 4, 5, and 6, when we had 13°, 15°, and 12° respectively. Previously we had a splendid show of healthy blossom, which could not have failed to have produced a good crop. I attribute the failure of our Apple crop to very high winds which prevailed during the week ending May 27. They were so high with us that they blew the blossom off in showers before it had time to set. The weather was also very dry and cold during that week, no rain having fallen, and the wind being east and north-east.—OWEN THOMAS.

Worcestershire.—Impney Hall, Droitwich.—Fruit crops are generally thin in this district, and many of the trees (stone fruits especially) have suffered severely from biting, easterly winds, which continued several weeks in April and May, accompanied by hail and cold rains. Apples are not plentiful, except the common kinds used for cider, which seldom fail, and for that reason they are allowed to form boundaries of fields and to grow by the sides of lanes and bye-roads, with little attention except at the period of fruit gathering. Orange Pearmain, Cellini, Peach Apple, Brown Russet, and Blenheim Orange, are bearing full crops. Apricots are thin in this district, though in many cases they set well and were promising in the early part of the season. Cherries are a fair crop, but the trees have been much infested with black aphids. Currants and Gooseberries of all kinds are abundant and good; young trees planted here last season are loaded; some old bushes lifted from an old garden and planted in new ground last January are also bearing fine crops. Figs on open walls, which promised well, have cast much of their fruit since the copious rains which we have had fallen. Filberts are a fair crop. Peaches and Nectarines are scarce on open walls, and at every place which I have visited blister and insects have been very destructive. The trees planted here last season are generally healthy and have made good growth, but they suffered severely in May from blistering; those under glass, which were planted from pots last August and received no fire-heat, set a fine crop, and no blistering is to be seen among them. Plums are a small crop, except the common kinds, but all have suffered from green aphids. Pears are thin, except in sheltered positions. Raspberries are a fair crop, but generally small and late. Strawberries are plentiful; British Queen and Elton are excellent.—M. TEMPLE.

Madresfield Court.—Apples of all the best kinds are more or less a failure in this district; but cider fruits, owing to their being generally later, are somewhat better, and some kinds in sheltered situations are tolerably well fruited; among dessert Apples the hardiest are Blenheim Pippin and Starmer Pippin. Of culinary kinds Lord Suffield, Hawthornden, Golden Spice, and the old but not-to-be-despised Keswick Codlin, are the most certain croppers; of these Lord Suffield is a never-failing variety, and one which should be extensively grown. Apricots set well and promised an abundant crop, but owing to the severe check experienced by the ascending sap, most of them dropped when commencing the process of stoning. Pears also are very thin, except on well-sheltered walls; here, on west walls, we have a fair crop, but on bushes and pyramids they are a complete failure. Peaches and Nectarines are good here, but in many other places there are none, and the trees are very unhealthy, so much so that extensive plantations of young trees must be made next season. Plums are all but a total failure both on walls and standards; Black Diamond and Rivers' Early Prolific are the only kinds that are producing any fruit here. Early Cherries are very poor, and Morellos not more than one-fourth of a crop; many of the trees are in a dying state. Bush fruits are a moderate crop, with the exception of Currants, which are fine, clean, and good. Nuts are a fair average crop; Coppice Nuts abundant. Walnuts very partial, but a crop on trees in sheltered situations.—WILLIAM COX.

Witley Court.—Fruit crops in this district, as far as Apples, Pears, Plums, and Cherries are concerned, are almost a total failure, and what few fruits have escaped are inferior in quality, owing to the cold, sunless, ungenial weather which has characterised the whole season. There are, it is true, isolated instances where moderate crops of Apples are to be seen, but these are very exceptional, and pointing out particular sorts which have escaped would be somewhat invidious, as upon both early and late-blooming varieties may be seen a few fruits, thus showing that not only have the early varieties suffered, but that late cider sorts have also succumbed, dropping their fruits in the embryo state. Pears are quite a failure, both as regards orchards and walls. Of Plums we have none, a statement which also includes Damsons. Cherries are also very scarce and poor in quality, with the exception of the Kentish and Morello kinds, which carry full average crops. Apricots are a scanty crop. Peaches and Nectarines are carrying full average crops, and the trees are

healthy; the varieties which showed early in the season derangement of the tissue from excessive cold were Noblesse, Walburton, and Stirling Castle Peaches, and Victoria Nectarines. Strawberries have produced abundantly upon an adhesive soil; the most serviceable have been Keen's Seedling, President (still one of the best), Vicomtesse Hericart de Thury (a fine, free-cropping variety, producing moderate-sized fruit with a brisk sub-acid flavour), Sir Joseph Paxton (a sort which produces fine, large, well-coloured fruit in abundance, but which at best is but moderate in quality), and Lucas (a very finely-flavoured variety, but one which does not crop so abundantly as some upon this soil); to these may be added The Queen and Dr. Hogg, which still maintain their pre-eminence as regards quality. Of Raspberries we have famous crops of good quality; Antwerp and Prince of Wales are fine kinds for general culture. Gooseberries and White and Red Currants are abundant. Thus it will be seen that whilst we have lost our tree fruits we have an abundant supply of bush fruits, which may be accounted for by their being more sheltered from the long continuation of cold, cutting winds and low temperature which prevailed throughout the spring. Nuts are profusely cropped. I may add that Potatoes are healthy, and so far quite free from disease.—G. WESTLAND.

— **Westwood Park, Droitwich.**—Standing in the grand old Deer Park here and looking over the village of Hadley this spring, when acre after acre of healthy fruit trees were in bloom, was a sight never to be forgotten; but the result is a very small quantity of fruit. Of Plums, including Damsons, there are none, though scores of acres are planted with them. Bush fruit has been a good crop. Apples, with few exceptions, may be said to be a failure; one grower, however, a few miles off, who has some old Blenheim Pippin trees that bore nothing last year estimates his crop at 100 pots of five pecks each; no doubt owing to the trees having no fruit the wood got better ripened than that of those that bore a crop, and they were better able to stand the piercing east winds that prevailed here throughout May; the Blenheim is a great favourite, and makes more than any Apple that goes to market here; another favourite here is Knott's Kernel, a streaked good culinary kind and an immense cropper; Prince's Pippin is a great favourite for market and a handsome dessert kind; several with local names are largely grown in this neighbourhood. In the gardens here Strawberries have been most abundant; in fact we have good crops now of Elton, and on a north border, of Carolina Superba. Currants are a fine crop, Red, White, or Black—good clean fruit. Of Gooseberries we have a full crop. Of Cherries, except Morellos, which are a good crop, we have none; and the same may be said of Damsons and other Plums. Of Pears on walls there are a few on most varieties; Jargonelles on a south wall are a full crop. Of Apples we have very few—the trees here were loaded last year. We have two large pyramids of Cellini, on which there is a fine crop; it is a good Apple for cooking, coming in early and keeping till Christmas, and it is also fine for dessert. I have grown this as a standard, pyramid, bush and espalier in three counties, Hereford, Worcester, and Stafford, on light medium and stiff soils, and never knew it to fail. In a plantation consisting of some thousands of fruit trees, the only Apples bearing anything like a tenth of a crop are Lord Suffield and Keswick Codlin; these are much grown, but they are comparatively a failure this year. We have one large bush of old Hawthornden bearing a full crop. The new Worcestershire Pearmain will be much grown, as it is a good bearer and one of the handsomest of all Apples; on Stirling Castle and Normanton Wonder we have also a few fruit. Of Apricots we have none, except a few from late blooms under Parham's glass coping. As regards Peaches and Nectarines, not only have the east winds killed all the fruit, but they have also killed the young wood; it will be two years before the trees will be as good as they were this time last year. Three trees under glass coping have a few fruit on them, and they are making good wood for next season. Much disappointment is experienced in this uncertain climate in the case of Peach trees on open walls; every two or three years just as the trees have got some bearing wood, comes such a season as the present, and the crop is destroyed and the trees often injured so much that it ends in death! If people would only erect inexpensive houses and put into them a flow and return pipe, the trees would be saved and a crop secured every year. In this way as many fruit would be produced in a 50 ft. house as on 300 ft. of wall, taking, say, ten years successively.—JOHN GOUGH.

NORTH MIDLAND DIVISION.

Nottinghamshire.—Welbeck, Worksop.—I have never before observed such a general failure in the fruit crops in this district as is apparent this year—Pears, Plums, Cherries, and Apples have all failed alike, only a few varieties of each sort showing a scattering of fruit. There was abundance of blossom, but the cold

north-east winds, and the frosty nights and mornings in April and May must have done great injury to the setting of the fruit. There must, too, have been another cause of failure, for the Apples flowered very late, and after the frosts in May, nevertheless a great part of the young fruit when set dropped off. There is little doubt that the abnormal state of the weather in the winter and spring months was one of the causes of the failure of the fruit crops this year. In January and February there were such heavy rainfalls with a mild temperature that fruit trees commenced to swell their buds, but afterwards received a great check in the spring months from cold north east winds and frosts. The only varieties of Apples here bearing a middling crop are the Oldenburgh, Manks Codlin, and Irish Peach; amongst late sorts the Alfriston and Sturmer Pippin seem to have set best. Of Cherries the only variety that is furnished with a crop is the Morello on the walls. The Pears trained on a trellis here have never failed before in bearing well, but this year there is only a scattering of fruit on Williams' Bon Chrétien, Louise Bonne, and Catillac. Small hardy bush fruits such as Gooseberries, Red and Black Currants, and Raspberries are bearing abundant crops. Strawberries are likewise showing good crops, Vicomtesse Hericart de Thury being the earliest and best for all purposes; of the largest and best-flavoured varieties British Queen is still the best on the strong soil in the kitchen garden here, and President Lucas, James Veitch, and the new sort called Premier are all excellent and bearing good crops.—WILLIAM TILLERY.

— **Chilwell.**—Apricots here are a failure; the only trees bearing any fruit are a few in very warm and sheltered situations; these came into flower early, and their blooms experienced from 12° to 15° of frost for three successive nights; the air was dry at the time: still we thought it impossible they could survive so much cold; all the later blooms are a total failure. Peaches and Nectarines are also a failure on walls, but in houses we have a fair crop of fine fruit. Of Apples we have just a sprinkling, some trees being quite bare; there was a splendid show of bloom, but the continuous cold easterly winds, aided by the excessive wet of last winter, which on our clayey subsoil seemed to starve the roots of the trees, made it all drop off: the only sorts that may be called a crop are Barton (a free bearer), Pike's Pearmain, and Russian or Duchess of Oldenburg; these are very general croppers and rarely fail, whereas many other first-class varieties fruit but once in two, three, or even five years; of these last may be named Old Bess Pool, &c.: I am, of course, speaking of old standard trees, I know that young pyramids will produce a few fruits more frequently. Pears are a failure in orchards and also on walls; the only sort which seems to have retained a little fruit is Glon Morcean on the wall. Plums, including Damsons, are a total failure; Cherries are the same, with the exception of a few Morellos on the walls. Strawberries are a wonderful crop, but owing to the weather they do not possess much flavour. Raspberries are a good crop. Currants and Gooseberries a fair crop. Nuts are a failure.—ALFRED H. PEARSON.

— **Thoresby Park, Ollerton.**—Of Apricots we have very few. Apples none. Currants, both Red and White, a plentiful crop, but Black kinds are scarce. Of Filberts we have none. Gooseberries are a good crop. Of Pears we have a few, but of Plums none. Cherries on some trees are about half a crop. Raspberries are good. Strawberries a heavy and fine crop. Small fruits in general are a fair crop in this neighbourhood. Apricots, Pears, and Plums had to contend with 10° and 12° of frost for several nights, which destroyed the bloom, and many branches have also died off since. Apples were not exposed to frost, but such dry, parching, east winds made the bloom look as if it had passed through a fire. Even this morning (July 19) the tips of young Braeken in exposed places of the Park are black through frost.—A. HENDERSON.

Leicestershire.—Coleorton Hall, Ashby-de-la-Zouch.—Of Apricots we have scarcely any. Apples about half a crop. Cherries, very few indeed. Of Nectarines, on some trees there is a good crop, but few on others; and the same may be said of Peaches. Pears are nearly a complete failure—next to none. All sorts of Plums are a failure. Strawberries of all kinds are an abundant crop; Nuts, too, are a good crop. Gooseberries were injured by frost, but, nevertheless, they are a good half crop. Raspberries and Currants are a heavy crop, and Figs are a very good crop.—MONTGOMERY HENDERSON.

Lincolnshire.—Aswarby Park.—Of Apples we have half a crop; Apricots, a few; Currants, all three varieties, a good full crop; Figs (outside), a heavy crop, and the fruit promises to be large and good; Gooseberries, a heavy crop—the best varieties here being Whitesmith, Warrington, and Scotch Red. Of Pears, we have a few—our best this season are Napoleon, Brown Bauré, Bauré Boze, Althorp Crasanne, Winter Nelis, and Ne Plus Meuris. Plums are a failure—a remark which also applies to Peaches and Nectarines, and many of

the trees are so injured that they will not recover. Strawberries are a full crop: our best varieties are Keen's Seedling, President, British Queen, and Sir Joseph Paxton. Walnuts are a good crop. I may add that the Potato disease has made its appearance here.—RICHARD NISBET.

Derby.—Osmaston Manor.—Of Apples, Apricots, and Plums we have about half a crop; Damsons and Medlars, none; Pears, a good crop; Gooseberries, half a crop; Red and Black Currants, good; Walnuts, half a crop; Filberts, none; Peaches, Nectarines, and Figs (indoors), good crops—none grown outside; Strawberries, Raspberries, and Cherries are good crops.—J. BOOTH.

Rutlandshire.—Barleythorpe Gardens.—Plums with us are a failure; the kinds that do well here are Victoria Green Gage and Washington. Peaches and Nectarines are also failures; the best sorts of Peaches are Royal George, Prince of Wales, and Early York; and of Nectarines, Violette Hâtive. Figs are a good crop. Apricots on trees well sheltered are a fair crop; the best are the Moor Park and Blenheim. Cherries generally, with the exception of Morellos, are a failure, though in some instances they are very good; the kinds that do best here are, as a rule, the May Duke and Morello. Of Pears we have very few indeed; the varieties that do well with us are Marie Louise, Louise Bonne of Jersey, Winter Nelis, Williams' Bon Chrétien, Beurré Diel, and Beurré Bosc. Apples are very scarce; the sorts that succeed best here generally are Normanton Wonder, Lord Suffield, Blenheim Orange, King of Pippins, and Margil. Strawberries are a fair crop but small. Raspberries an average crop. Red Currants a fair crop, but Black kinds are scarce in some places near here. Gooseberries are below the average. Filberts are a failure. It was the cold east winds which prevailed during April and May, accompanied by storms of hail, that destroyed the fruit crops, which at that time promised to be unusually good.—F. CLARKE.

SOUTH-WESTERN DIVISION.

Dorsetshire.—Sherborne.—Fruit crops are worse in this neighbourhood this season than they have been for the last twenty years. Apples bloomed and set well, but they are now much blighted, and I fear there will not be more than half a crop. Apricots are a complete failure, and the trees are in a very bad state, many of them having lost half their branches. Morello Cherries may be set down at about two-thirds of a crop; other varieties do not succeed here. Currants—Red, White, and Black—are plentiful. Figs will be a moderate crop. Gooseberries are abundant. Medlars, poor. Peaches and Nectarines on open walls are a failure, and the trees are nearly ruined, having suffered severely from blister, and what growth they make will be so late that I fear it will not ripen properly. Those who happen to have their Peach walls covered with glass will have a good sprinkling of fruit. We have a moderate crop of the following sorts of Pears—viz., Gansel's Bergamot, Beurré Diel, Ramilles, Délices d'Hardenpont, Flemish Beauty, Glou Morceau, Jargonelle, Joséphine de Malines, Marie Louise, Ne Plus Meuris, Passe Colmar, Hayshe's Victoria,* and Van Mons Leon Leclerc. Plums of all kinds are very scarce. Strawberries have not been more than half a crop, and very small; our best have been Keen's Seedling. Walnuts appear to be plentiful in some places; Filberts and Cobnuts but a very moderate crop.—W. G. PRAGNELL.

Moreton.—The fruit crop in this vicinity is far from satisfactory, although the prospects early in the season were promising; all kinds of fruit trees bloomed abundantly, and were a fortnight later than usual in flowering, but unfortunately cold winds and frost were very destructive even at that late period. We have here a good sprinkling of Apples, particularly of the Blenheim Orange, which is altogether the most satisfactory variety we have: in some gardens the Apple crop is very thin indeed. Pears are a poor crop; some trees on wall are bearing tolerably well, but trees in open quarters are a complete failure. Plums, too, are a failure. Cherries are a fair crop in some places; in others none except Morellos, which are good in most places. Figs are good, particularly the Brown Turkey. The Strawberry crop has been a good one; and Currants of all kinds are abundant; as are also Gooseberries where the buds have not been eaten out by bullfinches in winter, which was the case in some places. Of Apricots we have none, and Peaches and Nectarines are almost a failure on open walls, but good crops in orchard-houses. Of Plums there are scarcely any.—D. UPHILL.

Cornwall.—Enys Penryn.—The fierce east wind which swept through the country when the fruit trees were in bloom, and just on the point of setting, committed sad havoc in this neighbourhood, as well as elsewhere. Here is a tale of woe which I was told a few days ago:—"I have not," said my informant, "a Peach, a Nectarine, a Plum, a Pear, an Apple, a Raspberry—even my Roses are killed."

His garden is exposed to the east. Raspberry canes in many places are killed; dwarf-trained and espalier-trained trees had the best of it, while tall, scraggy trees, whether Apple, Pear, Plum, or Cherry, if in exposed places, were stripped. In the sheltered spots there is some fruit. Apples are much under the average; Pears are also under average; Cherries a failure, except Morellos, which against north walls are an average; of Peaches and Nectarines we have a sprinkling; Raspberries and small bush fruits are under average; Figs against walls are an average crop; Plums are scarcer than they have been for many years past.—HENRY MILLS.

NORTH WESTERN DIVISION.

Lancashire.—Waterdale, St. Helens.—Around this neighbourhood fruit crops are on the whole very unsatisfactory; stone fruit of all sorts bloomed well, but scarcely a single fruit is the result, with the exception of Cherries, the sweet varieties of which are a fair crop, and the Morellos are also good. The Pear bloom was never finer than it was this year, and the Jargonelles set as thickly as possible, and were getting a good size, when the last severe frost in May caused every fruit to drop; even on the commonest sorts we have scarcely a single Pear. Amongst Apples Lord Suffield and a local variety called Hollyherry are literally loaded with fruit, the Manks and Keswick Codlins, Hawthornden, and Pott's Seedling are also carrying good crops, but all other sorts as a rule are failures. Black and Red Currants, and Raspberries are well loaded—the Fastolf Raspberry is the best. Strawberries made a fine show, but the fruit is very deformed, and ripens unkindly, the best sort on this cold clay soil is Vicomtesse Héricart de Thury.—JAMES SMITH.

Otterspool.—Fruit crops in this neighbourhood are, with few exceptions, a complete failure. Of stone fruits, such as Peaches, Nectarines, and Plums, there are none, consequent on the chilling easterly and north-easterly winds that prevailed almost without intermission during the months of March and April. In many places the trees themselves seem to have a struggle for existence, unless where prompt measures have been taken to arrest the ravages of green and black fly, and other aphides, which appear to be a sort of sequel to chills brought about by an ever-varying climate. The prospects of an extraordinary Pear crop were cut short by the unusually severe frosts that occurred during the first week in May, and the Apples narrowly escaped a similar fate. The old Hawthornden, Keswick Codlin, and Lord Suffield are bearing a fair crop, but the same cannot be said generally. Small fruits are a moderate crop throughout. Strawberries abundant; Vicomtesse Héricart de Thury ranks first for general purposes, and President, Oscar, Sir Charles Napier, and Dr. Hogg follow in rotation. Red, White, and Black Currants, Raspberries, and Gooseberries are plentiful, but from a fortnight to three weeks later than usual. I may add that Potatoes are clear of disease, and an excellent crop, as are all other vegetables, but we are fully three weeks behind our ordinary time of gathering.—W. HINDS.

Haigh Hall, Wigan.—The cultivation of hardy fruits in this, the centre of extensive coal fields, is not encouraging; for, owing to a continuance of cold easterly winds and frost during the month of May, many of the trees present a deplorable appearance, being nearly denuded of leaves. Peaches, Nectarines, Apricots, and Figs, do not succeed here in the open air. Apples are above an average crop; Keswick Codlin, Lord Suffield, King of the Pippins, Yorkshire Greening, Dumelow's Seedling, Cellini, Ribston Pippin, and Hawthornden are the best. Of Pears there are scarcely any: Marie Louise, Louise Bonne, Easter Beurré, Beurré Diel, Beurré Hardy, and Jargonelle are the most suitable sorts, and usually succeed on south and west walls. Cherries are a complete failure; Plums are very thin, and the trees are infested with aphides; Strawberries are very good, but they have suffered from the rain during the last week; Duc de Malakoff is our best sort, but Improved Black Prince, Vicomtesse Héricart de Thury, and President also do well. Gooseberries and Black Currants are thin but good; Raspberries and Red and White Currants are about an average.—ANDREW JAMIESON.

Cheshire.—Abney Hall, Cheadle.—Small fruits generally have been good in this district, but Apples, Pears, and Plums are almost a failure; indeed, I have not seen a Pear or Plum tree bearing anything like a crop this season. Of Apples, the best I have seen is the Cellini Pippin. Amongst Strawberries, the Elton Pine, just ripening, is heavily loaded; I have never, indeed, seen such a number of fruits upon single plants as I have seen on some of these: the soil in which they are growing is a stiff clay. We have no fruit on the walls here with the exception of a few Cherries, Beurré d'Arenberg, and Easter Beurré Pears, and some Plums.—ROBERT MACKELLAR.

EASTERN DIVISION.

Essex.—Audley End.—Many kinds of fruit here this season are a total failure, not caused altogether by the severe frosts of May, when we had 12° and 14°, but from the long continued cold weather which prevailed during March and April; owing to this and the badly ripened wood of the preceding autumn, many Peach and Nectarine trees are nearly killed, curl or blister being very prevalent. Apricots, too, have lost very many shoots from the same cause. The sorts of Pears that have stood the frost best here are Glon Morceau, Bezy de la Motte, Bergamotte d'Espéren, and Ne Plus Meuris as pyramids, and Beurré Rance and Beurré d'Aremberg on walls; on these we have a good crop. Of Apples the following are bearing a good crop, viz., King of Pippins, Cellini, Court Pendu Plât, Shepherd's Fame, Kentish Fill-basket, and Ribston Pippin. Of Cherries, Morello may be said to be good, other kinds half a crop; of Plums we have none on pyramids and very few on walls; Currants (Red and White) are a good crop, Black middling; of other small fruits the same may be said.—J. BRYAN.

— **Cossey Park, Norwich.**—Wall fruit of all kinds in this quarter is a failure, both protected and unprotected trees being nearly alike in this respect. Peaches and Nectarines under good clear glass, and even with the aid of heat, are only bearing thin crops, while those under old dark glass have suffered nearly as much as trees on open walls. Pears are scarce, and Apples far below the average, and in many cases worse than the bad crop of last year. Of Plums there are few or none, and the same may be said of Cherries. Gooseberries, Currants, and Raspberries are in general below the average. The same applies to Strawberries, whose stools or old plants suffered much, owing to the long and wet spring, which caused many blanks to occur in beds. Figs and Filberts are fair crops, but Walnuts, in many instances, are a failure. All kinds of fruit trees promised well until the blossoms suffered by ungenial weather, especially lack of sunshine. Potato crops good, but in damp spots diseased as usual.—J. WIGHTON.

Suffolk.—Culford Hall.—Fruit crops hereabouts, as far as Peaches, Nectarines, Apricots, Plums, Apples, and Pears are concerned, are a failure. Morello Cherries on north walls are carrying a fair crop, although lighter than usual; and Fig trees on walls and under glass without artificial heat are also carrying a somewhat light crop. Some Medlar trees, which here seldom fail to bear in abundance, have this season but a very light crop upon them. Walnuts are almost a failure. Filberts and Cobnuts are a fair, but by no means a heavy crop. Bush fruits, including Gooseberries, Raspberries, and the various kinds of Currants are abundant; and Strawberries of all kinds, but more particularly British Queen, are unusually plentiful, and the fruit remarkably fine. The heavy fall of rain which occurred on the 30th of June (exceeding an inch), followed by frequent and considerable rainfalls, proved very beneficial to such crops as the Strawberry, on the dry and warm soil of this locality. Among Pear trees on walls, a few of the more hardy kinds are bearing a light crop, notably Beurré Diel, a variety which hardly ever fails here. And among Apple trees there are a few exceptions to the general failure, a young healthy tree of Bedfordshire Foundling being furnished with a really good crop. The present season has been very peculiar as regards fruit crops. Early-forced Peaches and Nectarines here have been abundant, and the fruit remarkably fine; while in another structure devoted to the culture of the same kinds of fruit, and furnished with a heating apparatus which was only used to exclude frost, on account of the house containing bedding-plants, the crop is nearly a failure, as is also the case in a similarly constructed house in which there is no heating apparatus. The wood of the trees in each house had every appearance of being thoroughly ripened, and the bloom was abundant in each case; and although the very low external temperature at the time when the trees were in bloom may have proved injurious to those contained in the structure unprovided with a heating apparatus, still this cannot be supposed to have been the case as regards the other, and the result must, I think, be ascribed to other atmospheric influences or peculiarities of the season not yet recognised or under the control of the cultivator. Several of the older Apricot trees here were almost in full leaf about the end of January or early in February, and all have since died.—P. GRIEVE.

— **Hardwicke House.**—In general terms there is no very good outdoor fruit this season; there are exceptions, it is true, and these are among the most singular and unaccountable phenomena of the season. The havoc is general among Apricots, Nectarines, Peaches, Plums and Pears; but Apples are a fair crop in gardens and orchards here and there, in some cases even an exceptionally heavy crop; and yet Apples ought not to have failed, as they flowered freely and also flowered late—several weeks after the frost was over. This failure of the Apples arose either from the embryo fruit hav-

been frozen in the bud state or from the prevalence of a north-east wind during the blooming season. Those who advocate setting Grapes and other fruit crops by the syringe, will also note that it was not only cold but dry during the whole time the Apples were in bloom. Walnuts, again, which flowered much later than the Apples, are also a failure, whereas the Filberts, that flowered much earlier than either, are a good crop in some districts. As to the causes of failure in the case of Peaches, Nectarines, Pears, and Plums, there exists no doubt whatever; they were simply frozen right through, after, in many cases, having attained a considerable size. As to sorts that yield the best results none have escaped this year; the failure of Plums is however the most complete. Referring to the gardens here only, we have a few Apricots, Peaches, Nectarines, Pears, and Apples, but not a single Plum in open quarters that I have yet seen. Outdoor Figs are a wonderfully full crop generally, and here in particular. Gooseberries and Currants are also plentiful. Raspberries are a good crop. Strawberries hardly an average, though President has been remarkably good; of Keen's Seedling there is not more than a third of a crop, and British Queen is a failure; yet in other gardens within a few miles British Queen, Dr. Hogg, Sir Joseph Paxton, and Carolina have been particularly good. Gooseberries, again, were entirely cut off in many gardens, and in some within a mile of Hardwicke not one was left; in fact, the more carefully one notes the changes of the frost and east wind among the fruit crops, the more one is impressed with the apparent capriciousness of the laws or conditions that cause twenty or a hundred crops to be taken and one every now and then left.—D. T. FISH.

— **Henham Hall.**—Apricots are a poor crop, but far better on south aspects than on any other—a circumstance, doubtless, owing to the better ripened condition of the wood. Peaches, very poor; Plums, thin on walls, scarcely any on standards; Cherries, a good crop, especially Morellos and Dukes: Cherries are not largely grown in this locality, as the soil is not naturally suited for producing healthy trees. Figs are very fine and abundant; Gooseberries, Currants, and Raspberries are exceptionally fine, clean, and abundant, the midsummer rains having kept the soil continually moist; on that account Raspberries have been especially benefited, and promise to continue in bearing a long while, as the lateral growths are producing a fine crop. Strawberries are a good crop, and, although shorter in flower-stalks and foliage than usual, they have produced a lengthened supply of good fruit. Pears on walls are a good crop, middling on espaliers, and a failure on standards and pyramids; Apples are very variable, but quite an average crop; a great quantity of them have fallen lately, but the trees are healthy and in good foliage. Filberts and Walnuts are good. Taken collectively, stone fruits are much below an average—a circumstance which I consider quite as much attributable to unripened wood and imperfect blossoms as to the action of frost, for last summer's heat and drought were followed by a wet and sunless autumn and winter in which the trees could scarcely be called in a resting or dormant state, and this being followed by a prolonged period of cutting winds and frosty nights, completely paralysed them, so that only a small percentage of such blossoms as escaped frost have yielded fruits in perfection.—JAMES GROOM.

— **Shrubland Park.**—Fruit crops in this neighbourhood are a failure, with the exception of small fruit. We have no Apricots and no Peaches, and the trees suffered severely; but they are now partially recovering. There are some Apples and Pears in a few sheltered places, but in a general way they are almost a blank; Plums of all sorts and Cherries are very scarce; Morellos are however a fair crop. I do not recollect having seen such a crop of Strawberries, and as regards size and quality they are all that could be desired: the sorts which we grow are Keen's Seedling, Sir Charles Napier, British Queen, and Dr. Hogg, and we force them in the order named, Raspberries, Gooseberries, and Currants are abundant. Walnuts are a light crop; Filberts rather better.—THOMAS BLAIR.

— **Woolverstone Park, Ipswich.**—Excepting Gooseberries, Raspberries, and Strawberries, the fruit crop in this district is almost an entire failure. Of Peaches and Nectarines there are very few indeed, and the trees here and in many other places have suffered to a serious extent, so much so that unless we get a fine autumn to ripen the late growth, little can be expected from them next season. Apricots at one time looked as if they would die altogether, and as it is they have lost most of their spurs and many of the main branches; but since fine warm weather has set in they have made good deal of young wood, so that there will be no difficulty in filling up most the vacant spaces, and refurnishing the walls. Cherries are thin everywhere, but with us are unusually fine, owing to the light crop which the trees have to carry, and from the sandy nature of the soil suiting them so well. Morellos, however, from being in less favoured aspects, are likely to be small and poor, as they suffered

much from the May frosts. *Passe Colmar* and *Marie Louise* Pears on west walls set freely, and had to be thinned severely, but the fruit is swelling very irregularly, and looks as if it would never attain its proper size or form. The bloom on standards and pyramids was all destroyed, although it was unusually late in opening, which was likewise the case with that of Apples, so that the frost evidently injured the embryo fruit. It is very remarkable that Figs are more plentiful than they have been for years, which is probably owing to the mildness of the winter, and the late season at which they started into growth. Plums are a total failure, as they were caught in a tender state just after setting. Altogether this year is the worst one for fruit I ever remember, and must seriously affect growers for sale, besides being a great national loss.—J. SHEPPARD.

YORKSHIRE.

Sheffield, Wortley Hall.—In this district, all fruit-tree crops, save Cherries, are a failure, not so much owing to frosts and bad weather as scarcity of bloom; I have seldom seen so little blossom. All small fruits, where they have escaped the bullfinches and other bud destroyers, are tolerably abundant. Strawberries are a heavy crop. Indoor fruit crops are very fair, and I have never known first and second early crops of Grapes to be finer or better coloured, nor the foliage to be in better health or cleaner, notwithstanding that fire-heat has been so extensively used. Vegetables are good generally, except Potatoes, but unusually late. Potatoes, both on farms and in the garden, lack vigour, and the disease has appeared in an aggravated form upon the foliage of the variety called *Snowflake* in several places in this district.—J. SIMPSON.

Grimston Park, Tadcaster.—The fruit crops generally are the worst I have known for these past five years in this district. Apricots are a complete failure; our standard variety is *Moor Park*, which usually does very well with us. Apples are partial; we have a fair sprinkling of the following sorts, viz., *Cockpit*, *Lord Suffield*, *Tower of Glamis*, and *Cox's Orange Pippin*; the latter are on bush-formed trees on *Paradise* stocks; the trees are planted on small mounds on a stiffish soil, and well mulched in hot seasons. Of Peaches we have almost none: *Royal George*, *Early York*, *Red Magdalen*, and *Bellegarde* are the sorts most grown. Nectarines, too, are a failure: *Elange* and *Violette Hâtive* are our best varieties. Plums are fruitless; in fact, stone fruits generally are almost a complete failure. Nuts are very scarce; even *Horse Chestnuts* are dropping off in shoals. Small fruits are generally a good average. Strawberries have been very good as to quantity and size, but not good in flavour, owing to the sunless weather which we have had; *Vicomtesse Héricart de Thury*, *President*, and *Keen's Seedling* are our standard sorts; amongst a batch of fresh varieties, *James Veitch* promises well. Red and Black Currants are a good crop with us, but on low lands by the banks of the river (where much fruit is grown within a few miles) the crops are very partial; they were much damaged by frosts in May. Gooseberries are a good crop; at *Cawood*, about five miles from here, there are acres of Gooseberries grown to supply the markets of the great manufacturing towns in this county; the crops there are this season are very fair: *Crown Bob* and *Whitesmith* are the principal sorts grown. Cherries are very scarce; some bush-shaped trees of *Morello* have hitherto usually borne good crops. I am of opinion that the dull, wet autumn, with the consequent non-ripening of the wood and fruit-buds, is the principal cause of the thin crops of fruit this year.—H. J. CLAYTON.

Stourton Park, Knaresborough.—Fruit crops in this neighbourhood in general are light. Pears and Plums are great failures; Cherries and Apricots are also light. Of Peaches there is here a fair sprinkling on some trees. Raspberries are a fair crop, and so are Red Currants, but the fruit is small. Black Currants are a light crop. Gooseberries are a very light crop in some places, but in sheltered situations they are better. Strawberries are a fair crop, but not abundant. Apples in general are light—even *Keswick Codlin* on trees that were one sheet of bloom; on *Cockpit* there is a fair crop.—M. SAUL.

Ribston Hall, Wetherby.—The fruit crop this season is the worst which we have had for many years in this neighbourhood. Plums and Pears are a complete failure, and Peaches, Nectarines, and Apricots are very light indeed; many of the latter dropped at the stoning season. We shall not have the fifth of a crop of Apples; many of the trees are without fruit. Red, White, and Black Currants are a good crop; Strawberries the same, but the late rains have caused many of them to mould, *Sir Harry* being very bad in that respect, though with fine weather it is one of our finest varieties; I have a few of the *Vicomtesse Héricart de Thury*, which are doing unusually well; it will prove a very useful sort, both for market and preserving. Cherries are thin, though we had a fine show of bloom; *Governor Wood* is the sort that does best with us. Raspberries will ripen a good crop.—THOS. JONES.

NORTHERN DIVISION.

Cumberland.—Whitefield House.—The fruit crops in the north, though not such a complete failure as last year, will be very poor. Through May and June we had withering east winds, and frost at night; till the end of the latter month the hills were quite white with snow every morning, and in the valleys there was ice. The fruit in the earlier and better climate suffered most, and was entirely cut off after being well set. The show of blossom in the backward and high-lying districts was immense; a few days of terrible heat—one day 123° —scorched the most part. The Apples which have stood the best are *Lord Suffield*, *Emperor Alexander*, and *Normanton Wonder*. Currants are very plentiful but small, and have been much blasted by lightning. Strawberries very plentiful but small, and the heavy rains bring slugs (small white slugs) in such quantities that they eat the fruit as it ripens. Gooseberries are a wonderful crop, the branches so heavily laden that they have to be propped up with forked sticks. Raspberries plentiful but small. The leaves on all the large wall fruit trees are withered and brown, and the young wood curled and full of insects.—J. GILLBANKS.

Durham, Seaham Hall.—Of Apples we have a moderate crop; on some trees there is abundance, while on others there are but few, although they were in full blossom after the spring frosts had occurred; while they were in bloom, however, we had a continuance of cold east winds from the sea, the effect of which was a large amount of scorched foliage. Of Pears we have none worth speaking of; although we had a fine show of blossom on some of the trees, the fruit dropped off soon after setting. Of Plums we have none, this being a bad locality for this fruit. Of Peaches, Nectarines, Apricots, and Figs, none are grown out of houses. Gooseberries are abundant on trees that had been left unpruned, while from those that had been pruned all fell off soon after flowering; it is therefore now a question whether I shall prune oftener than once in two years, and then only remove branches that are too close. My attention was first directed to this by having a hedge of Gooseberry trees on which I never fail to have a crop; early spring frosts and winds cannot hurt the blossom under such circumstances, owing to its being in the middle of the bushes. Black Currants are a fair crop, although the sea winds scorched the foliage in exposed places. Red Currants are also a good crop; like the Black kinds they flower late, and are sure bearers. Raspberries are a fair crop, although on the top of the bushes all the shoots were scorched by the east winds. I never stake my Raspberries, but cut them off at about 4 ft. from the ground, allowing them to follow their own natural habit, which suits them better than tying them to stakes.—R. DRAPER.

Northumberland.—Shawdon Hall, Alnwick.—Fruit crops in Northumberland vary so much that it is difficult to give a correct estimate of them as a whole, but there is no doubt that they are below the average. Owing to the lateness of the season, too, many sorts of fruit, such as Strawberries, Cherries, Currants, &c., are ten days behind their usual time of ripening. Pears in this district never gave a finer promise, but the low temperature and heavy deluges of sleet that beat upon them for days in succession at the time when they were in blossom, destroyed the pollen and in some cases even rotted the truss of flowers. The same fate befel the Apricot bloom, and in many places the crop is meagre in the extreme, and in others an entire failure; indeed, this statement holds good regarding all wall fruits in this district. Apples were late in coming into blossom and escaped the late frost, therefore an abundant crop will be the result in most places. Bush fruit (with the exception of Gooseberries) is a fair crop. Raspberries are the finest crop that I have seen for years. There is a variety of this fruit grown in this district called *Fill-the-basket*; it was found (like the *Fastolf*) growing wild by a nurseryman in his grounds at Alnwick. It is a very dwarf sort, requiring no stakes to support it; bears very abundantly—so much so in some places that *Fill-the-basket* is both an appropriate and correct name for it. Here it bears only an average crop, but it has many qualifications to recommend it, especially for small gardens. The fruit is round in shape, with a fine rich aromatic flavour. In connection with the subject of fruit I may remark that among all the new varieties that are from time to time being tried in the gardens of this district, the old and long-tried sorts still hold their place.—JAMES THOMSON.

Alnwick Castle.—Fruit crops in this part of the country are very light—much below the average. The bloom on fruit trees of all kinds was abundant, and gave every indication that there would be good crops, but the long continuance of wet weather and little sun prevented the blooms from setting, and the consequence is that Peaches are not half a crop, and that Apricots, Plums, Pears, Cherries, and Apples are much below the average. Small fruits are, however, abundant, and likely to be very fine. Strawberries I never had finer, both as regards quantity and quality.—A. INGRAM.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

IN THE KENTISH FRUIT GARDENS.

KENT, it has often been said, is the garden of England, both as regards soil and climate; its fruit farms, for which it has long been celebrated, are daily on the increase, although the space already devoted to them amounts to upwards of 12,000 acres. Of this area a great part is occupied by small fruits—such as Gooseberries, Currants, Strawberries, and Raspberries—and the quantities of these fruits sent annually to London and other large towns are enormous; people, indeed, unacquainted with fruit culture on a large scale can form no conception of the wide breadths of Strawberries and the vast plantations of orchard and bush fruits that are here to be found. About Swanley and its neighbourhood, from any hill-top, may be seen miles of the higher-lying grounds crowned with Gooseberries, Raspberries, or Strawberries, and the valleys filled with Hops. In some places may be seen patches of Potatoes or Mangel, crops which are always grown on land to be afterwards devoted to fruit culture. This is done in order to get the ground thoroughly clear of Bindweed (*Convolvulus arvensis*) and other weeds, which it would be difficult as well as expensive to do after the fruit trees had been planted. Most people, when planting fruit trees, prefer a southern aspect; but in Kent an easterly one is always chosen—and this for two reasons: one, because the produce is always later, thus escaping to some extent the late frosts in spring; the other, because should frost occur, the sun strikes the trees gradually, thawing and drying the blooms without injuring them; whereas, in a southern aspect, they are more suddenly exposed to the full force of the sun, and serious injury is often the result. It is a well-known fact, too, that crops in elevated positions escape frosts better than those in valleys. This was particularly noticeable in the case of Raspberries, which on the hills wholly escaped the severe frost of the 5th of May this year (so fatal to fruit crops in general), whilst in low grounds the early blooms suffered severely. The climate of this part of Kent is remarkably good, and fruit culture the staple trade. The hedgerows are overrun with Blackberries and wild Raspberries, amidst which are growing in abundance Damson, Plum, and Walnut trees. Everywhere may be seen gangs of women and boys busily engaged in gathering Strawberries, Raspberries, and Gooseberries. Collectively they earn large sums of money, good hands making as much as 11s. per day at Gooseberry picking, but the average rate is only about 6s. per day, and that only by means of hard work from light till dark. This year, even in this comparatively favoured locality, there is a total absence of stone and other hardy fruits; while in good seasons the trees are literally bent down by the Damsons and other Plums with which they are so heavily cropped. One fruit grower stated that if his trees of these fruits in the hedgerows were set 10 yards apart, they would occupy over twenty-two miles in length. On Walnut trees there is even this year a fair crop; but of Pears and Apples there are none worth mentioning, and in some cases avenues half-a-mile in length consisting of fine pyramidal trees, from 17 ft. to 20 ft. high, may be seen completely fruitless, and many trees have again begun to blossom.

Raspberries.

Of these there is this year a fair crop, though the fruit is not so large as could have been desired. The sort most preferred by growers is Carter's Prolific; its fruit, which is large, is of a deep red colour, a circumstance which renders it worth more money in the market than paler-fruited sorts, and moreover it is an abundant cropper, and the fruit ripens nearly all at one time—a great desideratum, as it always pays better to pick and sell at once than to gather at intervals. Raspberries are planted on thoroughly cleansed land heavily manured; the young plants are obtained from suckers saved from selected stools that have borne the largest crops and the finest fruit.

These are cut back to two or three eyes in the autumn, and planted in rows 3 ft. apart, and 6 ft. asunder in the row. For the first three years after planting Potatoes or Mangels are in some cases grown between them, but after that if the Raspberries have grown well they require all the room. Three of the strongest suckers are always left for fruit bearing, and these are shortened back to about 3 ft. from the ground, the others being cut away. Late in autumn the ground between the rows is heavily manured and roughly ploughed up, a state in which it is allowed to remain until spring, when it is harrowed down, always choosing a time for the operation when the soil crumbles readily. Neither stakes nor ties of any kind are used, the canes being sufficiently strong to support themselves, and in some plantations of long standing may be found bushy-headed standards with stems about 12 in. or 18 in. high, and as thick as a broom-handle, bearing heavy crops. The ground between the rows is kept rigidly clear, both of weeds and young suckers, with the exception of such canes as are near the old stools. This work is performed by horse hoes, to which is attached a small harrow, which levels the ground and lays the uprooted weeds and suckers on the surface to be dried up by the sun. Picking usually commences the first week in July and continues until the beginning of August. It is performed by women and children, each of whom carries two baskets of the form of a flower-pot, one in front and one behind, slung over the shoulders; these when full are emptied by boys into wooden tubs provided for the purpose—that is, if the fruit be intended for preserving, but if for Covent Garden baskets are used. Few Raspberries, however, come to Covent Garden, compared with what go direct to fruit-preserving depôts—a fact which will be evident when I state that at Swanley the other day there was a merchant ready to purchase 100 tons of them at £40 per ton for that purpose. One grower, too, informed me that he had contracted with a manufacturer of preserves to supply him with 10 tons. Few of the Kentish Raspberries are picked with stalks attached to them; most of the fruit seen in Covent Garden furnished with stalks is supplied by growers near London, who pick their finest fruits for the purpose and put them at once in small punnets, which are packed, in quantities together, in large wooden boxes.

Strawberries.

For these the climate and soil of Swanley is admirably adapted; I say the soil, because the plants appear to succeed in it so well, but in reality the climate must have the most beneficial effect, or else cultivators as a rule are decidedly wrong in their statements with regard to the most suitable soil for Strawberries. It has often been said that a stiff clayey loam of a rich character is indispensable to the perfect culture of the Strawberry; the soil at Swanley is, however, exactly the reverse of this: in some places it may be termed rather solid and stiff, but in the majority of cases it is of a light sandy and remarkably stony character, and in this the plants appear to succeed quite as well, and bear crops equal to those planted in soil of a heavier nature. Indeed the soil which produces the best crops here is one in which no gardener would think of planting his Strawberries, and yet the yield is enormous: in well-established plantations may be seen as many as 100 good fruits on a single plant. This year I am told the fruits are not quite so large as usual on account of the dry weather, but still there are in places some very fine ones. The chief kinds grown are Keen's Seedling, Sir Joseph Paxton, and Sir Charles Napier; British Queen may be found here and there, but not in very large quantities. The plants are put out in well-manured soil in autumn, in rows about 2½ ft. apart, and 1 ft. 6 in. from plant to plant. Other crops are seldom planted between the rows, the aim being to give the Strawberries the full benefit of the soil. The plough is run between the rows in autumn, which keeps the plants on ridges, thereby keeping the roots well drained. In spring the horse hoe is used and the ground levelled, after which in many cases a slight coat of litter or straw is laid between the plants in order to prevent the fruit being splashed by the rains. The majority of Strawberries are grown in open fields by themselves, but large quantities are to be found between young Gooseberry or Currant bushes, a position in which they succeed well until the trees get so large as to injure them by their

shade. For preserving Strawberries are not in such great demand as other small fruits; therefore they are invariably picked with stalks attached to them. These, like Raspberries, are picked in small baskets, which when full are emptied into sieves holding about 24 lb. For each of these the pickers get 5d. in ordinary seasons, and at this rate they make good wages. The crop this year is not so heavy as last, but even now one grower informed me the other day that he had sent away nearly 6 tons. Altogether last year one extensive grower sent away 125 tons of Strawberries to the London markets; and in one day this year one grower sent away 2500 pecks, the weight of which is nearly 16 tons. All runners are kept regularly cut off the plants, and the ground is kept free from weeds. The best fruit finds its way to the London and other markets, but what are termed squashers, which means the bruised or over-ripe ones, are picked without stalks, put into tubs and disposed of at the jam factory.

Currants and Gooseberries.

These are chiefly grown between orchard trees, but in some cases large fields are wholly devoted to them. In the latter case they are planted in rows 6 ft. apart each way, with the exception of Black Currants, which are allowed a little more room. Between the rows, until the trees get too large, a row of Peas is planted; these are chiefly early sorts, which can be picked before very dry weather is expected, and the value of the crop is of such importance that from an acre of ground is often picked 200 bushels. A woman picks in a good season 10 bushels per day, for which she is paid 3s. 4d. One man told me that he and his wife and his neighbour and his wife one day gathered 47½ bushels between four o'clock in the morning and eight o'clock at night. The only kinds of Currants grown are the Black and Red kinds, White ones being very little in request, except for dessert. The trees are in all cases well shaped and open in the centre, and they yearly make luxuriant growth and seldom fail to bear heavy crops. The ground between the rows is kept frequently stirred by the hoe, and in the case of Currant bushes growing under orchard trees, of which there are hundreds of acres, many of the rows being half a mile in length, it is impossible for man and horse to work the hoe on account of the branches of the orchard trees; therefore a boy is sent to guide the hoe, and a long rope is attached to it, the end of which is encircled round a wheel placed firmly on the grass paths that run through the plantation. To this rope a horse is yoked, and by walking straight up the path the hoe is readily drawn up the rows, the wheel, which is of course placed immediately at the end between two rows, keeping the rope in its proper place. Gooseberries are likewise grown in a similar manner, but the greatest amount is to be seen in open fields in elevated positions. Plenty of space is allowed for the trees to expand. The branches are not shortened back to any great extent, the object being to get the trees as large as possible, and so increase the amount of the crop. One very good arrangement I noticed was standard Pears and Plums placed alternately 20 ft. apart each way, the straight lines between them one way of the field being occupied by a row of Gooseberries. Between these were two other rows of Gooseberries 6 ft. apart, and between these again were rows of Strawberries. When the Gooseberry bushes are large enough they will of course require all the room, and the Strawberries will be done away with. This is, however, a very profitable method of cropping the ground, as it admits of all necessary operations being carried on without injury to either crop. Gathering commences as soon as the berries are at all saleable, and continues until they are ripe. In all cases the bushes are stripped at one picking, as much as 10 acres per week being sometimes cleared, ending with 20 to 30 in proportion as the markets require it; and as a week in favourable weather consists of only four-and-a-half days, the best market being on Saturday (to prepare for which it is necessary to leave off picking at two o'clock on Friday), the quantity of work to be done in a short time is immense; and if wet weather which bursts the fruit, or intense heat which scalds it, set in, picking the whole quantity is impossible. Some growers employ during the last two weeks of picking as many as 300 women and children. It only lasts a short time, and one grower told me he had sent to the north of England in two

days about 300 bushels of fruit. Women sometimes pick as many as 30 sieves of Gooseberries per day, for which they receive about 10s. 6d. The chief kinds grown are Rough Reds and a yellow kind which is generally picked when green, and also many others; the red ones are those left to ripen. A smooth green kind is likewise largely cultivated for dessert. Some growers in good seasons have been known to gather more than 3000 bushels of Gooseberries.

Cherries.

These are chiefly grown in Grass orchards, in which the trees are managed on the run-wild system; many of them are very old indeed, and in good seasons they yield heavy crops. When in flower the Kentish Cherry orchards are well worth seeing, covering as they do the distant hills for miles round; and this year the quantity of blossom was unusually great, though the crop of fruit is far below the average. Cherry trees are planted on land overlying a dry subsoil; in clayey soil they are, as a rule, but short-lived. The kinds chiefly grown are the Kentish, Cluster, and Bigarreau; these are good croppers, and from well-established trees have frequently been gathered as much as 1000 lb. of good fruit. In some seasons the Cherry crops are sold by auction, and also by private contract, the purchaser paying the expenses of gathering; this is supposed to be the most profitable way of disposing of them. The buyer erects a wooden shed, in which the daily gatherings are put, and when all are gathered, they are sent to market as soon as possible. At Swanley, however, there are few Cherry orchards compared with those to be found in other parts of Kent.

Nuts.

Nut trees when young are cut back to within 1 ft. of the ground, which causes them to emit side shoots, which are regularly trained outwards by being tied to a wire or wooden hoop, which is placed in the centre, so as to give the tree a cup-like form. This is a capital method, inasmuch as it allows the sun to shine in the centre as well as all round the trees, and thus the wood gets well ripened, a circumstance indispensable to the production of large crops of Nuts. The trees are, as a rule, to be found alternately planted with standard Apple or Pear trees; in height they are seldom allowed to exceed 6 ft., severe pruning being yearly resorted to, in order to keep them within bounds. Many of the established bushes are 15 ft. in diameter at the top, and are as flat as a table, and on them this year, when Apples and Pears are scarce, it is satisfactory to find a fair crop both of Cobnuts and Filberts.

C. W. S.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Manure Water in Vineries.—It is well known that guano water is useful in the evaporating troughs in Vineries. I have had no guano this season, but I think I have been using a better substitute. For some time past I have kept the troughs in one of the Vineries in which the fruit is nearly ripe filled with manure-water made from pig manure. This year's wood is hard and brown, and the leaves are as healthy and green as when the Vines were in flower.—VITIS.

Best Remedy for Phylloxera.—A French grower believes that the best way to combat the Phylloxera is to keep the soil very loose and open round the stems of the Vines, thus allowing a free ingress of air to their roots; then a good soaking of water, impregnated with tar or carbolic acid, not only kills the insects, but, we are assured, forms a good manure. The woollen refuse, so generally used as a manure in the south of France, is condemned, as it is believed that it is favourable to the propagation and development of the Phylloxera.—N.

Oranges and Lemons in Greece.—Greece and the Levant are countries in which Lemons and Oranges grow in abundance, and Dr. Landerer, of Athens, in a communication received from him on the subject, states that more than 100,000,000 Lemons, Oranges, and Citrons are consumed or exported by the inhabitants of various parts of Asia Minor. There are also met with all the other sorts of fruits of the family Hesperidae, such as Citrus indica, commonly known as Mandarins. The fruits of Citrus Cedro and Citrus decumana are collected for the preparation of the confection Citrinat.

Eating Pine-apples.—To eat a Pine-apple, do not peel it; cut off the bottom. insert a fork over one of the lower "eyes," press downward, and then pull off a little cone. The cones gradually turn off are much softer than slices of the Pine bitten across the grain.—"Herald." [Some of the finest samples of West Indian Pine-apples now so common in our markets are as juicy and well flavoured as any Pine-apple could be.]

NOTES OF THE WEEK.

THE SACRED BEAN.—This, of all the plants generally relegated to the Botanic Garden, is the most deserving of general culture wherever there is a warm house and a tank—it need not be a large one. A plant now in flower at Kew is the handsomest plant in the place. In Japan it grows in masses in the swamps, and, though very handsome there, is even more striking when seen in small quantity but well grown.

DAILY GARDEN OPERATIONS.—We commenced last week publishing the diary of work carried out in the gardens at Sherborne Castle, Dorset, by Mr. Pragnell, in succession to the excellent diary based on Mr. Denning's work. Mr. Pragnell has long been known to visitors to our principal flower shows as one of the best cultivators in England. He has contended with our best growers of garden produce and generally won. The acknowledged neglect of kitchen gardening for years past makes it all the more desirable that one thoroughly acquainted with this department should record his operations. We are convinced that this diary is the simplest guide to the best practice that can be given in such a form.

PHILESIA BUXIFOLIA IN A COOL HOUSE.—This remarkably beautiful but rarely-seen plant is grown out-of-doors by clever cultivators in certain favoured districts, but throughout the country generally much the best way to treat it is to plant it out in a cool Fernery or in any kind of cool house, where convenient, associated with Ferns. It may now be seen on a little rocky bank of Ferns in the temperate house at Kew in good flower. Illustrating the cultivation of uncommon and difficult plants like this is, we submit, one of the right functions of a great garden like Kew; besides, such efforts to rival the bedding-out of the ordinary flower gardener should not be thought of for a moment.

ALLAMANDAS IN DORSETSHIRE.—Mr. James, gardener to Lord Wolverton, at Inverne House, Blandford, has sent us some sprays of an Allamanda literally loaded with bloom. They were cut from a plant which covers the upper part of a span-roofed house 20 ft. by 18 ft. Last year it bloomed more than eight months, and it had upwards of 600 blooms expanded at one time. This year it began to flower before Easter, and has now 137 expanded blooms on it. It was cut back in February, and this year enough wood to make a large faggot was thinned out of it. It is planted in a box 2 ft. square.

LOMARIA PROCERA HARDY IN CORNWALL.—This very distinct and beautiful Fern, which has proved hardy in Cornwall, should be tried by all on the south coast and elsewhere who possess a well-sheltered outdoor Fernery. It has a very wide geographical range, being found from Mexico to Chili in the New World, and in South Australia, South Africa, and many other countries in the Old. The fronds submitted to us measured from 2 ft. to 3 ft. and had each from twenty to thirty pinnae, the lower ones measuring 6 in. by 1½ in.—G.

GLADIOLUS TRISTIS.—This little known Cape species is flowering freely at Tottenham, each flower-stem bearing from three to six blooms of a pale lemon colour slightly stained with purple; the segments are of equal length, the three upper ones having a purplish band running through the centre of each, and the three lower ones a few faint spots near the tips. The flowers have a perfume something like that of a Clove Carnation, but not so strong. *G. cruentus*, *G. dracocephalus*, and *G. purpureo-auratus*, are also just showing flower.—A.

STRIPED PETUNIAS.—One of the prettiest flower-beds which I have seen for a long time is now in the Rectory garden at Ealing, and consists entirely of an even, circular mass of striped Petunias. Of these the best forms have medium-sized, perfectly round flowers, and from a packet of seed there will not be found two that are exactly marked alike. The growth is free yet even, and until the end of the summer a well-formed mass is easily maintained. In hot, dry situations these Petunias will thrive where many other plants would starve. Seed should be sown in pans early in March, the young plants pricked out into small pots when large enough to handle, and gradually hardened off so as to be ready for turning out about the middle of May.—A. D.

NEW PELARGONIUMS AT SWANLEY.—Amongst the many Pelargoniums now in cultivation, it is difficult to discover which are the best and most attractive; notwithstanding the number, however, of so-called varieties that are daily being raised, there are yet some new and really distinct kinds. Of these I saw a few the other day in Mr. Cannell's nursery at Swanley. Here the plants are grown in good sandy loam in 6-in. and 8-in. pots, arranged on each side of a span-roofed house 100 ft. in length, and the quantity of flowers which each plant bears is remarkable. Amongst kinds likely to prove best

for pot culture may be named Sir Garnet Wolseley, a brilliant scarlet; Malcolm, a kind with large trusses of crimson flowers, with an eye of the same colour; Jealousy, the nearest approach to a yellow which I have yet seen; and a magenta kind called Joseph Sonnen. In the same collection were also Apple-blossom, a very free-flowering variety with large-petalled blossoms of a delicate pink and rose colour; and John Denny, a very distinct kind with orange-scarlet flowers tipped with bright purple. Amongst semi-double sorts may be named J. C. Rodbard, a fine kind with bright scarlet flowers. Quite a new race has also been obtained here, the result of a cross between the Zonal and Ivy-leaved kinds, the plants being for the most part intermediate between their parents. A mauve-coloured, semi-double Ivy-leaved variety was also very effective, very small plants of it flowering freely.—S.

SWEET PEAS FOR MARKET.—In Mr. Henry Bailey's garden at Feltham are several rows of the white-flowered Sweet Pea, the blooms of which are gathered expressly for market purposes. A bright scarlet-flowered kind is also largely cultivated here, and seen together the scarlet and white flowers are very effective. These kinds, on account of the flowers being of decided and striking colours, are much more valuable for market purposes than any others.—C. S.

BEGONIAS AT PINE-APPLE PLACE.—These fill a span-roofed house here 80 ft. long and 25 ft. wide, and being just now in full flower, they are very attractive. They number upwards of 2000, presenting a varied mass of scarlet, orange, and rose. For decorative purposes, Begonias, grown as they are here, are unsurpassed; and considering their easy culture, they deserve to be largely grown. Many of the better kinds make good room plants, lasting as they do a long time in flower. They are also beginning to make their appearance in Covent Garden.—C. W. S.

NEW BOTANIC GARDEN, HULL.—This, which is to comprise about 35 acres, is to contain a winter garden, consisting of a range of glass houses 400 ft. long. The centre house, which is to be lofty, will be devoted to Palms and other tropical plants, the houses at each end being intended—one for aquatic plants, combined with tropical Ferns and their allies, and the other for special groups of Camellias and otherwise interesting Australian plants. In front of these houses is to be an Italian flower garden, and there is also to be an open lawn about 5 acres in extent, and a lake, covering some 3 acres, adapted both for boating and skating. Such rare trees and shrubs as are adapted to the locality will be interspersed in groups throughout the grounds, which under Mr. Niven's superintendence cannot fail to be skilfully laid out. In addition to the purely horticultural buildings, it is also proposed to erect a large room adapted for meetings, and which will answer the purpose of a lecture hall, botanical museum, and library of botanical works for reference; and it is hoped that arrangements may be made at some future time for erecting an aquarium.

DRAWINGS OF CHINESE PLANTS.—The Botanical Department of the British Museum has lately been presented with a large series, amounting to nearly a thousand examples, of drawings of Chinese plants by native artists. They were drawn under the direction and at the expense of the late Mr. John Reeves, who was for many years resident at Canton, where he formed collections of native drawings illustrating not only all branches of national science, but also the manners and customs of the Chinese; and in honour of whom the genus *Reevesia* was named by Lindley. The whole of these have been presented to the Museum by Miss Reeves, mainly through the instrumentality of Mr. Carruthers, of the Botanical Department. The plant drawings are all life-size and remarkably accurate in form and colouring—of some of the more characteristic Chinese plants, such as the *Chrysanthemum*, a very large series of varieties is presented: the drawings of fruit are also of special interest. It is not, we believe, generally known that the Museum is extremely rich in unpublished drawings of plants. The magnificent series of Australian plants by Ferdinand Bauer has recently been placed in sunk mounts and arranged in suitable and handsome cases; it may be doubted whether any other establishment possesses a series so accurately executed and so exquisitely finished. Besides these, there is a large collection of folio drawings of plants from various parts of the world, by Sydney Parkinson, John Polydore Nodder, John Fredk. Miller, and other good artists, dating for the most part about a century back; also original drawings by Anblat, and coloured figures by Elvet and Jacquin, these being very elegant productions. The Kew Herbarium possesses a very extensive collection of figures of plants (mostly published) from various sources; these are arranged in a series parallel to that of the herbarium, to which they form a most useful adjunct, especially in connection with the work of naming plants from the Royal Gardens and other places.

ALPINE FLOWERS ON THE FAULHORN.

On the lower slopes of the Faulhorn, which is 8802 ft. above the sea, the usual Alpine pastures are passed, and where they have not been already cut they are gay with *Campanulas* (the pale blue *C. barbata* being one of the commonest), *Astrantias*, *Phyteumas* (white and blue), *Hieracium aurantiacum*, and other Hawkweeds and *Ranunculuses* in variety. Here and there, between the green Alps, a rocky brow is mounted, and on one of these rocks we found a fine plant of *Dianthus sylvestris*, the first we have seen this year. About a quarter of the way up Pine woods begin, with a luxuriant undergrowth of Whortleberries, Alpen-rosen (*Rhododendron ferrugineum*), White Heather (*Erica carnea alba*), *Polygala Chamæbuxus*, and *Maianthemum bifolium*. The last is an exquisite plant, which should be found in every English garden where peat beds abound, not only for the sake of its dainty heads of dwarf white flowers, but for its delicious Lily of the Valley scent, and its lasting powers in a cut state. Shady spots were full of Ferns, consisting of *Lastrea Filix Mas*, *L. Oreopteris*, *Athyrium Filix Femina*, and *Blechnum*. In the bogs we found plenty of our old English friends, *Caltha palustris* and *Pinguicula alpina* and *P. vulgaris*. Above the half-way house we reached a long stretch of heathery moors; the turf by the side of the rocky path was gay with *Gentiana verna*, *G. acaulis*, and the white *G. frigida*, and a Pansy (*Viola calcarata*) of an intense rich purple, which produced a most beautiful effect when seen in large masses on the short, green Grass. At Bachalp, 5649 ft. above the sea, the real Alpine vegetation began, and now we had a rich feast. Every rock was covered with *Saxifrages* in full flower, *Androsace Chamæjasme*, *Primula farinosa*, *P. villosa*, and *P. integrifolia*, which latter we found here for the first time. Bright pink cushions of *Silene acaulis* spread over the turf side by side with the yellow *Ranunculus montanus*, *Gentiana bavarica*, and the still more beautiful *G. brachyphylla*, of the same intense blue, but much larger, and with a white corona (I can describe it in no other way) in the centre of each flower. I found on the calcareous rock of which much of the Faulhorn is composed, a solitary specimen of the smallest of white Lilies (*Lloydia serotina*), for which I had hitherto searched in vain, but its small flowers look at a distance so like many of the Alpine *Saxifrages*, &c., that it may easily be passed by unnoticed. Near the summit of the hut a pitiless storm of rain and wind broke upon us, but as we struggled up over great sheets of yet unmelted snow, wherever a bit of ground or rock appeared, it was covered with the white blooms of *Ranunculus glacialis*, a close-growing species, with thick, bright green leaves, and large, white and sometimes cream-coloured flowers, which would make a beautiful addition to any English collection of Alpine plants. Altogether the Faulhorn is well worth a visit from the botanical collector, as the plants are those which in most places are only found on the highest and most inaccessible mountains, while here they can be obtained by a walk of four hours-and-a-half going up and three hours coming down; but the expedition should be made in one day, so as to avoid the necessity of sleeping at the wretched hotel at the top. ROSE G. KINGSLEY.

ANOTHER TROPICAL DESSERT FRUIT.

To the list of tropical fruits given by Mr. Hobday (see p. 77) we may add *Carica candamarcensis*, of which there is at present a good specimen, both in flower and fruit, in the cool compartment of the economic house at Kew. It is a native of the Andes of Ecuador, where, for the sake of its edible fruits, it is cultivated up to 9000 ft. Monsieur Van Volxem was the first, we believe, to introduce living plants of this species into this country, and he spoke very highly both of the beauty of the tree and the quality of its fruit. Mr. Spruce, in the "Journal of the Linnean Society," informs us that when he visited the mountain of Tunguragua in 1858, the ground was strewn with its ripe and rotting fruits, which were smaller and sweeter than those of the common Papaw, and were the favourite food of the bears that infest the forests of that mountain. The trunk he describes as being as stout as that of the common Papaw, and the leaves even longer than in that species, the fruits as being 8 in. to 9 in. long, and sometimes nearly as broad; the flesh white (not yellow, as in the common Papaw), soft, and with a pleasant flavour, being sometimes very acid in cool sites. Moreover, we have the testimony of Sir Joseph Hooker

on the subject. In describing the plant in the volume of the "Botanical Magazine" for 1875, he says:—"I can vouch for the delicious smell and grateful taste of the fruit, in both which qualities it differs from the common Papaw, which is not in my opinion worth cultivating for the dessert table, while this is so decidedly." The fruit of the common *Carica* was found by Vauquelin to contain fibrine, a substance previously supposed to be peculiar to the animal kingdom. The whole tree possesses the singular property of rendering tough meat tender by separating the muscular fibres, and its leaves are used as soap. The Kew plant mentioned at the commencement of these remarks has a naked stem about 4 ft. high, and a fine head of leaves, from the axils of which spring the flowers and fruit. It makes a handsome greenhouse plant, and with care might succeed outside in warm, sheltered spots in the south-western counties.

LEAVES AND TREES.

It might appear not unadvisable that every leaf should, as it grew, pay a small tax to the stalk for its sustenance, so that there might be no fear of any number of leaves being too oppressive to their bearer: which, accordingly, is just what the leaves do. Each, from the moment of its complete majority, pays a stated tax to the stalk, that is to say, collects for it a certain amount of wood, or materials for wood, and sends this wood, or what ultimately becomes wood, down the stalk, to add to its thickness. As the leaves, if they did not thus contribute to their own support, would soon be too heavy for the spray; so if the spray, with its family of leaves, contributed nothing to the thickness of the branch, the leaf families would soon break down under their sustaining loads. Each leaf adds to the thickness of the shoot, branch, and stem, with so perfect an order and regularity of duty, that from every leaf in all the countless crowd at the tree's summit one slender fibre, or at least fibre's thickness of wood, descends through shoot, through spray, through branch, through stem; and having thus added in its due proportion to form the strength of the tree, labours yet farther and more painfully to provide for its security; and thrusting forward into the root, loses nothing of its mighty energy until, mining through the darkness, it has taken hold in cleft of rock or depth of earth as extended as the sweep of its green crest in the free air. . . . If ever in autumn a pensiveness fall on us as the leaves drift by in their fading, may we not wisely look up in hope to their mighty monuments? Behold how fair—how far prolonged in arch and aisle, the avenues of the valleys, the fringes of the hills! so stately, so eternal, the joy of man, the comfort of all living creatures, the glory of the earth—they are but the monuments of those poor leaves that flit faintly past us as they do. Let them not pass without our understanding their last counsel and example—that we also, careless of monument by the grave, may build it in the world—monument by which men may be taught to remember not where we died, but where we lived.—"Modern Painters," vol. v.

ZEPHYRANTHES AS BORDER FLOWERS.—As flowers of analogous properties to those of the *Crocus* tribe, these pretty and showy plants ought to prove attractive additions to our mixed flower borders as successors to the early spring bulbs, most of which have disappeared when the *Zephyranthes* come into bloom in July and August, at which time the large, star-like flowers, when fully expanded, produce a bright, spring-flower appearance that is very charming in the hot days of summer. Both the white and pink species figured in the coloured plate of last week's number of *THE GARDEN* were blooming freely at Mr. Wilson's, Heatherbank, about this time last year, when the original drawing was made. Doubtless some of the other species, of which an interesting account was furnished last week, will prove equally hardy and free-blooming, and if so, the *Zephyranthes* family, as summer-flowering bulbs, will form a very pleasing addition and variety to our more well-known border flowers. At all events they are well worthy of cultivation.—H. N. H.

THE COLORADO BEETLE.—The following extract from a letter from Messrs. Bliss & Sons, of New York, dated July 19, has been sent to us by Messrs. Hooper, of Covent Garden:—"We see by the papers that the Colorado Beetle is expected to make its appearance in England. Your people need not be frightened; a few doses of Paris Green will destroy it. It was feared a month ago that the Potato crop here would be destroyed, but the Beetles were soon disposed of, and Potatoes never looked better than they do now, and judging by present appearances there will be an abundant crop here this season."

A Fir tree 133 ft. high has just been cut down in Hungary. The proprietor had it cut because the top was too far away from the bottom.—"Fun."

A GARDEN OF ROSES.

THIS may with truth be said of Messrs. William Paul & Son's Nursery at Waltham Cross at the present time; for the moment it is entered from the railway platform at Waltham one finds Roses on all sides—Roses in borders, Roses on palings, which literally glow with them; and further on a line of Roses with heads just high enough to be seen above the railway hedge. What Roses are capable of effecting in a decorative way is, however, best seen on the central walk, a wide grass promenade 600 yds. in length and 36 ft. in width, on the sides of which are beds of Roses, among which we noticed the old Crimson China, Souvenir de Malmaison, and others, with here and there clumps of pillar Roses which, seen against a background of ornamental trees and shrubs, have a much more pleasing effect than standards. Bourbons and Hybrid Perpetuals seem to be driving what are called summer Roses out of cultivation; but we think unjustly—an opinion from which few would dissent could they have seen a fine old untrained specimen of Madame Plantier, as we saw it here the other day, loaded with snowy blossoms, strikingly visible from all quarters of the nursery. Among crimson Roses in the Hybrid Perpetual class, Star of Waltham, Lord Macaulay, and Beauty of Waltham are three kinds which it will be difficult to supersede; and if two more be wanted of the same colour, we would select Duke of Edinburgh and Charles Lefebvre. Of the dark maroon class, none are better than Xavier Olibo, Prince Camille de Rohan, and Baron de Bonstetten. Of rose or pink Hybrid Perpetuals, Magna Charta, quite a new Rose, stands at the head: it resembles Princess Beatrice, but is somewhat paler and altogether fuller and finer. The Marquise de Castellane, François Michelin (figured in Vol. X. of THE GARDEN), and Edouard Morren will be found to be its best associates. The finest white Hybrid Perpetual is still Madame Lacharme, a noble Rose, greatly superior both in size and beauty to Boule de Neige, Madame Noman, or Elise Boëlle, all white kinds. Almost the only colour now wanting among Hybrid Perpetuals is a good yellow, of which that class is still deficient. Among Moss Roses, none yet beats the common sort, which is said to have been a sport from the old Cabbage Rose, a kind that it resembles in fragrance and doubleness. The Crested Moss is, however, a good Rose, and so is Lanei; but the deepest crimson is perhaps Cellini; Little Gem, too, is a miniature Moss which few would like to be without, its small half-open buds being excellent for button-hole bouquets. Of white Moss Roses, none are thoroughly good; the best is perhaps Comtesse Murinais. As pillar Roses, few are better than Glory of Waltham, Coupe de Hebe, Charles Lawson, and Paul Perras, and for walls Amadis and gracilis are both brilliant; but their beauty is short-lived. On good aspects, Noisettes and Teas succeed well, and amongst these few are more desirable than Cloth of Gold where room can be afforded it. Then there are Maréchal Niel, Climbing Devonienensis, Gloire de Dijon, Solfaterre, Celina Forestier, and Fortune's Yellow; to which may be added the rose-coloured Belle de Bordeaux. Fine, however, as the display of Roses here is, this nursery possesses an interest for planters in other ways.

The Blue Poppywort (*Meconopsis Wallichiana*).

It contains one of the best and most extensive collections of ornamental trees and shrubs anywhere to be found. The diversity of both colour and form obtainable amongst them is remarkable, and if ornamental grounds now-a-days be destitute of pieces of brightly-coloured planting, not only in autumn, but at all seasons of the year, it is not from lack of material suitable for the purpose. Purples of different shades are represented by the coloured-leaved variety of the common Berberry, the purple Beech, Birch, Nut, some of the Japanese Oaks, and the Black Oak (*Quercus nigra*); yellows, by the Golden Elder, Yew, Holly, Euonymus, Ivy (of which there is in this nursery a fine collection), *Spiræa opulifolia lutea*, the Golden Elm, Oak (*Quercus concordia*), the golden variety of *Cornus Mas*, and the Corstorphine Plane; whites, in the Silver Elder, Willow, Holly, Sea Buckthorn, Acer Negundo, Elm, and the

silver-leaved variety of the Mahaleb Cherry. Of these principal colours, too, there are many gradations, and even blue in *Picea nobilis glauca*, a fine variety, without which no collection of Conifers can be complete. Golden Yews may be seen here of all sizes and forms—from little pyramids of the brightest yellow set on a grassy carpet, to round-headed standards with clean stems, like those of standard Roses. Form, indeed, is no less diversified than colour. Amongst standards, in addition to the Yews just mentioned, there are multitudes of Hollies, Box, and Portugal and Colchic Laurels; and if pyramids of various sizes and shades of colour be wanted, they may be found among the fine specimen Conifers (one of the most beautiful of which is *Picea larioarpa*), ornamental-leaved Hollies, and other trees and shrubs of a handsome character, of which these grounds contain a remarkably rich and varied collection.

M.

Rock Gardening at Kew.—

Those who have noticed with various feelings the style of the "rockworks" at Kew, will be interested to hear of the most recent attempt in this direction. In the pleasure grounds a long and wide border has recently been devoted to Sun Roses (*Helianthemum*). They do not require to be elevated on, or accompanied by, rocks in such soil as that of Kew; but for æsthetic or other reasons it has been thought right to scatter a great number of old bricks about them. These bricks have the white plaster still adhering to them, and, it need hardly be said, are not very comforting to

those who seek for natural beauty or right design in a garden. Writers on landscape gardening who torment themselves and their readers with such definitions as "gardenesque," &c., may add another term to their vocabulary. Brick-rubbishesque will form a fine long word, and be as useful as the others in advancing the art of landscape gardening. Seriously, what we allude to is a feature that few poor amateurs cultivating cottage gardens would tolerate.

The Sky-blue Poppywort (*Meconopsis Wallichiana*) has been finely in flower at Kew lately. It is a very peculiar and beautiful plant, and well deserves to become generally grown. It is a native of the Himalayan Mountains. It is tall and stately in habit; a beautiful tuff of golden stamens in the centre contrasts with the rare blue of the corolla.

Gymnothrix latifolia.—Mr. Ellacombe informs us that this Grass is a very valuable one, on account of its rich green foliage and very elegant habit. It is particularly suitable for putting in the centre of a bed.

FORGET-ME-NOTS IN POTS.

EVERYONE is fond of the Forget-me-not in all its forms, and yet how seldom does one meet with it in small gardens! Many who think Forget-me-nots beautiful in a wild or semi-wild state, imagine that they cannot be kept alive in gardens, especially in the neighbourhood of towns: true, they often fail, but the fault lies with the cultivator. People take the common Forget-me-not out of a ditch or a swamp and set it in or on a bed or border of dry earth, and of course it withers up. Other varieties of the Forget-me-not are also often planted in most ungenial places, as, for instance, right in the eye of the sun, and in soils only fit for making bricks. The roots fail to get a good hold or suitable food, and their tops soon get burnt up. All these causes of failure are easily avoided by growing Forget-me-nots in pots, and by thus rendering them portable a choice or a change of site and of soil may be commanded at any time. All the Forget-me-nots do well in pots, and some of the prettiest plants for windows may be found in the common Forget-me-not of our ditches. As a bracket plant, or suspended in small vases or bottles of water, too, it is alike interesting and beautiful. All that is needed to get a fine mass of it is to take off a few cuttings, root them in damp soil or in water, and fill a vase, pot, or hanging basket with the young plants as they show flower. A glass basket makes a charming receptacle for the Forget-me-not; it will almost fill it with roots, and profusely cover it with flowering shoots and branchlets. If grown in pots or vases in soil, a mixture of equal parts leaf-mould and loam, or any rough vegetable matter, kept sufficiently moist, will answer. As soon as the plants show signs of fading fresh cuttings should be made and started afresh; or the plants may merely be pulled to pieces, the old, exhausted roots thrown away, and the branches already covered with roots formed into new plants by inserting any number of these cuttings, from six to a dozen or a score, into a fresh pot, vase, or basket. A shady situation, such as a north window, is the best situation for this Forget-me-not during the warm summer months, though earlier and later in the season it will thrive well in a southern or western window. One of the prettiest masses ever seen was suspended from the centre of an east window in a Hyacinth glass, which it filled to overflowing with beauty. I have been thus particular about the culture of this common Forget-me-not, because it is within reach of all, and, being half-aquatic, needs special treatment in regard to water. It must not, however, be thought that water is essential to success in its cultivation; it grows well in damp soil in a shady situation, and is an admirable plant to associate with Musk for clothing and sweetening outlying damp nooks and corners.

It must not be assumed that the other Forget-me-nots are also semi-aquatic. Such fine Forget-me-nots as *Myosotis Imperatrice Elizabeth*, *M. azorica coelestina*, *M. semperflorens*, *M. sylvatica*, *M. alpestris nana cœrulea*, *M. a. nana alba*, and last, but not least, *M. dissitiflora*, thrive best in soil, and succeed under treatment similar to that given to other plants. For pot culture, *M. dissitiflora* is perhaps the best of all the Forget-me-nots. The colour, when the blossoms are fully expanded, is a most exquisite blue, and the plant is good in habit. It grows to a height of about 6 in., and spreads out freely, soon furnishing a 4-in. or 6-in. pot. The flowers open in succession from the base of the stem upwards, something like those of the Lily of the Valley; it therefore remains long in bloom. *M. azorica coelestina*, an improved variety of a well-known rich dark blue Forget-me-not, is also a plant of great beauty. *M. semperflorens* is a hardy variety that continues flowering with little trouble from spring to autumn. The white and blue dwarf Forget-me-nots (*M. alpestris nana*) only grow about 4 in. in height, and are little gems for pot culture. These might be kept in small pots or even in saucers, as they require but little soil.

The whole of the Forget-me-nots are easily raised from seed or increased by cuttings, but seeds are the only practical mode of acquiring a stock of most of them. They may be sown as soon as they are ripe in spring or summer, or kept till next spring and sown in March or April. If sown at once, the plants will flower the next summer; and, of course, if not sown till next spring, they will hardly flower till late in the autumn or winter. They may be sown in the open air or in

pans or pots, and being remarkably small, they can hardly be covered too lightly. They should also be sown rather thinly, for if sown too thickly, the plants are apt to damp off as soon as they are out of the ground. As soon as the young plants are large enough to handle, they should be pricked off or potted singly in the smallest thumb-pot. If placed under a hand-light or cold frame for a time, they will make rapid progress, and speedily form useful little plants. Shift as they require it into 2-in. and then into 3-in. pots, in which some of the smaller varieties, such as *Myosotis alpestris* and *M. nana cœrulea*, may be flowered, and almost any of the Forget-me-nots grow into excellent window or room plants in 4-in. or 6-in. pots. The best place in which to grow all these Forget-me-nots, when once they are established, and until they reach the flowering stage, is a partially-shaded, sheltered situation out-of-doors. They grow well in a mixture of rotten leaf-mould with about a fourth part of sand. The drainage should be ample, as most of these Forget-me-nots are semi-alpine plants, and cannot endure stagnant water at the roots, though during both the growing and flowering periods, they must not be allowed to become dry. They must not be treated to water so freely as the *Myosotis palustris*, or they will become unhealthy, and ultimately die. With *M. dissitiflora*, any garden and house might be enriched with Forget-me-nots the whole year round. Sow a few seeds in July, again in March and May, and a succession of flowering plants would be always available; or, perhaps better still, put in a few cuttings, either in pits or in the open air, from four to half-a-dozen times a year, and this Forget-me-not would be always in flower in the window, greenhouse, or open air. No plant pays better for a little extra shelter and cultivation than this lovely Forget-me-not. Plants of it, potted from the open ground in October or November, and placed in moderate heat—a temperature of 50° or 55° would be in flower at Christmas. It may easily be had in bloom by little stimulants of this kind indoors till March at which season it bursts into full beauty in the open air. Its continuance in beauty throughout the summer depends on two things—good feeding, and frequent renewal of plants by cuttings or from seeds. By the first only the old plants can be induced to bloom throughout the summer; but, as a rule, younger plants flower more freely. D. T. FISN.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Browallia elata and alba.—These are two most useful annuals for indoor decoration at this season, being easily cultivated and prolific bloomers. Sown in gentle heat in March, and potted and stopped as required to induce a bushy habit, they form very effective plants from this time onwards. We usually make two or three sowings during the season, as plants of such easy culture are best in a young, vigorous condition, and as soon as they begin to fade they are thrown away.—J. GROOM, *Henham*.

Aerides virens.—One of the most attractive sights in the Exotic Nursery at Chelsea just now is a group of plants of this *Aerides* placed in a corner of one of the Orchid houses, where they are producing a profusion of gracefully-drooping flower-spikes covered with white, pink-tinted, waxy blossoms. These, like other plants, are seen to best advantage when grouped together as is now done here.—C.

Zygopetalum Sedeni.—A plant of this new hybrid *Zygopetalum* is now in good condition in Messrs. Veitch's Nursery at Chelsea. It bears four or five strong flower-spikes, which are beset with flowers having crisp chocolate petals, which contrast effectively with the vivid purplish-blue lip. This plant was raised by Mr. Seden, and is the result of a cross between *Z. maxillare* and *Z. Mackayi*.—S.

An Hotel Garden.—That excellent plan which we have so often advocated of turning the tops of houses in cities into gardens, has been carried out by the Palmer House in Chicago, and a portion of the roof in that hotel is now covered with a magnificent conservatory. The structure is entirely of glass and iron, and as it is built on an extension, its location is such that it opens directly out of the fifth floor corridor of the main edifice, which rises some two stories above. A fine collection of tropical and rare plants has been provided, and the regular heating apparatus of the house supplies ample warmth. The conservatory is open to guests of the hotel, and furnishes a delightful resort.—"Scientific American."

The Cultivation of *Cytisus proliferus*.—This, the Escobon of the Canary Islands, where it is much grown and highly esteemed as a forage plant, is now being attempted in stony and barren land in the southern provinces of Spain. There are many places at the Cape of Good Hope and in Australia, where this plant would succeed well, and probably prove of great value.—G.

THE FRUIT GARDEN.

EARLY PEARS.

As a rule early Pears, by which I mean Pears that ripen by the end of July and middle of August, are but of second-rate quality, and also lack what is of no less value, viz., keeping qualities; nevertheless, in a season like the present, when other fruits for dessert are so scarce, they are of the greatest value, and a tree or two of each variety should be grown in every moderately-sized garden. The following list includes those only that have come under my own observations:—Summer Doyenné, or as it is more frequently called Doyenné d'Été (fig. 2), is the earliest kind to ripen, being generally

Fig. 1.—Beurré Giffard.

quite over by the end of July. It a delicious little Pear, and is faithfully portrayed in the subjoined woodcut, but its season being so short militates against its ever being generally grown; and the same remark also applies to Citron des Carmes, the next kind to ripen, a fruit about the same size and form as the preceding, though of very different flavour, having a rich aromatic taste, which, however, is absent if the fruit be left to ripen on the tree, as the flesh then becomes mealy and insipid; in order to obviate this it should be gathered as soon as there are the least signs of maturity, and left to ripen in the fruit room. Another very excellent early kind, larger, though otherwise of much the same character as the preceding, is Peach or Pêche. This generally ripens about the end of the month or beginning of August, and is one of the most prolific of early Pears. Beurré Giffard (fig. 1) is one

Fig. 2.—Summer Doyenné.

Fig. 3.—Jargonelle.

of the largest early ripening Pears that has come under my observation, being in all respects first-rate. The tree is of good habit and wonderfully prolific on the Quince stock. Jargonelle (fig. 3), which is too well known to require description, usually ripens from the beginning to the middle of August, its one great fault being that it soon rots at the core; in this respect it is very deceptive, and the only preventive is to gather early, as has just been recommended in the case of other kinds. There are several other very early sorts, such as Summer Rose, Early Rousselet, Beurré précoce, &c., but those to which I have just adverted are the best. W. W. H.

THE KITCHEN GARDEN.

SEASONABLE NOTES.

Endive.—This is indispensable for autumn and winter salads; the early-sown plants quickly bolting and thus becoming useless, a good breadth should be sown now in some open situation. The land need not be freshly manured for this crop, unless it be very poor. Sow in drills 1 ft. apart and 1 in. deep; thin out betimes, and transplant the thinnings if required, allowing each plant at least a square foot of space. Sow again about August 10, and plant out when ready on a dry warm border. The French Moss-curl and Large-leaved Batavian are two useful varieties.

Spring Cabbages.—Carter's Heartwell is well adapted for present sowing, as are also Atkins' Matchless, Enfield Market, and Wheeler's Cocoa-nut; three or four good kinds are better than a greater number. In the midland and northern counties the seeds should be sown at once, but there is no hurry for a week or so in localities situated to the south of London.

Globe Artichokes.—As fast as the heads are cut remove the stems. If the heads be thinned out, those that remain will be finer and better. A thorough soaking of liquid manure will help greatly to swell off the late ones.

Liquid Manure for Melons and Cucumbers.—Tie up a bushel of soot in an old guano bag, place it in a 50-gallon tub or barrel with 3 lb. or 4 lb. of guano, fill up with soft or pond water, stir it up well with an old birch broom, and throw in a lump of lime to clarify it. When using dilute it with an equal quantity of pond water, and use regularly when required. Soot has a wonderfully invigorating effect upon the foliage, and good substantial foliage is essential to the production of well-flavoured fruit. Red spider seems to fight shy of such foliage when grown without shade and in a well-ventilated atmosphere.

Tomatoes.—These are later in the open air than usual this year. It is therefore doubly necessary to keep the growth thin, to give the fruit a chance to ripen. All young shoots that spring from the main stems should be pinched or cut off, to throw all the strength of the plants into the main crop, as the fruit on the lateral growths will stand a poor chance of ripening. Stop all fruiting branches one joint beyond the cluster of blossoms, and do all tying or training betimes.

Close Cropping.—Vacant plots need not remain uncropped longer than is necessary for the completion of manuring and cultivating operations. Land does not need rest if well managed, and the more it is surface-stirred and cultivated the better for the succeeding crops. This has especial importance at this season, as when providing for the demands upon the vegetable department during winter and spring it is always better to have a surplus than a scarcity. Plants derive a good deal of their sustenance from the atmosphere, and a green crop, if not required for use, will, if dug in, return more to the land than it takes from it.

Open-air Mushroom Beds.—Collect some short stable manure and place it under cover till enough has accumulated to form a bed; do not allow it to heat violently; to every five or six barrowfuls of manure add a barrowful of fresh loamy soil, turning it and mixing all together. If convenient the bed may be made in a turf pit, or in a deep, old-fashioned frame. A somewhat shaded position will be better for the first bed; build up the beds as firmly as possible, and spawn as soon as the temperature of the bed falls to 85°. If the beds or ridges be altogether in the open air, they should be at least 2 ft. thick at the apex of the ridge.

Gathering, &c.—Gather all Peas and Beans as soon as they become fit for use, but at the same time avoid injuring the plants; this and securing a robust growth by thin planting, is the only way to secure a succession of pods from the same plants. E. HOBDAV.

A Good New Broccoli.—At this, the season for planting out Broccoli, allow me to recommend to your readers the new variety called Veitch's Self-protecting Autumn Broccoli. I grew a quantity of it last year and can honestly assert that it possesses excellent quantities. If planted now it will be ready for use about the middle of November, and by two other plantings at intervals of a fortnight or three weeks a supply may be had till the end of the first month in the new year. I think so highly of it that it is with me this season wholly taking the place of that excellent old kind, Snow's Winter White.—W. W. H.

Dipping Beans in Paraffin.—With reference to previous correspondence on this subject allow me to say that all the Beans which, I dipped in paraffin have come up, and I therefore conclude that wire worm, with which I am tormented, did not like either the taste or the smell of the oil.—C. DOUGART, Hampton Park, Hereford.

THE LIBRARY.

COTTAGE GARDENING.*

In this book it is sought to give concise instructions as to the best modes of cultivating the various products sought for in the smaller class of gardens. The enjoyment to be derived from a garden by no means depends on its size. Many persons find more pleasure in cultivating with their own hands a small garden than can possibly be enjoyed by those who leave their gardens to others. A garden need not be large to afford a great variety of edible products; and, as for flowers, many will probably agree with a saying of the late Mr. Mowbray Morris, long the manager of the "Times" newspaper, that "the best displays of 'bedding-out' in large places did not equal in beauty the simple flowers in a cottage garden." The writer has endeavoured to develop still further this purer taste in the cottage garden; to select among fruits and vegetables the very best and most productive kinds only; and, generally, to bring the information on all the subjects of which the book treats down to the time of issue.

GARDEN FERNS.

In an early volume of THE GARDEN (see Vol. II., p. 9) we noticed at some length the work on "Ferns, British and Foreign," from the pen of Mr. John Smith, the veteran ex-curator of the Royal Gardens, Kew. We are glad to find that the favourable opinion which we then expressed of the book has been shared by the public, and that it has been found necessary to issue a new and enlarged edition of what is perhaps the most useful of Mr. Smith's pteridological works. The appendix to this edition contains about 230 species which have been introduced to our gardens since 1864. With regard to cultivation he tells us he has nothing to add to what had already appeared in the first edition; and this we can readily believe, as the chapter on that subject was so complete as to leave little to be desired.

Medicinal Plants.—The work on "Medicinal Plants," by Prof. Bentley and Dr. Henry Trimen, which we announced some time ago as in course of publication, has reached its twenty-second number, and demands a word of notice. The promises made at the commencement of the work seem to have been conscientiously fulfilled by the authors and artist (Mr. D. Blair); the figures are in almost every case thoroughly original in every detail, while the letterpress, both of the botanical and medical portions, is carefully brought up to date. In this last part are figured the Ground-nut (*Arachis hypogæa*), the Common Elder, the Chamomile (*Ipomæa (Pharbitis) Nil*), the Pennyroyal, the Darnel, and the Maize, this last occupying a double plate. In so many figures it could hardly be expected that all would be equally good. The Pennyroyal, the Maize, and the Ground-nut seem to us the best in the present number.

Familiar Wild Flowers.—We have received the two first numbers of a little work entitled "Familiar Wild Flowers," by Mr. F. E. Hulme, which aims at presenting coloured plates and popular descriptions of British plants. The intention of the book is good, for, in spite of the various published plates of our English wild flowers, there are none, with the exception of those in Curtis's "Flora Londinensis," which can be deemed satisfactory from an artistic point of view. We regret, however, that we cannot speak favourably of the figures before us, which are sometimes ungraceful in form (as in the case of *Convolvulus arvensis*, which looks as though stamped out in metal), or exaggerated in colouring (as the leaf of *Geranium pratense*), while the letterpress is scarcely up to the mark.

THE GREAT FLOWER PAINTERS.

DAVID DE HEEM—BORN 1600, DIED 1674.

DAVID DE HEEM, though he occasionally painted flowers with all the care and minute precision which he devoted to fruit painting, and such table ornaments as are used for its display, was nevertheless avowedly inferior to Van Huysum in the treatment of flowers. In the design and high finish of his fruit, however, he surpassed all his contemporaries. The extraordinary care and finish which he lavished upon his compositions, representing various kinds of fruits accompanied by suitable accessories, rendered his works so precious in the eyes of the Dutch connoisseurs of the day, that he was enabled to command higher prices than any other painter of a similar class; and so great became the demand for his pictures, even at their extravagantly high market value, that only princes could hope to become their possessors. From one of his royal patrons he received the honour of knighthood, and he eventually realised a handsome independence as the reward of his skilful and ever-active pencil. He was born at Utrecht, where his father before him had acquired considerable fame as a fruit painter, whose skill was, however, eclipsed by the superior

Works of the great Flower Painters.—Group of Fruits by De Heem.

abilities of his son. Our large engraving offers a favourable example of the artist's manner, and exhibits a selection of his most favourite subject-models, among the most prominent of which is frequently found, as in our illustration, a partially-peeled Lemon. He became a wonderful adept at the delineation of this often-chosen model, as will be seen in the carefully rendered reproduction of our engraving. The juicy appearance of the cut end of the Lemon, and of the other portions of the interior of the fruit where the inner skin has been pared away, are most exquisitely rendered; while the granulations of the exterior of the rind are wrought out with a persevering labour and accuracy that makes the artist's work seem almost the actual reality. The transparency of the Grapes is equally well rendered, and the foliage of the Vine branch is as graceful as if painted by Van Huysum himself. The underside of the wings of the "Red Admiral" butterfly (*Vanessa Atalanta*), just settled on the bunch of Grapes, would satisfy an entomologist—even a lepidopterist—by the excessive

accuracy with which the most minute markings have been reproduced; while the branch of Plums, the solitary Cherry, and all the inferior accessories are wrought up with the highest conceivable degree of finish. Our smaller example represents a dish of Raspberries, painted with a laborious care and juicy brush-handling that is beyond all praise; and the bunch of Grapes and ever-recurring peeled Melon exhibit an equal amount of careful and successful treatment. Some of his pictures represent such subjects as a dish of oysters, rendered with an attractive realism that might delight the greatest gourmand of those bivalves; at other times a dish of crayfish, a group of dead birds, and various other subjects formed his models; but these do not concern the readers of THE GARDEN, to whose appreciation the fruit paintings of the master chiefly appeal. After the troubles in the town of Utrecht which, in 1671, drove so many of its inhabitants to seek an abode elsewhere, De Heem took shelter in Antwerp, where he passed the remaining years of his life. It was there that he became acquainted with Snyders, whose paintings of fruit, &c., on a Rubens-like scale, influenced to a certain extent the style of De Heem in his later works, and it was there that he became the friend of the celebrated Teniers, in one of whose greatest

* "Cottage Gardening: or, Flowers, Fruits, and Vegetables for Small Gardens." By E. Hobday. London: Macmillan & Co., 1877.

works—a kitchen scene—De Heem painted the fruits, vegetables, and other accessories. This picture was last sold to M. Thibcaudeau for the large sum of 5,500 francs.

H. N. H.

Symphytum orientale.—Among hardy spring-flowering plants an eastern species of Comfrey (*Symphytum orientale*) deserves a place. It is not often met with in gardens, but may be seen in masses every spring and early summer on the embankment immediately below the down platform of the Isleworth railway station, (where it must have been established for some years), and proves a striking and conspicuous object. It is a handsome plant of bushy habit, growing about 1½ ft. high, with much branched stems and a profusion of pure white flowers, which are produced much more

These pretty country folks would lye.
As You Like It, act v., sc. 3.

The Rye of Shakespeare's time was identical with our own

Works by the great Flower Painters.—Group of Fruits by De Heem.

freely than those of the common Comfrey, and do not fall off so readily as those of that species. Roots removed to a garden have at once established themselves, and the only drawback to its usefulness as a spring garden flower is the probability of its degenerating into a weed, from the rapidity of its increase. It is figured in the "Botanical Magazine," t. 1932.—JAMES BRITTON.

Dried Peaches.—The Cambridge "Maryland Chronicle" says:—"Accounts still agree that the Peach crop will be immense, although in some parts of the peninsula the yield will be very small. Not one-half of the crop will be sent to the market in the natural state, owing to the great excess of the supply over the demand. Last year experiments were made in drying the fruit by intense heat, and this year that branch of the business will be prosecuted extensively, especially in Delaware. A bushel of Peaches contains two gallons of water, which can be driven out in a few hours by evaporation, and the slices, when brought into contact with water again, are found to be not materially altered in taste. Europe is the market in which the dried Peaches are to be sent."

(*Secale cereale*). It is not a British plant, and its native country is not exactly known; but it seems probable that both the plant and the name came from the region of the Caucasus.

As a food plant Rye was not in good repute in Shakespeare's time. Gerarde said of it, "It is harder to digest than Wheat, yet to rusticke bodies that can well digest it, it yields good nourishment." But "recent investigations by Professor Wanklyn and Mr. Cooper appear to give the first place to Rye as the most nutritious of all our cereals. Rye contains more gluten, and is pronounced by them one-third richer than Wheat. Rye, moreover, is capable of thriving in almost any soil."—"Gardeners' Chronicle," 1877.

Saffron.

- (1) *Ceres.* Who (*i.e.* *Iris*), with thy Saffron wigs upon my flowers,
Diffusest honeydrops, refreshing showers.
Tempest, act iv., sc. 1.

(2) *Antipholus of Ephesus.*

Did this companion with the Saffron face
Revel and feast it at my house to-day?
Comedy of Errors, act iv., sc. iv.

(3) *Clown.* I must have Saffron to colour the Warden pies.

Winter's Tale, act iv., sc. 2.

(4) *Lafeu.* No, no, no, your son was misled with a snipt-taffeta fellow there, whose villanous Saffron face would have made all the unbaked and doughy youth of a nation in his colour.

All's Well That Ends Well, act iv., sc. 5.

Saffron (from its Arabic name, *al zahafaran*) was not in Shakespeare's time limited to the drug or to the Saffron-bearing Crocus (*C. sativus*), but it was the general name for all the Croci, and was even extended to the Colchicums, which were called Meadow Saffrons. We have no Crocus really a native of Britain, but a few species (*C. vernus*, *C. nudiflorus*, *C. aureus*, and *C. biflorus*), have been so naturalised in certain parts as to be admitted, though very doubtfully, into the British flora; but the Saffron Crocus can in no way be considered a native, and the history of its introduction into England is very obscure. It is mentioned several times in the Anglo-Saxon leech books—"When he bathes, let him smear himself with oil; mingle it with Saffron" (Tenth century Leech Book, ii., 37). "For dimness of eyes, thus one must heal it: take Celandine one spoonful, and Aloes, and Crocus (Saffron in French)" ("Schools of Medicine," tenth century, c. 22). But in these instances it may be only the imported drug; but the name occurs in an English vocabulary among the nomina herbarum (*i.e.*, names of herbs or plants)—"Hic Crocus, A^e Saffuroun;" and in a pictorial vocabulary of the fourteenth century, "Hic Crocus, An^e Saffryn;" so that I think the plant must have been in cultivation in England at that time. The usual statement, made by one writer after another, is that it was introduced by Sir Thomas Smith into the neighbourhood of Walden in the time of Edward III., but the original authority for this statement is unknown. The most authentic account is that by Hakluyt in 1582, and though it is rather long, it is worth extracting in full. It occurs in some instructions in "Remembraunces for Master S.," who was going into Turkey, giving him hints what to observe in his travels:—"Saffron, the best of the universall world, groweth in this realme. . . . It is a spice that is cordiall, and may be used in meats, and that is excellent in dying of yellow silks. This commodity of Saffron groweth fifty miles from Tripoli, in Syria, on an high hill, called in those parts Gasian, so as there you may learn at that part of Tripoli the value of the pound, the goodnesse of it, and the places of the vent. But it is said that from that hyll there passeth yerely of that commodity fifteen moiles laden, and that those regions notwithstanding lacke sufficiency of that commodity. But if a vent might be found, men would in Essex (about Saffron Walden), and in Cambridgeshire, revive the trade for the benefit of the setting of the poore on worke. So would they do in Herefordshire by Wales, where the best of all England is, in which place the soil yields the wilde Saffron commonly, which sheweth the natural inclination of the same soile to the bearing of the right Saffron, if the soile be manured and that way employed. . . . It is reported at Saffron Walden that a pilgrim, proposing to do good to his countrey, stole a head of Saffron, and hid the same in his Palmer's staffe, which he had made hollow before of purpose, and so he brought the root into this realme with venture of his life, for if he had bene taken, by the law of the countrey from whence it came, he had died for the fact" ("English Voyages," &c., vol. ii.). From this account it seems clear that even in Hakluyt's time Saffron had been so long introduced that the history of its introduction was lost; and I think it very probable that, as was suggested by Coles in his "Adam in Eden" (1657), we are indebted to the Romans for this, as for so many of our useful plants. But it is not a Roman or Italian plant. Spenser wrote of it as—

Saffron sought for in Cilician soyle—

which information he derived from Pliny. It is a native of Asia Minor, but so altered by long cultivation that it never produces seed either in England or in other parts of Europe. This fact led M. Chappellier, of Paris, who has for many years studied the history of the plant, to the belief that it was a

hybrid; but finding that when fertilized with the pollen of a Crocus found wild in Greece, and known as *C. sativus* or Græcus (Orphauidis) it produces seed abundantly, he concludes that it is a variety of that species, which it very much resembles, but altered and rendered sterile by cultivation. It is not now much cultivated in England, but we have abundant authority from Tusser, Gerarde, Parkinson, Camden, and many other writers, that it was largely cultivated before and after Shakespeare's time, and that the quality of the English Saffron was very superior. The importance of the crop is shown by its giving its name to Saffron Walden in Essex, and to Saffron Hill in London, which "was formerly a part of Ely Gardens" (of which we shall hear again when we come to speak of Strawberries), "and derives its name from the crops of Saffron which it bore" (Cunningham). The plant has in the same way given its name to Zaffarano, a village in Sicily near Mount Etna, and to Zafaranboly, "ville située près Inobole en Anatolie, au sud-est de l'Ancienne Héraclée" (Chappellier). The plant is largely cultivated in many parts of Europe, but the chief centres of cultivation are in the arrondissement of Pithiviers in France, and the province of Arragon in Spain, and the chief consumers are the Germans. It has also been largely cultivated in China for a great many years, and the bulbs now imported from China are found to be in many points superior to the European—"l'invasion tartare aurait porté le Safran en Chine, et de leur côté les croisés l'auraient importé en Europe" (Chappellier).

I need scarcely say that the parts of the plant that produce the Saffron are the sweet-scented stigmata, the Croci odores of Virgil; but the use of Saffron has now so gone out of fashion, that it may be well to say something of its uses in the time of Shakespeare, as a medicine, a dye, and a confection. On all three points its virtues were so many that there is a complete literature on Crocus. I need not name all the books on the subject, but the titlepage of one (a duodecimo of nearly three hundred pages) may be quoted as an example:—"Crocologia seu curiosa Croce Regis Vegetabilium enucleatio continens Illius etymologiam, differencias, tempus quo viret et floret, culturam, collectionem, usum mechanicum, Pharmaceuticum, Chemicum-medicum, omnibus pene humani corporis partibus destinatum additis diversis observationibus et questionibus Crocum concernentibus ad normam et formam. S. R. I. Academiæ Naturæ curiosorum congesta a Dan: Ferdinando Hertodt, Phys. et Med. Doc. &c., &c. Jenæ. 1671." After this we may content ourselves with Gerarde's summary of its virtues—"The moderate use of it is good for the head, and maketh sences more quicke and lively, shaketh off heavy and drowsie sleep and maketh a man mery." For its use in confections this will suffice for the "Apparatus plantarum" of Laurembergius, 1632—"In re familiari vix ullus est telluris habitatus angulus ubi non sit croci quotidiana usurpatio, aspersi vel incocti cibis." And as to its uses as a dye, its penetrating powers were proverbial, of which Luther's Sermons will supply an instance—"As the saffron bag that hath bene ful of saffron, or hath had saffron in it, doth ever after savour and smel of the swete saffron that it containeth; so our blessed Ladye which conceived and bare Christe in her wombe, dyd ever after resemble the maners and vertues of that precious babe which she bare."—"Fourth Sermon," 1548. One of the uses to which Saffron was applied in the Middle Ages was for the manufacture of the beautiful gold colour used in the illumination of missals, &c., where the actual gold was not used. This is the recipe from the work of Theophilus in the eleventh century—"If ye wish to decorate your work in some manner take tin pure and finely scraped; melt it and wash it like gold, and apply it with the same glue upon letters or other places which you wish to ornament with gold or silver; and when you have polished it with a tooth, take saffron with which silk is coloured, moistening it with clear of egg without water, and when it has stood a night or the following day cover with a pencil the places which you wish to gild, the rest holding the place of silver."—"Book 1., c. 23" (Hendrie's Translation).

Though the chief fame of the Saffron Crocus is as a field plant, yet it is also a very handsome flower; but it is a most capricious one, which may account for the area of cultivation being so limited. In some places it entirely refuses to flower,

as it does in my own garden, where I have cultivated it for many years but never saw a flower, while in a neighbour's garden, under apparently the very same conditions of soil and climate, it flowers every autumn. But if we cannot succeed with the Saffron Crocus, there are many other Croci which were known in the time of Shakespeare, and grown not "for any other use than in regard of their beautiful flowers of several varieties, as they have been carefully sought out and preserved by divers to furnish a garden of dainty curiosity." Gerarde had in his garden only six species; Parkinson had or described thirty-one different sorts, and after his time new kinds were not so much sought after till Dean Herbert collected and studied them. His monograph of the Crocuses, in 1847, contained the account of forty-one species, besides many varieties. The latest arrangement of the family, by Mr. J. G. Baker, of Kew, gives forty-seven species, besides varieties; of these all are not yet in cultivation, but every year sees some fresh addition to the number, chiefly by the unwearied exertions in finding them in their native habitats, and the liberal distribution of them when found, of Mr. George Maw, of Broseley, to whom all the lovers of the Crocus are most deeply indebted. And the Croci are so beautiful that we cannot have too many of them; they are, for the most part, perfectly hardy, though some few require a little protection in winter; they are of an infinite variety of colour, and some flower in the spring and some in the autumn. Most of us call the Crocus a spring flower, yet there are more autumnal than vernal species, but it is as a spring flower that we most value it. The common yellow Crocus is almost as much "the first-born of the year's delight" as the Snowdrop. No one can tell its native country, but it has been the brightest ornament of our gardens, not only in spring but even in winter for many years. It was probably first introduced during Shakespeare's life. "It hath floures," says Gerarde, "of a most perfect shining yellow colour, seeming a far off to be a hot glowing coal of fire. That pleasant plant was sent unto me from Robinus, of Paris, that painful and most curious searcher of simples." From that beginning perhaps it has found its way into every garden, for it increases rapidly, is very hardy, and its brightness commends it to all. It is the "most gladsome of the early flowers. None gives more glowing welcome to the season, or strikes on our first glance with a ray of keener pleasure, when, with some bright morning's warmth, the solitary golden fringes have kindled into knots of thick-clustered yellow bloom on the borders of the cottage garden. At a distance the eye is caught by that glowing patch, its warm heart open to the sun, and dear to the honey-gathering bees which hum around the chalice."—Forbes Watson.

With this pretty picture I may well close the account of the Crocus, but not because the subject is exhausted, for it is very tempting to go much further, and to speak of the beauties of the many species, and of the endless forms and colours of the grand Dutch varieties; and whatever admiration may be expressed for the common yellow Dutch Crocus, the same I would also give to almost every member of this lovely and cheerful family.

Samphire.

Edgar.

Half-way down
Hangs one that gathers Samphire, dreadful trade!
Methinks he seems no bigger than his head.

King Lear, act iv., sc. 6.

Being found only on rocks, the Samphire was naturally associated with St. Peter, and so it was called "in Italian Herba de San Pietro, in English Sampier and Rock Sampier;"—in other words, Samphire is simply a corruption of Saint Peter. The plant grows round all the coasts of Great Britain and Ireland, wherever there are rocks on which it can grow, and on all the coasts of Europe, except the northern coasts; and it is a plant very easily recognised, if not by its pale green, fleshy leaves, yet certainly by its taste, or its "small delightful and pleasant." The leaves form the pickle, "the pleasantest sauce, most familiar, and best agreeing with man's body," but now much out of fashion. In Shakespeare's time the gathering of Samphire was a regular trade, and Steevens quotes from Smith's "History of Waterford" to show the danger attending the trade:—"It is terrible to see how people gather it, hanging by a rope several fathoms from the top of the impend-

ing rocks, as it were, in the air." In our own time the quantity required could be easily got without much danger, for it grows in places perfectly accessible in sufficient quantity for the present requirements, for in some parts it grows away from the cliffs, so that "the fields about Porth Gwylan, in Carnarvonshire, are covered with it." It may even be grown in the garden, especially in gardens near the sea, and makes a pretty plant for rockwork.

There is a story connected with the Samphire which shows how botanical knowledge, like all other knowledge, may be of great service even where least expected. Many years ago a ship was wrecked on the Sussex coast, and a small party were left on a rock not far from land. To their horror they found the sea rising higher and higher, and threatening before long to cover their place of refuge. Some of them proposed to try and swim for land, and would have done so, but just as they were preparing to do so an officer saw a plant of Samphire growing on the rock, and told them they might stay and trust to that little plant that the sea would rise no further, for that the Samphire, though always growing within the spray of the sea, never grows where the sea could actually touch it. They believed him and were saved.

Savory.

Perdita.

Here's flowers for you—
Hot Lavender, Mints, Savory, Marjoram.

Winter's Tale, act iv., sc. 3.

Savory might be supposed to get its name as being a plant of special savour, but the name comes from its Latin name *Satureia*, through the Italian, *Savoreggia*. It is a native of the south of Europe, probably introduced into England by the Romans, for it is mentioned in the Anglo-Saxon recipes under the imported name of Savorie. It was a very favourite plant in the old herb gardens, and both kinds, the Winter and Summer Savory, were reckoned "among the farsing or farsetting herbes as they call them" (Parkinson), *i.e.*, herbs used for stuffing. Both kinds are still grown in herb gardens, but are very little used.

Sedge.

- (1) *2nd Servant*. And Cytherea all in Sedges hid,
Which seem to move and wanton with her breath,
Even as the waving Sedges play with wind.
Taming of Shrew (Introduction, sc. 2).
- (2) *Iris*. You nymphs, called Naiads, of the winding brooks,
With your Sarged crowns and ever-harmless looks.
Tempest, act iv., sc. 1.
- (3) *Julia*. The current that with gentle murmur glides,
Thou knowest, being stopped, impatiently doth rage;
But when his fair course is not injured,
He makes sweet music with the enamell'd stones,
Giving a gentle kiss to every Sedge
He overtaketh in his pilgrimage;
And so by many winding nooks he strays
With willing sport to the wild ocean.
Two Gentlemen of Verona, act ii., sc. 7.
- (4) *Benedick*. Alas, poor hurt fowl! now will he creep into Sedges.
Much Ado About Nothing, act ii., sc. 1.
- (5) *Hotspur*. The gentle Severn's Sedgey bank.
1st Henry IV., act i., sc. 3.

Sedge is from the Anglo-Saxon *Seeg*, and meant almost any waterside plant. Thus we read of the Moor Seeg and the Red Seeg, and the Sea Holly (*Eryngium maritimum*) is called the Holly Sedge. And so it was doubtless used by Shakespeare. In our own day Sedge is confined to the genus *Carex*, a family growing in almost all parts of the world, and containing about 1000 species, of which we have fifty-eight in Great Britain; they are the most graceful ornaments both of our brooks and ditches, and some of them will make handsome garden plants. One very handsome species—perhaps the handsomest—is *C. pendula*, with long tassel-like flower-spikes hanging down in a very beautiful form, which is not uncommon as a wild plant, and can easily be grown in the garden, and the flower-spikes will be found very handsome additions to tall nosegays. There is another North American species, *C. Fraseri*, which is a good plant for the north side of a rockwork; it is a small plant, but the flower is a spike of the purest white, and is very curious, and unlike any other flower.

Senna.

Macbeth. What Rhubarb, Senna, or what purgative drug
Would scour these English hence?

Macbeth, act v, sc. 3.

Even in the time of Shakspeare several attempts were made to grow the Senna in England, but without success; so that he probably only knew it as an imported "purgative drug." The Senna of commerce is made from the leaves of *Cassia lanceolata* and *Cassia Senna*, both natives of Africa, and so unfitted for open-air cultivation in England. The *Cassias* are a large family, mostly with handsome yellow flowers, some of which are very ornamental greenhouse plants, and one from North America, *Cassia Marylandica*, may be considered hardy in the south of England.

Speargrass.

Peto. He persuaded us to do the like.

Bardolph. Yea, and to tickle our noses with Speargrass to make them bleed, and then to beslobber our garments with it and to swear it was the blood of two men.

1st Henry IV., act ii, sc. 4.

Except in this passage, I can only find Speargrass mentioned in Lupton's "Notable Things," and there without any description, only as part of a medical recipe—"Whoever is tormented with sciatica or the hip gout, let them take an herb called Speargrass, and stamp it and lay a little thereof upon the grief." The plant is not mentioned by Lyte, Gerarde, Parkinson, or the other old herbalists, and so it is somewhat of a puzzle. There is no Grass so named, but perhaps any Grass used to tickle the nose and make it bleed might have been so called. Steevens quotes from an old play, "The Victories of Henry the Fifth"—"Every day I went into the field, I would take a straw and thrust it into my nose, and make my nose bleed." *Asparagus* was called Speerage, and the young shoots might have been used for the purpose, but I have never heard of such a use, and *Ranunculus Flammula* was called Spearwort, from its lanceolate leaves. Mr. Beisly suggests the Yarrow or Milfoil, and quotes several authorities for the suggestion, but there seems no reason to suppose that it was ever called Speargrass, or could have been called a Grass at all. Dr. Prior suggests the common Reed, which is very probable; but I should be more inclined to suppose it to be one of the Horse-tails (*Equiseta*). They are very sharp and spearlike, and their rough surfaces would soon draw blood; and as I find that a decoction of Horse-tail was a remedy for stopping bleeding of the nose, I should think it very probable that such a supposed virtue could only have arisen when remedies were sought for on the principle of "*similia similibus curantur*"; so that a plant which in one form produced nose-bleeding, would, when otherwise administered, be the natural remedy. The Horse-tails are, moreover, common plants which would be ready to hand for Falstaff's purpose.

Squash (See Peas).

Stover.

Iris. Thy turfy mountains where live nibbling sheep,
And flat meads thatched with Stover them to keep.

Tempest, act iv, sc. 1.

In this passage, Stover is probably the bent or dried Grass still remaining on the land, but it is the common word for hay or straw, or for "fodder and provision for all sorts of cattle; from *Estovers*, law term, which is so explained in the law dictionaries. Both are derived from *Estouvier* in the old French, defined by Roquefort—"Convenance, nécessité, provision de tout ce qui est nécessaire."—Nares. The word is of frequent occurrence in the writers of the time of Shakspeare. One quotation from Tusser will be sufficient—

If house room will serve thee, lay Stover up dry,
And every sort by itself for to lie;
Or stack it for litter if room be too poor,
And thath out the residue, nozing thy door.

November's Husbandry.

H. N. ELLACOMBE.

(To be continued).

PLATE LXXXV.

TRITOMA (KNIPHOFIA) MACOWANI.

Drawn by H. HYDE.

THIS handsome species is only one of many recent additions to a most valuable African genus of hardy plants. It was originally described by Mr. Baker, early in 1874, in Trimen's "Journal of Botany," where he expresses a hope that it would soon be introduced into cultivation; but even at that date young plants of it existed in Mr. Green's Nursery, at Reigate. Mr. Baker's description was doubtless written some months before it was published, for in September of 1874 Mr. Green succeeded in flowering *K. Macowani*, and in the following October he showed a plant of it at South Kensington, for which he received a first-class certificate. Professor Macowan of Gill College, East Somerset, South Africa, discovered it growing on grassy slopes of the Boschberg Mountains, at an elevation of 4500 ft., and he sent seeds of it to Mr. Wilson Saunders, in whose garden at Reigate the plants were raised which afterwards came into Mr. Green's possession. This species is probably as hardy as its more familiar congener, *K. aloides* (better known to cultivators as *Tritoma Uvaria*), which was introduced into this country as long ago as 1707; or rather it was growing in Chelsea physic garden at that date. Moreover, our plant being of only about half the stature, it will find a place where *K. aloides* could not be employed. Whether like the latter it will flourish in almost any kind of soil remains to be seen; but as far as our knowledge of it goes, it cannot be too highly recommended. It is a very distinct species in a genus now numbering upwards of a score, and easily recognisable by the texture, strong veins, and distinct toothing of its rigid leaves. In the Linnean Society's Journal, vol. xi., Mr. Baker describes fourteen species—nine South African, and the remaining five natives of the mountains of tropical Africa. Of these the following from South Africa are, or have been in cultivation. *K. sarmentosa* (syn. *Tritoma media*, Bot. Mag., t. 744), which is like a miniature state of *K. aloides*, *K. pumila*, (*Tritoma pumila*, Bot. Mag., t. 764), also a small-flowered species of small size, readily known by the flowers being constricted above the ovary. *K. præcox* (Baker), "Refugium Botanicum" t. 168, and *K. Cooperi* (Lemaire), "Jardin Fleuriste" t. 362; both having leaves about 2 ft. long, and flower-scapes 12 in. to 18 in. high, short dense spikes, and scarcely exerted stamens. Subsequently Mr. Baker published, in the same place and at the same time as *K. Macowani*, six more species. Amongst them the fine *K. caulescens* (Bot. Mag., t. 5946): this also appears to be quite hardy. It was discovered by Mr. Thomas Cooper, in the Stormbergen Mountains, in the province of Albany, and sent home by him to Mr. W. W. Saunders. Mr. Baker says it is the most distinct of all the species of this intricate genus, having a decided stem to the rosette of leaves like a caulescent *Aloe*. It is also remarkable for its very broad, relatively short, very glaucous leaves. Of the few perfectly hardy plants we have from South Africa, that is, hardy in the sense in which *Kniphofia aloides* is entitled to be called, there are none more beautiful and requiring less attention than this species of *Kniphofia*.

W. B. HEMSLEY.

Veronica Dabneyi.—This differs in colour from that of most of the species, having whitish or pink flowers, with the two uppermost petals pink inside. It is dwarf in habit, and sends up a copious supply of flower-spikes about 6 in. or 9 in. high. It is certainly fit for the mixed border, if for nowhere else.—J. F. R.

Bedding Tropæolum Bedfont Rival.—We find this *Tropæolum* to be excellent for bedding purposes. We have some lines of it that are a complete mass of bloom, quite outstripping *Scarlet Pelargoniums* this wet sunless summer; on several plants of it I counted over thirty flowers the other day, and the plants were only struck from cuttings early in May. It grows about 10 in. high, and the flowers are on regular-sized footstalks, and in colour a beautiful soft scarlet.—H. J. C., *Grimston*.

Gombo (*Hibiscus præcox*).—This is cultivated at Marseilles for its fruits, which are much appreciated by the Greek colony there. In Brazil (of which country *Gombo* is a native), not only are the fruits used as food, but the young shoots are eaten as a vegetable; from the older stems, cords and paper are manufactured; the seeds, too, have their use, being made into a kind of Coffee.—G.

THE DWARF FLAME FLOWER (TRITOMA MACOWANI-BAKERI).

THE DEGRADATION OF WATER.

THE annexed sketch faithfully represents one of the "ornamental" waters with which our French neighbours frequently deface their pretty little town and suburban gardens. If there be only a mere napkin of a lawn, it is sure to have a cemented tub placed in it; the Yuccas and the Grass, and the Thujas and the Cannas, all look happy as one expects them to be, but the whole is generally marred by the most ridiculous of fountain basins. If these could only be moved indoors, it would be a great relief to the travellers who have to deplore the diminutive washing-basins. As near as the writer can calculate he has seen between 7000 and 8000 of such saucers disfiguring as many pretty gardens in the neighbourhood of Paris. It is

another evidence of the futility of forming artificial water in any form in the small garden: those who find gratification in surveying a tub full of unclean water should enjoy that in a more convenient place.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

August 6.—Sowing Mustard and Cress. Putting in a batch of Tricolor Pelargonium cuttings. Clearing off a piece of Turnips and forking the ground; also a piece of Strawberries, and planting the same with Coleworts and Conve Tronchada Cabbage that had been previously transplanted. Tying Raspberry canes temporarily up to prevent the wind from blowing them about.

Aug. 7.—Sowing Chirk Castle Black Stone Turnips. Putting in Crystal Palace Gem and Ivy-leaved Pelargoniums. Lifting a piece of Gloucester Kidney Potatoes for seed. Planting a small border with Leeks. Staking William the First and Laxton's Unique Peas. Looking over Peaches and Nectarines and removing ties, nails, &c., where not required. Thinning Turnips and Spinach. Cutting Laurels overhanging walks, and hoeing and weeding between the same. Turning manure for Mushrooms. Watering Fig trees, Celery, Cardoons, Vegetable Marrows, and Cabbage Plants.

Aug. 8.—Planting a border with Endive and Lettuces; also Savoy for small green heads, and planting out the last batch of Melons. Putting cuttings under hand-lights of Viola Blue Perfection and Golden Gem. Layering Strawberry runners on square pieces of turf, in order to obtain plants for a new plantation. Thinning, weeding, and hoeing Turnips. Giving Fig trees a good soaking with water. Pruning Apple and Pear trees.

Aug. 9.—Sowing Early White Naples, Giant Rocca, and Giant White Tripoli Onions for spring use; also Fraser's Broad-leaved and Green-curbed Endive in well-watered ground. Putting in cuttings of Coleus and Centaurea. Potting Campanula pyramidalis, and also C. calycanthema. Stopping shoots of Tomatoes, and exposing the fruit to the full force of the sun. Digging heavily-manured ground for Endive and Lettuces; lifting Porter's Excelsior and Scilly Red Potatoes. Watering Peach-houses and late Vinery borders.

Aug. 10.—Sowing Early London, Large Asiatic, Walcheren, and Veitoh's Autumn Giant Cauliflowers. Potting Queen Pines in peat, loam, and rich bones, emptying the pit and rearranging the plants. Earthing-up Celery, Cardoons, and Leeks. Hoeing amongst Gooseberries and Currants. Gathering Green Gage Plums for preserving. Watering part of the Pines, also Celery and Cabbage plants. Fruit in use for dessert:—Pines, Melons, Grapes, Figs, Plums, Cherries, Pears, Apples, Gooseberries, and Currants.

Aug. 11.—Sowing a few pots of Mignonette, and also a border of Turnip Radish. Clearing off Peas that have ceased bearing. Picking over and weeding carpet beds. Mowing and cleaning in the pleasure grounds, and weeding and cleaning gravel walks in kitchen garden.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Epiphyllums that have made their growth, both of the truncatum and larger-growing kinds, will be benefited by being placed out in the open air on the south side of a wall fully exposed to the sun. If ranged in a row as near the wall as possible, so that the sun's rays act directly upon them, combined with the heat radiated from the wall, that will form the nearest approach to the dry, roasting process they undergo in their native habitats, and will greatly increase their flowering abilities; many of the stronger-growing kinds producing double the quantity of flowers when so treated than when kept under glass all through the summer, where they have a tendency to continue growing rather than to get fully matured. Whilst they are out-of-doors in this way they should receive no more water than will just keep them from shivelling.

Large-flowered Pelargoniums turned out in the open air a short time since should be cut back; previous to which allow the soil to get moderately, but not quite dry. The roots of these plants cannot bear any excess of moisture, and if headed down with the soil in a wet condition they generally rot to such an extent as to injure materially the succeeding year's growth. When cut back the plants should be stood in a cold frame or pit, fully exposed to the light and syringed overhead every afternoon, shutting up the frame at the same time, which will accelerate the breaking of the buds; give them plenty of air during the early part of the day. Fancy Pelargoniums must be similarly treated as to the condition of the soil before the heads are reduced; but, as previously recommended, they must not be cut in nearly so close as the large-flowered kinds, only removing about one-half the current season's growth, and being particularly careful that the plants do not get too much wet after heading in. If any aphides be molesting them at the time they are cut down, they should be twice well fumigated at an interval of ten days—the foliage being in a hard mature condition they will bear a strong application of smoke; lay them on their sides and syringe freely with clean water after smoking. Cuttings of any varieties that it is deemed desirable to increase may now be put in; the tops severed from the points of the shoots with three or four joints each will generally strike and grow more quickly than cuttings from the harder portion of the shoots, although the latter will strike; there is no more convenient way of treating them than inserting six or eight in 6-in. pots, well drained and filled with a mixture of half sandy loam, plunging the pots in a bed of ashes fully exposed to the sun in the open air, where they may remain for a month or five weeks, watering as required in dry weather; so treated they are much less liable to damp off than when shut up in frames.

Primulas, sown early, potted off some time back, and put into cold frames facing the north with some hexagon netting over them for a few hours in the middle of the day, must be kept close to the glass, otherwise they will become drawn and weak, and when this occurs they are much more liable to damp off through the winter; and by no subsequent treatment can they be induced to flower so well as those plants that have made short stout sturdy growth. Give them abundance of air at all times, and when there is no appearance of rain, leave the lights off during the night, at which time the dews have a most beneficial effect upon them.

Veronicas grown in pots for autumn flowering, and now plunged out-of-doors require an abundant supply of water, especially when the pots are filled with roots: if they suffer for lack of moisture the bottom leaves will turn yellow, which gives the plants a most unsightly appearance; they should be turned round once every few weeks to prevent the roots protruding through the bottom growing into the surface soil.

Solanums grown in pots must be similarly treated, with the addition of having the whole of their leaves freely syringed once a week to keep down red spider: both the Solanums and the Veronicas are better planted out in the summer, and taken up and potted about the beginning of September; so managed they make better growth, producing their berries and flowers respectively freer, the leaves always having a more vigorous, healthy appearance; they are also not so subject to the attacks of insects, and require much less attention generally.

Chrysanthemums now plunged out-of-doors should at once be staked and tied; if this work be neglected, the considerable growth which they have made will endanger their being broken by the wind. For decorative purposes I should not recommend amateurs to tie them out to the flat shape as usually seen when exhibited, for although that form displays the flowers in the most prominent position, it is objectionable on account of giving them an unnatural appearance, and when blooming (which they do at a time when greenhouses are the most crowded) they occupy too much room. Eight or ten sticks to

each plant, in order to support the branches and keep them sufficiently open for the admission of light and air, will be quite sufficient. I should recommend the use of dry willow in preference to deal sticks either painted or unpainted, on the score both of appearance and economy. The plants should now be syringed overhead every afternoon when the weather is dry; this not only assists growth, but if persevered with will prevent their being troubled with aphides; should these already affect them, syringe with Quassia or Tobacco-water until they are destroyed. The plants must be regularly and liberally fed with manure-water. By the old treatment, viz., of not giving manure-water till after the flowers were formed the blooming capabilities of *Chrysanthemums* were never fully brought out. They are the grossest-feeding subjects cultivated in pots, and will bear liquid manure stronger and in greater quantities than anything else.

Gooseberries and Currants.—Where these are grown on walls, especially such as have an eastern, western, or northern aspect, a few trees of the different kinds should not have their fruit gathered, and should be netted to keep off birds, which generally attack them as soon as the fruit in the open quarters is scarce. So grown Gooseberries and Currants, particularly the latter, may be kept for a long time beyond their usual season, as on walls they are greatly protected from rain, in the absence of which Currants will keep on the trees in good condition for a couple of months or more after they are ripe. Gooseberries in the open quarters may also be preserved for a considerable time by covering the trees with bast mats, in order to keep out birds and throw off the wet. Amateurs will find the trouble involved in these matters well repaid, especially in a season like the present, when there are so few Plums, early Pears, or Apples. The ground amongst bush fruits should be regularly hoed over at intervals of a few weeks to keep down weeds, which will grow apace after the recent rains.

Carrots.—Where the land is tolerably dry, and of a porous character, favourable for the production of good Carrots, a little seed may be put in now to stand over the winter for spring use; these will not be liable to run to seed so soon in the spring as those that were sown a fortnight earlier; they come in very useful, being plump and fresh after the stored Carrots become stringy and tough. The ground ought to be well dug, breaking it fine to the full depth it is moved; sow thinly in rows 1 ft. apart.

Turnips should be sown immediately wherever ground can be cleared from the early crops. At this time of the year showery weather should always be taken advantage of to sow the seed whilst the surface is moist, as a few days' sun and wind make it too dry for them to vegetate freely.

Onions.—A piece of ground should at once be dug whereon to sow winter Onions; the place selected should be where it is tolerably dry through the winter, in which case, if the season be wet, they are much more likely to succeed. The time for sowing this crop should be varied quite a fortnight in different parts of the kingdom; in late backward districts in the north, if it be deferred too long, the crop does not attain its full size the ensuing summer; in the southern parts, if sown too early, considerable numbers run to seed; consequently the beginning or middle of the month for the later districts, and towards the end in early situations, will be the best. In cold, bleak places, the White Lisbon is suitable, being very hardy; it is one of the best for using in spring in a small state. In addition to the Globe and Flat Tripolis, generally grown for making large bulbs for summer, the Giant Rocca is also an excellent kind, as, when well cultivated, it attains a large size and is particularly mild. Dig the ground deeply, and select if possible a piece that has been well manured for the spring crop, which will be better for the Onions than if applied at the present time. Winter Onions, like most other things, are unusually late this year, and in most places are only just completing their growth; they should now be taken up and dried. It is necessary to handle them very carefully, as if bruised in the slightest degree, they will decay, being much more liable to suffer in this way than spring-sown kinds.

Parsley.—Where this has been well grown by sufficient thinning so as to give it plenty of room, it will from this time increase rapidly, and bear much more frost than when in the insufficiently-thinned, overcrowded state the crop is too often permitted to remain; if it have been neglected in this way, it will be advisable to transplant a portion to newly-dug ground, inserting the plants 9 in. apart, making the hole with a planting trowel or dibble, pressing the soil quite firmly to them, and giving water as the state of the weather may require until growth has commenced.

Endive and Lettuce.—A little more Endive, as well as Cos and Cabbage Lettuce should be sown; thin out the plants that have been sown in rows where they are to be grown. Where these are at

all likely to be deficient for the supply some may be planted, as they will not be apt to run to seed after this time. As soon as the plants are large enough to handle some of the earliest-sown Endive should be planted; the land for these can scarcely be too rich. They should be well attended to with water until they have got fully established, for if their growth be much checked, the plants from this early sowing are liable to run to seed.

Herbs of all kinds that are grown for drying should be cut as they come into flower; they ought to be spread out thinly in an airy shed, without being exposed to the sun.

Hardy Flowers.

CALCEOLARIAS.—Seed of these should now be sown without delay. The Calceolaria is not a hardy flower in the ordinary acceptance of the term, but nevertheless it may be included under that head, as it is a plant which nearly every one grows. Seed of it can be raised with but little trouble; an acquaintance of mine raises both it and his Cineraria seed by scattering it on the floor of a small cold frame at the front of a north house—a frame in which hardy plants are wintered. It is cleared in July; a little fine sandy soil is strewn over the ash bottom, the seed is sown thinly on it, the lights are shut down, and an excellent crop of plants is the result. Early sowing is to be recommended, because it is a great advantage to have strong plants in the autumn, and so ensure an early bloom. Late-flowering plants are rarely satisfactory. Those who sow seed in pans should put some rough peat and loam at the bottom, and cover it with a fine surface soil, which should be pressed gently down; then sow the seed and do not cover it. Place a piece of glass over the pan and shade it, keeping the soil cool and moist, and when the seed begins to vegetate, sprinkle a little silver sand over it. Shrubby Calceolarias can be wintered in a cold frame by pulling the plants to pieces and pricking out the shoots like cuttings; they will all root if kept close. To winter the plants effectually the frame should be placed above the level of the ground, so as to have the bed as dry as possible.

CARNATIONS AND PICOTEES.—Those who are hoping to get exhibition flowers up to the middle of August—and in Lancashire and other northern districts there are but few yet open—will need to watch the flowers attentively, in order to see that the pods do not burst, as a burst pod is a disqualification on the exhibition table. Those plants that are grown for border purposes may be left to themselves, but it is well to tie a piece of matting round the pods if good symmetrical flowers be required. There are some very fine Clove Carnations that make capital border flowers if they be selected for their robust growth and free flowering properties. One in particular may be mentioned—a large, bright, fleshy, rose-coloured variety which originally came from Russia; it is very free, and a remarkably vigorous grower. Layering should now be commenced; make a clean incision about the third joint and peg them down tightly into some light sandy soil, sprinkling with water occasionally for a few days.

PINKS.—Rooted pipings should be potted off as fast as necessary, and kept in a cool frame for a time till planted out. Such forcing varieties as Mrs. Pettifer, Lady Blanche, Lord Lyon, and coccinea, should be grown on in pits to get well established by the end of the summer. Those who grow Pinks in beds should commence the work of getting them ready for planting out in autumn, digging in a good supply of manure and leaf-mould, so as to get a light, free soil. The bed should be dug and turned over occasionally to sweeten and pulverise.

RANUNCULUSES.—Early-flowered Ranunculuses may now have their roots taken up and put by for the winter. If the roots be lifted and put away in a dry cool place in paper bags, they will keep plump. Around London large beds of the old scarlet Turban Ranunculuses are much grown for cutting from for market; and there its cultivation may be said to begin and end. Every bulb list contains some named Ranunculuses, and then what is known as the superfine mixed Persian contains varieties of considerable beauty, the best of which could be selected for making a choice bed. Those who grow Ranunculuses, if they wish to have good flowers, should plant them in a well prepared bed; and after the roots are lifted, it will do the bed good to turn it in a dry state, and give it a good coating of manure.

VIOLAS.—Plants that are now beginning to fade will be much helped by cutting them over, giving them a good soaking of water if the weather be dry, and top-dressing with some refuse soil from the potting bench. A new and profuse growth will spring up, which will not only yield stock for cuttings, but flowering wood also. Some of the tops that are cut away in this manner will make good cuttings, and if they be put in a shady place will readily strike. Among new varieties that are well adapted for bedding purposes Vestal takes a high place. It gives us what has long been wanted, a thoroughly good bedding white Viola. The flowers are pure in colour, of good shape, freely pro-

duced and well above the foliage; the habit, too, is free and branching, and altogether it is superior to the white varieties in cultivation. Vestal is very fine just now in the Gardens of the Royal Horticultural Society at Chiswick.—D.

Indoor Fruit Department.

Pines for the winter supply in many cases will be past their blooming period, and swelling rapidly; let their wants be steadily supplied by watering them regularly, and examine them minutely twice a week; weak guano water may be used at any time. Maintain a bottom-heat of 88°; shut up with sun as early as possible with safety to the plants, allowing the temperature to run up in the afternoon to 90°, with abundance of moisture in the house; bedew the plants freely but lightly every fine afternoon, and where it is necessary to encourage growth damp well all available surfaces. If the crows become proportionately large for the size of the fruit, and the houses are placed in shady positions, withhold moisture to a certain extent. When the fruit is ripe keep up a dry, warm air, by making the ventilation somewhat freer; and where necessary to retard the fruit, remove it to a Vinery where the fruit is ripe or gathered, maintaining therein a steady, cool atmosphere. Queens for early work next year should have their pots well filled with roots by this time, and the bottom-heat should not exceed 83°, with a night temperature of 70°, being 5° less than for plants in active growth. Prevent overwatering, but at the same time do not allow them to become too dry; if so they will be likely to push their fruit, which renders the plant useless at this particular period of the year. Where a second lot of Queens are required, these should be encouraged to grow for some time, and managed as already directed. Suckers from plants from which the fruit has been cut should be placed in 6-in. or 8-in. pots, drained in the usual way, using the strongest suckers of Smooth Cayennes, Jamaicas, Retschids, or other late sorts; but in the case of Queens, if too early, they frequently throw up in the autumn, which renders them useless, as already stated. Keep the sucker frame close, shade during strong sunshine, and sprinkle frequently, when they will soon root at this early season; gradually reduce the shading, water sparingly for a time until the roots get into action, when they should be kept in a moderate condition, and shifted on as the roots become slightly ceiled round the ball. Let the drainage be perfect; the compost should consist of turfy loam that has been stacked for a time, with a fair sprinkling of bones and soot mixed when dry, and rammed firmly with a blunt-ended piece of wood. Keep the houses or pits clear and light, and thus prevent the plants from becoming drawn before winter.

Vines.—Where early Vines are exhausted, and it is intended to replant them, a year's growth will be nearly gained by commencing at once. Plant young Vines from eyes this year; and if free-growing plants be at hand, extricate the points of the roots, with as much earth adhering as possible, and they will root freely and readily, giving them late in the autumn plenty of fire-heat with a free circulation of air. Such canes will produce four bunches of good Grapes the following season if allowed to start themselves. Water with tepid water, and top-dress to prevent evaporation. Keep the house close for a time, and shade the Vines during bright sun, when growth with renewed vigour will soon take place, and the shading may be gradually withheld. See to Grapes swelling off on Vines where the borders are raised or subject to become dry through position. Mulching should be done immediately, and watering twice a month in this stage is requisite. Where the Vines are in a state to receive manure-water, now is the time to apply it—guano may be safely used at every watering. Keep up a brisk temperature, and assist sun-heat by fire in cold localities. Where colouring has not taken place, do not let the temperature fall below 70° with a circulation of air; where such treatment is rigidly followed, red spider seldom puts in its appearance, but should this unwelcome pest arrive, hand-washing is the best means of removing it. Mildew is of common occurrence this year, and where it makes its appearance increase the temperature 5°, with a freer circulation of air; withdraw the water from the evaporating troughs, and allow the interior of the house to become drier; sulphur the pipes and dust sulphur on the bunches and leaves most affected. Mildew makes rapid progress, and on its first appearance should be treated as described. We have tried every remedy prescribed for it as a means of testing the result, and find the old cure the best. Keep ripe Grapes cool and airy, and whenever cut use the syringe freely to keep the foliage clean, and to assist in retaining it as long on the Vines as possible. Examine the fruit to prevent decay by water lodging on the bunches or otherwise. Where Grapes are intended to hang until the spring, thin the berries at once. Pinch out superfluous growths, but allow the Vines to carry sufficient foliage to keep them in robust health; where overcrowding does not take place, the foliage will improve the plants. In the case of early pot Vines which are intended for early forcing next year,

their canes will be ripening, and should not be allowed to make any more lateral growths. Retain them in a light airy position, where the ripening process may be assisted, so as to admit of a long rest. Early and well ripening is of the greatest importance in pot Vines.—J. HUNTER.

HARDY FLOWERS OF THE WEEK.

THE late rains have been very favourable for hardy perennials, many of which are now in excellent condition. *Campanula Hendersoni* is a fine plant, apparently a hybrid between *C. turbinata* and *C. fragilis*; it grows from 15 in. to 18 in. in height, forming a pyramid of erect, deep blue, salver-shaped flowers. *C. (Platycodon) autumnalis*, one of the best of our autumn-blooming perennials, will continue in flower for five or six weeks; it is distinct from *C. grandiflora*, flowering much later, being more erect in habit, and taller; its flowers vary from white to blue, both single and double. *Anthericum graminifolium* forms a bush 3 ft. in diameter composed of erect, slender, branching stems, smothered with white flowers; *A. Huteri*, only 1 ft. in height, is somewhat similar in character, but has flowers double the size of those of the preceding. The Giant Thrifts are still very showy, and will continue so

Kanfussia amelloides var.

for at least another month; they began to flower in the latter end of May. The best of the group are *Armeria alpina grandiflora*, *A. cephalotes rubra*, *A. plantaginea rosea* and *rubra*, and *A. mauritanica*—all distinct and good perennials. Amongst Foxgloves in bloom may be mentioned *Digitalis lutea*, which has spikes of small yellow flowers; *D. ochroleuca*, large pale yellow; and *D. (Isoplexis) canariensis*; the latter scarcely hardy. *Lysimachia Ephemerum* forms fine clumps 3 ft. in diameter, composed of numerous stiff spikes thickly beset with white flowers having purple anthers; but the best of this family now in flower is *L. clethroides*, a kind having drooping spikes of white flowers of a peculiar character; both are useful plants for a damp, shady border. *Stobaea purpurea*, a curious Thistle-like plant, is now in bloom; it has large, lilac flowers splashed with purple. *Jaborosa integrifolia* is also flowering freely, and its blossoms are fragrant and last long in perfection. *Verbascum pyramidalis* is producing spikes 3 ft. in length; *V. nigrum* has deep golden-yellow flowers, and is bold and striking in appearance. The double Sneezewort (*Achillea Ptarmica*) is a good plant, and its pure white and very double flowers are useful in a cut state. Among early-flowering Asters are *A. pyrenaicus* and *A. sibiricus*, both dwarf and sturdy, bearing large heads of light purple flowers 2 in. across. *Helonias erythrosperma* has peculiar greenish-white flowers on branching spikes 18 in. in length; it is not a showy but an interesting plant. *Pentstemon Richardsoni* is somewhat

shrubby, bearing an abundance of rosy-purple flowers. *P. cordifolium*, an evergreen species with deep red flowers, is hardy in warm, sheltered situations, especially on the south coast. Several of the Sages are in flower; *Salvia taraxacifolia*, a dwarf rock plant, is not showy by any means, but interesting; the white variety of *S. patens* and *S. dulcis* are also in full flower. *Wyethia arizonica* is a good yellow Composite, but is completely eclipsed by *Coreopsis lanceolata* and *tenuifolia*, which form large bushes smothered with golden-yellow flowers. *Echinacea angustifolia* and *purpurea* are both good plants with large purple flowers on stems 3 ft. in height. *Viola gracilis*, deep purplish-blue, is pretty, and so are many of the dwarf *Statice*s, which are now flowering freely. *Acanthus latifolius*, now in bloom, forms a stately plant for isolated positions on the lawn. The blossoms of *Agapanthus umbellatus* and its white variety are beginning to expand, and so are those of the lovely twin-flowered *Bravoa* (*B. geminiflora*), which bears spikes of *Peutstemon*-like flowers. *Brodiaea grandiflora*, deep lilac; *Zephyranthes sulphurea*, pale sulphur; and *Cyclamen europeum*, red, are all at present finely in flower. *Tropæolum speciosum* is just opening. What a grand plant this is where it does well; a cool shady spot is what it requires. *Convolvulus Scammonia* is another good climber which produces abundance of white flowers; last year it was in bloom in December. Many of the Lilies are now in good condition, especially those belonging to the longiflorum section; *Takesimæ*,

Dwarf China Aster (*A. sinensis multiflorus*).

Wilsoni, and *Liu Kiu* are three distinct varieties; *chalcedonicum* and its varieties are also in flower, and their fiery scarlet blossoms can be seen at a great distance; *L. armeniacum*, a variety of elegans, with large heads of erect flowers of an apricot-orange, is very distinct, and a good showy Lily; *L. tigrinum*, *L. superbum*, and *L. auratum* are fast opening. *L. philadelphicum*, *L. canadense*, and *L. Krameri* are still in flower, although past their best: while *L. Humboldtii* and its variety *Bloomerianum* are still in perfection. What could be more beautiful for a quiet cool bed than the common *Calla*, *C. æthiopica*, planted in March or April in a dry state? It will flower luxuriantly during July and August, and from the moment it issues from the ground it has a pleasing appearance, which it retains until cut down by frost. If planted in a moist, shady bed, it will flower even as late as September, and produce luxuriant foliage from 3 ft. to 4 ft. in height. *Arum albo-maculatum* is still more interesting; its rich olive-green foliage, smothered with conspicuous white spots and crowned with creamy-white spathes, renders it attractive, and it is a plant which ought to be grown extensively for summer decoration. *Calandrinia umbellata* is now one mass of vermillion flowers, so dense and bright as to be perfectly dazzling. It has only one failing, and that is, it will only open during full sunshine. What a glorious plant for old walls, ruins, and similar situations, in which few plants will thrive. The new Musk, *Mimulus moschatus Harrisoni*, is likely to prove a valuable plant for summer decoration. It flowers freely in hot, dry situations; and as the blooms are

large, bright, and continuous, it must be regarded as a valuable addition to summer bedding plants. *Sparaxis pulcherrima* is now flowering freely, forming a graceful object in the border among other hardy plants. The foliage is about 4 ft. in height, very slender, rising erect from the root, and then drooping gracefully. The flower-stems rise well above the foliage, and bear large, variously-coloured blooms; when they have become thoroughly established they form magnificent clumps, producing forty, and in some instances as many as fifty spikes of flowers upon a single plant. They will thrive in

Leptosiphon luteus.

any friable loam, in almost any situation; are perfectly hardy, and easily propagated. Several of the Californian *Pentstemons* are very pretty; *P. centranthifolius* and *P. heterophyllus* are two of the best. Among Lilies the Californian varieties are the most prominent; of *Humboldtii* there are numbers in the open ground 5 ft. high, with over a score flowers on each; *Robinsoni*, *pardalinum*, and several others of this group, are still in flower. The different varieties of *L. canadense* are very showy; *L. longiflorum* and its varieties, *excelsum* and

Common Sunflower
(*Helianthus annuus*).

Californian Double Sunflower
(*Helianthus annuus* var. *californicus*).

Browni, and the different kinds of *L. elegans* are also good, and invaluable for the decoration of the flower garden during July. P.

I is *Kämpferi*.—I have raised this from seed which I brought from America, and I have numbers in bloom; one flower which is before me as I write is excellent as regards colour, and measures fully 7 in. in diameter.—C.

Lee's Prolific Currant in America.—Among the new fruits on trial this year we notice an especially fine crop on the *Lee's Prolific Black Currant*, imported a year ago last spring from England. The fruit is at least half larger than the *Black Naples* in an adjoining row, and treated precisely the same; the stems are very long and full, and the amount of fruit astonishing. It is evidently a profuse bearer, and the quality superior that of any other *Black Currant* grown.—"Country Gentleman."

Gladiolus psittacinus.

Late-flowering Evening Primrose (*Oenothera serotina*).

Sanvitalia procumbens fl.-pl.

Gypsophila paniculata.

Sanvitalia procumbens fl.-pl.

Whitlavia grandiflora.

Double Tiger Lily (*Lilium tigrinum fl.-pl.*)

Willow-leaved Loosestrife (*Lysimachia Ephemerum*).

Waitzia anrea.

Centaurea suaveolens.

Lophospermum scandens.

Double Sunflower (*Helianthus annuus fl.-pl.*)

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

THE FRUIT CROPS.

SCOTLAND.

Drumlanrig, Thornhill, Dumfriesshire.—Hardy fruit crops here are not very satisfactory. Last winter was one of the mildest ever experienced, the spring the coldest on record, and contrary to what was at one time anticipated, vegetation was very backward at the end of May. Of summer weather there has not been any except a few days towards the end of June. Since then I do not think there has been ten hours' continuous sunshine, and heavy cold rains have been the rule. At present vegetation is quite three weeks behind, and the weather wet, cold, and gloomy. We gathered the first Strawberries for preserving yesterday (July 18), in a very unsatisfactory condition. In the average of seasons they are generally over by this date. Of Apples there are what would make a very fair crop on the trees, but being so late, unless the autumn proves exceptionally fine, they will be next to worthless. The sorts that do best here are Lord Suffield, Stirling Castle, Blenheim Pippin, King of the Pippins, Bedfordshire Foundling, the round and ordinary Catshead, and a variety under the name of Croftaury: these seldom miss a crop even in this climate. Of Pears we have none, and very few trees yet in bearing condition. Plums irregular. Peaches none. Apricots none grown. Cherries a poor crop. Raspberries a great crop. Gooseberries thin. Currants (except the Black) good. Strawberries a heavy crop, but rotting instead of ripening. The leafage on forest trees and indeed all hardy plants is wonderfully fine, owing to its being so unusually late, and thus escaping spring frosts.—DAVID THOMSON.

Marchmont House, Dunse, Berwickshire.—The long and continuous wet autumn of 1876 and the want of sunshine hereabouts have been the chief causes of failure in the fruit crops this season. Everything, too, is quite a fortnight later than usual. Apples and Pears are only middling crops. Early Plums are plentiful, but of late kinds we have none. Cherries are about half a crop. Gooseberries not half a crop, in some districts none. Currants (Red and Black) abundant, White medium. Raspberries plentiful but very late. Strawberries about half a crop, late varieties best. Nuts are a fair crop. Fruit as well as forest trees are growing luxuriantly, 4-4½ in. of rain having fallen during the first seventeen days of July.—PETER LONEY.

Bothwell Castle, Paisley, Lanarkshire.—Excepting Strawberries, Currants, and Gooseberries, the fruit crops hereabouts are greatly below the average. Wall Peaches and Green Gage Plums are almost an entire failure; standard Plums, of which there are a good many in this district, are quite a failure. Apples are very irregular, some trees being loaded with fruit and many bearing no crop at all; Stirling Castle and Lord Suffield are more planted here than any other sorts, and that is the case taking the west of Scotland generally. Gooseberries are largely grown in this locality; they were sold by auction very recently, and realized much higher prices than usual.—ANDREW TURNBULL.

Dalkeith Park, Midlothian.—Fruit in this locality is a good average crop, except Peaches and Apricots on the open walls, which were much injured by the severe weather in April and the first half of May. Since the middle of May the weather has been generally favourable. Apples and Pears are a fair crop and swelling off satisfactorily, the trees being healthy and freer than usual from insects. Plums and Cherries are a good crop. Gooseberries partial; in some places a very heavy crop, in others scarcely any. All sorts of Currants, Strawberries, and Raspberries are a heavy crop, if we only get dry and warm weather to ripen them; at present the very wet weather is much against them. Potatoes look well, and no disease has yet appeared. All crops are fully a fortnight late at present.—M. DUNN.

Tynningham, Prestonkirk, East Lothian.—Apricots are a fair crop, but the trees are much damaged by the cold east winds which we had in spring. Apples flowered abundantly, but the majority of the blossoms were imperfectly developed, and consequently a middling crop only is the result. Pears, Plums, Cherries, and Gooseberries are scarce, the buds of the latter having been eaten in winter by small birds. Currants of all kinds are most abundant, as are also Raspberries. Strawberries are unusually plentiful, but the damp weather which we had lately and the excessive rainfall which we now experience will make the crop ultimately anything but a large one. Peaches are almost entirely under glass, and are an average crop. Early Hamburg Grapes have been as a rule poor in this district, but taking the crops as a whole, they will be good. Kitchen garden crops are in general from three to four weeks later than usual; heat is all that is required now to ensure good late crops.—R. P. BROTHERSTON.

Eglinton Castle, Ayrshire.—Fruit trees when in blossom promised to yield heavy crops, especially of Apples, but a general failure took place during the period of setting. In some districts of this county there are no fruit, in others a medium crop, and only in one or two instances is there a full crop. The following is a fair return:—Apples and Pears below the average; Plums very scarce; Peaches, none outdoors; Apricots do not succeed outdoors, except in sheltered situations; Cherries a middling crop; Gooseberries in some places an average crop, in others scarce; Currants below the average, especially Black; Raspberries and Strawberries abundant. The following are the best varieties of fruit for this country, viz.:—Dessert Apples—King of Pippins, Cambusnothan Pippin, Kerry Pippin, and Thorle. Kitchen sorts—Lord Suffield, Ecklinville, Stirling Castle, Bedfordshire Foundling, and Wellington. Dessert Pears on walls—Louise Bonne of Jersey, Marie Louise, Jargonelle, Beurré de Capiaumont, and Beurré Diel. Standards—Hessle, Moorfowl Egg, Doyenné Bonsooch. Plums on walls—Jefferson, Kirke's Seedling, Green Gage, Purple Gage, Magnum Bonum, and Victoria. Standards—Victoria. Strawberries—President, Keen's Seedling, Elton Pine, and Vicomtesse Héricart de Thury. Ayrshire generally is a bad fruit-producing county, being very subject to late spring frosts and long, continuous, easterly winds during April, May, and June.—JOHN GRAY.

Culzean Castle, Ayrshire.—Our fruit crops this season are not good; all small fruits, except Gooseberries, have been about an average, but Pears, Apples, and Plums are very scarce. The following are a few varieties that bear well with us in general, viz.:—Plums—Victoria, Kirke's Blue, Rivers' Early, and Jefferson. Pears—Williams' Bon Chrétien, Beurré Diel, Knight's Monarch, and Ne Plus Meuris. Apples—Ecklinville, Lord Suffield, King of Pippins, Monk's Codlin, Keswick Codlin, and Royal Rosset.—D. MURRAY.

Blythwood, Renfrewshire.—Fruit crops in this vicinity are nearly a failure. Peaches are very thin. Of Apricots we have none. Plums are better, but not a full crop. Of Morello Cherries we have a fair crop. Pears on walls are quite a failure, and Apples and Pears on standards are very thin; sorts that for years past have always yielded at least part of a good crop are without a fruit. Small fruits are plentiful. Strawberries are most abundant, and fine. Gooseberries a full crop with us, but in some places they are but half a crop, and in others there are none. Currants, Red and White are also fine. Black Currants are not abundant, a circumstance which I attribute more to disease than to the weather. Raspberries are a full crop. We are much in want of sunshine and dry weather to ripen the fruits.—JOHN METHVEN.

Dupplin Castle, Perthshire.—Fruit crops hereabouts are very poor indeed. The bloom was most abundant; but the months of April and May being excessively cold, it did not set. Apricots here are a scarce crop, the Kaisha being the only sort that is bearing any fruit. Apples I expected would have been a heavy crop, but here we have only Lord Suffield and Cellini bearing full crops. Pears are also under the average. Amongst Plums Victoria and Jefferson are the only sorts that are bearing full crops. Strawberries are most abundant, but greatly spoiled by wet. Other small fruits are bearing fair crops, but very late. Peaches are not grown out-of-doors here.—JOHN BROWNING.

Fordell, Inverkeithing, Fifeshire.—Small fruits, such as Strawberries, Gooseberries, and Currants, are a plentiful crop hereabouts. Cherries on walls are a fair crop, but Peaches are nearly a failure, the foliage having suffered severely from blister. Apricots in some situations are abundant, but about three weeks later than usual. Plums in general are rather a thin crop, and the finer sorts, such as Washington and Green Gage, are almost a failure. On the Belgian and French sorts of Pears there is but a thin sprinkling, but on some of our old sorts there is a fair crop; we have an old Moorfowl Egg on a west aspect showing a good crop, making the fiftieth crop which it has produced while under my charge and all good; kitchen Apples, such as Lord Suffield, Hawthorndean, and the Codlins are bearing good crops, but the finer table sorts are very thin; even our old favourite the Ribston Pippin is producing but a very spare crop. The weather continues cold, wet, and sunless, and altogether appearances are against our obtaining a good crop of hardy fruit.—ROBERT FOULIS.

Cawdor Castle, Nairnshire.—Spring, and I may say summer this year have been so wet and cold, with occasional high winds and late frosts, that it is almost a miracle we have any fruit at all. The buds remained so long in a half-opened state, that both flower and leaf were weakened, and in consequence the fruit fell as fast as it formed. Everything, too, is a fortnight later than in ordinary seasons. Apples on old trees are thin, on young espalier trees plentiful; Lord Suffield and Stirling Castle are our best croppers. Of Pears we have almost none. Plums on walls are poor, but we

have fine crops of Victoria on standards. Cherries are about half a crop. Peaches have lost both fruit and leaves; the best is Royal George. Gooseberries are thin, especially on old unpruned bushes; the leaves are falling and caterpillars plentiful. Red Currants are abundant; Black about half a crop. Of Strawberries, which are a good crop, we gathered our first dish to-day (July 18). Our best sorts are Garibaldi, President, and Elton.—JAMES MAITLAND.

Gordon Castle, Banffshire.—Apricots with us are under average; Apples much under average; Jargonelle Pears good, most other sorts under average. Of Early Purple and Victoria Plums we have a fair crop both on walls and on standards; all other sorts are under average. Strawberries fully an average. Cherries, Peaches, and Nectarines under average. Small fruit all very good in quality, and fully over average.—JOHN WEBSTER.

Adross Castle, Ross-shire.—Amongst fruit crops in this district we have many failures. Pears, Apples, and Plums are very poor; Gooseberries moderate; Black and Red Currants good; Raspberries a fair crop, but late; Strawberries very abundant, but also very late. This is a late place any season, but much more so this year than usual. We have no Peaches except under glass; in gardens along the sea-board Peaches have failed in some places on open walls where they usually succeed. Pears are also a failure in most places in this neighbourhood.—R. MASSIE.

Glamis Castle, Forfarshire.—This is perhaps the most backward season which we have experienced for a quarter of a century. In the months of March, April, and May very low temperatures were registered, consequently both seeds and blossoms kept dormant till late in spring. As regards the blossoms the result has not been unfavourable, as they have escaped the late frosts which prevailed so much in this quarter. The temperature of June has been an average one, but the present month has been from its first day wet and sunless, and very unfavourable for the Strawberry harvest, which is abundant, and would be all that we could desire if we only got dry weather. Our standard varieties are Vicomtesse Héricart de Thury, President, Keen's Seedling, Elton, Glengarry, Sir J. Paxton, and Bountiful. Cherries are an average crop; most of the common kinds are grown here and do well. Small fruits of all kinds are an average crop. Plums on walls are a full crop; they consist chiefly of Jefferson, Victoria, Prince of Wales, Orleans, Goliath, and Magnum Bonum. Apricots are thin; Breda, Hemskerk, Musch Musch, and Moor Park being our standard varieties. Pears are also thin on walls, and few are grown as standards; we grow and ripen the following on the wall, viz., Gansel's Bergamot, Beurré Bosc, Beurré d'Arenberg, Beurré d'Amanlis, Beurré Rance, Beurré Superfin, Williams' Bon Chrétien, Doyenné d'Été, Duchesse d'Angoulême, Glon Morceau, Jargonelle, Louise Bonne of Jersey, Marie Louise, Passe Colmar, Thompson's, Van Mons Léon Leclerc, and Winter Nellie. The following Apples on standards are a good crop; Court Pendu Plat, Cox's Orange Pippin, Pitmaston Golden Pippin, Kerry Pippin, King of the Pippins, Braddick's Nonpareil, Northern Spy, Claygate Pearmain, Pearson's Plate, Syke House Russet, Sturmer Pippin, Blenheim Orange, Brabant Belle Fleur, Cellini, Keswick Codlin, Domelow's Seedling or Wellington, Gravenstein, Hawthorndean, Lord Suffield, Nonsuch, Ecklinville, &c.—G. JOHNSTON.

IRELAND.

Viceregal Gardens, Dublin.—East wind, continuous wet, and want of sunshine have had a fatal effect upon fruit crops in this neighbourhood. Frosts were comparatively light, not exceeding 4° or 5° any night during the blooming period. The results nevertheless have been very unsatisfactory, as all sorts of fruits showed a profusion of vigorous bloom. Apricots set well, but perished on reaching the size of Kidney Beans. Peaches, even where protected, are a thin crop. Pears which looked unusually well are a failure, only a few of the sorts having a sprinkling of fruit on them. The following are a few of the sorts that do well here as pyramids:—Colmar d'Été, Marie Louise, Beurré d'Amanlis, Beurré Diel, Napoleon, Glou Morceau, Van Mons Léon Leclerc, and Beurré Hardy. Plums are a complete failure; Cherries are very scarce. Apples, too, are thin, and the trees have a stunted appearance. Many of them have been overrun with aphides, no doubt the effect of the cold season or a stoppage of growth. As regards small fruit we are more fortunate. Currants of all sorts are a heavy crop, and so are Gooseberries and Raspberries. Strawberries are a fair crop, though not so heavy as the crop of bloom led us to expect.—G. SMITH.

Knockmaroon Lodge, Chapel-Izod, Co. Dublin.—Outdoor fruits here are below the average. Apricots are very scarce. Peaches in some favourable positions are a fair crop, but their old enemy mildew seems almost unconquerable. Of Plums of the Green Gage

type we have none anywhere, and of Magnum Bonum just a sprinkling. Figs are abundant and promise well. Apples middling; the sorts that do best here are Ecklinville, Lord Suffield, Yorkshire Greening, and Cellini. Pears in general are very scarce; here Jargonelle and Williams' Bon Chrétien are the best both in quantity and appearance. Raspberries are good and abundant, a remark which also applies to Red and Black Currants and Gooseberries. Strawberries, which are largely grown for market in this locality, are below the average, irregular or deformed fruit being the rule. Potatoes and all kitchen garden crops are very good.—D. PRESSLY.

Powerscourt, Co. Wicklow.—The abundant show of fruit-blossom which we had this spring gave promise of a most fruitful year, but the blossom was weak, and cold winds being experienced at setting time, fruit is not so plentiful as was expected. Apples will be a fair crop; such sorts as Keswick Codlin, Ecklinville, Lord Suffield, King of the Pippins, and Tower of Glamis promise to ripen full crops. Pears, too, will be a fair crop; among the best are Jargonelle, Williams' Bon Chrétien, Passe Colmar, Glou Morceau, Easter Beurré, and Ne Plus Meuris. Peaches, Apricots, and Plums have suffered the most. Small fruits are abundant, with the exception of Strawberries, which are thin this season. Gooseberries are very plentiful, and the bushes are in fine health.—CHAS. PENFORD.

Kilkea Castle, Mageny, Leinster.—We had severe frosts late in the spring, accompanied by keen, cutting winds, which entirely destroyed what at one time promised to be a remarkably good crop of Peaches, Plums, and Apricots; and partly destroyed Gooseberries, Currants, Apples, Pears, and Cherries. Raspberries and Strawberries are a good crop. The weather here is very cold and wet.—W. A. EMERY.

Headfort, Kells, Co. Meath.—Fruit crops hereabouts this year are nearly a failure, with the exception of Currants, Gooseberries, Raspberries, and Strawberries; but owing to so much wet, both Strawberries and Raspberries are rotting. Strawberries are a fine crop, especially President, Sir Harry and Eclipse; the fruit of Wizard of the North, being so much later, we may be able to save, but we have had nothing but rain with few exceptions for the last ten months. We had ten very warm days in the middle of June, but none before or since. Peaches set well and had every appearance of being a fine crop, also Apricots and Nectarines, but owing to frosts and cold east winds there are very few left; I expect, too, that we shall be worse off next year, for the wood will not ripen. Of Apples, Pears, and Plums we have very few. Figs are a good crop, but it will be impossible for them to ripen. Of Nuts we have none. Cherries were a good crop, but most of them have fallen off; in fact, I might say that I have never experienced a worse fruit season than this. When you were having fine weather in England, we were having rains and frost and cold winds, and no growth at all was made. Potatoes I am afraid will be very bad. In some places the haulm is already quite black and the tubers small, the ground being very wet and cold.—JOHN CLEWS.

Florence Court, Enniskillen.—Fruit crops in this district are light this year, and late Strawberries are under average; Gooseberries and Currants about half a crop; Apples in some places a fair crop, and in others very light. There are numerous orchards in this district, consisting chiefly of Apples, Plums, and Cherries; Pears do not succeed with us, therefore few are grown. We have had a trying season; the latter part of April and May was dry, with slight frosts almost every night, which proved injurious to the fruit blossoms. Peaches, Nectarines, and Apricots are not worth growing here out-of-doors.—J. McDONALD.

Woodstock Park, Inistioige.—Early in spring the fruit crops hereabouts promised to be one of the heaviest we ever had; the blossoms set beautifully and in great quantities on Apples, Pears, Plums, Cherries; and bush fruits were equally satisfactory, but the weather at the end of May and beginning of June proved disastrous; and although we had no actual frost, many Peach trees lost their leaves, and Apple trees had the appearance of being roasted. Strawberries also suffered a good deal. Black and Red Currants are plentiful, but small. Apples, Pears, Plums, and Cherries are a light crop. Peaches very poor. Figs good, but late. Filberts good. Gooseberries good, but very late. Varieties have little to do here in the way of securing a crop, for should the trees be just in bloom or have set their fruit, a few days of cutting east winds make them fall off.—G. DODD.

Ravensdale Park, Newry.—Apricots are not grown out-of-doors here, and of Peaches we have but few. Apples are a very bad crop, late frosts having destroyed the blossom, and the trees are looking anything but healthy. Pears are a light crop. Plums and Cherries are both under average. Strawberries are a moderate crop.

Gooseberries abundant, and Currants plentiful. With us the season is late, and prospects indifferent.—F. FOWLER.

Birr Castle, Parsonstown, King's Co.—The late spring frosts which we experienced in this district when the trees were in blossom committed sad havoc. We have, however, good crops of all kinds of bush fruits, but they are late, and ripening slowly. Strawberries, too, are plentiful, but ripening badly; in fact, they are rotting on the ground owing to continuous wet and sunless weather. Apples are an average crop; all kinds of them, indeed, do remarkably well here in most seasons. Pears are thin and poor. Plums are a total failure here, and I believe throughout the district, although the trees were loaded with blossom. Apricots are very thin. Peaches on open walls that were protected during frost are a fairish crop, but I doubt they will not ripen unless a great change takes place in the weather. Figs are abundant and good; they seem well adapted to this district. Nuts, both Filberts and Cobs, are plentiful.—T. J. HART.

SUPPLEMENTARY ENGLISH REPORTS.

Southgate, Middlesex.—Apples, where there are any at all, are a light crop, and in many places a total failure; any exception met with is where the soil is of more than usual depth for the neighbourhood, of good quality, and inclined to be a little moist, conditions under which the season's growth was not prematurely stopped by the drought early last summer, and consequently not again excited by the influence of the rains which fell about the end of August and beginning of September, through which great numbers of the trees hereabouts were affected, retaining their leaves in a green state long past their usual period. Old trees are carrying more fruit than young ones, and Keswick Codlin, Lord Suffield, Yorkshire Greening, Cox's Orange Pippin, and Irish Peach, are bearing more than any other kinds. Pears on walls in most places are a thin crop, and standards and espaliers are bearing little or none. Peaches and Nectarines are about a third of a crop. Apricots are a failure, and of Figs there are very few. Plums on walls are very thin, and there are next to none on standards. Cherries light. Gooseberries and Currants a fair crop, and Raspberries an average crop. Strawberries have been abundant, but late and soon over. Filberts are a very heavy crop, but Walnuts are very thin.—T. BAINES.

The Deepdene, Dorking, Surrey.—Fruit crops in this neighbourhood are only moderate. Of wall fruits there is indeed a great scarcity, there being no Peaches, Nectarines, or Apricots. Of Pears, there are a few in some places; but in others there are none. Plums are almost a total failure; the only tree that has a crop on it is Rivers' Early Prolific. Apples in places are a fair crop, in others light. Figs on walls are plentiful, as are also hardy Grapes. Gooseberries, Currants, and Raspberries are good and plentiful, especially the latter, owing to the fine rains which we have had. Strawberries have been a good crop. The promise of fruit in spring was abundant, but the long-continued east winds and sharp frosts which were experienced in May reduced the crops to very moderate ones, with the exception of bush fruits.—JOHN BURNETT.

Latimers, Bucks.—We have about forty varieties of Apples here, on most of which there are a few fruits; King of the Pippins, Cellini, and Lord Suffield are loaded, and will require thinning. Pears, both standards and wall trees, are a complete failure. Of Apricots we have very few on the Moor Park. Plums are a fair crop, the best being Prince of Wales and Jefferson. We have no Damsons. Peaches and Nectarines are a failure, and the trees are nearly killed, although protected by means of branches. Gooseberries are a first-rate crop; the best are Warrington and Whitesmith. Currants (all sorts) are excellent; and the same may be said of Raspberries. Strawberries have been fine, but they did not last long; the best were President, Sir J. Paxton, and Vicomtesse Hélicart de Thury (Garibaldi), the latter very prolific; I counted 140 fair-sized fruit on one plant. I have never seen such large crops of Nuts as there are this year; but of Walnuts we have only a very few on the large trees in the park. Cherries are very good both on walls and on standards. As the garden here stands high, we suffered a good deal from want of rain up to St. Swithin's Day; but since that time we have had plenty. I am sorry to say that although Potatoes have looked remarkably well hitherto, I found the other day disease in the Early Rose and Myatt's Ashleaf.—A. DONALDSON.

Mentmore, Bucks.—In this district fruit this season will be scarce. Apples are a partial crop. Plums and Pears a failure. Small fruits good, especially Strawberries, which have been very fine—the best kinds have been Vicomtesse Hélicart de Thury and Elton; Bickton White Pine is also a good cropper, and makes a pleasing change for dessert. Cherries set a good crop, but a great many

dropped in stoning. Walnuts are a moderate crop. There is a very fine old Mulberry tree in a sheltered part of the ground here, which always bears good crops, but this year it has fruited better than usual. We have a great many acres of orchards, consisting of young trees planted seven and eight years ago, all of which are growing remarkably well this year, and are more free from insects than usual.—J. SMITH.

Cleveland, Lyme Regis, Dorset.—The fruit crop generally in this neighbourhood is much below the average. In the early part of the season the prospects were encouraging, but subsequent cold winds and uncongenial weather, especially during April and May, considerably damaged our fruit prospects. Pears with us are almost a failure. The Apple trees were one mass of bloom, but severe south-west winds and cold nights prevented more than half a crop setting. Wall fruits, too, are deficient; Peach and Nectarine trees are much injured, and suffering in many places from mildew. Plums are very scarce, but of Cherries we have a fair crop. Bush fruit is more satisfactory, Gooseberries and Currants being an average crop, and Raspberries are plentiful and good. Strawberries are also a good crop, but some of the fruit is deformed and small. Walnuts and hedge Nuts are fair crops.—HENRY MUNRO.

Sandringham, Norfolk.—After thirty-four years' experience this has been the worst season as regards fruit which I have seen. We had a mild winter and tolerable April, though there was an absence of sunshine, but May was disastrous to all fruit trees in this district. Peaches and Nectarines are only now recovering from the effects of the north-easterly winds which prevailed at that time, and which were much more destructive than a very severe frost. Pears, Plums, Peaches, Nectarines, and Gooseberries have all succumbed; Apricots, too, are gone, and now our only fruit is Strawberries, which have been a fair crop; Raspberries and Currants have also been good, and there is a fair crop of Apples. Potatoes look well and, as yet, show no disease.—C. PENNY.

Killerton, Exeter.—Peaches and Nectarines hereabouts are scarce; the trees were much blistered in spring, but they are now recovering. Apricots are very scarce, and Cherries are only a moderate crop. Plums on walls are scarce, and there are none on pyramids; the best croppers here are Mitchelson's and Prince Englebert. Pears on pyramids are very scarce; some sorts on walls are bearing fair crops, viz., Glou Moreau, Joséphine de Malice, Jargouelle, Knight a Monarch, Zéphérin Grégoire, and Beurré Rance. Figs are a good crop, and so are Strawberries, especially Newton's Seedling, which is a great bearer, but being acid it is only grown here for preserving purposes. Raspberries are good. Black, Red, and White Currants, and Gooseberries are also abundant, and Filberts and other Nuts are plentiful, with the exception of Walnuts, which are scarce. Apples are very plentiful in some orchards, in others very moderate. Since wet weather has set in the Potato disease is spreading rapidly, the American Early Rose being at present affected the most.—JOHN GARLAND.

Bicton, Sidmouth, Devon.—Peaches and Nectarines with us are almost a total failure; and the same may be said of Apricots. Plums, both on walls and standards, are quite a failure, and early Cherries are a scanty crop; but Morellos on walls are a heavy crop. Some sorts of Pears, too, are a heavy crop. Apples in some places are a very heavy crop, in others scanty; the kinds grown here are mostly Cider Apples. Strawberries are a fair crop. Raspberries scanty, the wet winter having killed the greater part of the bearing canes. Gooseberries and Currants a full crop. The Potato disease is showing itself very badly in some places in this neighbourhood.—ALFRED GEORGE.

Wroxton Abbey, Banbury, Oxon.—Of Gooseberries, Strawberries, Raspberries, and Red, Black, and White Currants, we have very good crops. Of Pears we have almost none, both on walls and standards. Plums on walls, very few. Apples are not a fourth of a crop. Morello Cherries are good; but of other varieties we have not half a crop, and these very much damaged by the heavy rains which we have had lately.—WILLIAM FINLAY.

Morningside, Kidderminster.—I am sorry to have to report from this neighbourhood an almost total failure of the fruit crops, the only exceptions being in Apples and some of the smaller fruits. Of Apples, there are here and there a fair sprinkling; the sorts most in favour are Lord Suffield, Cox's Pomona, Blenheim Orange, Domeslow's Seedling, and Brabant Belle Fleur; for culinary purposes and for dessert, Cox's Orange Pippin, Lord Burghley, Ribston Pippin, Claygate Pearmain, Melon Apple, Golden and Kedleston Pippins, White Nonpareil, Pine, Golden Pippin, Starmer Pippin, Reinette Van Mons, Irish Peach Apple, and Kerry Pippin, on most of which there is rather better than a quarter crop, the largest bearers being Lord Suffield, Domeslow's Seedling, Claygate Pearmain, Cox's Orange

Pippin, Lord Burghley, Sturmer Pippin, and Melon Apple. Pears are conspicuous by their total absence; there is scarcely a Pear of any sort to be seen. The sorts which generally bear well here and in this neighbourhood are named in the order of succession, viz.:—Bourré Giffard, Summer D'Aremberg, Madame Treyve, Bon Chrétien, Gratioli, Louise Bonne of Jersey, Bourré Superfin, Bourré D'Aremberg, Doyenné du Comice, Marie Louise, Bourré Diel, Nouvelle Fulvie, Easter Bourré, and Olivier de Serres; all bloomed immensely, and some sorts set their fruit, but it gradually dropped off, till scarcely one was to be seen. Of Plums, the only sorts bearing a very few are Early Prolific, Victoria, and Pershore, the latter the greater bearer here this season; sorts that usually succeed in addition to the above are Coe's Golden Drop (one of the best Plums grown), Jefferson, Kirke's, Bryanstone Green Gage, Reine Claude de Bayay, Cox's Emperor, Mitchelson's, Pond's Seedling, and Belle de Septembre; Transparent Green Gage is here, but is a shy bearer, and requires repeated root-pruning to check its exuberant growth; I am trying it in pots with this view, as I regard this variety as the best of all Plums in quality, and worth taking a little pains with. Apricots, Peaches, and Nectarines are a total failure out-of-doors, and a diminished crop under glass. The Peaches which usually succeed here are Early Rivers, Alexandra Noblesse, Bellegarde, Raymackers (a kind of Noblesse, very late and good, and an excellent bearer), Royal George and Princess of Wales (another excellent late sort, large, and of good flavour). The best Nectarines here are Lord Napier, Downton, Elruge, Hardwicke Seedling, Pine-apple, and Victoria. Of Mr. Rivers' new seedling Peaches, Merlin has fruited here in pots in the conservatory, and bids fair to be a good, moderately-early Peach, large, and of rich and racy flavour. Strawberries are generally a good crop, but vary considerably in different localities; here the crop is the largest ever seen, but the fruits in consequence run somewhat smaller than usual; there is, however, a large amount of fine fruit, large plants of eight and nine years' standing measuring between 2 ft. and 3 ft. across, and bearing 5 lb., 6 lb., and 7 lb. of fruit each, and strange to say, the nine-year-old plants are carrying the largest crop; I shall, therefore, allow them to stand the tenth year before digging them in; all sorts alike are good this year, but the following are in great favour, viz., British Queen, La Constante, Enchantress, Carolina superba, Early Crimson Pine (one of the best for a general crop), Sir John Falstaff, Early Prolific (unusually fine this year), Amy Robsart, Hundredfold, Scarlet Pine, and Excelsior; Duke of Edinburgh, Amy Robsart, Early Prolific, and Excelsior are excellent forcers, and bore heavy crops in March and April; Amy Robsart will probably supplant all other sorts for a first early, being of easy cultivation, much larger than Black Prince, quite as early, and of exquisite flavour; it is also a heavy cropper. Mrs. Laxton—a hybrid between Laxton's Alliance (a new starting-point from the original Pine and Alpine races) and my *Fragaria tardissima*—bids fair to be a great acquisition; fruit very rich, remarkably solid (almost buttery), juicy, nearly black when fully ripe, and much increased in size by the cross; it is also late, a good bearer, and in flavour quite unique. Raspberries are also bearing well, and the fruit is very fine; the sorts which succeed well here are Red and White Fastolf, Red and White Antwerp, and Carter's Prolific, all very good, and quite equal and more to be relied upon than any of the new-fangled sorts. Cherries are very scarce, and the same may be said of Medlars. Quinces are also a total failure. Gooseberries and Currants are a heavy crop all round; the Gooseberries in favour here are Hopley's Companion, Warrington, Leader, Snowdrop, Leveller, Broom Girl, Pitmaston Green, and Yellow Gage. Lee's Prolific Black Currant is an acquisition; we have a heavy crop of fine fruit this season, which is sweeter than the old sorts for dessert, and at the same time makes a rich piquant preserve with less sugar. Nuts and Filberts are the heaviest crop seen in this neighbourhood for some years past; the best bearers and sorts most prized are the Cosford Nut (a very large kind with well-flavoured kernel and thin shell), and the Lambert and White Filberts, the former being large, late, and an excellent keeper; the Purple Filbert is also cultivated here for its beautiful foliage, and though not so good a bearer as the others, it makes a pleasing variety in the dessert. Notwithstanding these successes, the loss of the Pear and Plum crop is so serious to people generally, that the year 1877 will be long remembered as one of the most disastrous on record.—WM. RODEN, M.A., M.D.

The Priory, Warwick.—We had a profusion of blossom on all our fruit trees, but nevertheless, with a few exceptions, the fruit crop is a failure. On Peaches, Nectarines, and Apricots there is no fruit. Pears and Plums on walls, standards, and pyramids are likewise fruitless. On Apples there is a fair sprinkling, Lord Suffield, Hawthorndean, Normanton Wonder, King of the Pippins, Devonshire Quarrenden, and Newtown Pippin being the best. Cherries are very scarce. Raspberries, Gooseberries, Red, White, and Black Currants

are good crops, and extra fine in quality. Strawberries are heavy crops, but the fruit is small. Walnuts are a fair crop, and Filberts very abundant. Early Potatoes are sadly blighted.—ROBERT GREENFIELD.

Wimbledon House, Surrey.—Of Apples, the following varieties are producing a fair crop on standards, viz., Ribston Pippin, Cockle Pippin, Fearn's Pippin, and Lord Nelson; the best dwarf trees are Court of Wick, Claygate Pearmain, Mannington Pearmain, Summer Golden Pippin, Yellow Ingestre, Scarlet Nonpareil, Cornish Aromatic, Golden Reinette, Alexander, and Devonshire Quarrenden; crops on cordon-trained trees are a failure. Pears are also in every case a failure; I protected a quantity of pyramids this spring with thick canvas and mats, putting on the covering at night, and having it removed every morning; but the trees so treated are producing no more fruit than those fully exposed. Walnuts are plentiful, and Filberts, Cob, and common Hedge Nuts are a very heavy crop. Mulberries, too, are plentiful, but of Medlars and Quinces we have none. Currants, Raspberries, Gooseberries, and Strawberries are good crops. Peaches, Nectarines, and Cherries are very scarce, and of Plums we have none either on walls or standards, not even common Damsons and Bullaces. Of Apricots we have very few indeed; the Moor Park is the best. Figs are a poor crop.—JAMES OLLERHEAD.

Belvoir Castle, Grantham.—In regard to fruit crops, the present year has afforded another instance of the injurious influences of abnormal warmth in winter and prolonged and unusual cold in spring, when a certain vegetating temperature is so much required both for root and flower buds. The ill effects of an east wind were never more marked and evident than during the months of April and May, and wherever fruit is found this year it is in spots sheltered from its ongenial influence. The earliest-blooming trees have suffered the most. Apricots, which were excited to action early in the year, and which blossomed fairly well, were so severely checked by cold, wet, gloomy weather, that the result as regards setting of the fruit was altogether disastrous; indeed the failure is more complete in this crop than I ever remember to have observed. The weather during the time of the blossoming of Plums was equally adverse and destructive, and their failure is also very general, a little fruit on Denyer's Victoria being the exception. Pears blossomed vigorously, but chilled rather than frozen the blooms fell off, and standard trees are generally quite bare of fruit; on walls with a west aspect Doyenné d'Été and Bergamotte d'Espérance are bearing heavy crops. Some grafted branches of Poire Pêche are also loaded, and there are trees of Doyenné Boussoch, Orpheline d'Égghien, and Winter Nelis bearing light crops. Peaches suffered greatly from the cold in May, and the crop is very thin and the trees much injured. Apples blossomed rather late, and there was a promising amount of bloom, much of which fell off and left many orchard trees quite bare of fruit. Sheltered trees of Frogmore Prolific, Northern Greening, Herefordshire Pearmain (a sort that has never failed here for twenty years), Besspool and King of Pippins are bearing good crops, but the general result will not equal an average crop. Cherries are very thin. Nuts and Walnuts are bearing abundantly. Black and Red Currants are bearing fair crops. Gooseberries, with the exception of the Early Green, are scarce. Strawberries have not been large, but the crops have been moderately good; Frogmore Late Pine will carry on the Strawberry season until the middle of August.—WILLIAM INGRAM.

Bloxham Hall, Sleaford, Lincolnshire.—Fruit crops here are the worst I have ever experienced. We had a mild, open winter, with heavy rains, and up to the end of February vegetation was very forward; but from that date we had cold east winds with frosty nights, and the last week in April and the first nine days in May were stormy and cold, and on two or three occasions in May we had from 8° to 10° of frost. Apricots, Pears, Plums, Peaches, and Cherries were completely scorched, as it were; both blossom and shoots were destroyed, although covered with Frigi Domo. The trees about the end of May looked as if they were killed, but since that date they have made fresh growth and are now healthy. Apples, although late in blooming, are a very poor crop; their failure I do not attribute to frost, but to the cutting east winds which we had when they were in bloom, and as we had a wet autumn and an open winter the trees had not their proper rest; consequently the wood was not ripened sufficiently to enable it to bear a crop. Of Strawberries we have had a very abundant crop; Vicomtesse Hélicart de Thury being the favourite both for early forcing and for the main crop out-of-doors. Of Raspberries we have a good crop of fine fruit. Red Currants are a fair crop, but not so fine as usual. Black Currants are a good crop; and White Currants a good average crop. Walnuts and Filberts are also a fair crop.—DAVID LUMSDEN.

Radcliffe-on-Trent, Nottinghamshire.—In favoured places, which, as a rule, lie higher out of the valley than their neighbours, and which were out of the line of the north-east winds, there are fair crops of some kinds of fruits, and bush fruits in all places are a fair, and in some cases a full crop. Of Apples we have scarcely any, except in sheltered positions and on low-growing trees. Lord Suffield, Keswick Codlin, Alexander, Normanton Wonder, Caldwell, Pike's Pearmain, Besspool, and Cox's Orange Pippin are generally our most trustworthy sorts. On Apricots we have one or two fruits on the largest trees, on many none; under glass copings they are a fair crop, but many of them fell off in stoning. Of Peaches, Nectarines, Winter Nells and Cherries we have none; the May Duke and Downton are our best sorts. Currants (Black, Red, and White) are good generally; the best are Ogden's Black, Black Naples, Red Marcellaise, Red Grape, Ruby Castle, and White Grape. Pears on walls are a fair crop in sheltered places, but on orchard trees there are none; the best are Jargonelle, Beurré de Capiaumont, Beurré Diel, Easter Beurré, Superfin, Langelier, Beurré Rance, Beurré d'Amanlis, Glou Morcean, Bergamotte d'Espéren, Marie Louise, Louise Bonne de Jersey, Fondante d'Automne, Doyenné du Comice, Doyenné Boussoch, and Catillac for stewing. Of Plums we have a very few on walls, none on standards; the best are Early Prolific, Jefferson, Washington, Green Gage, Kirke's, Coe's Golden Drop, and Victoria—the last the market gardeners' mainstay. Of Strawberries, which are a good crop, the best are Vicomtesse Héricart de Thury, President, Sir J. Paxton, Sir C. Napier, La Constante, and John Powell. Raspberries, chiefly Fillbasket, are a good crop. Of Walnuts we have very few, just a sprinkling on the south and sheltered side of some trees.—N. H. POWNALL.

Eastnor Castle, Herefordshire.—A mild winter, followed by a late spring, led us to believe that we should have an abundant crop of fruit, especially as fruit trees of all kinds were thickly set with bloom-buds; but numerous checks, caused by sharp frosts and keen winds up to the end of May, have produced disastrous results both as regards orchards and gardens. Apples, although partial, are more promising than they were some time ago, some kinds being heavily laden, while others are a complete failure. Apricots set well but soon commenced dropping, and still continue to fall; they will be a very poor crop. Cherries, particularly Morellos, are almost a failure. Plums, a complete failure. Peaches and Nectarines, protected by coping boards and nets, are a light crop, and the foliage is badly blistered; where protected by glass copings 2 ft. wide, they have required a good deal of thinning, and the foliage is clean and free from blister. Pears are a failure on standards and espaliers; on walls they are partial, some kinds having to be thinned, while others adjoining are quite barren. Bush fruit is abundant and fine. Raspberries were injured by May frosts, and are below the average; but the fruit is unusually fine. Strawberries, with the exception of very early kinds, are producing excellent crops of large fruit; but the early sorts, which seemed to have made a second growth after the hot weather which we had last year, and which kept moving all winter, produced a number of imperfect flowers which could not set; Keen's Seedling and La Grosse Sacrée suffered most; President, Sir J. Paxton, British Queen, Oxonian, Frogmore Late Pine, and Amateur (a first-rate variety) have all done well. Nuts and Filberts are laden with fruit. Walnuts thin, many trees having cast their fruit. Potatoes are plentiful, good in quality, but small, and disease may be detected in low, damp situations. Peas of all kinds are remarkably good; William the First is the best early Pea I have grown, and Dr. Maclean is all that can be desired for succession.—W. COLEMAN.

Althorp, Northampton.—All small fruits are good, with the exception of Gooseberries; other fruits are very scarce indeed. Apricots, Plums, and Gooseberries were destroyed by bullfinches, which took nearly every fruit-bud. Pear and Peach blooms were killed by the severe frosts which occurred on May 5 and 6, when we had 8° of frost. Apples were loaded with bloom, but owing to the cold weather in May they set badly, and will be very much under the average this year. Nuts are abundant. As regards Potato crops the best plan is to get them up as early as possible; last year I dug my late crop the third week in August, and laid them in small lots, and out of a very large quantity I had not a dozen bad Potatoes. Others about this neighbourhood left them in the ground until the middle and end of September, and lost nearly the whole crop. For a good early I can find nothing better than Myatt's Improved, and for a late crop Patterson's Victoria, but they require good ground.—J. SMITH.

Strathfieldsaye, Winchfield, Hants.—Fruits in this neighbourhood are only a partial crop. Apples are a fair crop; but of Pears we have none. I doubt, indeed, if I shall be able to gather as many Pears as there are trees, though up to the first of May we never had fairer prospects, the trees being covered with healthy

blossoms, but the bitterly cold north-east winds which occurred during the first eight days of May, and 8°, 9°, and 11° of frost at night, completely destroyed them. Much of the Apple blossom perished at the same time, but a considerable portion of it not then open fared better. I do not think I could find a single Plum on standards, and very few on walls. Cherries promised well and set thickly, but about the end of May they fell off in handfuls. Gooseberries, Currants, and Raspberries are plentiful. Strawberries suffered from the long wet weather which we had in winter; where the plants were strong the crop has been heavy, and has lasted longer than usual. The blossoms of Apricots were plentiful, strong, and vigorous, but the frost which happened on March 1st killed them, though carefully protected with good unbleached sheeting. I have proved this to keep them safe while there is not more than 10° or 11° of frost, but anything beyond that is sure to destroy the embryo fruit. I have, however, a sprinkling left on Moor Park, and a full crop upon Early Orange, evidently by far the hardiest; indeed, I have seldom failed to obtain a crop from that variety, while a crop once in three years is as much as I expect from the Moor Park and other large varieties. Trees of the Early Orange are likewise much less liable to die off than those of Moor Park; indeed, I may say that they are the only perfect Apricot trees I have on a wall 150 yds. long. I have succeeded in securing a fair crop of Peaches and Nectarines on walls; the trees were sadly infested with black fly even before the blooms were open, but by keeping the syringe constantly at work we got them clean, and they have made fine wood. Nothing can beat Royal George, Violette Hâtive, and Grosse Mignonne for general crop. Barrington and Walborton Admirable are still in my opinion superior to many of the new late varieties; one cannot reckon much on the quality of the Salway in November (its season here), but it is eatable and makes a good-looking dish.—JAMES BELL.

Crewe Hall, Cheshire.—Peaches, Nectarines, and Apricots with me are about an average crop, but Plums, Pears, and Apples in most places are very scarce. With me Apples are something less than an average crop; some sorts are bearing well, while others have none on them. All small fruits, such as Currants, Gooseberries, Strawberries, and Raspberries, are plentiful, but the continued rains in July injured Strawberries when ripe. Owing to the prevalence of frost and cold east winds when Pears and Plums were in bloom, and the young leaves beginning to open, both fruit and foliage were much injured, but the latter now look healthy and fresh. The sorts of Peaches which I find to do best here are Rivers' Early Beatrice, Early Louise, Early Alfred, Crimson Galande, Alexandra Noblesse, Lord Palmerston, Grosse Mignonne, Dymond, and Walborton Admirable. Of Nectarines the best are Elrage, Violette Hâtive, Rivers' Orange, Pine-apple, and Victoria. Amongst Apricots Moor Park is the principal one grown here. Of Apples those which bear best with me are Keswick Codlin, Hawthorndean, Irish Peach, Cathcart, Minshall Crab, Yorkshire and Northern Greening, Ribston Pippin, Lord Suffield, and Court Pendu Plat. Of Pears the best are Jargonelle, Williams' Bon Chrétien, Marie Louise, Benrre Diel, Winter Nells, Glou Morcean, and Easter Beurré. Amongst Strawberries I find President to be one of the best, and James Veitch, President Delacour, Macmahon, and Countess, as well as La Grosse Sacrée and Vicomtesse Héricart de Thury, have been very good with me. Damsons are largely grown in this district, but owing to the severe frosts which occurred in April and during the early part of May, the greater part of the embryo fruit was injured, and in consequence there will be but a small crop this season.—W. WHITAKER.

Eaton Hall, Chester.—All kinds of fruit trees bloomed well, and we looked forward for an exceptionally good fruit year. Pears, however, and stone fruits generally succumbed to the severe spring frosts which we experienced in this district. Apples, which bloomed unusually late, were looked upon as a safe and heavy crop, but the long-continued and severe east winds which we had seemed to prevent the setting of many of the flowers, and consequently those which did set have a poverty-stricken appearance, even although somewhat improved by the heavy rains of last week. Apricots, where well protected, are a fair crop, but the trees looked very bad until the late rains set in; and the same remark applies to Peaches and Nectarines. Strawberries are a fair average crop. Raspberries, Gooseberries, and Currants very plentiful. Nuts, especially Walnuts, abundant. The season is almost three weeks later than usual.—THOS. SELWOOD.

Worsley, Manchester.—The past season has been a most disastrous one in this district as regards outdoor fruit crops. Plums and Pears were almost totally destroyed by the frosts in spring. Apples bloomed most satisfactorily, and being late, we anticipated good crops, but the dry weather in May was so favourable to green fly that the trees got completely smothered with it. Gooseberry and Currant bushes also suffered much from the same pest; these we

were able to clear by applications of insecticide, but the Apple trees we could not manage, and the crop suffered in consequence; some few trees are, however, bearing heavy crops, but that is the exception rather than the rule; altogether Apples are a light and patchy crop. Strawberries are a fair crop, but great quantities rotted during the past fortnight of damp weather. Small fruits are a good crop, especially Gooseberries, and there is every appearance of its being a good season for Nuts. Peaches and Apricots do not succeed out-of-doors here. Morello Cherries, which are our only outdoor stone fruit, are carrying good crops.—W. B. UPHORN.

Lancashire.—Knowsley, Prescott.—Apples are an average crop, but irregular; Lord Suffield, Boston Russet, Ribston Pippin, and Dutch Mignonne are amongst our best croppers. On Pears, as on all other fruit trees, there was a fine show of bloom, but it failed to set, as did also that on Plums; many Pear trees have bloomed a second time. Strawberries and Cherries suffered through being too much subjected to rain at the time of ripening. Apricots, Peaches, and Nectarines are a medium crop; small fruits generally are good, but later than usual.—F. HARRISON.

—**Sale, Manchester.**—The Apple crop here is a failure; there are no Damsons; and of Apricots there are only a few in sheltered situations. Of Pears we have also a few; Gooseberries are a good crop, and so are Currants; but of Cherries we have none. Strawberries in market gardens here are abundant, but spoiled by the late rains.—CHARLES TURNER.

Thorpe Perrow, Bedale, Yorkshire.—Apricots, Peaches, and Plums are a failure in this part of Yorkshire, and Pears are little better; we have not had so few since 1861. Apples on some trees are a fair crop, others very thin; here self-thinning is thought to end on St. Swithin's day—that is, all the Apples on the trees at that date are considered safe—but this year is an exception, as the self-thinning process is still going on, and if much further prolonged will be disastrous. Of Black, Red, and White Currants we have very heavy crops, and the late rains have swelled them up finely. Cherries are very thin, with the exception of the Kentish, of which there is a good crop. Strawberries and Raspberries are also good, and the same remark applies to Filberts. Gooseberries are good in some places; with us the best kinds are thin. February being mild, brought Apricot and Peach trees almost into leaf, and the disastrous cold north-east winds which we had in March destroyed all the early growth as well as flower-buds; some of our best trees are even past recovery. The Apple and Pear blooms were very weak and poor, the result of want of sunshine last autumn.—WILLIAM CULVERWELL.

Lambton Castle, Durham.—Fruit crops in Durham, owing to the severe weather experienced during the flowering period, are the worst which we have had for a number of years. Apples, which are very thin, are perhaps best represented by Rymer, Court Pendu Plat, Cellini, Danelov's Seedling or Wellington, Court of Wick, Lord Suffield, Ribston Pippin, Cockle Pippin, Manks Codlin, Mannington Pearmain, Claygate Pearmain, and Lemon Pippin; cooking sorts, although a little better than dessert kinds, are also thin. Of Pears we have very few; the best are Jargonelle, Althorp Crassane, Beurré de Capiamont, Green Yair, and Beurré Incomparable; half of our trees are in bloom at the present time. Of Peaches and Nectarines we have none, and in three or four instances the trees are nearly killed. Frost destroyed our early sorts of Cherries, but late ones are good both as regards crop and quality; Morellos are thin. The Plum crop was entirely destroyed by frost. Strawberries are plentiful, but owing to the rains which we are having, they get mouldy before they ripen; Duc de Malakoff, President James Veitch, Mammoth, Amateur, and Elton succeed well in this district. Gooseberries are thin but good. Currants, thin. Raspberries a good crop.—J. HUNTER.

—**Glyn Garth, Anglesea.**—Small bush fruits with us are a good average crop, and the same may be said of Strawberries; but wall fruits are a complete failure, as are also Apples and Pears; and the same remarks apply to this neighbourhood generally.—ROBERT WEBSTER.

Rust on Grapes.—Amongst all our Grapes this season all the rusted berries do not exceed a dozen, and previous to thinning not one showed this disfigurement. I am, therefore, of opinion that the scissors, while working amongst the berries, engender rust. Any one who has thinned Grapes will have observed that the scissors soon become quite moist on the part used for clipping. If they are laid down then on a piece of clean wood they will leave a rusty mark, and I am of opinion that the same stain is left on some of the berries, thus producing the disease. Wiping the scissors frequently with a dry cloth keeps them quite clean.—VIRIS.

FRUITS, FLOWERS, AND VEGETABLES TRIED AT CHISWICK.

A MEETING of the Fruit Committee was held on the 24th ult., at Chiswick, to examine subjects grown there for trial this season.

Gooseberries.—These were first examined, a small basket of each variety (200 in number) having been gathered for comparison and classification. The Committee selected the following as especially worthy of cultivation, viz.:—*Reds*: Red Champagne, Warrington, Monarch, and Starling. *Green*: Roseberry, Overall, Green Globe, Pitmaston Green Gage, Cheshire Lady, Shiner, and Gretna Green. *Whites*: Whitesmith, Orleans, Keepsake, Safety, and Top Gallant. *Yellow*: Sulphur, Rumbullion, Aston Hepburn, and Yellow Globe.

Red Currants.—These were examined with great care as to their nomenclature, so much confusion still existing amongst them in that respect. Of the most approved varieties noted the earliest and the largest is the Red Cherry, which has the following synonyms, viz., Bertin No. 9, Grosse Rouge de Boulogne, Fertile d'Angleterre, La Hâtive, La Fertile, Fertile de Bertin, Hâtive de Bertin, Chenonceau, Belle de St. Gilles, Fertile, Fertile de Pallua, and La Versailles. The Red Dutch, which is the variety most generally cultivated in gardens, has the following synonyms:—Knight's Large Red, Knight's Sweet Red, Goliath, Fielder's Red, Palmer's Late Red, Pitmaston Red, Pitmaston Prolific, Large Sweet Red, Bertin No. 1, Dancer's Selected, and Jackson's Mammoth. The Red Grape, a long-bunched sort, of a pale red. Synonyms:—Rouge Transparent, Queen Victoria, Fertile de Pallua. Houghton Castle, the best constitutioned variety. Synonyms:—Houghton Seedling, Orangefield. A fuller report of these will appear in the Society's journal.

An examination of the Turnips, of which about 150 varieties are this season being grown, was then made; the earliest was the Green Strap Leaf (Carter & Co.). Tomatoes were also examined, a very large collection of which is being cultivated in pots, the only one showing signs of ripening being Early Gem, sent by Messrs. Veitch & Sons. Of these a later examination will be made.

A meeting of the Floral Committee was held at Chiswick on the 25th ult. for the examination of the various collections of plants growing in the gardens for trial this season.

1. Zonal Pelargoniums.—Of these a large selection of the most approved newer varieties which were grown in pots last season have been bedded-out along with some of the best older sorts for comparison. First-class certificates were awarded to Mr. J. R. Pearson for Atlas, a large-trussed crimson scarlet Nosegay; Rev. A. Atkinson, crimson-scarlet. To Messrs. James Cocker and Sons for John Fraser, light magenta. To Mr. J. George for Mrs. J. George, rosy cerise; and Beauty of Surrey, crimson-scarlet, very free and excellent habit. Of the older varieties conspicuous for their excellence were noted Vesuvius, Princess of Wales, Vesta, Cleopatra, Violet Hill Nosegay, and Claude de la Meurthe, &c. Of the newer varieties which have been sent out this season, and grown in pots under glass, first-class certificates were awarded to Mr. J. R. Pearson for Rebecca, a very beautiful magenta-scarlet Nosegay; Louisa, a sort of shaded magenta-pink, mottled with rose; Blanche Gordon, light pink. To Mr. J. George for Lord Mayo, bright scarlet. Specially noticeable also were Miss Wakefield, Lizzie Brooks, and Lord Giffard.

2. Bedding Violas.—A large collection of those reported on last year are again under cultivation, the most noticeable amongst them being Crown Jewel (Grieve), Blue Beard, Blue Bell, Queen of Lilacs, lilacina, rubra lilacina, Princess Teck, and Pilgrimage Park. Of new varieties first-class certificates were awarded to Mr. R. Dean for Vestal, a pure white variety of a fine free habit; to Messrs. Dickson & Co. for Holyrood, a very rich, dark blue variety of good habit; to Mr. Frowen for Golden Prince, a clear yellow variety with distinct white eye.

3. Begonias.—A fair selection of these have been grown in pots, chiefly of the tuberous-rooted class, the most striking being Acme and Kalista (Veitch), Froebel, &c. A first-class certificate was awarded to a seedling from rosafiora raised at Chiswick, and named by the Committee Mrs. Barron. It is of very robust growth, forming a large plant; flowers large, roundish, and produced freely, of a pale rosy pink; a very distinct sort. Moonlight, a hybrid raised by Col. Clarke and certificated last year, is exceedingly attractive. This, which is something of the habit of Weltoniensis and producing long racemes of pure white flowers, will become a very popular decorative plant.

4. Fuchsias.—Of these a selected collection has been grown, occupying one house. A first-class certificate was awarded to Messrs. Laing and Co. for Lord Beaconsfield, a hybrid from the old

fulgens, and possessing a good deal of its character. As a free-blooming decorative plant it will prove very valuable. Very conspicuous amongst others is *Champion of the World*, a very large, dark, double sort—almost a monster.

5. Verbenas.—Only a few varieties of these are on trial. For habit *Purple King* still stands pre-eminent. *Blue Bell* (Smith) is very effective. A first-class certificate was awarded to Messrs. John Fraser for *Carl Sieglig*, an intensely dark blue variety, of good habit.

Hardy Annuals.—Complete collections of *Iberis*s, *Clarkias*, *Godetias*, *Viscarias*, *Dianthus*es, *Stocks*, *Balsams*, &c., are on trial this season, and when in full flower are exceedingly showy. Of *Iberis* first-class certificates were awarded to Messrs. Vilmoren & Cie. for two splendid novelties—viz., *I. coronata hybrida nana rosea*, a variety of fine dwarf growth with large rosy-salmon flowers, not unlike *gibraltarica* and exceedingly beautiful; *I. coronata hybrida nana alba*, a variety of the same character with pure white flowers. Amongst the *Godetias* *Lady Albemarle*, which was certificated last year, is by far the finest. Of *Viscarias* none exceed in beauty the true *V. cardinalis*.

Mr. Charles Turner, Royal Nurseries, Slough, sent cut blooms of his seedling *Roses Penelope Mayo* and *Harrison Weir*. This latter variety is of a rich dark crimson colour, and is very promising. The Committee highly recommended it, at the same time requesting that it be again brought before them, being unable to give a final decision from seeing only one bloom.

THE EFFECT OF BLUE LIGHT ON PLANTS.

MR. PETER HENDERSON has some interesting notes on this subject in the "American Agriculturist":—"Five years ago (though utterly sceptical as to the value of blue glass) I, at the urgent solicitation of a friend, used a blue transparent wash on the glass of one of my greenhouses, thus changing the glass practically into blue; on the glass of another house, of similar size, I used whitewash. Both greenhouses were filled with plants of a similar character. In a few weeks we found that the plants in the house under the blue glass were "drawing," or spindling up more than under the white, and on examination of a thermometer, placed in each house, it was found that, during the first two weeks in June, the average temperature under the blue glass was 90°, while under the white it was 80°. This was just such a result as might have been expected, the darkened glass absorbed the sun's rays, and the heated glass gave off its heat to the interior of the house, while the whitened glass reflected them—that was all. The temperature was simply increased under the blue glass, and to the great detriment of the plants, for all cultivators know that in our hot summer months, the difficulty we have to contend against is too high a temperature. If General Pleasanton started to force his Grapery in midwinter, his blue glass would be apparently beneficial—not because it was blue, but because it would assist him in getting a higher temperature, which would at that season be desirable; or, for the same reason, his Figs might feel somewhat more comfortable and ripen more quickly. But were he to carry on the culture of either under the blue glass into midsummer, both Pigs and Grapes would be likely to remonstrate. Upwards of thirty years ago it was claimed that seeds would germinate and cuttings root more quickly under dark-coloured than under light-coloured glass; this is no doubt true, and from the same cause—an increased temperature under the dark glass, but all who have had experience in such matters, well know that this "forcing" process is at the health of the subjects so treated, unless they are plants indigenous to tropical countries, to which a high temperature is natural. To claim that blue glass, or any other coloured glass, has any properties capable of affecting health, in other manner than what is due to an increased temperature produced by any other means, is undoubtedly false. Mr. Henderson no doubt assigns the proper reasons for whatever seemingly favourable influence blue glass may have upon the plants growing beneath it. That there is any peculiar power in the blue ray to accelerate plant-growth—which our readers are well aware depends primarily upon the decomposition of carbonic acid, liberating the oxygen and the assimilation of the carbon—is disproved by the results obtained by various careful experimenters. Indeed, the rays of the blue end of the spectrum are much less favourable to the decomposition of carbonic acid by plants, than yellow rays, and either alone greatly inferior to all the rays together—or white light. The experiments of Pfeffer show that the amount of decomposition under white light being 100, the red-orange rays had a decomposing power equal to 32.1; the yellow, 46.1; green, 15.0; while the blue and violet rays are only 7.6. We were quite amused with the strong common-sense view of a friend, who, in speaking of the subject,

remarked: "if blue light were best for plant growth, the Creator would have provided it in the beginning." Should any of our readers desire to give their plants blue light instead of white, we would warn them that its application is patented! Blue rays are an essential part of white light, and some court may yet decide that the use of the greater involves the less, and that we are all infringing upon the patent. At last accounts white light is not yet covered by a patent, but one can not tell what may happen.

Paisley Pansy Show.—This was held on July 27 and 28 under the auspices of the Paisley Amateur Florists' Society, and was a decided success, no fewer than seven exhibitors having competed in the class for the best twenty-four Show Pansies. The prizes (which were £6, £2, £1, and 10s.) were awarded to Mr. William Paul, nurseryman, Paisley; Messrs. Dickson and Peacock, nurserymen, Paisley; Mr. Peter Lyle, Kilbarchan; and Mr. William Barr, Linside, Paisley, in the order named. Mr. Paul's twenty-four blooms, which were in excellent condition, were as follows:—Dark selfs—Michael Saunders, Alexander Watt, Oceola, J. P. Barbour, Mauve Queen, and Captain Knowles. Yellow selfs—The Mint and Citron. White self—Bessie Peacock. Yellow grounds—Robert Burns, Lord Derby, Defoe, Dr. Livingstone, Alexander McLennan, James Orr, and Clonard. White grounds—Jeannie Grieve, Mary Robertson, Minnie, Beautiful, Mary Paul, Elie Goudie, Mrs. Henderson, and Delicate. The following flowers (including some of the above), selected from other stands, are worthy of mention:—Dark selfs—Sir P. Coats, Dean's Glen, Count Bismarck, W. B. Speirs, and Hugh Austin. White selfs—May Queen and Purity. Yellow selfs—Mrs. Horsburgh and Unique. Yellow grounds—Ebor, J. Waterston, and Rev. J. Ferguson. White grounds—Captain Speirs, Bessie McAslan, Mrs. Arthur, Mrs. Eyles, and Miss E. Cochran.

NOTES AND QUESTIONS—VARIOUS.

Green Petunias.—I have sent you blooms of *Petunias* which seem to me very curious. I have grown them year after year, but never had any so singular: are they common?—H. D. PALMER. [Flowers more or less green may be found in nearly every bed of *Petunias*, especially in dull wet seasons.]

Potatoes.—These are badly affected hereabouts with disease, which commenced before they were half grown. In damp, low-lying gardens the haulm is already quite decayed—a sorrowful prospect for the labouring classes, a not half a crop can be expected.—G. B., Longleat.

Wild Fruits.—Beech mast is this year an extraordinarily heavy crop, indeed, so heavy that the branches are literally bent down with its weight. Hazel Nuts are also an abundant crop, and Walnuts are plentiful. Holly-berries, too, are a good crop, and the same may be said of Haws, while of Acorns there are scarcely any.—G. B., Warminster.

Small's Admirable Apple.—Amongst culinary Apples, I find that Small's *Admirable* is, perhaps, carrying the largest crop this year of any. This is a variety of the old Hawthorndean, which comes in about October or November, and lasts frequently till February. The tree is of small growth, a good bearer, and one of the best to grow as a bush in small gardens, or where the space is limited.—Wm. Rorex, Kidderminster.

Autumn-sown Onions.—Will White Spanish Onions sown in autumn, and transplanted the following spring, keep the same length of time as those sown in the spring and gathered the same year?—W. T. W. [Spring-sown Onions if well attended to and thoroughly ripened in the autumn, will keep in good condition for a much longer time than autumn-sown ones, however well the latter may be ripened. Autumn-sown Onions are chiefly grown for furnishing a supply in summer before spring-sown crops are ready for use, and if allowed to come to maturity and harvested in the usual way, they are invariably need first, leaving the spring-sown crops for winter and spring use.]

The Cellini Apple.—In your reports of the fruit crops (p. 94-100) I find little mention made of this Apple. Such a season as the present affords a very good test of the properties of any particular fruit as regards bearing, and Cellini, as I have always hitherto found it to do, comes out well. Of two pyramid trees here, one has a fair crop, and the other almost more than it ought to have at any time. Lord Suffield, undoubtedly an excellent Apple, has with me this year not a single fruit on it, though it had, as all had, a beautiful bloom. Of the excellence of Cellini as an Apple, it is scarcely necessary to speak. It is good as a culinary or dessert Apple, and is as handsome as it is good. Two years ago, on a small pyramid, in its second season, I had twenty-two Apples, scarcely one of which was under $\frac{1}{2}$ lb. in weight.—E. C., East Notts.

To Preserve Fence Posts.—The American "Chemist" says that a western farmer discovered many years ago that wood could be made to last longer than iron in the ground. Time and weather, he says, seem to have no effect on it. The posts can be prepared for less than two cents a-piece. This is the recipe: Take boiled linseed oil and stir it in pulverised charcoal to the consistency of paint. Put a coat of this over the timber, and, he adds, there is not a man who will live to see it rot.

"This is an art
Which does mend Nature: change it rather: but
THIS ART ITSELF IS NATURE."—*Shakespeare.*

NOTES ON THE FLORA OF ZERMATT.

SOME of the readers of THE GARDEN will, I trust, sympathise with the efforts of the writer—his failures and his very partial successes—in the cultivation of hardy, and especially Alpine plants; and may accordingly be interested in an expedition he made this summer to one of the best reputed Swiss valleys for the replenishment of his stock, sadly reduced, as it was, by winter floods and spring damps. Without now saying anything in general of my experiences, let me give some account of my fortunes in quest of Alpine plants in the neighbourhood of Zermatt, its glaciers, and its far-famed Matterhorn. I must preface what I am about to say by the remark that my botanical knowledge is very unscientific. I have never been able to bring myself to pull flowers to pieces, and examine them with a magnifying glass, to decide whether the form of a style should place them in this genus or in that, but I have lived amongst them for weeks and months, learning to know them as friends, getting used to the habits of each one, both such as were visible on the surface, and those which needed careful observation to ascertain. And so I have come to know many of them as intimately as any scientific investigation would have enabled me; and, moreover, my acquaintance is thus one which is capable of continuation under changed conditions when they become (I will not venture to say with how much or how little of involuntariness) my companions in home scenes far away from their native haunts, and respond, as best they are able, to the honest attempt to make them as happy as may be in their new lot.

Zermatt and its immediate vicinity are, on the testimony of more competent persons than myself, more than commonly rich in plants. I think I never in my life saw a more varied flora, if not of the rarest flowers, than on the sunny slopes of the main valley south of the little village. My first regular expedition was to the base of the Matterhorn, where I was led to expect the higher Alpine plants to flourish abundantly; nor was I disappointed. Our way thither, as we wound along the west side of the valley, furnished a considerable variety of the less-distinctively Alpine plants; amongst them, *Lactuca perennis*, very closely resembling the *L. sonchifolia* of our gardens, though I know not as yet whether as easily acclimatised; *Astragalus monspessulanus*, in rich flower wherever any *débris* had been brought down from the rocks above; *Epilobium Dodonæi*, and in great profusion St. Bernard's Lily (*Anthericum Liliago*). With this last the warm, dry slopes of the valley were, in places, literally white, while at a higher level of the same slopes, but more sparingly, and where the greenness of the vegetation indicated greater moisture, grew its more graceful companion, St. Bruno's Lily (*A. Liliastrium*). It was early in the season on this our first excursion, for the Edelweiss (*Gnaphalium Leontopodium*), we gathered only a half-opened flower or two; but a week later, while passing over much the same ground, it is no exaggeration to say that a good-sized basket might have been filled with blooms without moving ten yards away from any given spot thereabouts. What is to hinder the successful cultivation in England of this interesting plant? It has evidently no special whims as to soil. At Zermatt where the rocks were for the most part a micaceous schist, it grew amongst the crumbling particles of these and a scanty admixture of loam; elsewhere I have taken it up in a tuft of regular English turf which might have come from a Kentish orchard. It wants abundance of sun and perfect drainage, and where these can be given, and the first young shoots are protected from slugs, I believe it can be grown successfully. But we were bent on higher game than such plants as I have spoken of; so crossing the remarkable stream which has worn itself a way from the Zmutt glacier, the banks of which are steep and deep enough to make the head giddy to look down from, we mounted on the other side of the valley towards the great mass of the Matterhorn, which guards the whole valley

like the giant warder of a castle in some book of fairy tales. It would take too long to mention even by name one half the beautiful flowers we found there on the more shady slopes in their fullest bloom, even so late as the latter half of July. *Gentiana verna* fringed the rich posy in its lower edge, intermingled with *Viola calcarata*. This by the path we chose gave place again to *Dryas octopetala* in untold luxuriance, with *Linaria alpina* (wherever the watercourse had left sufficient loose grit), and amongst the woody banks on either side, not to speak of *Rhododendron ferrugineum* in masses of any size, *Pyrola rotundifolia* in bud, with *Primula viscosa* nestling between the larger rocks just passing out of bloom, and *Primula farinosa* at our feet everywhere. I must digress for a moment to say that in the comparison I cannot help making between the flora of Zermatt and that of other lofty valleys in Switzerland which I have explored, Zermatt seems to me deficient in its *Primulas*, for besides the two I have just mentioned, I could only find or hear of from others, one other (*Primula longiflora*), which grew in abundance somewhat lower down, not to mention our own home favourites, the common Primrose and Cowslip.

But in Alpine flower-hunting, up to a certain altitude at least, increased exertion brings increased reward; and the higher we climbed the choicer were the treasures laid at our feet. *Ranunculus pyrenæus* and *rutæfolius* were as abundant as Buttercup; in an English meadow, the latter almost rivalling in the silveriness of its cup the incomparable *glacialis* when growing in its full perfection. *Androsace carnea* was not unfrequent in little, compact tufts, with the commoner *Chamæjasme*. In the less sunny hollows *Anemone sulphurea* was indescribably beautiful, with occasional patches of *baldensis* and *vernalis*. *Lloydia serotina* was to be gathered on every moist slope, with *Gagea Liotardi*, looking like bridegroom to the bride, though less frequently; and last, though not least, where beauty and refinement are the characteristics at issue, *Soldanellas*, just outside each patch of lingering snow, if I remember rightly, both *alpina* and *pumila*. But I must not forget amidst greater varieties to notice the singularly beautiful effect of a large bunch of a white variety—the clearest, purest white—of *Viola calcarata*, which I have been able to bring to England almost unscathed, and which I hope will repay me next spring for the special care bestowed on its transport. If the readers of THE GARDEN care to hear more of the results of other expeditions in the same neighbourhood, it will be a pleasure to me thus to recall hours of such unalloyed and elevating enjoyment, and I may afterwards, if they please, add some few of the axioms with regard to the cultivation of my treasures which my experience, sometimes dearly bought, has led me to adopt.

CANONICUS.

The Old *Araucaria imbricata* at Kew.—This for many years has produced a few cones which, however, have never grown to any great size, owing to their not having been fertilised. The species is normally dioecious; we say normally, because only a year or two ago a large specimen at Bicton, the seat of Lady Rolle, bore several spikes of male flowers and some female cones on the same branch. This is, however, a rare occurrence. This year the Kew plant is bearing a great many cones. Perhaps this is because it is failing in vigour, and, as is so often the case with plants or trees under such conditions, it seems to be expending all its efforts to fulfil its mission, *i.e.*, reproduce its species before it dies. From its label, we learn that it was introduced in 1796 by Mr. A. Menzies. On the slopes of the Cordilleras of Chili this species forms vast forests and grows to a great size, attaining a height of from 100 ft. to 150 ft.; the wood is very hard and durable; the cones, about the size of a child's head, are sessile on the extremity of the branches. Each cone yields a good many large seeds, somewhat the shape but about double the size of an Almond. These seeds are eaten in Chili, just the same as those of the Bunya Bunya Pine, (*Araucaria Bidwillii*) are eaten in Queensland; or, to come nearer home, as the seeds of *Pinus Pinea* are eaten in Italy. Captain Vancouver, Mr. Menzies (the surgeon of his voyage), and some other officers were dining at the table of the Governor of Chili, when a dish of *Araucaria* seeds was brought in for dessert. Mr. Menzies obtained permission to sow instead of eat his portion. Five of the seeds germinated on board ship on the passage home, and the Kew plant is one of the seedlings!

NOTES OF THE WEEK.

FLOWER GARDENING AT KEW.—The flower gardening at Kew this year consists chiefly of a loud shout of colour along the main walk backed by the never-ending kidney-shaped *Rhododendron* beds. The flower garden in front of the great Palm-house has the effect of a dowdy carpet bag not much toned down by time. These statements will only seem too forcible or unwarrantable to those who have not seen what is alluded to. It is sad to think that this is all that is done in flower gardening in the most richly-endowed and important garden in the world.

A BEAUTIFUL CANNA.—The most striking plant among scarce ones at the present time in flower is *Canna iridiflora*, some time since figured in *THE GARDEN*. It differs from all the other kinds in our gardens by its large and handsome flowers, more than 3 in. across, and of a deep pure rose. Unlike the other Cannas, its flowering shoots are held boldly up and out of the foliage, and from these the blossoms droop very gracefully. The habit is as graceful and stately, and the foliage as fine as those of other kinds. It is worth a trial in warm spots in our southern districts in summer, and it also deserves culture for the cool house or conservatory. It is now in blossom in various municipal gardens about Paris, where it is the finest plant among recent introductions to the flower garden.

THE FINCHLEY GRAPE VINE.—This Vine, which has for years been noted for its size and the large crops of fruit which it bears, is this year as prolific as usual. It is furnished with some 500 perfectly-formed bunches, each of which will average about 2 lb.; the berries are very large, and promise when ripe to be quite equal in colour to the excellent specimens which have from time to time been exhibited at our metropolitan shows from this establishment. The stem and branches of this Vine have increased greatly in size since we saw it a year or two ago.—S. C.

FINELY-FLOWERED ORCHIDS.—We have at present in flower *Dendrobium crepidatum*, a beautiful kind, the sepal and petals of which are white tipped with rosy-pink, the labellum being all but crimson with a very large orange central blotch; on this there are thirty-two flowers. D. McCarthy has forty expanded flowers; in order to grow this successfully it should always be kept in a warm, moist temperature, suspended from the roof of an East India-house. *Dendrobium sulcatum*, which is prettier than D. Farmeri, has ten spikes; on *Masdevallia Davisii* there are seventy-one flowers; *Odontoglossum Andersonii* has four spikes, and on each there are eighteen blossoms, in all seventy-six, one of the finest varieties I have seen. O. Roezli has nineteen flowers, each measuring $4\frac{1}{2}$ in. across, and on *Uropedium Lindenii* there are thirteen flowers.—A. FALCONER, *Leyton*.

SWEET WILLIAMS.—It is satisfactory to find that steps are now being taken to raise improved varieties of these old-fashioned border plants. Mr. Cannell, of Swanley, has thousands of Sweet Williams raised from seed, the result of crosses from kinds likely to produce something new. In a large plantation of them we found many beautiful dark smooth-petalled flowers arranged in shapely clusters, and great improvements on existing kinds. As the young seedlings come into flower, those seen to be no better than their parents are at once discarded, and if this course be persevered in, greatly improved sorts must necessarily be the result. A dwarf double scarlet kind shown to us by Mr. Cannell seemed admirably adapted for small beds or borders where taller-growing sorts would not be admissible.—S.

TWO WELL-GROWN ODONTOGLOSSUMS.—At the meeting of the Royal Horticultural Society on Tuesday last, Sir Trevor Lawrence exhibited two plants of *Odontoglossum vexillarium*, which were probably the most profusely-flowered specimens of the kind that have yet been seen in cultivation. One was the ordinary form, the other the rose-coloured variety, and in both cases many of the blossoms measured nearly 6 in. in length and 3 in. across. On the two plants were nearly 150 fully-expanded blooms. Such specimens as these enable us to form a just estimate of the value of such plants, which received, as they well deserved, a cultural commendation, and it was recommended that a medal should be awarded them.

A FLOWER GARDEN UNDER GLASS.—The extensive range of glass recently erected at Drunlanrig for the growth of stone fruits not having been completed in time to plant the trees this season has been converted into a flower garden in which 14,000 plants have been planted, consisting chiefly of Pearson's *Pelargoniums*. In order to break the even surface and thus produce variety, tall pyramid *Fuchsias*, *Coleuses*, and similar plants have been introduced; and hanging baskets and a few creepers up the rafters subdue to some extent the bareness of the roof. The building being 500 ft. long, the effect of the display thus made is very striking, and the way in which *Pelargoniums* bloom planted in this manner compared with those out-of-doors serves to show that under glass they make a far more effec-

tive and long-continued display than four times their number out-of-doors; it is not improbable that the time may yet come when such tender and gorgeously-blooming plants will be grown chiefly under glass, and that more attention will be paid to our fine hardy plants.

LARGE TOMATOES.—Mr. Miles, gardener to Lord Carington at Wycombe Abbey, exhibited at South Kensington the other day the largest Tomatoes we have seen this season, consisting of a variety named Stamfordian, which is supposed to be a good selection of Hathaway's *Excelsior*, a kind which it closely resembles. Their skin was smooth and beautifully coloured, the flesh remarkably firm, and the fruit symmetrical in shape. If such ill-formed Tomatoes as we now see in Covent Garden be worth 3d. each, Mr. Miles' fruit ought to realise treble that sum, and even should the Stamfordian variety prove not so fruitful as others, one of its fruit would be equal to three or four of the ordinary market sort.—S.

A NEW FUMIGATOR.—Those who are acquainted with the difficulties attending the fumigation of plant-houses with Tobacco, will welcome Tebb's Universal Fumigator, which does its work free from unpleasant consequences. All that is required is to tear up a few pieces of brown paper and place them loosely on the perforated bottom of the fumigator; then fill in the fumigating material, close the top down, and set light to the brown paper with a match; the blaze will soon ignite the fumigating material, and when fully in action the draught can be regulated by a sliding door. When in full operation this fumigator may be left with perfect safety inside the house, which it will soon fill with smoke.

TABLE DECORATIONS AT CARLISLE.—Lady Musgrave, of Eden Hall, has increased the prizes already offered by her for table decorations, and will present a cup, valued at £25, to the successful competitor. The latest date for entries is now extended to August 30, and no doubt there will be a keen competition. Lady Musgrave, Lady Lawson, and Mrs. Percy Wyndham have consented to act as judges on the occasion.

WEST INDIA PINE-APPLES.—These have been abundant in Covent Garden this season, and they are moreover much larger and better in quality than usual. They are now being extensively used in London for preserving; a week or two ago one salesman alone received a consignment of over 7000 fruits, many of which weighed from 3 lb. to 4 lb. each, and they were well ripened and as juicy and good as could be desired. They may be bought for from 1s. 6d. to 2s. 6d. each.

QUEEN ANNE'S POCKET MELON.—This old and remarkably handsome Melon, though not cultivated to a great extent, forms one of the most ornamental dishes for the dessert-table from July to October. Good examples of it may now be seen in Covent Garden, where they meet with a ready sale at from 9d. to 1s. each. The cropping properties of this variety fully compensate for its small size, and although it is inferior in flavour to many of the larger kinds, that deficiency is more than counterbalanced by the beauty of the fruit. It may be grown during the summer months in any ordinary frame or pit with every chance of success, and the fruit will keep good for some time after it is out.—C.

ALEXANDRA PALACE FRUIT SHOW.—This is to take place on the 13th, 14th, and 15th of September, when prizes amounting to about £350 will be awarded to collections of fruit, vegetables, and other subjects—in all sixty-seven classes. It is added that growers in the Channel Islands will not be allowed to compete with English cultivators, except in the open classes, an arrangement which will doubtless be approved of, as on former occasions much dissatisfaction has arisen from allowing Jersey growers, who are favoured with a better climate than ourselves, to compete in the same classes with English cultivators.

A PRETTY TOWN GARDEN.—With a little trouble and taste the small but valuable spaces to be found in front of town houses might be converted into charming little gardens. One of these which I noticed the other day in the neighbourhood of Chelsea might be advantageously taken as an example. It is about 25 ft. square, and fenced round, but the fences are completely hidden by a white Jasmine, literally covered with blossoms. Two plants of this Jasmine are also trained on each side of the windows which themselves as well as a small balcony, are gracefully draped with a mixture of Virginian Creeper, scarlet *Nasturtiums*, Blue *Convolvulus*, Creeping Jenny, and *Tropæolum canariense*, all easily grown plants and admirably adapted for such purposes. On the shady side of the Jasmine hedges are planted Ferns amongst rough stones, and on the sunny side annuals of various kinds. In the centre (which is Grass) is a fine specimen of *Rhus glabra* (one of the most valuable of town shrubs), and round its base is a mass of Blue *Lobelias*. The effect of this arrangement was charming. Where more variety is desired it may easily be had, as there are numbers of other plants which thrive equally well in most of our small suburban gardens.—S. E.

THE KITCHEN GARDEN.

VEGETABLE CROPS.

SELDOM have vegetables of all kinds been better or more abundant than they are this year, a circumstance for which we ought to be thankful, seeing that our fruit crops are a failure. Potatoes have never been finer; all our Ash-tops are now (August 4) safely stored in the seed sheds, laid thinly on boarded shelves, and not one do I find diseased. We are now using Myatt's Kidney—the yield of which is marvellous, and the quality unique. I have this day lifted for a local exhibition twenty-two roots of International Kidney which yielded $6\frac{1}{2}$ st. of Potatoes, such as would gladden the heart of any cultivator, being large in size and clear in the skin, level all over, the eyes almost invisible, and, above all, although not nearly ripe, very excellent in quality. Another Kidney of the silver-skinned type, called Patterson's Milky White, although not so large as International, is of the very best description; in fact, for making what our chefs call Sausage Potatoes, for second-course vegetables, it is all that could be desired. Regents, Victorias, and later Potatoes generally, promise to be abundant; the haulm is strong and healthy, and has that deep green colour which is so desirable. Peas, except those sown in November, have been and still are most abundant. A west border here, manured heavily and dug deeply, is planted with four of my especial favourites, viz., G. F. Wilson, Marvel, Dr. Maclean, and Standard. These grow from $3\frac{1}{2}$ ft. to $4\frac{1}{2}$ ft. high—a very good height—and they are literally one mass of pods from top to bottom. Criterion, a new Pea grown here this season, promises to be remarkably sweet and sugary; with me it grows from 5 ft. to $5\frac{1}{2}$ ft. in height, and bears its pods in pairs. It is a fine cropper, and withstood the biting east wind last April bravely. Taylor's new Pea Richard Gilbert, a cross between Ne Plus Ultra and Silver Gem, will be heard of by-and-by. Sutton's Main Crop is surely a pure stock of G. F. Wilson and New Wrinkled Marrow, of the British Queen type; it grows 6 ft. in height, and is a Pea which promises to be in all respects good. Last, but not least, comes a selection of my Hobart Pasha, which I shall be happy to distribute in small quantities for trial next season. Onions, both autumn and spring-sown, are very fine, clean, and large, and amongst them none are better than the true Reading and James' Long Keeping. Red Tripoli is so strong that I have discarded it; White Italian Flat, on the contrary, is so mild and good that no other is needed, except Little Queen for earliness and pickling purposes. Carrots, half of which have always failed here, are this year a full crop, the result of dressing the land at seed time with salt, soot, and lime. Of varieties we use Early Horn and James'; Early Nantes, grown so admirably by Mr. Pragnell at Sherborne, I never yet got true. Beet, Parsley, and Salsify are full crops. Cauliflowers and Broccoli have been in every way excellent; Snowball is a little early gem; for winter, Veitch's Self-protecting Broccoli is one of the best, but for a later crop I like Watt's Excelsior. For planting all kinds of winter vegetables I have never known a finer season; we have Brussels Sprouts 3 ft. high, and they are just beginning to button. For sowing seeds, too, of Endive, Lettuces, Cabbages, Onions, and Carrots for next spring, the glorious rains which we have had have left the land in the best possible condition. R. GILBERT.

Burghley.

AUTUMN-SOWN ONIONS.

In this neighbourhood these have almost superseded the spring-sown crop, which during the past few years has suffered dreadfully from the ravages of the Onion fly, whilst the autumn-sown crops have escaped with little or no injury from that pest. The ordinary routine of culture is to sow the seed during the month of August, according to locality and situation, usually in beds 5 ft. or 6 ft. wide, and in drills 10 in. or 12 in. apart. If the soil be dry, the seed-bed must be kept moist by watering until the young plants are up, when the only attention required is keeping the surface clean by frequent hoeings until March, when beds of deeply-cultivated and well-enriched soil must be prepared for the reception of

the seedlings. We usually spread a good dressing of soot or wood ashes on the surface of the ground, working it in with a rake, and finely breaking the soil; the beds are then marked off and the plants inserted in rows 1 ft. apart, varying the distance in the row according to the size which the variety usually attains. The Giant Rocca and similar sorts may be 1 ft. apart each way, as they grow to a large size. As regards culture, the principal points are frequent surface stirrings and dressings with any rich material, such as fowls' or pigeons' manure, guano, or wood ashes. Any that show signs of running to seed or becoming thick-necked are pulled up for use, and the bulk of the bulbs will be fit for harvesting about the first week in August, for if left in the ground too long, they are liable to start rooting and growing afresh, whereby the keeping qualities of the crop are considerably diminished. J. GROOM.

Henham.

WINTER BROCCOLI.

A GOOD Winter Broccoli is invaluable where a continuous supply of vegetables is required; for, although where efficient means of protection are at hand, Cauliflowers or Snow's Broccoli may be had in good condition up to Christmas, there is still a long interval before the so-called early spring kinds can be relied on to come into use. Veitch's Self-protecting Autumn Broccoli, however, promises to be a most useful addition to our list of early winter vegetables, for if planted in succession it continues to produce heads from November onwards. I have just planted a large quarter of this and Snow's After Early Peas. I do not dig, but merely level the ground and draw deep drills 2 ft. 6 in. apart, making the holes with a crowbar 2 ft. asunder in the rows; strong plants are then inserted with the roots a good depth in the ground, and one good soaking of water starts them into active growth. They do not suffer from drought in solid ground nearly so much as in loosely dug soil, as the evaporation is reduced to a minimum; the growth is also more solid and robust, and better calculated to withstand sudden variations of temperature. I also make later plantings in a similar manner, but in smaller quantities, as in mild autumns they continue to grow very late; in fact, Snow's Broccoli has oftener come in too soon than too late; but in cold weather Broccoli heads may be kept in good preservation by laying and covering with Fern fronds or litter, which I consider preferable to lifting and storing in pits or houses, as a confined atmosphere soon deteriorates the flavour. J. G.

Potatoes.—Although fears were entertained early in the season that Potatoes would prove an indifferent crop, on account of the haulm generally coming up thin and spindly, the recent genial rains have caused the plants to make excellent growth, and at the time of writing the crop generally has seldom looked better. Evidences of the disease are not wanting, both in leaf and tuber, but only in a restricted sense; its spread will greatly depend upon the weather, and if warm sunny days should prevail no great cause for despondency will result. Already considerable breadths of Ashleaf Kidneys, Bresee's Prolifio, Dalmahoy, and other early kinds have been lifted, as from 3s. 6d. to 4s. 6d. per bushel is a tempting price, with the certainty of no bad Potatoes at present. The main crop growths are Regents and Victorias, with here and there Dawe's Matchless and White Belgian Kidneys. Dawe's Matchless is a first-rate market Potato, as, if grown in soil of a moderate quality, it will return a good crop of clear white Kidneys of a good size immediately in succession to the Ashleafs, and such a sample will invariably command a good price in the market. The American Rose, although still largely grown, is not in good favour with the consumer, but its cropping qualities are tempting to the grower. White kinds invariably meet with most favour at all times. Flourball was largely grown for a few years, but it is now seldom met with in the market gardens in this neighbourhood. Victoria still holds its place here as a late Potato, and it is probable that it may shortly be supplemented by such robust field kinds as Schoolmaster and Magnum Bonum.—A. D., Bedford.

Veitch's Self-protecting Broccoli.—Allow me to endorse the remarks of your correspondent "W. W. H." (see p. 107) in reference to this fine self-protecting Broccoli. It is without doubt the finest early winter Broccoli in cultivation; your correspondent's remarks, too, could not have been made at a better time, as all who wish can now procure plants of it, and I feel sure that when once grown it will afterwards recommend itself.—R. GARNFIELD, Priory, Warwick.

ASPECTS FOR FRUIT GARDENS.

IN the interesting description of Kentish fruit gardens (see p. 101), allusion is made to the high estimation in which eastern aspects are held by fruit growers in comparison with southern slopes, not only, as the writer says, because vegetation is later (a statement with which I fully agree), but because in the event of destructive spring frosts the sun strikes the trees more gradually, thawing and drying the blossoms without injuring them, whereas in southern aspects they are suddenly exposed to the full force of the sun's rays while in a frozen state, and suffer accordingly. I have no wish to question the soundness of the views in this respect held by Kentish fruit growers, as circumstances alter cases as much in fruit growing as anything else; but from my own experience of the effect of the sun's rays on frozen blossoms or vegetation of any kind, I am positive that eastern aspects suffer more than others. In flat districts like this, the ground-level has perhaps not so important a bearing on aspect as more hilly districts, but walls and borders in various aspects illustrate the effect which the sun's rays would have on hill-sides, and certainly the advantage is in favour of western aspects, not only as regards receiving the sun's rays after the crops on them are gradually thawed and dried, but what is of equal importance, they get the benefit of the latest sun's rays and also an increased amount of latent heat given out during the night. This is the conclusion at which I have arrived: but if I am wrong I shall be glad to be set right. The best aspect on which to plant is well worth careful consideration, as every year fruit culture assumes more important dimensions; and even in the best private establishments what are generally termed common fruits constitute the staple supply, not only for everyday consumption for culinary and dessert purposes, but for preserving for use during the long winter months. The great demand that exists this year for fruit for preserving is shown by the fact that purchasers from great preserving factories are traversing even remote districts like this and buying up all the market garden produce at higher rates than local retail dealers can afford to give in order to ensure a profit. That this branch of fruit culture, with a reasonably intelligent investment of skill and capital, might be converted into a flourishing trade is certain, as the demand for such fruits is always in excess of the supply.

J. GROOM.

Henham.

NOTES FROM KEW.

WE are glad to see that the cultivation of *Stapelia*s is now being attended to at Kew. The flowers of these peculiar plants exhibit a great variety of form, colour, and size. More than 100 species have been in cultivation, but at present we doubt if more than half that number can be found in European gardens. Many of those figured and described by Masson in his "*Stapeliae Novae*," at the close of last century, have been totally lost, and we fear that some may have been exterminated in their native haunts, owing to the wholesale sheep-farming which has obtained of late years in the South of Africa. We thought that the *Stapelia*s were perfectly safe from attack; we, however, now learn, on undoubted authority, that the bitter (though, it appears, non-poisonous) stems are readily eaten by goats. At present there are in flower *S. variegata*, *S. europaea*, *S. mutabilis*, *S. coronata*, and the new *S. Sarpedon* var. *major* and *S. flavirostris*. *Duvallia radiata* and *D. angustiloba* are in good condition. No figure of *Huernia primulina* has as yet been published; it is a charming little plant, and, as might be expected from its name, the flowers are somewhat Primrose-like, both in size and colour. *Hoodia Barkleyi* is also in bloom; the flowers are large, campanulate, not nearly so prettily marked as in many allied genera. H. Gordon finds a place near the last species, and will interest all lovers of these extraordinary and extremely rare succulents. The new *Decalobone Barkleyi* is flowering freely; its flowers are very like those of *D. elegans*, but the branches have nearly twice the number of angles; the spines, too, are different. In the same house there is a fine specimen of a South American terrestrial Bromeliad—*Bromelia antiochiantha*—with a fine panicle of purplish flowers. The young leaves, which are of a reddish colour, and the large white bracts render this plant very attractive; the full-grown leaves are from 3 ft. to 4 ft. long, armed with stout hooked spines, some pointed towards the tip of the leaf, others towards its base. In some parts of Brazil and the Argentine Republic, this and some allied Bromeliads cover immense tracts of country, and form in some places almost impenetrable

barriers, through which the traveller has to cut every yard of his way; this has earned for them the name "plague of the camp," by which they are known to travellers and soldiers. We expect shortly to hear much more about them, as an English gentleman has obtained great concessions from the Argentine Government, and intends utilising the fibre which abounds in the leaves; we believe that it has been proved very good both as a textile and paper-making material. In the cool end of the New Range there are several specimens of *Campanula Vidalii*, one of the most distinct and beautiful of the plants of the Azores. So far as is known, this species is absolutely confined to a single rocky island off the east coast of Flores. It has never been gathered but once, and that was some twenty years ago by Captain Vidal, during his survey of the island. The long, upright racemes of waxy, pure white, drooping flowers make this a most desirable acquisition. The deep orange annulus seated on the disc, when one looks into the flower, affords a fine contrast to the ivory-like whiteness of the corolla.

In the Winter Garden the Mexican *Rhodochiton velubile* is admired by every one. The mass of the plant is trained to a horizontal wire near the glass, and extends for more than 20 yards. From this bar a fringe of branches from 3 ft. to 6 ft. long is allowed to hang naturally; each branch is covered with flowers, and the whole forms a splendid object. Even after the dark tubular corollas have fallen, the large, somewhat persistent, lilac calices are very handsome. As seen at Kew, this is one of the most beautiful of climbers.

Seeds Injurious to Animals.—Mr. Francis Darwin, in his interesting paper on "Hygroscopic Mechanism," by which certain seeds are enabled to bury themselves in the ground, refers to the fact that the seeds of *Stipa pennata* are said to be capable of injuring the intestines of animals which feed upon it. A similar property is shared by *Aristida hygrometrica*, a Grass which is locally abundant in the northern parts of Queensland. Mr. Charles Prentice says of this species that it is fatal to sheep by reason of its long tripartite awns getting entangled in the wool, and ultimately piercing the skin and penetrating to the viscera of the thorax and abdomen, causing death after prolonged wasting and suffering; the heart, liver, and kidneys are sometimes, on dissection, found pierced by these mischievous awns in all directions.—B. M.

The Edelweiss Protected by Law.—This fluffy white flower, dear to Alpine climbers and superstitious brides, is at length, according to the "Graphic," to be legally protected, such a measure being rendered necessary to prevent the plant from becoming totally extinct. In the Eogadine a law has been passed prohibiting the sale of the Edelweiss in its fresh and living condition, the first offence to be visited with a fine of 4s. The Swiss children are the worst offenders, as they pull up the plant roughly by the roots, and pester travellers to buy a small bouquet of Edelweiss, or other "Alpen blumen," for 50 cents., while in the tourist season nearly every passenger in the homeward-bound steamers to the Swiss lake-side towns wears a tuft in his hat as a trophy of his mountaineering exploits, be they even confined to a railway trip up the Righi.

Grapes Setting Without Fire-heat.—There is one of our houses here—half Vinery, half Peach-house—not heated. The Vines consist of Black Hamburgh, Lady Downes, Buckland Sweetwater, and Black Alicante. They were all in flower in May, and all are now furnished with finely-formed, well set bunches, except the Black Alicante; not one of the berries on this variety has stoned; therefore they have not swelled, and I can attribute this to nothing else than want of sufficient heat when the berries were setting.—VIRIS.

Carmine-flowered Candytuft.—Messrs. Carter & Co. have sent us out blooms of this Candytuft, which will doubtless be largely grown when better known, its colour being somewhat unusual amongst Candytufts. It is of good habit, and flowers freely in spring and early summer.

Soft or Silver Maple.—The well-known Soft Maple (*Acer dasycarpum*) is highly esteemed for shade and timber, on account of its exceedingly rapid growth and beautiful foliage. It ripens its seed in this latitude about the last of May, and the seed should be sown as soon as possible after it is gathered. If sown in June or July, it makes a larger growth the first season than Sugar Maples sown the previous autumn.—"Country Gentleman."

Cercasus ilicifolia.—This fine Californian evergreen has lately been in flower at Syon House. It is a native of Western America, and has beautiful evergreen leaves like those of a Holly. It bears in its native woods on the Pacific coast numerous deep red berries about 1 in. long.

Egg-plants.—Fruit of these may now be seen in Covent Garden, where they find a ready sale. Though too tender for outdoor culture in this country, where frames and pits exist they may be grown successfully in that way, and with little or no trouble.—S.

HIGH ROCKS IN BOLD PARK SCENERY.

THESE high rocks in the foreground of our sketch once formed parts of the walls of an old quarry; now they are richly draped with the common Ivy and with Virginian Creeper. Given a knowledge of plants and some feeling for their wants, almost any kind of surface may be made beautiful—perhaps this kind easiest of all. Such rock walls invite a novel kind of decoration easy to carry out. Cliff and wall drapery—curtains of flowers as well as the usually graceful wandering shoots of climbing and creeping plants. A whole world of beauty exists in hardy flowering climbers and creepers (both shrubby and herbaceous) which, with a little care and thought, would show to great advantage in our gardens. There are without the garden proper in many country seats surfaces and positions more or less like that illustrated, which could with ease be made beautiful gardens. By flowering climbers and creepers are meant such subjects as the various hardy species of Clematis among shrubs, and the Everlasting Pea among herbaceous plants.

THE GARDEN OF BRITISH WILD FLOWERS.

THE CROWFOOTS (RANUNCULUS).—The popular name Crowfoot, taken from the divided leaves of our Buttercups, is hardly applicable to all the 160 species of this genus, since many have undivided leaves. Still less generally applicable is the name Buttercup, since others have white flowers; they all agree, however, in possessing numerous stamens and heads of numerous dry fruitlets, with other technical characters. The genus inhabits the temperate regions of the globe, and extends partly into Arctic Europe, being represented in Britain by some thirty or forty species, mostly inhabitants of the water or the neighbouring moist meads, of which some eight or ten are of interest to us as gardeners. Mention or suggestion has been already made of the bank, the clump, the rockwork, the lawn, the wood, and the corn-field, as the scenes on which the varied beauties of our wild flowers are displayed. We now come to a group entirely inhabiting the water, and as the water, natural or artificial, should be one of the most attractive features in

Ivy-clad Rocks in Park.

The large-flowering new Clematises are likely to be taken care of in gardens, but there is a host of wild species even more graceful in habit, and bearing crowds of pretty flowers which are rarely seen in cultivation. Planted above the walls, banks or rocks, and allowed to fall naturally over them, such plants would arrange themselves in various charming ways, and annually increase in beauty. Opportunities for planting on the face of the cliff should also be taken advantage of. Broad ledges or deep fissures may sustain subjects of vigorous growth, while many plants will grow in such places without any apparent nutriment. Varied charms are only to be added to a scene of this kind by developing different types of vegetation on different parts of the rocks or banks instead of the usual error of repeating the same note everywhere. Where such a system is carried out, curtains both of Ivy and Virginian Creeper would find a place, but would not be the main or the only features. Attention may be called to the wide open lawns beyond the rocks in our sketch, which show a breadth and simplicity very desirable in bold garden scenery.

any garden possessing it, we must be glad of every additional charm we can lend it. The Water Crowfoots are distinguished by their white flowers, smooth leaves floating on the surface below which they often bear finely-cut, thread-like leaves, suited for this submersion, and by an absence of those acrid properties which distinguish the land plants of the group. This last peculiarity renders them a useful food for cattle, who are very fond of them. The forms valuable for beauty belong to the aggregate species (*Ranunculus aquatilis*), and though we need not concern ourselves as to the relative systematic value of the variations to which different botanists assign specific, sub-specific, or varietal rank, the beauty of these forms is very diverse. All agree in having white petals, each with a yellow base, between which in some may be seen the green points of the sepals, but while some have no floating leaves, others have no submerged ones, and the size of the flower is very variable. Thus *Ranunculus circinatus*, which is recorded in Dr. de Crespigny's "New London Flora," from the Roding, near Hainault Forest, and from ditches in Moor Park, Farnham, though

without floating leaves, is noteworthy for its large flowers; *Ranunculus fluitans*, a large and distinct form, growing in the deep and rapid parts of the Thames, the Lea, and the Colne, is also destitute for the most part of floating leaves, but has large flowers, sometimes with two whorls of petals and

Water Crowfoot (*Ranunculus floribundus*).

fine, long submerged leaves, often from 6 in. to 10 in. in the length of their segments; but perhaps the most generally useful will be *Ranunculus floribundus*, a form with, as its name implies, numerous flowers, which are large and are admirably set off by three-lobed floating leaves, whilst, if the water be clear, as all ornamental water should be, the short, radiating segments of the submerged leaves render this form an epitome of the beauty of the group. It is fortunately not uncommon—being recorded from near Sunningdale, from Walthamstow, and from the Wey at Elstead, whilst I believe it is this form which occurs in a pond south of Surbiton, on Epsom Common, and at Burgh Heath, Banstead. A locality may probably be found for it in most neighbourhoods. It is suited for stagnant or gently-running water, and should be grown in an isolated patch or island not touching the bank. A very different plant is the Great Spear-wort (*Ranunculus Lingua*), one of our grandest waterside plants, inhabiting marshes and ditches, unfortunately rather rarely from Moray southwards. It grows about 3 ft. high, or even more, and has smooth leaves nearly 1 ft. in length and 1 in. broad, with yellow flowers nearly 2 in. in diameter, which appear from July to September. It is altogether a noble plant, and should be associated on the water's margin with the Water Plantain and Great Water Dock, the Iris, the Bulrush, and the Royal Fern; or it may be planted with advantage in the marshy, long-grassed, water meadow, with Marsh Marigolds, Ragged Robin, and Cotton Grass. It is recorded as growing on Totteridge Green, Herts, in ponds on Uxbridge Moor, on Iver Heath, Bucks, and at Cookham, Berks. Every one knows, or

Double Buttercup (*Ranunculus acris* fl.-pl.).

thinks he knows, a Buttercup. Under this name, however, three or four distinct species are confounded. The Meadow Crowfoot (*Ranunculus acris*), distinguished by having no runners or bulbous base to the stem, is universally common in moist meadows or by roadsides, and is the first of the group to

flower. It varies in height from a few inches to 3 ft., and blooms from April to September. The beauty of this plant consists in its branching habit, cut leaves (closely resembling those of some *Pelargoniums*), and the glossy golden-yellow of its petals contrasting with its pale green calyx. A valuable double form is in cultivation, in which shape is not all lost, whilst the mass of colour is increased. It is suitable to grow anywhere, but would seem specially in place where the Grass is left to grow. The Creeping Buttercup (*Ranunculus repens*) is similar in many points of beauty to the last; but has long runners, and a lower, more compact habit. It grows, moreover, on waste ground, and mostly in dry situations, and is, therefore, suited to the rock-garden. A double form of this also is in cultivation; it blossoms from May to August, and the wild plant is common in every neighbourhood. The Bulbous Buttercup (*Ranunculus bulbosus*) is not quite so universally distributed as the two last-mentioned species, and

Double Creeping Buttercup (*Ranunculus repens* fl.-pl.).

perhaps loses in beauty by the green sepals being reflexed. It has no runners, but a bulbous stem: it frequents the same situations as *Ranunculus acris*, but flowers only during May and June. Here again we have a double form in cultivation. This species seldom exceeds 1 ft. in height, and its blossoms

Double Bulbous Buttercup (*Ranunculus bulbosus* fl.-pl.).

are rather smaller than in the two others. Among bright little annuals suited for the company of Pheasant's-eye, Poppies, and Corn-flowers, we may notice the Corn Crowfoot (*Ranunculus arvensis*), whose numerous lemon-yellow flowers afford a shade somewhat unfrequent among our wild plants. It is a low-growing, nearly smooth plant, flowering from May to July, but not very common in the corn-fields round London. The love of flowers is perhaps more real and universal with us in our heaven-encircled infancy than in maturer but more sordid manhood, and among the favourites of our childhood none were more treasured than the Nature-gilt Kingcup, Pilewort, or Lesser Celandine (*Ranunculus Ficaria*), with the bright gloss of its kidney-shaped leaves, which act as mirrors for the yet brighter star-pointed flowers "that come before the swallow dares"; the companions of the first Violets, Primroses, and Anemones of the year. This plant is common everywhere, in woodland and hedge-row, in cool damp places, and, bright in the "raging moon of Daffodil and Crocus," well deserves a place on some bank or in some coppice of the

wild garden, amid its just-named compeers, Mossy stumps and trailing Ivy. A special beauty, which this flower has apart from other *Ranunculi*, is, in addition to its extraordinary gloss, the sharply-pointed outline of the petals, the triangular rays of a star rather than the bellying sides of a *Goldencup*, as in the *Buttercups*.

THE PHEASANT'S-EYE (*ADONIS AUTUMNALIS*).—It is chiefly in the corn-field, the domain of Ceres, that this plant occurs. This, with its scarlet flowers and somewhat southern distribution, shows it plainly to be only a naturalized alien in this country. Its finely divided leaves and bright petals with a dark centre render it a most attractive plant for dry, sunny spots or for the rock garden. It grows from 6 in. to 10 in. in height, branched and very leafy, and it flowers from May to July. It is not uncommon in the chalky corn-fields of Kent, in Suffolk, Essex, the Isle of Wight, Dorset, and Wiltshire, but is local in other counties. It occurs on the continent of Europe, in Western Asia and North Africa, but is only an introduced plant in America. The park or garden is generally separated from the surrounding fields by an impenetrable fence;

The Pheasant's-eye (*Adonis autumnalis*).

but it would surely be often feasible and seemingly most nature-like, and therefore desirable that the two should merge into one another through a strip in our corn-fields, in which such plants as this, with Poppies, Corn-cockle, Corn-bluebottle, Scabious, and such like, might luxuriate without dread of the practical agriculturist. If necessary this half-cultured strip might be divided from the clean land by a ditch or sunk fence of any width.

G. S. BOULGER.

TREES IN TOWNS.

THIS is a subject which naturally occupies a large share of public attention, especially among those whose lot is cast in or near our more important centres of industry. Londoners are much better off for trees than the inhabitants of such commercial centres as Manchester and Liverpool, not to mention many smaller, but still very important, manufacturing towns of Lancashire and Cheshire; and the noxious agencies against which tree life has to contend in these districts are more varied, as well as more deadly, than those with which we in the south have to deal. It is only by the bringing together and comparing of experiences that satisfactory information upon the subject can be obtained; and it is, therefore, with much satisfaction that we observe the Manchester Field Naturalists' Society has taken up the matter. From their last report, which is now before us, we glean a few facts which we think will be useful to our readers; a recent visit to Manchester and one or two other places in the neighbourhood enables us to supplement these from our own observation.

Most visitors to Manchester probably include the Cathedral, or "the old Church," as it is more generally called, in the objects of interest which they feel it incumbent on them to inspect; and these cannot fail to be struck with the fact that there are few places where practical knowledge upon tree-growth in towns is more urgently needed. They cannot avoid seeing the miserable results of the attempt to beautify the churchyard by the planting of trees and shrubs—results which

might be anticipated from the following accurate criticisms offered by Dr. Bahin:—It struck him, he says, from casual observations made in other places, and more particularly in Continental towns, "that the trees recently planted in the Cathedral yard were too small, that they were planted too close to each other, that they had no protection whatever about the stems or roots, nor any provision for collecting or retaining moisture, and lastly, that they were imbedded in a soil which was not congenial to them." We have received from an eye-witness an account of the *modus operandi*—differing but little from that adopted of old by Procrustes towards the unfortunate wretches who fell into his hands—observed in the planting of the unhappy dying or dead Poplars, Rhododendrons, &c., which at present lend an additional melancholy to the Manchester Cathedral yard, and afford scope for the small witticisms of the local comic papers; and we can testify that the end attained is exactly what might have been expected from the means employed. The Manchester city authorities have certainly much to learn with regard to tree planting. It was only the other day that Mr. Faraday, the Secretary of the Manchester Field Naturalists' Society, read a paper on the subject, in which he speaks of yet more recent operations in this direction. Richmond Grove, Longsight, has been flagged, and circular holes have been cut in the flags so that these latter might fit neatly round the trunks of the trees which adorned the margin of the road! The same plan had been adopted towards a tree in the Oxford Road, which is already dying; and Mr. Faraday justly characterised such a proceeding as "spoiling good flags without saving the trees."

The two principal sources of danger to which trees in Manchester are exposed, arise from noxious matter present in the atmosphere, and pernicious to the food taken in by the leaves; and from equally noxious matter permeating the soil and finding its way to the roots. Besides these, Mr. Faraday directs the attention of the Corporation to the ravages of those whom the ardent dendrophilist might term, with Mrs. Leo Hunter, "fiends in shape of boys," who have "literally hacked to pieces" an avenue of Lime trees in the Albert Road. But the conduct of these persevering trees under such adverse circumstances speaks volumes in favour of their suitability for town culture. "Even while suffering from the most frightful wounds," says Mr. Faraday, "the foliage looked fresh and green, and when only a few inches of stump were left protruding from the ground they continued to put out leaves." The Lime, according to Mr. Faraday, is the tree which thrives best in the Manchester district, and this opinion is supported by Mr. R. H. Alcock, who finds that at his residence at Bury, about nine miles north of Manchester, his Limes indicate perfect health. Mr. Grindon gives as a result of the opinions of those whom he consulted a recommendation of the Hawthorn as the tree most likely to thrive under the adverse influences of the Manchester atmosphere; then the Elder, and after that the Plane. There is no doubt that the Plane is a capital London tree, indeed, it shares with the Lime the honour of being considered the most useful tree in the metropolis; but it may be doubted whether it would be equally successful at Manchester; at any rate, six Plane trees planted by Mr. Alcock at Bury, would not grow at all: the last-named gentleman, however, speaks very highly of the Hawthorn. The condition of Victoria Park, Manchester, is very encouraging, in spite of the smoke and noxious emanations to which it is exposed from the more important manufacturing suburbs during the prevalence of east and north winds. "With slight exceptions, the trees all looked well. In the flowering season they were richly adorned and fragrant; and, bearing in mind that the park was comparatively quite a modern creation, their increasingly umbrageous character and fine proportions were subjects for congratulation. The Sycamores were very healthy, and the Elms, Beeches, and Birches showed no symptoms of deterioration; the Ash also was doing well." The experience of practical men is quite opposed to the planting of Poplars in Manchester, although they have been recommended, and are among the present occupants of the cathedral yard. At Bury they make very rapid growth at first, and then die; Mr. Alcock pointed out to us many instances where they had been planted, and in all cases with this result. He has at present two Black Italian Poplars, a Balsam Poplar, and four or five Abeles, which have all been

planted within the last six years, and look healthy enough, but he knows from experience that they will soon die, as he has already removed about two score of them. Only a week or two since we observed at the Clifton Junction Station, between Bury and Manchester, a long row of Poplars which, with scarcely an exception, were quite dead. Curiously enough, Mr. Alcock says that "at Gatley, which is about the same distance from Manchester on one side that Bury is on the other, the Poplar in all its sorts grows well; but the climate is quite different, and the flora on the Gatley side of the city is altogether more rich."

The Rhododendron is the shrub which seems to do best in the smoky neighbourhoods of these manufacturing towns. We were at Bury just at the time when these beautiful plants were in full blossom, and we have never seen better examples, either for size and healthiness of the shrubs themselves, or for the magnitude and colour of the trusses of flowers as well as the individual blossoms. With the exception of those in the Manchester churchyard, all that we saw in the district were doing well. Mr. Alcock, after between twenty and thirty years' residence at Bury, says that it will grow satisfactorily even in the most smoky situations, and without any particular care being taken as to the soil in which it is planted, while, curiously enough, at Evesham, in Worcestershire, where the atmosphere is pure and the climate genial, Rhododendrons will not grow. At Bury the Wych Elm, Sycamore, Birch, Horse Chestnut, Turkey Oak, and Beech do well; so do Laburnums and Hollies, but Laurels are not satisfactory. In the neighbourhood of this town, however, the native or quasi-spontaneous tree vegetation shows in many cases the sad effects of smoke. The upper and younger branches are naturally the more early affected, dying off at the tips and showing symptoms of feebleness in growth; while the native vegetation of hedgebanks and roadsides is sparse and monotonous. The small woods and cloughs are often, however, remarkably verdant, owing to the dense undergrowth of *Holcus mollis*—a Grass which seems to luxuriate in the atmosphere which is fatal to so many other herbs, and literally covers the ground for spaces of considerable extent.

But bad as are the effects of smoke, "worse remains behind." The noxious emanations from alkali and other chemical works are far more disastrous in their effects; and Mr. Edward Green, chief gardener for twenty-five years at Bank Park, Warrington, has recorded with painful accuracy the changes which have been caused during that period by dense smoke and noxious vapours. He has recorded these changes in connection not only with trees but as regarding shrubs and undershrubs; but we shall confine ourselves to such extracts from his notes as concern the former only. Since the development of manufacturing, Conifers have fared the worst. *Pinus austriaca* is the only Fir which will exist, and even this has

failed in many places, while Yew trees which were very healthy fifteen years ago have given way: so that it would appear that Conifers can scarcely exist in a chemically impure atmosphere. We have lately visited Norton, a small village not more than four miles from Runcorn, an important manufacturing town, itself only about eight miles from Warrington: and in company with Mr. Robert Holland, agent to Sir Richard Brooke, of Norton Priory, have inspected different portions of the estate. As is probably known to most of your readers, a Royal Commission is still sitting with the object of investigating the damage which the estate has received from certain alkali works; and the evidences of such damage are painfully apparent to the most casual observer. At Norton, however, the Scotch Fir, as well as the Austrian Pine, is comparatively uninjured by the gases, while Larches will not grow. The Sycamore does well here, at any rate, for a considerable period, and, being a quick grower, soon attains a respectable size; at Warrington, too, according to Mr. Green, it stands moderately well, except in very exposed situations, the several varieties being, however, very dissimilar in constitution. "Different

varieties growing side by side have been observed, and year after year the same varieties are affected, those standing best that are earliest in foliage." The Variegated Sycamore, however, is nearly extinct at Warrington, where it has "struggled hard." "I have seen," says Mr. Green, "the leaves reappear three times in one season, after being successively destroyed; under such conditions the tree must eventually succumb. The Horse Chestnut," he continues, "is fast giving way; in early spring the leaves look very promising, but when the winds carry the

Pilocereus fossilatus (Houlletii) in fruit.

vapours to them they are severely damaged, and this occurring from time to time, the wood cannot ripen, and the ends of the shoots die." The Lime, which, as we have seen, is proof against the smoke of Manchester and Bury, cannot stand the vapours of Warrington, and suffers in a similar manner, while the Ash, Beech, and Lombardy Poplar, which stood the smoky atmosphere very fairly until a few years ago, have begun to disappear very rapidly before the increased quantity of noxious vapours which has recently been given off from forges and chemical and other works. The Weeping Ash, however, is standing very well, although the common one is fast decaying. Besides the trees just named, the Acacia (*Robinia Pseudacacia*), Lilac, Common and Portugal Laurels, *Laurustinus*, *Pyrus japonica* and *Pyracantha* may be added to the list of plants which have survived smoke, but have become dead or sickly since the increase of vapours. At Norton, Oaks and Beeches are the principal sufferers; at Warrington, however, two Oaks (*Quercus pedunculata* and *Q. Cerris*) are reckoned by Mr. Green among the more hardy trees. Some of the evergreen shrubs are much disfigured by chemical products falling upon them; but smoke is probably quite as disagreeable in this respect. Mr. Green considers that

smoke alone does some damage, as the coating of the leaves with carbon prevents the free respiration of the plants, which are found to grow much better when frequent showers wash the dirt off the leaves; plants subject to the exudation known as honeydew, and also some with rough leaves, get coated and suffer most. This was the case in Warrington until there was an increase in sulphurous and other chemical emanations, and then the smooth-leaved trees began to give way. The following is Mr. Green's catalogue of trees and shrubs, planted in Bank Park two or three years ago in an exposed situation. The plants are classified according to their success; they constitute a border 400 yards long, with a west aspect:—(1) Ontario Poplar, English Elm, Alder, Plane, Elder, Privet, Hypericum, Rhododendron, Eonymus japonica, Aucuba, Evergreen Oak, Holly. (2) Birch, Abele, Willow, Sycamore, Turkey Oak, ornamental Thorns, Laburnum, Dogwood, Ailantus glandulosus, Sumach. (3) Double-blossomed Cherry, Lilac, White, Yellow, and Spanish Broom. (4) Ribes, Ash, Acacia, Azalea pontica, Box, Mahonia Aquifolium, Pinus austriaca. (5) Walnut and Flowering Ash (very sickly). (6) Juniper (all dead). The whole of these trees have been exposed to smoke and vapours from a series of works, extending from the south-west to the north-west, the emanations being of a very deleterious character. We trust that the Manchester Field Naturalists will continue to devote attention to this most important subject of the growth of trees in towns; and we shall look with interest for their next report, which we believe will contain much additional information bearing upon the matter in question. J. B.

Pilocereus fossulatus (Houlletii) in flower.

***Pilocereus fossulatus* (Houlletii).**—This is one of the most singular plants in the genus to which it belongs; it is known in some collections as *P. Celsianus*, but it is a stronger grower than that kind, and is crowned with more and longer tufts of white hair, which, however, on the old plants disappear, vanishing gradually as growth increases. I only once saw its flowers, which closed in about three hours after they first opened. They are blackish-green or mouse-coloured, and are produced nearer the top than in the *Cereuses*. It likes plenty of sunshine, and will succeed in the temperature of an ordinary greenhouse. Has any one seen the Old Man Cactus (*P. senilis*) in flower in this country? There is something so weird-looking about these Old Men Cacti that one feels half inclined to question them as to their origin and utility. Their individuality is so striking that to many people they are full of interest.—J. CROUCHER, *Sudbury House, Hammersmith.*

Bird's-nest in a Human Skull.—The cases of birds building in hothouses recorded in *THE GARDEN* have brought to my mind an instance perhaps still more remarkable. When at Hockwold Hall in Norfolk, five or six years ago, one of the workmen brought me a human skull, which he had dug up. Owing to the place where it was found, and its peculiar shape, I hung it up in the potting shed on a nail by the wall, when some time after I was surprised to see a wren fly out of it, and on taking it down found that it had built its nest in it, and laid four or five eggs.—F. TRIBETT CHILVERES, *Hunstanton.*

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Fine-leaved Plants.—One of the greatest evidences of an improved taste in gardening matters is the estimation in which fine-leaved plants are now generally held, so different from the prevailing taste that so long existed in growing little in our greenhouses save blooming subjects, amongst which those producing the most gaudy flowers were often awarded the preference. For room and window decoration, many plants grown for the beauty of their leaves are much better adapted than the majority of flowering subjects, not only for the effect they produce, but, on account of their enduring character. Many amateurs who only possess a cool greenhouse are under the impression that there are comparatively few fine-leaved plants that they can grow, supposing that most of these require a stove or intermediate-house for their cultivation; yet this is by no means the case, as there are numbers of handsome variegated-leaved plants, in addition to those with green foliage, that vie in their elegance of form, or the beautiful colours of their leaves, with many from tropical countries. Amongst the most beautiful of the variegated-leaved subjects suitable for a greenhouse is the Japanese *Eurya latifolia variegata*, a plant almost hardy in the south of England, but particularly suited for greenhouse culture; the centres of the leaves, which are about the size of those of an Orange, and similar in substance, are bright green, margined with white when fully matured, tinged with red whilst young; the habit of the plant is not unlike that of *Croton variegatum*, to which it is quite equal in appearance; it is easily grown, succeeding well in either peat or loam, to which a moderate amount of sand has been added. Drain the pots well; as it is a free rooter, care must be taken that it never wants for water. The plant is of a naturally pyramidal habit, branching freely without much shoot pinching. It

is little subject to insects, but should be syringed freely with clean water once or twice a week during the growing season to keep it free from red spider, which will sometimes attack it. Whilst small, it is a capital plant for a sunny window.

Abutilons.—*A. vexillarium variegatum* is a small-leaved, variegated variety, which, in addition to its handsome foliage, bears very attractive flowers. *A. Thompsoni* has a fine appearance intermixed with flowering subjects on a greenhouse stage; it looks the best for this purpose grown on a single stem some 2 ft. or 2½ ft. in height, in which condition it can be had in a 6-in. or 7-in. pot; both these plants are of the easiest possible growth, succeeding in ordinary loam to which has been added a little leaf-mould and sand; cuttings put in now from half-ripened wood will make plants quite large enough for the above purpose next summer, after which they can be headed down or replaced by young ones annually prepared.

Aralias.—The gold and silver variegated forms of *Aralia Sieboldi* grown to single stems are handsome plants; they have ample palmate foliage, thrive well in any ordinary soil, and are best raised from cuttings taken off with a heel from plants that have been headed down; they strike readily at any time of the year when procurable 5 in. or 6 in. in length, inserted in small pots in sand, kept moist and covered with a bell-glass in a little heat. *A. reticulata* is an elegant-growing, handsome-leaved species, of much more slender habit than

the preceding; it does well in peaty soil, not requiring so much room as the above-mentioned kinds.

Aspidistra lurida variegata.—This is an evergreen herbaceous plant that attains a height of 2½ ft.; the leaves are lanceolate in form, stout and persistent, marked longitudinally with broad bands of green and white in about equal proportions; it is easily increased by division of the roots at any time when not in active growth; it will succeed with the simplest treatment in ordinary garden loam. It is one of the best room plants, the foliage remaining in good condition in an ungenial atmosphere longer than most plants; when so used it should be syringed and sponged occasionally to free it from dust.

Centaureas.—*C. argentea*, *C. Clementei*, and *C. ragusina* associate well with other plants, either in the greenhouse or the window of a living room. Seeds sown at the present time, or within the next two months, will make healthy plants for the ensuing season if grown in any ordinary soil in 6-in. pots.

Coprosma Baueriana variegata is another easily-grown, variegated plant of a somewhat soft-wooded character; for decorative purposes it looks best grown up with a single shoot tied to a neat stick, stopping it from time to time to induce it to break outside branches, which also occasionally should have their points nipped out to produce a sufficiently compact habit; it strikes best from comparatively soft young shoots, produced from branches that have been stopped, taken off with a heel, inserting them, half-a-dozen together, in 4-in. pots in sandy soil in a little warmth, kept moist and covered with a propagating glass; any common soil, to which has been added a little leaf-mould and sand, will answer its requirements.

Phormium tenax variegatum (Variegated New Zealand Flax).—This is a tall-growing, evergreen, herbaceous plant, with leaves not unlike those of the common English Iris; they rise to a height of 4 ft. or 5 ft., and are striped longitudinally with yellowish-white over about one-third the surface, the rest green. From its erect habit of growth it looks well mixed with Pelargoniums, Fuchsias, or other ordinary greenhouse plants, for which purpose it is much better confined to moderate-sized (say 8-in. or 10-in.) pots, than when grown in masses, such as often seen when exhibited. It is easily managed, succeeding perfectly in loam, to which add a little leaf-mould and sand; it is increased by division of the roots, which operation should be performed before growth commences in the spring.

Yuccas.—*Y. variegata*, *Y. quadricolor*, and *Y. Stokesi*, all forms of the Aloe-leaved variegated Yucca, are amongst the best and most enduring of fine-leaved greenhouse plants; the two latter species are of comparatively dwarf habit, and are many years before they get too large for even a small house; they will succeed well in either peat or loam, made sufficiently porous by the addition of sand; they may be increased from suckers, which the plants at times, but not always, throw up from the root; if these be severed in the spring from the parent stock, they will generally be found to have some roots; they should be placed singly in pots just large enough to hold them, and kept if possible in a little warmth until they have commenced growth and got established. Any old specimens that have got naked and bare at the bottom should have their heads taken off either early in the season or at the present time, removing a few of the bottom leaves, inserting in pots sufficiently large to hold them, in a mixture of half sand and loam, keeping them a little confined until they have rooted, but not too moist for fear of causing them to rot; if the portion of stem remaining be cut into pieces 1 in. long, and these be put half their depth in sandy soil in pots placed in a little warmth and kept just moist, they will root through the winter, the stump left will break up from the bottom, or the stool, after heading down, may be allowed to remain, when if the roots just receive enough water to keep the soil slightly moist, it will break out young growths, which, when they have made half-a-dozen leaves each, may be taken off with a heel and struck singly. *Y. filamentosa variegata* is a very distinct and beautiful plant, and although hardy in some parts of the kingdom, is never so handsome when grown out-of-doors as when in a pot under glass, for the leaves in the open air are short and erect, whereas when cultivated indoors they attain double the length and curve in an elegant manner, the plant altogether growing much larger than outside. Though long in the country, through the great demand there has been for it, it is anything but plentiful, a circumstance in some measure attributable to the majority of people being ignorant as to the best mode of propagating it. Any one possessing a stout plant should now take it out of the pot, shake away the whole of the soil, and then remove all the strongest leaves, cutting them clean away from the underground stem. The thicker roots should then be cut up into pieces 1 in. in length and inserted 1 in. apart in pots drained and filled with a mixture of half sand or loam, or sand and peat, dibbling them in so as to leave nothing above the surface except the extreme upper end; they

should then be gently watered and at once placed in a moderate hot-bed, or in any house or pit where they will be kept a little warm; in the course of a couple of months they will commence growth, forming small crowns, at the same time making root-fibres; they may thus be kept on growing through the autumn, when they should be moved singly into small pots, or if there be not the means of keeping them during the winter in a temperature of 50° or 60°, they had better not be potted until spring. In the course of the ensuing summer they will make good plants. The old plant thus partially deprived of its roots should immediately be placed in the same or a smaller pot, and put where it will get a little warmth till it is re-established in growth.

Acacias.—Amongst handsome green-leaved subjects suitable for greenhouse decoration may be named *Acacia lophantha*, a plant with elegant Fern-like leaves, which may be grown to a very large size, but for the purpose under consideration amateurs will find it much more useful confined to a single stem in pots from 6 in. to 8 in. in diameter; it is one of the freest of free growers, doing well in either sandy peat or loam; it can be increased from either seeds or cuttings put in now in a hotbed and kept on growing through the autumn. *Aralia crassifolia*, *A. leptophylla*, and *A. quinquefolia* are all handsome plants; they, too, look the best confined to a single stem, as the leaves are of a persistent nature. If kept clear from insects they will remain fresh down to the base of the plants until they have attained a height of from 3 ft. to 5 ft.; they are not quite so free to strike as some things, but with these, as almost everything else that does not root readily, amateurs will succeed the best by making cuttings of the young shoots that break after a plant has been partially cut down. When these are removed entire from the old wood that has produced them, that is, taken off with a heel, as is understood by this process, few will fail to root; put in small pots, kept warm, and a little moist, and covered with a propagating glass, they will make good plants in a single season.

Dracena indivisa is a plant of large growth, but one of the most elegant subjects in existence, suitable for occupying a central position in an amateur's greenhouse. If small plants be obtained now or in the spring, and moved on into larger pots as they require it, they will go on for years until they have attained a height of 8 ft. or 10 ft. Evergreen plants of this sort must never be allowed to want for water at the roots; a Geranium or Fuchsia, if left to get so dry as to cause it to flag, although in nowise benefited by it, is generally not much worse; but subjects of this description, whose leaves are of a persistent nature, it causes the lowest near the base to decay and fall off prematurely—a condition which destroys half the beauty of the specimens. This *Dracena* should be well syringed on both upper and under sides of the leaves once a week during summer, to prevent the attacks of red spider, to which it is somewhat liable, and which, if allowed to gain a footing, will soon affect the bottom leaves, so as to make the plant bare at the base. *Grevillea robusta* is another Fern-like plant of the most elegant description, and will succeed well in every way, both as to propagation and after management, if treated as recommended for *Aralias*.

Lomatias.—*L. elegantissima*, *heterophylla*, *silafolia*, and *fernginea* are all beautiful plants; they are of a hard-wooded, slow-growing nature, and are years before they get too large for even a small house. They are easily grown in loam or peat, but are rather difficult to propagate; cuttings in a half-ripened condition, obtained from shoots that have been cut back, should be taken off with a heel and put singly in small pots in a mixture of sand and peat—keep warm and cover with a bell-glass. They sometimes take months to form roots: when they are plentifully furnished with these, move into pots a size or two larger; they do not at any time require a great amount of root-room.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

August 13.—Sowing Black-seeded Brown Cos, Stanstead Park and All the Year Round Lettuces. Putting in cuttings of Heliotrope, Fuchsia, and Tricolor Pelargoniums. Planting Endive and Lettuce. Preparing soil for Pine-apples; potting and re-arranging the Black Jamaica Pine-apples. Cutting back Laurels and other shrubs overhanging the walks in the pleasure grounds. Stopping the laterals through all the Vineries; watering Celery, Lettuce, Endive, Cabbage, and Walcheren Broccoli, the weather being dry.

Aug. 14.—Sowing Sweet Basil in pots, also Mustard and Cress. Potting a few more Cinerarias and Primulas. Putting in Pelargonium cuttings. Putting one house-full of Smooth-leaved Cayenne Pines into

fruiting pots, using equal parts of loam and peat, and adding abundance of silver sand. Mowing. Clearing off Strawberry runners. Watering the Pines all through; also Carrots, Onions, Celery, Lettuces, Endive, Cabbage and Broccoli plants.

Aug. 15.—Sowing Chirk Castle Black Stone Turnips. Potting Cyclamens and Coleus. Putting in a few more Centaurea outtings. Lifting Ashpot Fluke Potatoes. Thinning Spinach, Lettuce, and Endive. Turning manure previously mixed with salt and soot for general crops. Mowing, weeding, and cleaning in the pleasure grounds. Gathering first out-door Peaches. Watering carpet bedding plants, also the early Peach-house, Scarlet Runner and Dwarf Beans.

Aug. 16.—Potting and re-arranging a large house of Smooth-leaved Cayenne Pines. Putting tiffany over Vinery lights to keep off wasps and flies. Looking over the Peach trees and removing nails, ties, and leaves, where not required. Picking over carpet bedding. Turning manure for a Mushroom bed. Mowing, weeding and clearing in the pleasure grounds. Watering late Peas, Celery, and Strawberry runners on turf.

Aug. 17.—Sowing last crop of Spinach; also Mustard and Cress. Covering the Peach walls with netting. Pulling up all spring-sown Onions and laying them out with the roots upwards to dry. Lifting part of a collection of Potatoes. Clearing off a batch of Broad Beans. Watering Peas, Celery, Lettuce, Endive, and Strawberry runners; also Pines.

Aug. 18.—Potting and putting away Pine snokers. Looking over all the Vineries, and taking off laterals and the shanked berries. Renovating manure linings round all frames. Picking over and weeding the carpet bedding. Cleaning the gravel walks in the kitchen garden. Clearing off a piece of Peas and hoeing the ground ready for other crops. Cleaning up mould-yard, sheds, tools, &c. Fruit in use for dessert:—Pines, Melons, Grapes, Peaches, Figs, Cherries, Pears, and Apples.

SEASONABLE NOTES.

Late Gathering of Rhubarb.—Rhubarb should only be gathered sparingly after this date. I have known plantations seriously injured by clearing off the late crop for wine making. A moment's consideration will assuredly convince any one that a certain amount of foliage is necessary for the healthy development of the buds or eyes for next year's supply.

Sowing Winter Onions.—The first or second week in August is the best period for sowing Winter Onions. A well-drained, well-cultivated plot should be selected, but if in good heart it need not be freshly manured. In addition to the Tripoli varieties, sow a good breadth of Spanish, Globe, and James' Keeping for transplanting early in spring. This is the only plan in difficult situations and seasons to ensure a good crop of large bulbs. South of London the sowing of the three latter kinds I have named may be delayed till towards the end of the month. The Silver-skinned is a good kind also for autumn sowing, as it turns in quickly in spring.

Sowing Winter Spinach.—It is well to make two or three sowings of Winter Spinach at intervals of ten days or so, commencing at the present time. Where the soil is of a heavy, retentive character, at least one of the sowings should be made on the driest and warmest spot available, as it not unfrequently happens, during a wet or cold winter (unless some such precaution be taken) that a great number of the plants will perish. Ground that has not been deeply dug just previous to sowing is usually less retentive of moisture, and consequently warmer in winter than if freshly and deeply stirred. I am speaking of heavy land only.

E. HOBDAV.

MARKET GARDEN NOTES.

Bush Fruits.—These generally have been a fine crop, and are being now cleared off with great rapidity; indeed, ere this appears in print, the bulk will have been marketed. In spite of recent rains the fruit has been gathered in good dry condition, and as a rule, in well-cultivated gardens, it is exceedingly fine. Black Currants are paying well this year, bringing to the grower 3s. 6d. per strike of 16 lb. of fruit. At this price few crops can pay better, as the Black Currant is not only one of the most regular croppers, but is easily cultivated. Fine young clean bushes of about five or six years old, kept well thinned and shortened back, have produced really superb crops; I have seen nothing better as a paying crop this season than long lines of such bushes as these at 6 ft. apart, and single rows of stout Strawberry plants between. Gooseberries sold well whilst green, and although not a heavy crop the berries were exceedingly fine; the ripe

fruit is now fetching 3s. 6d. per strike, and selling freely; the favourite sorts are Crown Bob and Lancashire Lad. Red Currants are but sparingly grown in this locality, but as the old fruit gardens around London are being crowded out by builders, the supply will gradually fall off, and more bushes must be planted to meet the inevitable demand; the Houghton Castle is one of the best of all Red Currants for market work. With Red Currants should be grown Raspberries, as both are simultaneously inquired for. One of the very best of all market Raspberries is Northumberland Fillbasket.

Winter Greens.—The proverbial "oldest inhabitant" almost fails to remember a more favourable season for the setting out of Winter Greens than this has been. Curiously enough, also, the greater part of the plants in the seed-beds were comparatively free from the fly in the spring. Potatoes are more commonly intercropped with Winter Greens than are Peas, as the pickers amidst the latter do the young plants considerable mischief; the Peas can also be gathered soon enough to allow the ground to be ploughed and the plants well established for the winter supply. Brussels Sprouts are usually put out at about 3½ ft. apart, with a row of Runner Beans sown between. Brussels Sprouts have little market value unless got out early, and induced by plenty of room and manure to make a very robust growth during the summer. The principal Winter Green crops of the Brassica family grown for market are Brussels Sprouts, Sprouting Broccoli, White Broccoli, Drumhead, Savoy, and Enfield Market Cabbages, and Coleworts; other spare ground is filled with Winter Spinach (a good paying crop, if well grown) and White Turnips. Sowings of both these should be made at once in order to secure a good crop; and if showers continue, it will be possible to have plenty of Turnips ready for winter consumption.

Peas.—The Pea crop has been one of the best known for many years, in spite of late frosts and cold chilling winds. The light showers that fell during the latter part of June, and the heavier rains since, assisted materially to set the bloom and swell the pods. Peas have been fetching various prices, ranging from 3s. to 6s. per bushel, according to time and quality, and the result has always been remunerative. Peas are less time in the ground and are, as a crop, less risky than Potatoes; the earlier kinds are cleared off by the end of the first week in July, and all the main growths by the end of the month, thus leaving the ground at liberty for a second crop quite early in the summer. Sorts do not greatly change, the principal varieties being Sangster's No. 1, Harrison's Glory (a dwarf early round blue), Laxton's Supreme (a robust kind that crops well), and Veitch's Perfection (a tall marrow). The three first kinds are hardy, but deficient in flavour, and are grown chiefly because they are hardy and safe croppers. It is rather singular that so few of our fine dwarf marrows have come into use generally for market cultivation; such excellent garden sorts as Premier, Best of All, Omega, G. F. Wilson, and others, are scarcely known in market gardens, yet they are all good croppers, and, as a rule, more productive than Veitch's Perfection. Perhaps they have not yet been brought down to the market growers' price, or perchance to many they are unheard-of novelties. I have been endeavouring to obviate this want of acquaintance with good dwarf marrows by furnishing some growers with small quantities of sorts that appear to me to be both well suited for market work and superior to the sorts generally grown, and during the present season have induced one grower who sends to market some thousands of bushels annually to sow in an open field several kinds so as to give them the test of field culture. Of these there were included both Laxton's Unique and William the First, the former a dwarf selection from the latter. Perhaps the one is as much too dwarf as the other is too tall, but as Unique can be sown at 20 in. apart, wants but little handling, and is a real first early, I think it is a most useful market kind, in which opinion the grower coincided, and decided upon giving it a trial next year. In immediate succession came Dean's Dwarf Marrow, a new first early marrow of the Advancer type, but dwarfer, hardier, and a better cropper; this grows 20 in. in height, and is of the finest quality. Of other kinds in immediate succession came Robert Fenn, Dr. Maclean, Premier, James's Prolific, East Anglian, Market Favourite, and Omega. Of these East Anglian and Market Favourite are nearly allied to Supreme, and are of similar quality; Robert Fenn is a very large-podded, dwarf marrow, 20 in. in height, a heavy cropper, and of the finest flavour, evidently well suited for the market. In the field Dr. Maclean grows 2½ ft. in height, as does also Premier; these Peas closely assimilate in general character, but Dr. Maclean has rather longer pods; both, however, proved to be fine market Peas. James's Prolific, although productive of fine pods, affords but one good picking in the field; Omega, on the contrary, is a first-class late Pea. 2 ft. in height, crops heavily, the pods rich deep green, well filled, and of fine flavour. Dean's Dwarf Marrow and Robert Fenn are not yet in commerce; but Dr. Maclean, Premier, and Omega may be safely recommended as good market marrows.

A. D.

PLATE LXXXVI.

LILIUM THOMPSONIANUM.

It may surprise some to be told that the plant of which the annexed is a representation is sometimes a Lily, and sometimes a Fritillary. It has been alternately referred to the genera *Lilium* and *Fritillaria* by different botanists, and even now it is doubtful whether it has found a permanent resting-place; it is one of those plants which puzzle botanists, and it illustrates the fact that it is often as difficult to characterize genera as it is to define species. It reminds us that there are no hard and fast lines in Nature, and that all Orders, Genera, and Species are more or less artificial, and liable to be disturbed in their limitations by new forms found in a wild state or raised in gardens. Admitting this law, we must also recognize the fact that all definitions of groups of plants of whatever degree are more or less arbitrary, according to the views of their authors; therefore, when we get a plant like the present, which is intermediate in character between two otherwise easily-defined genera, botanists are almost certain to disagree as to what it should be called. For convenience it must have a name, and in giving it a name several things have to be considered—amongst others, whether, seeing that it is intermediate between two previously distinct genera, these two genera should be united; whether a new genus should be established for this troublesome plant; or whether it should be referred to one of the existing genera. And the proper course to be followed appears to be that which least upsets existing nomenclature or unduly increases the number of genera. Our plant was originally described by David Dou ("Prodromus Floræ Nepalensis") as *Fritillaria macrophylla*, and Mr. Baker, in his revision of the Tulipeæ ("Linnean Society's Journal," vol. xiv.), retains this name for it, placing it in a sub-genus having the floral characters of *Lilium* and the scariosus-coated bulbs and distinctly three-lobed style of *Fritillaria*. Messrs. Loddiges imported and flowered it about the year 1844, and it was figured in the "Botanical Register" under the name of *Lilium Thompsonianum*. Previously, however, D. Don had described a second variety or state in Royle's "Illustrations of Indian Plants," t. 92, as *Fritillaria Thompsoniana*. Some years after its first appearance in English gardens, Strachey re-introduced it from the Himalaya Mountains, where it occurs up to an elevation of 8000 ft.; and in 1853 it flowered at Kew, and was figured in the "Botanical Magazine," t. 4725, as *Lilium roseum*. Although the figures quoted represent different varieties, it was not disputed that they should be referred to one and the same species; hence the value of this somewhat complicated synonymy to Lily growers. In different collections some of these various names are still in use, and there is always a risk of purchasing or otherwise obtaining at some trouble a plant that one already possesses under another name, unless one knows that certain names belong to the same species. With limited means or space it is vexing to be taken in in this way. Respecting the development of the bulb of this species and its propagation from bulblets, Duchartre has written very fully in the "Annales des Sciences Naturelles," série 5, vol. xvi., and his paper is illustrated with three plates. Mr. Baker's description, drawn up from a number of dried and living plants, will aid in giving an idea of the general range of variability of this species:—Bulb ovoid, 1 in. thick, clothed with several scariosus coats 2 in. or more in length, striped on the outside, and bearing bulblets in their axils; stem $1\frac{1}{2}$ ft. to 3 ft. high, erect, round, and smooth; leaves twenty to thirty, directed upwards, narrow, bearing bulblets in their axils, lower ones crowded, 12 in. to 18 in. long, 3 lines to 4 lines broad, upper ones looser and shorter; flower-spike 12 in. to 18 in. long, bearing six to thirty flowers; flowers, when expanded, 3 in. to 4 in. across, lower ones nodding, upper ones smaller, half erect; a native of Afghanistan and the North-west Himalayas. There is only one other species of this sub-genus (*F. Hookeri*), and this is very closely allied, differing more in size and in the shape of the perianth segments than in anything else. This is a native of Sikkim Himalaya, where Dr. Hooker collected it at an altitude of from 9000 ft. to 10,000 ft.

W. B. HEMSLEY.

Concerning the cultivation of this Lily, Dr. Wallace of Colchester writes to us as follows:—As there has been a difficulty experienced in flowering this Lily in Europe, I subjoin a communication from a correspondent, since dead, in which its native habitat and mode of growth are described. The elevation of the locality of *Lilium roseum* (*Thompsonianum*) about Mussoorie varies from 5000 ft. to 6000 ft. on the outer or southern spurs running down towards the plains. Latitude about 26° N. The temperature of these slopes in March and April, which is the flowering season of this species, is frequently very warm, and the earth, from the rocky nature of the soil, retains considerable heat. At this season refreshing showers are usually frequent. The plants are always as a rule found growing upon the slopes, and I might say never in flat ground. The surface-soil to a depth of from 2 in. to 3 in. is a rich vegetable mould composed of decayed leaves and grasses, acting like a top-dressing; beneath this is a bed of small broken fragments of limestone, through which the flower-stalks descend to the bulb, which is formed in what may be termed a fine limestone sand. This becomes from the bulb upwards to the surface coarser and coarser, the bulb lying at various depths, sometimes near the surface and sometimes 4 in. or 5 in. deep. From the slope of the hillside and the porous nature of the soil the drainage is perfect, but the sand is by no means so dry as to be devoid of moisture. Some European cultivators are inclined to cavil at my saying that these bulbs do not thrive well in earth, although at the same time they prove me to be correct, from their statement that their bulbs so treated are annually exhausted and rot away, leaving only a number of small bulblets in their place. Now I did not mean to assert that this bulb can never be reared in earth, because I have myself sometimes succeeded in doing so: but then the soil was carefully kept from too much moisture. I can but record what I see to be the mode of treatment to which Nature resorts, and I do not seek to improve or teach her. The natural soil is a fine, highly porous, limestone gravel, becoming a limestone sand as it descends; it is often hundreds of feet deep, and beneath it runs a belt of greenstone, by which when the hills were upraised the limestone was crushed into fragments of every size, and in some places, instead of the limestone, we encounter an outcrop of greenstone, or a deep bed of finely-comminuted Lydian stone. Nature then points out that the proper soil for this species is a porous limestone gravel, with a top-dressing of fine, rich vegetable mould; but if, disregarding her instructions, we plant the bulb in a rich earth and on a flat surface, the moisture being greater than the plant requires, the bulb rots away and expends its strength in flowers and bulblets. This year I planted several roots of full size in good earth, and nearly the whole rotted away, leaving plenty of offspring, but the flowers were poor; others planted in poor, stony soil, and sheltered, gave good flowers, and all remained sound. Now they are all in limestone sand, and for the future will remain so. In this soil they remain exposed to the full force of the wet monsoon, from the beginning of June to the end of September, and although the rain descends sometimes for a week together in a perfect deluge, such is the porous nature of the soil that the Lilies thrive and remain uninjured. When once they are found to succeed in their own soil, let them alone, for I hold that the system of digging them up every autumn is injurious and wrong; they will stand any amount of cold, and are sometimes covered for a month or more with 2 ft. of snow. Left in their natural soil, and if possible on a slope among long coarse Grass and dwarf shrubs, the bulbs, far from rotting, will annually increase in size until full grown, throwing off numerous bulblets, while the flowers produce an abundance of seed. Cultivators at home are far too fond of coddling, forcing, and manipulating.

The plant was figured in the "Revue Horticole," and our plate was made after M. Riocreux's original drawing, acquired from the proprietors for this purpose.

The Cut-leaved Birch.—Mr. W. C. Barry, of Rochester, New York, who is now travelling in this country, tells us of his surprise in not noticing examples of this valuable tree in our gardens. It is a very graceful and remarkable tree at Rochester, a specimen having already attained a height of 40 ft. Five thousand trees of it are annually worked in the Mount Hope Nurseries at Rochester (Messrs. Elwanger & Barry's).

LILIUM THOMPSONIANUM

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 112).

Strawberry.

- (1) *Iago*. Have you not sometimes seen a handkerchief
Spotted with Strawberries in your wife's hand?
Othello, act iii., sc. 3.
- (2) *Ely*. The Strawberry grows underneath the Nettle
And wholesome berries thrive and ripen best
Neighbour'd by fruit of baser quality;
And so the prince obscured his contemplation
Under the veil of wildness.
Henry V., act i., sc. 1.
- (3) *Glo'ster*. My Lord of Ely, when I was last in Holborn,
I saw good Strawberries in your garden there:
I do beseech you send for some of them.
Ely. Marry, and will, my lord, with all my heart.
Where is my lord protector? I have sent
For these Strawberries.
King Richard III., act iii., sc. 4.

The Bishop of Ely's garden in Holborn must have been one of the chief gardens of England in the fourteenth and fifteenth centuries, for this is the third time it has been brought under our notice; it was celebrated for its Roses (see Rose); it was so celebrated for its Saffron Crocuses that part of it acquired the name, which it still keeps, Saffron Hill; and now we hear of its "good Strawberries," while the remembrance of "the ample garden," and of the handsome Lord Chancellor, to whom it was given when taken from the bishopric, is still kept alive in its name of Hatton Garden. How very good our forefathers' Strawberries were, we have a strong proof in old Isaak Walton's happy words: "Indeed, my good scholar, we may say of angling as Dr. Boteler said of Strawberries—'Doubtless God could have made a better berry, but doubtless God never did;' and so, if I might be judge, God never did make a more calm, quiet, innocent recreation than angling." I doubt whether, with our present experience of good Strawberries, we should join in this high praise of the Strawberries of Shakespeare's or Isaak Walton's day, for their varieties of Strawberry must have been very limited in comparison to ours. Their chief Strawberry was the wild Strawberry brought straight from the woods, and no doubt much improved in time by cultivation. Yet we learn from Tusser that it was the custom to grow it just as it came from the woods.

Wife, into thy garden, and set me a plot
With Strawberry roots of the best to be got:
Such growing abroad, among Thorns in the wood,
Well chosen and picked, prove excellent food.

The Gooseberry, Respis, and Rose all three
With Strawberries under them trimly agree.

September's Husbandry.

Besides the wild one (*Fragaria vesca*), they had the Virginian (*F. virginiana*), a native of North America, and the parent of our scarlets; but they do not seem to have had the Hautbois (*F. elatior*), or the Chilian, or the Carolinas, from which most of our good varieties have descended.

As a fruit the Strawberry is among fruits what the Primrose and Snowdrop are among flowers, the harbinger of other good fruits to follow. It is the earliest of the summer fruits, and there is no need to dwell on its delicate, sweet-scented freshness, so acceptable to all; but it has also a charm in autumn, known, however, but to few, and sometimes said to be only discernible by few. Among "the flowers that yieldeth sweetest smell in the air," Lord Bacon reckoned Violets, and "next to that is the Musk-rose, then the Strawberry leaves dying, with a most excellent cordial smell." In Mrs. Gaskell's pretty tale, "My Lady Ludlow," the Strawberry leaves act an important part. "The great hereditary faculty on which my lady piqued herself, and with reason, for I never met with any other person who possessed it, was the power she had of perceiving the delicious odour arising from a bed of Strawberry leaves in the late autumn, when the leaves were all fading and dying." The old lady quotes Lord Bacon, and then says:—"Now the Hanburys can always smell the excellent cordial odour, and very delicious and refreshing it is. In the time of Queen Elizabeth the great old families of England were a dis-

tinged race, just as a cart-horse is one creature and very useful in its place, and Childers or Eclipse is another creature, though both are of the same species. So the old families have gifts and powers of a different and higher class to what the other orders have. My dear, remember that you try and smell the scent of dying Strawberry leaves in this next autumn, you have some of Ursula Hanbury's blood in you, and that gives you a chance." "But when October came I sniffed, and sniffed, and all to no purpose; and my lady, who had watched the little experiment rather anxiously, had to give me up as a hybrid." ("Household Words," vol. xviii.). On this I can only say in the words of an old writer, "A rare and notable thing, if it be true, for I never proved it, and never tried it; therefore, as it proves so praise it."

There is a considerable interest connected with the name of the plant, and much popular error. It is supposed to be called Strawberry because the berries have straw laid under them, or from an old custom of selling the wild ones strung on straws. In Shakespeare's time straw was used for the protection of Strawberries, but not in the present fashion.

If frost do continue, take this for a law
The Strawberries look to be covered with straw,
Laid evenly trim upon crotches and bows,
And after uncovered as weather allows.

Tusser—"December's Husbandry."

But the name is much more ancient than either of these customs. Strawberry in different forms, as Strea-berige, Streaberie-wisan, Streaw-berige, Streaw-berian wisan, Streberilef, Strabery, Strebere-wise, is its name in the old English vocabularies, while it appears first in its present form in a pictorial vocabulary of the fifteenth century, "Hoc ffragram, A^c a Strawberry." What the word really means is pleasantly told by a writer in Seeman's "Journal of Botany," 1869:—"How well this name indicates the now prevailing practice of English gardeners laying straw under the berry in order to bring it to perfection, and prevent it from touching the earth, which without that precaution it naturally does, and to which it owes its German name *Eidbeere*, making us almost forget that in this instance 'straw' has nothing to do with the practice alluded to, but is an obsolete part-participle of 'to strew,' in allusion to the habit of the plant." This obsolete word is preserved in our English Bibles, "gathering where thou hast not strawed," and in Shakspeare—

The bottom poison, and the top o'erstrawed
With sweets.

Venus and Adonis.

From another point of view there is almost as great a mistake in the second half of the name, for in strict botanical language the fruit of the Strawberry is not a berry; it is not even "exactly a fruit, but is merely a fleshy receptacle bearing fruit, the true fruit being the ripe carpels, which are scattered over its surface in the form of minute grains looking like seeds, for which they are usually mistaken, the seed lying inside of the shell of the carpel." It is exactly the contrary to the Raspberry, a fruit not named by Shakespeare, though common in his time under the name of Rasps. "When you gather the Raspberry you throw away the receptacle under the name of core, never suspecting that it is the very part you had just before been feasting upon in the Strawberry. In the one case the receptacle robs the carpels of all their juice in order to become gorged and bloated at their expense; in the other case the carpels act in the same selfish manner upon the receptacles" (Lindley, "Ladies' Botany.")

Shakespeare's mention of the Strawberry and the Nettle (No. 2) deserves a passing note. It was the common opinion in his day that plants were affected by the neighbourhood of other plants to such an extent that they imbibed each other's virtues and faults. Thus sweet flowers were planted near fruit trees with the idea of improving the flavour of the fruit, and evil-smelling trees, like the Elder, were carefully cleared away from fruit trees, lest they should be tainted. But the Strawberry was supposed to be an exception to the rule, and was supposed to thrive in the midst of "evil communications" without being corrupted. Preachers and emblem-writers naturally seized upon this—"In tilling our garden we cannot but admire the fresh innocence and purity of the Strawberry, because although it creeps along the ground, and is continually crushed by ser-

pents, lizards, and other venomous reptiles, yet it does not imbibe the slightest impression of poison, or the smallest malignant quality, a true sign that it has no affinity with poison. And so it is with human virtues," &c. "In conversation take everything peacefully, no matter what is said or done. In this manner you may remain innocent amidst the hissing of serpents, and, as a little Strawberry, you will not suffer contamination from slimy things creeping near you" (S. Francis de Sales).

I need only add that the Strawberry need not be confined to the kitchen garden, as there are some varieties which make very good carpet plants, such as the variegated Strawberry, which, however, is very capricious in its variegation; the double Strawberry, which bears pretty white button-like flowers; and the *Fragaria lucida* from California, which has very bright shining leaves, and was, when first introduced, supposed to be useful in crossing with other species; but I have not heard that this has been successfully effected.

Sweet Marjoram (see Marjoram).

Sycamore.

- (1) *Desdemona* (singing). A poor soul sat sighing by a Sycamore tree.
Othello, act iv., sc. 3.
- (2) *Benvolio*. Underneath the grove of Sycamore
That westward roveeth from the city's side,
So early walking did I see your son.
Romeo and Juliet, act i., sc. 1.
- (3) *Boyet*. Under the cool shade of a Sycamore
I thought to close mine eyes for half an hour.
Love's Labour's Lost, act v., sc. 2.

In its botanical relationship, the Sycamore is closely allied to the Maple, and was often called the Great Maple, and is still so called in Scotland. It is not indigenous in Great Britain, but it has long been naturalized among us, and has taken so kindly to our soil and climate that it is one of our commonest trees. The history of the name is curious. The Sycamore, or Zicamire tree of the Bible and of Theophrastus and Dioscorides, is the Fig-mulberry, a large handsome tree indigenous in Africa and Syria, and largely planted, partly for the sake of its fruit, and especially for the delicious shade it gives. With this tree the early English writers were not acquainted, but they found the name, and applied it to any shade-giving tree. Thus in Ælfric's Vocabulary in the tenth century it is given to the Aspen—"Sicomorns vel celsa æps." Chaucer gives the name to some hedge shrub, but he probably used it for some thick shrub, without any very special distinction—

The hedge also that yedde in compas
And closed in all the greene herbere
With sicamour was del and eglateere
Wrethen in fere so well and cunningly
That every branch and leafe grew by measure
Plaine as a bord, of an height by and by.

The Flower and the Leaf.

Our Sycamore would be very ill suited to make the sides and roof of an arbour, but before the time of Shakespeare it seems certain that the name was attached to our present tree, and it is so called by Gerarde and Parkinson.

The Sycamore is chiefly planted for its rapid growth rather than for its beauty. It becomes a handsome tree when fully grown, but as a young tree it is stiff and heavy, and at all times it is so infested with honeydew as to make it unfit for planting on lawns or near paths. It grows well in the north, where other trees will not well flourish, and "we frequently meet with the tree apart with the fields, or unawares in remote localities amidst the Lammernmirs and the Cheviots, where it is the surviving witness of the former existence of a hamlet there. Hence to the botanical rambler it has a more melancholy character than the Yew. It throws him back on past days, when he who planted the tree was the owner of the land and of the Hall, and whose name and race are forgotten even by tradition. . . . And there is reasonable pride in the ancestry when a grove of old gentlemanly Sycamores still shadows the Hall" (Johnstone). But these old Sycamores were not planted only for beauty: they were sometimes for a very unpleasant use. "They were used by the most powerful barons in the west of Scotland for hanging their enemies and

refractory vassals on, and for this reason were called *dool* or grief trees. Of these there are three yet standing, the most memorable being one near the fine old castle of Cassilis, one of the seats of the Marquis of Ailsa, on the banks of the River Doon. It was used by the family of Kennedy, who were the most powerful barons of the west of Scotland for the purpose above mentioned" (Johns).

The wood of the Sycamore is useful for turning and a few other purposes, but is not very durable. The sap, as in all the Maples, is full of sugar, and the pollen is very curious; "it appears globular in the microscope, but if it be touched with anything moist, the globules burst open with four valves, and then they appear in the form of a cross" (Miller).

Thistle (see also Holy Thistle).

- (1) *Burgundy*. And nothing teems
But hateful Docks, rough Thistles, Kecksies, Burs.
Henry V., act v., sc. 2.
- (2) *Bottom*. Good, Monsieur Cobweb, good, monsieur; get your weapons ready in your hand, and kill me a good red-hipped humble bee on the top of a Thistle, and, good monsieur, bring me the honey-hag.
Midsummer Night's Dream, act iv., sc. 1.

Thistle is the old English name for a large family of plants occurring chiefly in Europe and Asia, of which we have fourteen species in great Britain, arranged under the botanical families of Carlina, Carduus, and Onopordon. It is the recognised symbol of untidiness and carelessness, being found not so much in barren ground as in good ground not properly cared for. So good a proof of a rich soil does the Thistle give, that a saying is attributed to a blind man who was choosing a piece of land—"Take me to a Thistle;" and Tusser says—

Much wetness, hog-rooting, and land out of heart
Makes Thistles a number forthwith to upstart;
If Thistles so growing prove lusty and long,
It signifieth land to be hearty and strong.

October's Husbandry.

If the Thistles were not so common, and if we could get rid of the associations they suggest, there are probably few of our wild plants that we should more admire: they are stately in their foliage and habit, and some of their flowers are rich in colour, and the Thistledown, which carries the seed far and wide, is very beautiful, and was once considered useful as a sign of rain, for "if the down flyeth off Coltsfoot, Dandelion, or Thistles when there is no winde, it is a signe of rain" (Coles). But it is owing to these pretty Thistledowns that the plant becomes a most undesirable neighbour, for they carry the seed everywhere, and wherever it is carried, it soon vegetates, and a fine crop of Thistles very quickly follows. In this way, if left to themselves, the Thistles will soon monopolize a large extent of country, to the extinction of other plants, as they have done in parts of the American prairies, and as they did in Australia, till a most stringent Act of Parliament was passed about twenty years ago, imposing heavy penalties upon all who neglected to destroy the Thistles on their land. For these reasons we cannot admit the Thistle into the garden, at least, not our native Thistles; but there are some foreigners which may well be admitted. There is the Fish-bone Thistle (*Chamaepence diacantha*) from Syria, a very handsome plant, and, like most of the Thistles, a biennial; but if allowed to flower and go to seed, it will produce plenty of seedlings for a succession of years. And there is a grand scarlet Thistle from Mexico, the *Erythrolena conspicua* ("Sweet," vol. ii., p. 134), which must be almost the handsomest of the family, and which was grown in England fifty years ago, but has been long lost. There are many others that might easily deserve a place as ornamental plants, but they find little favour, for "they are only Thistles."

Any notice of the Thistle would be imperfect without some mention of the Scotch Thistle. It is the one point in the history of the plant that protects it from contempt. We dare not despise a plant which is the honoured badge of our neighbours and relations, the Scotch; which is ennobled as the symbol of the Order of the Thistle, that claims to be the most ancient of all our Orders of high honour, and which defies you to insult it or despise it by its proud mottoes, "Nemo me impune lacessit," "Ce que Dieu garde, est bien

gardé." What is the true Scotch Thistle even the Scotch antiquarians cannot decide, and in the uncertainty it is perhaps safest to say that no Thistle in particular can claim the sole honour, but that it extends to every member of the family that can be found in Scotland.

Shakespeare has noticed the love of the bee for the Thistle, and it seems that it is for other purposes than honey gathering that he finds the Thistle useful. For "a beauty has the Thistle, when every delicate hair arrests a dew-drop on a showery April morning, and when the purple blossom of a roadside Thistle turns its face to Heaven and welcomes the wild bee, who lies close upon its flowerets on the approach of some storm cloud until its shadow be past away. For with unerring instinct the bee well knows that the darkness is but for a moment, and that the sun will shine out again ere long" (Lady Wilkinson).

Thorns.

- (1) *Ariel*.
Through toothed Briars, sharp Furzes, pricking Goss and Thorns,
Which entered their frail skins.
Tempest, act iv., sc. 1.
- 2) *Quince*. Some one must come in with a bush of Thorns and a lan-
thorn, and say he comes in to disfigure or to present the person
of moonshine.
Midsummer Night's Dream, act iii., sc. 1.
- (3) *Puck*. For Briars and Thorns at their apparel snatch.
Ibid., act iii., sc. 2.
- (4) *Prologue*. This man with lanthorn, dog, and bush of Thorns
Preventeth moonshine.
Ibid., act v., sc. 1.
- (5) *Thorn*. All that I have to tell you is that the lanthorn is the moon;
I the man in the moon; this Thorn bush, my Thorn bush; this
dog, my dog.
Ibid.
- (6) *Dumain*. But alack! my hand is sworn
Never to pluck thee from the Thorn.
Love's Labour's Lost, act iv., sc. 3.
- (7) *Carlisle*. The woe's to come; the children yet unborn
Shall feel this day as sharp to them as Thorns.
Richard II., act iv., sc. 1.
- (8) *King Henry*. The care you have of us
To mow down Thorns that would annoy our foot
Is worthy praise.
2nd Henry VI., act iii., sc. 1.
- (9) *Gloucester*. And I, like one lost in a Thorny wood,
That rends the Thorns and is rent with the Thorns,
Seeking a way, and straying from the way.
3rd Henry VI., act iii., sc. 2.
- (10) *King Edward*. Brave followers, yonder stands the Thorny wood.
Ibid., act v., sc. 4.
- (11) *King Edward*. What! can so young a Thorn begin to prick.
Ibid., act v., sc. 4.
- (12) *Romeo*. Is love a tender thing? It is too rough,
Too rude, too boisterous, and it pricks like Thorn.
Romeo and Juliet, act i., sc. 4.
- (13) *Boult*. A Thornier piece of ground.
Pericles, act iv., sc. 6.
- (14) *Leontes*. Which being spotted
Is goads, Thorns, Nettles, tails of wasps.
Winter's Tale, act i., sc. 2.
- (15) *Florio*. But O, the Thorns we stand upon.
Ibid., act iv., sc. 3.
- (16) *Ophelia*. Do not, as some ungracious pastors do,
Shew me the steep and the Thorny path to Heaven.
Hamlet, act i., sc. 5.
- (17) *Ghost*. Leave her to Heaven,
And to those Thorns that in her bosom lodge
To prick and sting her.
Ibid., act i., sc. 5.

(See also Rose Nos. 6, 18, 22, 30, the scene in the Temple gardens, and Brier No. 11).

Thorns and Thistles are the typical emblems of desolation and trouble, and so Shakespeare uses them; and had he spoken of Thorns in this sense only, I should have been doubtful as to admitting them among his other plants, but as in some of the passages they stand for the Hawthorn tree and the Rose bush, I could not pass them by altogether. They might need no further comment beyond referring for further information about them to Hawthorn, Briar and Rose, and Bramble, but in speaking of the Bramble I mentioned the curious legend

which tells why the Bramble employs itself in collecting wool from every stray sheep, and I find a very curious account of another unexpected connection between Thorns and wool. The original document is given in Latin, in Blount's "Antient Tenures," and is dated 39th, Henry III. It may be thus translated:—"Peter de Baldwyn holds in Combes, in the county of Surrey, by the service to go a wool gathering for our Lady the Queen among the White Thorns, and if he refuses to gather it he shall pay into the Treasury of our Lord the King xxs. per annum." I should almost suspect a false reading, as the editor is inclined to do, but that many other services, equally curious and improbable, may easily be found.

H. N. ELLACOMBE.

(To be continued).

USEFUL WINTER FLOWERING PLANTS.

ALLOW me to give for the guidance of some of your readers a small selection of useful winter-flowering plants that are quick-growing, easily cultivated, showy, and soft-wooded, that anybody can grow with only moderate conveniences in the way of glass structures. Most of them are commonly classed in catalogues as stove plants, but with a close warm pit or low house to propagate and grow them on till July, and with a cold pit or some freely-ventilated structure to mature their growth during summer, they will flower freely and well during winter in a warm greenhouse or conservatory. If very large specimens be required, a few plants of the previous year may be cut back in March and grown on for that purpose; but for most of the decorative purposes for which such plants are applicable, cuttings struck in February will produce plants large enough, and give less trouble, and be in every way more satisfactory than saving the old plants; furthermore, if it be required to fill a large vase, and one plant is not sufficient, three or more may be used. It is scarcely necessary to enter into details, as any one who can grow a Fuchsia or Zonal Pelargonium will meet with no difficulty. The main features in their successful culture are to put the cuttings in as early as possible, selecting good healthy shoots, and as soon as they are rooted, pot them off, and when the roots have become active again, pinch out the leader, and continue potting on and pinching as often as necessary, giving the last shift not later than the end of July, or if they be needed for early autumn blooming, then they should not be potted after the beginning of that month. Equal portions of sandy turfy loam and peat—or if peat be difficult to procure, leaf-mould will answer equally as well—with a sprinkling of sand, to ensure the necessary porosity in the soil, as they will require to be watered freely. The last-named—*Manettia bicolor*—is a small neat creeper, well adapted for planting round the edges of wire baskets, and should be allowed to hang gracefully about over the sides. The following is the selection referred to above:—*Hebeclinium ianthinum*, *Thysacanthus rutilans*, *Begonia insignis*, *manicata*, and *fuchsioides*, *Justicia speciosa*, *Linum trigynum*, *Stevia Lindleyana*, *Eranthemum pulchellum* and *strictum*, *Plumbago rosea*, *Pentas carnea*, and *Manettia bicolor*.

E. HOBDAV.

A Good Time Coming.—Consumers and the better class of growers have long laboured to have fruits sold on some honest plan, by which uniform quality and correct measure could be insisted on in the fruit package. The Common Council of Chicago have just passed a wise ordinance, so that the honest growers and the dishonest commission men, if indeed there be any of the latter, may in the one case be protected and in the other be punished. The dishonest dealer will no longer be allowed to sell pints for quarts, nor honest-looking boxes at top filled as to the interior and bottom with fruit rotten or inferior to that at the surface; no longer may gnarled and wormy Apples, with a veneering of sound fruit on top, be palmed off upon the unsuspecting purchaser as sound to the core; Peach baskets containing a fraction of a peck may no more be sold three for a bushel to the fruit-loving citizen. The ordinance provides first, that "it shall be unlawful for any person to sell or offer for sale fruits or berries within the City of Chicago except by the barrel, bushel, or some aliquot part of a bushel, according to the table of dry measures, nor shall it be lawful to sell fruit or berries in packages, except every such package contains a barrel, a bushel, or some aliquot part of a bushel, according to the table of dry measures; and, in the second place, that all fruits or berries, fresh or dried, sold or offered for sale in the City of Chicago in packages, shall be of equal goodness in every part of the package,"—"Prairie Farmer."

HARDY FLOWERS OF THE WEEK.

MANY of the autumnal flowers are fast opening; the white, red, and pink varieties of *Anemone japonica* are fairly sprinkled with flowers; the Mexican Dahlias are brilliant, their rich, abundant foliage, and large, bright-coloured blossoms, rendering them very attractive, far more so than *Dahlia viridiflora*, that curious monstrosity, which is at present covered with blossoms. The hardy Fuchsias are now very gay, especially *F. simplicifolia*, *Riccartoni*, *pumila*, *globosa*, *gracilis*, and several more; in many places in the west and south of England they are used for making hedges. *Veronica salicifolia*, a neat little shrub, with narrow, lanceolate foliage, and abundance of white flowers in spikes, is very pretty; it is one of the hardest of the shrubby section. *Oenothera speciosa*, one of the finest of the Evening Primroses, and one of the best of border plants, is now literally covered with its large, white flowers. Many of the Gypsophilas, especially *G. prostrata* and *G. muralis*, are well worth cultivation, the numerous white flowers on slender stems presenting a graceful appearance. *Gillenia trifoliata* (*Spiræa*) has a peculiar and very pleasing effect; it is a stiff, much-branched little bush, with small foliage, and covered with showy, pure white flowers. *Bupththalmum salicifolium* (a showy Composite with yellow flowers), and the old *Coreopsis lanceolata*, are both flowering luxuriantly. *Harpalum rigidum* (*Helianthus*) is one of the best of the Sunflower family, with immense golden-yellow flowers 4 in. in diameter; the golden spikes of *Asphodelus tauricus* are striking, the abundant Grass-like foliage setting the plant off to great advantage. Many of the *Aconitums* are very good, their deep purplish-blue flowers being an acquisition at this time of the year; one of the best blues in flower is the old *Anchusa italica*, indispensable for cutting. *Helenium autumnale* (with full, deep yellow flowers), and *Helenium grandicephalum* (yellow splashed with crimson), are both good. *Potentilla fruticosa*, a shrubby species with yellow flowers, is very distinct. *Centaurea Phrygia* has a neat, dwarf habit, producing purple flowers freely; but the best of this group is *C. aurea*, the tassel-like flowers of which make up well in bouquets. *Geum coccineum* fl.-pl. is now a sheet of brilliant, scarlet flowers, and so is the old double *Lychnis* (*L. chalcædonica* fl.-pl.) invaluable for cutting purposes, and the more it is cut the more it flowers. Many of the Campanulas are still a mass of flower, notably the new varieties of *C. turbinata*, *nobilis*, *nobilis alba*, *Hendersoni*, *rotundifolia* fl.-pl., *Hosti alba*, and many of the dwarf varieties of the Garganica section. *Liatris spicata* and *L. macrostachya*, with stiff, dense spikes of purple flowers, are both good; they last a long time in bloom. *Asteriscus maritimus*, a tender Composite with golden-yellow flowers, would make a fine bedding plant; also *Agathæa cœlestis* (Cape Aster), lovely blue Aster-like flowers; *Dracopcephalum canariense*; the Balm of Gilead (*Cedronella cana*), having very fragrant foliage and purplish-red flowers. *Lythrum alatum* is a charming pot plant, having erect, slender stems covered with purplish-red flowers; the latter I have known to stand an ordinary winter: this used to be grown as a market plant. *Phloxes*, *Antirrhinums*, *Pyrethrums*, and *Violas*, are a blaze of colour; to enumerate the best would be impossible, but I would strongly recommend any one to visit some of the establishments where these are grown and make their own selection. I believe the *Pyrethrums* are better than they were in May: they are now flowering a second time. *Nymphaea alba*, *N. odorata*, *N. tuberosa*, *Nuphar lutea*, *N. advena*, and *N. pumila* (the yellow and white Water Lilies), are also in flower. One of the most elegant aquatics is the Flowering Rush (*Butomus umbellatus*); I saw a ditch full of it the other day; it ought to be planted in every ditch and swamp in the land. *Alisma Plantago* and *A. lanceolata* were also growing near and in full flower. On the different pieces of rockwork near London are to be found the hardy *Opuntia Rafinesquiana*, with large citron-coloured flowers; it grows freely when planted among stones. *Onosma echinoides*, with white tubular flowers, is very distinct; both this and the golden-yellow *O. taurica* are well worth growing. *Silene Schaftæ* is covered with bright red flowers and will last for some time; the innumerable spikes of blue flowers of some of the dwarf *Statices* are very attractive; there are a number in flower both of the tall and dwarf varieties. Among the border

ones *S. latifolia*, *S. Limonium*, and *S. Smithi* stand conspicuous. *Epilobium obcordatum* (the Rocky Mountain Willow Weed) is improving in appearance; it is now covered with rosy-purple flowers. *Myosotis azorica*, a Forget-me-Not, with intense blue flowers, is very good. *Lychnis Lagascæ*, *L. Presti-multiflora*, *Veronica austriaca*, *Sedum pulchellum*, *Saxifraga autumnalis* with yellow flowers, *Sempervivums* of sorts, and many others which were enumerated last week tend to make the rockwork very gay. Among bulbous plants Lilies

Cobweb House-leek (*Sempervivum arachnoidum*).

stand first; early-flowering plants of *auratum* are now in their glory; these, as a rule, have the finest flowers. I saw the variety called *L. virginale* last week; what a gem it is! not a spot, just a faint yellow band running through each petal. It was the only *auratum* that had opened; it had fine flowers. *L. superbum* is now at its best; it does not vary in colour so much as its neighbour *L. canadense*. The varieties of *L. longiflorum* are still good, and so are *L. Krameri*, *tigrinum*, *chalcædonicum*, and *Humboldti*. The Mexican Tiger-flowers

Rhodanthe Manglesi maculata.

are as gorgeous as crimson and gold can make them; they will produce fresh flowers daily for the next two months. In *Zephyranthes candida* (the Flower of the West Wind), charming white flowers surmount tufts of dark green grassy foliage. *Anomatheca cruenta* is very charming; its brilliant crimson flowers, on stalks 6 in. high, show well when grown in pots: this plant will also remain for years bright and attractive on the rockwork. I do not say that the same bulbs flower year after year, but the seedlings will; it seeds freely, and the seedlings flower the first season. Many of the *Gladioli* are at their best—varieties of *G. gandavensis*, *G. Brencleyensis*,

Sky-blue Didiscus (*D. cœruleus*).

Ipomœa (*Pharbitis*) *purpurea*.

Lilium speciosum.

Symphyandra pendula.

Ivy-like *Ipomœa* (*I. hederacea*).

Sphenogyne speciosa var.

Mexican Tiger-flower (*Tigridia Pavonia*).

Harpalium rigidum.

Downy-leaved Mallow (*Lavatera Olbia*).

Tropæolum Lobbianum hybridum.

Bromus brizæformis.

Chelone barbata.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

G. natalensis; *G. psittacinus* is also in bloom—its curious green and scarlet flowers have a peculiar charm; it is a strong, vigorous species, and well worth cultivating. *Antholizas* and *Watsonias* are also in flower: some of the colours are very singular. I fancy they want a peculiar situation, as I have never seen them in first-class condition away from the Channel Islands—there they grow like weeds. There are two remarkable Orchidaceous plants in flower at Totteuham, which I have never seen before in such fine condition, planted in the open air, in a shady, moist bed, viz., *Satyrion aureum* and *S. carneum*, both from the Cape; the flower-spikes of both are 18 in. in height, having large fleshy foliage, and numerous showy flowers—the former golden yellow, the latter varying from flesh to a bright lively rose.

P.

THE LIBRARY.

HORTICULTURE.*

THIS is one of the series of books on "British Industries," edited by Mr. Bevan, and published by Mr. Stanford—a series which has had a merited success, and which has been well done in matter, as in type, paper, &c. Mr. Burbidge, in dealing with horticulture from this point of view, has dealt with the following subjects as one acquainted with them would do:—Commercial gardening, fruit culture, vegetable culture, culinary vegetables, salad vegetables, herbs, decorative plant culture, Covent Garden market, fruit and vegetable preserving, plant propagation, hybridizing and cross-breeding, public gardens, gardening industry abroad, and collateral industries of gardening. Gardening, he remarks, as a profitable industry has made enormous strides during the last twenty or thirty years, and at the present time it absorbs an immense amount of capital and skilled labour in, or near, all our large towns, where we now find men of means investing money in choice Orchids, Ferns, and other exotic decorative plants, as well as in tasteful dwellings, fine pictures, or other works of art. Commercial gardening may be summarised as follows:—1. Importation and culture of new and rare exotic plants, shrubs, and trees. 2. Hybridization, or artificial origination of new plants, fruits, and vegetables. 3. Culture of decorative plants and cut flowers. 4. Fruit, vegetable, and seed culture for market. And to these general departments may be added the enormous trade in other horticultural products and appliances, to which I shall more fully allude elsewhere. So long as we enjoy peace and commercial prosperity, the introduction and sale of beautiful decorative plants will continue as profitable, or even more so, than the production of necessities in the way of fruit and vegetables, and so long shall we find our Veitchs, Lows, Bulls, Van Houttes, and Vilmorins ready to employ an enormous amount of capital in sending abroad collectors, and in increasing, improving, and disseminating their discoveries at home. A visit to any large nursery, say that of Messrs. Veitch & Sons, in the King's Road, Chelsea, for example, will be amply sufficient to show that the trade industry of gardening is a most important one. In many of our leading metropolitan nurseries, the capital employed varies from £10,000 to £50,000, or even more, and these large sums are invested in plants and seeds, together with appliances for their cultivation and distribution. One of the most profitable branches of the nurseryman's business of late years has been the collection and importation of the Indian and South American Orchids, Lily bulbs from America and Japan, and seeds of various kinds, notably those of the American Coniferae, all of which have found as ready and remunerative a sale at Stevens' Auction Rooms, near Covent Garden Market, as have the Apples, Oranges, Bananas, Pine-apples, and other food products sold weekly in such enormous quantities at Keeling & Hunt's and Grant & Gask's, in Monument Yard and its neighbourhood. In many cases the improvement of foreign introductions by means of hybridism, or cross breeding, has been adopted by trade cultivators with advantage, notably the Indian and American Rhododendrons, Calceolarias, Pelargoniums, Camellias, and other popular flowers; and even now, notwithstanding the increased intelligence of professional gardeners and amateurs, nursery growers still

rely on their superior skill and appliances in the way of plant propagation and cross breeding, to render their home trade profitable. Many thousands of acres of land in this country, and also in France, Belgium, Holland, and Germany, are devoted to the production of flower and other seeds of various kinds for our gardens, and here, as a rule, the nurseryman or seedsman is the middleman who buys seeds in bulk from the grower or his agent, after which he packs and prepares them for distribution to his customers. The adulteration of garden and other seeds has of late years been made a subject for legislation, but still the practice largely prevails; sometimes it is the grower who is at fault, but more generally adulteration takes place after the goods leave his hands. A common plan of adulteration is to kill inferior seed by baking or other processes, after which it is sold as "ooo" for mixing with good seeds. Some English growers harvest vegetable and the more hardy sorts of flower seeds on their own farms, the more tender kinds being purchased in quantity from Continental growers. The culture of fruit trees is not now so remunerative as I hope it will be when the demand becomes greater, which it assuredly will as soon as residents in districts in which good land is cheap fully recognise the importance of fruit growing as a food-producing industry. This would long ago have been the case, had the elements of gardening been taught in our schools as it is in those of Continental countries. A national garden, established on sound principles, in which to test all kinds of fruits, vegetables, and flowers, would not only be the means of preventing the sale of adulterated seeds, or old sorts at high prices under new names, but would form an excellent school of horticulture, and would give an immense impetus to gardening as now practised in this country.

In Kent, Surrey, Middlesex, and Hertfordshire, hundreds of acres are devoted to the culture of fruit trees, Roses, Rhododendrons, and ornamental trees and shrubs of all kinds for garden ornaments, and immense quantities of fruit come to our London markets from what are called the home counties, but principally from Kent, Herts, and Middlesex, where most landed proprietors prefer letting their land for gardening purposes, knowing, as they do, that it will be well cultivated, and that it will yield them at least 50 per cent. more rent than if let for farm culture. The influence of trade gardening on the labour market is, on the whole, a beneficial one. In all the great fruit and vegetable growing districts there is a periodical, and in many cases, a constant demand for the assistance of women and boys in fruit picking, flower gathering and bunching, or otherwise preparing vegetables for market. All our great nursery establishments are in some measure schools for the hundreds of young gardeners employed in them, and from which they are sent to private gardens throughout the country or to the Colonies, as openings occur in the Tea, Coffee, Vanilla, or Cinchona plantations, established either by Government or private speculators.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Rust on Grapes.—I have many a time had Grapes badly rubbed in thinning by beginners, but I have never known the rubbing to produce rust; it merely spoiled the appearance of the Grapes by depriving them of their bloom.
—JAMES SMITH, *Waterdale*.

Manure-water in Vineries.—Manure-water in the evaporating troughs is used by many, but a great many more do not use any, and still obtain quite as good results. Liquid made from pig manure would be disagreeable enough put on the inside border, but it would be much worse if used continually in the evaporating pans.—JAMES SMITH, *Waterdale*.

The French Vineyards.—The wine growers in France are always complaining of Phylloxera, or Oidium, or bad crops—any excuse to keep up the price of wine; but they will be much embarrassed to find any cause for grumbling this year, as the yield will, it is said, be the most productive that has been registered during the present century.

Eastnor Castle Melon.—Having just cut a fine crop of this variety, I can recommend it highly as an abundant bearer, excellent in flavour, and a handsome fruit for dessert. When growing, it had a striking resemblance to Gilbert's Victory of Bath, inasmuch as it has a long foot-stalk and rather long fruits of a deep green colour, but as they approach maturity they become beautifully netted, and when ripe assume a golden tint. This has hitherto been rather an unfavourable season for Melons, as the small amount of sunshine which we have had has been all against high flavour.—J. GROOM, *Henham*.

* By F. W. Burbidge. London: Edward Stanford, 55, Charing Cross.

EXTRACTS FROM THE KEW REPORT.

THE number of visitors to the Royal Gardens exhibits a considerable falling off as compared with last year, being just below 600,000 (596,865). This is the smallest number since 1872. On the 7th of August the Royal Gardens were visited by 64,163 persons, the largest number which has ever been recorded for any one day. During the past year the assemblage on Kew Green on all holidays of large crowds of persons, who do not appear to visit the gardens, has become a difficulty of considerable magnitude. Men with articles of different kinds for sale, music, games, &c., have been, of course, attracted by the concourse, and the whole green has had, on these occasions, the aspect of a fair. Two facts lead me to bring the rapid development of this state of things under the notice of the Board. The Green is scheduled under the Parks Regulation Act of 1872, and as regards general control has been placed under my authority. In the next place, and this is perhaps the most serious consideration, the excitement which naturally arises in large crowds of persons bent upon amusement, and with nothing else to engage their attention, has shown a tendency to spread amongst those who visit the Gardens, where it can only lead to grave difficulty and annoyance to quietly-disposed visitors. With the assistance of additional police, possessed of the necessary tact and experience, matters were very materially ameliorated during last summer, and I am in hopes that the evil, when once checked, will not require further attention. In my report for last year (p. 5) I drew the attention of the First Commissioner to the rapidly progressing decay of the beautiful Eyot in the Thames immediately above Kew Bridge, and upon which the beauty of this part of the Thames depends. Owing to the gradual encroachment of new suburbs upon the ground in this neighbourhood, till lately used for market gardens, very large tracts of Osier beds, over which the high tides formerly spread themselves unimpeded, have been embanked. The tidal water is now apparently driven farther up the river, and the consequent inundation of low-lying places has become an evil which formerly was but little felt. One result must be the complete destruction of the Eyot above alluded to, which is known locally under the name of Mattingshawe. Not merely is the soil, which is often entirely covered at high tide, being gradually washed away, but the trees, many of which no doubt have reached their prime, are being one by one undermined and uprooted. The present process of destruction without some active intervention is inevitable. I feel sure that when complete, and the view of the town of Brentford, with the gasworks and goods station of the Great Western Railway replaces one of the most beautiful compositions of wood and water to be found on the lower Thames, the regret felt by the public at the loss will be very great. In the latter part of 1875 complaints were made as to the quality of the water supplied to the drinking fountains and residences. At the request of the Board, Major F. Bolton, water examiner to the Local Government Board, made a visit of inspection to the Gardens. The following is the substance of his report:—The intake of the water is from the River Thames at a point situate in Kew Gardens, immediately opposite Syon House. From the river the water flows into the lake (which is used as a subsiding reservoir) of about 5 acres area, whence it is passed through a small filter-bed. It is then pumped up into reservoirs in Richmond Park, and from here supplies the gardens and official residences at Kew, as well as drinking fountains in the Gardens. Pembroke Lodge and the White Lodge are also supplied with water from these reservoirs. The intake of water opposite Syon House for any except garden purposes is probably illegal, inasmuch as the Metropolis Water Act, 1852, prohibits any corporation taking water for domestic use below Teddington Lock. The water (at the time of examination) was very foul and strongly charged with sewage matter, from which the present filter-beds had proved quite inadequate to free it, and from which, indeed, no system of filtration would suffice to purify water so charged. In accordance with this report the Treasury sanctioned (Jan. 8, 1876) the expenditure of £960 for laying mains from the Southwark and Vauxhall Company's service to the residences, drinking fountains, and museums in the Royal Gardens, and an annual sum of £250 in payment of the Company's charges for the supply. The lessons given to the young gardeners in the evening, in chemistry, meteorology, structural, systematic, and economic botany, and upon which the attendance is voluntary, continue to give satisfactory results.

Botanic Gardens.

The further re-arrangement of the plants in the Palm House was proceeded with in the course of last spring, and may now be regarded as practically completed. A great improvement has been obtained in the general effect. As mentioned in my report of last year, it has been found necessary to cut down nearly all the large Palms on the north side of the transept, and plant out others in their

places. The following are the more important changes:—*Arenga saccharifera* cut down and replaced by *Sabal glaucescens*. *Livistona inermis* (*L. australis*) Bot. Mag., 6274, cut down and replaced by *Phoenix dactylifera*. *Sabal glaucescens* transplanted and replaced by *Astrocaryum rostratum*. *Acrocomia sclerocarpa* cut down and replaced by *Thrinax aculeata*. *Sabal umbraculifera* cut down and replaced by *Livistona chinensis*. *Voitchia Canterburyana* transplanted and replaced by *Ceroxylon andicola*. *Phytelephas macrocarpa* removed and replaced by *Attalea Cohune*. *Areca alba* cut down and replaced by *Euterpe pisiifera*. A selection of the larger tropical Ferns, Aroids, Marantaceæ, &c., has been planted in the beds under the Palms, which have hitherto been quite bare. They are now covered with an undergrowth of singular picturesqueness and luxuriance. The gigantic Screw Pines (*Pandani*), which are such a conspicuous feature in the north wing, are rapidly becoming too large for the positions they occupy, and, as it is impossible to give them more space, they will have to be cut down in the course of one or two years at the farthest. I must again urge the desirability of a reform in the heating apparatus of this house, as detailed in my last year's report, as a measure of economy even more than of efficiency. With the exception of the immense improvement in both heating power and reduced consumption of fuel, obtained by bringing the flues up through the roof of the wings instead of conducting them underground to the shaft near the Richmond Road, no material improvement has been introduced into this building since its construction nearly thirty years ago. The re-arrangement of the staircases leading to the gallery, proposed in my last report, has been reported upon by the Board's works' department, and unfortunately proves to be impracticable. Some means of draining off the moisture due to condensation which accumulates on the gallery floors during the winter is, however, urgently needed.

In the Aroid House (No. 1) the superb Tropical Tree Fern (*Cyathea princeps*), having outgrown suitable dimensions, was with great reluctance on my part, taken down in the course of the summer, and replaced by a smaller specimen from the Tropical Fern house. The whole collection of Aroids has been very carefully revised, and a catalogue prepared by Mr. Brown, second assistant in the Herbarium. It comprises upwards of 300 species, and should eventually be printed for distribution to other botanical establishments. The whole collection of Calami (Rattan canes) is now also arranged in this house, the moist heat of which suits them better than the Palm House.

The Fern Houses (Nos. 2 and 3) retain their pre-eminence, whether for the number of species in cultivation or the health and vigour of the plants, but the constant humid temperature necessary to their growth so damages the painted woodwork of the houses that they are under frequent repair. I am strongly of opinion, that seeing how much shade Fern-houses require, the side walls should be of bricks up to the eaves, with large side sashes, and that the woodwork of both roof and sashes should be of some of the durable Colonial woods, as the Jarrah of West Australia, which would probably not require internal painting. The species of *Cheilanthes* in the Cool Fern House, which have proved very impatient of pot culture, have been planted on a broad side shelf covered with stones, pots, and soil well drained below, and promise to do well under this treatment. Many of the smaller Ferns in the same house, which, when in small pots, were watered either too much or too little, have been similarly accommodated with obvious success. The number of species and varieties of Ferns in the Royal Gardens is now upwards of 1000.

The labour and expense of keeping up both the interest and beauty of the Ornamental Conservatory (No. 4) throughout the year, by a mixture of commoner with the rarer ornamental plants, is a subject to which I have, especially of late, devoted a considerable amount of attention. It has occurred to me, that as regards the common plants of merely decorative interest, of which it is desired to display a fair quantity as affording a very great gratification to many visitors, it might be more economical and satisfactory to buy than to raise them ourselves. Within recent years the cultivation of certain kinds has become a speciality with suburban nurserymen, who raise and supply the London trade with them by tens of thousands, and at a comparatively trifling cost per pot. The number of each kind required for this house at any one time is comparatively small, and the material labour, skill, space, and attention, &c., that these few require would almost suffice to raise double the quantity or more. Under these circumstances, I believe it might be to our advantage to devote our attention to the cultivation of the rarer sorts alone and to purchase the commoner.

The Succulent House (No. 5), which is by far the most interesting in the garden in respect of the magnificent collection of plants of grotesque habit and singular form, has also been re-arranged, and some of the large duplicate *Euphorbias*, *Aloes*, and *Cacti* removed to

the Palm House. Several of the largest Agaves and Fourcroyas (commonly called American Aloes) have flowered during the past summer, and the flowering stems rising to a considerable height were allowed to pass through the roof, presenting a striking and singular appearance.

The collection of **Economic Plants** has been carefully revised, extended, and entirely re-arranged. It is now probably one of the most complete series of medicinal and useful plants ever brought together. The nomenclature has been checked, and a manuscript catalogue prepared. I may take this opportunity of noting that a well-known stove foliage plant of gardens, *Theophrasta imperialis*, Linden proves from the examination of specimens in fruit sent to us by M. Glazion, to be a species of *Chrysophyllum* belonging to a different natural family, Sapotaceæ.

Baleam of Copaiba.—Some well-ripened seeds of the Para Copaiba (*Copaifera multijuga*) have been brought by Mr. Cross from the forests of Para and germinated freely. The tree which produces it is described as gigantic, the trunk sometimes rising to a height of 80 ft. before branching. The Para Balsam, called *Copaiba blanca*, is chiefly sent to France, where it obtains the highest price of any. A single tree, if tapped at the right season, is said to yield about 84 imperial pints of balsam. Very little is known of the history or botanical characters of this plant, which has been only imperfectly described. It is greatly to be desired that this tree should be introduced into the East Indies.

Balsam of Peru.—This beautiful tree (*Myroxylon Pereiræ*) was introduced into Ceylon in 1861 by the exertions of the late eminent pharmacist, Daniel Hanbury. It has succeeded there admirably, and last year I received several parcels of seeds from Dr. Thwaites, which I have distributed to various tropical colonies. Dr. Thwaites speaks in warm terms of the beauty of its foliage and habit.

India-rubber.—On the 14th of June of last year Mr. H. A. Wickham, a resident on the Amazons, who had been commissioned by the India Office to collect seeds of the *Hevea brasiliensis*, arrived in England with 70,000, obtained on the Rio Tapajós. In consequence of their retaining vitality for but a very short period, they were all sown the day after arrival, and though not contained in pans, covered a space of over 300 square ft. closely packed together. About 3½ per cent. germinated, some as early as the fourth day after sowing, and many in a few days reached a height of 18 in. Upwards of 1900 plants were transmitted, August 12, in thirty-eight Wardenian cases made specially to accommodate the rapid growth of the seedlings, to Ceylon under the charge of a gardener. Of the whole consignment, 90 per cent. of the plants reached Dr. Thwaites in excellent condition, and they will remain in Ceylon for the present under an arrangement which I suggested between the Indian and Colonial offices, that the young plants which could not thrive in the climate of Calcutta or any of the more accessible gardens of continental India, should be nursed and established in Ceylon for subsequent transmission through the Indian gardens to Assam, Burma, and other hot damp provinces of India proper. I am happy to say that the plants are thriving under the management of Dr. Thwaites, who has obtained the authority of his Government to establish a supplementary tropical garden at a lower elevation than Peradeniya (1700 ft.) for the more rapid multiplication of the *Hevea*, *Castilloa*, *Chocolate*, and other plants that require a maximum of heat and moisture. On November 21, Mr. Robert Cross, who, in addition to the commission given to Mr. Wickham, had been sent to S. America to bring home live plants in the event of its proving impossible to transmit alive to this country the very perishable seeds, reached Kew with about 1000 living young *Hevea* plants. The most promising of these have been retained at Kew during the winter, and a portion will be sent to India as soon as the weather permits. The stock of *Castilloa elastica*, brought last year to Kew by Mr. Cross, has been propagated as rapidly as possible, and plants have already been distributed to Africa (West Coast), Ceylon, and Java. Dr. Thwaites reports that of 31 plants transmitted to him 28 have arrived in perfect health and have thriven vigorously. A plant to which I alluded in my last report, and which is to be found in some Continental and English gardens under the name of *Castilloa elastica*, proves under cultivation at Kew (although possibly a species of *Castilloa*) to be certainly distinct from that plant both in the form of the leaves and in habit. Along with the *Heveas* Mr. Cross brought seeds and plants of an undescribed rubber-tree, which furnishes the "Ceará scrap" of the English market. The export of this has been reckoned at 1100 tons annually. The botanical nature of the plant is at present uncertain, but it may possibly prove identical with *Manihot Glaziovii* already mentioned. It is at any rate perfectly different from *Hevea* and *Castilloa* in character, habit, and habitat. It grows in a climate with a marked dry season, amongst a scrubby vegetation, and has stout short branches and

deciduous leaves. Forty-one of the imported stems have grown, and as many young plants have been obtained from these by cuttings. The seeds were raised with difficulty during the winter, owing to the seedling damping off soon after germination, a characteristic of plants of similar habit from similar climates; 14 plants, however, are growing from this source.

Ipecacuanha.—Dr. King reports that he fears this drug cannot be grown profitably so far north in India as Bengal; but the secret of its successful propagation being now perfectly understood, any quantity of seeds can be sent out. A quantity of the dried root has been prepared by Dr. King for use in the Medical College Hospital of Calcutta, and found to be quite as efficient as the best South American drug. The disadvantage attributable to the extreme slowness of the growth of this plant, and hence small annual return of root wherever it has been cultivated, must be met by a greater extension of the cultivation, as to which there should be no difficulty, seeing that the plant is increased with astonishing facility by ordinary cuttings, root division, or by merely pegging a leaf to the earth.

Liberian Coffee.—The demands for this plant (first grown in this country at Kew in 1872), which has excited the expectations of Coffee planters in all parts of the world to the highest degree, far exceed our means of supply. Now, however, that the function of this establishment in introducing the plant into the Coffee-growing districts of India and our Colonies is amply fulfilled, and both the seed and plants are to be had from Mr. Bull, of Chelsea, and Messrs. James Irvine & Co., of Liverpool, as well as other firms, no further supply will be kept in Kew than suffices for exchange of specimens with other Botanic Gardens and correspondents. Mr. Hiern has examined the African species of the genus *Coffea* in preparing the Rubiaceæ for the forthcoming third volume of the "Flora of Tropical Africa." He has determined the claims of the Liberian Coffee to be regarded as a distinct species, as was indeed the opinion of its scientific discoverer, Afzelius, and he has described it in the "Transactions of the Linnean Society" [second series, Botany, I., p. 171, tab. xxiv.] under the name of *Coffea Liberica*. I am indebted to Mr. Hiern for the opportunity of distributing with this report copies of the plate of the plant which he has published in his memoir. I may enumerate as the most important recipients during the past year:—*Bombay, *Burma, *Cape of Good Hope, Dominica, Java, Madras, Montserrat, *New Granada, Queensland, Rio de Janeiro, *Trinidad. The places marked with an asterisk had not received it the previous year. Amongst the numerous favourable notices of the plant which I have received I will content myself with quoting two from opposite sides of the world. Dr. Thwaites (Ceylon) writes under date 29th August 1876:—"Some of the first plants of Liberian Coffee you sent to me have become large bushes and are producing berries. These latter are of a large size, but they ripen very slowly, evidently from the want of a higher temperature, so I am distributing some plants in the low country and near the sea. In his report for 1875, he also expresses the opinion that though the plants have become affected with the leaf disease, they do not apparently suffer here [Peradeniya] from *Hemileia* so severely as our ordinary Coffee." In the Malabar district of South India, the Liberian Coffee has also disappointed the expectations which its large and leathery foliage seemed to encourage of its capacity for resisting the *Hemileia*. Its more vigorous habit of growth may, however, enable it to bear, without succumbing, the ravages of this insidious parasitic mould. Dr. Inray (Dominica) writes while this report is in preparation:—"I am thoroughly convinced that the Liberian Coffee will in time take the place of our native Coffee, if I may so call it. I think you would be pleased were you to see my Liberian trees with their healthy vigorous branches and large dark green bright shining leaves. Many of the trees have blossomed, and are still flowering, and a small crop of berries is coming on. The plant must evidently be very prolific. I count as many as fifteen or twenty berries, even more, in the axils of the two opposite leaves. . . . It appears to me that the new species of Coffee is peculiarly adapted to this island. So far as the temperature and rainfall are concerned, the climate approximates very closely to that of Liberia, whence the plant comes. If the cultivation of Liberian Coffee be generally taken up in Dominica, as I think it will be, there is a future for this little country. There are thousands of acres of splendid Coffee land that might be cultivated in this island with no fear of the 'white fly' before the eyes of the planter, for the Liberian tree bids defiance to its attacks. Indeed there is a very eligible field for settlers here, with a little money in their pockets, who wish to cultivate Coffee. It might be pleasanter, and more profitable in the long run, to set their faces towards the west, instead of the 'far east.'" The suppression of this product generally in Dominica, which island once yielded the finest West India Beans, has been the subject of correspondence with the Colonial Office. This led to the mission of Mr. Prestoe, the Government botanist of Trinidad, to Dominica, with a view of reporting on the subject. Mr. Prestoe's

report, which is in every way an admirable one, deals with all the vegetable products of the island in an exhaustive and most instructive manner; and in respect of Coffee, it shows that the cessation of its cultivation was not due to the larva of a small moth (*Cemistoma coffeellum*), which can be extirpated from a plantation with great ease, but to causes which are far more general, affecting the well-being of the whole island, and especially to mismanagement on the part both of the Government and the colonists.

Eucalyptus in India.—Hopes still appear to be cherished that the Blue Gum of Tasmania (*E. globulus*) will succeed in the plains of India, and in other tropical countries. This expectation has hitherto, as might have been expected, in every case led to disappointment. A paper by Dr. Brandis on the "Cultivation of the Different Species of Eucalyptus in Northern India" issued by the Indian Government, will no doubt be held conclusive as far as that country is concerned. Dr. Brandis remarks:—"It seems to be acknowledged that in the open country in the plains of North India stations are improved and become more healthy by the planting of trees. If this be admitted, then obviously the object desired is gained in the shortest time by planting those species which grow most rapidly." Eucalypti are probably not better adapted for this purpose than other quick-growing trees, but have the merit of producing very hard timber. Two species which have succeeded well at Lucknow, have been sent to Kew for identification. They appeared to be *Eucalyptus rostrata*, (Schlect.), and *Erebinifera*, (Sm.). Other species from the better parts of Australia would probably be equally available.

Gutta-percha.—Literally nothing is known as to the botanical history of the commercial varieties of gutta-percha. Several kinds of different qualities and even exhibiting different properties are imported into England, and are in immense request, especially in telegraph cable manufactories, but neither the plants which produce them nor the localities in which they are produced are approximately known. I attach great importance to the prompt investigation of gutta-percha-yielding plants. There is reason to believe that they are very local and restricted in their geographical occurrence. The collection of products of this kind for commercial purposes is shown by experience to lead inevitably to the destruction of the trees producing them, since these are recklessly destroyed and never replaced. It is not merely, therefore, a matter of scientific interest to ascertain the exact nature of gutta-percha-yielding trees, but it is the first step in securing the perpetuation of the supply. The botanical investigation of a product or plant simply means getting such complete knowledge about it as to leave no difficulty in the way of recognising it at any time without uncertainty.

Melons from Turkestan.—Dr. King forwarded to the Royal Gardens a collection of seeds of the best kinds of Melons grown at Kashgar. These were distributed partly to M. Naudin, the well-known monographer of the Cucurbitaceæ at Collignon, in the South of France, partly to the Royal Horticultural Society at Chiswick. Seeds from kinds which proved the best have been again distributed to several of the best Melon growers in England. They are at any rate likely to give rise to new strains, even if not of themselves of sufficient value for actual horticultural use.

Poisonous Grass in Kashmir.—Dr. Aitchison has sent specimens of a Grass poisonous to cattle in Kashmir. It proves to be *Stipa sibirica*, and it is possible that its injurious effects are due rather to the mechanical irritation produced by fragments of the awns than from any noxious principle contained in it. A closely-allied species of *Stipa* has been described by Dr. Hance ("Journal of Botany," 1876, pp. 210—212) as producing somewhat similar effects in Tibet.

Large Sugar-canes.—Inquiries have been addressed to me respecting an enormous and apparently little known variety of the Sugar-cane, called the Elephant Cane of Cochin China, which has been stated to reach a height of 11 ft. and a diameter of 7 in. in six months. At my suggestion the Superintendent of the Botanic Garden at Singapore has obtained from Cochin China plants of this cane, which he has succeeded in establishing. I am also indebted to M. Pierre, Director of the Botanic Garden at Saigon, for the following information, which I think may prove interesting to sugar growers in British colonies:—"This variety is only cultivated for eating or chewing. I do not think it would prove a good sugar-producing cane . . . but varieties, especially in the case of sugar-canes, often improve by change of climate. Perhaps this might have the good fortune to succeed better elsewhere. The dimensions as to diameter and height which this variety attains, depend on the length of time during which its growth continues. It requires in a good soil two years to reach 10 ft. in height. After five years or six years, it may reach 16 ft. to 32 ft.; such specimens may be seen near native houses, where it is allowed to grow undis-

turbed as an ornamental plant. In the province of Mythe this variety is cultivated in humid, alluvial soils on a considerable scale, but simply for sale in the bazaars and for chewing. It has the peculiarity of possessing a very brittle, epidermal layer, so that instead of becoming pressed out and giving up its juice when passed through the wooden mills employed here, it breaks up into small fragments."

Museums.—In my last report I adverted to the necessity of giving increased accommodation in Museum No. 2, in order to allow of a proper display of specimens illustrating the Cryptogamic groups of plants. These are at present most meagrely illustrated from want of space. They are, however, objects of increasing interest to the large numbers of persons who make the study of some branch of natural history their recreation, and with whom our museums are extremely popular. The whole of the museums are in a most crowded condition. No. 1 has long been waiting for the relief which throwing out the staircase at the back would give to it. No. 3 contains quite as many objects as there is room to properly display, having a regard to the necessity of preserving proper thoroughfares on crowded days. In order to provide accommodation for new objects, and also to more strictly define the scope of the collections, the curator, with the aid of the assistant-director, has commenced a systematic revision of the whole collections. For the future only one series will be maintained, and every specimen, whether structural or economic, will, as far as possible, be ranged in its systematic position. No separate collections of merely technological interest will be kept, and those already existing have been now broken up and distributed. A large number of duplicates and of other objects which on various grounds did not seem to be properly congruous with the object of the museums as illustrating structure and usefulness throughout the vegetable kingdom, have been as far as possible placed at the disposal of other Government institutions. Dr. Hugo Müller has published, in German, an exhaustive and most valuable treatise on paper materials amongst the reports of the Vienna Exhibition. Dr. Müller largely availed himself of the resources of the Kew museums during its preparation. It will no doubt remain the standard authority on the subject, and I trust that a translation may be published for English use. H.R.H. the Prince of Wales most graciously placed at our disposal the large collections of fruits, seeds, woods, &c. collected during his Indian tour. These specimens were materially enhanced in value for the purposes of our museums by H.R.H.'s expressly stipulating that we should be entirely free from any conditions in introducing the specimens into our arranged collection.

Physiological Laboratory.—The physiological laboratory, which the Royal Gardens owe to the munificence of T. J. Phillips Jodrell, Esq., M.A., and the commencement of which I reported last year, has been completed, and though as yet only partially provided with the necessary equipment, has been already used by Dr. Tyndall in researches on the conditions by means of which the minute organisms (*Bacteria*), the germs of which are always present in the air, and which determine putrefactive changes in infusions of organic substances, can be effectually excluded from them ("Proceedings of the Royal Society," Jan. 18, 1877). I have the satisfaction of stating that the internal arrangements of the building, which were intrusted to the assistant-director, have been pronounced by both English and continental authorities to be (considering the size) more convenient than those of any other establishment of the kind known to them.

Two other physiological researches have been carried on at Kew during the past year, although the laboratory was not sufficiently advanced to be available for them. Professor Burdon-Sanderson has continued his examination of the electrical phenomena of the leaf of *Venus's Fly-trap*, *Dionæa muscipula* ("Proceedings of the Royal Society," Dec. 14, 1876), and Mr. S. H. Vines, Fellow of Christ's College, Cambridge, has studied the digestive ferment of *Nepenthes* ("Journal of the Linnean Society," vol. xv., pp. 427—431).

I may also mention here that leaves of *Chamærops humilis* have been supplied to Dr. Hugo Müller, F.R.S., for the purpose of an investigation which has led to the detection in them of a peculiar sugar, Quercite, the occurrence of which in Palms was altogether unknown.

Herbarium.—The new building for the accommodation of the Herbarium is in a very advanced state. It will consist of a hall attached to the back of the present house. The whole of the latter will be preserved, except the drawing room, a single apartment that was added on to its north side, and which has been removed to make room for the new hall, which is 86 ft. long by 40 ft. broad, and contains two galleries 10 ft. broad running round it. The galleries will communicate with each other and with the ground floor by two circular iron staircases placed one at each end of the building. On

each floor there will be an entrance from the old building, closed by double iron fire-proof doors. The long sides of the building will be lighted with forty-eight windows, eight on each floor on each side. The cabinets for holding the specimens will be arranged in blocks 8 ft. high, of two tiers projecting like buttresses between the windows on the ground floors and galleries, thus accommodating the greatest number of cabinets with the least loss of space, a very important consideration considering the extent of the collection and the time that would be otherwise lost in consulting it. At the present time the number of cabinets is upwards of 600, and the estimated number of specimens contained in the whole is now considerably over a million, reckoning as one all the individuals of the same plant from the same locality.

The whole building will be heated with hot-water pipes. Water-mains charged at high pressure, sufficient to throw a jet more than the height of the whole building, will be carried to each floor. When complete the old building will be cleared out, as much as possible of its combustible fittings and woodwork removed, and the rooms arranged for the better accommodation of the library and of persons, besides the staff, engaged in the study of the collections.

THE SOIL IN TOWN GARDENS.

In reference to this subject, allow me to say that lime is a necessary constituent of all productive soils. In its absence the organic matter, consisting of the remains of leaves and roots of plants, &c., accumulates to an injurious extent, and as a consequence thereof soluble silicic acid is formed in the soil—one cause of what is technically known as sourness. But when to such a soil lime is applied it combines with the soluble silicic acid, rendering it insoluble, and aids in the decomposition of the excess of organic matter by neutralizing the acids formed by oxidation. It will, therefore, be evident that lime plays a very important part in the economy of soils. Now, one of the striking properties of lime is that it has a tendency to work down in a soil, inasmuch that if a meadow be turned up some years after it has been limed, a layer of that substance can be found 4 in. or 5 in. from the surface. This being the case, it is apparent that a soil left long to itself without being turned up or disturbed in any way would, in the course of time, become deficient or void of lime. This is the condition of most plots of ground in towns. They frequently remain for years without being touched or turned up in any way, and often have not had anything like an application of lime for generations, except such an accidental application as occurs through strewing the land with mortar during the process of pulling down and rebuilding houses in the neighbourhood. To sum up, my experience teaches me that the soil of plots of ground in the centre of smoky towns is almost always sour, and over and above the effect the absence of lime exerts in producing this result, they are more liable to suffer from this cause from their sheltered position and the decreased oxidising power of the air of towns, and from the fact that frequently no trouble is taken in turning them up so as to get the full benefit of the oxygen that may come in contact with them. Therefore, as the evil for which lime is a corrective is liable to be more prevalent in towns than in the country, it is evident that its application is more necessary. My advice, therefore, to those who undertake the cultivation of London gardens is, at first starting, to give a large dressing of lime, and dig it well in to the depth of 12 in. or 15 in., and during the subsequent cultivation every care should be taken to keep the ground in a loose state by continual digging and turning.

A. A. NESBIT, F.C.S., in "Globe."

Count Moltke on the Treatment of Water.—He describes Peterhof: the palace—white and gold with golden cupola, surrounded with dark fir trees and a "most peculiar alley of jets of waters," between which the sea and the horizon of the coast of Finland can be seen—making "a most surprising impression," and the park full of cascades, temples, and statues, "recalling Wilhelmshöhe and Sans Souci; but—"What pleased and surprised me most in the park was a brook, a real natural stream, with crystal-clear water rushing over blocks of granite. I could not have believed there was so great a fall in flat Russia from the Valdai Hills to the level of the sea. It is always perfectly unaccountable to me how landscape-gardeners in flat countries will contrive waterfalls instead of using their labour to make, at least for a short distance, a splashing, murmuring brook. The artistically victimised water is sent over a plank into a 6-ft. deep chasm, whence it seems to creep away ashamed, not knowing where to go! To make the thing complete, the cataract should only be set off when the spectator is standing ready to be astonished.

At Norfolk, Virginia, the Strawberry pickers, paid by the quart, have been having about 15,000 dollars a day distributed among them.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 7.

This meeting, though sparingly attended, was above the average as regards exhibits. Two very fine specimens of *Odontoglossum vexillarium* shown by Sir Trevor Lawrence attracted universal attention, as did also a bank of cut Roses from Messrs. Geo. Paul & Sons. A collection of *Phloxes* in pots, from Messrs. Laing & Co., Forest Hill, was deservedly awarded a cultural commendation, the plants being well grown and the blooms all that could be desired.

First-class Certificates.—These were awarded as follows:—

Pelargonium (echinatum) Spotted Gem (Cannell)—A beautiful Cape variety, bearing neat trusses of small, bright, rose-coloured blossoms, with white centre, and golden-tipped anthers. It looks to be a useful kind for pot culture, and for furnishing cut blooms in winter.

Dendrobium suavisimum (Williams).—Described previously in THE GARDEN.

Dracæna Bausei (Williams).—A compact-habited kind, with broad, drooping leaves of a bright bronze colour, conspicuously margined with bright crimson; well worth attention.

Rose, Marquis of Salisbury (George Paul & Son).—A Hybrid Perpetual, with large, well-formed blossoms resembling those of *Alfred Colomb*.

Eulophia guineensis (Sir T. Lawrence).—An African Orchid, with Calanthe-like leaves, and flower-stalks from 2½ ft. to 3 ft. in length, the upper portion of which is beset with chocolate-coloured, five-petalled flowers, having rosy-purple-striped lips.

Miscellaneous Subjects.—Mr. B. S. Williams, Holloway, furnished a miscellaneous group of plants, consisting of well-grown examples of *Acalypha musaica*, *Croton fasciatum*, *Eranthemum El Dorado*, *Lilium neilgherrense*, and a fine-leaved *Dioffenbachia* called *marmorata*. A group of hybrid *Begonias* came from Mr. J. Chambers, Westlake Nursery, Isleworth. Amongst them were kinds remarkable alike for compactness of habit and for the varied and brilliant colours of the flowers. From the same exhibitor also came plants of *Adiantum Feei*, and several other Ferns. An exceedingly free-flowering new dwarf Candytuft named *Tom Thumb* came from Messrs. Sander & Co., St. Albans; and a collection of variegated *Celosia* (*C. cristata variegata*) came from Messrs. Vilmorin & Co., Paris. The plants were robust in habit, and the flowers of various colours, but more singular than beautiful. Mr. R. Dean, Ealing, sent cut blooms of African Marigolds, large in size, and bright in colour; the same exhibitor had also cut blooms of *Stock Mauve Beauty*, a summer-flowering kind, which should find a place in every garden, even small plants of it producing flowers in abundance, and useful for cutting purposes. Mr. Woodbridge, Syon House, contributed branches of the graceful *Spiræa-like Tamarix gallica*, and of *Ceanothus americanus roseus*. Mr. J. Pattick, Acton, showed some remarkably well-grown Balsams, which were good both in form and colour. Among Messrs. Paul's Roses were better blooms of *Reynolds Hole* than we have seen anywhere else this season. Messrs. Jackman & Son furnished green and golden-leaved varieties of *Biota orientalis* and *Thujopsis borealis*. A collection of *Abutilons* came from the Society's gardens at Chiswick; also a group of double-flowered *Pelargoniums* and *Stocks*. Messrs. Carter & Co., High Holborn, contributed plants of a new *Hose-in-Hose Gloxinia*, the blooms of which are said to last in good condition for a longer period than those of other kinds. Mr. R. Parker, Tooting, showed cut blooms of *Asclepias tuberosa*, which received a vote of thanks.

Fruit and Vegetables.—Good examples of *Grosse Mignonnas* Peaches and *Welbeck Seedling* Nectarines came from Mr. Tillery, gardener to the Duke of Portland at Welbeck; and *Barrington Peaches* in good condition were furnished by Mr. Pressley, gardener to G. Jennings, Esq., Clapham Common. Mr. Douglas sent good examples of *Kerry Pippin Apples*; Mr. Gilbert showed from *Burghley* a seedling *Scarlet-fleshed Melon* of large size and fair quality. Good fruit of *Hale's Early Peach*, grown in a cool house, came from Messrs. Rivers & Son, Sawbridgeworth, and were awarded a cultural commendation; as were also a dish of Peaches from Messrs. Lane. Mr. Ollerhead sent a handsome *Queen Pine-apple*. Good dishes of *Cherries* were shown by several exhibitors. Mr. Miles, gardener, to Lord Carington, Wycombe Abbey, showed unusually large fruit of *Stamfordian Tomatoes*; they were cut from plants grown in pots.

Blooms of *Lilium candidum* for Indoor Decoration.—This Lily is still one of the best for cutting for large glasses or tall vases where a few bold and striking flowers with plenty of greenery are more effective than if they are crowded amongst *Pelargoniums*, or any of the more common-place flowers. What a time, too, they last in good condition in water! and if cut before all the blooms are expanded, the stalk will remain fresh till every bud has opened. The great lasting power of Lilies in a cut state forms one of their chief recommendations. October is the best month for planting hardy Lilies; *L. candidum* should be planted in clumps of several bulbs about 6 in. apart, and they should be covered about 6 in. deep.—E. HOBNAV.

EXPERIMENTS ON THE FLOW OF THE SAP.

By ANDREW MURRAY.

At the beginning of this session I directed attention to the course of the sap, being of opinion that recent researches rendered some modification in our views necessary on that subject. The proposition that I submitted to the committee was, pure and simple, that there was no such a thing as descent of the sap at all, but that its course was always upwards. I found the committee quite in accord with me, so far as regarded anything like circulation. I think most of them, if not all, repudiated any belief in the old theory of the ascent of the sap by the fibro-vascular bundles of the wood, and its descent by the cellular layers of the inner bark; but I found the majority still imbued by the theories of Sachs, and holding with him, and on his grounds, that descent by some means was absolutely necessary, in respect that assimilation could only take place in the light, and consequently that the whole of that function must be performed in the leaf, whence the assimilated matter there produced must be transported in some way or other to the other parts of the plant in which it is found; and as these are lower down, and some of them even underground, as in the case of tubers, it followed that there must be a descent in some way or other, and the prevailing opinion seemed to be, as was I think first suggested by Mr. Herbert Spencer, that this took place by a slow swaying, or wandering motion, by means of endosmose and exosmose, through the walls of the cells, which imperceptibly and independent of the current of the sap mixed the whole up together, or carried the different ingredients to where they were wanted. Since I last alluded to this subject I have endeavoured to see if actual experiment would throw any light upon it, and as a contribution to its elucidation I now submit to the committee the particulars of one or two experiments that I have made. I made experiments with the Vine, the Fig, the Horse Chestnut, and the Hyacinth, but as they all, so far as they went, tended in the same direction, I will speak principally upon the Vine, which was much more manageable, and took up my infusions more readily than any of the others. Thanks to the experiments of Prof. McNab and Prof. Church, I knew of the virtues of lithia as an easily absorbed agent, whose presence could be detected anywhere by the spectroscope in however small a quantity it might be present, and I had the advantage of Prof. Church's own assistance in determining for me whether it was present or not. As lithia, however, is colourless, I added to my infusion enough of litmus to colour them deeply, and I must state as the result of my experience, that the lithia told me nothing that the litmus did not equally well. I then passed gutta-percha funnels over the shoots to be experimented on, and secured them as cups, with the shoots growing up the middle, by means of cork and tallow. My experiments were made in April and May, when the leaves were beginning to open. I put one cup on the stem of the Vine. It held perfectly, and no escape of the liquid took place. After the cup was properly luted to the stem with tallow, I cut a nick in the bark a little above the fitting, and then filled the cup with the lithiated litmus-mixture, so as to cover the nick. I then allowed it to remain on for six weeks, constantly renewing the mixture in the cup as it disappeared. After the expiration of six weeks I took up the plant and examined it: and here let me see that the Committee and I are in accord as what I should have found had Sachs' theory been well founded. I imagine that I should, on the ordinary principles of gravitation, have found the severed vessels below the nick and on the same side filled with the infusion in consequence of its descent. So far as regarded that part of the plant it was no longer a closed tube, and there could be no ascent, but being, as it were, merely an open tube, whatever was poured into it should simply find its way to the bottom. And so in fact it did—the infusion below the nick descended to the very fibrils of the roots. In like manner the part above the nick being a closed tube—closed by the cup at the bottom and by the leaves acting as a sucker at the top—we should expect that the infusion would ascend; and so it did, nearly as completely as it descended below the nick. But how as regards the parts that were on the opposite side of the nick. According to Sachs' theory, whether you call it the result of metastasis or of endosmose and exosmose, the infusion should have been found extravasated and infiltrated through that side, both above the nick, and below the nick, and up the ascending branches, and in fact everywhere a little; but in point of fact there was not the slightest extravasation nor a solitary particle of lithia or litmus in any of these places. The depth of the nick was the measure of the extent of the penetration of the infusion, and it was as sharply defined as a line could be; and this is just what I said should be the case. I said that the rapidity of the current would prevent any intermingling of ingredients by endosmose or exosmose, just as a small boat finds a difficulty in getting into the current of a heady river, even with the external aid of oars, or a small stream pouring with the force of gravitation into a more powerful one is shoved aside and driven down the banks. The sap has neither oars nor gravity by

which to force its way from one part of the ascending current to another, and it must be content to go with the flow of that part of which it is a component particle. At night there can be no ascending current, for the force that produces it, the sun, is withdrawn, but the tube is full and in equilibrium. To my mind the above is conclusive on the question. Sachs must be wrong; and we must now re-examine his arguments, and see where the flaw lies. If the committee will allow me a few minutes, I do not think we shall have very far to seek. His position is thus stated in his "Physiologie Végétale":—"The absolute necessity (says he) of the intervention of light for assimilation in plants with chlorophyll is proved directly by their mode of development in darkness. When we cause seeds to germinate under such conditions, roots, internodes and leaves are developed generally in proportion to the mass of the seed. When all the provision of elaborated principles contained in it are exhausted for development ceases. If up to that period the seeds be allowed to germinate in the light, and then removed into darkness, the result is the same—the young leaves, although green, assimilate nothing; but if they be allowed to remain long enough in the light to have assimilated a little, there will be developed in darkness leaves and internodes until that new provision be exhausted also." But there is one important fact that Sachs omits to keep in view here. If the plant in darkness assimilate nothing, neither does it take any food to assimilate. It is well known that plants do not feed in the dark, and nothing is easier than to prove it by experiment. Let any one with a Hyacinth growing in water in a glass, mark by a thread or narrow strip of paper glued to the glass the height at which the water stands at night, he will find it at the same height to-morrow morning, but very different to-morrow night. But the fact is not disputed.

Now on what ground are we to hold that the reason why the plant does not assimilate is the absence of light in preference to the absence of food? Either will account for it, and the one will suit Sachs' theory, but the other not. No doubt the food is not taken up during the absence of light, but it may very well be that if the plant were placed in such conditions that it could take food generally, although secluded in darkness, we should find that assimilation went on as well in the dark as in the light; and this, in fact, is just what Nature does with tubers. They are in darkness while the plant is in light, and they contain assimilated matter in as great abundance as any Apple in the blaze of sunshine. Sachs would say that this was derived from the elaborated stores assimilated by the leaf; but this is taking the thing to be proved as part of the proof. He has to prove that assimilation cannot take place except in light. I offer an instance of its apparently taking place in darkness, and the reply is that that cannot be, because assimilation cannot take place in darkness. It is not that the fire will not burn because it is dark, but that it stops burning when the coals are consumed, because no more are supplied to it. During the day the light and heat of the sun draw up the sap to all the terminal parts of the plant, such as the axial extremities of the branches, the buds, the leaves, the tubers (which are only subterranean buds), where it is partly evaporated and partly assimilated—and as it is used up, the roots absorb a corresponding flow to supply the consumption; but at night, when the motive power is withdrawn, the upward flow of sap ceases, the roots become inactive, and cease to feed; at the same time there is nothing to hinder growth growing on—it may pile up cell upon cell, whether the machine is working or not, and it does so, but assimilation ceases. Allow me, however, further to cite a well-known fact in favour of my views, which it reflects no credit upon us not to have sooner so interpreted. Here am I narrating, and you listening to, my clumsy experiments, and yet we have all had always before our eyes—and our ancestors for ages have had then before them too, a constant series of beautiful and conclusive experiments, proving much more clearly than I have done what I have attempted to show. I allude to what we see in the case of grafts. We know that the stock has certain properties differing from those of the scion; we all know that the properties of the stock affect the scion; they are carried up into its system, but those of the scion are not carried down into the stock. If the theory of descent and wandering and mixing of the sap were true, the qualities of the scion ought to descend just as much as those of the stock ascend, but they do not.

I meant to have stopped here, but I am in the position of a man, who, having begun to take a rotten beam out of an old house, finds a whole superstructure of dependencies, offsets, lean-tos, and rookeries tumbling about his ears. The system of vegetable physiology now in credence was built upon the faith of the existence of a circulation of the sap, and everything has by degrees been arranged to fit neatly into it. That rotten beam was removed and its place supplied by Sachs' theory; that, I think, I have shown to be rotten too, and in removing it, without having any other props to put in its place, down must come the hypothesis that the plant derives all its carbon from carbonic acid in the atmosphere, or its nitrogen from free uncombined

nitrogen through the leaves, and all power of taking anything into the system through the leaves, and, of course, all hypothesis of feeding, whether vegetarian or carovorous, through these organs. These theories of circulation by imbibition, diastasis, endosmosis, and exosmosis, to me are already defunct. Six weeks' unavailing effort to get the slightest indication of any of these phenomena in the living plant seem enough for me. The current is upward steadily, and not only permits nothing to come down against it, but is too powerful to permit anything to deviate from its own place, and force its way into another, even by uniting with it on the way upwards. My position therefore is that for a plant to absorb carbonic acid, whether free or not, through the leaves for the purpose of supplying it with that important element involves a physical impossibility.

[We regret that we have not space for the remainder of the arguments which Mr. Marray adduces in support of his views. We must refer for them to the August number of the "Journal of the Royal Horticultural Society," in which his paper will be found at length.—Ed.]

STREET PAVEMENTS.

SINCE the days of MacNeill, Telford, McAdam, Parnell, and others, volumes have been written upon this subject; yet we have in many localities pavements which are a disgrace to a community making any pretensions to scientific knowledge. This results either from a misunderstanding of all the conditions of the problem or an inability to fulfil them. The conditions, it is true, are intricate and variable, depending upon location, grades, nature of merchandise, vehicles, power, subsoil, finances, &c.; but in this monograph we propose to discuss briefly only the requirements of the surface covering, and to determine in the light of a long and varied experience what material will best fulfil all the conditions of a crowded thoroughfare. The requirements of the surface are that it shall be: (1) firm and elastic; (2) noiseless, clean, and dry; (3) smooth yet rough; (4) permanent, yet easily removed; (5) light yet heavy; (6) it should be durable, producing a minimum amount of wear and tear; (7) it must also be cheap and readily attainable, and (8) non-combustible. The impossibility of selecting any one of the available materials, wood, stone, brick, cement, iron, or asphalt, which will fulfil all the above conditions, is apparent. A compromise must therefore be made, and one or more selected which will approximate most nearly to the requirements of the case.

It is interesting to observe the ingenuity displayed by advocates of a particular material in making it conform to every want, and in theory all the above materials have been found to answer equally well; but from a practical, rational, and disinterested point of view it is impossible that such should be the case; e.g., Vegetable Substances, containing within themselves nitrogenous principles, elements of decay and putrefaction, should be rejected from sanitary considerations alone, but in additions to this, their combustibility, softness of fibre, permeability, and cost are serious obstacles, and the experiences of numerous trials on both continents, under varied conditions, has proved them failures as to durability. We feel entirely justified, therefore, in omitting this material from the list of available substances until some more efficient means be successfully introduced of preserving the block, draining the foundation, and preventing dry rot. Iron has been used in various forms, but, being a manufactured article, it is more expensive than stone or wood, which are natural products. Hexagonal and other forms of blocks, covered with studs, and standing on legs which were driven into the foundation, have been discarded because of the noise, expense, and insufficient foothold. Whenever tried in the form of blocks, iron has been found very objectionable, and its use is now restricted to tram and railroads. Bitumen is a natural mineral product, belonging to the class of hydrocarbons, and may be found either solid, as in asphaltum, or liquid, as in mineral tar. It is used chiefly as a matrix for harder materials. The best asphaltum is imported from Seyssel, in France, and Neuchâtel, Switzerland, but a tolerably good article is also obtained from the island of Trinidad. This substance melts at a comparatively low temperature, and is quite brittle when cold, so that it possesses properties which render it inappropriate for roads when subjected to great ranges of temperature and heavy traffic. When used, however, with sand and cement, it forms an excellent surface, so far as smoothness and durability are concerned. The wooden pavement on Pennsylvania Avenue, Washington, has recently been replaced by another, part of which is composed of Neuchâtel bituminous limestone, 1½ in. thick, laid on a foundation of 8 in. of cement, and the remainder of "Grahamite" (pure asphalt from Ritchie County, Va.), 2½ in. thick on a similar foundation. Brick, being merely clay indurated by burning, is too brittle for ordinary travel; we find ourselves, therefore, restricted to the

use of stone or cement as fulfilling most nearly the requirements of a good road covering. But stone occurs in a variety of forms, as in "cobblestones," boulders, "spalls," or blocks, and in sizes which vary as the ratio of their three dimensions. Of the three first-mentioned forms, it is difficult to decide which is most injurious, yet these are the favourites with the community, because of their cheapness (?), and with the contractors because of the proportionately large margin of profit and necessity of frequent repairs. By this general and brief analysis, we are induced to believe that stone of a regular geometrical form is that which is most suitable for the purpose; cement being an artificial monolith, whose dimensions may be extended at pleasure, is included in this class.

A tramway in connection with a "Belgian" block system would fulfil all the requirements in the best and most economical manner. Trams, 8 in. deep and 2 ft. wide, if well laid, would oppose the least possible resistance to the wheels of vehicles, and would be noiseless, whilst the blocks between would furnish the desired foothold, and the clicking of the horses' feet give sufficient warning of the approaching vehicle. This arrangement supposes the conditions of the horse and carriage to remain constant, and until lately it has been assumed that these elements of the problem were fixed, but rubber tires have been introduced and give great satisfaction. Still the roughness of the pavement required to furnish the necessary foothold has been found to cut and destroy them so rapidly as to render their general introduction improbable. If now we can substitute for the present shoe a material that will prove as durable and as secure, at the same cost, it will open the way to great reforms in all the elements of locomotion—viz., the pavement, the vehicle, and the power. Such an improvement has, indeed, been made and tested satisfactorily. It consists of a hollow shoe of the ordinary shape, open at the bottom, and having iron studs projecting vertically downwards through a ¼-in. tarred rope, which they hold in place, and which serves as a packing. The shoe is put on without heating, and held in place by six nails. It has been used until worn down to a knife edge, and its life is quite as long as that of the ordinary iron shoe. The rope is not kicked out by use, but is, in fact, riveted firmer by the pounding down of the studs. The general introduction of such an improvement would undoubtedly lead to the substitution of concrete for the rumbling pavements now in use. The chief objection, lack of sufficient foothold, having been overcome, minor difficulties need have but little weight, as that portion of the surface overlying sewers, &c., might be divided into blocks, which could be readily removed and replaced. The necessity of breaking the surface for pipes could easily be avoided by laying them hereafter under the sidewalks or in rear of the dwellings, in streets of the second class. What must be the waste of energy that will set in vibration the horses on both sides of a street whenever a vehicle passes? Yet the injury is not limited to the vehicle, the edifice, nor the road covering, all of which are badly shaken up, but extends in a greater degree to the animal life affected by it: the horse, and the individuals in the house or conveyance. It is a constant strain upon the nervous system of women, invalids, and children, whose sleep is disturbed and restless. This enormous waste of energy can, and should, be avoided by recourse to proper engineering expedients, and no one will deny that a uniformly smooth, even, and continuous surface, such as that furnished by a good cement pavement, with only joints enough to permit of expansion, would fulfil in the most perfect manner all the requirements for the horse, carriage, passenger, and resident, could be kept perfectly clean, and when once laid, would require the minimum amount of expense for repairs and police.

NOTES AND QUESTIONS—VARIOUS.

Tom Thumb Candytuft.—This new White Candytuft is a valuable addition to border annuals; it is dwarf, very compact in habit, and flowers most profusely, the blossoms being as white as snow.—R. GREENFIELD, *Priory, Warwick.*

Large-flowered Cereus.—When looking over the collection of plants belonging to Mr. C. M. Major, Cromwell House, Duppas Hill, Croydon, I saw a *Cereus grandiflorus* with larger flowers than those of the common one; it is evidently a fine variety. The petals are wider and paler than those of the type, and the stems are more spiny and stronger. It was imported from Demerara, and is evidently quite distinct. Have any of your readers seen this variety?—J. CROUCHER.

Godetia Lady Albemarle.—This fine new crimson Godetia deserves a place in all gardens where a bold, showy flower is desired. It is compact in habit and free-flowering, commencing when it is about 6 in. high, and continuing on in bloom until it is nearly 2 ft. in height. The flowers, which are bell-shaped, are deep crimson, with white centres; with me it has been in bloom for six weeks, and promises to keep on flowering for some time to come.—R. GAASNFIELD, *Priory, Warwick.*

* By Prof. Lewis M. HAYES, in the "Journal" of the Franklin Institute.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

WILD FLOWERS IN FLORAL DECORATIONS.

SOME weeks ago (see Vol. XI., p. 465) I gave a description of a vase of wild flowers which I had arranged, and I now propose to describe the same vase decorated with early autumn flowers, as it presented even a prettier effect than when done with spring or early summer blossoms. As some of my readers may not have read my former paper on the use of wild flowers for floral decorations, I shall again describe the form of stand in which I arranged my blooms. It was made of basket-work varnished dark brown, and its form was that of a flat tazza, out of which rose three rods tied gipsy-fashion in the form of a tripod, on which rested a tazza of smaller size than that below from which the tripod rose. Round the edge, lightly placed so as to show up against the damask cloth, I placed small fronds of Bracken (*Pteris aquilina*), and then filled in the tazza with blooms of Hemlock, Ox-eye Daisies, Clover, Fairy Flax, Marsh Marigold, Vetch, Tormentil, Trefoil, Mallow, Blackberry, Tansy, Horse-tail, Grasses, and Oats; up the tripod stems I twined sprays of the Deadly Nightshade, some of which bore blooms and others tinted berries. I then filled the upper tazza with similar flowers to those employed below, but selected smaller-sized blooms and branchlets; round this stand I grouped four specimen glasses, in which were arranged similar flowers and Grasses, and a few sprays of Oats. Just at this season the latter will be found most useful for floral decorations, be they vases of wild or hothouse flowers, as in either case they will tend to give a light and effective appearance, and Grasses are not now easy to obtain, save by those who cut and dried them last month for autumn and winter use, as, owing to the hot weather and the mowers, many cannot now be found in the meadows or hedgerows. Sprays of Horse-tail will also be found useful to intermix with blooms; it is often to be found in damp ditches and along the sides of old or unused roadways. I have often found varieties of this plant growing freely on railway embankments; along the latter, where much chalk is used in their construction, can often be found charming bits of colouring at this season in the way of sprays of the wild Geranium and similar flowers, the foliage of which, when growing on chalk, limestone, or any very dry spot, and exposed to the rays of the sun, assumes a lovely crimson tint, in shade similar to the Virginian Creeper; I have found even leaves of the common Dandelion growing in such places, tinted with the most lovely shades. Unless one saw an arrangement with these descriptions of scraps employed in its construction, it can hardly be believed what a pretty effect is obtained; branchlets of Blackberry blooms are very pretty to employ in floral decorations, but the thorns of this plant should be removed from the stems before they are placed in a vase amongst other flowers, as otherwise they catch in the other stems and drag the arrangement out of shape. I know that many are under the impression that arrangements of wild flowers last but a few days; but that is a mistake, as by introducing a few fresh leaves and Grasses I have kept an arrangement of the above description on my breakfast-table quite a week; indeed, at the present moment I have one in use which has lasted in good condition four days, and it looks as fresh as ever, though I have not added a single spike of Grass to freshen it up. I do not employ many Poppies in my decorations, only just a few to give a dash of colour, as they do not last so long as other flowers, though I have kept them fresh four days; after that they change their colour if they do not drop their petals. Just at present large quantities of the pretty mauve-coloured *Ononis arvensis* (Rest Harrow) are to be found on Streatham Common; this will be found most useful for floral decoration in vases of trumpet shape or in specimen glasses.

ANNIE HASSARD.

BOUVARDIAS FOR WINTER.

FEW plants have gained popularity more rapidly in our flower markets than the beautiful white-flowered *Bouvardia jasminiflora*, the cut blooms of which form the principal white flowers obtainable during the winter and spring months. Another kind, though not new, *B. Humboldtii corymbiflora*, is now being grown extensively, and will no doubt soon become as great a favourite as *B. jasminiflora*. Its flowers, though not so freely produced, are much larger than those of the kind just named, and they possess the valuable property of lasting longer in a cut state. This sort, however, grows too large ever to become a really good market plant, as unless bushy plants loaded with flowers can be obtained in from 6-in. to 8-in. pots they are of little value in Covent Garden, large plants not being appreciated. Bouvardias are brought to market in a flowering state nearly all the year round, and no flowers in bouquets are more universally admired and prized. The white-flowered kinds are mostly used, but a scarlet variety, probably *B. Hogarthii*, is sometimes employed with good effect in floral decorations in which bright colours are desirable. *B. jasminiflora* was formerly grown under the name of *B. longiflora*, but from this kind it differs in being of a much freer-branching habit of growth, its leaves are longer and narrower than those of that sort, and the flowers are produced in greater abundance; no kind, however, can equal in habit and floriferous properties *B. jasminiflora*, the flowers of which are also more fragrant than those of any other kind. Visitors to Covent Garden Market during the summer time must have remarked the difference that exists between Bouvardias offered for sale and those with which one generally meets in private establishments. Country growers, as a rule, use the knife too sparingly in the case of Bouvardias, and, therefore, instead of handsome, bushy plants 1 ft. or so high, and as much through, clothed with healthy foliage to the pot, as may generally be seen in Covent Garden, we find long, spindly shoots furnished with brown-looking foliage, and bearing at the points a single truss of starved-looking flowers. The more that bloom is cut from Bouvardias, the more profusely do they flower, and, of course, they become more bushy. For supplying cut bloom during winter and early spring, some florists near London grow as many as 5000 plants. These are obtained from cuttings struck in spring, and also consist of older cut-down plants that had not hitherto been disposed of. During the winter months a somewhat brisk temperature is kept up in houses in which Bouvardias are grown to supply cut bloom, and some, as soon as the flowers begin to expand, remove the plants into a cooler temperature in order to harden the blossoms a little before they are cut. After the blooms have been cut the plants are again placed in a warm, moist temperature, in order to promote new growth and another crop of bloom. In summer, when cut flowers begin to get cheap, these Bouvardias are allowed to come fully into flower, and are sold in the market in the form of plants. One London grower annually sells wholesale between 20,000 and 30,000 plants of *B. jasminiflora* and a scarlet-flowered kind, in 5-in. and 6-in. pots. The way in which they are grown is as follows:—In autumn the old plants which have done flowering are cut down and placed in a moderately dry and cool temperature. After Christmas is over a little more heat is given them, and they are occasionally syringed overhead; this has the effect of starting into growth a number of shoots from the bases of the old plants; these, when sufficiently firm, are taken off and inserted in sharp sandy soil in thumb or 3-in. pots, and placed on a bed of Cocoa nut fibre in which there is a gentle heat. These cuttings under favourable circumstances soon strike root, when they are potted in 5-in. or 6-in. pots in good fibrous loam, peat, and leaf-mould, or rotten manure. As they advance in growth they are gradually subjected to a cooler and more airy atmosphere than that in which they were struck, and when fully established abundance of air and light is admitted to them, and they receive copious supplies of water at the roots. From these plants cuttings are taken to come on in succession; they are taken off when the plants have made three or four joints, the two lower joints only being left on the plant. From these joints strong shoots are soon emitted, and these, when 4 in. or 5 in. long, are also stopped, an operation which is continued until the plants have been stopped

four times. Each set of cuttings is treated in the same way. Those struck first in the year make excellent bushy plants by the following autumn; and the last taken off, which is in August and September, make good plants early in the following spring. The old plants, from which the early cuttings were taken, are also grown on and make bushy, well-flowered plants early in summer. In order to obtain large specimens, which are, however, seldom needed in market gardens, old plants are cut back year after year, shaken out, and re-potted. During the summer, *Bouvardias* are grown in cool houses or cold pits, and sometimes in temporary frames, but in autumn, winter, and spring a temperature of about 55° is maintained, except in very severe weather, when a few degrees lower will not injure them. Some have lately taken to plant out their *Bouvardias* in the open air, and lift them in the autumn. For this purpose cuttings are struck in autumn or early in spring, and stopped in the same way as just mentioned; after being hardened off, they are planted out in June in beds, or in shallow trenches of rich soil, the surface of which is mulched with manure; abundance of water is given to the roots, and early in September, when the plants show bloom, they are carefully lifted with as much ball attached to them as possible, potted, and afterwards put into a shady place; they are well watered overhead and at the roots, and when fully established are placed in houses or pits to come into bloom. In staking, market growers only place one neat stick in the centre of each plant, to which, by means of fine pieces of bast, shoots are supported. Red spider and green fly sometimes attack the foliage, but frequent fumigations, syringings, and liberal culture soon counteract this evil, and little damage is done. C. S.

Gynerium jubatum.—This variety of the Pampas Grass, recently introduced from Chimborazo by the well-known plant collector Roezl, and sent to me by M. Lemoine, of Nancy, in the spring of last year (producing a single spike last autumn), seems to be by far the earliest blooming of its family that I have yet seen, as though none of my numerous other large plants are yet showing any sign of throwing up their bloom-spikes, my plant of *G. jubatum* has nine of them now fully developed, several of which are now nearly 4 ft. high, and look as if they would expand their feathery inflorescence within the next fortnight. This early flowering will make this variety intermediate between the *Arundo conspicua* and the ordinary Pampas Grass.—W. E. G.

Ornamenting Stove Walls.—I was very pleased a few days ago, when going over the grounds of Mr. Marsh, at Hardwicke, Chesham, by an arrangement, novel to me, as regards the back wall of the stove. It was lined with Moss, enclosing about 3 in. of a compost consisting of peat and leaf-mould, the whole being kept in its place by wire-netting. In this lining have been carefully planted, with due regard to artistic effect, various Orchids, Begonias, Tradescantias, Ferns, &c., the whole of which are flourishing remarkably well, the Begonias being furnished with better leaves than I ever remember seeing elsewhere. The wall in question presented a charming appearance, so different from a whitewashed wall simply relieved by a few climbers, which is generally to be found in such houses. One end of a greenhouse was also treated in a similar manner, but it was planted with hardier plants, mostly Ferns.—S. H., Epsom.

The Colorado Beetle at Liverpool.—As our readers are doubtless aware, two living specimens of this beetle were last week discovered in the docks at Liverpool. One was found in a cattle ship from New York, and had evidently come out of the fodder brought to feed the cattle on board, and although the other was not so well traced, it was taken about the same time, and it is said at no great distance from the cattle ship. The fodder was fortunately exhausted by the time the vessel had got into dock, so that there is no reason to fear that the beetles have been distributed by the sale of the surplus fodder. There is, however, still room for anxiety from the incident. If both, as seems not unlikely, came from the same ship, we can hardly expect to have been so fortunate as to capture all that came. The chances are that there would be more than two, and these will have made good their landing unnoticed. We shall not, therefore, be at ease about this vessel's importation until three weeks or a month have elapsed. If no field be attacked by that time, the probability is that we have escaped; until then every one about Liverpool should keep a sharp look-out for the insect. Since the above was in type, a supplement to the "London Gazette" has been issued, containing an Order in Council on the subject of this beetle. The Order extends to Great Britain only, and is to have effect from the 31st inst. The

Order states that "it shall not be lawful for any person to land Potato haulm, leaves, or stalks brought from the United States of America, Canada, or the German Empire;" and that "the Commissioners of Her Majesty's Customs may in any case, if they think fit, order the collection and destruction of any sand, dirt, or other refuse imported with Potatoes brought from the United States of America, Canada, or the German Empire, and detain the Potatoes until such destruction has been effected." The Order contains the following provisions:—"If the owner of, or any person having under his charge, any crop of Potatoes, or other crop, or vegetable, or substance, finds, or knows to be found thereon, the Colorado beetle, in any stage of existence, he shall, with all practicable speed, give notice of the fact of the same being so found to a constable of the police establishment for the place where the same is found. The constable shall forthwith give notice thereof to the local authority, and the local authority shall forthwith give notice thereof by telegraph to the Privy Council. It shall not be lawful for any person to sell, or expose or offer for sale, or keep any living specimen of the Colorado beetle, in any stage of existence, or to distribute in any manner any such specimens. If any person fails to do anything which he is required by this Order to do, or does anything in contravention of this Order, he shall be deemed guilty of an offence against this Order, and shall, for each offence, be liable to a penalty not exceeding £10."

Influence of the Scion on the Stock.—In reading in THE GARDEN (see p. 147) your extract from Mr. Murray's account of his experiments on the flow of the sap, I was surprised to find him stating as an unquestioned fact that the scion never influences the stock, and this he holds to be confirmation of his theory. But is it strictly true? Mr. Burbidge, in "Cultivated Plants, their Propagation and Improvement," gives a list of well-authenticated cases in which the scion had affected the stock in a very marked degree. Two rather remarkable instances have also come under my own notice this summer, and which may perhaps interest those who are paying attention to the sap controversy. In one case a line of Laburnums had been budded in 1876 with a variegated variety; most of the buds died, but this summer many of the stocks are variegated precisely like the variety which was budded on them. In the other case several Laburnums had been budded (some of them grafted) about 5 ft. from the ground with the golden variety lately sent out by Mr. Smith, of Worcester. Most of them "took," but, strange to say, suckers on several of them which had been allowed to grow assumed a beautiful golden-yellow hue, just like that of Mr. Smith's variety. The suckers were all below the bud or graft, some of them close to the ground, a circumstance which seems to me to present a strong argument against Mr. Murray's theory.—A YOUNG PROPAGATOR.

Emmenanthe penduliflora.—This interesting novelty is a member of the Natural Order, Hydrophyllaceæ, which contributes *Nemophila*, *Phacelia*, *Whitlavia*, and a few other genera to our gardens, and like the plants just named, is an annual of low growth, not usually exceeding 1 ft. in height, and of neat tufted habit. The foliage is pinnatifidly cut, with rounded lobes, and resembles that of the *Nemophilas*, the flowers being produced in loose terminal racemes, and are somewhat pendulous in their full development, but at first erect. The corolla is of pale primrose yellow, campanulate in form, about $\frac{1}{2}$ in. in length, slightly exceeding the calyx-lobes. It is not improbable that careful cultivation and selection may bring about an increased development of the corolla, which at present is scarcely so long as could be desired, but the very neat habit of the plant and the character of its foliage render it quite deserving of attention on the part of amateurs and others. It is a native of Southern California, and succeeds perfectly as a hardy annual on any ordinary soil.—W. THOMPSON.

Regular-bearing Apples.—The following are not only regular and abundant bearers, but they become fruitful at a very early date after planting, viz.:—Cox's Orange Pippin, King of the Pippins, Keswick Codlin, Collini, Old and New Hawthornden, Lord Suffield, Dumelow's Seedling or Wellington, Dutch Mignonne, and London Pippin. These are well adapted for small gardens, either as espaliers or bush trees.—J. GROOM.

Victoria Marrow Pea.—This is a fine variety for the late summer months. We have at present some rows of it literally loaded with pods from near the base to as high as a man can reach. This has certainly been an exceptionally favourable season for Peas; but what is of importance is that the pods are not only fine and numerous, but are quite full of Peas, which is not the case as regards some of the newer kinds, the yield of which is greatly out of proportion to the bulk of the pods.—J. G.

Liquid Manure in Vineries.—I have used manure-water extensively for over eight years in my Vineries, and with excellent results; that from pigsties is the best.—H. HARRIS, *Denne Park, Horsham*.

NOTES OF THE WEEK.

CURIOUS FACT ABOUT VARIATION.—Three or four years ago I had a plant of a variegated Rhubarb given me, the leaves being a good deal blotched with yellow; and not knowing very well where I could put it, I planted it in the kitchen garden at the end of one of three rows of Rhubarb, in quincunx order, as in the subjoined plan. Last year two or three of the plants nearest to the original variegated one became more or less blotched with yellow. This year four have become as much variegated as the original plant. Can any of your readers give an explanation of this (to me) singular fact?

$$\begin{array}{ccccccc} & 2 & & 5 & & & \\ 1 & & 4 & & & & \\ & 3 & & & & & \end{array}$$

1, original variegated plant. 2, 3, 4, 5, much variegated this year.—J. G. N.

STRAWBERRY DUKE OF EDINBURGH.—This is the favourite market Strawberry round Edinburgh; it is a very large and highly-coloured fruit, a free grower, hardy, prolific bearer, and has a very good flavour. Ten fruits of this variety sometimes weigh 1 lb.; it is a medium variety as regards the season of ripening. It was raised by Mr. Moffat, market gardener, of Caldwells, near Dalkeith, and is now being sent out by the Lawson Seed and Nursery Company, of Edinburgh.

OPUNTIA RAFFINESQUIANA IN FLOWER.—Mr. Barr, of King Street, Covent Garden, has sent us some blooms of this Cactus. They measure nearly 4 in. across the petals, which are of a rich satiny texture, and of a pale canary colour, surrounding a tuft of orange-coloured stamens. It is quite hardy, and well fitted for rock-gardens, raised borders, or any position where its succulent vegetation may not be bruised or otherwise injured.

ERYTHRINA CRISTA-GALLI.—A fine specimen of this Coral tree, growing at the end of one of the plant-houses in Messrs. Veitch's nursery at Chelsea, now forms a striking object. It is furnished with some fifty strong shoots, from 2½ ft. to 3 ft. in length, all of which are thickly beset with blossoms and healthy green foliage. In sheltered positions this Erythrina might be isolated on lawns or large borders with good effect.—S.

THE CATALPA.—This tree is now in full flower in the London parks, and even in some of the squares. In the distance it resembles a cloud of flowers, or closely examined it is a lovely object, and its form and stature fit it well for town and city gardens; its shade is also dense and long-enduring. It might with great advantage be planted near houses in town gardens, and in streets for which the Plane is too large and the leaves of the Lime too short-lived. It also deserves attention on account of its season of flowering, inasmuch as a tree full of blossom early in August is not a common sight. We want more trees that flower in summer and autumn, most of our wealth being in spring-flowering trees.

THE NEW ZEALAND FLAX FLOWERING IN SCOTLAND.—While visiting the fine old garden at Fordell, near Inverkeithing, the other day, I was delighted to see in a clump on the terrace lawn, lying to the south of the old Castle, a fine specimen of this Flax in flower. It has produced two spikes 9 ft. high, each spike being furnished with about eighteen clusters of reddish-brown flowers. The leaves, which are upright, are about 5½ ft. long. This plant has been growing in its present situation for about twenty-five years, and this is the first time it has ever shown flower; it is, too, the first plant of the kind that I ever saw in bloom in the open air in Scotland.—J. McN.

DOUBLE IVY-LEAVED PELARGONIUMS.—Amongst the many kinds of Pelargoniums which have been introduced into gardens of late years, few excel in usefulness the double-flowered Ivy-leaved kinds, of which there is a good collection now in flower in Mr. Bull's nursery at Chelsea. Either for pot or outdoor culture, these Pelargoniums are very valuable, and they are also very effective as vase or window plants. The flowers, which are of good form, vary in colour from white to pink and rose. Such plants cannot fail ere long to be largely grown for bouquet-making and other floral devices, for which they are admirably adapted, as they last in good condition in a cut state much longer than some kinds of Pelargoniums.—S.

FUCHSIA EARL OF BEACONSFIELD.—This seems to be one of the best Fuchsias for general decorative purposes that have been raised of late years. It is the result of a cross between *F. fulgens* and *F. Perfection*. In form the flowers resemble those of *F. fulgens*, but they are produced in much greater profusion than in that species. Plants of it growing in pots in Mr. Laing's nursery at Forest Hill show how freely it flowers, many of the shoots bearing clusters consisting of no fewer than fifty blossoms. The plant is robust in habit and well furnished with large, glossy green leaves, which set

off the carmine and salmon-coloured flowers to advantage. For training under the roof of conservatories or greenhouses, or for draping pillars, this plant is well adapted, and if planted in good soil and liberally supplied with water, it will continue to bloom the whole year round. It will no doubt soon be largely grown for market purposes.

DARLINGTONIA CALIFORNICA AT GLASNEVIN.—The noble specimen of the Californian Pitcher-plant at Glasnevin is just now swelling a fine seed capsule, the result, it is hoped, of a cross with one of the kindred *Sarracenias*.—"Irish Farmers' Gazette."

ANTIRRHINUMS.—A large bed of the semi-dwarf forms of this hardy biennial, now in bloom here, is truly beautiful, the colours and markings being of a very varied description. Among them may be found flakes, selfs, and bicolors in rich variety—pure white, yellow, rose, red, purple, crimson, and all sorts of intermixtures. The seed was sown under glass early in March; the seedlings were pricked out into a frame in the first instance, and thence planted out into the open ground early in June. They began to bloom about the middle of July, and will continue to flower in profusion until the end of October.—A. D., *Bedfont*.

DWARF FRUIT TREES BEST.—That a decided advantage is gained by market gardeners who plant dwarf, standard, or bush-trained Apple trees between taller-growing ones, is this year proved by the fact that in many orchards in the neighbourhood of London, on old-established trees, with stems 12 ft. high and heads in proportion, scarcely a fruit is to be found, whilst trees between them, with stems about 2 ft. high and bushy heads, are bearing a fair crop. This is at least the case with Apples, and no doubt it also applies to other fruits.—C. S.

THE WATER MELONS.—A few of the seldom seen fruits of the Water Melon may now be seen in Covent Garden. They are quite distinct from the oval-shaped kinds generally seen about London under this name. When grown and well ripened in hot countries the Water Melon is a great favourite. In the true Water Melon the flesh is scarlet and the seed is black. In summer, Melons of this kind are exceedingly refreshing. Perhaps they might be grown successfully in any ordinary pit or frame in this country in summer. The fruits in the market weigh about 12 lb. or 13 lb. each, but they sometimes attain a weight of from 40 lb. to 50 lb.

SEEDLING PETUNIAS AT SYDENHAM.—In the Crystal Palace Nursery large beds of single-flowered seedling Petunias form a remarkable feature. The plants throughout are one mass of bloom, consisting of colours varying from pure white to dark purple. Selfs and striped flowers occupy separate beds, and considering how easily such plants as these may be grown, and how effective they are, either in mixed colours or otherwise, their value for forming masses on banks, or for covering mounds of roots or stones, or, where preferred, for border-planting, cannot be overrated.

A NEW PARK AT WESTMINSTER.—It is stated on good authority that London is to have a new park, to be made by the demolition of a small number of houses, mostly private, situate in the immediate neighbourhood of the new Palace of Westminster. The details of the plan have not been settled, but it is pretty generally understood that its object is primarily to isolate the palace from certain dangerous neighbours, and, in the second place, to contribute by picturesque landscape adornment to the architectural effect of that agglomeration of buildings which now covers Thorney Island.—"Tatler."

DASYLIIRIONS after Flowering.—I have a good plant of *Dasyliirion gracile* which has thrown up a flower-stem; would it injure the plant or not to cut it off? It is now about 3 ft. above the top of the leaves, and has reached this height in about eight days, though in a perfectly cold greenhouse. What height may the flower-spike be expected to reach?—SCRIBBER. [The flowering of *Dasyliirions* is not a very common occurrence, inasmuch as they usually attain a considerable age before they bloom. If the flower-stem had been cut out when it first began to push, it is just possible that the plant might have formed a growing crown that would have gone on producing leaves in the way the plant has done heretofore; but as the spike has made so much progress, nothing will be gained by cutting it out. The height which it will attain will wholly depend upon the strength of the plant; it may reach 8 ft., or 10 ft., or more. In all probability, after flowering, the plant will form a number of small crowns in the shape of suckers near the collar, or at the top, just below where the flower-stem has sprung, or both; these, as they are produced, may be taken off and struck, and thus a considerable stock may be obtained; but it is not likely that the plant itself will again be equal to what it has been previous to flowering.—T. B.]

A large Mshroom is said to have forced its way through 12 in. of concrete covered with a thick layer of asphalt, in the floor of the Savings Bank department of the General Post Office in London.

TREES AND SHRUBS.

LARGE WALNUT AND OTHER TREES.

HAVING observed in THE GARDEN of July 14 the description of two large Walnut trees, the one at Downland House, Hants, the other at Rufford Abbey, Notts, and also an inquiry as to where the largest Walnut trees are to be found in Great Britain, allow me to bring under the notice of your readers a very fine Walnut tree growing at Edmonstone, near Edinburgh, the seat of Sir J. D. Wanchope, Bart. Its girth at 3 ft. above the ground, where it divides into three limbs, is 16 ft. 9 in.; the girth of the limbs severally is 8 ft. 8 in., 8 ft. 6 in., and 6 ft. 2 in.; the branches cover a circumference of 242 ft. At the same place there are also some fine Spanish Chestnuts. The girth of one of these at 3 ft. above the ground is 15 ft. 3 in., and at 6 ft. 6 in. from the ground, where it divides into two limbs, it is 18 ft. 9 in. Another of these, at 3 ft. above the ground, measures 14 ft. 6 in. I may also mention that there is at the same place an Oak grown from an acorn planted by the present proprietor's grandfather, about 110 years ago, which now measures 12 ft. 6 in. at 3 ft. from the ground. There are also two handsome Tulip trees in the grounds, one of which has flowered profusely every year for certainly upwards of fifty years. Unfortunately this was much damaged last year by an unusually early snow-storm in November before the leaves were off the tree.

SCOTIA.

— There is a large Walnut tree at Leversdown, near Bridgwater. Its girth 2 ft. above the ground is 17 ft.; and at 5 ft., 14 ft. 8 in.; the length of the stem up to the crown, is 10 ft.; girth of first branch, 10 ft.; circumference of branches, 275 ft. The branches would have covered a greater circumference, but a huge limb was blown down a few years ago.—D. K. T.

SALE OF TIMBER AT LONGLEAT.

THE following are the average prices realised for the principal lots sold at our annual timber sale, which took place last week:—

	Average contents	Average price realized.
	ft. in.	per ft. s. d.
100 Oak trees	16 0	2 2
187 "	12 0	2 1
31 Beech trees	30 0	1 3
135 "	19 0	1 3½
26 Ash trees	21 0	2 7
16 Elm trees	31 0	1 2
15 Scotch, 2 Spruce, and 2 Larch Fir trees	12 6	0 11½ each.
176 Oak Saplings		4 8
193 Fir and other poles		2 3

The bidding was brisk throughout; although the timber was mostly of small dimensions, and the British timber trade still flat and depressed, the prices are higher than those obtained last year; indeed, the sale altogether was very satisfactory, and commanded higher prices, in proportion to the size of the timber, than any sale that has taken place in the neighbourhood during this season.

G. B.

CONIFERS IN SOMERSET.

THE late owner of Mells Park, the Rev. J. S. H. Horner, was an ardent lover of trees, and was one of the early Conifer enthusiasts; his son (the present owner) is also equally interested in Conifers, and is continually adding some choice plants to the collection. The Pinetum was commenced about 1845, and occupies one of the higher portions of the park. Unfortunately, the strata underneath the immediate surface are the least favourable beds on which to establish a collection of Conifers, the percentage of lime in the soil, perhaps, being too great for them to flourish in perfection, the result of which is that many of the oldest specimens present a rusty and withered appearance. As may be judged from the appended list, there is a great variety of Conifers, some of which are uncommon. *Pinus Ayacahuite* is a distinct and beautiful variety, and is healthy and thriving. This tree somewhat resembles *Pinus excelsa* in the habit and length of its leaves, but the colour of the latter is nearer to that of *P. Strobus*; it is, I believe, a very rare specimen—indeed, it is the only

one I ever remember to have seen. *P. romana* is a distinct variety, its globular-shaped head being very conspicuous. *P. monticola* is a good neat, pretty Conifer; it is healthy and thriving. *P. Escarena*, *P. Lemoniana*, *P. Pallasiana*, and *P. pyrenaica* are robust specimens; they are, however, to my mind, coarse-growing trees of the Pinaster type. *Wellingtonia gigantea* is thriving beautifully in the coal measures clay; the specimens exhibit healthy, robust pyramids of foliage; probably if the Pinetum had been formed on the clay, instead of the conglomerate and limestone formation, the Conifers generally would have been much larger and healthier than they now are. *Picea grandis*, *P. cephalonica*, *P. Nordmanniana*, and *P. Pinsapo* are all beautiful varieties. *Abies Albertiana* is growing rapidly—it is a graceful Spruce; *A. orientalis*, too, forms a neat, handsome specimen for a lawn; *A. Douglasi* and *A. Smithiana* are of grosser growth, but both are handsome specimens. *Taxodium sempervirens* is well represented by a fine, vigorously grown tree; it would have been probably the tallest specimen in Britain had it not lost its leader for several years; it has, however, now formed a new leading shoot, and promises to thrive well. The three Cypresses are noteworthy plants, each presenting a distinct and beautiful habit. *Libocedrus decurrens* is a good plant, its deep green glossy foliage and columnar habit being very distinct. The following Table contains a list of some of the best specimens, the measurements of which were taken on April 3, 1877:—

NAME.	Height	Girth at 5 ft. up	Geological formation.
	ft. in.	ft. in.	
<i>Abies Albertiana</i>	19 0		Mountain Limestone.
" <i>Douglasi</i>	66 3		"
" <i>orientalis</i>	30 0		"
" <i>Smithiana</i>	34 5		"
<i>Arthrotaxis selaginoides</i>	6 3		Conglomerate.
<i>Biota orientalis</i>	17 0		"
<i>Cryptomeria elegans</i>	9 10		"
<i>Cupressus Lawsoniana</i>	20 0		"
" <i>macrocarpa</i>	47 6	4 8	"
" <i>sempervirens</i>	24 0		"
<i>Fitzroya patagonica</i>	9 10		"
<i>Juniperus venusta</i>	12 0		"
" <i>recurva</i>	18 0		"
" <i>virginiana</i>	27 8		"
<i>Libocedrus decurrens</i>	20 0		"
<i>Picea pectinata</i>	103 0	9 5	"
" <i>cilicica</i>	7 4		Mountain Limestone.
" <i>cephalonica</i>	46 0	3 10	"
" <i>bracteata</i>	9 3		"
" <i>grandis</i>	25 10		"
" <i>Lowiana</i> (<i>lasiocarpa</i>)	6 10		"
" <i>Nordmanniana</i>	34 6		"
" <i>Pinsapo</i>	36 0	3 10	"
" <i>Webbiana</i>	26 9		"
<i>Pinus Ayacahuite</i>	37 0	3 0	"
" <i>insignis</i>	53 0	6 1	"
" <i>monticola</i>	58 3		"
" <i>densiflora</i>	11 2		Conglomerate.
" <i>Escarena</i>	46 0	5 4	"
" <i>Lemoniana</i>	43 0	5 8	"
" <i>Massoniana</i>	7 5		"
" <i>monspeliensis</i>	8 0		"
" <i>Pallasiana</i>	35 0	5 2	"
" <i>ponderosa</i>	37 0	3 10	"
" <i>parviflora</i>	13 6		"
" <i>pyrenaica</i>	42 5	4 9	"
" <i>romana</i>	30 0	3 2	"
" <i>uncinata</i>	25 0		"
<i>Taxodium sempervirens</i>	53 0	5 9	"
<i>Wellingtonia gigantea</i>	38 0	4 9	Coal measures Clay.
	32 3	4 0	"

There are also many smaller plants of recent introduction, while some large specimens that appeared to be deteriorating I did not think worth measuring. To all lovers of Conifers a visit to Mells Park and an inspection of its trees could not fail to be interesting.

GEORGE BERRY.

Longleat.

Pine Tree Oil.—Between Bordeaux and Bayonne there is a large stretch of sandy desert, whereon there is little vegetation save here and there patches of Pine trees. From these trees there runs a resinous matter which is collected and sold by the inhabitants of the region. This substance has recently been studied by M. Guillemare, and he has now announced to the French Academy of Sciences that he has produced three kinds of oil from the material, all rich in carbon, containing respectively 80, 90, and 92 per cent. of that element. The light yielded on burning the oils is remarkable for its whiteness and steadiness, and is said to be suitable for lighthouse illumination.

THE INDOOR GARDEN.

THE DOVE-PLANT (*PERISTERIA ELATA*).

THIS beautiful Orchid is a native of Panama, where, on account of the striking resemblance which the column of the flower bears to a dove, it has been looked upon with no little consideration. The same religious feeling that gave the Passion-flower its name by the inhabitants of this country, is shown in the name "El Spirito Santo," the Holy Ghost plant; it is also called the Dove-plant, and the connection between these two appellations is very evident, when we remember that the dove is an emblem of the third person of the Trinity. Many plants have been placed in this genus by different botanists, which have since been removed into *Acineta*. *P. elata* is the handsomest of the four or five species which are retained. Its green, striated, pseudo-bulbs, are about as large as a swan's egg, and bear from three to five strongly-ribbed leaves, sometimes 3 ft. or more long by 6 in. broad; the flower-stems

The Dove-plant (*Peristeria elata*).

spring from the base of the pseudo-bulbs, and attain a height of from 4 ft. to 6 ft.; the upper third of this is occupied by the spike of nearly globose, beautifully-scented flowers, measuring about 1½ in. across; the colour is creamy-white, with the exception of the labellum, which is dotted with purplish-rose. The plant will succeed in either the East India or Cattleyahouse; it should be potted in loam or leaf-mould and well drained, as during its period of growth it requires a good deal of water, while when at rest it should be kept nearly dry. It is usually propagated by division. Q.

TIMELY AND JUDICIOUS RE-POTTING.

THE shifting of a plant from one pot into another is an operation which calls forth a considerable amount of judgment and care on the part of the operator. In this, as in most other gardening operations, it is difficult to lay down a code of rules. The growth, general habits, and root-action of most kinds of plants vary to such an extent that only extensive practice, combined with close observation, will enable even the amateur or professional cultivator to work with confidence

and certainty. When one considers, for instance, the contrast which two such plants as the Cape Heath and Fuchsia afford—the one making its growth and capable of being grown into a large specimen in a few months, the other requiring years of patient toil to bring it to the same dimensions—it is not difficult to realize how vast is the field over which this branch of gardening extends. A suitable compost must be chosen, proper drainage ensured, and not the least important point deserving of careful attention is that of seizing the right moment in which to transfer the plant into a pot of larger dimensions. Those who may wish to grow pot plants to any degree of perfection (especially if large, well-developed specimens be desired), must not fail to make timely shifting an especial study. In the case of thick, free-growing genera this latter point cannot be neglected with impunity, for although a few days' delay may not at the time produce any very marked effect, yet to this cause may often be attributed the want of freedom in growth, which later on is often observable. Given a quantity of healthy plants possessing, so to speak, a lively root-action, some very marked and even surprising results may be obtained by a judicious choice of the right moment when to re-pot. Those who may never have devoted any especial consideration to this part of plant culture would find it very interesting and profitable to institute a few experiments therein. Take, for instance, a batch of *Cinerarias*, plants that must be grown on without a check if handsome specimens be desired. Suppose them to be in 3-in. pots with the roots touching the sides, shift a portion of them, reserving the remainder to be operated upon at intervals of two days, finishing the whole within ten days. Treat them all alike, placing them where they may enjoy the same conditions of light, air, &c., and mark the difference in a month's time. The size will vary according to the time of potting: those first potted will take a lead that they will never lose, and, as I have before stated, this difference will often be so great in the ultimate size and appearance of the plants thus treated that the grower will scarcely be able to realize that the few days' delay in re-potting should alone be sufficient to produce such an effect. There is, however, not much difficulty in accounting for this, as a plant when once brought to a standstill either through want of nutriment or from some other cause, commences to harden and solidify its tissues; it lapses, in fact, into a state of semi-rest, from which it must be moved before free growth can again ensue, and hence the loss of time which can never afterwards be regained.

The rule generally observed is to allow the pot to become well filled with roots before placing the plant in another; this, though applicable to many tribes of plants, cannot be invariably adhered to. Those plants possessing very fine fibrous roots, such as the Azalea, Cape Heath, &c., should not be shifted until they have fairly filled the soil with fibre; in fact, great care must at all times be exercised not to overpot plants of a hard-wooded nature. There is, nevertheless, no advantage to be gained by retarding the shift when once this object is attained, the great point being to catch the plant at the moment or rather just before it comes to a standstill, for every hour's delay after that stage is reached is so much time lost, and will detract in a proportionate degree from the future excellence of the specimen. Even in the case of such comparatively slow-growing subjects as *Ericas*, *Epacris*, &c., a great increase of size and vigour may be attained by well-timed and judicious shifting. I say judicious, for herein must the grower summon his judgment and powers of observation to his aid; he must be enabled to tell by the general appearance of the plant before him how far it will be capable of responding to the call which he may make upon its growing powers. The health, vigour, and general appearance of the plant as well as the state of the root will all have to be taken into account. If a healthy young plant be placed so that the roots enjoy a free uninterrupted root-action in congenial soil, it will outstrip those grown in pots; the reason of this naturally is that the plant receives no check during its growing season, and as it grows the roots extend, and find nourishment in proportion; it does not therefore cease to increase in bulk until it has either attained its full development, or the season arrives when it should mature and perfect its growth. This affords a good illustration of the necessity of keeping up

the supply of nutriment when grown in pots, and tells us that if we wish to make the most of the growing season we must pay timely attention thereto. In some cases we may with advantage transfer a plant from a small pot into a larger one in which it is destined to remain and perfect itself; where this is practicable, a much more rapid development takes place, and plants thus treated acquire proportions not to be attained in the ordinary way. This one-shift system, however, can only be practised with success by those possessing great experience in pot culture, as the subsequent treatment in the way of watering, &c., must be carried on with considerable judgment. It is chiefly plants of a free-growing, somewhat succulent nature, such as the *Calceolaria*, *Cineraria*, and some of the freer-growing kinds of stove plants and climbers, that may be operated upon in this manner, and certainly magnificent specimens may be obtained by this mode of treatment. Amateurs should, however, feel their way in this matter; a few plants may be experimented upon, but, as a rule, the comparatively inexperienced should not run the risk of over-potting. The less quantity of earth used at each shift, the less danger is there of the same becoming sour and unfit for the fibres to penetrate, and the slower the natural growth of the plant the greater care must be exercised in this respect. It may be adopted as a general rule in re-potting that plants of a free habit of growth (which will include the greater portion of the so-called soft-wooded section) should be shifted as soon as the ball is sufficiently permeated with fibres to allow of its being handled; but those having wood of a harder nature should have the pots well filled with roots before being placed in larger pots.

The rules just given will, of course, be found susceptible of considerable modification and variation, which the grower will gradually be enabled to adapt to his particular wants, and to the peculiarities of the plants which he desires to cultivate. The one important point to be always held in view is to re-pot as soon as the need for it is observed. It is, I fear, a somewhat common failing to imagine that a few days' delay will not make much difference, but it is often just those few days of neglect or attention in which the future career of the plant is made or marred.

JOHN CORNHILL.

Byfleet.

Torenia Fournieri.—This new species of a well-known old genus will doubtless be much used for pot culture when better known; the habit of the plant is more compact than that of *T. asiatica*, and its flowers, though smaller, are richer in colour and more freely produced. For pans, baskets, or vases this will be found to be a very useful and interesting plant. It has been in flower in several of the London nurseries during the whole of the summer, and with liberal treatment would no doubt flower quite nine months out of the twelve. It is also now blooming freely as an edging plant in flower gardens in Paris. No doubt it would also thrive in sunny spots in southern England.—S.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

A Winter-flowering Plant for the Dinner-table.—On *Pereskia* stocks about 4 ft. in height and tied to stakes, insert grafts of *Epiphyllum truncatum* in March, placing Moss round the grafts and keeping them in a moist heat. When "taken," remove the Moss and any superfluous shoots belonging to the stock. Grow on the plants thus treated all summer, ripening them as much as possible in autumn, and by Christmas they will come finely into flower.—R. GILBERT.

Dracæna Goldieana.—This, one of the most distinct *Dracænas* that has been introduced of late years, is now very attractive in one of the plant houses in Mr. Bull's nursery at Chelsea, where its green and bronzed tessellated leaves form a striking contrast to the brightly-coloured foliage of *Crotons* and other fine-leaved plants with which it is associated.—C. S.

Semi-doubles Gloxinias.—These are by no means rare, but as yet they can scarcely be termed meritorious. I have recently seen a number of them in flower, but I cannot help considering them good flowers spoiled. The outer calyx is not continuous but disjointed, a circumstance which gives the flower a ragged appearance; if, however, it can be so far improved upon as to be developed into a perfect outer calyx, as is seen in some of the forms of the *Canterbury Bell*, it may then become very effective. These forms of *Gloxinia* are well worth the attention of the florist.—D.

THE FLOWER GARDEN.

CULTURE OF PANSIES AND VIOLETS.*

Let us suppose that an amateur cultivator has procured a collection of Pansies of all classes, say in September or October, and that being afraid to risk them in the open ground all winter, he has prepared a compost of about three parts good rich loam and one part leaf-mould and silver or pit sand; let us suppose further, that he has got the plants into 4-in. pots and in a cold frame close to the glass, that he has plunged them, giving them at all times as much light and air as possible, all he will then have to do will be to water them with soft water when required, and guard against too much damp, as damp is a far greater enemy to Pansies than frost. If it be intended to bloom the plants in pots, then they should be re-potted in February or March into 8-in. or 10-in. pots, using the same compost as before, but with the addition of one-fourth part of the best old manure obtainable (old well-rotted cow-manure being preferable). The compost should be in good working order, by being prepared beforehand and protected from too much wet at this season of the year. The pots must be well drained, and after potting they should be again plunged in cold frames or pits, close to the glass, as before, admitting at all times plenty of light and air. When the plants have become established in the pots, and the days longer and milder, they should be supplied with plenty of good soft water, and it will be advantageous, in the case of weakly plants especially, to add a little guano to the water occasionally, or what is better, have a cask with a mixture of liquid manure, consisting of guano and soot, and add a small quantity of this mixture to every pan of water, as it is much safer to give a small quantity often than to give a large dose say once or twice a week. As the plants grow it is advisable to furnish them with small stakes, to keep them from being broken by the wind. If blooms be wanted early, say for competition in May or beginning of June, the lights will require to be taken off the frames only seven or eight hours during the heat of the day; but if they be required for the end of June or July, then the plants should be grown as coolly as possible, with the lights altogether off, except for protection from heavy rains or wind.

For growing Pansies in the open ground any good piece of ground will do. As regards the position of the beds, much difference of opinion exists, but for my part I would prefer an open piece of ground, free from the shade and the roots of trees, and for early sorts a border facing south or west is best. If the ground be poor it might be trenched over and plenty of good old manure, and any good free soil forked into it, and thoroughly exposed to the winter's frost and rain; and if the situation be wet it ought to be drained. When it is convenient to prepare the ground the year before it is wanted for Pansies, it should be well trenched, adding plenty of good manure, and a crop of Potatoes, Turnips, or other vegetables may be taken off it, when it could either be planted in autumn or ridged up all winter, and be ready for planting in spring. Autumn planting ought to be finished by the end of September; during hard frost the beds might with advantage be protected by branches or mats, or in cases where the collection is not extensive a pot could be put over each plant. Spring planting ought to be finished by the end of March; the plants require to be inserted up to their shoulders firmly, leaving only the head out of the ground. Plant from 10 in. to 12 in. apart each way, and I would recommend small stakes to be put to them at once, as it would save many from being broken by the wind. Water them with soft water in order to settle them into the ground; give the surface of the bed from time to time a good stirring, and in dry weather a good watering will be beneficial; but were the beds well mulched with old manure or Moss it would serve to keep the plants damp and cool all summer, and save much watering.

These remarks apply more particularly to what are now known as Show Pansies, but the cultivation of Fancy or Belgian Pansies may be said to be the same, except that the soil in which they are grown should be a little poorer, and that

* Read by Mr. James Grieve, of Pilrig Park Nurseries, at a recent meeting of the Scottish Gardeners' Association.

they should not be planted in the open ground until spring, as they do not seem to be quite so hardy as the Show kinds. They ought also to be planted a little wider apart, as they are, as a rule, more vigorous in growth. This class of Pansy is rapidly improving, so rapidly, indeed, that each year's seedlings cast those of the previous year into the shade. Bedding Pansies and Violas have proved to be most useful, although at first they met with some opposition. When I first began to improve them I collected all the kinds that would hybridize together, and very soon I had under cultivation *V. cornuta*, *montana*, *calcarata*, *stricta*, *lutea*, *amœna*, *palmaensis*, *tricolor*, &c.; by means of these I obtained a good start, and complete success has been the result. I have found it to be a matter of the first importance to breed yellows from yellow, whites from white, and so on. I am indebted to *V. stricta* for substance, to *V. amœna* for habit, and for yellow to *V. lutea*, and without observing the above rules success in hybridising need not be expected. The qualities to be looked for in the bedding Pansy and Viola are habit and good foliage, and profusion, substance, colour, and size of blooms. The best way to succeed with the Viola is to practise deep cultivation, to give plenty of good old manure, and plant early, so as to get the plants well established before hot weather sets in. These remarks of course apply equally to the culture of the Show and Fancy Pansies, and I may add that both must have a change of ground every year.

Pansies and Violas are propagated by means of seeds, cuttings, and division of the roots. Seed should only be gathered from the best sorts, and care should be taken to see that it is ripe before it is gathered; it may be sown at any time, but I have found it best to sow in August and September in pots, and as soon as the young plants will bear handling, to prick them out in pans or boxes, and winter them with the general collection; they will then be ready to plant out in lines the following March and April. Cuttings may also be taken at any season, but July, August, and September are the best months for propagating the general collection; select for this purpose young shoots from the centre and sides of the plants; good short-jointed pieces from 2 in. to 3 in. in length are best, and if a heel or small root can be got with them, so much the better. Where a large stock is wanted, it is a good plan to nip out the centres of the main shoots, when a host of small ones will soon spring up from the centre of the plant, and if a handful of sand be shaken loosely into the middle of the plants, it will encourage small roots to form at the base of every shoot, and thus enable them to be taken off ready for planting every two or three weeks. For cuttings, no place is better than the foot of a north wall or hedge, and for late cuttings a cold frame or pit. The soil should consist of a mixture of loam, leaf-mould, and plenty of good sharp river or pit sand. They should be sheltered during severe storms of wind or rain, but when shading is required, it ought only to be continued as short a time as possible, as it is apt to make the cuttings "draw" too much and not root; when rooted, they require to be removed from the cutting bed and planted in the open ground, watered, and shaded for a short time. A damp day or evening is best for this purpose, and by this means a stock of well-rooted, short-jointed plants will be secured for either autumn or spring planting. The old stools may be lifted and divided if required, but propagation by means of cuttings is preferable as well as more economical where stock is required.

In exhibiting Show and Fancy Pansies they are seen to best advantage on neat stands painted green, without paper cards. The largest blooms should be placed in the back row, and the colours should be arranged so as to produce the best effect. Violas are best shown in bunches, and a Dahlia or Rose stand is very suitable for that purpose. As the show day approaches it will be well to collect the blooms as they expand every morning and place them in large bowls of clean water, changing it every day; place them in a cool, shady house, and they may be preserved fresh from three to six days, according to the state of the weather. When shading the blooms on the plant is resorted to, use a small covering sufficient to shade the bloom only and not the whole plant. Before arranging the blooms on the exhibition stands, I lay them all out on clean paper for about an hour, by which time they will be a little flagged and more easily handled without the risk of breaking their stalks or splitting the under petals in laying them on the stands.

PROPAGATING CENTAUREAS.

AMONGST silvery-leaved plants these are unrivalled, either for masses in contrast with dark-foliaged or brilliant-flowered plants, for which *C. ragusina* and *candidissima* are well adapted; or as vase or single specimen plants, for which *C. gymnocarpa* and *Clementei* are the most effective. There is, however, a very prevalent opinion that Centaureas are difficult plants to increase by means of cuttings; and so they are if one adopts the ordinary moist bottom-heat plan, as being of a woolly, fibrous character, they require a longer and slower process than soft-wooded plants, in order that the base of the cutting may be properly callused before roots can be emitted, after which success is certain. Where Centaurea cuttings are struck in heat and moisture, a great percentage of them rot, whereas by adopting a cooler and drier method, I have annually struck hundreds of them with only few losses. The cuttings are always selected with a heel of old, firm wood attached to them, and they are taken off with a very sharp knife; they are prepared in the usual manner, and are inserted singly in 3-in. pots, the soil in which is pressed firmly, and the leaves are tied up to a single stake, as both leaves and roots are very brittle. A good soaking of water is then given, and they are placed in an ordinary frame on a coal-ash foundation, and shaded from direct sunshine for a week or ten days, after which they may gradually be inured to more light and air until they commence to grow, when the sashes may be kept off entirely. The hardier they are kept the better, as they will mostly withstand an ordinary winter; but the protection of a glass structure is indispensable, in order to ensure success. They should not be excited into growth during the dark days, but, on the other hand, they must not suffer from drought; about the end of March they may be set out-of-doors in a sheltered position, and finally in April planted in their summer quarters. Thus treated, young plants make good edgings for Coleus, or for any dark-foliaged plants; they grow up into an even mass without pegging or training, and continue in good condition the whole season, flourishing alike in moist or dry weather, and they even continue unblemished when the frost has cut down the more tender occupants of our summer gardens; in mild winters, indeed, the majority of them will remain uninjured, but the plants get too large for ordinary bedding purposes where uniformity of size is desired. They may also be increased from seed, but cuttings procured about the first week in August will, as a rule, be found the most satisfactory.

J. GROOM.

Henham.

HARDY ASCLEPIAS.

To this genus belongs a large group of plants exclusively confined to the New World, and with but few exceptions, to the northern portion of it; consequently almost all of them are hardy in this country. Some of the species furnish excellent fibre, the silky down of the seed-vessels of others is used for bedding purposes, and the young shoots of certain kinds are eaten by the Canadians, who also extract from the flowers a kind of saccharine matter. The genus contains about forty species principally herbaceous plants, with stout creeping roots, and a thick milky juice, which in some species is very abundant, and in others scarcely perceptible. They are for the most part very ornamental, and will be found useful both in the wild garden and shrubbery borders, where they can ramble at pleasure. Amongst the few which are suitable for select borders that figured on p. 156 is one of the best. The following are a few of the most distinct:—

ASCLEPIAS TUBEROSA (the Butterfly Weed) is one of the most beautiful of our autumnal flowers; it is a hardy perennial, having a thick, ligneous root, and erect leafy stems about 2 ft. in height, crowned with terminal corymbs of bright orange-red flowers. It prefers a warm, sandy soil, and when thoroughly established is a very ornamental plant. It bears seeds occasionally during hot autumns; from which good flowering plants may be obtained in three years.

A. CORNUTI—*SYRIACA* of some (the Common Milk Weed).—This is a strong-growing species, which attains 4 ft. in height; it has large, oval, downy foliage, and erect stems, bearing nodding

umbels, lateral as well as terminal, of deep purple flowers, which are exceedingly fragrant. Bees seem to be fond of this plant, and from the fact of its being quite hardy, easily increased, and lasting a considerable time in bloom, it would prove valuable as a bee flower.

A. INCARNATA (Swamp Milk Weed).—This attains 3 ft. in height, and has long, lanceolate leaves, and smooth stems, leafy to the top and divided, bearing erect umbels of rosy-purple flowers in pairs. The variety called *pulchra* has broader foliage than that of the type, and pubescent.

A. PURPURASCENS (amona, Mich.).—This is a very distinct species, the stems of which are slender, and from 2 ft. to 3 ft. in height; the leaves are elliptical, the upper ones more pointed than the others, smooth above and silky beneath, having terminal and lateral umbels of bright purple blossoms.

A. VARIEGATA (Variegated Asclepias).—Stems spotted and downy, from 2 ft. to 3 ft. in height; leaves ovate, somewhat undulated; flowers white, with a reddish centre, in large umbels, both terminal and lateral. This is one of the showiest of Asclepias.

A. RUBRA (acuminata, Pursh.).—This very distinct kind has long, lanceolate, bright green foliage, and stems from 3 ft. to 4 ft. in height; umbels large, deep purplish-red, from two to five on a naked, terminal peduncle.

A. QUADRIFOLIA.—Leaves in whorls of four, generally leafless on the lower portion of the stem, which is slender and about 2 ft. in height; flowers pink with white centres.

A. SULLIVANTII.—This is a tall-growing kind, somewhat similar to *A. Cornuti*, but the flowers are larger and deeper in colour, and very fragrant; the leaves are ovate-oblong and smooth. A few others are also worth mentioning, viz., *A. tomentosa*, *salicifolia*, *mexicana*, *obtusifolia*, *ovalifolia*, *laurifolia*, *nivea*, and *phytolacoides*, all of which are more or less showy and valuable for shrubby borders or the wild garden.

A. P.

Eustoma exaltatum.—The genus *Eustoma* has been long represented in our gardens by *Lisianthus Russellianus*, a plant which now unfortunately is seldom seen. Though inferior in the size of its flowers to that species, the *E. exaltatum* is described by collectors as having blossoms of a beautiful deep gentian blue, spotted at the base, the corolla being somewhat tubular and less expanded than in *E. Russellianum*. It grows about 1½ ft. high, having opposite heart-shaped, stem-clasping, entire glaucous leaves, the flowers terminating the stems on slender peduncles. It is probably a greenhouse biennial, requiring to be sown in a hotbed or forcing pit, and should be transplanted singly as soon as large enough to handle, the long slender rootlet suffering if disturbed at a more advanced period of growth. Sandy peat and loam will probably meet its requirements. Seeds of it were collected in Southern California.

Delphinium cardinale.—This, the original Scarlet Larkspur, first introduced to cultivation by Messrs. Veitch & Son about twenty-five years ago, had, as is well known, been almost, if not entirely lost to gardens at the date of the introduction of the hardier and dwarfer

Delphinium nudicaule, now recognised as being one of the most valuable of recent acquisitions. This gradual disappearance of a plant so distinct and novel has been supposed to indicate a constitution unsuitable to the English climate, but it was more probably due to the fact that, unlike its hardier congener, it failed to produce seed in any quantity, and being like that, a short-lived perennial requiring frequent renewal by seed, the means for this perpetuation being wanting, the plant naturally died out. That it would be extensively cultivated, in company with the *D. nudicaule*, were its merits known and seed available, there is no doubt. It is perfectly distinct from the *D. nudicaule*, to which it is closely allied, being a taller plant, in which feature it agrees with the variety *elatus*. It differs, however, from all the forms of *D. nudicaule* in the shape and colour of its flower, which is more open and rather larger, of a brighter scarlet with a decided yellow centre. The foliage is also larger and more deeply cleft, usually nearly to the base. As affording an easy means of identifying this species in its very earliest stages of growth, it may also be stated that when germinating the seed invariably produces distinct cotyledons or seed leaves, between which the plumule or embryo stem arises as in most other plants, whilst in *D. nudicaule* the seed-lobes and their foot-stalks are confluent and the plumule emerges laterally. The same peculiarity shows itself in the germination of *D. tricolor*. *D. cardinale* blossoms at a later period of the summer, and continues longer in flower than *D. nudicaule*, owing in part to its slower development. It is a most desirable plant, apparently as hardy as *D. nudicaule*, having survived the winter of 1875-6 without the least protection in sandy soil. Seedlings will probably not flower till the second season. In very damp soil it would be prudent to protect the root with a hand-light or inverted pot in winter.

Eriogonum umbellatum Sileri.—This was received under the name of *E. corymbosum*, but having flowered during the past summer, it has proved to be a very showy and robust large.

flowered form of *E. umbellatum*, to which it is so much superior that it will eventually supersede it. In its general habit it agrees with the type, but has taller and stouter scapes, broader umbels, and larger flowers of a brighter yellow. The foliage is oblong-lanceolate, more or less white on the upper surface, and slightly so above, forming a tuft with a few sterile, procumbent shoots, from the centre of which the scapiform stem, 12 in. to 15 in. high, is produced. As in the other species of this genus, the perianth of the flower retains its colour for a considerable time, especially in fine dry weather, and continues its development during the growth of the nut-like fruit which it encloses. The plant is a native of Utah, and probably of the adjacent States, and is, of course, perfectly hardy.—W. THOMPSON, Ipswich.

Orchis foliosa.—I recently saw over seven hundred plants of this in flower at one time in the Lawson nurseries at Edinburgh. They are planted out in sheltered corners in peat soil, and are only disturbed occasionally for purposes of increase.—V.

Embothrium coccineum Flowering a Second Time.—This beautiful flowering shrub (known as the Fire-bush) after blooming most abundantly here (Co. Cork) in its ordinary season during nearly the whole of the month of May, when it was covered almost from top to bottom with brilliant bunches of scarlet Honeysuckle-like blossoms, has during June made a most vigorous growth of young wood all over the tree, and is now showing on the extreme top two bunches of its bright scarlet bloom. I should like to know if other growers of this fine shrub have noticed a similar second blooming in one and the same year.—W. E. G.

Asclepias tuberosa.

THE LARGE VINE AT FINCHLEY.

AS AN indoor market fruit garden Mr. Kay's establishment at Finchley has long been known as one of the most important near London, especially as regards Grape culture. Its glass structures consist of low span-roofed or lean-to houses, varying from 40 ft. to 80 ft. in length, and by growing late and early sorts of Vines in them a supply of good Grapes is secured from early in April until the following March. The kinds which succeed best here are Black Hamburgh, Black Alicante, Lady Downes, and Muscat of Alexandria; a few others are grown, but not to a great extent. The principal Vine here, however, is that known as the Finchley Vine, which has for years produced very heavy crops of fine fruit. The house, a span-roofed one, in which this Vine is grown has on several occasions been lengthened, in order to give it additional room; it is now 90 ft long and 18 ft. wide, a space wholly occupied by this one Vine, which enters the house at one side, about the middle. Its main stem, which measures at the bottom nearly 2 ft. in circumference, crosses the roof, and from this issue ten strong rods, 6 in. to 8 in. in circumference, half of which are trained each way horizontally under the roof. On this Vine there are at the present time about 500 well-formed bunches of Grapes, which average about 2 lb. each, the berries being very large and promising to colour perfectly. The border, like those of other Vineries here, is outside; it is about 15 ft wide and 4 ft. deep, and was made on a hard, clayey bottom, on which was placed a quantity of brick rubbish, &c., to form drainage; the soil consists of ordinary loam and brick rubbish, such as can be obtained in any place where building is going on. No manure was mixed with the soil, but the border receives a yearly dressing of manure in the autumn to protect the roots during winter and spring, and from which the roots no doubt derive considerable nourishment. This Vine is pruned on the spur system; the wood is well ripened every year by allowing abundance of air and light, and could the house be farther enlarged, and the border also, it would doubtless become one of the very finest in the kingdom. The earliest Vineries have of course long since been cleared of their fruit, and are being succeeded by that on the large Vine and a fine crop of Muscat of Alexandria, the bunches of which are remarkably compact, and the berries of a bright amber colour covered with a rich bloom. Among late Grapes a house filled with Lady Downes Seedling and Black Alicante is well worthy of notice. It is a low lean-to, about 70 ft. in length, and in a northern aspect. The crop is in every way excellent, and in such a position the fruit ripens equal to that grown in a more sunny situation, and being late in ripening it can be preserved in good condition for a long time, provided the atmosphere of the house is kept dry and airy. Most of the Vines have from four to five canes each, old ones being removed when desirable. As soon as the Grapes are cut, the houses are thrown open and the Vines exposed to the full influence of the weather, in order to properly ripen the wood and clear it of insects, should any exist. Most of the canes in the late houses are allowed to carry from twelve to fifteen bunches each, all of which they ripen perfectly.

To Peaches are devoted two span-roofed houses, each about 40 ft. in length. Each house contains two trees, which completely cover the roof; these trees are of great age, the stems, where they enter the house, being at least 2 ft. in circumference, and they have this year borne a very heavy crop of large, well-ripened fruit, although in many places complaints have been heard of Peaches dropping off this season. The wood is kept thin by timely disbudding and pruning, and when the crop is gathered every means is employed to get the wood thoroughly ripened, a condition indispensable to the production of good crops. During the time the Vines and Peach trees are at rest, plants are grown under them, such as Pelargoniums, Fuchsias, Solanums, Hydrangeas, Cytisus, &c. Cuttings of these are struck during the summer and autumn, potted and placed out-of-doors or in cold frames until unfavourable weather sets in, when they are removed to the Vineries, in which there are erected stair-like stages within a few feet of the glass, on which the plants are placed. Hydrangeas are remarkably well grown here; a large piece of ground outside is occupied by fine bushy plants of them, which furnish a supply of cuttings whenever required, and from here come many of the plants in 6-in. pots, bearing enormous heads of bloom to be seen in Covent Garden during the spring and summer.

In this way all available space in the garden, both indoors and out, is turned to profitable account—conditions very essential in market gardens near London, where land is so valuable.

C. S.

Flowers of *Asclepias tuberosa* (natural size).

TERMS IN DESCRIBING FRUITS.

It is only by a uniform and definite use of terms that descriptions can be made intelligible to the reader. Hence a full explanation of these terms becomes a matter of importance. Distinctive characters should be permanent, and not liable to variations with a change of

locality, soil, season, or climate; or, if variable, the nature of such variation should be distinctly pointed out. To assist the cultivator the more fully to understand written descriptions, the devotion of a few columns to a clear explanation of the terms used may prove useful.

I. Growth of the Tree, Shoots, and Leaves.

The form of growth often affords a good distinctive character of varieties, not liable to great variation. Young trees, only a few years old, usually exhibit peculiarities of growth more conspicuously than old trees of irregular spreading branches. Hence, in all cases, where this character is mentioned, it refers to young trees not more than three or four years from the bud or graft, unless otherwise expressed.

1. Shoots are *erect*, when they rise nearly perpendicularly from the main trunk or stem, as in the Early Strawberry Apple and Bartlett Pear (fig. 1).

Diverging, when they deviate from the perpendicular at an angle of about 45°, considerable variation being found in the same tree; as in the Domine and Ribston Pippin (fig. 2).

Spreading, when they more nearly approach a horizontal direction, as in most trees of the Rhode Island Greening (fig. 3).

Drooping, when they fall below the horizontal, a form which many spreading shoots assume, as they become the large branches of older trees.

Ascending, when they curve upwards, as in the Gravenstein Apple, and small Red Siberian Crab (fig. 4). Erect trees usually

partake more or less of this quality, but the Early Harvest is free from it.

Irregular, when they assume no very distinct growth, but more or less a mixture of the preceding, as Black Gilliflower, and Summer Bon Chrétien Pear.

Straggling, similar to the next preceding, but with shoots more slender and curved, as Winter Nelis and Black Worcester Pear (fig. 5).

Shoots are *straight*, as in the Early Harvest and Northern Spy Apples; *flexuose*, or more or less deviating from a straight line, as in the Swaar and Roxbury Russet. This distinction is very apparent and uniform in young and very thrifty trees, but not in older ones of feeble growth.

They are *stout*, as in the Red Astrachan; *slender*, as in the Jonathan Apple, and Winter Nelis Pear.

Trees with erect straight shoots when young, usually form more regular and compact heads in older trees; and those of a spreading habit, more irregular or drooping heads.

Some trees which grow very rapidly when young, are small when of full size, examples of which are found in the Late Strawberry and Tallman Sweeting. Others at first grow more slowly, but ultimately become large, as the Esopus Spitzenburgh. Some varieties, again, continue to increase rapidly in size at all periods, as the Northern Spy; while others of feeble growth when small, never attain much magnitude as the Early Joe and Sine Qua Non.

2. *The colour* of the shoots varies greatly in the same variety at different periods of the year, as well as with different degrees of exposure to the sun, and with a change of soil, climate, and season. When fresh or very young, all have a greenish colour, but gradually assume various shades of yellow, olive, brown, red, purple, and nearly black, as the season advances, and as they become bare and are exposed to the sun and weather. For this reason, in describing the colour, the terms must be relative, and can only be correctly applied

Fig. 1. Fig. 2. Fig. 3. Fig. 4. Fig. 5.
Erect. Diverging. Spreading. Ascending. Straggling.

by a comparison at the time with the colour of other sorts. During winter, and early in the spring, the shoots of most trees become so much darker than at other times, that it is only by practice and by placing the different sorts side by side, that accuracy may be attained. Skilful culturists will readily distinguish, by a glance at the colour of the shoots, many of the kinds they cultivate; but the peculiar cast is hard to describe in words, in the same way that it is impossible to describe the handwriting of an individual, so as to be known from fifty others, although many can, at a glance, know the penmanship of hundreds of different persons. A few of the most strongly marked cases, however, present peculiarities of colour, which form useful points of distinction. No one, for instance, could easily mistake the yellow shoots of the Bartlett and Dix Pears, for the dark brown or purple of the Tyson and Forelle; or the light greenish cast of the Bough and Sine Qua Non Apples, for the dark colour of the Northern Spy, or dark brown of the Baldwin; nor the downy or greyish appearance of the Ladies' Sweeting and Esopus Spitzenburgh, for the clear shining brown of the Gravenstein and Red Astrachan. Nearly all shoots are more or less downy at first, but the down disappears as they grow older. Hence the terms must be used relatively. In Plums, the smooth or downy shoots afford in most cases good distinctive points.

3. *The buds* sometimes afford distinct characteristics. As examples, the large, compact, and projecting buds of the Summer Bon Chrétien always contrast strongly with the smaller, more rounded, and softer buds of the Madeleine. Buds are large on the Swaar and Golden Sweet, small on the Tallman Sweeting and Rhode Island Greening.

4. *The leaves*, in a large number of instances, are of use in distinguishing different varieties.

They are *even* (not wrinkled), as in the Bartlett Pear and Baldwin Apple (fig. 6).

Waved, as in the Tallman Sweeting and Beurré d'Amanlis Pear (fig. 7).

Wrinkled, when the waves are shorter and more irregular, as in Green Sweet (fig. 8).

Flat, as in the Madeleine and Skinless Pears (fig. 9).

Fig. 6. Fig. 7. Fig. 8. Fig. 9. Fig. 10.
Even. Waved. Wrinkled. Flat. Folded.

Folded and recurved, as in the Easter Beurré and Bon Chrétien Fondante (fig. 10).

Large and wide, as in the Red Astrachan and Huling's Superb.

Narrow, as in the Dyer Apple, and Van Mons Leon le Clerc Pear. *Erect*, as in the Early Strawberry (fig. 11).

Drooping, as in Domine (fig. 12). But these two last are indistinct characters, and only to be resorted to in a very few remarkable instances, as most leaves are erect on new shoots, and become spreading or drooping as they grow older.

The colour of the leaves may sometimes assist in description, as *light green* in the Yellow Bellflower and Rambo; *deep green*, as in the Rhode Island Greening; and *bluish green*, as in Peck's Pleasant.

Fig. 11. Fig. 12.
Erect. Drooping.

The *serratures*, or saw-teeth markings on the margins of leaves, are characteristics of importance, in many varieties of the Apples, and on the Peach they are so well defined as to form a basis of the classification of varieties.

Leaves of Apples are,

Serrate, or cut with teeth like those of a saw.

Sharply serrate, when every serrature ends in a sharp point, as in the Fall Pippin (fig. 13).

Doubly serrate, when the serratures themselves are again minutely serrated, as in the Vandevere and Drap d'Or (fig. 14).

Coarsely serrate, as in the Swaar.

Crenate, when the teeth are rounded, as in the Esopus Spitzenburgh (fig. 15).

Obtusely crenate, when the teeth are unusually rounded, as in the Bough.

Finely crenate, when the teeth are small, as in the Summer Queen.

When the serratures are partly rounded, and irregularly and rather deeply cut, they become *toothed*, as in Lady's Sweeting (fig. 16).

Fig. 13. Fig. 14. Fig. 15. Fig. 16.
Sharply serrate. Doubly serrate. Crenate. Toothed.

Many varieties present intermediate degrees, as, *Serrate-crenate*, partaking somewhat of both, as the Jersey Sweeting and Summer Rose.

Crenate-toothed, as in Bevan's Favorite.

Serrate, slightly approaching *toothed*, as in Rambo.

Flowers. In Apples, Pears, Cherries, and most other kinds, but little difference exists in the flowers. In the Peach and Nectarine, however, an important division in classification is made by the great difference between those with large and small petals; one class, including the Early Ann, Grosse Mignonne, and others, having large showy flowers; and another class, comprising the Early Crawford, George IV., and many more, having flowers with small narrow petals

II. Form of the Fruit.

In the following descriptions, the *base* of a fruit, or any other part or production of a tree, is the portion towards the branch or root. This is in accordance with the language universally adopted in describing plants. It has, however, been more or less departed from in the common language used to describe fruits, and especially so as applicable to the Pear. This deviation from scientific accuracy tends to confusion, and if simplicity of expression be sought, ambiguity must be avoided. The apex of the stalk of a fruit, however, to avoid the chance of a mistake, may, in all cases, be termed the *insertion*.

The term *apex* should be understood as applying to the part most remote from the branch or root. In fruits it is the part opposite to the insertion of the stalk. In Pears, this part is usually denominated the crown.

The *axis* is a line connecting the base and apex.

A *longitudinal section* is made by cutting an Apple from base to apex.

A *transverse section*, by cutting it at right angles to the axis.

The *length* is the longitudinal diameter; the *breadth* the transverse diameter.

A fruit is *round* when nearly spherical, as the Famense and Green Sweet.

Roundish, when varying slightly from round, or when the length and breadth are nearly equal, as the Dyer and Gravenstein.

Fig. 18.
Oblate.

Fig. 19.
Conical.

Fig. 20.
Ovate.

Fig. 21.
Conic.

Oblate, flat, or flattened, when the height is much less than the breadth, as the Rambo and Maiden's Blush (fig. 18).

Conical, when tapering slightly from the base to the apex, as Bullock's Pippin (fig. 19).

Ovate, or egg-shaped, when the length rather exceeds the breadth, with a rounded taper from base to apex, as in the Esopus Spitzenburgh (fig. 20).

Conic, when tapering from the base to the apex as in fig. 21.

Obovate, or reversed ovate, is when the smaller end of an egg-shaped fruit is at the base, as the Buffum and Dearborn Seedling Pears (fig. 22).

Fig. 22.
Obovate.

Fig. 23.
Oblong.

Fig. 24.
Round-ovate.

Fig. 25.
Oblate-conical.

Oblong, when the length exceeds the breadth, and the sides are nearly parallel, as Kaighn's Spitzenburgh (fig. 23).

Obtuse, when the parts are rounded or blunt.

Acute, when any part, as neck of a Pear, tapers to nearly a point.

Fruits may partake of forms variously combined, as,

Round-ovate, when nearly round, with a slight rounded taper to apex, as Ladies' Sweeting (fig. 24).

Round-conical, nearly the same as the last, but with the taper less rounded.

Oblong-conical, as the Yellow Bellflower.

Oblong-ovate, as the Black Gilliflower.

Oblate-conical, as the Rhode Island Greening, and Hawthornden (fig. 25).

Depressed, pressed down, sunk, or shortened, applied to the apex of Peaches, Strawberries, &c.

Fattened at the ends, when the base and apex only are flattened, as the Winter Pearmain. An oblong fruit, though not flat may be flattened at the ends; a conical fruit may be flattened at base.

Compressed, pressed together where the sides are flattened, as in some Apricots, Plums, &c.

Fig. 26.

The *CAVITY* is the hollow in which the stalk or stem of a fruit is placed.

The *BASIN* is the depression which contains the calyx, eye, or remains of the blossom (fig. 26).

A cavity may be *shallow*, *narrow*, *deep*, or *broad*.

It may be *obtuse*, or somewhat blunt or rounded at bottom, as in the Petre Pear and Pomme Grise Apple (fig. 28).

Acute, when simply ending in a sharp point at bottom, as the Baldwin (fig. 27).

Acuminate, when ending in a long drawn-out taper, as the Fall Pippin (fig. 29). The Holland and Fall Pippin are distinguished from each other by the rather obtuse cavity of the former, and acuminate cavity of the latter.

The *BASIN* is always narrow in any fruit having a narrow or

Fig. 27.
Acute.

Fig. 28.
Obtuse.

Fig. 29.
Acuminate.

pointed apex (fig. 30); it is usually wide in fruits having a wide or obtuse apex, as the Rambo (fig. 31); but where the rim or boundary is broad and obtuse, the basin may be narrow, as in the St. Lawrence and Gravenstein (fig. 33).

Fig. 30.
Basin Narrow.

Fig. 31.
Basin Wide.

Fig. 32.
Rim Abrupt.

Fig. 33.
Rim Broad.

It is *distinct* when well defined.

Abrupt, when the depression breaks off suddenly from the rim (fig. 32).

Even, when not furrowed or wrinkled.

Angular, with several corners.

Wrinkled, having small irregular hollows and ridges.

Waved, with gentle and irregular undulations of surface.

Furrowed, when more regularly channelled.

Plaited, having small, straight, and regular ridges.

Ribbed, with larger and more obtuse or rounded ridges.

The peculiar forms of PEARS render some additional terms necessary:

Many Pears have a *neck*, or narrower part towards the stalk, and a *body*, or larger part towards the crown (fig. 34).

They are distinctly *pyriform*, when the sides formed by the body and neck are more or less concave or hollowed in, as in fig. 34, shown by the dotted lines.

Turbinate, or top-shaped, when the body is nearly round and a short rounded acute neck, as in the Bloodgood (fig. 35).

The form of different Pears is further distinguished by the form of the different parts:

Fig. 34.
Pyriform.

Fig. 35.
Turbinate.

Fig. 36.
Narrow.

Fig. 37.
Short.

Fig. 38.
Acute.

The neck may be long, as in the Calebasse.

Narrow, as in the Beurré Bosc (fig. 36).

Short, as in the Glou Morceau (fig. 37).

Obtuse, as in the Bartlett.

Acute, as in the Jargonello (fig. 38).

Distinct, as in the Beurré Bosc.

Obscure, as in the Seckel.

The body may be *heavy* or *large*, when greatly exceeding in size the neck, as the Catillac.

Light or *small*, when not much larger than the neck, as the Washington; in which case the fruit approaches oblong in form.

Oblate, or flattish, as in the Frederick of Württemberg.

Round, as in the Jargonelle.

Conical, as in the Vicar of Winkfield.

Ovate, as the Marie Louise. Cultivation influences considerably the form of Pears. Thus on a young thrifty tree, the Seckel Pear has a slight neck; on an old heavily laden tree, the neck is obsolete. The body, when ovate or slightly conical on young trees, becomes rounded on older trees, and even flattened in rare instances.

CHERRIES may be *round*, *cordate* or heart-shaped, or *ovate*.

STONE FRUITS usually have a furrow on one side, extending from the stalk to the apex, termed a *suture* (literally meaning a *seam*), which sometimes occurs on both sides. It is *large*, when wide and deep; *distinct*, when clear or well defined; *obscure*, when faint; *obsolete*, when not existing, or only a faint line on the surface.

COLOUR OF FRUIT. The lightest coloured fruit is white, as the Snow Peach; next, yellowish-white; pale yellow; yellow; and deep yellow. The addition of red produces successively, orange-yellow, orange, orange-red, rich warm red. Shades of red, clear red, crimson when darkened, purple when blue is added, violet, less blue than in purple. Amber is a very light yellowish-brown. Fawn colour is a light reddish-brown, with a slight admixture of grey.

A fruit is *striped*, when in alternating broad lines of colour.

Streaked, when the lines are long and narrow.

Marbled, when the stripes are wide, faint, irregular, or waving.

Blotched, of different abrupt shades, without any order or regularity.

Clouded, when the blotches are broader and more softly shaded.

Stained, having the lighter shades of a blotched or clouded Apple.

Splashed, when the stripes are much broken and of all sizes.

Mottled, covered with nearly confluent dots.

Dotted, when these dots are more distinct.

Spotted, when the dots become larger.

TEXTURE OF FRUIT. *Hard*, those which need the artificial aid of cooking to soften them sufficiently, as the Catillac Pear.

Breaking, when tenderer than the preceding, but not yielding to the simple pressure of the month, as in the Summer Bon Chrétien.

Buttery, when the flesh forms a soft mass, yielding to the pressure of the month, as in the White Doyenné and Seckel Pears.

Melting, when the flesh becomes nearly or entirely liquid by this pressure, as in the Madeleine. These qualities may be combined, as breaking and melting, in the Washington; breaking and buttery, in the Osondaga; buttery and melting, in the Tyson, and in most of the best varieties of the Pear.

The texture may be fine, granular, coarse, gritty, fibrous, tough, crisp, or tender.

THE FLAVOUR may be *sweet*, *neutral*, *slightly sub-acid*, or mild *sub-acid*, *acid*, *very acid*, or *austere*; *aromatic* or *spicy*; *perfumed*, or possessing odour, and with more or less of a shade of *musk*; *astringent*, usually a defect, but sometimes an excellent quality, if in a very minute proportion; *rough*, *astringent* and *austere*; *vinous*, rich, high-flavoured, and rather acid; *sugary* or *saccharine*, sometimes nearly sweet, possessing the qualities of sugar, which may be mixed with acid.

THE QUALITY is designated by *first*, *second*, and *third* rates; and fruits perfectly worthless by still lower grades. A second-rate fruit, to be worthy of cultivation, must possess other good qualities in a high degree, as hardness, productiveness, fair appearance, &c. Very few fruits, as low as third-rate, can ever be worth retaining, and only for extreme earliness or other uncommon quality. Fruits that possess desirable qualities are usually designated by three degrees of flavour; the lowest, including the best of second-rate fruits, or "good second-rate," are termed *good*; the lower grades of first-rate fruits are termed *very good*, or *fine*; and the highest quality of all are *best*, *very fine*, or *excellent*. Examples—Maiden's Blush Apple, Napoleon Pear, Lombard Plum, and Crawford's Early Peach, are *good*; Rhode Island Greening, Bartlett Pear, Grafton or Bigarreau Cherry, and Red Gage Plum, are *very good* or *fine*; and Swaar Apple, Seckel Pear, Downton Cherry, and Green Gage Plum, are *excellent* or *best*.—"Thomas's Fruit Culturist."

Salt v. Vine Mildew.—M. Chatot recommends common salt as an antidote to mildew on Vines. By sprinkling a handful of salt around the base of each Vine, the effect, he says, was marvellous; and Vines hitherto covered with this fungus grew luxuriantly, and had an abundance of Grapes entirely free from oidium.—"Paris Paper."

PLATE LXXVII.

EDWARDSIA GRANDIFLORA.

ALL the Edwardsias are very ornamental, and well deserving of more attention than they generally receive; so rarely, indeed, do we meet with them in gardens that they may be fairly classed among neglected plants. They are all more or less tender, and even the hardiest of them will only succeed under the protection of a wall with a warm, sunny aspect. By far the most desirable of them is *E. grandiflora*, a deciduous shrub of from 6 ft. to 10 ft. in height, indigenous to New Zealand, and introduced into this country so long ago as 1772. In its native habitats it forms a spreading bush, and in some districts occurs in such abundance as to form a prominent feature in the landscape, especially in spring when covered with graceful pendulous clusters of golden-yellow flowers. As seen under favourable circumstances in this country it is a distinct-looking, densely-branched shrub, with handsome pinnate leaves, producing flowers in great profusion in April or May before the leaves are fully expanded. Like all the other species it grows freely in almost any kind of soil, but it prefers such as are deep, rich, and at the same time dry, the latter condition, owing to the plant having a tendency to make late autumn growths, being of great importance, inasmuch as under such circumstances it is enabled to ripen its young shoots thoroughly before winter sets in, and thus escape the injury which they would otherwise sustain from severe frost. From its free habit of growth, and the abundance of its twiggy branches, as well as from its great patience under the pruning knife, this fine shrub is admirably adapted for walls or such other buildings as it is desirable to have clothed with foliage; and to those who are making a selection of plants for such a purpose, I cannot too highly recommend it, even although it should be necessary to protect it somewhat from the rigours of exceptional winters, or in very exposed localities. Our figure is from the "Revue Horticole."

HUGH FRASER.

A REMARKABLE HAILSTONE.

AMONGST the most redoubtable enemies sent by mother Nature to prevent the horticulturist and fruit-grower from becoming too prosperous, hailstones must take a very high rank, for they not only beat down his flowers and fruits, but they

smash hundreds of pounds' worth of glass in a few seconds. It is not often that these destructive messengers from the sky arrive here under such a form as the one depicted above. This remarkable hailstone weighed nearly 2 oz., and fell at Grotta Ferrata, a small village near Monte Cavo, in Italy, in September, 1876. The crystals were generally four-sided or hexagon prisms, surmounting by a pyramid attached and at their base to an irregular mass of ice. Some of the hailstones weighed as much as 8 oz., and even more. The damage done to the horticultural produce in the district was enormous. The cut is from a drawing made on the spot by Father Secchi, the learned director of the Roman Observatory.

By recent forest fires in Michigan over 1,500,000 standing Pine and other logs have been destroyed.

LARGE-FLOWERED EDWARDSIA (E. GRANDIFLORA).

MOMORDICA CHARANTIA.

THE Momordicas are annual or perennial plants of a climbing, herbaceous habit, belonging to the natural Order Cucurbitaceæ; they are found in tropical and sub-tropical countries, and their flowers, which are large and showy, are either white or yellow, solitary, the male and female being borne either on the same or on different plants. The calyx and corolla are each in parts of five; the male flowers have three stamens seated on short filaments, the anthers on which are irregular or waved; in the female flowers the style is short, surmounted with three two-lobed stigmas. The fruits are fleshy, covered with warts or spines, and vary in size from 1 in. to 3 in. or 4 in. in length, the size to which those of the well-known species *M. balsamina* attain. *M. Charantia* is perhaps the most showy plant of

all the Momordicas; it is an East Indian species, over which country it is widely spread, either naturally or by cultivation. The flowers are pale yellow, appearing from August to October; the fruit varies from about 1 in. to 2 in. long, thickly covered with tubercles or spines; as the fruits dry this spiny coating easily separates from the vascular, fibrous portion beneath, which is then very similar in appearance to a miniature Luffa or Towel Gourd; the seeds are oblong, tuberculated, and seated in an arillus, which, when fresh, is of a blood-red colour. Two distinct varieties of this plant are said to be known in India, between which, also, many intermediate forms occur. The principal difference in these varieties seems to be in the form of the fruits, some being longer and more oblong, while the others are smaller, more ovate, and more thickly tubercled or covered with prickles. The fruit, which is intensely bitter, is however quite wholesome, and is eaten in India by the natives, usually in their curries, after first being steeped in salt and water: the smaller varieties are mostly selected for this purpose. For medicinal purposes the juice of the leaves mixed with warm water is considered anthelmintic; the whole plant pulverised and applied externally is said to be efficacious in leprosy and malignant ulcers; and the plant beaten up and mixed with Cinnamon, Pepper, Rice, and the oil of *Hydnocarpus inebrians*, is applied as an ointment in cutaneous diseases. These uses, however, are entirely in native practice, the plant not being included in the Indian pharmacopæia. The fruits of most, if not all the species of *Momordica*, burst when ripe by an irregular dehiscence. The central or drooping flower in the woodcut represents the female, the young spiny fruit being also seen. The plant generally takes from two to three months to mature its fruit from the time when the seeds are sown, and then it keeps in bearing condition for some months. The seeds should be sown in spring in a light soil, and assisted to germinate with a little bottom-heat.

Momordica Charantia.

When the young plants are large enough to handle, they may either be planted out and trained on a trellis, or grown on in pots. As it is a gross feeder, a rich soil suits it best, and the fruit is improved in size by an occasional application of liquid manure. J.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Late Melons planted out in frames—after these were cleared of bedding plants—should by this time have occupied all the space and set their fruit. Every assistance should be given to this late crop to facilitate growth, in order to ripen it before the cool weather sets in, as in ordinary manure frames they cannot be kept

on growing with the same vigour as those in pits, where fire-heat can be applied. The plants ought to be well thinned out, cutting away all superabundant shoots without leaving them too thin, as when too much denuded of leaf-surface, the power of the roots becomes stagnated. Give enough water to help the fruit to swell freely, and try to keep up a genial bottom-heat by the use of linings, which may consist of fresh manure mixed with Grass-mowings, weeds, or vegetable refuse of any kind. Where there is a considerable extent of lawn kept mown, the Grass-mowings alone, mixed with the linings that have been applied previously, will generally suffice to keep up the requisite heat for one or two frames at this season. Continue syringing these late Melons in the afternoons at the time of shutting up, which should be early enough to enclose a good amount of sun-heat, giving air as soon as the sun comes upon the glass in the morning, and admitting as much during the day as will keep the plants in a stout, healthy condition. Melons that are now about ripening should be kept sufficiently dry without carrying this so far as to stagnate the roots, for although when the soil is too moist during the ripening stages of the fruits it both injures the flavour and often causes them to crack,

still it is possible to keep them too dry.

Cucumbers in frames that have been bearing for some time, and that are required to keep on fruiting as late as possible, should now be well thinned out, cutting away the old exhausted shoots, retaining as many of the young growths that spring from the base of the plants as possible. These may with advantage be laid in so as to induce them to make roots by putting a few handfuls of soil over them at a short distance from where they spring; the young roots thus emitted will impart fresh vigour to the plants, and keep them bearing so long as there is sufficient atmospheric heat. Bottom-heat is not so necessary for Cucumbers during the summer season as it is for Melons, but as soon as the nights get cooler they will be benefited by a little, which can be secured by means of linings.

Herbaceous Plants.—A frame should now be got ready in which to put cuttings of any fine kinds of Antirrhinums, Pentstemons, Phloxes, and Hollyhocks, that it may be desirable to increase; 6 in. of fine sifted soil, to which has been added some well-decom-

posed leaf-mould and sand, should be put into the frame, inserting the smaller cuttings 1 in. or so apart. The Hollyhocks will succeed better if placed in small pots, as when struck such mode of growth will obviate the necessity of the check which they would receive in being potted after they were rooted: besides, they winter more satisfactorily in pots. In most cases these summer-struck cuttings of the above herbaceous plants, especially the Phloxes, will be found preferable to old stock; the additions of late years to the family of herbaceous Phloxes have been such as to place them in the very first rank of hardy plants, being easily grown and particularly adapted for cultivation by amateurs.

Bedding Plants.—If a sufficient number of Verbenas, Lobelias, Heliotropes, Ageratums, and similar bedding subjects were not potted on for stock when the bedding-out was completed, cuttings of all these should at once be inserted, eight or ten in 6-in. pots; these will strike, with the herbaceous plants above mentioned, in a cold frame placed under the influence of the sun, which will give sufficient warmth to effect the rooting process, using a thin shade to break the direct rays during the day; keep the soil continually moist, also the atmosphere, by not admitting air in such quantities as to cause the cuttings to flag, yet still giving enough to prevent their damping.

Border Carnations and Cloves should at once be layered; like most other plants the growth has been unusually late this year, but the layering should not be longer delayed, or there will not be sufficient time for them to root before autumn.

Gladioli planted late should have a neat stick put to each, to which they can be tied; it is always necessary to secure them in this way, but more especially such as bloom late through the autumn, and are under the influence of the stronger winds then prevalent.

Hydrangea japonica.—The Silver and Golden varieties of this elegant plant are worth growing, not only for their handsome leaves, but also for their flowers, which are produced just as freely and as effectively as by the green form of the plant.

Tritoma Uvaria, now throwing up its flowers, will likewise require support or it will get broken with the wind, except in the most sheltered situations. Give similar attention to Hollyhocks and Dahlias as they need it; if fine flowers of the latter be desired, the shoots and buds should be thinned out from this time as required. Earwigs are extremely destructive to the young buds; they may be trapped in various ways:—by pieces of paper crumpled up in the hand and thrust in betwixt the forks of the branches; small bundles of Broad Bean stalks cut in lengths of 5 in. or 6 in., and tied together (the insects shelter in the hollows of the stalks and may be shaken out and destroyed); and by the use of little pots inverted and filled with Moss, hung in the plants.

Kitchen Garden.—**Strawberries** recommended to be layered in small pots a short time back should immediately be transferred to those in which they are to fruit. Were it not that in most places runners were so unusually late this year this potting should have been performed a fortnight earlier, as there is now barely sufficient time for the plants to attain their wanted strength before the growing season is over, to assist which they must be stood in an open, sunny situation, and never allowed to become dry; 6-in. pots should be used with an inch of crocks at the bottom for drainage, and over them a few bits of turfy soil, on the top of which a little soot should be dusted to keep out worms; they should be potted in good, moderately heavy loam, rammed well into the pots so as to make it solid, not filling them too full, to allow sufficient room for watering. When potted they should be placed as close as possible in a square, not in a long thin row. Under the former arrangement the pots protect each other from the drying influence of the sun acting upon their outer surface, to which they are too much exposed when stood in a straight row. Later in the season they may be put in single file, which will assist the ripening of the crowns; a few inches of coal ashes under them will exclude worms. The late showery weather has been most favourable to runners rooting for permanent planting in the open ground; if this be immediately carried out, the moist condition of the soil will enable their getting established in a few weeks, and they will acquire enough strength to bear a good crop next year. In planting, press the soil quite firmly to their roots, and if the weather be bright, give a good soaking with water at the same time. Amateurs who have small gardens, and who require to make a new plantation of Strawberries, but who possibly may not yet have enough land cleared from other crops for the purpose, should at once prepare a small piece of ground as a nursery bed, wherein the runners can be planted out 5 in. or 6 in. apart, and from which they can, where there is room at disposal, be transferred to their permanent position. This will be found much better than allowing the runners to remain in the ground where produced until the place

where they are to be grown is at liberty, as under the latter condition they will not produce so much fruit next year. The following are a few of the best varieties of Strawberries suitable for amateurs to grow:—Keen's Seedling, the best for an early crop. Black Prince is a little earlier, but the fruit is so small that I should not advise its being used in gardens where the space is limited. Sir Joseph Paxton—a very free grower, bears abundantly; fruit of good quality. President (Green) will succeed Keen's Seedling; it is a large, handsome sort, an immense cropper, of good flavour, doing well in most soils and situations; if confined to a single variety, this is the one I should select. Sir Charles Napier will follow; it grows well in most soils, and produces an enormous quantity of fruit of good quality. British Queen is unsurpassable in both the appearance and flavour of its fruit; but it requires ground naturally well adapted for Strawberry culture, or if of a light nature, to receive a liberal addition of marl or clay. Eleanor, a good large fruit, comes in very late. Amongst the large number of Strawberries that find favour more or less, amateurs are often perplexed what to grow, but they may rely on the above half-dozen kinds giving satisfaction and representing all the properties required in this fruit. Established beds of Strawberries that have discontinued bearing should have all the runners cleared away, as these, if allowed to remain, do not improve the fruiting capabilities of the plants for another year; at the same time the ground should be well hoed, so as to kill all weeds as they appear.

Cauliflowers, for wintering in frames and under hand-lights should in the north of the kingdom be immediately sown; in the southern parts it will be better deferred till a week later. If a small quantity of the Early London and the late Asiatic be sown they will give a succession. I should recommend these seeds being dressed with red lead in the way that has previously being described, which will effectually prevent their molestation by birds; it is quite necessary to do this, for should the seed now put in get destroyed, by the time the failure is discovered it will be too late to sow for the requisite early crop in the spring.

Endive and Lettuce.—A little more Endive should be sown; as also Tom Thumb Lettuce, to come in for use late in the autumn. I should likewise suggest that a little Hardy Green Lettuce be put in, especially in localities subject to sharp frosts in autumn, as I have always found this variety stand when others have failed.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

August 20.—Sowing Early White Naples, Giant White, Tripoli, and Giant Rocca Onions for spring and summer use. Putting in Santolina cuttings under hand-lights in sharp sandy soil in a shady situation. Earthing up Celery and Cardoons whilst the plants are perfectly dry. Putting a little fresh soil on the roots of newly-planted Cucumbers and Melons. Salting gravel walks in order to kill weeds. Watering all newly-planted trees and shrubs that are likely to suffer from drought; also Celery, Carrots, Turnips, and Radishes.

Aug. 21.—Planting Antirrhinums and Sweet Williams; also Lettuce and Endive in good rich soil. Potting Cinerarias: also small Dracenas for table decoration. Pruning and nailing Rose trees on walls. Heavily manuring and trenching a large piece of ground previously occupied by Raspberries in which to plant Strawberries. Removing all overgrown heads from Globe Artichokes to prevent them weakening the plants. Watering newly-made Asparagus beds with liquid manure; also Pines, Celery, Scarlet Runners, Beans, Lettuce, and Endive.

Aug. 22.—Sowing Walcheren, Early London, Large Asiatic, and Autumn Giant Cauliflowers on well-prepared borders for spring and summer use. Taking up sorts of Potatoes in the following order:—Snowflake, Porter's Excelsior, Ashtop Fluke, Scilly Red, King of the Potatoes, Hundredfold Fluke, Yorkshire Hero, Breadfruit, Lady Paget, Perfection Kidney, Model, Rector of Woodstock, Fenn's Bountiful, Fenn's Early Market, Magnum Bonum, Blanchard, Favourite, and Red-skin Flourball. Watering Vine borders, Celery, Tomatoes, Cauliflowers, and Peas.

Aug. 23.—Sowing Red and White Turnip Radishes on moist soil. Putting in a batch of Pelargonium cuttings for border use. Sorting over Potatoes, and placing those intended for seed in shallow boxes. Making new gravel walks. Cleaning and weeding shrubbery and Ivy

banks in the pleasure ground. Watering Pines with soot water; also the Peach-house border, Lettuce, Endive, and Carrots.

Aug. 24.—Cleaning out Melon-pit, turning and well watering the soil, and planting it with Osborn's Forcing French Beans. Pruning pyramid Apple and Pear trees. Nailing and tying Peach trees. Earthing up Celery and Leeks. Gathering Plums, Jargonelle Pears, and a few Tomatoes. Watering Peas, Celery, and young Cabbage plants.

Aug. 25.—Potting Cyclamens. Planting Lettuce and Endive. Looking over Vines, and taking off laterals and any decayed berries. Stopping shoots of Melons and Cucumbers. Hoeing surface soil between all growing crops. Cleaning and weeding gravel walks.

SEASONABLE NOTES.

Fruits Ripening in Orchard Houses.—Some people have an idea that stone fruits ripened on the open wall are better flavoured than those ripened in cool houses. Where such is the case it should be taken, I think, as a sign that something has been wrong in the management of the house. The chief sources of colour and flavour in stone fruits are light and air. Fruit trees that are growing in a dark, crowded, ill-ventilated house, and that during the last week of approaching maturity receive the same quantity of water that had been given previously, are not likely to produce fruit worth eating. But if the fruit be exposed to strong light, abundant ventilation insured, and less water given during the last ten days or so of their ripening, good-flavoured fruit will generally be obtained. Of course, I am assuming that the trees are healthy, the foliage in good condition, free from red spider and other insect-pests, and only allowed to carry a reasonable crop.

Fruit for Tarts.—Owing to the great dearth of stone fruits, autumn-bearing Raspberries will this season pay for extra attention in the way of mulching, thinning out the weakly growths, and tying up the fruiting canes, if necessary to keep them off the ground, or to improve the flavour of the berries by a freer exposure. If dry weather continue, a good soaking of water will assist them. Red and White Currants on north walls will keep in a good condition through the autumn if well preserved from birds and wasps: Haythorn's hexagon netting will do all this effectually, and at the same time admit a free circulation of air. The common Blackberry rarely fails to produce a good crop, and no doubt this year its fruit will be eagerly sought after. What has become of the improved varieties of Blackberries that were introduced from America some years ago? Will any of your readers who may happen to grow them kindly give us the result of their experience in regard to them.

Tomatoes in Pots Under Glass.—I think I have never known Tomatoes in the open air so late as they are this year, but fortunately we have been able to gather plenty from pots standing on the front shelf in one of the houses, and trained up near the glass. Wherever there is shelf room in a warm house Tomatoes may be had in abundance without much trouble.

Late Peas in Pots.—Where very late Peas are required, some of the dwarf early kinds, such as Blue Peter, Gem, and Unique, might be sown now, not too thickly, in 8-in. pots. There is an advantage in growing the last crop in pots, because in the early period of their development they can be grown on the north side of a fence surrounded by a cool, genial atmosphere, and, when the sun loses power and the heat is moderate, they can be moved to a warmer position, or be placed, if necessary, under glass, to set their blossoms and fill out their pods.

Late French Beans.—Plant any of the small early kinds in a frame or pit—one from which early Melons have been cut will do. Fork up the soil, and pick out the roots, and give a good watering if the soil be dry a few hours before planting the Beans; the lights may remain off till the approach of cold weather. A few may also yet be planted on a warm south border, if a frame and lights can be placed over them before frost comes. In the event of a mild autumn they will come in useful.

Cauliflowers.—From the 18th of this month to the 1st of Sept., according to situation and other circumstances, will be a suitable time to sow the main crop of Cauliflowers, but if they are to be wintered under glass, the last week in this month will be in most places quite early enough. I always sow with the early kinds a few seeds of Veitch's Autumn Giant, it is so valuable for cutting now and onwards, and it produces a close firm heart in the hottest weather, when frequently the Walcheren is useless. This year has been an exceptionally good year for Cauliflowers: they are both fine and free from insects.

Treatment of Old Cabbage Beds.—In very many gardens the old Cabbage stems are allowed to remain for the sake of the second crop of little hearts they produce in autumn. The soil amongst them should now be well scarified, and if a top-dressing of manure of some kind can be given the produce will be equal to early spring Cabbages in flavour and tenderness. Where no attention is given to them they are tough and leathery, unless the land be deep and rich.

E. HOBDAY.

AUTUMN AND WINTER CUCUMBERS.

For late autumn and winter bearing, sow now one or more of the following varieties of Cucumbers, viz., Telegraph, Masters' Prolific, and Munro's Duke of Edinburgh. The last-named is a great bearer, but the Telegraph produces the longest and handsomest fruit. Plant each seed in a 3-in. pot in a compost of rich turfy loam and leaf-mould in equal proportions, and plunge the pots in some close pit or frame near the glass. An old, nearly-spent hotbed turned over and freshened up will be a suitable place, as it is not necessary to hurry them, but it is important to have strong vigorous plants grown without any kind of check. It is well also to raise a few more plants than will be required, as in that case one has the chance of selecting strong plants only, and in any given number raised there will always be a small percentage of weakly ones. In growing early and late Cucumbers, there should be a thorough command over the heating power, especially the bottom-heat, and as regards the latter 75° should not be much exceeded if steady and continuous bearing be desired. Where the autumn and winter supply has to be obtained from one house, leave three plants—one in the middle and one at either end—altogether uncropped through the autumn by pinching off all fruits as soon as they show themselves, and keeping the growth pinched back moderately close at the same time. The advantages of this plan will be seen when about Christmas the exhausted plants are pulled up, giving those left room for development. Cucumbers do not require a great depth of soil in which to start—from 9 in. to 12 in. will be ample; but what they do require is very frequent top-dressing, at least once a week. They require a good deal of moisture both at the root and in the atmosphere, and frequent top-dressing not only supplies fresh food to the roots in small quantities as required, but it freshens up, and by preventing stagnation, purifies the atmosphere of the house at a time of year when much ventilation cannot be given without too great a sacrifice of heat. Where good loam can be had, full of fibre and free from wire-worms, it should always form the main bulk of the compost used, adding soot or any other stimulating substance to enrich it where necessary, bearing in mind that although light, rich soils may produce rapid growth at first, yet when the pinch comes the plants often fail, while others grown more slowly in heavier soil will have continued bearing freely, and have furnished fruit in a satisfactory manner.—E. HOBDAY.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Mushrooms and Saltpetre.—At a recent meeting of the Horticultural Society of France an enormous Mushroom was exhibited by M. Courcier, who took occasion to point out that equally remarkable results can often be obtained by watering the beds on which these fungi are grown with a solution of nitrate of potash. Under this treatment a bed usually producing Mushrooms of but very small size will frequently bear specimens upwards of 20 centimetres in diameter in an incredibly short space of time. Occasionally they attain really gigantic proportions, and Mushrooms weighing as much as 7 lb. each have been grown in ordinary beds by the aid of such solutions. Nor is this increase in size attended with any loss of quality, the monstrous specimens thus obtained being equally palatable with those of more moderate dimensions. The simplicity of the plan is not the least of its recommendations, since any Mushroom grower possessed of a handful of saltpetre can test it for himself without either trouble or expense.

Too Soon.—The Rector of Hitcham suggests that coloured illustrations of the Colorado beetle should be distributed among schools, and then all village children might look about for it for a small pecuniary reward. Where that reward would tempt the village children to search for the beetle goodness only knows; but if they were let loose on the Potatoes; there would be a chance of the distinguished visitor being starved out.—"Fun."

THE SCREW PINES.

THE accompanying woodcut represents a typical member of the genus *Pandanus*, which includes about seventy species, all

Screw Pine has been generally applied to all the species, on account of their resemblance when young to the Pine-apple, and because of their long, narrow, spiny, imbricated leaves

Pandanus sylvestris.

confined to the tropics of the Old World. The present species, as defined by Rumphius, has a wide distribution, and its names are as numerous as its uses. This, *P. odoratissimus*, and *P. utilis* are perhaps the most important. The name

being arranged in three spiral rows at the extremity of the branches. The three above mentioned and some other species sometimes attain a height of 30 ft., assume a candelabra-like form, and impart a most peculiar aspect to the coasts, &c., on

which they grow. To support the tree, thick, adventitious roots are freely given off from the branches and stems, and rapidly elongate until they reach the ground. These afford

spathes. The male has numerous stamens, the filaments of which are often connate, as shown in our drawing. The fruits vary considerably, ranging in size from that of a small orange

Male flower of *Pandanus sylvestris*.

perhaps the best illustration of the pileorhiza (a sort of cap or hood of loose tissue which sheathes the growing points of the roots of some plants). The flowers have no perianth or flower envelope of any kind, are dioecious, and enclosed in

to large globular heads more than 1 ft. in diameter. In the tertiary series in our latitude, fossil *Pandanus* fruits are by no means uncommon, thus showing that a torrid climate prevailed in Europe during the tertiary period. The flowers and flower-

spathes of our present plant emit a delightful odour, much weaker, however, than that of *P. odoratissimus*, which we are assured is the richest and most powerful of all perfumes. If a panicle of the latter plant be left in a room, it will scent it for months. Perhaps the largest specimen in Europe of this species may be seen in the Palm-house at Kew. In the Museum No. 2 also there is a good collection of articles illustrating the uses to which different parts of the *Pandanus* plant may be applied, viz., mats, hammocks, beautiful baskets and boxes from the leaves, and cords, &c., from the fibre. A considerable trade is done in the flowers, the best (from Java) fetching a high price as an article for the toilet. This and other *Pandanads* when young are most graceful plants as single specimens in vases, owing to the recurved form of their leaves and the light and elegant appearance which they present, especially when kept to single stems. As regards culture, they should be grown in well-drained pots in a compost consisting of loam, peat, and silver sand; they require the temperature of a stove, and the variegated kinds should have plenty of light in order to bring out their colours.

Q.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 139).

Thyme.

- (1) *Oberon*. I know a bank where the wild Thyme grows.
Midsummer Night's Dream, act ii., sc. 1.
- (2) *Iago*. We will plant Nettles or sow Lettuce, set Hyssop and weed up Thyme.
Othello, act i., sc. 3. (See Hyssop).

It is one of the most curious of the curiosities of English plant names that the Wild Thyme—a plant so common and so widely distributed, and that makes itself so easily known by its fine aromatic, pungent scent, that it is almost impossible to pass it by without notice—has yet no English name, and seems never to have had one. Thyme is the anglicised form of the Greek and Latin *Thymum*, which name it probably got from its use for incense in sacrifices, while its other name of *serpyllum* pointed out its creeping habit. I do not know when the word Thyme was first introduced into the English language, for it is another curious point connected with the name, that *thymum* does not occur in the old English vocabularies. We have in Ælfric's Vocabulary, "*Pollegia, hyl-wyrt*," which may perhaps be the Thyme, though it is generally supposed to be the Pennyroyal; we have in a vocabulary of the thirteenth century, "*Epitime, epithimum, fordboh*," which also may be the Wild Thyme; we have in a vocabulary of the fifteenth century, "*Hoc sirpillum, A^ce petergrys*," and in a pictorial vocabulary of the same date, "*Hoc cirpillum, A^ce a pellek*" (which word is probably a misprint, for in the "*Promptorium Parvulorum*," c. 1440, it is "*Peletyr, herbe, serpillum, piretrum*"), both of which are almost certainly the Wild Thyme; while in an Anglo-Saxon vocabulary of the tenth or eleventh century we have "*serpulum, crop-leac*," i.e., the Onion, which must certainly be a mistake of the compiler. So that not even in its Latin form does the name occur, except in the "*Promptorium Parvulorum*," where it is "*Tyme, herbe, Tima, Timum*—Tyme, floure, *Timus*. And it is thus a puzzle how it can have got naturalized among us, for in Shakespeare's time it was completely naturalised. I have already quoted Lord Bacon's account of it under Burnet, but I must quote it again here:—"Those flowers which perfume the air most delightfully, not passed by as the rest, but being trodden upon and crushed, are three, that is Burnet, Wild Thyme, and Watermint; therefore, you are to set whole alleys of them, to have the pleasure when you walk or tread;" and again in his pleasant description of the heath or wild garden, which he would have in every "prince-like garden," and "framed as much as may be to a natural wildness," he says, "I like also little heaps, in the nature of mole-hills (such as are in wild heaths) to be set some with Wild Thyme, some with Pinks, some with Germander." Yet the name may have been used sometimes as a general name for any wild, strong-scented plant. It can only be in this sense that Milton used it.

Thee, shepherd! thee the woods and desert caves,
With Wild Thyme and the gadding Vine o'ergrown;
And all their echoes mourn.

Lycidas.

for certainly a desert cave is almost the last place in which we should look for the true Wild Thyme.

It is as a bee-plaut especially that the Thyme has always been celebrated. Spenser speaks of it as "the bees-alluring Thyme," and Ovid says of it, speaking of Chloris or Flora—

Mella meum manus; volucres ego mello daturos
Ad violam et cytisos, et thyma cana voco.

Fasti, v.

so that the Thyme became proverbial as the symbol of sweetness. It was the highest compliment that the shepherd could pay to his mistress—

Nerine Galatea, thymo mihi dulcior Hyblæ.

Virgil, Eel. vii.

and it was because of its wild Thyme that Mount Hymettus became so celebrated for its honey—"Mella thymi redolentia flore" (Ovid). "Thyme, for the time it lasteth, yeeldeth most and best honni, and therefore in old time was accounted chief (*Thymus aptissimus ad mellificum*—*Pastus gratissimus apibus Thymum est.* ("Plinii His. Nat").

Dum thymo pascentur apes, dum rore cicadæ.

Virgil, Georg.

Hymettus in Greece and Hybla in Sicily were so famous for Bees and Honni, because there grew such store of Thyme; propter hoc Siculum mel fert palmam, quod ibi thymum bonum et frequens est" (Varro).—"The Feminine Monarchie, 1634."

The wild Thyme can scarcely be considered a garden plant, except in its variegated and golden varieties, which are very handsome, but if it should ever come naturally in the turf, it should be welcomed and cherished for its sweet scent. The garden Thyme (*T. vulgaris*) must of course be in every herb garden; and there are a few species which make good plants for the rockwork, such as *T. lanceolatus* from Greece, a very low-growing shrub, with narrow, pointed leaves; *T. carnosus*, which makes a pretty little shrub; and others; while the Corsican Thyme (*Mentha Requeini*) is perhaps the lowest and closest-growing of all herbs, making a dark-green covering to the soil, and having a very strong scent, though more resembling Peppermint than Thyme.

Toadstools.

Ajax. Toadstool, learn me the proclamation.
Troilus and Cressida, act ii., sc. 1.

I quoted this passage under Mushrooms, in order to speak of the fungology of Shakespeare generally; but I quote it again to give myself the opportunity of supplying another passage which I had then overlooked, but which clearly refers to fairy rings—

Quickly. And nightly meadow fairies, look you sing,
Like to the Garter's compass, in a ring,
The expressure that it bears green let it be,
More fertile-fresh than all the field to see.

Merry Wives of Windsor, act v., sc. 5.

There can be no doubt that the reference is to fairy rings. (See Mushrooms).

Turnips.

Anne. Alas! I had rather be set quick in the earth and bowled to death with Turnips.

Merry Wives of Windsor, act iii., sc. 4.

The Turnips of Shakespeare's time were like ours, and probably as good, though their cultivation seems to have been chiefly confined to gardens. It is not very certain whether the cultivated Turnip is the wild Turnip improved in England by cultivation, or whether we are indebted for it to the Romans, and that the wild one is only the degenerate form of the cultivated plant; for though the wild Turnip is admitted into the English flora, yet its right to the admission is very doubtful. But if we did not get the vegetable from the Romans we got its name. The old name for it was *neep*, *nep*, or *neps*, which was only the English form of the Latin *napus*, while Turnip is the corruption of *terre napus*, but when the first syllable was first added I do not know. There is a curious

perversion in the name, for our Turnip is botanically *Brassica Rapa*, while the Rape is *Brassica Napus*, so that the English and Latin have changed places, the *Napus* becoming a Rape and the *Rapa* a Nep.

The present large field cultivation of Turnips is of comparatively a modern date, though the field Turnips and garden Turnips are only varieties of the same species, while there are also many varieties both of the field and garden Turnips. "One field proclaims the Scotch variety, while the bluer cast tells its hardy Swedish origin; the tankard proclaims a deep soil, and the lover of boiled mutton, rejoicing, sees the yellower tint of the Dutch or Stone Turnip, which he desires to meet with again in the market" (Phillips). It is not very easy to speak of the moral qualities of Turnips, or to make them the symbols of much virtue, yet Gwillim did so:—"He beareth sable, a Turnip proper, a chief or gutte de Larmes. This is a wholesome root, and yieldeth great relief to the poor, and prospereth best in a hot sandy ground, and may signifie a person of good disposition, whose vertuous demeanour flourisheth most prosperously, even in that soil, where the searching heat of envy most aboundeth. This differeth much in nature from that whereof it is said, 'And that there should not be among yon any root that bringeth forth gall and wormwood'" (Gwillim's "Heraldry," sec. iii., c. 11).

Vetches.

Iris. Ceres, thou bounteous lady, thy rich leas
Of Wheat, Rye, Barley, Vetches, Oats, and Peas.
Tempest, act iv., sc. 1.

The cultivated Vetch (*Vicia sativa*) is probably not a British plant, and it is not very certain to what country it rightly belongs; but it was very probably introduced into England by the Romans as an excellent and easily-grown fodder-plant. But there are several Vetches that are true British plants, and they are among the most beautiful ornaments of our lanes and hedges. Two especially deserve to take a place in the garden for their beauty; but they require watching, or they will scramble into parts where their presence is not desirable: these are *V. Cracca* and *V. sylvatica*. *V. Cracca* has a very bright pure blue flower, and may be allowed to scramble over low bushes; *V. sylvatica* is a tall climber, and may be seen in copses and high hedges climbing to the tops of the Hazels and other tall bushes. It is one of the most graceful of our British plants, and perhaps quite the most graceful of our climbers; it bears an abundance of flowers, which are pure white streaked and spotted with pale blue; it is not a very common plant, but I have often seen it in Gloucestershire and Somersetshire, and wherever it is found it is generally in abundance.

The other name for the Vetch is Tares, which is, no doubt, an old English word which has never been satisfactorily explained. The word has an interest from its biblical associations, though modern scholars decide that the *Zizania* is wrongly translated Tares, and that it is rather a bastard Wheat or Darnel.

H. N. ELLACOMBE.

(To be continued).

SEED SAVING v. VEGETABLE GROWING.

A VERY popular error in connection with vegetable culture is that of saving seed from growing crops that are intended to supply the wants of the household, under the impression that such a proceeding is economical; a greater fallacy could scarcely be indulged in, more especially with regard to crops that continue to furnish successional gatherings for any length of time, as, for instance, Vegetable Marrows, Cucumbers, Kidney and Runner Beans, etc. It is by no means a rare occurrence to find some of the earliest and finest produce left for seed, whereby the fertility of the plants is brought to an abrupt termination, as the formation of seed is far more exhaustive in its effects than an unlimited number of blossoms or pods up to the period of the maturity of the seed. In the case of Beans of the Kidney or Runner sections, it is the pod that furnishes the edible portion: also with Vegetable Marrows and Cucumbers, the seed-vessel or covering is at its highest state of excellence as food before the seed commences to draw

on the resources of the plant; and in proportion as they are more or less carefully removed will be the duration of period in which successional gatherings will be produced. I always gather all such crops at regular intervals, according to the season and the rapidity with which they attain development, and should any of the produce become too old, from having escaped observation at previous gatherings, it is pulled off and thrown away, as a very small quantity of seed-pods is sufficient to arrest the successional development of the crop.

When it is desirable to save seed of any select stock, it is by far the best plan to set a row (or a portion of one, according to the quantity required) specially apart for seed, and not gather any produce from them, drawing out any plants that do not appear true. By this means one may greatly prolong the season of production, in comparison with which the trifling cost of seed is little or nothing. If any one be sceptical of the power of seed-pods in arresting the production of successive crops, let them select two rows of Sweet Peas, and gather the blossoms of one row as fast as fully expanded, and allow the others to mature their seed; the latter will cease blooming and be thoroughly exhausted and dried up by the time the seed-pods are ripe, while the latter will continue growing and producing fresh blooms until checked by frost. It is of course not practicable to pursue the same plan with Peas grown for the table, and the only way to secure a continuous supply of Peas is by successional sowings. But Scarlet Runners will continue bearing the whole season, equally as well as Vegetable Marrows or Cucumbers, if well attended to in the matter of moisture at the roots, and above all, in preventing any portion of the produce from going to seed. The saving of the seed of vegetable crops is also an important matter as regards future crops, for a careful selection will eventually produce a good strain, as will indiscriminate seed saving eventually deteriorate the most select stock in existence. From careful observation, I should say that seed saving and vegetable growing are, as a rule, both more satisfactory and remunerative when carried out as totally distinct operations.

Henham.

JAMES GROOM.

Trees and Electricity.—We gave an account the other day of some of M. de Moncel's observations on the electric conductivity of trees. In a further note to the French Academy he gives a table of the comparative resistances of a large number of trees. The method of experiment was to apply two platinum electrodes of square surface, one at the upper part and the other at the base of the tree; they were 6.44m. apart, and the lower electrode placed slightly above the ground. Such an arrangement with a galvanometer itself gives a current from above downwards through the galvanometer; and this had to be allowed for before the battery (of three Daniell elements) was connected. The table shows that soft woods of spongy tissue and vigorous vegetation, such as Elm, Chestnut, Lime, Poplar, &c., are the best conductors, while the hard woods of slow vegetation are the most resistant. Birch seems to form an exception. The order of conductivity is pretty much the same as that of the same woods when dry and exposed to moisture.—"English Mechanic."

The Reservoirs Bill.—This will enable any landowner, however limited his interest, to collect water on his estate from any pure source at his command, and having entered into a contract to supply it to any sanitary authority within reach, he can borrow the money required for the necessary works, and, with the approval of the Enclosure Commissioners, charge his estate with the cost on two conditions—first, that the amount is repaid by instalments extending over a limited period of years; and second, that the income to be derived from the water shall be sufficient to satisfy the Commissioners that the reversionary interests—i.e., the property—will be benefited by the transaction. In many localities this measure will be found of great advantage, for the reservoirs and works contemplated by it will not be limited in their use to the storage of surface or surplus waters, but will be found available for the collection of spring and subterranean waters where they are only to be favourably obtained on private estates. The sanction given by the Legislature to landowners to become suppliers of water, and to local sanitary authorities to become customers, with a legalized power to contract and pay for it, will remove many objections and difficulties which now stand in the way of water supply to small communities.

A Natural Bridge, said to be far more wonderful than that in Virginia, is reported to have been recently discovered in Elliot County, Kentucky. It is of solid stone, in form a magnificent arch, 182 ft. long, and 15 ft. wide at the top, the river, the Little Chaney, rolling 100 ft. below. Fifty yards above the bridge is a waterfall, 63 ft. high, and the view from the bridge is said to be extremely beautiful.—"Builder."

Five-leaved Indian Cress
(*Tropaeolum pentaphyllum*).

Showy Prince's Feather
(*Amarantus speciosus*).

Amarantus tricolor.

Downy Thornapple (*Datura Metel*).

Martynia fragrans.

Alonsoa incisifolia.

White-flowered Thornapple (*Datura meteloides*).

Purple Thornapple (*Datura fastuosa*).

Love-lies-bleeding (*Amarantus caudatus*).

Eremostachys laeiniata.

Common Sweet Flag (*Acorus Calamus*).

Martynia proboscidea.

HARDY FLOWERS OF THE WEEK.

THE best plant in our list this week is *Senecio pulcher*, figured in THE GARDEN of June 17 of last year. Although it comes from Buenos Ayres, it has proved quite hardy with us during the past three years in the open border. The foliage is large, of great substance, and deep green in colour; the flower-stems stout, erect, and branching from 2 ft. to 3 ft. in height, bearing numbers of purplish-crimson flowers, measuring from 2 in. to 3 in. across. *Echinacea angustifolia* and *purpurea* are also useful plants, with stout, erect stems, from 3 ft. to 4 ft. in height, bearing large purple flowers. *Pentstemon barbatus* Torreyi, bearing pyramidal spikes of crimson flowers 4 ft. in height, is a striking plant; and so are the various sorts of *Tritoma*, especially *T. grandiflora* and *T. glaucescens*, the noble spikes of scarlet and yellow flowers of which stand out in bold relief from among their associates. The little *T. Macowani*, figured the other day in THE GARDEN, is also now in flower, and is a perfect gem. Two members of the Spiderwort family, *Commelina cœlestis* and *C. cœlestis alba* are both well worth growing; the one is a lively gentian blue, the other white, and they continue in flower until very late in the season; in cold, heavy soils, they should be taken up and stored away like

Canna Bihorelli.

Dahlias. *Acanthus latifolius*, now in flower, is an imposing object, its flower-spikes reaching a height of from 4 ft. to 6 ft. *Digitalis ferruginea* is now in blossom; but it is not so showy as *D. grandiflora*, which is now also covered with spikes of soft yellow flowers. *Bocconia cordata*, with handsome foliage, surmounted by numerous feathery panicles, arrests the attention of all who see it: although vigorous in growth, and apt to encroach upon its neighbours, yet for the wild garden or shrubby border few plants equal it. To these may be added the white-flowered *Polygonum amplexicaule*, the double perennial Sunflower (*Helianthus multiflorus* fl.-pl.), *Echinops* of various sorts with globular heads of Thistle-like blue and white flowers, *Monardas*, and several of the *Aconitums* or Monk's-hoods, amongst which *A. Anthora* deserves special mention; it grows from 2 ft. to 2½ ft. in height, forming a pyramid of showy yellowish flowers; *Leucanthemum alpinum*, with numerous large, white, Daisy-like flowers, is also very conspicuous. It is closely allied to the *Chrysanthemums*, the best of which is *C. frutescens*, a kind extensively used in Paris for summer decoration; the flowers, which are white, completely cover the plant, which is also very useful for pot culture, flowering, as it does, in a cold house until January; it is, however, not quite hardy. *Physostegia virginiana* bears spikes of purple flowers, which are abundant

and lasting; *Geranium striatum*, with its delicately-pencilled white flowers, and *G. nodosum* (purple), are also good border plants, both forming neat bushes. *Dianthus superbus* is an erect-growing species, about 1 ft. in height, with light purple fragrant blossoms, the petals of which are cut into narrow segments, giving them a fringed appearance. *Potentilla formosa* is one of the best of the genus to which it belongs, its flowers being very numerous and of a bright cherry-red. *Statice umbrosa* (a dwarf species, with large heads of blue flowers) and its white variety form neat, attractive border plants. The white variety of the Musk-scented Mallow (*Malva moschata alba*) is a showy plant. *Gentiana asclepiadea* and its white variety are also good perennials, revelling in any shady, moist spot; I have seen plants of them 3 ft. high with from fifty to sixty stems, each bearing from twelve to eighteen lovely blue flowers, and this in a wild state. Of these plants I saw hundreds during a recent visit to Dalmatia of immense size, growing with *Dondia Epipactis*, *Lilium carniolicum*, *Veratrum album*, and many others, the *Gentian* especially seeking cool, shady spots. One of the best of this family is *Gentiana Froelichii*, a perfect gem, but rather difficult to grow; its flowers are large, on stems 3 in. in height, varying from blue to white; in habit it somewhat resembles *G. pneumonanthe*. *Scabiosa vestita*, a neat-growing species, with deep lilac flowers on stems 1 ft. in height, is now flowering freely; it is a desirable plant. The Grass of Parnassus (*Parnassia palustris*) is a pretty bog plant; its delicate white pencilled flowers, on stems varying from 6 in. to 12 in. in height, are very pretty, and the plant can be grown either in pots or in the open ground. *Gaultheria procumbens* (a well-known evergreen with drooping white bells), and many kinds of *Cistus* are now flowering freely; *C. crispus* is exceedingly bright. *Calystegia Sepium grandiflora*, a large variety of the Common Bindweed, with large, white flowers; *C. S. incarnata*, a rose-coloured variety; and *C. pubescens* fl.-pl., with double rose-coloured flowers, are all now in bloom and make excellent climbers. *Habitzia tamnoides*, a rapid-growing climber, with greenish-white flowers; *Metaplexis Stauntoni*, with umbels of white flowers; *Convolvulus Scammonia*, white; *Apios tuberosa*, with brown flowers; *Tropæolum speciosum*, vermilion; and *T. pentaphyllum*, green and red, are all hardy. The Purple-fringed Orchis (*Habenaria psycodes*) is flowering freely in shady peat beds, along with a few others of this family. Many varieties of the Tiger Lily are now in fine condition, especially *Lilium tigrinum Fortunei* and *L. t. splendens*; the latter is one of the finest of the Tiger group. *L. longiflorum Wilsoni* is now 3 ft. in height, and is producing white, trumpet-shaped flowers of large size; this is the latest in flower of this section, and certainly the finest. *Alstroemerias* are still in perfection, the two best being *A. Pelegrina* (with large, rose-coloured flowers heavily splashed with purple) and its white variety; both are dwarf and hardy in warm, sheltered spots. *Gladioli* are now flowering freely, especially *G. gaudavensis* and *G. Brenchleyensis*, of which there are numerous varieties; among the species at present in bloom are *G. purpureo-aureatus*, a curiously-shaped flower, of a creamy-yellow colour, having three irregular purplish blotches; *G. dracocephalus*, with bronzy flowers; and *G. Colvillei albus*. *Begonias*, especially the bulbous ones, are now a mass of bloom; as pot plants they are very effective, and for bedding purposes in warm, dry soils, they rival even the *Geranium*. Many of the early-flowering *Chrysanthemums* are opening their blooms, and the *Hollyhocks* bid fair to make a good display a little later in the season; they seem to be much better than last year, and in many places are clear of the disease which has almost annihilated collections of this favourite flower. *Delphiniums*, *Pentstemons*, *Phloxes*, and *Violas* are a blaze of colour, and greatly assist in making the borders gay at this time of the year. P.

Viola Ve-tal.—This beautiful white bedding *Viola* received a first-class certificate recently at Chiswick, and well does it deserve that distinction. Its habit is dwarf and compact, and it flowers freely, the blooms being of medium size, excellent in form, and of a pure paper-white hue. It has proved this season to be the most constant and striking of all the white varieties. Bedding *Violas* have flowered unusually well this year; at Castle Coch they have been the best of all bedding plants.—A.

THE LIBRARY.

A NEW LONDON FLORA.*

THIS is the latest addition to the series of local British floras which has already reached considerable dimensions, and to which many additions are in course of preparation. It differs from the majority of such works in that it is not confined to any one county or to a very limited district, but includes such plants as grow within an average radius of thirty miles from London. Of course, among local floras, as among most other things, there are many varying methods of work, and a still greater range of excellence or the reverse; and we fear we cannot place Dr. de Crespigny's little volume very high up in the list. Its appearance suggests that it will form a handy companion for a Saturday half-holiday stroll, or a day trip to some of the more favoured but more distant localities mentioned in its pages; but a very slight inspection of its pages dispels this pleasing illusion. It is no drawback to the book that it is in great measure a compilation; this is inevitable from the nature of the work, and is, moreover, openly avowed, but the compilation is executed in a manner which is far from satisfactory, and when tested, shows its incompleteness only too distinctly. The authorities on which each locality rests are only acknowledged generally at the beginning of the book, and the localities themselves have no indication of their respective counties affixed. It is thus impossible to form any estimate as to the probability or otherwise of any particular statement without tracing it to its original source to see upon whose authority it rests; and this is often not only difficult and tedious, but well-nigh impossible. For instance, a rare Spurge (*Euphorbia portlandica*) is indicated, with some doubt, as growing in "bogs in Charlton Woods" (Kent). This is certainly an error which should never have been perpetuated; the plant in question is almost as unlikely to occur in the London flora as an inhabitant of the Scotch mountains; yet we have no means of tracing this blunder to its source, and the future historian of Kentish plants will have an additional "ambiguity" to investigate, for which he is scarcely likely to be grateful to Dr. de Crespigny. The author has occasionally gone out of his way to be critical. For instance, a rare plant (*Bupleurum tenuissimum*) was found on Ealing Common, and he suggests that a common one (by no means resembling it) may have been mistaken for it. Yet seeing that the authors of the "Flora of Middlesex," who were by no means likely to make such a mistake, say that they have themselves seen a specimen of the plant from the locality in question, Dr. de Crespigny's criticism is, to say the least of it, unnecessary. A guide to London botany, from which doubtfully, or at any rate certainly, extinct plants should be excluded, would be a useful *vade mecum* for many a half-holiday ramble; but the "New London Flora" can in no sense be said to occupy this position.

JAMES BRITTEN.

FLORA OF MAURITIUS AND THE SEYCHELLES.

THIS has just been published under the authority of the Colonial Government of the Mauritius, who have entrusted the execution of the work to that active botanist, Mr. J. G. Baker. As in the other instalments of the series of colonial floras, of which this volume forms one, the descriptions of the species are purely technical, and the book is intended for the professed botanist. A few of the facts adduced by Mr. Baker in his prefatory remarks are, however, not without interest. It appears that here, more than in any other part of the world except St. Helena, the indigenous vegetation has been replaced to a very great extent by introduced trees, shrubs, and weeds. Many of the Orchids, Ferns, Pandani, and other plants affecting shade and damp have become very rare or are entirely exterminated in consequence of the indiscriminate cutting down of the aboriginal forests which culminated in the last century, while some at least of the interesting trees and shrubs peculiar to the island have shared the same fate. The remarkable proportion borne by introduced plants to the indigenous flora will be seen when it is stated that it is almost as one of the former to three of the latter—269 introductions being enumerated against 869 native species. The island of Mauritius being situated two degrees within the Tropic of Capricorn, it is curious to find some of our commonest British plants represented in its indigenous flora, such, for instance, as the Bindweed (*Convolvulus arvensis*), Male Fern (*Nephrodium Filix-mas*), two Plantains (*Plantago major* and *P. lanceolata*), *Juncus effusus*, *Caramine hirsuta*, and *Cerastium glomeratum*. Among the more familiar exotics which have completely established themselves in Mauritius may be named *Vinca rosea*, two *Clerodendrons* (*C. fragrans* and

C. macrophyllum), the Marvel of Peru, three *Cæsalpinias*, *Canna indica*, and *Watercress*. The cultivation of sugar was introduced to Mauritius in 1740, and in ten years afterwards it had become so extensively adopted that it almost supplanted the previously grown crops of Cloves, Indigo, Coffee, and Cotton. From 467 tons in 1812, the amount of sugar exported increased until 1860, when it reached a maximum of 131,000 tons, at which time it was calculated that this island, which is scarcely as large as the county of Surrey, produced about one-tenth of the exported sugar of the entire world. Trees are now being extensively planted in the neighbourhood of Port Louis, and the advantage of this course from a sanitary point of view is already apparent; the remains of the aboriginal forests linger only in the recesses of the hills. The large proportion which the Ferns bear to the other Orders included in the flora is very remarkable; 168 species are enumerated, being more than double the number of the Orchideæ, which Order stands next on the list in point of numbers.

B. J.

SCOTTISH HORTICULTURAL ASSOCIATION.

AT the monthly meeting of this Association, held the other day in Edinburgh, Mr. Dunn, the President, gave an interesting account of the hardy fruits cultivated in the Lothians. After pointing out the great advantage of every one making himself familiar with the sorts of fruits suitable for the locality in which he may be placed, he offered a few observations on the following Strawberries:—Garibaldi, he said, was one of the most useful, being very prolific, and not requiring to be renewed so frequently as the majority of other sorts: he saw no difference between this and the variety named Vicomtesse Héricart de Thury. James Veitch, although not generally cultivated in the Lothians, is an excellent variety; Keen's Seedling he finds is still the best forcing Strawberry in cultivation; Princess Alice Maud he found to be a very useful sort at Dalkeith; while Elton Pine was the best of all the late kinds. These, he said, were the standard sorts. Duke of Edinburgh he considered to be an excellent variety; and New Margaretta did well on light soils; British Queen was the best-flavoured Strawberry in cultivation; Eclipse he considered to be but second-rate in point of flavour. Of Cherries, May Duke is one of the best, and so well known as to require no comment; Black Tartarian he found to be, however, a better cropper. The best late Currant is Ruby Castle, but for keeping purposes there is no better than White Dutch; Black Naples was thought to be the best Black Currant—he could, however, find no difference between it and a variety named Lee's Prolific. Of Raspberries none was stated to be equal to Falstolf. Mr. Dunn concluded his remarks by inviting any of the members present to name any other variety not mentioned which they had found to be useful in the Lothians.—Mr. McKennon, Melville Castle, observed that Keen's Seedling, President, and British Queen did well with him.—Mr. Syme (of the Lawson Co.) gave an interesting account of the origin of Garibaldi and Vicomtesse Héricart de Thury, which he considered to be synonymous. He remarked that cultivators should not lose sight of the Black Prince, which he said was the earliest of all known Strawberries.—Mr. Johnston observed that he had lately travelled over the north part of Perthshire, and that there he found Reeves' Eclipse to be the favourite; for fruit of this sent up to London from Kilkerran Castle first prizes were awarded at the great shows; fine samples of the above-named fruits were exhibited by Mr. Dunn and Mr. McKennon. Mr. Grieve furnished a variety of Rhubarb named Stott's Monarch, which he remarked was not new, but in every way an excellent variety, which ought to be more generally known than it is. He also showed a new seedling Campanula of the turbinata section. Mr. Lauder, Goshen, sent a new seedling Gooseberry which he has cultivated for a number of years, and which was excellent in quality. Mr. McLaren, Balleucriff, also sent a new seedling Gooseberry, raised by Mr. Wright, Preston, similar in appearance to the Hedgehog, but it has the merit of being three weeks earlier than that kind; both these were from East Lothian. Mr. George Thomson, Viewfield, Dalkeith, showed a new seedling Strawberry, a hybrid between Grove End Scarlet and Elton Pine, and the best variety for preserving that is brought to the Edinburgh market. Mr. John Rae, White Lins, furnished a white variety of the Black Currant.

M.

COMPLAINT FROM A LADY-BIRD.

WHAT false alarms, resounded here and there
By dolts precipitate or hoax-designers,
Excite your "Colorado Beetle Scare,"
Penny-a-liners?

The Beetle seen at Hereford was I;
Preserver, not destroyer of the "Tater";
Who eat not it, but off it eat the fly,
Aphis vastator.

The donkeys, from a foe that could not tell a
Friend! No Doryphora decemlineata,
The Lady-bird am I, the Coccinella
Septempunctata.

"Wolf" is a cry that soon gets counted flam,
Till comes the Wolf indeed, at last unheeded.
Worse folly 'tis to cry out "Wolf!" on lamb,
As Muffs on me did.

—"Punch."

* "A New London Flora; or, Handbook to the Botanical Localities of the Metropolitan Districts." By Eyre de Crespigny, M.D., &c. London: Hardwicke & Bogue, 1877.

HARDY FLOWERS.

AURICULAS.—The continued heavy rains which we are now experiencing make it necessary that considerable care should be taken of these plants, or they will get injured through being too wet at the roots, especially those that have been recently potted. Those that were repotted in June will now be growing freely in the centre, while the large outside leaves put forth in spring will be decaying. The plants are now making what will be their winter garb, and the more firmly they are rooted into the soil the better. In all places where the atmosphere is pure and genial, an occasional soft shower will benefit the plants, if it be not too drenching. The Auricula at this season of the year requires to be moist at the roots, not wet, and the plants will be much healthier in consequence. The difficulties which beset some growers of the Auricula—and successful growers, too—can scarcely be comprehended by those who have had no experience of such adverse conditions. Mr. B. Simcoe, Rough Bank, Sheffield, dares not allow a drop of rain to fall on any of his plants, and for this reason, that during a dry time the atmosphere of Sheffield becomes so charged with sulphuric acid, that when rain descends it carries it down to the soil, and it would be almost certain death to his Auriculas. Consequently he grows them in a plant-house all the year round, and in the act of watering the leaves are not wetted. The same difficulty—though in a lesser degree—besets some parts of Manchester. Mr. Samuel Barlow, Stakehill House, Chatterton, grows his collection under glass on a raised stage in a somewhat low house, which he had constructed specially for choice hardy plants; a kind of wooden bed has been constructed 6 in. in depth, and the pots are plunged in coal ashes up to their rims. This keeps the roots cool and moist, and but little water is required. Mr. Barlow has potted his plants in a soil consisting of powdered charcoal, rough turfy loam, and a little manure; and the appearance of the plants indicates how they revel in it. Finally, a piece of tiffany is spread over the glass roof on the outside, and plenty of air is given in favourable weather. Some young cultivators may perhaps be astonished on seeing a plant throw up a late summer truss. The flowers are rarely true to character, and they are out of season; besides, they rather tend to divert the energies of the plant from the production of leaf-growth. Except in the case of seedlings that bloom at what the Yorkshiremen term the “back-end,” it is not advisable to allow plants to flower; but to prevent this, do not pinch out the stem entirely, but simply the truss of buds, allowing the stem to dry away gradually, which it will do in a few days. It is not well to pinch out stem and all, as a portion of it will be left, and it may rot and spread decay to the plant. Seed of Auriculas just harvested should be sown as soon as gathered, and that because some of it will germinate at once, and thus nearly a season is gained. Sow the seeds in pans or shallow boxes of fine soil, and place them in a greenhouse or cold frame in a shady position; a little Moss may be laid on the surface of the soil to keep it moist. As soon as the plants are large enough to handle, they should be pricked off into pots that will contain four or five plants, and grow on into size as quickly as possible. The value of sowing seed in August is this—that the autumn and winter's growth is thereby gained, as compared with seedlings raised in spring.

CYCLAMENS.—A sowing of seed of these beautiful spring-flowering plants should be made without delay. There is nothing like shallow pans in which to sow the seed, and the soil should be a fine, free, sandy one. The pans require to be placed in a brisk, moist bottom-heat, with a piece of glass over the pans. The seed, if full and well-ripened, soon germinates, and when the plants are large enough to have put forth three leaves they should be pricked off into 5-in. pots, in a rich, light soil; the pots should be well drained. The growers of Cyclamens in quantity are now busily engaged in getting their seed sown, and their practice is the one just set forth. Seedlings raised from seed sown in August make good plants to flower fifteen months afterwards, if they be grown on as fast and as liberally as possible.

FORGET-ME-NOTS.—Now is the time to make a sowing of these beautiful flowers for spring decoration. *Myosotis dissitiflora* should be used for early work, and the white and blue varieties of *M. sylvatica* for later flowering. Though *M. dissitiflora* is a true perennial, it is much better grown from seed each year than trusting to divided plants. The latter will sometimes stand remarkably well; they did so in a cold, wet, clayey soil in West Middlesex during the past winter, but they cannot always be depended upon; seedlings are more trustworthy. Then there is a very useful summer-flowering Forget-me-not, known as *M. semperflorens*, which has a particularly durable habit, and which stands well in hot weather; I recently saw this in the neighbourhood of Manchester flowering quite freely in a full sunny exposure. The varieties of *M. azorica*, and especially that known as *Impératrice Elizabeth*, make capital summer-flowering plants in pots; and that dwarf but exceed-

ingly beautiful form, *M. rapicoola*, which has the richest blue among all the Forget-me-nots, is a lovely gem for pot-work, but requires some care to have it in all its beauty. D.

JAPANESE TREES AND SHRUBS AT HOME.

PROFESSOR REIN, who has travelled widely in Japan, recently delivered a lecture on the vegetation of Japan before the Horticultural Society of Berlin, and we are indebted to the “Monatsschrift” of that Society for the following extracts:—Of all the species of *Hydrangea*, *H. paniculata* is the most widely dispersed in a wild state, ascending to an altitude of 5000 ft., where it forms large bushes. In many places it is used for paper making. The genus *Actinidia* comprises four or five species, all of which inhabit the mountain forests, climbing from tree to tree, to a height of 65 ft. or more. The fruit of *A. rufa* and *argata* is edible and eaten, being of a bitter-sweet taste, and by no means disagreeable. The fruit of *A. polygama* is not edible, but it possesses in a remarkable degree the power of attracting cats, and this property is common to the whole plant. This peculiarity is so marked that it has given birth to the proverb, “He sticks to it like a cat to a Matalabi.” *Schizophragma hydrangeoides*, a shrub of climbing habit, closely allied to *Hydrangea*, is also found in the mountains up to 5000 ft., and on account of its beautiful pure white flowers is highly esteemed. To illustrate his remarks on the timber trees of Japan, Professor Rein exhibited a collection, of Japanese preparation, of 100 vertical and horizontal sections of Japanese woods, mounted in a kind of album on paper. The method of mounting is European, which the Japanese saw in the Exhibition at Vienna in 1873, and the collection was made at the expense of the Government. The most noteworthy among these specimens is a number of differently-coloured varieties of the wood of *Cryptomeria japonica*, the largest tree in Japan. This sometimes attains quite extraordinary dimensions; Professor Rein measured the trunk of one breast-high, which was nearly 35 ft. in circumference. *Retinospora pisifera* and *obtusata*, and *Thujopsis dolabrata*, are trees of moderate size, occasionally with a trunk 3 ft. in diameter. Professor Rein thinks there are only three species of *Pinus* native of Japan, namely, *P. densiflora*, *P. Massoniana*, and *P. parviflora*. The two first are favourite trees of the Japanese, and are represented in lacquer and on porcelain ware, and living specimens are found in nearly all gardens. Some of the latter are curiously distorted, and from 200 years to 500 years old, and they are regarded with an amount of veneration bordering on worship. Some of them have very long, horizontal branches resting on the ground. *P. Massoniana* loves a sandy soil, is hardier, and perhaps rather larger than *P. densiflora*, and consequently more generally cultivated. It forms magnificent avenues, its rich dark green, long leaves being very beautiful. It attains a height of 100 ft., with a diameter of 6 ft. *P. parviflora* belongs to the group with five leaves in each sheath. It is widely dispersed in Japan, and reaches an altitude of 9000 ft., where it becomes shrubby. *P. koraiensis* is only cultivated in Japan. *Abies Tsuga* is extremely common in mountain forests up to from 5000 ft. to 6000 ft., as also *A. pulita*, *A. firma*, and *A. Alcockiana*. *Salisburia adiantifolia* is not wild in any part of Japan, and is exclusively planted near the temples. The largest specimen seen by Professor Rein, which is regarded by the Japanese as the largest in the empire, measured nearly 23 ft. in circumference, but it was scarcely 50 ft. high. *Juglans mandshurica* and *Pterocarya sorbifolia* are the only *Juglandaceæ*. Among the *Cupuliferæ* Oaks are represented by twenty-two species, about one-third of which are evergreen. The latter are mainly confined to the southern parts, and probably do not extend further north than the Bay of Yeddo. About the town of Yeddo they are very much cultivated.

Forests of evergreen Oaks were only seen in the southernmost island, Kiouson. One species, *Quercus cuspidata*, has edible acorns, which, boiled or roasted, are offered for sale in the streets in winter. The wood of the evergreen species is regarded as better and tougher than that of the deciduous species, and is preferred for many purposes. *Castanea vesca* is wild throughout Japan; Professor Rein observed it in sixty districts. Beeches are abundant, and are of two species, *F. sylvatica* and *F. Sieboldi*. *Planera japonica* (*P. Kaki*) furnishes the most valuable wood, for cabinet furniture and turnery, of all the deciduous trees of the country. The wooden plates and dishes generally used are made of this wood, and it is universally affirmed that it never cracks. This tree, *Laurus Cinnamomum*, and *L. Camphora* are the largest of Japanese trees, occasionally as much as 20 ft. in circumference. *Buxus sempervirens* is exceedingly common in the south, and its wood is almost exclusively used for making combs. *Distylium racemosum* occurs only in the southern districts; it has a very hard wood, which is likewise used for making combs, and the bark is burnt and the ashes sent to the different porcelain districts,

where mixed with the earth it is used as a glaze. There are two species of *Ilex*, *I. crenata* and *I. integrifolia*. *Magnolia hypoleuca* furnishes a most important wood, and the ashes serve for rubbing down lacquered work. From the extremely fine-grained flexible wood the familiar elliptical bread baskets are made, and all sorts of thin lacquered ware. This *Magnolia* is a stately tree, with leaves about 10 in. long, arranged in whorls, giving the tree at a distance the appearance of a Horse Chestnut. It grows in the mountain forests associated with Beeches and *Abulus turbinata*, and trunks more than 1 ft. in diameter are not uncommon. *Paulownia imperialis* is another example of a tree commonly cultivated which is not indigenous to Japan. The soft wood is employed in making shoes, and for making light boxes, in which the more fragile articles of lacquered ware are packed. *Eurodia glauca* is rapidly disappearing from the forests, and it is not yet cultivated. The inner bark is eagerly sought for dyeing silk of a yellow colour. Six species of *Rhus* have been observed in Japan, though two of them, *R. succedanea* and *R. vernicifera*, are only cultivated, and originally introduced from China. The cultivation of *R. vernicifera* and the collection of the lacquer is one of the principal industries of Japan. Some of the villages are completely surrounded by forests of this small tree. Like *R. Toxicodendron* and some other species, this is venomous to some, in fact, to most persons on first touching it; but it is averred that the same person suffers only once. Contact with the plant, or the lacquer it produces, or even inhalation of the vapour, causes the softer parts of the hands between the fingers, the tips of the ears, margins of the eyes, cheeks, scrotum, &c., to swell and inflame, and during four or five days the effects are very painful. The *Camellia* occurs wild as a shrub on the eastern side northwards of the Bay of Yeddo (36° N. lat.), and, strange to say, up to nearly 39° on the colder western side where Professor Rein found it as underwood, rarely exceeding 1 yd. high in hill forests up to an elevation of 800 ft. to 1000 ft. Advancing southwards it is gradually larger, and in the southernmost island it is quite arborescent, though never so large as the largest cultivated specimens seen. It is a noteworthy fact that Professor Rein found *Camellias* growing and flowering under Beech trees, with *Asperula odorata* carpeting the ground beneath. Many large cultivated specimens were measured, and some were found with a trunk 4½ ft. in girth, and over 30 ft. high. Though not found wild so far north, it succeeds up to 40° N. lat. on the western coast, where it is cultivated mainly for the oil furnished by the seeds, which is used for anointing the hair. With regard to *Bronsonetia papyrifera*, Professor Rein mentioned that attempts were being made to cultivate this useful tree in Germany, on account of the dearth of material for the manufacture of paper. At his instigation, 10,000 seedlings have been procured from France, and planted on the railroad banks near Frankfort-on-Maine and Wiesbaden, besides 1000 young trees.

Other plants used for paper-making in Japan are *Edgeworthia papyrifera*, *Wickstroemia canescens*, *Aphananthe aspera*, and *Morus alba*. Paper from *Aralia papyrifera* is only made in Formosa. In answer to some inquiries, Professor Rein stated that *Wistaria sinensis* is wild throughout Japan, and not introduced, as Siebold affirmed, from China; it fruits freely. *W. brachystachys*, which was not found growing wild, may be a variety of *W. sinensis*. Miniature varieties of native trees were not observed, though artificially-dwarfed specimens of numerous species are so largely cultivated.—Translated in "Gardeners' Chronicle."

Origin of the Name May Duke.—Would you kindly before the next meeting of our Horticultural Society (23rd August) give me the derivation of the British names of *Duke* and *May Duke* as applied to Cherries? For want of a better I imagine it must be the English corruption of the French adjective *doux*, sweet—as the *Dukes* are all, I believe, sweet Cherries, but having no authority for my surmise, I contented myself with pooh-poohing the very ridiculous ones seriously brought forward to-day of *My Duck*, a term of endearment because they were good, and *Médoc*, because they came from that French province, which latter is very problematical, to say the least of it.—FREDERICK PALMER, *Fersailles*.—[The notion that *May Duke* is a corruption of *Médoc* has frequently been brought forward, and is the most reasonable of the three you mention. But a little research shows that this is untenable: for the name *Duke* is of earlier date than that of *May Duke*. Parkinson in 1629 speaks of a kind then known as the Archduke's Cherry. Ray in 1688 enumerates "the May Cherry, so called from its being ripe in May," the *Duke Cherry*, the *Archduke Cherry*, &c. Rea, in 1702, has the *May* and the *Archduke*; and Miller, in 1731, is the first to mention the *May-Duke*, which he places between the *May Cherry* and the *Archduke*. This position suggests that the "*May Duke*" was thought intermediate in character between the *May Cherry* and the *Archduke*, and if this were so, the origin of the name is explained. The *Duke Cherry* was

evidently a well-known kind; Martyn names Harrison's *Duke Cherry* as a special variety of it, and later writers have different kinds of *Duke Cherry*. By slight alterations the original meaning of the name is lost: thus Miller mentions the *Lukewards Cherry*, a name which we can trace back to Gerarde, who calls it "*Luke Warde's Cherrie*," and says it is "so called because he was the first that brought the same out of Italy."—J. B.]

Mesembryanthemum cordifolium variegatum.—Have those who use this charming bedding plant observed the great difference of growth that exists between autumn and spring struck plants? I find the former to produce a close, compact growth with foliage of a very bright silvery hue, and to make the most dense and neat carpet. Spring-struck plants, on the other hand, run about almost wildly, require no end of attention and pinching, and the foliage is less bright in colour. Where very neat lines and good contrasts are desired, in conjunction with the green *Mentha*, the *Golden Feather*, or the *Red Alternanthera*, autumn-struck plants are much the best. Cuttings should be put in pans or boxes thickly early in September, and be placed under glass to root; these can remain in the store pans until March, when they should be potted off or be planted out in frames to make farther growth.—A. D.

Cypripedium spectabile.—A photograph of a group of this fine terrestrial *Lady's Slipper*, growing in the Botanic Garden, Birmingham, has just been sent to us, and shows to what perfection this plant may be brought by means of skilful treatment. Mr. Latham, Curator, informs us that it was sent to him from Canada—some of the clumps three years ago, others last autumn. They were firmly potted in good peat, in well-drained pots, then they were placed in a cold frame, where they remained all winter—in fact, till they were in flower; the only attention which they received was careful watering through the winter months, the soil being kept moist (not wet) till the plants were in vigorous growth. They then got plenty of water, and have been kept well watered during the summer months. A little frost will do them no harm when at rest, but if the frost be severe they must be protected. They start early into growth in spring, and should be kept back as much as possible till the weather is such that they can have plenty of air. They should not be coddled, neither should the cold spring frosts or keen winds be allowed to touch them when they have once started into growth.

NOTES AND QUESTIONS—VARIOUS.

A Showy Climber.—I shall feel obliged by your naming the accompanying fruit, seeds of which were brought from Berlin. They were sown in March and the seedlings were planted out in April along with some *Melon* plants. They began fruiting in July, and, when ripe, the fruit cracks like that enclosed. It is very handsome.—R. D., *Newark*.—[The fruit sent is that of *Momordica Charantia*, of which a representation is given at p. 161.]

Veitch's Perfection Pea.—This I find to be one of the best of Peas. Its flavour is good, its habit dwarf, and it is also an excellent cropper. I sowed six rows the first week in March, and began to gather on the 2nd of July. I have been gathering nearly every day since; in fact, one of the principal points in *Pea* culture is to gather often, and so prolong the bearing properties of the plants. I have to-day (August 15) gathered a fine dish from the same Peas, which are growing on a sandy soil, and have only been watered twice.—T. SELLE, *Manor House, Market Lavington, Devizes*.

Wimbledon Common and Gravel Digging.—An application was made to the magistrates of the Wandsworth division on the 21st ult. by the Wimbledon Local Board, for permission to dig gravel on the common. The ground on which the application was made was that a considerable saving would be effected if the Board could avoid going a long distance for the gravel they required. Evidence was given that the common would be destroyed in a few years if the required permission were given, and the bench unanimously refused it.

Irises from Seed.—Will you kindly give me some information as to the best method of raising *Irises* from seed?—S. [Seeds of all the strong-growing *Irises* I sow in a well-prepared bed of light soil in the open ground immediately they are gathered; also many of the bulbous and tuberous-rooted species such as *I. tuberosa*, *anglica*, *hispanica*, *alata*, &c. The smaller and more delicate kinds, evergreen, bulbous, and tuberous-rooted, I sow in pans in sandy, well-drained soil, plunging the pans in Cocoa-nut fibre or ashes in a cold frame, where they are sheltered from wet. If sown immediately they are gathered they will invariably germinate early in spring, and form strong plants the first year. If the seed be not sown until spring, in many cases they will not germinate until the following spring, and during that time they become a prey to mice and other vermin which frequently destroy them.—P.]

Red Ants.—The house in which I reside is infested with minute red ants and I do not know how to get rid of them. For a time Keating's Insect Powder kept them down, but so soon as the strength of the powder was exhausted they returned seemingly more numerous than ever. I have tried carbolic acid solution, but it does not answer. Can any of your readers tell me of anything which I can use to drive them away, as they are a serious nuisance.—W. MILNER, *Birkenhead*.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

SCENT-YIELDING ROSES.

By G. W. SEPTIMUS PIESSE, Ph.D., F.C.S.

I PROPOSE to describe the scent-yielding plants—their culture and their products—so must needs say a few words by way of preface, because certain parts of nearly all plants yield odour, as, for example, Mint and Patchouly from the leaves, Orris and Sumbul from the root, Cinnamon from the bark, Nutmeg and Caraway from the seeds, Roses and Violets from the flowers, Santal and Cedar from the wood; yet, of the thousands of plants that are somewhere in themselves fragrant, there are but few—wonderfully few—that are cultivated as scent-yielding plants in a commercial point of view. To these I will more particularly confine my observations, and first of all I will take

The Rose,

because

Its breath
Is rich beyond the rest, and when it dies
It doth bequeath a charm to sweeten death.

There are two methods of obtaining scent from the Rose, both operations being carried on to a considerable extent. In Roumelia the flowers are distilled for the purpose of obtaining the Attar or Otto of Roses. In the south of France the

The Cabbage Rose (*Rosa centifolia*).

enfleurage process is adopted, which yields a spirituous scent of the Rose. The principal Rose farms on which the distilling process is adopted are situated in the valley of Kézanlik, in Roumelia, at the foot of the Balkan Mountains; the principal town, Kézanlik, bears the same name as the province, and can now easily be picked out in the war maps of the day. The province of Kézanlik extends for about 40 miles east to west, and is watered principally by the River Thunga. It contains many small villages, the peasants of which are employed in the culture of the Rose. The only Rose cultivated for its scent, both in Roumelia and in France is the Provence or Cabbage Rose. It can be planted either in spring or in autumn. On Messrs.

Collas & Christoff's farm, where Roses are grown, parallel furrows are cut at distances of 5 ft. apart, 4 in. deep, and the same in width; into these furrows shoots from the old Rose bushes are laid, not cut, but so broken off as to have a portion of the old root attached to them; these are then covered up with earth and a little manure; if water be near, the furrows are inundated, otherwise the grower trusts to what may fall in the shape of rain. In six months young shoots appear which are then earthed up. During the first year they make about 4 ft. of wood; the second year a few flowers are produced; but a crop is only secured in the third year; the plants then

Rosa damascena.

begin to have the aspect of thickets, which soon become perfect hedges 6 ft. high, and which will bloom well for fifteen years. During this period dead wood is cut out, but the bushes are not pruned in the ordinary sense of the word. The Balkan Mountains keep off in a great measure north and west winds; nevertheless, in spring the Roses often sustain great injury from these and frost.

As a rule, the Rose harvest begins in the middle of May, and consequently this is the time for distilling, an operation which lasts for, say twenty-five days. Supposing a plantation to produce in one season 50,000 lb. of flowers, there must be garnered and distilled 2000 lb. each day. The flowers are gathered before sunrise, and are distilled by noon of the same day. As seasons differ, so do the crops and the quantity of Otto produced. The amount of Otto is greatest when the temperature at the time of distilling is low, and *vice versa*. When the weather is warm there is an abundance of bloom, but the yield of Otto is less; favourable weather is, therefore, better than large crops of blossom. The stills are on the same principle as regards construction in all parts of the world where there are flower-farms, but they vary considerably in size. At Mitcham, in Surrey, Piesse & Lubin's stills hold one ton and three-quarters of a ton respectively; these are used for distilling Peppermint and Lavender, Cloves and Caraways, &c., while the stills employed by M. Herman, of Cannes, only hold half-a-hundredweight; these are used for distilling Orange flowers. The Rose stills used at Kézanlik hold about two-and-half hundredweights. The still is a copper vessel or boiler, known as the alembic, broad at the base, and becoming narrower towards the top, on which is fitted the dome or neck to which is attached the condensing pipe. Water and Roses are put into the alembic, then a fire is lighted under it, and when the water boils the steam generated carries forward the Attar from the Roses into the refrigerator; the Otto floats on the condensed water, and is thus collected. On an average it requires 3000 lb. of blossom to produce 1 lb. of Otto—say 16 oz., Otto of Roses always being sold by the ounce, which in Turkey is somewhat more than the English ounce.

Baring, in his report on the exports of Roumelia, recently published by order of the Government, says:—"One of the chief manufactures is that of Attar of Roses, the average annual amount produced being 800,000 'Mescals' of about 1½ dram each, at about 16 piculs the mescal, and the whole is exported to England, &c."

Mr. Baring adds that "one of the effects of the insurrection will be to diminish the amount by about one-half. The village of Derwent produced large quantities of this valuable perfume, but the stills have been burnt or stolen, and it will be years before the inhabitants can replace them. In the other villages of the district which have not been burnt the insecurity of the country renders it impossible for the peasants to go to the Rose field before dawn in order to be able to pick the flowers when the dew is on them." The insignificance of the Roses at Derwent will be shown by comparing the total production of the districts. Derwent is a village in Zaaghra, in which there are ten others. Let us therefore summarise the production of Attar in Roumelia, thus:—

	ounces.
Kézanlik	27,776
Guenpsa	12,064
Karaja-Bahg	6,144
Tehirpan	2,592
Koyoun-Tépó	1,888
Pazardjik	1,760
Yeni-Zaaghra	1,728
Zaaghra	1,568
	55,520

This estimate is based on the average production of the last ten years, but in 1866 it reached 96,000 ounces, and in 1872 it fell to 27,200 ounces. As to the commercial value of the Attar it may fairly be estimated when pure at from 25s. to 30s. per ounce. In round numbers we may therefore say that the Rose farms of Roumelia are worth £70,000 to £80,000 per annum. That Rose and other flower farms could be established in Fiji, Queensland, and at Swan River I have but little doubt, and to landowners there I commend the figures just recorded.

Modes of Obtaining the Scent.

Many flowers, according to the method adopted to extract the perfume, yield more than one scent; it is so with even the same variety of Rose; when distilled it furnishes the well-known Attar, and coming as it does direct from the flowers, one would imagine that it would smell like them, but it does not; it has a very pleasing odour, but certainly not exactly that of the Rose, which is only obtained by the process of *enfleurage* and *macération*. It is now a well-known fact that fatty substances absorb scents. If we spread very clean grease—say a butter made of a mixture of lard and beef suet—upon a plate, then sprinkle freshly-gathered scent-yielding flowers upon it and cover the whole with another plate, leaving them thus together for a few hours, the butter will absorb the odorous particles, and become itself fragrant; again, if the butter be melted at as low a heat as possible and flowers be put bodily into it and left there for a time, the grease also in this way becomes scented; the former is called the *enfleurage* process, the latter the *macération*. Roses are treated by these joint operations, but some other flowers for practical reasons are worked by one or the other only. In the valley of the Var, Alpes Maritimes, France, an important industry in this direction exists. Farms for the growth of flowers, and vast laboratories for their manipulation are to be found at Grasse, Cannes, and Nice, where Roses are cultivated in a very similar manner to that already described, but they are not allowed to form themselves into hedges, as in Roumelia. During the flowering season the air is laden with fragrance, and women and children gather the blossoms, which they place in little panniers like anglers' baskets hung over the shoulder; they are then carried to the laboratory and weighed, the weighing determining the earnings of the little garnerers. In the laboratory, anticipating the harvest, great quantities of the butter have been collected, melted, washed, and clarified. The success of this process depends on the absolute purity of the grease, and no pains are spared to effect this end, the fat being repeatedly melted with a good bulk of alum, salt, and nitre; then it is washed over and over again with plain

water, and Rose and Orange water; finally, it is again melted with a little gum benzoin. The butter, thus purified, loses all traces of its animal origin; it is odourless as the purest water, but wonderfully ready to absorb fragrance from scent-yielding substances near it. In each laboratory there are several thousand *chassis* (sashes), or framed glasses, upon which the grease to be scented is spread, and upon these the blossoms are sprinkled or laid; the *chassis en verre* is, in fact, a frame with a glass in it, as nearly as possible like a window-sash, except that the frame is 2 in. thicker, so that when one *chassis* is placed on another there is a space of 4 in. between every two glasses, thus allowing room for blossoms; each *chassis* or sash is about 2 ft. long and 18 in. wide. The Roses are changed every day, or every other day, as may be convenient; the same butter remains in the *chassis* for, say, about two-thirds of the time during which the Roses are in bloom; but each time fresh flowers are put on it is "worked," that is, serrated with a palate knife, so as to present a new surface to the flowers; the butter being inflowered in this way for the given time, is then scraped off the several *chassis* and liquefied in an appropriate vessel placed in a hot-water bath. Fresh Roses are then put into the liquefied grease, and there they remain for a few hours; then the butter is carefully strained into a similar vessel, to which fresh flowers are added, and this operation—macération—is repeated until the end of the Rose season; finally, the butter is again strained and poured into tin canisters. When cold it has a most delightful and natural scent of Roses, and is now fit for exportation to all parts of the world.

Olive oil can be inflowered in a similar way to butter, but in place of glass the frames are filled with coarse wire gauze; these are called *chassis en fer*. Upon the wire net is laid a *molleton*, or very thick cotton fabric resembling the fluffy towel now in use, soaked with fine oil; after continuous changing of the blossoms the *molletons* are folded together and the oil is squeezed out by the aid of a screw press; then this same oil is slightly warmed and charged with fresh flowers for many days, and finally strained; it is then ready for sale. Both the butter and the oil acquire a good colour through the pollen of the flowers, but no tint is communicated by the petals.

The Perfume.

In order now to obtain the scent of the Rose in the form used for scenting handkerchiefs, we have to infuse the inflowered butter or oil in strong alcohol, that is, a spirit containing not less than 90 per cent. of absolute alcohol; the solid butter has to be cut up fine or granulated under what may be termed a Macaroni press; it is then put into the spirit and there allowed to remain for several days. If oil be used, it must be shaken up daily with the spirit, the result being that the spirit extracts all the odour from the fatty body and becomes itself "perfume," while the grease on the other hand becomes odourless. As a rule, it requires 5 lb. of blossoms to inflower 1 lb. of grease, and 8 lb. of the best of this is used to every gallon of alcohol. The spirit comes away from the butter quite bright, of a pretty pale emerald colour. To every gallon of Rose perfume thus made must be added 1 oz. of Roumelia Attar, and in this way the finest Rose scent is obtained. Numerous valuable products are got from the *Rosa centifolia* and the *Rosa damascena*, but their manufacture is too technical for description in THE GARDEN.

Hughenden House, Chiswick.

Godetia Lady Albemarle.—A correspondent writes (see p. 143) in somewhat glowing terms of the beauty of this new hardy annual, and without doubt it is a charming plant; but it only displays its beauties in sunny weather. I have to complain regarding it that it has not received, before being sent out, the selection that it deserves, inasmuch as I find quite one-third of the plants to be tall and branching, whilst the others are very dwarf and compact; this diversity naturally spoils its value as a bedding plant.—D.

Pentstemon secundiflorus.—This is a handsome blue-flowered Pentstemon, taller than *P. lætus*, and of similar habit to *P. glaber* and *P. speciosus*. It differs from both these species, however, in its long one-sided raceme of flowers, the corolla being about 1½ in. in length, of a beautiful clear blue internally, and of purplish-blue externally. It is as hardy as *P. lætus*, and succeeds in ordinary soil, blooming the second season from seeds. It is a native of the subalpine districts of Colorado.—W. THOMPSON, Ipswich.

NOTES OF THE WEEK.

CHRYSANTHEMUMS GRAFTED.—At the Royal Nurseries, Slough, I observed the other day what to me seemed to be a novelty in Chrysanthemum growing, viz., over 200 fine plants worked as standards on 3-ft. stems, several sorts which bloom simultaneously being grafted into one head. Only one plant was grown in this way last year, but the effect which it produced was so striking as to induce Mr. Turner to cultivate Chrysanthemums largely in that manner.—D. S. E.

THE ROSE FARMS OF ROUMELIA.—The article which we publish to-day by Dr. Piesse deals in part with the very interesting culture of Roses for the extraction of their scent in that now unhappy country, Roumelia. Dr. Piesse's thorough knowledge of the subject makes his article useful at a time when various very incorrect statements about it are frequently published.

RHEXIA VIRGINICA.—This "Meadow Beauty," as now seen in the Fulham Nurseries, is very attractive. The plants are dwarf and profusely flowered, and being planted in moist, sandy soil, they look as if they would continue in bloom for a long time to come. A coloured illustration of this plant will be found in THE GARDEN, Vol. XI., p. 294.—S.

A NEW CAMPANULA (C. flexuosa).—This is now in full flower, and has been so for some weeks on the rockwork in the York Nurseries. The flowers, which are bright purple, are saucer-shaped, measure nearly 1 in. in diameter, and are borne on slender, wiry, much-branched stems from 4 in. to 6 in. in height. The specimen now in flower is a very fine one, having over 300 blooms on it. It is a sun-loving plant, and thrives in loam and limestone, which should be broken into small pieces, and thoroughly incorporated with the loam.—R. P.

HYPERICUM HIRCINUM.—This, one of the showiest of late summer and autumn flowering shrubs, is just now a feathery mass of light green leaves thickly plumed with golden blossoms. Like the rest of the family, it is rabbit-proof, an important qualification in these days, and is well suited for the wild garden and woodland shrubbery; it grows about 8 ft. high, and its only drawback is the unpleasant smell of goat which it diffuses before coming into flower. This is perceptible at a distance of several feet; therefore, it should not be planted close to a dwelling-house.—SALMONICEPS.

THE DELL IN HYDE PARK.—This is tastefully arranged this year; the groups "held together" better than before. The tropical plants look very well. A few bits of colour perhaps would have improved matters, especially in the distance. We, however, trust that this culture of the tender tropical plants for the open air will not be increased in our public gardens. Every day adds to our riches in hardy plants that require no hothouses and furnish as fine effects as any tropical plants. If we go beyond hardy plants, it should be in the direction of such subjects as *Chamærops excelsa*, the New Zealand Flax, and the Palmetto Palm. These are hardy in some parts of England, and large specimens might be placed in the open air about London for a much longer period than the tropical species, which languish out-of-doors for a short time with us.

THE NEW EARLY PEACHES IN 1877.—Considerable interest has been excited North and South, as to which Peach would eventually prove earliest. Prominent among the quick-maturing varieties are Amsden's June, Alexander, Early Beatrice, Early Rivers, and Early Louise. Careful inquiry in Virginia and North Carolina elicits the fact that, planted side by side, there is really little difference in the season of ripening between Amsden's, Alexander, and Beatrice, but that Amsden's is the handsomest and best of the three. Early Rivers is perhaps the finest of all, but rather later, coming in with Hale's Early, although greatly superior in quality to that famed variety. Under glass, when grown with especial care and skill, all of the foregoing have proved exceedingly fine; and if forced Peaches will pay at all, we certainly have in the foregoing a valuable list to select from. We hear also favourable accounts of Early Louise, yet as it is later than its near relative, Early Beatrice, it may not prove so valuable.—*New York Tribune*.

THE SORREL TREE (Andromeda arborea).—We are indebted to Mr. A. Waterer, of Knaphill, for free-flowering specimens of this fine tree-like shrub now coming into bloom and bearing many racemes of Lily-of-the-Valley-like blossoms. We learn from the "American Agriculturist" that "in its native country it is valuable for the fruit, which hangs on until winter. It is a native of Pennsylvania and southward, and is quite hardy in Massachusetts. One of its great merits is that though it will grow from 30 ft. to 60 ft. high, it will

bloom when only 4 ft. to 6 ft. high, and serves either as a shrub or a tree. Our reason for mentioning it now is to call attention to the beauty of its foliage in autumn. This year, when our autumn colours have been much less brilliant than usual, by far the most brilliant display of colour that we have seen has been made by our clump of Sorrel tree. The foliage began to turn a dull red, and finally blazed out in the most intense of crimsons, almost dazzling when the sun shone upon it. The tree has another good property—the leaves remain on a long while after they change, and we have this year enjoyed their brilliancy for between two or three weeks. The Sorrel tree is one that we can heartily recommend to the attention of all lovers of really choice trees and shrubs."

THE CALIFORNIA BUCKEYE.—We should be greatly obliged to any reader for good racemes of flower of this tree, *Aesculus californica*.

THE HUON PINE (Dacrydium franklini) at Longleat.—This most graceful Pine is now very beautiful in the open air at Longleat, where it is quite hardy and bears fruit. It has attained a height of 31 ft. The graceful twine-like branchlets are of a beautiful grass green.

ASPIDIUM FRAGRANS.—Ferns under all circumstances are beautiful and generally popular, but when sweet-scented as this is, they are doubly valuable. Messrs. Osborn have several plants of this *Aspidium*, the fronds of which, in addition to their beauty, which is great, are almost as fragrant as Violets. Though not entirely new this Fern is as yet very rare.—S.

FUCHSIA GRACILIS at Kensington.—Large bushes of this outdoor Fuchsia are very attractive just now in the Horticultural Society's garden at South Kensington; they are growing on banks and other raised surfaces in positions from which their branches droop over the dwarf terrace walls. Thus situated they have a graceful effect; but they are also very effective when planted in hollow tree stumps and places of that kind.—S.

A PRETTY COMBINATION.—One of the most effective combinations of colour for the wild garden may be obtained by grouping together *Clematis flammula*, *C. Hendersoni*, and *C. viticella rubra grandiflora*. If these be allowed to scramble unrestricted over old roots or dead trees, their white, blue and claret-coloured flowers intermixed will be found to be strikingly pretty. Being all plants, too, that will succeed near towns, they might be largely used for draping balconies, porches, &c., and even for covering ordinary walls.—C. S.

PASSIFLORA PRINCEPS.—This well-known Passion-flower is unsurpassed for training under the roofs of greenhouses or conservatories, for although generally considered a stove plant, it will flourish perfectly in a much cooler temperature than that of a stove. In one of the glass houses of the Fulham Nurseries, plants of this Passion-flower have been in blossom ever since Christmas, and their long drooping spray, laden with bright star-like flowers, intermixed with other flowering and ornamental-leaved plants, as may be seen here, is very effective.—S.

DISFIGUREMENT OF THE WATER IN REGENT'S PARK.—A long line of ugly black posts with chains attached stretches through one of the most beautiful reaches in the ornamental water in Regent's Park, and spoils its effect. The chains and posts were, we understand, placed in this position in order to prevent people landing from boats in a private garden. This, however, if allowable, might have been equally well secured by placing the posts near the shore. It is surely wrong to mar the effect of a beautiful piece of water in this manner.

MYOSOTIS IMPERATRICE ELIZABETH.—This is one of the most valuable of Forget-me-nots, inasmuch as, unlike other kinds, it will remain in bloom, if properly attended to, during the whole summer. All that is required is to keep the decayed blossoms regularly picked off in order to prevent the formation of seed. Thus treated, the plants will continually throw up young growths, all of which will produce in profusion little compact trusses of pretty dark-blue blossoms, which are admirably adapted for use in button-hole or other small bouquets. We saw a quantity of it the other day in good condition in Messrs. Carter's Nursery at Sydenham, where it is used with good effect as an edging plant.

ROYAL HORTICULTURAL SOCIETY'S GREAT SUMMER SHOW IN 1878.—This is to take place in the gardens at South Kensington on Tuesday, May 28, and will remain open until the evening of Friday, May 31. Schedules may be had on application to the secretary.

PELARGONIUM SOCIETY.—This Society has just issued its balance sheet for 1876-7, from which it appears that the annual subscriptions amounted to £88 12s.; that the amount of prize money distributed amongst exhibitors on June 19 was £87 2s. 6d.; and that the Society has a balance in hand of £42 6s. 8d.

HARDY LILIES.

As the time is at hand when bulbs have to be ordered, it should be borne in mind that however beautiful nearly all the known Lilies are, some of them are extremely fastidious; but there is a rare choice of beauty among those which are easily cultivated, and no one can go wrong in growing the following with ordinary care, especially avoiding digging in manure with the bulbs, though they accept it gratefully as a top-dressing liberally applied after being established a year. The only manure to be dug in at the time of planting is rich peat and sand, one-third of the latter. This is advisedly called manure. *Lilium auratum* in light soils is all the better for a top-dressing of clay put on dry and broken small. *L. Szovitzianum*, of which a coloured plate is given in *THE GARDEN*, Vol. IX., p. 204, is a gorgeous early-flowering kind of easy culture. *L. tigrinum*, though very common in some districts, is rarely seen in others, though easily grown in all; for splendour of colour and exquisite form, this old Lily is unsurpassed. *L. candidum* is equally common, yet unsurpassed for purity. No flower presents a better contrast than that of the golden stamens and snowy perianth. *L. chalcedonicum*, pure scarlet, grows in any soil, but revels in peat and sand; there is a pure white form which I have not yet obtained. *L. testaceum*, excelsum, or isabellinum—a delicate apricot or nankeen colour, with golden anthers, is easily grown, and very distinct; it prefers peat and sand. Of *L. Thunbergianum* there are many varieties, the best being the deep crimson and carmine dwarf sort. *L. speciosum*, which is quite hardy, succeeds beautifully in loam and peat. Dr. Wallace has given such complete directions for growing Lilies that the only excuse for offering these notes is that so many persons have been disappointed in attempting to grow delicate kinds such as *L. longiflorum*, *Thomsonianum*, and others, that the really easily-grown species should be better known. It should be remembered that bulbs of nearly all Lilies occasionally lie dormant a whole season, and push out luxuriantly the following summer. SALMONICEPS.

NOTES FROM KEW.

As has been before stated in "THE GARDEN," the Orchid collection at Kew is certainly much better in point of cultivation than it was a few years ago. At present, in addition to several species of mere botanical interest, there are in bloom some fine examples of *Cattleya crispata*, also a plant of the rare *Dendrobium bigibbum*, the handsomest of Australian Dendrobies, and, moreover, one of the most difficult to cultivate. Its flowers are fairly large, and of a fine rosy-purple colour. The only plant in the Palm house that struck us as worthy of special mention at the present moment is *Solanum venustum*, a species similar to, but finer than *S. jasminoides*. It has large drooping panicles of beautifully-tinted, pale-blue flowers. The individual blooms are about the same size as in the last-named species; like that, too, it is a native of Brazil. The large *Musa Ensete* is about to flower, and as a consequence is fast losing its freshness and beauty. In the old Lily house two splendid *Cannas* are planted out in one of the wet tank-beds; one (*C. flaccida*) has green leaves, very large yellow flowers, and is a much smaller plant than *C. limbata*, which has attained a height of 9 ft.; its leaves are very large, dark green, and banded with chocolate. The first is from Carolina, the other from Brazil. We also meet with *Alstonia sericea* in the same house. This is by no means one of the least handsome members of the Periwinkle family; its beautiful, pure white star-like flowers speak highly in its favour. It comes from the Indian Archipelago, and any treatment that will suit *Vinca rosea* and its allies will do for this. There are many fine *Amaryllids* scattered about in the cooler houses, perhaps the most showy being *Hippeastrum splendens*; its large, deep red flowers, with whitish bars running down the perianth segments, produce a fine effect. *Hedychium Gardnerianum* is planted out in No. 4. Where room can be allowed, this plant will certainly pay for it. Fritz Müller, who has observed the *Hedychiums* in Brazil, asserts that some are perfectly sterile with their own pollen; they are fertilized by pollen brought on the wings of butterflies, and deposited on the protruded stigmas during the fluttering of the insects about the flowers. The herbaceous department contains much to admire just now. In the small pond dedicated to aquatics we observe four American plants well worthy of cultivation in every place where water plants can be grown easily. They are *Thalia dealbata*, *Justicia pedunculosa*, *Pontederia corolea*, and *Peltandra virginica*. All are perfectly hardy. The first-named is generally cultivated as a stove or greenhouse plant; it, however, thrives thoroughly well planted out

under water like any ordinary aquatic. *Clematis Davidiana* is flowering near a wall. This species is nearly allied to *C. tubulosa*; like that, it has heads of pale blue flowers, and large trifoliate leaves; the stem is herbaceous (except at the base where it is rather woody), attaining a height of little more than 2 ft. This species was recently introduced from China into the Paris Jardin des Plantes. The three most beautiful Grasses at present to be seen in the Kew collection are *Sorghum halepense* (from South Europe), the Mexican *Panicum bulbosum*, and a very fine Feather Grass (*Stipa papposa*). The stems of the first-named are about 6 ft. high, with numerous drooping leaves from 1½ ft. to 2 ft. long, and nearly 1 in. broad at the widest part. The next is a light, airy-looking species, very graceful, of a totally different style from the last, less in all its parts. All three would answer exceedingly well as single specimens on lawns. G.

HARDY SURE-BEARING APPLES.

WHEN the reports of fruit on all sides are so unfavourable, and Apples are represented by a few kinds only which are bearing plentifully, it is well to consider what sorts should form the bulk of our collections. In the reports that have been published, it is observable that certain kinds are producing fairly well in nearly every district; and after travelling through this county (Worcestershire) for many miles, peering into orchards in all directions, I find the best Apples to be Lord Suffield, Cellini, Keswick Codlin, and Devonshire Quarrenden, the last easily distinguished among others by its bright, showy appearance. In every case the trees of this kind are loaded; though not a large Apple, it keeps well till January. Cellini, which seldom fails, can be had in good condition as late as May; I have exhibited them in that month sound and fresh. It is a safe practice to let an orchard consist of dwarf trees, and to plant largely of those hardy kinds which fruit annually without fail. I had charge of a large collection of Apples during a period of ten years, and every season certain kinds bore abundantly, and had to be thinned and propped up by stakes. The credit of such uniform success was however, due, to my predecessor, who had laboured for seventeen years in an untoward northern climate, with an altitude of 300 ft. above the sea, exposed to east and north-east. In the first instance he changed the nature of the ordinary garden soil by means of draining and the addition of large quantities of good loam. The trees were planted above the general ground-level, staked securely, and kept dwarf, averaging about 7 ft. each. Many kinds were planted, proved, and found to be quite unsuitable for the locality; others, which fruited freely, were planted in larger quantities—dozens of some kinds, and often when there were scarcely any Apples in the district, these dwarf trees were loaded. Among the best kinds for the purpose were Stirling Castle, King of Pippins, Northern Greening, Lord Suffield, Aitkin's No. 2, Tower of Glamis, Keswick Codlin, Cellini, Ringer, and Hawthornden. By frequently lifting the roots piecemeal, keeping them well up, giving liberal mulchings, and doing all the pruning in the summer months (leaving little to do in winter), these dwarf trees never were a season out of the ten referred to without bearing a heavy crop of fruit over the average in size. Often when the blossoms seemed entirely destroyed by late frost, hail, and cold rains, the buds, which appeared to be in a dormant state, would burst and set a heavy crop. I have always advocated planting such hardy kinds in great numbers and treating them on the spur system. Last season I planted about 100 maiden trees of these kinds, and numbers are fruiting freely this year. M. T.

Rudbeckia bicolor.—Few gardens are without some representative of this showy genus, but no species with truly annual roots has hitherto been available. In *Rudbeckia bicolor* this desideratum is supplied. It unites a dwarf branching habit of growth with the effective contrast of colour afforded by a bright yellow ray and blackish purple disc. It grows about 1½ ft. high, having a hairy stem with numerous spreading branches, and oblong, blunt leaves obscurely serrated, the flowers being terminal, on long grooved foot-stalks, and about 3 in. in diameter, resembling closely those of the well-known *Rudbeckia speciosa*. The blackish disc is at first globose, but becomes at length conical, the rays consist of from ten to fourteen florets of an orange yellow colour, which continue some time in perfection. A form of this plant exists in which the ray is marked with brown near the base. It is of easy cultivation as a half-hardy annual in any soil, commencing to bloom in July, and continuing in flower till very late in the autumn. As a free-blooming and showy annual it can be recommended to the notice of the horticultural world as well deserving of cultivation. It is a native of Texas.—W. THOMPSON, Ipswich.

THE FLOWER GARDEN.

MUSA ENSETE IN BERKSHIRE.

THIS stately plant is proving as useful and becoming as popular in our gardens as those who knew it long ago supposed it would become. In sheltered nooks in the southern counties it makes a very fair growth in the summer. We have lately been struck with the health and vigour displayed by some plants of it at Park Place, Henley-on-Thames. Mr. Stanton, the gardener there, raised a batch from seed (obtained through Messrs. Hooper), and it is surprising to notice what noble plants these have become in the course of fifteen months from the time of sowing. They were sown last April twelve-months, and planted out early in June; they became fine plants during their first summer and autumn. Placed indoors early last October they remained throughout the winter in a warm greenhouse, and were again planted out in June of the present year. They are now forming very fine young leaves as yet rarely injured by the wind, from which they are well protected. The plant is as effective in conservatory or any large glass house in winter as it is out-of-doors in warm places in summer.

ALPINE PLANTS AT HOME.

At the north-east corner of the mighty Matterhorn there rises what in such company one calls a little mountain, though its summit is more than 9000 ft. above the sea-level, named the Hörnli, an outwork of the vast natural fortification which it adjoins; and just below it is a small lake called the Schwarzsee, or Black Lake, with a small chapel close to its edge. On the Schwarzsee shoulder, formed of the shaly *débris* brought down by the melting snow from the Matterhorn and moraine of the glacier, which is the direct road from the lake to the Hörnli, several rare plants grow. Foremost in interest to myself, as having never found it before, was *Saxifraga biflora*. It grew in considerable quantities amongst the slushy stones and mud, intermingled sometimes with *Campanula cenisia*. I must own to having been disappointed by it, especially in comparison with its very common kinsman, *S. oppositifolia*, which on the higher ground round about Zermatt attains a point of excellence, in respect of size of blossom and rich profusion, I have never seen equalled, each little mountain rill being fringed with it so brightly and in such considerable patches, as in spite of the difference of dimensions, to recall the streams of Greece, and their pink ribbon-borders of Oleander. But *S. biflora* is wanting (such at least as I found it), in the rich colour of *S. oppositifolia*, and altogether though an interesting flower, there was a pinched ungainly look about it, which conveyed the impression of its having found the difficulties of its struggle for existence too great for it. *Campanula cenisia* in some degree lays itself open to the same criticism, though there is a neatness and distinctness about its single flowers, which would make it of much value in a collection of Alpine

Musa Ensete in Berkshire.

plants, if it can be got to establish itself there—a problem which, from the sort of habitat I found it in (and I may add the present condition of the two or three specimens I brought home with me), I am inclined to answer in the negative. *Crepis jubata* was another rare denizen of the same locality. I have no knowledge whether it has been ever acclimatised in England; but its single, large, orange flower is bright and showy, and it is so distinct from its allied species as to be well worth trying. But on the same shoulder of which I am speaking grew in some abundance a plant, if not more rare, yet certainly more beautiful than either of the foregoing, and highly prized by those who have carried on the absorbing pursuit of flower-hunting amid the higher elevations of the Alps; I mean *Eritrichium nanum*, the queen of the Alps, as I heard it designated amongst the flower-loving frequenters of our *table d'hôte*. It is to be found not sparingly on the rocky banks, so to call them, which overhang the loose, shaly soil which made a home for *Saxifraga biflora* and its companions. It roots itself in the crevices of the rock, or attaches itself to their flatter surfaces, but always—so far as my experience enables me to decide—growing horizontally, and never, as some of its congeners, from vertical chinks. But the *Eritrichium* of the Zermatt stratifications is not to be compared with its far more perfect form which it assumes on the granite of the Engadine, and probably elsewhere. No words can exaggerate its beauty when it sends its long slender tap-root into a crevice of a granite block, and thence, as I have seen it often, spreads its compact mass of flowers of the loveliest sky blue with scarcely the least intervention of any particle of leaf. On the softer, flaky schist of the Hörnli, the leaves as a rule occupied a large part of the surface, and the brightness of the blue was proportionately toned down. Is it to be cultivated in any degree worthy of its merits in our very different climate? I am not able to answer the question from either experience or observation, but

it would be worth any reasonable pains to succeed; and possibly, if plants can be secured in good condition and were established amongst broken granite, fully exposed to sun and air in the summer, and protected by some equivalent for a mantle of snow in the winter, success might be attained. Of another inhabitant of the same stony *débris* as the *S. biflora* and the rest, and its capacity for naturalization, I can speak with some positiveness, I mean *Geum reptans*. It grew plentifully amongst the loose shingle; and I know none of the higher Alpines which, if treated kindly, by being planted in grit and loam, with space for the roots to ramble freely in, and abundance of water, will make a more grateful return. The first considerable excursion generally made by ordinary visitors to Zermatt is one of some three or four hours' easy mountain ascent to the Riffel, and thence to the Gorner Grät; the former a well-marked ridge overhanging the little village, the latter an eminence above it of some 10,000 ft. above the level of the sea, affording one of the most perfect panoramas of near snow mountains of the first magnitude to be found in

the Alps. As a district rich in botanical treasures, adapted for horticulture, it is probably unsurpassed. To enumerate these would be in part to repeat the names of those assigned to the lower regions of the Matterhorn; a few occur to me which I did not notice when engaged in my explorations there. In the immediate neighbourhood of the little hotel on the Riffel, *Lychnis alpina* grew in abundance and in great perfection; little compact, rosy plants, which no horticulturist could ever improve in form or habit. It seemed to prefer an exposed western slope, as dry as could be amidst frequent mists and rainfalls, in good turfy loam. I have never seen it in English gardens half so attractive. As we mounted towards the Gorner Grat the loose rocky shingle was studded at intervals with patches of bright-lilac flowers, growing close to the surface, and shading off into white on the one hand and rose-colour on the other, which proved to be *Thlaspi alpestre*, if not also *rotundifolium*. I have failed in bringing home specimens in sufficiently good condition to give any reasonable hope of success in cultivating it, and it may help some future collectors if I explain the reason of my failure. On July 18, when, it may be, English people at home were wooing the cooling breezes to mitigate the heat of the dog days, we awoke on the Riffel to a white world up to our very doors. A botanical excursion under such circumstances had a touch of novelty about it. The purple blossoms of *Saxifraga oppositifolia* were amongst the first to assert themselves; then a tuft of yellow *Geum montanum* would make itself visible, and so on, till by the time folks in dear old England were sitting down to breakfast the sunshine of those clear mountain heights had stripped away every vestige of the earth's unseasonable covering. But all my plants of that morning's forage have more or less entirely damped off. Though partially dried in my tin box, and then packed separately in paper and dry Moss for home transport, the melted snow had so saturated the balls of earth that all in this one batch amongst all my acquisitions have turned out comparative failures, teaching me the practical lesson as to the real source of danger to plants which are to undergo several days' confinement, not, as most would apprehend, want of moisture, but excess of it. But the distinctive "thing of beauty," to my mind, about the Riffel was the wealth of *Androsace Vitaliana*, not only colouring the moister yet sunny slopes, but repaying close inspection by its delicacy and fragrance. One serious rival it had, indeed, in a near relative, as unlike it as well could be, both in habitat and general appearance, but still very beautiful, though occurring only scantily, and in the vertical and often overlapped crevices of the steeper rocks—*Androsace imbricata*. I found this latter very difficult to extract from its crannies, though I see no reason why, when got up unharmed, it should not have all its requirements supplied in a well-made English rock-work. I never realised more than on this excursion the delightful independence of all received arrangements of seasons to which an Alpine landscape may lay claim. A few minutes' walk takes you from midsummer, indicated by the petalless stalks of hundreds of spring-blooming plants, as we should esteem them, in their several degrees of seed-bearing, to the freshest vigour of early spring, where the same plants are bursting into bloom—*Anemones*, *Lloydias*, *Ranunculuses*, *Gageas*, and so forth—and this not merely in consequence of the greater altitude attained, but of the change from a sunny slope, from which the snows have been early dispelled, to one in fuller shade, where they have lingered. I have said little of the *Gentians* of the Riffel and its neighbourhood, nor do I know that there is anything distinctive to report about them; I can only confess in general terms that I find it very difficult to discriminate between some of the species which abound on the higher elevations, as *G. bavarica*, *brachyphylla*, and *imbricata*. Sometimes what looks like an inner circle of petals disappears in a great degree in more fully-developed blooms of the same plant, and apparent distinctions of habit are clearly dependent on more or less moisture or exposure. *G. bavarica* evidently chooses for itself the highest zone, and assumes the deepest colour, while it is the least patient of translation of the three. *G. verna* readily conforms to English habits, and so, as every one knows, does *G. acaulis*, and what is apparently often confounded with it, *G. excisa*. I know nothing of any attempts to naturalize in our

gardens the charming little annual, *G. nivalis*; nor have I ever heard of the cultivation amongst us of another very elegant species (*G. utriculosa*), which is found in some abundance on both sides of the Zermatt valley, branched like the *G. campestris*, and of a blue almost as deep as that of *G. bavarica*. But my store of Zermatt treasures is far from being exhausted, and I have material enough for at least another contribution.

CANONICUS.

The Edelweiss in Scotland.—"Canonicus," in his interesting remarks on the flora of Zermatt (see p. 125), asks what is to prevent the successful cultivation of the Edelweiss in Britain? There is no great difficulty in cultivating it. Plants which I brought from the Engadine in 1875 have grown and flowered most vigorously, both in frames and in the open air. It does not seem at all fastidious, nor does its culture present any of the difficulties attendant upon that of many of the Alpine Primulae. The chief point to be attended to is that it should not be shaded or overgrown by earlier and more robust plants, that the drainage be perfect, and care be taken lest it is thrown out during the dormant period, when it shrivels into what looks like a little lump of black, decayed roots and leaves.—SALMONICEPS.

August-sown Annuals.—Anybody for a very trifling outlay may have a gay garden next spring by sowing now a few seeds of the following annuals, viz., *Nemophila insignis*, *Collinsia bicolor*, crimson and white Candytuft, *Saponaria calabrica*, crimson and white Godetia, Virginian Stock, white and pink *Silene*, *Limnanthes Douglasii*, and *Myosotis dissitiflora*. It is late for the *Myosotis*, but it is better to sow late than be without it. I have no occasion to sow this now, for so many self-sown plants come up that one has only to refrain from hoeing them up to have plenty to plant anywhere. Sow thinly either in drills or broadcast in some open situation, and transplant to their blooming quarters early in November, as a good early bloom cannot be ensured by late sowing and late planting.—E. HOBDAY.

The Globe Artichoke as an Ornamental Plant.—Hans Christian Andersen, in one of his pleasing stories, "The Gardener of the Manor," describes how a flower of this Artichoke, placed on a leaf of the Water Lily floating in a large crystal vase astonished the family of the manor by its beauty and rarity. It is true that a revulsion of feeling set in when they discovered that instead of being the sacred Lotus of Hindostan it was only a common flower from the kitchen garden; yet then the admiration in the first instance was genuine. In good, deep soil, with space enough for development, the Globe Artichoke, either as a single specimen, or two or three together, makes an effective background plant, especially at this season when in flower, and one or two of its flowers placed in a vase with plenty of foliage have a striking effect. The foliage of the various forms of *Canna* seems also to set them off to good advantage, and they are very lasting in water.—E. HOBDAY.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Queen Victoria Pelargonium Out-of-doors.—I planted out *Pelargonium* Queen Victoria last May against an Irish Yew, in light rich soil, and now there is not a more showy *Pelargonium* in the garden. It has been in bloom ever since it was planted. It is a two-year-old plant, and 2 ft. high.—O. CHISHOLM, *King's Road, Chelsea*.

Blue Lobelias.—These have been exceedingly effective and continuous this season; the genial rains and moist atmosphere have been more conducive to growth than seed-bearing, and consequently the plants have not been exhausted. A really good selection of *L. speciosa* makes a most excellent border plant; but for marginal edgings the more compact kind called *L. pumila grandiflora* is all that can be desired.—J. GAEON.

A New Erythronium.—The following description of this plant is by Mr. Sereno Watson, in a recent number of the "Proceedings of the American Academy of Arts and Sciences":—*Erythronium purpurascens*.—Leaves undulate, oblong to narrowly lanceolate, 4 in. to 6 in. long; scape low, often stout, occasionally divided, racemously or somewhat umbellately four to eight flowered or more; pedicels very unequal, the upper becoming 2 in. to 4 in. long; flowers light yellow, more or less tinged with purple, deep orange at base; the lanceolate segments spreading, 9 lines to 12 lines long; anthers oblong, 1½ lines to 2 lines long, yellow, on very slender filaments; style thickened above, three-lobed at the summit; capsule erect, narrowly oblong and obtusely triangular, faintly nerved, 1½ in. long.—*E. grandiflorum* var. *multiflorum*, Torrey, Pac. R. Rep. iv. 93; Baker, Journ. Linn. Soc. xiv., 298. In the Sierra Nevada, near Downieville, Sierra Co. (Dr. J. M. Bigelow), and frequent in Plumas Co., whence fine specimens have been received from Mrs. M. E. Pulsifer Ames and from Mrs. R. M. Austin. Abundantly distinct from *E. grandiflorum*, and a very pretty species, well deserving cultivation.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 167).

Vines.

- (1) *Titania*. Feed him with Apricocks and Dewberries,
With purple Grapes, green Figs, and Mulberries.
Midsummer Night's Dream, act iii., sc. 1.
- (2) *Menenius*. The tartness of his face sours ripe Grapes.
Coriolanus, act v., sc. 4.
- (3) *Song*. Come, thou monarch of the Vine,
Plumpy Bacchus, with pink eyne,
In thy vats our cares be drowned,
With thy Grapes our hairs be crowned.
Antony and Cleopatra, act ii., sc. 7.
- (4) *Cleopatra*. Now no more
The juice of Egypt's Grape shall moist this lip.
Ibid., act v., sc. 2.
- (5) *Timon*. Dry up thy Marrows, Vines, and plough-torn leas.
Timon of Athens, act iv., sc. 3.
- (6) *Timon*. Go, suck the subtle blood of the Grape,
Till the high fever seethe your blood to froth.
Ibid.
- (7) *Touchstone*. The heathen philosopher, when he had a desire to eat a
Grape, would open his lips when he put it into his mouth, mean-
ing thereby that Grapes were made to eat and lips to open.
As You Like It, act v., sc. 1.
- (8) *Iago*. Blessed Fig's end—the wine she drinks is made of Grapes.
Othello, act ii., sc. 1.
- (9) *Lafeu*. O, will you eat no Grapes, my royal fox?
Yes, but you will my noble Grapes, an if
My royal fox could reach them.
All's Well That Ends Well, act ii., sc. 1.
- (10) *Lafeu*. There's one Grape yet.
Ibid., act ii., sc. 3.
- (11) *Clown*. I was in "The Bunch of Grapes," where, indeed, you have
a delight to sit.
Measure for Measure, act ii., sc. 1.
- (12) *Constable*. Let us quit all
And give our Vineyards to a barbarous people.
Henry V., act iii., sc. 5.
- (13) *Burgundy*. Her Vine, the merry cheerer of the heart,
Unpruned, dies.
Our Vineyards, fallows, meads, and hedges,
Defective in their natures, grow to wildness.
Ibid., act v., sc. 2.
- (14) *Mortimer*. And pithless arms, like to a withered Vine
That droops his sapless branches to the ground.
1st Henry VI., act ii., sc. 3.
- (15) *Cranmer*. In her days every man shall eat in safety
Under his own Vine what he plants, and sing
The merry songs of peace to all his neighbours.
Henry VIII., act v., sc. 5.
- (16) *Cranmer*. Peace, plenty, love, truth, terror,
That were the servants to this chosen infant,
Shall then be his, and like a Vine grow to him.
Ibid.
- (17) *Lear*. Now our joy,
Although the last, not least, to whose young love
The Vines of France and milk of Burgundy
Strive to be interested.
King Lear, act i., sc. 1.
- (18) *Arrivagus*. And let the stinking Elder, grief, entwine
His perishing root with the increasing Vine.
Cymbeline, act iv., sc. 2.
- (19) *Adriana*. Thou art an Elm, my husband, I a Vine,
Whose weakness married to thy stronger state
Makes me with thy strength to communicate.
Comedy of Errors, act ii., sc. 2.
- (20) *Gonzalo*. Bound of land, tilth, Vineyard, none.
Tempest, act ii., sc. 1.
- (21) *Iris*. Thy pole-clipt Vineyard.
Ibid., act iv., sc. 1.
- (22) *Ceres*. Vines with clustering bunches growing,
Plants with goodly burden bowing.
Ibid.
- (23) *Richmond*. The usurping boar,
That spoils your summer fields and fruitful Vines.
Richard III., act v., sc. 2.

- (24) *Isabella*. He hath a garden circummured with brick,
Whose western side is with a Vineyard back'd;
And to that Vineyard is a planced gate,
That makes his opening with this bigger key:
This other doth command a little door,
Which from the Vineyard to the garden leads.
Measure for Measure, act iv., sc. 1.
- (25) For one sweet Grape, who will the Vine destroy?
Rape of Lucrece.

Besides these different references to the Grape Vine, some of its various products are mentioned, as Raisins, wine, aquavita or brandy, claret (the "thin potations" forsworn by Falstaff), sherry-sack or sherry, and malmsey. But none of these passages gives us much insight into the culture of the Vine in England, the whole history of which is curious and interesting.

The Vine is not even a native of Europe, but of the East, whence it was very early introduced into Europe; so early, indeed, that it has recently been found "fossil in a tufaceous deposit in the south of France" (Darwin). It was no doubt brought into England by the Romans. Tacitus, describing England in the first century after Christ, says expressly that the Vine did not, and, as he evidently thought, could not grow there. "Solum, præter oleam vitemque et cætera calidioribus terris oriri sueta, patiens frugum, facundum." Yet Bede, writing in the eighth century, describes England as, "opima frugibus atque arboribus insula, et alendis apta pecoribus et jumentis Vineas etiam quibusdam in locis germinans."

From that time till the time of Shakespeare there is abundant proof not only of the growth of the Vine as we now grow it in gardens, but in large Vineyards. In Anglo-Saxon times "a Vineyard" is not unfrequently mentioned in various documents. Edgar gives the Vineyard situated at "Weceat, with the Vinedressers" (Turner's "Anglo-Saxons"). Domesday Book contained thirty-eight entries of valuable Vineyards; one in Essex consisted of six acres, and yielded twenty hogsheads of wine in a good year. There was another of the same extent at Ware. (H. Evershed, in "Gardener's Chronicle.") So in the Norman times, "Giraldus Cambrensis, speaking of the Castle of Manorbier (his birthplace), near Pembroke, said that it had under its walls, besides a fish-pond, a beautiful garden, enclosed on one side by a Vineyard and on the other by a wood, remarkable for the projection of its rocks and the height of its Hazel trees. In the twelfth century Vineyards were not uncommon in England" (Wright).

In the time of Shakespeare, I suppose that most of the Vines in England were grown in Vineyards of more or less extent, trained to poles. These formed "the pole-clipt Vineyards" of No. 21, and are thus described by Gerarde—"The Vine is held up with poles and frames of wood, and by that means it spreadeth all about and climbeth aloft; it joyneth itselfe unto trees, or whatsoever standeth next unto it"—in other words, the Vine was then chiefly grown as a standard in the open ground.

There are numberless notices in the records and chronicles of extensive vineyards in England, which it is needless to quote; but it is worth noticing that the memory of these Vineyards remains not only in the chronicles and in the treatises which teach of Vine-culture, but also in the names of streets, &c., which are occasionally met with. There is "Vineyard Holm," in the Hampshire Downs; the "Vineyard Hills," at Godalming; the "Vines" at Rochester and Sevenoaks, the "Vineyards" at Bath; and probably a closer search among the names of fields in many other parts would bring to light many similar instances.*

Among the English Vineyards those of Gloucestershire stood pre-eminent. William of Malmesbury, writing of Gloucestershire in the twelfth century, says:—"This county is planted thicker with Vineyards than any other in England, more plentiful in crops, and more pleasant in flavour. For the wines do not offend the mouth with sharpness, since they do not yield to the French in sweetness" (De Gestis Pontif., book iv.). Of these Vineyards the tradition still remains in the county. The Cotswold Hills are in many places curiously

* I shall feel much obliged to any reader of THE GARDEN who would inform me of any places named after the Vine.—H. N. E.

marked with a succession of steps or narrow terraces; these are traditionally the sites of the old Vineyards, but the tradition cannot be fully depended on, and the formation of the terraces has been variously accounted for. By some they are supposed to be natural formations, but wherever I have seen them they appear to me too regular and artificial; nor, as far as I am aware, does the oolite, on which formation these terraces mostly occur, take the form of a succession of narrow terraces. There seems nothing improbable in the idea that the ground was formed into these terraces with very little labour, and that they were utilised for some special cultivation, and as likely for Vines as for any other. It is also certain that as the Gloucestershire Vineyards were among the most ancient and the best in England, so they held their ground till within a very recent period. I cannot find the exact date, but some time during the last century there is "satisfactory testimony of the full success of a plantation in Cromhall Park, from which ten hogsheads of wine were made in the year. The Vine plantation was discontinued or destroyed in consequence of a dispute with the rector on a claim of the tythes" (Rudge's "History of Gloucestershire"). This, however, is not quite the latest notice I have met with, for Phillips, writing in 1840, says:—"There are several flourishing Vineyards at this time in Somersetshire; the late Sir William Basset in that county annually made some hogsheads of wine, which was palatable and well-bodied. The idea that we cannot make good wine from our own Grapes is erroneous; I have tasted it quite equal to the Grave wines, and in some instances, when kept for eight or ten years, it has been drunk as hock by the nicest judges" ("Pomarium Britannicum"). It would have been more satisfactory if Mr. Phillips had told us the exact locality of any of these "flourishing Vineyards," for I can nowhere else find any account of them. At present the experiment is again being tried by the Marquis of Bute, at Castle Coch, near Cardiff, to establish a Vineyard, not to produce fruit for the market, but to produce wine; and as both soil and climate seem very suitable, there can be little doubt that wine will be produced of a very fair character. Whether it will be a commercial success is more doubtful, but probably that is not of much consequence.

I have dwelt at some length on the subject of the English Vineyards, because the cultivation of the Vine in Vineyards, like the cultivation of the Saffron, is a curious instance of an industry foreign to the soil introduced, and apparently for many years successful, and then entirely, or almost so, given up. The reasons for the cessation of the English Vineyards are not far to seek. Some have attributed it to a change in the seasons, and have supposed that our summers were formerly hotter than they are now, bringing as a proof the Vineyards and English-made wine of other days. This was Parkinson's idea. "Our yeares in these times do not fall out to be so kindly and hot to ripen the Grape to make any good wine as formerly they have done." But this is a mere assertion, and I believe it not to be true. I have little doubt that quite as good wine could now be made in England as ever was made, and wine is still made every year in many old-fashioned farmhouses. But foreign wines can now be produced much better and much cheaper, and that has caused the cessation of the English Vineyards. It is true that French and Spanish wines were introduced into England very early, but it must have been in limited quantities, and at a high price. When the quantities increased and the price was lowered, it was well to give up the cultivation of the Vine for some more certain crop better suited to the soil and the climate, for it must always have been a capricious and uncertain crop. Hakluyt was one who was very anxious that England should supply herself with all the necessities of life without dependence on foreign countries, yet, writing in Shakespeare's time, he says:—"It is sayd that since we traded to Zante, that the plant that beareth the Coren is also broughte into this realme from thence, and although it bring not fruit to perfection, yet it may serve for pleasure, and for some use, like as our Vines doe which we cannot well spare, although the climat so colde will not permit us to have good wines of them" ("Voyages," &c., vol. ii., 165). Parkinson says to the same effect—"Many have adventured to make Vineyards in England, not only in these later days but in

ancient times, as may well witness the sundry places in this land, entituled by the name of Vineyards, and I have read that many monasteries in this kingdom having Vineyards had as much wine made therefrom as sufficed their convents year by year, but long since they have been destroyed, and the knowledge how to order a Vineyard is also utterly perished with them. For although divers both nobles and gentlemen have in these later times endeavoured to plant and make Vineyards, and to that purpose have caused Frenchmen, being skilfull in keeping and dressing Vines to be brought over to perform it, yet either their skill faileth them or their Vines were not good, or (the most likely) the soil was not fitting, for they could never make any wine that was worth the drinking, being so small and heartlesse, that they soon gave over their practise."

There is no need to say anything of the modern culture of the Vine, or its many excellent varieties. Even in Virgil's time the varieties cultivated were so many that he said—

Sed neque quam multæ species, nec nomina quæ sint
Est numerus; neque enim numero comprehendere refert;
Quem qui scire velit, Lybici velit aquoris idem
Discere quam multæ Zephyro turbeatur arenæ;
Aut ubi oavigiis violentior incidit Eurus
Nosse quot Ionii veniant ad littora fluctus.

Georgica ii., 103.

And now the number must far exceed those of Virgil's time. "The cultivated varieties are extremely numerous; Count Odart says that he will not deny that there may exist throughout the world 700 or 800, perhaps even 1000 varieties; but not a third of these have any value" (Darwin). There are the Grapes that are grown in our hothouses; some also of a fine quality are produced in favourable years out-of-doors. There are besides these a few which are grown as ornamental plants. The Parsley-leaved Vine (*Vitis laciniata*) is one that has been grown in England, certainly since the time of Shakespeare, for its pretty foliage, its fruit being small and few; it makes a pretty covering to a wall or trellis. The small Variegated Vine (*Vitis* or *Cissus heterophyllus variegatus*) is another very pretty Vine, forming a small bush that may be either trained to a wall or grown as a low rockwork bush; it bears a few Grapes of no value, and is perfectly hardy. Besides these there are several North American species, which have handsome foliage, and are very hardy, of which the *Vitis riparia* or *Vigne des Battures* is a desirable tree, as "the flowers have an exquisitely-fine smell, somewhat resembling that of *Mignonette*" (Don). I mention this particularly, because in all the old authors great stress is laid on the sweetness of the Vine in all its parts, a point of excellence in it which is now generally overlooked. Lord Bacon reckons "Vine flowers" among the "things of beauty in season" in May and June, and reckons among the most sweet-scented flowers, next to Musk Roses and Strawberry leaves dying, "the flower of the Vines; it is a little dust, like the dust of a bent, which grows upon the cluster in the first coming forth." And Chaucer says—"Scorners faren like the foul toode, that may nought endure the soote smel of the Vine roote when it flourisheth" ("The Person's Tale").

Nor must we dismiss the Vine without a few words respecting its sacred associations, for it is very much to these associations that it has been so endeared to our forefathers and ourselves. Having its native home in the East, it enters largely into the history and imagery of the Bible. There is no plant so often mentioned in the Bible, and always with honour, till the honour culminates in the one great similitude, in which our Lord chose the Vine as the one only plant to which He condescended to compare Himself—"I am the true Vine!" No wonder that a plant so honoured should ever have been the symbol of joy and plenty, of national peace and domestic happiness.

H. N. ELLACOMBE.

(To be continued).

Phellodendron amurense, a very hardy ornamental tree, flowered last season at the Cambridge Botanic Garden. It has been there fifteen years, so it is quite hardy. The plant is dioecious, and a native of Mandchuria. It grows in its native habitat at 50 ft. high, and has a trunk 1 ft. thick, with a corky bark. It is allied to *Ptelea* and *Xanthoxylon*. Prof. Sargent contributes a fuller note on the subject to the April "American Naturalist."

CAPER PLANTS.

REGARDED in the light of ornamental plants, Capers do not rank highly in the estimation of many; nevertheless several species, as well as those of allied genera, are cultivated for the sake of their large and showy flowers. Most of the Capers are plants of a shrubby nature, and are characterised by two little recurved spines seated at the bases of the leaves. The fruit is

upon which writers and commentators have differed so widely that great doubts exist as to this as well as to other plants. The Caper plant grows abundantly in the south of Europe, on the shores and in the islands of the Mediterranean; besides being found naturally in these countries growing on walls and rocks, it is also cultivated to a great extent, as well as in many parts of France, Italy, and Sicily; and it is from the last-

The Caper Plant in Flower.

elevated upon a long gynophore, and the mark or scar of the fallen petals is very distinct as the fruit ripens. Irrespective of any interest the plants may have in themselves, the history of some and the uses of other species are of sufficient importance to justify a few words about them. It was at one time endeavoured to be proved by Dr. Royle that the Hyssop of Scripture was identical with the common Caper (*Capparis spinosa*); but the identification of biblical plants is a subject

named country that we get our principal supply of Capers. The flowers, as will be seen from the annexed figure, are borne on single stalks rising from the axils of the leaves, the petals being of a delicate light pink colour, and the numerous stamens longer than the petals; the flower-buds form the Capers of commerce, which are so well known as a pickle, and as an ingredient in Caper sauce. In some parts, however, the young fruits are used in a similar way. The plants begin to

flower in the early part of the summer and continue flowering almost successively till the beginning of the winter, or for a period of six months. The flower-buds, which are gathered while they are in a very young state, are plucked every morning and thrown at once into casks of salt and vinegar. This harvesting goes on during the whole flowering period, and at the end of the season the Capers are sorted carefully by hand, according to size and colour; those of the smallest size and of the brightest green are considered the best, and are known as Nonpareils, the second quality being called Capucines; these are again put into vinegar in small glass bottles, and after being securely fastened down, are packed in cases for exportation. Those packed in barrels are those that are left remaining after the above selections have been made, and fetch a lower price.

CAPPARIS SPINOSA, under several distinct varieties, is found in many parts of India—in the Punjab, Scinde, Guznar, north-west Himalaya, &c., ascending in the inner arid valleys to an elevation of 12,000 ft. Dr. Brandis says that in India the time of flowering varies according to the locality and elevation. In the Peshawur valley and the trans-Indus territory it flowers from April to July, the fruit ripening about November, while in the inner Himalaya it flowers from June to October. The shrub is described as being in India strikingly handsome, owing to its large flowers, long purple stamens, and the long-stalked ovary protruding from among them. The buds are not used in India as they are in Europe, though there is no reason why they should not be, as the plant flowers freely. The fruits, however, are pickled and eaten both in Scinde and the Punjab. Goats and sheep are particularly fond of the leaves and ripe fruits. We have flowered the *Capparis spinosa* freely in a large pot of light soil, with brick rubbish intermixed. This Caper is, however, very difficult to grow in this country. There probably would be least difficulty in growing it on the back wall of a greenhouse—its roots being in the wall, as they so often are where it grows wild.

CAPPARIS APHYLLA is a branched, glabrous tree or shrub with brownish-red or scarlet flowers borne in lateral and terminal fascicles or corymbose racemes. It is very common in India through the Punjab, Scinde, Rajputana, the central provinces, the Dekkan, also in Tinnivelly, and North-west India in the driest, hottest places, extending into Arabia, Egypt, Nubia, and North Central Africa. The wood is of a lightish yellow colour, very hard, close and fine-grained, and has a distinctly bitter flavour, which protects it from the attacks of white ants. It is used in India for agricultural implements, rafters for houses, ribs for boats, &c. It burns quickly with a good deal of flame, and leaves a quantity of ash; throughout Borneo in North Central Africa a salt is prepared from this ash which is largely used for culinary purposes. It is remarkable that while the flower-buds of the true Caper are not pickled in India, those of *C. aphylla* are so used in Scinde, while the unripe fruits are cooked and eaten, and in both the ripe and unripe states they are prepared with salt and pepper, and made into a pickle which has a strong bitter taste, and is exported into Hindustan. This plant is the *Capparis Sodada* of Robert Brown, and is known in India as the Karil or Kiral, in Arabia as the Sodada, in Sinai as Lasaf, and in Central Africa as Suag.—J.

A Portable Hot-water Boiler.—Good, portable hot-water boilers, that can be easily shifted about from place to place, have not been common. We note that one exhibited at the Centennial Exhibition by Smith & Lynch, of Boston, received from the judges the following award, which is highly creditable:—1. Saddle-shaped boiler with good-sized fire-box, the interior surface of which is furnished with a series of deep, narrow water-cells, projecting towards the fire, giving a large amount of fire surface, insuring prompt and efficient action and consequent rapid circulation of water. Construction simple, strong, and portable; amply supplied with fittings which are readily adjusted; an excellent heater. 2. Adaptability to secure a combination of hot-water and fine heating, thereby economizing the products of combustion.—W. D. Brackenridge, Signature of the Judge. Approval of Group of Judges—George Thurber, William Saunders, F. Pentland.—“Gardeners' Monthly.”

A MAN who has not much experience of garden-work suggests that for laying-out and trenching, which he has lately tried, a cast-iron back with a hinge in it would be an improvement on the spinal column now in use. He is of course an American.

ADJUSTABLE PLANT BOXES.

VARIOUS contrivances have been proposed to allow boxes in which plants are grown to be taken away from the balls of earth, so as to permit the plants to be set in the ground without disturbing the roots; and among these we have seen none so well adapted to secure this end as an adjustable plant box, invented by Mr. C. M. Crandall.

Fig. 1.

Pieces of thin board, with dove-tailing, are used for the sides; four of these are put together and fastened by pivots as in fig. 1. It is but the work of a few seconds to put these into the shape of fig. 2, when the box is complete. As many boxes as are desired are set together upon a board, which serves as a bottom to all of them. They are then filled with earth, and are ready for the plants. In a short time the earth gets so solid, and is so held by the roots of the plants, that the box may be lifted, or may be taken quite away from the ball of earth, which will retain its shape. The readiness with which the plants may be transferred from the boxes to the open ground may be seen at once, and the plants are not at all disturbed by the operation. One advantage of these boxes is their

Fig. 2.

Fig. 3.

durability, and when not in use they may be laid flat, as in fig. 1, tied together, and put away for another season. If one chooses to make a lighter box, it can be done by uniting two in the manner

Fig. 4.

shown in fig. 3, and they are susceptible of a variety of combinations, as shown in fig. 4; and others will suggest themselves to those who may wish to use them for a miniature window-box.—“American Agriculturist.”

Cooked Radish Pods.—I sowed this spring a small border with Radish seed, but owing to the bad soil of a London garden, and the ungenial weather, they produced no roots fit to pull. In order, however, to have a few pods for pickling I allowed them to stand, and in consequence of the quantity of pods produced, I had a few of them cooked as an experiment in the same way as French Beans, when to my surprise I found them equal to marrow Peas, and very similar to the small Asparagus sold in Covent Garden under the name of “Sprue.” In future I shall always, after those fit for pulling are used, leave the remaining plants for this purpose. A useful property belonging to Radishes is, that should the border be wanted for other purposes, they may be transplanted without any fear of failure.—H. L.

Fly on Brussels Sprouts.—A small white-winged fly which attacks the Cabbage tribe in great numbers is thus got rid of by Kentish market gardeners:—An old sack is procured, and to each side of it is fastened a broomstick or strip of wood, to one of these is also fastened another piece of sack about 1 ft. wide which hangs down and is called a flapper; one side of the sack (but not the flap) is painted over with gas tar, and with one person on each side of the bed of plants, this sack is stretched tightly and drawn along about 12 in. or 15 in. above the plants, the flapper dragging over the plants and disturbing the insects, which fly upwards and stick to the gas tar. After this operation has been performed a few times, a bed of plants half a mile in length is entirely freed from the pests. The gas tar requires to be renewed several times during the operation.

THE FRUIT GARDEN.

EARLY PEARS.

AMONGST early Pears, to which allusion has already been made (see p. 107), Williams' Bon Chrétien (fig. 1) must have a foremost place, being one of the largest and most delicious. It is also a sure bearer; even this season, when other kinds are so scarce, it is producing a full crop. It generally comes into use about the end of August, but this season it will not be ready until the middle of September. Like most kinds of

Fig. 1.—Williams' Bon Chrétien.

early Pears it will not keep long after it is ripe, and it is quite spoiled if allowed to ripen on the tree. Doyenné Boussoch (fig. 2), is another good early Pear, which generally comes into use about the middle of September; it has a richly-perfumed flavour, and for an early kind keeps a considerable time after being fully ripe; with us it bears best on the Quince stock. Ananas de Courtrai (fig. 3) is another excellent early Pear, which is not so generally grown as it should be; it is always as large as Williams' Bon Chrétien, and sometimes

Fig. 2.—Doyenné Boussoch.

Fig. 3.—Poire Ananas de Courtrai.

larger, and it resembles that kind in having a strongly-perfumed flesh, though more brisk and refreshing; it is not such a free bearer as Williams' Bon Chrétien, but it must not by any means be classed amongst shy-fruited sorts. Other good August and September Pears are—Beurré de l'Assomption, Dearborne Seedling, Souvenir du Congrès, Ambrosia, and Madame Treve. W. W. H.

Figs in the Open Air.—This is the time for laying the foundation for a good crop next year, by keeping the shoots thin and well exposed. Well-ripened wood will pass through a severe winter with only a slight protection, where soft immature shoots would be killed. All young fruits now showing should be pinched off before they get any size, as they can never become useful, and only tend to exhaust the trees. Figs in the midland counties usually make more wood than they do in the South; therefore more attention must be given to summer pruning, and it may in some situations be occasionally necessary—unless the roots are growing in some circumscribed position—to lift and shorten their points. Rigid training is not necessary as regards fruitfulness, and in some instances it may have quite a contrary effect, but in many gardens neatness and order are essential requisites; therefore Fig trees against walls or buildings have to submit to training whether it suits them or not: if the shoots be

kept thin and laid in close to the walls, the extra warmth radiated from the bricks will help to ripen the wood. It is in cases in which the shoots are laid in so thickly that every inch of surface is densely covered with foliage that failure occurs. It would be far better to leave trees altogether untrained than to train the branches so thickly that neither air nor sunshine can have fair play. The Brown Turkey and White Marseilles are two of the best varieties.—E. HOBBAY.

The Phylloxera and its Changes.—At the August meeting of the Society of Inquiry held in the Museum, Thornhill, Dr. Sharp gave an account of the recent increase of knowledge regarding the Phylloxera. M. Lichtenstein, of Montpellier, and other observers had succeeded, he said, in overcoming the difficulties connected with so small an insect beneath the surface of the ground, and had made out its history, though some points still remained to be cleared up. It is certain, however, that the Phylloxera is as interesting to the man of science as it is to the Vine-grower, for it exhibits a series of changes which are without any parallel in the animal kingdom. The successive generations, instead of resembling one another, differ much, and after a number of generations have been produced by wingless females, a winged form appears, and by it insects in a stage of development corresponding to that of the chrysalis are produced instead of eggs being laid, and then from these chrysalids are at once produced the sexed individuals; these sexed individuals are, however, extremely peculiar, for they are very much smaller than the individuals of the preceding generations, and are completely without the organs of the mouth that would enable them to take food. M. Lichtenstein considers this series of changes to be analogous to cycles that are frequent in the vegetable kingdom.

A Successful Cool Orchard House.—A conviction has been growing up in the minds of many fruit cultivators of late that cool orchard houses, i.e., houses without artificial heat, are not trustworthy, and that from want of warmth frost penetrates the structure and cripples the crop just when it looks full of promise. This has unfortunately happened; but still there are exceptions to this rule. At Dawpool, Birkenhead, the residence of Mr. T. H. Ismay, there is a cool orchard house, which was built some fifteen years ago on the Cranston principle. It is 81 ft. in length, 21 ft. in width, and 14 ft. in height. It is a span-roofed house standing by itself, with one side to the south-west, facing the sea, which is about a mile distant. The trees, which consist of Figs, Cherries, Pinns, Peaches, Nectarines, and a few Reinette de Canada Apples are all potted, and are growing in pots about 15 in. in diameter, plunged in the soil about two-thirds their depth. Mr. D. Bryers, the gardener at Dawpool, states that during the fifteen years that have elapsed since the trees were purchased they have never missed carrying a crop, and this year, every tree is so heavily weighted with fruit as to be in danger of breaking down. Plums are especially plentiful; and the Cherries, which are now gathered, were an abundant crop. Vines are cultivated on the roof, the varieties being the Black Hamburgh and Dutch Sweetwater, the bunches of which are of good size, with well-developed, finely-coloured berries. The trees have been fifteen years in their pots without having been re-potted; but a top-dressing of rich soil is given them every year in October, and at the time of fruiting they are supplied with guano water. No special precautions are adopted to exclude frost beyond shutting up the house during the time it lasts. The position of the house is, however, elevated and dry, and the aspect warm and sunny. It will, therefore, be seen that where conditions are favourable unheated orchard houses are structures worthy the attention of fruit growers.—D.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Ripening the Wood of Fruit Trees.—The growth of fruit trees being now pretty well finished for the year, all laterals or breastwood remaining should be removed, to allow the free access of air and sunshine to the main leaves on the spurs or branches from which a crop is expected next year. This will also at the same time improve the colour and flavour of the fruit now approaching maturity.—E. HOBBAY.

Another Use for Grapes.—Grapes will be abundant this year in California, and a few Grape-growers who have the Mission variety will adopt the plan of fattening hogs on them, unless prices are good. Mr. Mertes says one of his neighbours, Mr. Gould, has tried the experiment thoroughly, and is perfectly satisfied with the results. Hogs will fatten as well on Grapes as on corn. They eat ravenously when first turned into the Vineyard, but soon become fat, and spend most of their time sleeping under the Vines, too fat to run about. They neither destroy the Vines nor waste the Grapes, but pick up all that drop on the ground, and the feed lasts much longer than one would suppose who has never tried the experiment. From the time Grapes are ripe until after frost the supply holds out unless the number of hogs is disproportionate to the size of the field. Two or three hogs can be kept several months on each acre.

PLATE LXXXVIII.

THE HERBACEOUS PHLOXES

(WITH A COLOURED FIGURE OF PHLOX BEAUTY OF EDINBURGH).

Drawn by H. HYDE.

OF neglected plants, the Phlox is one of the most striking examples, and when one considers with what ease it can be propagated and cultivated, it is surprising that so little use has hitherto been made of it. It can be freely propagated in spring in a little heat, and in summer and autumn in a cold frame or even in the open border, and it will withstand our most severe winters. It will grow in any good garden soil, but is much improved by the addition of some well-rotted manure; and if the beds or clumps can be mulched with the same material the plants will be thereby much invigorated, their season of flowering lengthened, and the quality of the flowers improved. By planting the early and late-flowering varieties alternately, the same beds can be kept gay for nearly four months. After the plants have begun to grow, all weak and superfluous shoots should be removed, leaving three or four only of the most vigorous on each plant. Herbaceous Phloxes produce a pleasing effect planted amongst Rhododendrons or other shrubs, and they can be obtained at a mere fraction of the cost of Gladioli, Lilies, and similar plants. Many of them are even useful for conservatory decoration, as, in addition to their other good properties, some of them are delightfully fragrant. They can be grown in 8-in. or 10-in. pots plunged in the open ground, treated like Chrysanthemums, and taken in as required; for this purpose, two-year-old plants are most suitable.

Summer-flowering Phloxes.

The summer-flowering Phlox, *P. suffruticosa* or *nitida*, although introduced to this country from Carolina as early as 1818, exhibited no marked improvement until nearly forty years later; but from that time so much attention has been paid to it, especially in the North, that it has now, one would suppose, almost reached perfection. While in the original the individual flowers had small narrow petals, and were produced so thinly as scarcely to show the outline of a spike, the most recent seedlings have massive spikes built up of large circular flowers so closely arranged as to overlap each other, and of sufficient substance to stand the weather well. The accompanying plate, somewhat reduced, represents a remarkably perfect example of a seedling sent to us by Messrs. Dicksons & Co., Waterloo Place, Edinburgh, which, for size and form of flower and arrangement of spike, is as perfect as a Phlox could well be expected to be. This section is extremely useful in the herbaceous border in June and July, when it is in flower, coming as it does between the spring and autumn-flowering sorts. The following are the names of twenty-four of the finest Phloxes for competition at present in cultivation (if only twelve be grown, those named first will be found the best):—Beauty, Beauty of Edinburgh, Bridesmaid, Conqueror, Caller Ou, George Eyles, James Nicholson, Mrs. P. Guthrie, Mrs. Burton, Mrs. Gellatly, Philip Pollock, William Mitchell, Allan Mc Lean, Dr. Robert Black, Duchess of Athole, Indian Chief, Mary Shaw, Mrs. Ritchie, President, Redbraes, Socrates, The Bouquet, The Deacon, and The Shah. While the number of competition varieties might be much extended, any one requiring Phloxes for park decoration might find it desirable to reduce the number to three or four having clear and distinct colours, large spikes, and a robust and vigorous habit of growth; and for this purpose we have seen large clumps of the following produce a charming effect, viz.:—Bridesmaid, pure waxy white; Dr. Robert Black, red; Mrs. P. Guthrie, white with dark lilac eye; and Mrs. Ritchie, rosy purple.

Autumn-flowering Phloxes.

The late or autumn-flowering Phlox, *P. decussata* or *acuminata*, was introduced from North America a few years earlier than the *P. suffruticosa*, but it appears to have long been neglected by growers in this country, probably on account of its tall habit and lateness of flowering, and we are entirely indebted to Continental raisers for having taken it up and improved it, especially as regards colour. It has been only

within the last ten or twelve years that English cultivators have paid special attention to this section, being dissatisfied partly with the quality of flowers sent out, so many of the new Continental varieties being quite inferior to those already in the market, and also because many of the finer varieties proved too delicate in constitution and their flowers too thin to stand our autumn rains. British hybridizers, having already all the best Continental kinds, directed their attention first to improving the constitution and habit of the plants, then to obtaining earlier blooming varieties, having flowers of good substance and form. The result of this care has been most satisfactory, as we have now got flowers possessing all the qualities of which many of the imported varieties were deficient. No doubt many of the Continental varieties, when seen at home, are very beautiful; but for our less favourable climate we require flowers of a more enduring character. The time of flowering of this section immediately succeeds that of the *suffruticosa* group, thus prolonging the season at least two months from the end of July. They are remarkable for their exceedingly bright and varied colours, including all shades from rich vermilion to pure white, some also being beautifully striped. A selected list of twenty-four of the best and most distinct varieties for competition in this section are as follows, the first twelve being the finest, viz.:—*coccinea*, David Syme, Gavin Greenshields, Jaue Welsh, Jenny Grieve, Lothair, Matthew Miller, Mrs. Keynes, Monsieur Rafarin, Rêve d'Or, Robert Paterson, William Blackwood, Andrew Borrowman, Carnation, Henry Cannell, James Alexander, James Cocker, Madame Verlot, Major Molesworth, Miss Wallace, Mrs. Tennant, Thos. Chisholm, Triomphe du Parc de Neuilly, and William Veitch. For large beds, back lines of borders, or for park decoration, the following are the most effective varieties, and can be used according to the shades of colour required, viz.:—*coccinea*, rich vermilion; Carnation, white and spotted with purple; James Alexander, rich crimson; Lothair, bright scarlet; Mrs. Keynes, pure white; Robert Paterson, rich crimson; William Blackwood, rosy salmon; Miss Wallace, pure white; and Major Molesworth, scarlet, with a crimson eye. G.

STRIKING CAMELLIAS FROM LEAVES.

It would be hard, indeed, to pronounce with absolute certainty what exogenous plant exists which will not grow from a cutting, provided the cutting be a portion of the axis, and that it be planted under favourable conditions. That numbers of the same great division of the vegetable kingdom may be propagated even from leaves is an interesting fact which of late years has been still more abundantly established by the skilful operators of our time. It is not so very long since leaf-propagation was a thing scarcely dreamed of, and when the only instance familiar or known to us was that afforded by the so-called Life Plant (*Bryophyllum calycinum*), the leaves of which, if laid upon a surface of soil, sand, or tan, produced a young plant from each of the crenatures. This, however, could scarcely be with strictness called a leaf cutting. The *Gloxinia* was, perhaps, the first plant which showed the capacity for emitting roots from, every cut or fractured portion of the stalk, or framework of the leaf. Then the succulent section of *Begonias*, of which *B. Rex* is the type, showed themselves to be so accommodating in this respect that a leaf might be cut up piecemeal, and the least fragment would emit roots and produce a plant. Zonal *Pelargoniums* were then found to be quite amenable to leaf-propagation, and, later still, ingenious manipulators have discovered that even the *Fuchsia* and small *Melastomads* are no churls in this respect. Further examples might be given, but the foregoing are sufficient to show that, at all events in the case of plants of a soft, succulent character, even the leaf may be calculated upon to grow a plant from. In the case of hard-wooded plants the matter is very different, and one would scarcely expect to find a hopeful subject for propagation in the leaf of any of them. And yet we are about to bring before our readers a very remarkable, if not altogether novel, instance of it. One would scarcely expect that in the *Camellia* we could have a subject for leaf-propagation. Yet such is a fact, of which only a few days since we had ocular demonstration in the propagating house at Glasnevin, where we saw several *Camellia* leaves with quite a bushwood of roots from their foot-stalks luxuriating in the *Coccoloba* refuse which formed the striking medium. To Mr. Buckley, who has charge of this department, and who is a most successful and intelligent manipulator, is due the credit of being the first (so far as we are aware) to demonstrate that *Camellias* may be struck from a leaf.—“Irish Farmer’s Gazette.”

PHLOX "BEAUTY OF EDINBURGH"

THE KITCHEN GARDEN.

JERUSALEM ARTICHOKE IN FLOWER.

In this country the Jerusalem Artichoke only flowers in warm situations and in exceptionally hot seasons. Its blossoms resemble those of the Sunflower, to which the plant is closely related. On the Continent its tubers are always in considerable demand, and before the Potato became plentiful they were a good deal in use in this country. Parkinson, writing in 1629 says they were then common in London. Hence it appears that, as the culture of the Potato extended it gradually displaced the Jerusalem Artichoke, and at the present time the latter is only grown to a very limited extent in gardens. Since

Flowering specimen of Jerusalem Artichoke.

the failure of the Potato crops the Jerusalem Artichoke has been strongly recommended as a substitute for that vegetable, but notwithstanding all that has been said and written in its favour, it is still far from common, and by no means esteemed so much as it deserves to be.

S.

Thinning Late Turnips.—To have well-shaped hardy Turnips to stand for winter use, plenty of space should be allowed them. Veitch's Red Globe and Orange Jelly—two of the best Turnips for all seasons, should be thinned to 15 in. apart. The Black and White Stones, which are also good for late sowing, will not need so much room: for those kinds a square foot will be sufficient.

—E. HOBDAY.

Lettuce and Endive to stand the Winter.—In cold bleak situations a considerable advantage is gained by planting these on sloping banks or ridges with the longest inclination to the south. They should be formed in some open airy place, and being well drained, if at the approach of frosty weather the Lettuces and Endive be covered with dry Fern or Oak leaves, they would not be so likely to suffer from damp, and would blanch readily and be very crisp.

—E. HOBDAY.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Evergreen Hedges, such as Holly, Yew, Laurel, Privet, or anything that is kept cut into a formal shape, and that have attained the full size to which they are required to grow, should now be clipped; there is no better time than the present for carrying out such an operation; where this work is delayed until near the close of the year and a severe frost ensues, the shoots are frequently killed back for some distance beyond where cut. In the case of any hedges of this description that are to be so far reduced in size as to necessitate cutting back into the strong wood that has become destitute of leaves, the work should not be done until spring, as the roots would be thereby seriously affected at this season of the year, and whatever little growth was made after this time would be so soft as to be unable to live through the winter; in like manner young Evergreen hedges should not be cut until spring, further than shortening back with the knife any over-strong shoots that are taking too much lead. In respect to young hedges of this description, I should by all means urge their being kept wide at the bottom and gradually reduced up to the top, which should be kept quite narrow. The old-fashioned form of hedge, with its perpendicular sides and square or rounded top, finds more favour with some on account of its general appearance, but there is no hedge (if we except Beech) that will ever retain its full strength in the lower branches where most needed, when cut in this way.

Deciduous Hedges, in and around gardens where it is desirable to keep up an orderly, trim appearance, and which have attained the full size required, may also now be clipped. Young thriving hedges that are not yet fully developed should on no account be cut until after the leaves have fallen, as the removal of the shoots of anything of a deciduous habit whilst the leaves are upon them has a most weakening influence, and has a far more disastrous effect upon the plants than the cutting away of the same shoots after the leaves have fallen. I frequently see amateurs so desirous of keeping everything so close and formal as to be induced to cut Thorn hedges twice in the year, that is, just before midsummer, and again in the autumn or winter; but it must be borne in mind that, except in the case of the most vigorous examples of this kind of fence grown under the most favourable conditions of soil and situation, this continual clipping, from its exhaustive tendency, will in the end permanently injure the hedge.

Box Edging.—Where this was not clipped in the spring it should now be done. There is nothing equals this edging in appearance when it is not allowed to get too large, and from its natural slow habit of growth, with ordinary care in cutting, many years will elapse from the time of planting before this occurs. When it has once attained sufficient size, like a well-managed hedge, it should annually be cut back to the same point to which it had been previously clipped; by being so treated at first sight it might be supposed that it would have for a time after cutting a bare look, through the old leaves in the course of time falling off; but this does not occur, as when cut close the old stems keep breaking out lower down and are always furnished with fresh green leaves.

Lawns and Shrubberies, &c.—Through the late abundance of rain lawns in even the driest parts of the country have kept their verdure much better than usual, and, as after this time there is no danger of their getting burnt up, in those places where the mowing machine was set early in the summer so as to leave the grass a moderate length, it may now be adjusted to cut a little closer, which will render the lawn more pleasant to walk upon when at all damp. In places where Dandelion, Plantain, or other weeds which usually affect lawns were numerous and cut out in the spring, the showery season will have been favourable to their again springing up: if they have made their appearance cutting out should be again resorted to, otherwise the labour already incurred will be lost, as by the spring they will be almost as strong as ever, whereas if persistently removed as often as they appear their destruction is certain, as no plant, including those weeds most tenacious of life, can bear incessantly cutting down so low as to remove the crown. I often meet with amateurs who, on coming into possession of gardens that have been neglected, express a feeling that in trying to exterminate weeds, especially on gravel walks, they have undertaken a hopeless task, yet such is by no means the case, provided the work is always done in time. Where one crop of weeds succeeds another without any diminution, it gives evidence of mistaken ideas as to their reproductive capabilities; those who have not had much experience in gardening matters are frequently under the impression that the seeds of weeds, like those of cultivated crops, require to be ripe or nearly so, previous to removal from the parent plant, to enable them to grow; yet this is by no means the case, for the seeds of great numbers will

grow almost as soon as they are formed, while those of an annual character in a very few days after their flowers are dead will be possessed of germinative vitality; hence there is no safe way but removing them as soon as they are sufficiently large with either hoe, or fingers.

Kitchen Garden.—All Potatoes for seed are much benefited by being fully exposed in the open air; the effect of such treatment is that the sprouts formed through the winter and spring previous to planting have a natural tendency to be much stouter, and consequently less liable to be broken off or injured in the operation of planting than when the Potatoes to produce the next year's crop have on taking up been at once stored without being subjected to this greening process; but in thus letting them remain in the open air it is necessary to keep a sharp look-out, for from the first commencement of the disease I have always found that any Potatoes that are exposed, even if quite sound when taken up, soon become affected with it; to such an extent has this occurred that on one occasion, with a beautiful lot of *Mona's Pride* that were dug before there was the semblance of disease in the neighbourhood, by letting them lie on the surface of the ground for some weeks (during which time it made its appearance) they were so affected that I did not save five per cent. of the whole. After being greened in the manner described, I should recommend all Potatoes intended for seed being put away in any cool building, as clamping in all cases possible should be avoided; even those that are intended for planting will be none the worse for being stored in a totally dark place, as although they can hardly have too much light after they begin to sprout, yet until there is a disposition thus to commence growth, they are just as well in the dark. The later varieties, especially the rank-growing American kinds, have in many places been attacked by the disease; if the weather continue dry, in all probability it will not seriously affect these later sorts; but if wet weather ensue, I should recommend amateurs to look over the tops every few days, and, as soon as ever they detect the leaves turning black instead of dying off the natural yellow colour, at once pull up the haulm; the disease is first apparent on the under leaves and stems, and if these be removed before it has attacked the tubers, the latter may be allowed to remain in the ground to ripen for a few weeks previous to being taken up. When this pulling up of the tops (cutting off will not do) is carried out on the first symptoms of disease in the leaves, I have invariably found it effectual; but it is not of the slightest use after the tubers are affected to any considerable extent. Many object to removing the tops in a green state, under the impression that the quality of the produce is injured thereby; they will not be quite so dry and mealy when cooked as if the tops had died down naturally when non-affected with disease, but their keeping properties will not be impaired in the slightest degree; and it is better to submit to the little deterioration in quality that thus occurs than to sacrifice the bulk of the crop.

Planting Coleworts, &c.—Whatever ground is cleared from Potatoes or other crops should immediately be planted with Coleworts, late Green-curl Kale, or other hardy vegetables for winter and spring. If plants of these have been prepared by pricking out in a nursery bed, they will have attained a considerable size, and if removed with no more mutilation of their roots than can be avoided, and sufficiently watered until their roots have got hold of the soil, they will grow on through the cooler autumn months to a useful size; or, if preferred, a portion of ground newly cleared may still be devoted to Turnips, as there is yet time, especially in the south and west of the kingdom, for them to attain a fair size before winter.

Runner Beans, planted with a view to keep on bearing so long as the frost will permit them, should have the ground well mulched with manure; this will have the effect of giving the requisite nutrition to the roots to enable the plants to continue bearing; without such treatment, in late, mild autumns they get exhausted before the arrival of frost.

Dwarf French Beans.—Where these are held in estimation, and are required to keep on bearing as late as they can be had, those that were sown late must have the first Beans they produce picked off as soon as they are fit for use, or their ability to continue making the necessary growth will be curtailed; to assist them in this, good soakings of manure water will be found the most effective, for even where the ground has been well enriched with solid manure liquid stimulants are of service by acting immediately upon the roots.

Peas.—In open situations, where there is a chance of growing for late gathering without their becoming affected with mildew, a little manure put on as a mulching for about 2 ft. on each side of the rows and well soaked with water will keep up the vigorous growth essential to late bearing.

Endive.—A good breadth of ground should be now prepared whereon to plant the principal crop of Endive for autumn use; do not plant too closely—18 in. between the rows and 15 in. between the plants in the rows will not be too much for the stronger-growing kinds, such as *Batavian* and *Large Green*; the small *French Curled* will do closer, but in all cases leave sufficient room for the use of the hoe.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

August 27.—Sowing Black-seeded Brown Cos, Stanstead Park and All the Year Round Lettuces; Fraser's Broad-leaved and Green-curl Endive. Manuring and digging borders for Endive and Lettuce. Earthing up Celery and Cardoons when the soil is dry and in suitable condition. Gathering ripe Peaches, Nectarines, Pears, Figs, and Plums, and putting them away in a dry, cool place to keep as long as possible. Watering Pines, newly-planted Strawberries, Endive and Lettuce.

Aug. 28.—Sowing Intermediate Stocks and Red and White Turnip Radishes. Potting off Mrs. Pollock and other Tricolor Pelargoniums. Staking Laxton's Unique Peas. Thinning Spinach. Clearing out a pit ready for Cucumbers. Looking over Cucumbers and Melons, stopping their shoots, and removing dead leaves, &c. Watering Vine borders, Peach trees, Scarlet Runner Beans, and Carrots.

Aug. 29.—Sowing Sweet Basil for winter use and Mustard and Cress in succession. Putting in cuttings of Viola Blue Perfection and Golden Gem under handlights against north wall. Planting a small breadth of Leeks for spring use. Thinning out Vegetable Marrows, and closely stopping their shoots. Filling in all Cauliflower drills, giving them a good earthing. Forking over the ground between Cabbage plants. Gathering Green Gage Plums and Morello Cherries for preserving. Watering late-sown Peas, Dwarf Beans, Celery, Endive, and Lettuce.

Aug. 30.—Sowing Turnips. Putting in cuttings of Heliotropes, Cupheas, and Ageratums. Transplanting Wallflowers, Antirrhinums, and Camellifers. Giving all Peach and Nectarine trees a good syringing where the fruit is gathered. Gathering Tomatoes and Devonshire Quarrenden Apples. Spawning a new Mushroom-bed and preparing more manure for another. Digging up ground previously occupied by Peas for planting with Coleworts. Giving Peach trees from which the fruit has been gathered a good soaking with water at the roots.

Aug. 31.—Potting off Fuchsias, Verbenas, and Cucumber plants. Putting in cuttings of *Salvia splendens* and *Lebelia pumila*. Cutting back and nailing Roses on walls. Clearing off Peas and heavily manuring the ground, afterwards digging it up roughly to remain through the winter. Gathering Victoria Plums and Noblesse Peaches for preserving. Thinning Turnips, Spinach, and Lettuce. Watering Pines, late-planted Strawberries, Camellifers, and Carrots.

September 1.—Potting seedling Cyclamens. Planting Endive and Lettuce under the walls. Weeding Strawberries and cutting off the runners which were laid in pots. Emptying and refilling the Grape bottles with spring water with a little charcoal added. Cutting and stacking away turf. Gathering Lord Suffield Apples and Jargonelle Pears. Watering Camellifers, late-planted Celery, Lettuces, and Endive. Fruit in use for dessert—Pines, Grapes, Peaches, Nectarines, Pears, Figs, and Plums.

Hardy Flowers.

CARNATIONS AND PICOTEEES.—Layering, the principal means by which the propagation of these is effected, should now be pushed on without delay. For convenience in carrying out the operation, and indeed for general safety, Carnations and Picotees are grown in large pots, and when that is the case, layering is an easy matter, and it can be performed without exposure to weather, for the plants in pots can be carried into a shed and the work performed in comfort. Mr. E. S. Dodwell, the foremost authority in the matter of Carnations and Picotees, states that it is most important not to proceed with the work until the layers are ripe, and it is equally important not to delay it until they have become hard. The necessary shading of the flowers (when the plants are grown to supply blooms for exhibition purposes) usually causes the layers to become somewhat drawn and soft, and in order to harden them, the plants must be fully exposed to the sun as soon as the bloom has faded. Some sorts produce a good quantity of Grass, others but very little, and sometimes these

spare producers include the best varieties. "Remove from each layer the leaves up to the third joint, counting from the top, which can generally be easily effected with a slight horizontal rift; but if the layers be soft, a pair of sharp scissors must be used," or else there is danger of the shoot snapping asunder. Next "remove all dead and decaying leaves, and about an inch of the old soil from the surface; the latter should be replaced with a compost consisting of equal parts of turfy loam, leaf-mould, and clean sand, which must be well incorporated and passed through a fine sieve. Take the layer between the left forefinger and thumb, hold it firmly, and thrust the point of the layering knife partly through the second or third joints, as the layer may be more or less firm; bend up the top until the joint thus cut opens freely; press it gently into the soil, and secure it firmly there by means of a peg. The pegs for which I have a preference are those made from the common Fern, which if cut in the autumn when thoroughly matured, and used with an ordinary degree of care, will last two seasons. Pegs made from a partly-worn Birch broom also do exceedingly well. When finished, water slightly with a watering-pot, to which a fine rose has been attached. It may also be well to mention here that as water can only be supplied through a fine rose after the layering is completed, it is needful to take care that the ball of soil be made thoroughly moist before commencing to work. Carefully shelter from brilliant sunshine and heavy winds until the rooting process has commenced." There are, however, many plants growing in borders, and when these are layered, the soil should first of all be loosened about the plants, and some fine soil added, as in the case of plants in pots, and into this the layers should be pegged. In the case of outdoor plants, it is a great advantage to layer as early as possible, so that the layers may become well rooted by autumn. In cases where the Grass is high up the stem of the plant, it may be necessary to use pots of soil for layering.

LARGE-FLOWERING CHRYSANTHEMUMS.—The leading shoots of these, whether in pots or in the open ground, should be kept securely tied out. The plants must be well watered in dry weather, and a little liquid manure once a week onwards will be found of great advantage. The Pompon varieties should now be stopped for the last time without delay; it should be done by the first week in August. Plants in pots are greatly helped by tying out the shoots so as to admit a free circulation of air; they must be also well watered, as the foliage quickly turns yellow when the plants suffer from drought. Sprinkling overhead night and morning is of great service: at this time of year green fly is apt to infest the points of the shoots—a washing with Fowler's Insecticide will soon dislodge the enemy.

CINERARIAS.—There are certain named varieties of Cinerarias that can only be propagated by means of cuttings or offsets, and there are promising seedlings that it is desirable to increase in the same way. At this season of the year the plants throw up offsets from the base of the main stem, and these, which may perhaps be more truthfully termed "suckers," should be carefully taken off with as many roots as possible adhering to them, potted off singly into 3-in. pots, and kept close for a time in a cold frame and shaded from the sun. The suckers that are not rooted are best put into store pots and kept close in a similar matter. While the suckers are rooting and making growth they require to be kept clear from green fly, damp, and mildew. The growing plants should be shifted into larger pots as they increase in size.

PHLOX DRUMMONDI.—The cool, moist weather which we are now experiencing is greatly prolonging the beauty of this showy annual. The seed-pods should be picked off so as to encourage the production of flowers, with the exception of the very best varieties, which should be allowed to carry a truss or two of seeds so as to furnish something good to sow next spring. A few cuttings could also be taken of the best varieties, as these would make capital plants for blooming in pots next summer.

D.

Three Feet of Fern-spores.—Bureau and Poisson have examined a substance found in large quantities in a cave at Reunion Island. The cave is 10 metres in depth by 6 metres square, and is covered to a depth of more than a metre by a yellow, soft, insipid, inodorous substance, which crumbles under the fingers to an impalpable powder. The dry powder burns without flame or odour, but when moistened gives off during combustion much smoke and the odour of a burning plant. By exclusion they have decided that this matter consists of the spores of species of Ferns, probably Polypodiaceæ. The spores are not those of Lycopodiaceæ, according to the writers, but they have the shape, markings, and colour of the spores of the Polypodiaceæ with large fronds now occurring on the island.

The flavour of Narbonne honey is said to be caused by the bees feeding on the flowers of the common Rosemary.

TREES AND SHRUBS.

THE SPIRÆAS.

By GEORGE GORDON, A.L.S., Author of "The Pinetum."

THESE are for the most part shrubs well suited for planting in the open border, as they grow freely in any good garden soil; they flower profusely, and are very distinct both as regards habit of growth and time and manner of flowering, as some produce their blossoms early in spring, others late in autumn. Their flowers are also produced in various ways, some in corymbs, and others in erect, compound, blunt heads or spikes; some are likewise pure white, while others are of a brilliant red or pink colour. Some few of the plants are rather tender, but the greater part are perfectly hardy. One of them (*Reevesiana*) is evergreen or sub-evergreen, and the leaves of the whole of them are either simple or pinnate.

Flowers in Thyrsoid Racemes or Spicate Panicles.

Willow-leaved Spiræa (*S. salicifolia*).—This forms an erect, growing dense bush, 4 ft. or 5 ft. high, with numerous smooth shoots which arise mostly from the ground; the leaves, which are lanceolate, are smooth, doubly serrated, and tolerably large; the flowers are red or rose-coloured, and disposed in dense, blunt thyrsoid racemes; the carpels are in fives, and smooth, and the lobes of the calyx triangular and spreading. This is a native of Siberia, Tartary, Silesia, and Bohemia, and it flowers in July and August. This kind is also found in England, but in that case it has pale flesh-coloured flowers, and bears the name of *Spiræa carnea*; there is also a white-flowered variety of it which bears the name of *Spiræa paniculata*, and which is a native of North America, Canada, and Newfoundland, but it in no way differs from the European one, except in the white colour of its flowers and the red colour of its branches. It is the *Spiræa salicifolia alba* and *S. canadensis* of collections, and the following are only wild forms of *salicifolia*, viz., *S. incarnata*, *S. urticifolia*, and *S. carnea*.

Tomentose Spiræa (*S. tomentosa*).—This forms a somewhat erect, stout shrub, from 4 ft. to 5 ft. high, with shoots and leaves (the latter on the under sides) clothed with a rusty-coloured tomentum. The leaves, which are ovate, are serrated towards the apex and entire near the base and deep green above; they are of medium size and have short foot-stalks. The flowers, which are small, are of a beautiful red colour and are disposed in large, dense, terminal, compound racemes; the lobes of the calyx are tomentose on the outside, triangular, and deflexed; the carpels are in fives and divaricate. It is a native of the mountains of Canada and many other places in North America, and it flowers in August and September. The *Spiræa Tobolski* is the same as this, and the *S. Douglasi* only a variety of it with less rusty leaves, which are more oval, less pointed, and broader. The flowers are in more open heads and less compact. It is a native of the north-west coast of North America.

Menzies's Spiræa (*S. Menziesi*).—This forms a dense, erect, bushy shrub 3 ft. or 4 ft. high, with quite the habit of the Willow-leaved one, bearing upright, rod-like shoots, which spring mostly from the ground every season. The branches, which are erect, are pubescent at the points and downy as regards the pedicels and calyx. The leaves are oblong or elliptic, coarsely serrated towards the apex and smooth above, but silvery-white beneath. The flowers, which are borne in large, crowded, terminal, oblong-obtuse panicles, are bright red and small, with the stamens twice the length of the corolla. It is a native of the north-west coast of North America, and flowers from June to August. It is sometimes named *S. californica* in collections.

Noble's Hybrid Spiræa (*S. Nobleana*).—This is a robust, erect, bushy shrub, with a great portion of the shoots rising from the ground, from 3 ft. to 4 ft. high. The branches, in the matured state, are smooth, but downy when young. The leaves, which are rather large, sometimes 4 in. long, are regularly lanceolate, very sharp pointed, tapering towards the base on very short stalks, and coarsely and acutely serrated beyond the middle; they are quite entire at the base, bright green and smooth above, and hoary-grey beneath. The flowers are borne in dense, blunt, branching, terminal, distinct, oblong racemes on longish foot-stalks, and of a pale red colour. It is a hybrid and flowers in July and August.

Hornbeam-leaved Spiræa (*S. carpinifolia*).—This is a robust, erect, open shrub, which grows from 4 ft. to 6 ft. high, with straight, stout, rod-like branches; the leaves oval-elliptic, acute at both ends, coarsely serrated on the edges, and glabrous. The flowers, which are borne in large, terminal, racemose panicles, are white. It is a

native of North America, and flowers in August. This is the *Spiræa obovata* and *salicifolia latifolia*, and a very distinct kind it is on account of its flowering so late in the season.

Mountain Spiræa (*S. alpestris*).—This forms a low-spreading, somewhat slender shrub from 2 ft. to 4 ft. high, with lanceolate, acute, finely-toothed leaves, which are sharply serrated almost to the base, and canescent. The flowers, which are in large, loose, terminal, thyrsoid racemes, are pale red or pink, and nearly double the size of those of the Willow-leaved kind. It is a native of Siberia, where it is found on rocks, and it flowers from June to September. This is the *Spiræa grandiflora* of Loddiges' "Botanical Cabinet," and the *salicifolia grandiflora* of London.

Taurian Spiræa (*S. taurica*).—This is a tall, upright, fastigate shrub, from 6 ft. to 8 ft. high, with lanceolate, serrated leaves and small white flowers in panicle racemes, which are produced very early in spring. It is a native of the Taurian Mountains, and is the same as *S. ulmifolia scopæ* of Loddiges.

Flowers in Loose Terminal Cymes.

Shady Spiræa (*S. ambrosa*).—This is a low, procumbent shrub seldom more than 1 ft. high, which flourishes best in the shade of other plants. The leaves are rather large, but variable in size, some of the larger ones on the stronger shoots being from 2 in. to 3 in. long and from 1 in. to 1½ in. broad, while those on the slender lateral shoots are comparatively small and finely serrated; they are broadly-ovate, obtuse, doubly and acutely serrated towards the apex, with a few coarse teeth, entire at the base, slightly tapering, smooth on both surfaces, bright green on the upper surface and pale beneath. The flowers, which are small, are borne in large, loose, terminal, smooth, branching cymes, sometimes 3 in. across, and composed of numerous small, dense heads of white flowers set on long, slender foot-stalks. It is a native of Northern India, and flowers in July and August.

Expanded-flowered Spiræa (*S. expansa*).—A robust, erect, dense shrub, 4 ft. or 5 ft. high, with an even-flowering head, composed entirely of spreading, loose, long-stalked, corymbose panicles. The leaves are rather large, strictly lanceolate, acutely and coarsely serrated on the upper part, entire, and slightly tapering to the base, set on longish foot-stalks, dull yellowish-green on the upper side, and glaucous beneath, quite smooth on both sides when fully matured, and tapering to a long, slender, sharp point. The flowers, which are rather small, are set on very long, slender foot-stalks, branching into large, expanded, open panicles, composed entirely of flowers of a pale red or pink colour. It is a native of Nepal, and flowers in August or even later. It is often confounded with *S. callosa*.

Whortleberry-leaved Spiræa (*S. vacciniifolia*).—This forms a neat, small, spreading shrub about 2 ft. high, with slender, thread-shaped, smooth, and extended branches. The leaves, which are rather small, are ovate serrated at the apex and glaucous beneath. The flowers, which are white, are borne in rather small, terminal, tomentose, compact cymes. It is a native of Nepal, and flowers in July and August; this is the same as *S. adiantifolia*.

Lax-flowered Spiræa (*S. laxiflora*).—This forms a slender, weak-branched, spreading shrub, 2 ft. high, very much resembling *S. vacciniifolia* as regards size and form of leaves, and glaucous colour on their under sides; but they are long-stalked, rather glaucous above, with long, taper-pointed serratures towards the apex. The flowers, which are arranged in large, loose, shaggy panicles, have reflexed petals, and are white. It is a native of Northern India, and flowers in July; this is the *S. vacciniifolia* of Loddiges' "Botanical Cabinet."

Pretty-flowered Spiræa (*S. bella*).—This is a loose-growing, branching shrub, with reddish, smooth stems, 3 ft. or 4 ft. high. The leaves, which are ovate, acute, smooth, and serrated, are set on longish foot-stalks, thin, and whitish tomentose on the under side. The flowers are terminal, spreading in pubescent corymbs loosely disposed, and of a beautiful rose-colour; the calyx is deflexed, and the carpels in fives and shining. It is a native of Nepal, and flowers in May and June. There is a white-flowered variety of this called *S. bella alba* and *S. callosa alba*, in which the flowers are much larger and in looser cymes. It is a native of Japan, and flowers in August.

Callous-leaved Spiræa (*S. callosa*).—A loose, branching shrub from 3 ft. to 4 ft. high, with rather large, smoothish, lanceolate, acutely-serrated, stalked leaves, tapering to both ends, and glaucous beneath; the stems, calyxes and peduncles are villous; the flowers are in terminal, branching corymbs, and of a deep red colour. It is a native of Japan and flowers in August. This is the same as *S. Fortunei*; and *S. syringifolia*, a hybrid produced between it and *S. bella alba*, is distinguished by its dwarf habit, and numerous large heads of pink flowers.

Flowers in Loose Panicles.

Split-leaved Spiræa (*S. fissæ*).—This forms a stout, erect shrub, 8 ft. or 10 ft. high, with angular, downy branches, and smallish leaves, which are smooth on the upper surface, and furnished on the under sides with extremely fine, close down; the leaves are lax, ovate-incise, and wedge-shaped at the base, with the lateral incisions, when young, usually split into a pair of unequal and very sharp teeth, but when the plant is old the leaves are much smaller and less serrated; the flowers are arranged in long, loose, terminal panicles, and are tomentose, with the petals small and greenish-white. It is a native of Mexico, and flowers in May and June. This kind is rather too tender for planting in the open border; it is the *Spiræa argentea* of Benth.

Whitebeam-leaved Spiræa (*S. arisæfolia*).—This forms a free-growing, dense, erect, bushy shrub, from 6 ft. to 8 ft. high, with elliptic-oblong leaves, broadest at the base, more or less deeply lobed, and villous on the under sides; the leaves are pale green, smooth above, and clothed beneath with a whitish tomentum, toothed on the edges of the lobes, and set on long foot-stalks; the flowers are in large, terminal, slender-branching panicles, which are white and villous; the lobes of the calyx are acute and spreading, and the carpels in fives, reddish, compressed, and hairy. It is a native of the north-west coast of North America, and flowers in June and July, or later. *Spiræa discolor* is the same as this.

Pubescent Spiræa (*S. pubescens*).—A small, grey shrub, about 2 ft. high, with little hemispherical umbels of pure white flowers, which are set on longish, terminal stalks; as regards foliage it has the appearance and the habit of a weak *Spiræa arisæfolia*; its leaves are ovate-oblong, somewhat three-lobed, unequally, coarsely, and acutely serrated, broad and entire at the base, quite smooth on the upper surface, and covered beneath with a short, dense tomentum, which becomes cinnamon-coloured as it grows old; the foot-stalks are rather long and, like the young wood, downy, while the uppermost leaves, beneath the umbels, are oval or oblong and less lobed than the others; the carpels are in fives and pilose. It is a native of China, particularly about Chusan, and flowers in April. It is rather too tender for planting in the open border.

Smooth Spiræa (*S. lævigata*).—This forms a stout, spreading shrub, from 2 ft. to 4 ft. high, very dissimilar in appearance from any of the other kinds. The leaves, which are rather large, are obovate-oblong, perfectly smooth, glaucous, quite entire, stalkless, and tipped with a small mucro at the apex; the flowers, which are white, are disposed in thyrsoid, racemose panicles, with the branches of the panicles cylindrical, and the bractæas linear and hardly the length of the calyx; the segments of the calyx are also triangular and ascending. It is a native of Siberia in valleys, at the foot of the more lofty of the Altaian Mountains, and flowers in May. It is the same as *Spiræa altaiensis* and *altaica*.

Fortune's Panicle Spiræa (*S. Fortunei paniculata*).—This, though a hybrid, is well worth attention. It is a plant which, like its female parent (*S. Fortunei*), thrives in almost every soil and aspect. The leaves are serrated, unequal, and pointed; the flowers, which are larger than those of the type, are of a deep rose colour. The accompanying woodcut was prepared from a specimen growing in M. Billard's nursery at Fontenay-aux-Roses.

Flowers in Hemispherical Corymbs or Loose Umbels.

Germander-leaved Spiræa (*S. chamædrifolia*).—This is a slender, bushy shrub which grows from 2 ft. to 3 ft. high, and which has ovate leaves acutely pointed, deeply serrated at the apex, set on long foot-stalks, pubescent and pale beneath. The flowers, which are white, are disposed in hemispherical corymbs on slender elongated stalks. It is a native of Siberia, and blossoms in June and July. It is a kind which in its wild state varies considerably, the Canadian *Spiræa media* (which has obovate, rather villous leaves, with few teeth at the apex) and the Hungarian *Spiræa oblongifolia* (which has oblong-lanceolate leaves narrowed at the base and deeply serrated at the apex), being the most distinct.

Elm-leaved Spiræa (*S. ulmifolia*).—This forms a dense twiggy bush 3 ft. or 4 ft. high, with broad ovate-lanceolate leaves, acute at the point, flat on the upper surface, sharply and coarsely serrated, set on long foot-stalks rounded at the base, and smooth in the adult state; the flowers, which are white, and placed on long stalks and terminal, sub-hemispherical corymbs, are quite round in the bud state, but when fully expanded have reflexed petals. It is a native of Siberia, and flowers in June and July. This is the *S. chamædrifolia* of Loddiges and Lindley.

Alpine Spiræa (*S. alpina*).—This forms a shrub 2 ft. or 3 ft. high, with long rod-like shoots, which are somewhat flexuose, light-brown, and little divided; the leaves are lanceolate, narrow, acute, set on short foot-stalks, tapering much to both ends, and coarsely and acutely serrated towards the point, entire near the base, and smooth on both surfaces; the flowers, which are white and terminal, are in stalked corymbs with ascending petals. It is a native of the Siberian Alps in woods, and flowers in June. This kind is easily distinguished by its long, narrow leaves.

Flexuose-branched Spiræa (*S. flexuosa*).—This is a tall, slender-growing shrub, 5 ft. or 6 ft. high, with long flexuose shoots. The leaves, which are lanceolate and pointed, are coarsely toothed from the middle to the apex; the flowers, which are arranged in rather large corymbs, are white, and either produced in terminal or lateral heads. It is a native of Dahuria, and flowers in June and July. Of this kind there is a variety with deeply-cut leaves; its synonyms are *chamædrifolia*, *latifolia*, and *dahurica*, and sometimes *laciniata*, and *incisa*.

Japan Spiræa (*S. japonica*).—This is a robust, twiggy shrub, 3 ft. or 4 ft. high, with large, broad, ovate leaves, acutely pointed, deeply and sharply serrated from the middle to the apex, smooth and greyish beneath. The flowers, which are small, are arranged in terminal, distinctly-stalked corymbs, and white; they are in rather small compact heads, and smooth. It is common in Japan, and flowers in June and July. This is the *Spiræa macrophylla* and the *callosa magnifica* of collections, and probably the doubtful *S. magellanica*.

Corymbose-flowered Spiræa (*S. corymbosa*).—A stout, erect, robust-growing shrub 4 ft. or 5 ft. high, with large oval-oblong leaves, unequally serrated, green above, hoary beneath, smooth, and set on short foot-stalks; the flowers are in large, close-branched, terminal corymbs, and white. It is a native of Virginia, and flowers in June and July. Of this there is a variety (*Sororia*) which is much dwarfer, seldom exceeding 2 ft. or 3 ft. in height, and which flowers much later in the season.

Ceanothus-leaved Spiræa (*S. ceanothifolia*).

—This forms an erect bushy shrub, 3 ft. or 4 ft. high, with broad, ovate leaves, either rounded or tapering to the base, sharply and unequally serrated from the middle to the apex; the flowers are in rather small terminal corymbs, on short peduncles and white. The native country of this fine shrub is uncertain, but it is probably North America; flowers in June and July.

Wedge-leaved Spiræa (*S. cuneifolia*).—An erect branching, dense, canescent shrub, 3 ft. or 4 ft. high, with the principal branches arched or nodding and the lesser ones slender and drooping; the leaves which are rather small are firm in texture, ovate or obovate at the point, wedge-shaped at the base, downy and either crenated or entire; on the upper surface they are bright green and glaucous, downy beneath; the flowers, which are white, are arranged in terminal, close, corymbose panicles, thickly placed laterally along the principal shoots, on the ends of the short lateral branchlets; the carpels are in fives lying close together. Native of Nepal, and flowers in July and August. Syns., *cuneata*, *canescens*, and *nutans*.

Round-leaved Spiræa (*S. rotundifolia*).—This has rather slender, angular, downy shoots and round blunt leaves, crenated at the apex; the leaves are much smaller than those of *S. cuneifolia*, of which it appears to be only a variety with rounder foliage. It is a native of Northern India and flowers in July.

Blume's Spiræa (*Spiræa Blumei*).—This forms a somewhat slender branching shrub, 4 ft. or 5 ft. high, with rather firm small ovate or obovate, bluntly pointed leaves, which are regularly toothed towards the apex and entire at the base; they are slightly hoary and when young pale beneath, smooth and bright green on the upper surface and set on long slender foot-stalks; the flowers, which are white, are arranged in compact, terminal, pedunculated cymes, and are glabrous. It is a native of Japan, and flowers in July. This is the *S. chamædrifolia japonica* of gardens.

Hawthorn-leaved Spiræa (*S. crataegifolia*).—An erect, rigid-branched shrub, from 2 ft. to 4 ft. high, with stiff, glaucous, broadly-ovate, or oval, obtuse leaves, netted on the under side and set on short, stiff, glabrous stalks, doubly and acutely serrated towards the point and of a dull green colour; the flowers, which are disposed in small, fastigate panicles or terminal compound, sub-capitate corymbs, are of a bright pink or red colour; the carpels are in fives, erect and glabrous. It is a native of Siberia, and flowers in June and July. This is the *S. betulifolia* of Pallas.

Hoary-leaved Spiræa (*S. cana*).—A small straggling shrub from 1 ft. to 2 ft. in height, with small, ovate, acute, quite entire leaves, thickly clothed all over with hoary, soft, loose hairs, the flowers which are white, are arranged in few flowered corymbs, somewhat spicate or racemose, with the lateral flowers pedunculated and lax; the petals are spreading, the styles thick and the carpels divergent and rather villous. It is a native of Croatia, where it is found on high rocks, and flowers in June and July. This is a pretty little shrub for rockwork.

Three-lobed Spiræa (*S. trilobata*).—This forms a neat little shrub, from 1 ft. to 2 ft. high, with short, stiff branches spreading horizontally; the leaves, which are rather

small, roundish and three-lobed, are reticulately veined, smooth and glaucous beneath, crenated on the edges and of a deep green above; the flowers are white and disposed in umbel-like corymbs, with ascending petals and smooth carpels. It is a native of the Altaian Mountains, and flowers in May. This is sometimes named *S. triloba*.

Plum-leaved double-flowered Spiræa (*S. prunifolia fl.-pl*). A long, slender, twiggy erectly-spreading shrub from 4 ft. to 5 ft. high, with for the most part long, undivided shoots, which produce their flowers in naked corymbs; the leaves which are about the size of those of the common Sloe, are oval, tapering a little to both ends, rather thick in texture, deep green and smooth on the upper surface, hoary grey, or somewhat downy beneath, finely and sharply toothed on the edges, and set on rather long downy stalks; the flowers are quite double, in numerous lateral stalkless corymbs, occupying the upper part of the shoots of the previous season, and when fully expanded pure white. It is a native of China and Japan, and flowers in April and May. Only the double-flowered form is known in England.

Fortune's Fanicled Spiræa (*S. Fortunei paniculata*). See p. 183.

Pikow Spiræa (*S. Pikowiensis*).—This is a doubtful kind, which is said to form a slender branched shrub 3 ft. or 4 ft. high, with small wedge-shaped, obtuse leaves, which are rarely spear-pointed, but three-nerved and unequally serrated at the apex; the flowers, which are white, are arranged in short stalked corymbs, laterally placed on the previous year's shoots. It is a native of Podolia at Pikow and flowers in June and July. There appear to be two different plants bearing this name, one nearly related to *Spiræa crenata*, and the other the same as *Spiræa sorbifolia*; the first is considered to be the true one.

Meadow Rue-leaved Spiræa (*S. thalictroides*).—A low, erectly-spreading, slender, long-twigged shrub, 2 ft. or 3 ft. high, with rather small, firm, obovate, blunt-pointed leaves, tapering to the base, on long foot-stalks, distinctly three-nerved beneath, serrated on the upper part, entire at the base, bright green above and glaucous beneath; the flowers are white, in lateral, stalkless, downy umbels, or close corymbose panicles, and produced in May and June. It is a native of the Dahnriun Alps, and the same as *Spiræa aquilegifolia* and *hypericifolia latifolia*. The *S. Van Houttei* is a vigorous variety of this kind, which bears white flowers in great profusion.

St. John's-wort-leaved Spiræa (*S. hypericifolia*).—This forms a slender, erect, long, wiry-twigged shrub, from 3 ft. to 6 ft. high, with very small, obovate, three or four-nerved leaves, slightly pointed, tapering much to the base, quite entire, on longish, slender foot-stalks, and either smooth or slightly downy; the flowers, which are small, white, and either in stalked corymbs or stalkless umbels, are thickly placed laterally on the top part of the last year's shoots. It is a native of Canada, and flowers in May and June.

[Synonyms—The *Spiræa Plukenetiana*, *inflexa*, and *hypericifolia alpina*; and there is a number of wild forms which are scarcely worth distinguishing from the original species.]

Acute-leaved Spiræa (*S. acutifolia*).—This is a wiry-branched, slender shrub, 3 ft. or 4 ft. high, very similar to *S. hypericifolia*; the leaves are small, ovate, wedge-shaped at the base, acute, with a small mucro, quite entire or rarely a little toothed at the top, and covered with spreading down; the flowers, which are in lateral stalkless corymbs, are white, the peduncles smooth, and the petals ascending. It is a native of Siberia, and flowers in May and June. This is the same as *S. ambigua*, *acuta*, and *sibirica*, and only a variety of *S. hypericifolia*, with ovate-cuneate, acute, slightly toothed or entire leaves, and with smaller flowers.

Crenated-leaved Spiræa (*S. crenata*).—This is another form of *S. hypericifolia*, with rather downy leaves, crenated at the apex, and very much smaller flowers, which have a yellowish tint; the flowers are arranged in stalked, lateral corymbs, and very small, the peduncles are covered with spreading down. It is a native of Spain, Hungary, and other parts of Europe, and it flowers in May. This is the same as *S. obovata* and *savranica*; and the *S. Besseriana* and *uralensis* are only slight varieties of it. Found on the Caucasian and Ural Mountains. *S. hypericifolia oblongifolia* of Loddiges is an upright, fastigiate variety, generally named *S. hypericifolia longifolia*.

Decumbent Spiræa (*S. decumbens*).—This is a small, decumbent shrub, from 6 in. to 9 in. high, with very slender shoots; the leaves, which are small, ovate, and blunt-pointed, regularly toothed towards the apex, entire at the base, are set on long, slender foot-stalks, tapering to the base, quite smooth, deep green above, and glaucous beneath; the flowers are in small, pedunculate, terminal corymbs, and white. It is a native of Siberia, and flowers in August; this is the same as *S. nana*, and the smallest of all the *Spiræas*.

Lance-leaved Spiræa (*S. lanceolata*).—An erect, neat little shrub, from 2 ft. to 3 ft. high, with rather small lanceolate leaves, which are deeply serrated towards the apex, quite smooth, deep green above, and pale beneath; the flowers are in close, few-flowered, pedunculate, axillary, umbels, and of a snow-white colour. It is a native of China, and flowers in August and September.

Reeves's Spiræa (*S. Reevesiana*).—This forms a spreading, slender, twiggy evergreen or sub-evergreen bush, 3 ft. or 4 ft. high, with lanceolate, acute pointed leaves, tapering to the base, and set on longish foot-stalks; they are coarsely and unequally serrated, quite smooth on both surfaces, glaucous beneath, and on the strong young shoots so deeply lobed as to be almost pinnatifid; but when old they frequently lose the three-lobed character; the flowers, which are rather large, and pure white, are arranged in terminal corymbs, and set on long peduncles. It is a native of China about Canton, and flowers from June to August. *Spiræa chinensis* and *cantonensis* are the same as this, and there is also a fine double-flowered variety of it.

Flowers in Corymbs, with Bladdery Carpels.

Guelder Rose-leaved Spiræa (*S. opulifolia*).—A large shrub 8 ft. or 10 ft. high, with rod-like shoots rather thinly furnished with leaves when young, and of a light brown colour when leafless; the leaves are mostly three-lobed and oval, doubly serrated, on longish foot-stalks, and frequently petiolated; the flowers, which are white and numerous, are disposed in stalked, hemispherical corymbs and smooth; the petals are spreading and slender; the carpels are in twos or threes, large, red when half ripe, and with the margins bladdery and membranous. It is a native of North America, from Canada to Carolina, on mountains, and flowers in June and July. There is a variety of it with much smaller leaves, which are greenish-yellow in colour.

Capitate-flowered Spiræa (*S. capitata*).—This grows from 3 ft. to 4 ft. high; it has ovate leaves, somewhat three-lobed, doubly serrated, netted beneath and tomentose, especially as regards the foot-stalks and calyx; the flowers are white, borne in terminal corymbs, somewhat capitate and set on long foot-stalks; the carpels are in twos and indented. It is a native of North America, on the eastern coast and on the banks of the Columbia, and flowers in June and July. This is the same as *S. opulifolia tomentilla*, and is generally considered to be a variety of *S. opulifolia*.

The Pinnate-leaved Spiræas.

Service-leaved Spiræa (*S. sorbifolia*).—This is a thick, stiff-branched, spreading shrub, from 4 ft. to 5 ft. high, with large pinnate, thin leaves, bright green on both sides; the leaflets are stalkless, lanceolate, opposite, doubly and sharply serrated, quite smooth and bright green; the flowers, which are small, are borne in large terminal, thyrsoid panicles, white and scented. It is a native of Siberia, where it is found in boggy places; it flowers in July and August. *S. pinnata* is the same; and there is a dwarf variety of it with much smaller leaves, and flowers twice the size, named *S. alpina* and *Pallasi*, found in moist places on the high mountains about Lake Baikal, Eastern Siberia, Kamtschatka, and the Amoor. This is the *S. sorbifolia*, *alpina*, *dauvarica*, *Pallasi*, and *grandiflora* of collections.

Lindley's Spiræa (*S. Lindleyana*).—A large, robust, thickly branched shrub, from 6 ft. to 8 ft. high, with very large pinnate leaves; the leaflets are lanceolate, regularly and doubly serrated to the base, slightly tomentose on the under side and feather-nerved, smooth on the upper surface, with the smaller teeth on the larger serrature, very small; the leaflets are very acute, stalkless, rounded at the base, and of a dull green colour; the flowers are in very large terminal thyrsoid panicles, and white. It is a native of Nepal, and flowers in July and August. This kind has the largest leaves of any of the *Spiræas*, and forms a remarkably handsome shrub in autumn, when few others are in flower. *Spiræa tomentosa* is the same thing, and the *S. Schizonotis* of Lindley, which means split back, is also another name for it.

Note.—The *Neillias* of Professor Don are considered by some botanists to be species of *Spiræa*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

A Bignonia Tree.—A mile or more from these premises (Rural Grounds) is a tree that, at this season of the year, everybody that catches a glimpse of in passing stops to examine more closely. It is the "Trumpet Flower" (*Tecoma radicans*). It is 12 in. in circumference at the ground, bifurcating 1 ft. above first into two, then, further up, into several stems, and 20 ft. in height. It is supported by a pole 19 ft. in height, and held to it by a chain. This pole is concealed by foliage, and the foliage is now covered with the large red trumpet flowers so well known everywhere. It is eleven years old from the cutting. Thus, from one of our most familiar climbers, a thing of singular and surpassing beauty is formed.—"Rural New Yorker."

An Ancient Oak Tree.—The following particulars concerning an old Oak tree just dug up at Burley will be read with interest. A day or two ago some workmen digging a trench on a roadside, opposite the Cardigan Arms, cut through several feet of black earth, thickly mixed with rolled and rounded sandstones, and then coming upon alluvial earth, struck at a depth of 15 ft. on a very long trunk of Oak, 8 ft. 9 in. in general girth, and of about the same girth throughout, from which they sawed out a length of 20 ft. The whole of the tree has, however, since been dug up, and it has been bought by Messrs. Hummerston, East Parade, Leeds. The dimensions of this Oak may be judged from the fact that it weighs 4 tons, and had to be cross-cut before being removed to the saw-mill. In colour it is of a ebony black, and the wood is sound throughout, though of course very wet, having been buried in the earth, it is conjectured, at least 200 years.

THE INDOOR GARDEN.

CULTURE OF COMBRETUM PURPUREUM.

THIS belongs to a somewhat numerous family, mostly ever green twiners from hot regions; but this is the only one that has met with much favour amongst plant growers. It does not grow so large as many stove climbers, and on this account it is more suitable for places where the space that can be afforded to it is limited. Its flowers, which are very handsome, are borne in large, spreading, fan-shaped sprays 1 ft. in length, and nearly as much in width: the colour, reddish crimson, is rich and deep; the flowers are individually small, but they are produced in large numbers, standing close and erect on the upper surface of the spike, which assumes a horizontal position. The plant is suitable for twining round a pillar, clothing a rafter, or training as a specimen on a trellis. In the latter case it can be used when in bloom for decorative purposes in a warm conservatory or heated Fern house; yet it must not be subjected to draughts in a cool house, as it is essentially a warm stove plant, coming from the hot, moist regions of Madagascar, and therefore cannot bear for any length of time either a low temperature or dry atmosphere. It is increased by cuttings, which by many are found rather difficult to strike. The strong young shoots are somewhat pithy, long-jointed, and liable to damp off. If cuttings made from growth of medium strength that has got two-thirds ripened in the summer be put singly in small pots, drained and filled with clean sand, and placed in a brisk heat moderately moist, and kept close, they will callus in a few weeks, and ultimately emit roots. As soon as these exist in sufficient quantities to support the cuttings, they should gradually be inured to air by tilting the propagating glasses more by degrees, until they can be dispensed with altogether. They should be kept at the warmest end of the stove, and when they have got enough roots to bear moving ought to be put in 4-in. or 5-in. pots. The soil should consist of good fibrous peat, without anything added, except sufficient sand to insure its keeping for years quite porous. This latter is essential, as the plant, from its evergreen character, cannot bear shaking out like some things. The soil must be kept moist, but not too wet. Syringe daily overhead, and slightly shade from the sun until the middle of September, when both may be dispensed with till the spring. As the days get shorter, reduce the temperature, which may be kept during the season of rest at 65° in the night, with 5° higher by day. Less water should be given through the winter. About the middle of February let them have 5° more heat by day and night, but do not pot them until the roots have begun to move freely, as they do not require nearly so much root-room as other plants. At the beginning of April they may be moved into pots 3 in. larger, giving them similar soil to that in which they were first potted. They should now have a few neat sticks inserted in the soil, round which to train them. They ought to have their points pinched out, so as to induce them to make several shoots. The night temperature may now be raised a few degrees, in the daytime letting it run up to 80°, after which give air, closing with sun-heat, and syringing each afternoon. A thin shade will now be required in bright weather. Do not overwater, as the *Combretum* is comparatively a slow-rooting plant, and until the roots have begun to enter the new soil, it is better to keep it a little dry. Continue to syringe overhead when the house is shut up in the afternoons, with a moist atmosphere day and night. As growth is made, keep the shoots trained regularly round the sticks, for if allowed to become entwined in each other, they are liable to get injured in undoing them. Nothing further will be required, except a continuance of this treatment, until the middle of July, when, if the plants have made sufficient progress to bear a second shift, again give them pots 3 in. larger, now using the peat in a little larger pieces than before. It is safer practice with subjects of this description that do not make rapid growth, to give two moderate shifts in the season than one large one, as, if the work be carefully done, they will not receive any check. They will now need larger and stronger sticks to support them, and through the remainder of the summer they will simply want attending

to as before. In September cease to syringe or shade, giving air and less moisture in the atmosphere, as well as at the root, so as to discourage their making much growth and to ripen up the shoots. Reduce the temperature 5°, both day and night, through the autumn, ultimately lowering it to the point I recommended for the preceding winter. During winter keep them in a light situation well up to the glass, for upon the wood being well matured will depend their flowering freely the ensuing summer. As the days lengthen again raise the temperature gradually as before, and in April move them into pots 3 in. or 4 in. larger, according to the quantity of roots they are found to have; in these they must remain through the summer. They should now be taken off the sticks, and stout wire trellises should be placed to the pots, round which the shoots should be trained, arranging them so that the bottom of the trellis shall be well covered. Their treatment through the growing season will require to be similar to that which was recommended for the preceding; by midsummer they will show flower, which will open some weeks later in the season. It will not be advisable to remove them from the stove to cooler quarters this season, as it would check their progress, and the object will be to increase their size and ability to bloom the ensuing summer. As the autumn advances, again give more air and less moisture, treating them as before through the winter. Before growth commences in the spring, if any over-long shoots exist they may be shortened back, but the knife must not be used too freely, or it will limit their power to flower. About the same time as previously they should be turned out of their pots, and any loose soil at the top of the ball that the roots have not taken hold of ought to be removed. Give them a 2-in. or 3-in. shift, and treat them subsequently through the season as before. When in flower they may be moved, as already mentioned, to a somewhat lower temperature during the warmest part of the summer. Each spring they ought to be turned out of their pots and as much of the soil removed as can be got away without much disturbing the roots, replacing it with new material, but the pots already recommended will be large enough for ordinary purposes, assisting them during the growing season with manure water once or twice a week. When grown on the roof or similar position, all that is required is to keep them regularly trained, not tying the shoots in too closely, but in most cases it will be found better to confine the plant to a pot than to turn it out, not the least advantage of which is that, so grown, it can be at any time moved to another place, and it will last for years in a pot when fairly treated.

T. BAINES.

Torenia Fournieri.—Allow me to call the attention of your readers to this most effective novelty. It was, I believe, introduced by M. Linden, of Brussels, as a species distinct from the old and well-known *T. asiatica*—a position to which I think it is fully entitled, notwithstanding that Mr. W. Thompson, of Ipswich, from whom I had the seed, is inclined to look upon it as only an improved variety of *T. asiatica*. It is of more upright habit, and branches in pairs proceed from every joint, giving the plant a candelabra-like form. The calyx is quinque-partite and angular, having the angles broadly winged. The corolla is much more irregular than in *T. asiatica*, having a broad standard petal, usually creased in the middle, so as to form a somewhat triangular hood. It varies in colour from pale lavender to almost white, while the two side petals and the lip are a glowing velvety-purple. The throat is pale lavender, with a bright yellow blotch, a similar blotch occurring on the lip just where the purple and the lavender join. It is extremely free-flowering, plants raised from seed in March last being now in full bloom, and showing numerous buds at every point. It grows freely in an intermediate stove, and has the valuable property of standing the atmosphere of an ordinary sitting-room without injury for a considerable time, and it will continue to expand its flowers there as well as in the stove. Its graceful habit of growth and chaste, elegant flowers, are sure to render it a great favourite wherever it is grown.—GREENWOOD PIN, F.L.S.

Worms in Pots.—The "Journal d'Agriculture Pratique" states that these can always be got rid of by using for the plants water to which a tenth part of grated Horse Chestnut has been added. Under this treatment, it is said, the worms must either fly or die.

Atamasco Lily (*Amaryllis Atamasco*).*Nemesia versicolor*.*Helichrysum Humboldtianum*.Immortelle (*Helichrysum orientale*).Three-horned Touch-me-not
(*Impatiens tricornis*).Japanese Windflower (*Anemone japonica*).*Loasa aurantiaca*.*Humea elegans*.The Bladder Ketmia (*Hibiscus Trionum*).American Nicandra (*N. physaloidea*).*Abrobra viridiflora*.*Chrysanthemum frutescens*.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDY FLOWERS IN LONDON GARDENS.

ANTIRRHINUMS, Phloxes, Pyrethrums, Hollyhocks, Violas, and Pentstemons are now in good condition in most gardens, and afford a good opportunity for making selections for the coming season. Among Phloxes *P. coccinea* is one of the best, a bright fiery crimson; *Frederic Soulie*, magenta; *Larina*, Queen of Whites, and *Miss Robertson*, white; *Walter Ware*, rich rose-lake; *Lierivalli*, purple with a white cross; *Mons. Marin Saison*, deep reddish-crimson; *Rifleman*, flesh with a dark rose centre; *Ruby*, deep crimson-purple; *Triomphe du Parc de Neuilly*, fiery salmon; and many others. The richest-coloured *Antirrhinum* I ever remember to have seen is *Mr. Swarbruck*, an intense deep velvety-crimson kind; *delicatum*, creamy-white with an orange centre; *Painted Lady*, white

Limncharis Humboldtii.

Leschenault's Loosestrife
(*Lysimachia Leschenaultii*).

striped and splashed with crimson; *album perfectum*, pure white; *Fire King*, crimson; and *King of the Yellows*; than these a better half-dozen could not be found. Some of the best double Pyrethrums are *Argentine*, *niveum plenum*, and *Olivia*, all pure white; *Haage et Schmidt*, velvety-crimson with a lighter centre; *Gloire de Stalle*, purple-carmine; *Marquis of Bute*, rich crimson; *Comte de Montbron*, magenta-red; *Herman Stenger*, rosy-lilac; *Garibaldi*, rose-lilac; *Prince de Metternich*, pure white with an orange centre; and *sulphureum*, pure white with a sulphur centre. Amongst Lilies all the *Tiger* varieties are now in flower, *splendens*, *erectum*, and the double form being the most distinct; if more be wanted add *Fortunei majus*, a kind with very woolly stems and large, bright flowers; *jucundum* (known also as *Lishmanni*) and *Maximowiczii*, cinnabar red; also the late and early forms of

Water Chestnut (*Trapa natans*).

Fruit of Water Chestnut.

the crimson *tigrinum*. Of the *speciosum* group I have only seen one variety, viz., *rubrum multiflorum*, a dwarf form, with very deep-coloured flowers and very floriferous; *L. superbum* and *auratum* are still in good condition. The Mexican *Tiger-flowers* (*Tigridias*) are very conspicuous, their large flowers and brilliant colours amply compensating for the short period during which the individual flowers last. Of *Rigidella flammea* and *Cypella Herberti*, plants closely allied to them, the former bears brilliant-flamed crimson flowers; this is, however, not quite hardy. *Tritonia aurea* is also finely in flower. Amongst tall-growing border plants the varieties of *Anemone japonica* stand in the foremost rank, their handsome foliage and innumerable flowers rendering them very attractive; the gem amongst all autumn flowers is still, however, as stated last week, *Senecio pulcher*, which when better known must

be everybody's plant. In the yellow-flowered *Centaurea babylonica* we have a good subject for the wild garden and shrubby borders. *Chelone Lyoni*, *obliqua*, and *obliqua alba* form a good group, in which the flower-spikes rise to a height of 2½ ft., and bear numbers of large, inflated, Pentstemon-like blossoms, both red and white. *Lychnis doica alba plena* is an excellent plant, which in strong soils often grows from 3 ft. to 4 ft. high, and bears flowers of the purest white, and very double. *Stevias* of different kinds look well in large clumps, their flowers being very abundant, and red, purple, and white in colour. *Catananche cœrulea* and *bicolor* are both good for cutting purposes, their flowers being bright and conspicuous. *Hypericum Gebleri*, which bears large yellow flowers on an erect stem 3 ft. in height, is one of the best of the large *St. John's Worts*. *Leucanthemum alpinum* and *L. lacustre* are effective plants when furnished in profusion with large, Daisy-like flowers; of the two the first is the best. *Bupthalmum salicifolium*, a fine, showy, yellow-flowered composite, makes a showy border plant, and one which is also useful for exhibition purposes. *Erythrina Crista-galli*, the Australian Coral-plant, is literally covered with rich crimson blossoms; in dry, warm situations it will live out-of-doors during warm winters. *Marvel of Peru* (*Mirabilis jalapa*), though a very old plant, is not grown half so extensively as it ought to be, and would be, could people see it in good condition bearing myriads of flowers of every shade of colour, as it is now doing. *Lithospermum prostratum* is flowering a second time; and of other plants fit for front rows in gardens may be mentioned *Eriogonum umbellatum*, a Californian species, with umbellate heads of yellow flowers; many *Campanulas*, especially the varieties of *turbinata*, *pusilla* (not *pumila*), *isophylla*, the white *cenisia*, *Hosti alba*, *garganica*, and many others, all of which are flowering beautifully in cool, shady spots. In similar positions are *Myosotis azorica* with indigo-blue flowers, the white variety, and *M. Impératrice Elizabeth*, a robust-growing form of *azorica* with lighter-coloured blossoms, all of which make good pot plants. *Potentilla sub-caulescens* and *P. alchemilloides*, the former yellow and the latter white, are interesting rock plants. *Thymus patavinus* is a neat and showy plant, having an erect habit and bearing large purple flowers; *Hypericum balearicum* and *ægyptiacum* are two interesting shrubs with yellow flowers; both are hardy on rockwork in dry, well-drained situations, and they also succeed well grown in pots in a cold frame. *Spiræa procumbens*, a shrubby species, scarcely 6 in. in height, is now covered with white flowers; this is quite hardy, and promises to be a most useful plant. *Linum monogynum* var. *candidissimum*, a graceful plant with snowy-white flowers, and *L. viscosum* with rose-coloured blossoms, are both interesting plants, that grow freely in any open loamy soil. *Delphinium chinense* and its varieties form a pleasing group of very dwarf plants, that will grow in almost any soil, and will continue in flower for a long time. The very interesting *Water Chestnut* (*Trapa natans*) is now in flower, and has been so for some time; the flowers are interesting but not conspicuous, but the fruit is the most remarkable part; the plant thrives in waters in the south of England. The showy *Limncharis Humboldtii* also flowers out-of-doors, but only, we believe, in water slightly warmer than it usually is in the open air with us.

[We this week terminate the series of illustrations of plants in flower from week to week, having now given them for more than a year. We propose to continue our notes on hardy flowers from week to week, however, and these can scarcely fail to be helpful to all readers interested in the matter, as they will be written by one thoroughly conversant with the hardy plants in cultivation and continually among them.]

Itea virginica is a native from New Jersey southerly, and there it attains the proportions of a large shrub; but here it is not so robust. Our plants are very small, nevertheless every little bit blooms; even plants scarcely 6 in. high are more flower than anything else. The flowers are white and in drooping racemes.

Hydrangea radiata and *H. arborescens* are now from 3 ft. to 5 ft. high, and every branchlet is terminated by a flat cyme of greenish flowers. The young wood is generally winter-killed a good deal, but the growth is very rapid, and though not very handsome, these species are the first to bloom.—W. FALCONER, in "Country Gentleman."

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 21.

THIS meeting was better attended than the last, and the exhibits, though not numerous, were in many instances of an attractive character. Messrs. Veitch & Sons sent a group of new and rare plants, which, together with a fine collection of cut blooms of seedling Gladioli from Messrs. Kelway & Sons, of Langport, formed the principal features of the show.

First-class Certificates were awarded as follows:—

Oncidium prætexum (Veitch).—A kind having dark green leathery leaves, and bearing branched spikes of drab-coloured blossoms, the centre of the lips being of a dullish yellow.

Phaius Dodgsoni (Williams).—A plant bearing large drooping clusters of Dendrobium-like flowers, with pure white petals, and orange coloured throat, surmounted on strong stalks, which are regularly furnished with lance-shaped leaves; a good addition to Orchids already in cultivation.

Ixora formosa (Fraser).—A seedling of compact habit of growth, and bearing an abundance of well-formed trusses of lemon and orange-coloured blossoms.

Begonia Queen of the Whites (Veitch).—A seedling from *B. roseiflora*, possessing the habit of *B. Veitchi*, and bearing pure white flowers with golden stamens. This is doubtless the best white kind yet raised.

Streptocarpus Greeni delicatus.—A free-flowering kind, bearing delicate white and lavender-coloured blossoms.

Gladiolus Prince George (Kelway).—A distinct kind with fiery scarlet blossoms, the centres of which are striped with white and purple.

Gladiolus Cymbeline (Kelway).—A variety with large flowers with delicate rosy-pink petals and pure white centre. A good sort for pot culture.

Gladiolus Baroness Burdett Coutts (Kelway).—A kind with bold, well-formed, pure white blossoms, the centres of which are conspicuously marked with violet-purple.

Gladiolus Charles Noble (Kelway).—A brilliant crimson flower with a white centre.

Gladiolus The Odalisque (Kelway).—A kind having cream-coloured, waxy, round flowers of good substance, with claret-coloured centre.

Pelargonium Lafayette.—A strong-growing kind, having large, horse-shoe leaves, and bearing fine clusters of salmon-pink, double blossoms. Well adapted for pot culture where large specimens are desired.

Pelargonium Littré.—A variety bearing bright rosy-pink blossoms very double and large in size. Useful for furnishing cut blooms.

Abutilon Lemoinei.—A good-habited kind having large, dark green, Vine-like leaves, and bell-shaped flowers of a pale yellow colour, produced freely from every shoot. A decided acquisition.

Blue Spruce (A. Waterer).—A silvery-leaved form of the type—of good habit, and ornamental in appearance.

Torenia Fournieri.—A desirable greenhouse plant, previously described in THE GARDEN.

Miscellaneous Subjects.—In Messrs. Veitch's collection of plants were good examples of *Dendrochilum filiforme*, *Lapageria alba*, *Cattleyas*, *Zygopetalum Sedeni*, and the brilliant-flowered *Begonia Davisi*. Mr. B. S. Williams, Holloway, sent a fine specimen of *Ixora Williamsi*, which was flowering for the third time this season; the same exhibitor also furnished *Croton fasciatum*, and a well-flowered plant of *Lilium auratum maculatum*. Mr. Cannell, Swanley, contributed examples of *Lobelia Brighton*, grown under glass and in the open air, to show its adaptability to both purposes; from the same source also came a box of cut blooms of the double pink *Pelargonium Thibaut* in excellent condition. Messrs. Kelway & Son showed cut blooms of *Hyacinthus candicans* which were much admired; a plant of the brightly-coloured flowered *Begonia*, *Empress of India*, was sent by Messrs. G. and J. Perkins, Leamington, who also exhibited cut blooms of *Phloxes*. Mr. Tong, gardener to J. S. Law, Esq., sent two baskets full of dwarf *Begonias* profusely flowered, evidently from the open air—a kind of treatment for which they appeared to be admirably adapted. A good plant of *Cologne* *corrugata* came from Mr. Green, Reigate, who had also a collection of *Streptocarpus*. Groups of double *Pelargoniums* and of cut blooms of *Dianthus* came from the Society's gardens at Chiswick, also cut blooms of *Salpiglossis sinuata*. Mr. Fraser, of Lea Bridge, sent baskets of seedling *Ixoras* in good flower; and Mr. A. Waterer sent flowering sprays of *Andromeda arborea* which were much admired.

Fruit and Vegetables.—Mr. Tillery, Welbeck, furnished good examples of *Queen Victoria* *Nectarines*; and Mr. Morse sent bunches of a new seedling *Grape*, the result of a cross between *Black Hamburgh* and *Muscat of Alexandria*; the bunches were large, as were also the berries, and the flavour was fairly good. A large scarlet-fleshed *Melon* of good quality came from Mr. Tong; and Mr. Burnett, The Deepdene, Dorking, showed a green-fleshed kind named *Incomparable*, of no particular merit. Well-ripened roots of *Trebon Onion* came from the Society's gardens, the flesh of which was very white and mild in flavour.

THE CAPSICUM AND ITS CULTURE.

THERE appears to be some uncertainty as to the native country of the Capsicum or Hot Pepper (*Capsicum annum*, *Peperoni* of the Italians, *Piment* of the French), now so universally spread over all tropical countries. Although long known under the name of Indian Pepper, it appears not to be indigenous in Asia, and there is no authentic record of its cultivation in Europe before the discovery of America. It is said to be really wild in that country, and *Cæsalpin* and *Clusius*, late in the sixteenth century, both speak of it as introduced from thence; yet, in the time of *Matthioli*, early in the same century, and, consequently, at a period when very few of the natural productions of the New World had been transplanted to the Old, we find, at least, three varieties well-established and abundantly cultivated in Italy under the name of Indian Pepper, which is hardly probable if it had been really introduced from America, then so recently discovered. A curious instance of the slowness with which the use of culinary vegetables is spread, is afforded by the large green mild variety of Capsicum, which is so much eaten over a great part of Spain and some of the adjoining French departments. It was carried by the Spaniards into Naples during their dominion in the sixteenth and seventeenth centuries, and has ever since remained in common use there, without spreading further. It makes an excellent ingredient in salads, having all the flavour of the ordinary Capsicum without the slightest pungency.

Cultivation.

Capsicums, in some parts of England, may be successfully grown in the open air, but where large supplies are needed it

Capsicum in open border.

is advisable to have some under glass also, in case of failure of the outdoor crop. The seeds should be sown early in April, in a gentle hotbed, or in pots or pans, well drained and filled with sandy loam and leaf-mould in equal parts, and if plunged in a gentle bottom-heat they will germinate more quickly and the plants will be much stronger than when only placed on bare shelves. As soon as they are large enough they should either be potted off singly into 4-in. pots, or three plants placed triangularly in 6-in. or 8-in. ones. In the latter case it will be found best to only fill the pots three parts full at first, with a view to earthing them up when the soil becomes full of roots. In order to have dwarf, shrubby, and healthy plants, it is necessary to place them as close to the glass as possible in a temperature of 65° or 70°, giving them liberal supplies of water, and admitting air freely on every favourable opportunity. Plants that are potted into 4-in. pots should not be allowed to become potbound, but should be shifted into 6-in. or 8-in. ones. Those plants that are to be turned out-of-doors should be gradually hardened off towards the latter end of May, and in June they may be planted out into a warm border under a south wall. They should be planted 10 in. or 12 in. apart, well watered when necessary, and in the event of cold weather setting in should have some slight protection afforded them; if the season be favourable, they will ripen their fruit from the end of August to the middle of September. Where, however, there are pits or frames available for Capsicums, they are the best places in which to grow them. Frames recently cleared of early Potatoes answer the purpose perfectly. The

plants should be put in 12 in. apart, kept well watered at the roots, and be frequently syringed overhead on sunny afternoons, and shut up with plenty of sun-heat. When in flower abundance of air must be given in order to assist them to set their fruit, after which time liberal supplies of manure-water may be given them with advantage. By adopting this method it is astonishing the quantities of fine, large fruit that can be gathered from a three-light frame. When Capsicums are planted out-of-doors or in frames, a light, rich soil composed of turfy loam, well-rotted leaf-mould, and cow manure in equal parts, with the addition of a little silver-sand, is best suited to them, but when grown and fruited in pots, a more solid soil will be found best, which can be gained by dispensing with the leaf-mould.

Varieties.

There are now many varieties of Capsicums, but the kinds mostly grown for culinary purposes are the Long Red, Long Yellow, and Small Red; the latter, which are the hottest, are sometimes called Chilies. The pods of these are used in a green state for pickling, when ripe for mixing with other things in sauces, and when in a dry state they are ground and used as Cayenne Pepper. Capsicums, although generally cultivated for culinary purposes, are far from being uninteresting as decorative plants. We have several varieties in our gardens, all bearing bright scarlet or yellow fruits, which contrast well with their deep green foliage. Yellow Gem is a dwarf-habited plant, with large, deep green leaves, and bright orange-furrowed, top-shaped fruits; Prince of Wales, a most elegant form, having slender branches laden with a profusion of small, oblong, sharp-pointed fruits of a pale yellow colour, is a sort that well deserves culture as one of the prettiest of all the smaller-fruited kinds; and C. Princess of Wales, which was the result of a cross between the two last-named varieties, is more robust than either, with fruits $1\frac{1}{2}$ in. long, top-shaped, and furrowed, the colour being intermediate between bright orange and pale yellow. These kinds are certainly worth growing for purposes of decoration only, and if grown dwarf and shrubby, the plants are very useful as well as beautiful, inasmuch as they last a considerable time when placed in a moderately cool house and kept well supplied with water. There are also several other valuable varieties for this purpose, namely Bird's Eye (very pretty), Cherry, Square, and the largest of all the Capsicums, The Monster. Well-ripened pods of Capsicums will keep good for several years if placed on a dry shelf, and the seed will germinate at six or seven years old if kept in the pods.

Insect Enemies.

The principal enemies of the Capsicum are green fly and red spider; the former may be easily kept in subjection by fumigation and the latter by a free use of the syringe on the foliage, and maintaining a warm, humid atmosphere in the house in which they grow. Those planted out-of-doors are generally most affected by red spider, their position being such as will not admit of those means recommended to keep the enemy in check being employed. The only way in this case to keep them in check is to give frequent waterings overhead and at the roots, and do all that is possible to promote a free and luxuriant growth in the plants. Curl in the leaf and fruit may often occur in outdoor plants in the autumn; this is, however, more or less occasioned by the cold nights following days of extreme heat. The only remedy is to shade slightly during the day, and afford a warm covering at night.

S.

Paraffin and Kerosene.—The English papers contain accounts of soaking Peas and other seeds in paraffin, to prevent their destruction by insects and birds. One correspondent wishes to know if the heat necessary to melt the paraffin will not injure seeds. His question is a very proper one, as paraffin is really a solid, like wax, which could only be used in the melted state, and it would probably have no protecting effect. The trouble rises from an incorrect use of terms. The illuminating oils, that we call kerosene, are in England known as paraffin oils, which have by usage come to be called simply paraffin. If our ("American Agriculturist") correspondent wishes to experiment, let him use kerosene, and he will be able to see how far the method of English cultivators will answer here.

The Society of Apothecaries intends to offer a silver medal for proficiency in botany, to be competed for by ladies only.

AMERICAN FLOWER AND FRUIT MISSIONS.

ONE of these Missions, established in 1869, has since that time been carried on successfully in Boston. From its "Proceedings," which have just reached us, we select a few passages which may prove useful to people interested in Flower Missions in this country:—The origin of this Flower Mission is entirely due to a Boston lady, to whom the idea of such an organization occurred as she was walking through the city with a bunch of Columbines in her hand, and noticed the eagerness with which a few hungry-looking children begged for the flowers. The same summer, she saw a great many Pears wasting in a friend's garden, merely because he knew of no one to whom he could send the fruit. These two incidents suggested to her a new charity. Through Mr. Chaney's influence, the use of Hollis Street Chapel was given, as a centre to which the flowers might be brought for distribution. A few friends living out of town were then consulted, and were kind enough to promise their help. The Chapel was opened May 10th, 1869, and a few young ladies received thirteen contributions of flowers and carried them to eight hospitals and thirty-six private cases. The average distribution for this summer was 121 bunches each day, which has since more than trebled itself, increasing in 1876 to an average of 370 bunches daily. As it began the first summer it has continued ever since, the chapel being open from eight to twelve o'clock every Monday and Thursday from May to October. Through June as many Roses and Lilies of the Valley as can be spared are gladly disposed of, for they are received with more enthusiasm than any flowers we have. One Rose goes a great way towards making a small, hot room more bearable, and an invalid more cheerful. But there is every variety of taste to suit, and if the sick are cheered with the more delicate, the work-room girl does not despise the Peony; and many old people, who have seen better days, ask affectionately for the Bachelor's Buttons and Hollyhocks familiar to them in their youth. One person we know has a fondness for Dahlias, some like curious specimens, and others ask for slips; whilst one very appreciative old lady says that even a green leaf reminds her of the "Great Giver," and is precious for that reason. Her daughter said to one of the ladies in the autumn, "You have no idea how much good you do with your flowers. I never realized it myself, although mother has always enjoyed them so much, until I was sick last summer; then I found I didn't care for anything so much as the flowers you brought me. Of course we need money and ever so many things that you can't give us; but somehow the flowers are better than anything else." We must also mention an old friend who shows us with pride a row of dried bunches which she pathetically says she can never bear to throw away. During the heat of July and August it is, we know, harder for our friends to send their contributions; but the flowers are especially needed in those months when there is more sickness and suffering of every kind, and those who cannot have country air should at least have a reminder that the world is not bounded by city walls. There is one woman who is paralyzed, and cannot stir from her bed unless lifted, who esteems the sight of a certain tree within view of her window, one of her greatest privileges. She is naturally only too happy to have a bouquet at her bedside. She almost lives on the fruit we are able to take her, as she is too old and sick to have any appetite for more substantial diet. As the tanks are filled, one or two ladies transfer their contents to baskets, and go out to the Bennet Street Dispensary or Diet Kitchen. At the Dispensary all sorts of people are assembled, waiting in the various rooms to consult the physicians. Of all the places that we visit this presents, perhaps, the possibility of a wider circulation of flowers than any other, as we rarely see the same persons twice. In fact, we always have to explain that our bouquets are not for sale, which creates surprise and pleasure. The Diet Kitchen, too, dispenses our flowers with its soup and milk, and the woman in charge says that many of the applicants for food, at the sight of the flower-basket in the corner, ask first for a bouquet and almost forget their proper errand. At twelve the carriage of some kind friend generally arrives, and we pile it high with baskets of flowers and send it off to the City Hospital. Much pleasure might be given if the flowers so freely used in the decoration of churches and at evening entertainments could be sent the next day to some hospital. A donation of this kind is always welcome, and the giver need not feel obliged to send it through the Flower Mission.

Opening Kew Gardens at Earlier Hours.—A public meeting was held on Tuesday evening last, at the Instructional Institute, Kew, to take into consideration the desirability of opening the Botanic Gardens at an earlier hour than at present, and the removal of the existing unsightly wall in the Richmond Road. The chair was taken by the Rev. P. W. Nott, M.A., Vicar of Kew, and amongst those

present we noticed E. C. Dermer, Esq., J.P., Lt.-Col. Burdett, J.P., Dr. Sellé, Major-General Nott, Dr. Atkinson, Hon. A. Turnour, Charles J. Cross, Esq., Edwin Ash, Esq., and C. Turner White, Esq. The first resolution was then proposed by Mr. White, and seconded by Mr. Bell, namely—"That the Royal Gardens of Kew having been dedicated to public use and enjoyment in the year 1840, and from that time maintained at the public expense, it is the opinion of this meeting that the same facilities for their free enjoyment should be afforded as at Hampton Court, Battersea Park, and other places, and that the present restricted hours of admission, namely, from 1 o'clock till sunset, is arbitrary, unnecessary, and quite out of harmony with the spirit of the age, and this meeting hereby pledges itself to use all constitutional means to procure the opening of the Gardens at 10 o'clock in the morning, without in any way interfering with the existing regulations regarding the houses." A gentleman from Northampton then addressed the meeting in support of the resolution, which was carried with acclamation. It was then proposed by Mr. Layton, F.S.A., seconded by Mr. Cross, and supported by Dr. Sellé, and carried unanimously—"That, in the opinion of this meeting, the present brick wall bounding Kew Gardens in the Richmond Road, which has been recently made more unsightly by being unnecessarily raised, should be removed, and a form of enclosure adopted, similar to that in use at the public parks and elsewhere, thereby giving increased light and air, and adding very much to the improvement of so important a highway." The third resolution—"That a permanent Committee be appointed to give effect to the foregoing resolutions, with instructions to take such steps during the next session of Parliament as they may be advised"—was proposed by Mr. Denton, seconded by Mr. Stock, and carried *nem. con.* Dr. Atkinson then proposed—"That copies of these resolutions be forwarded to all the Metropolitan Members of Parliament, the Members for the Home Counties, and the Members for the various boroughs in the same Counties." The resolution was seconded by Mr. Fletcher, and carried unanimously. The last resolution—"That a fund be raised, to be entitled 'The Kew Gardens Public Rights Defence Association Fund,' and that an account be opened with the Richmond Branch of the London and County Bank in the names of the Treasurer and two Members of Committee"—was proposed by Mr. Watson, seconded by Mr. Henry Pullman, and carried unanimously. After a vote of thanks had been accorded to the Chairman, the Honorary Secretary, Mr. C. Colman, jun., announced donations subscribed in the room to the amount of £68, and the meeting terminated.

Seedling Araucarias.—There are at present at Castle Wigg, Wigtownshire, several dozens of two and three-year-old seedling Araucarias, the progeny of a male and female tree there, which for the last four years have borne cones regularly. When the first batch was raised, I recorded the fact in your columns as the first Scottish Araucaria seedlings, and I have not seen any recorded since. Precocious fertility is, as you remark in your note (p. 125), very undesirable, but there are now many plants in the country between thirty and fifty years of age, and from these we may fairly look for a supply of edible seeds. The best seeds for propagation will for many years come from Chili; the best use to which we can put home fruits as yet is as an addition to dessert fruits.—SALMONICEPS.

Flow of the Sap.—In Mr. Murray's article on the flow of the sap (see p. 147) he states that in the case of a graft "the properties of the stock are carried up into the scion, but those of the scion are not carried down into the stock." Whilst walking through Mr. Barron's nurseries at Borrowash the other day, he showed me some common Laburnums that had been budded with the golden variety; several of the buds had died, but had remained attached long enough to inoculate the stocks, which had produced golden shoots both above and below the place where the bud had been inserted, and this was observable in several cases. I have also frequently seen in young Camellias that had been completely barked round the collar up to the surface of the soil by the larvæ of the *Otiorynchus*, a large callus form on the upper side of the wound, which I always supposed to be formed by the descending sap being arrested. Perhaps some of your correspondents who hold that there is no descent of the sap will kindly explain these facts.—CHAS. E. PEARSON, *Chilwell, Notts.*

Lifting Potatoes and Greening them for Seed.—Now that heavy rains have set in the disease is likely to be destructive, and all Potatoes that have finished their growth, if free from disease, should at once be lifted, dried, and carefully stored in some cool, dry place. If the disease have already made its appearance, lifting will not avail much. A *propos* of lifting Potatoes in a green state, especially for seed purposes, Nicol, writing in 1802, quotes a correspondent who had proved by actual experiment that the cause of the curl—which appears to have troubled cultivators about that period the same as it did last year—lies in the seed Potatoes being over-ripened, and recommends that they should be taken up whilst the

tops are green. It is, I think, a mistake to leave seed Potatoes spread out in the sun for the alleged purpose of greening or ripening them; it has an exhausting or weakening effect. An open, airy building or shed is the best place in which to store seed Potatoes for the present.—E. HOBDAY.

A New Anti-epileptic.—Professor Xavier Landerer, of Athens, states that he has been able to recognise in a substance that has locally acquired some reputation as a remedy against epilepsy, the root of the *Clematis cirrhosa* or *syvestris*. In two cases of epilepsy treated with a decoction of this root, which is strongly diuretic, there has been a cessation of the attacks for more than three months. The bruised fresh leaves of the plant act as a rubefacient, and sometimes even as a vesicant when applied to tender parts of the skin.—"Pharmaceutical Journal." [This is a beautiful, hardy, winter-flowering *Clematis*, which we have several times recommended for planting in mild southern districts.]

Birds Protected.—The civil tribunal of Melun, in the department of the Seine-et-Marne, has decided that a landowner is not entitled to destroy upon his own property birds which feed on animals and insects injurious to his neighbours. The plaintiff in this case alleged that M. de Segonzac had ordered his gamekeeper to place upon posts, not far from his (the plaintiff's) land, snares, in which owls, bats, and other night-birds were frequently caught; that in spite of the repeated complaints made, the destruction continued, and that in consequence the mice and other vermin had increased to such an extent as to spoil his crops. The tribunal, holding that these facts, if proved, would render the defendant liable for damages, have appointed three neighbouring farmers as experts to ascertain what damage, if any, has been done to the plaintiff's crops, and whether it has been caused by animals whose presence on his land is due to the destruction of birds of prey by the defendant. In the event of their answering these two questions in the affirmative, they are to assess the amount of damage done and report to the tribunal.—*Fall Mall Gazette.*

AUGUST.

THE eighth [month] was August, being rich arrayed
In garments all of gold down to the ground;
Yet rode he not, but led a lovely maid
Forth by the lily hand, the which was crowned
With ears of corn, and full her hand was found.
That was the righteous Virgin, which of old
Lived here on earth, and plenty made abound;
But after wrong was loved, and justice sold,
She left th'unrighteous world, and was to heaven extolled.
EDMUND SPENCER.

QUESTIONS AND ANSWERS.

Wood Ashes.—I have a considerable quantity of wood ashes from the burning of weeds and other refuse. Are they of any use mixed with earth?—M.N. [They are useful for adding to stiff clayey soils; also for killing Moss on lawns.]

Mignonette Destroyed by Insects.—Is there any remedy for the ravages of a minute insect which attacks the roots of Mignonette? When the plants are in full vigour they suddenly droop and die: this has only been the case with mine for the last three years, but now from a good thick border I have scarcely a plant left.—M. N.

Geranium Wallichianum.—Will any of your readers kindly inform me as to the period of the year at which this Geranium should bloom? It appears to have a remarkably robust habit, and carries a dense head of charmingly-cut foliage; also is it perfectly hardy? I should likewise be pleased if I could have the name of an older trailing Geranium which has flowers of good form about the size of those of the *Nemophila*, and of a bright, rosy-purple colour.—A. D.

Pond Weeds.—The enclosed is a fragment of fresh-water weed, which I presume is a species of *Alga* or *Conferva*. It infests two ponds in the public park here to such an extent that, if not raked out weekly, it fills the ponds like a huge green sponge. When taken out of the water it looks like so much green baize. Last summer I observed it for the first time, when it was confined to the lower of the two ponds; but this summer it is equally bad in both. Can you inform me what it is, and how, if possible, I am to get rid of it?—JOHN D. MITCHELL, *Kimberley Park, Falmouth.* [The plant sent is *Conferva littorea*.]

Bedding Plants from Seed Sown in Spring.—Would some reader of THE GARDEN be so obliging as to furnish me with a list of really effective bedding plants, which, sown in heat or otherwise in March, would flower the same summer, such, for instance, as *Lobelia* and *Tagetes*? Also kindly mention some fine-foliaged plants and their colour, the seeds of which might likewise be sown in the spring of the same year? The Dwarf Imperial Ageratum will not always flower in the same year in which it is sown, or very imperfectly. It is evidently a perennial in all its habits, and why it should be called an annual by seedsmen is strange. Castor-oil plants are very handsome this year; they have luxuriated in the heavy showers and gleams of sunshine. Associated with the ordinary bedding plants necessary for a formal set of beds, they would counteract the stiffness often disapproved of in this style of gardening.—M. S. H.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

MR. MONRO'S FRUIT GARDEN AT BARNET.

MARKET fruit growers, as a rule, adhere to the beaten track followed by their ancestors, but there are a few exceptions, and in some market gardens—Mr. Monro's, for instance—we find some entirely original methods of culture adopted. His garden, consisting of several acres, is, for the most part, covered with glass. It occupies a sloping position with a southern aspect, and therefore cold winds and frosts are to a great extent avoided, in proof of which we noticed a fine crop of Apples on a plantation of vigorous young trees which exists on one side of the grounds, whilst in other gardens in the same locality, not so favourably situated, scarcely a fruit can be found. The houses consist of about twenty lean-to and span-roofed structures, varying in length from 70 ft. to 250 ft., of proportionate width, and sufficiently high to admit of all necessary operations being conveniently carried on inside, and yet not so lofty as to necessitate a waste of artificial heat. All glass structures throughout the place are heated on improved principles, many of the boilers, which are Mr. Monro's own invention, heating, in some cases, several thousand feet of piping.

Grapes.

These form one of the most important crops grown here, many houses being devoted to their culture—a fact which will be understood when it is stated that a supply of excellent Grapes is obtained from April till the following March, or at least, as Mr. Monro remarks, he can depend upon a good supply nine months out of the twelve. The varieties grown are Black Hamburgh for early fruit, and Gros Colman, Lady Downes, Black Alicante, and Muscat of Alexandria furnish the mid-season and late supplies. The principal Vinery is a span-roofed one, 200 ft. long and 20 ft. wide. The Vines are planted inside, and the roots are allowed to run both inside and out, but no pretentious border has been provided for them. Their main stems are trained under the roof in the form of arches, and now that they are loaded with fruit they present a sight unusually interesting. From this house last year 2222 bunches of ripe Grapes were cut, and this year, as far as can be judged, there is probably a larger amount. Vine borders here receive little attention beyond being forked up and manured in spring, the soil being simply that of which the garden consists, which is of a yellow clayey character. In autumn, when the Vines need but little nourishment, the borders outside are planted with Broccoli or similar vegetables that can be removed before spring, when the Vines require to be again started. Heavy mulching and feeding when they are in full fruit, and when they require nourishment most are the principal points on which Mr. Monro depends, maintaining, as he does, that whilst at rest the ground can be turned to profitable account in the way just named without injury to the Vines. In a span-roofed house, 100 ft. long, planted with late sorts, no border whatever was made in which to plant the Vines; a sunk path was simply cut through the centre of the ground on which the house stands, and the Vines were planted on each side, the main stems being trained up one side and down the other alternately; on each of these there is now an average of twenty bunches, with the form and size of which any Grape grower might well be satisfied. As regards pruning the spur system is the plan adopted; no more fire-heat than is necessary is used, but in autumn, in order to finish the fruit properly, a brisk heat with plenty of air is applied to all Vines on which any fruit is hanging. Grapes are cut for market three times a week; each time all bunches which are perfectly coloured are cut and placed stalks upwards in wicker baskets, which hold about 8 lb. each. On some occasions 1 cwt. of ripe Grapes is sent from this place at one time, these supplies, as has just been stated, being obtained during the greater part of the year. As soon as the Vines have been cleared of fruit the

houses are closed for a few days and the syringe vigorously applied to the foliage to clear it of insects, &c., after which as much air as possible is admitted, and the roots receive a thorough soaking with water in order to plump up the buds and retain the foliage in a healthy state as long as possible, for whilst the fruit is ripening water is to a great extent withheld in order to improve the flavour and solidity of the berries; the roots consequently often get very dry before the crop is cleared, and hence the necessity of a good supply of water afterwards, a fact probably too often overlooked by Grape growers. A house planted fifteen months ago with small canes of Duke of Buccleuch, and only allotted a border about 2 ft. wide, has this year yielded some sixty-four good bunches of Grapes. The rods are planted closely together and fed with manure water, a system on which Mr. Monro intends to grow other Vines. He has lately planted a house 150 ft. long with young canes of Black Hamburgh for furnishing an early supply; this house, which is of singular construction, was originally intended for Cucumber culture, but these not succeeding in it so satisfactorily as could have been wished, it has now been converted into an early Vinery, a purpose for which it is considered admirably adapted. It is 20 ft. wide, and the roof, which is supported on side walls 3 ft. in height, is flat, 9 ft. fall lengthways in the roof only being allowed to throw off water. The interior arrangements consist of a series of beds, some 10 ft. wide and 15 ft. long, surrounded by low brick walls; between each of these beds are narrow paths, and also one the whole length of the house, on one side of which is likewise a bed 3 ft. wide, also the length of the house. In the centre of these beds the Vines are planted 3 ft. apart, and trained upwards, and when well established, good results in the way of large crops of Grapes may be reasonably expected. The beds are planted with Monro's Little Heath Melon, chiefly for seed; these, it might be thought, would greatly exhaust the soil, but this is easily counteracted by heavy manuring, mulching, and copious supplies of manure water whilst the Vines are in active growth; when the Melons have been cleared away, during winter this house is filled with bedding plants, which are grown here in quantity, over 30,000 being sometimes packed in one place. In spring it is used for Strawberries, and thus the whole space is kept fully occupied.

Peaches and Nectarines.

To the culture of these several large houses are devoted, and though the trees are planted outside in only the ordinary soil of the garden, the results obtained are very remarkable. Established trees in lean-to houses are trained on flat trellises fixed within 3 ft. of the glass; a path runs near the back wall, which is furnished with trees, and the ends of the shoots on the flat trellis are trained upwards, so that all available space is utilised in the most profitable manner, and yet the light and sunshine, so essential to the culture of the Peach, are in no way obstructed. A new plan as regards the growth of Peaches and Nectarines adopted here is worth notice; Mr. Monro calls it the ridge-and-furrow system, but it is, in fact, the cordon plan, which is largely practised in France. The trees, twenty-five in number, are planted 3 ft. apart, on the south side of a half-span-roofed house; their main stems are trained upwards to within 2½ ft. of the glass; each stem is furnished on both sides with healthy spurs, from which are emitted from five to eight shoots. When pruning, three or four of the best-ripened fruit-bearing growths are selected, and the rest are cut away, leaving in all cases a few eyes to furnish young shoots during the ensuing summer for supplying the next year's crop. The shoots which are left for fruit-bearing are not trained out horizontally, as is generally done in the case of Vines; on the contrary, they are trained towards the glass, and thus form, as it were, a ridge and furrow. The kinds of Peaches grown are Royal George, Noblesse, Grosse Mignonne, Late Admirable, Barrington, and other sorts, which naturally succeed each other, thereby prolonging the season during which fruit can be had in good condition. The Nectarines consist of such kinds as Violette Hâtive, Balgovan, and other popular sorts, all of which succeed on this system remarkably well. From this house Mr. Monro has this year gathered nearly 1500 large and excellent fruits, which have found a ready sale at good prices in the market. The house is

started in January, the trees being brought on gradually, and gathering commences towards the end of July, and until the beginning of August an abundant supply of fruit is obtained. The trees have only been planted three years, and so satisfactory have been the results that it is proposed to do away with trees trained in other ways and replace them with cordons—for whilst complaints are this year being made about Peaches falling off, these trees have carried a crop that would surprise many of our best fruit growers, three, four, and five large fruits being observable on single shoots. In order to still further utilise space, it is proposed next year to lower the main stems of the trees and train the shoots in a more upright way towards the glass, which it is considered will be an improvement. As yet the trees have only covered one side of the roof, but it is intended to train them down the other side, which is, however, for the time being planted with Tomatoes, on which there is a heavy crop—a result only attained by constant stopping of the young growths and the removal of superfluous foliage, so as to throw the vigour of the plants into the fruit. Peach trees, after being cleared of fruit, are well watered and the leaves kept well syringed, all air and sunshine possible being admitted in order to thoroughly mature the wood and buds. As soon as the leaves have fallen, all shoots which have borne fruit are cut back, and the young growths which have been selected for bearing next year are laid in their places.

Strawberries.

These are only grown for forcing purposes, some 9000 plants being annually fruited in pots. In the culture of Strawberries Mr. Monro's method differs from that generally practised. A plantation out-of-doors is always kept to supply runners, but instead of waiting until these have attained a good size, and layering them in pots (as is generally done), as soon as runners can be had with a pair of good leaves, they are severed from the plants and dibbled ten or twelve together in 6-in. pots filled with sharp sandy soil; they are then placed in a warm temperature, such as a Cucumber or Melon house, where a little shade and a moist atmosphere can be afforded them. When well rooted, they are shaken out of the pots and potted singly in 3-in. pots, and again placed in a warm house until they have become established, when they are hardened off and placed out-of-doors. Early in August they are potted into their fruiting pots in good, rich, stiff loam, and placed in an open, sunny situation on a bed of ashes, where they receive plenty of water, and all runners are kept regularly cleared from the plants, which are encouraged to ripen their crowns well before wet weather sets in, a point on which ultimate success greatly depends. Plants which have been forced are also used for that purpose a second time. As soon as the fruit has been gathered from them, they are hardened off and placed closely together out-of-doors in a shady situation, and are given plenty of water, and otherwise well attended to. In July they are shaken out of their pots and planted in well-prepared ground for a few weeks, where they get well hardened, and make a quantity of new roots close to the stems; they are then taken up, all the old roots cut off, and the stems cleared of dead leaves, &c.; the plants are then placed in their fruiting pots. Thus treated, they produce fruit quite as plentiful and good as that from runners. Strawberries here are placed in cold pits, &c., when bad weather sets in, and batches of about 1000 at a time are taken to Cucumber and Melon houses until they are in bloom, when they are removed to a more airy place to set their fruit; and when fully set they are placed in the large, flat-roofed house, already alluded to, to ripen, which by this time will have been cleared of bedding plants. Sir Charles Napier is the only kind of Strawberry grown here; its fine appearance makes it a good market fruit, and being firm-fleshed, it sustains little injury from travelling.

Cucumbers and Melons.

Many large houses are here devoted to the culture of these fruits, and the quantities cut every year for market are almost incredible. In one year over 25,000 Cucumbers were sent from this place to London, which represents some £533. These are principally grown in low span-roofed houses, with

3-ft. beds on each side, and in some cases a bed in the centre is devoted to Melons, the Cucumber plants at the sides being kept sufficiently within bounds not to injure the Melons by their shade. The Cucumber seeds are sown in the autumn, from which strong plants are obtained to furnish the winter supply; these are planted in loam and manure, and continue in bearing until spring, when they are succeeded by others planted out later in the season. During the summer Cucumbers are not grown here to any great extent, as, owing to such large quantities of outdoor or frame-grown ones coming from all the market gardens round London, house room is too valuable to be occupied by them. When the crops of Cucumbers are on the decline in summer the beds are covered with warm manure, spawned, and converted into Mushroom beds, from which bushels of good Mushrooms are gathered throughout the winter. The Cucumbers are then allowed to grow at will or die, but are not pulled up, as the foliage even when dead helps to darken the house, and thus furthers the growth of the Mushrooms. In Vineries, too, where no Vine roots exist in the inside borders Mushroom beds are made, *i.e.*, when sufficient heat is kept up in the houses to be favourable to their growth, which happens of course early in the spring. Perhaps this is as profitable a crop as can be employed to occupy such spare spaces, and if private growers, who are often short of a supply of Mushrooms, were to make up little beds in succession in similar positions, they would probably always have plenty. Melons, as before stated, are chiefly grown for seed, the large quantities of foreign fruit sent to market rendering the prices too low to be remunerative. Indeed, under any circumstances, Melons are not considered a paying market crop.

Pelargoniums of the Zonal and Variegated sections form the bulk of the plants grown here; these are struck in August from cuttings obtained from plants planted out for the purpose. They are roughly cut into shape and placed thickly in beds of sandy loam, surrounded by low, brick walls. When callused, these cuttings are taken up and potted. The chief aim here is to use all space to the best advantage; and valuable as land is near London, some is here spared for a few outdoor Roses and other flowers, which are planted round a well-kept Grass plot, giving the place a more interesting appearance than is to be seen generally in market gardens.

C. W. S.

The Caper Plant Hardy in England.—In the interesting account of the Capers (see p. 181), it is stated that *Capparis spinosa* is difficult to grow in this country, and greenhouse treatment is recommended for it: but the plant is perfectly hardy, and with a little care is very easy of management. It has been grown for many years at the Oxford Botanic Gardens, and I have had it here for the last four years, and this year it has been flowering very freely. I believe the secret of success to consist in only putting out well-established plants—young plants would be apt to perish. Plant it close inside a south wall, and if some stones be placed over it, it will find its way through them and trail very prettily over them; or it may be trained to the wall. It will entirely die down in the winter, but when in flower it is one of the prettiest plants that can be grown.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

English Names for Ranunculuses.—In describing two old garden favourites the other day in your weekly account of hardy flowers, you do not give their quaint old-fashioned names. The Double *Ranunculus acris* is well known in all old gardens as Bachelor's Button. The French call it *Bouton d'or*, and a particular kind of rich gold colour is always called *Bouton d'or*, after the time-out-of-mind old garden favourite. The double variety of a white *Ranunculus*—also an old garden favourite—is called *Fair Maid of France*, the double variety having perhaps been first introduced from France, as were many of our oldest garden flowers.—H. NOEL HUMPHREYS.

The Artillery Plant for Window Gardens.—A lady friend of ours has a large specimen of this curious plant, which she has grown since last autumn, in her kitchen window, and it has given her more satisfaction than all her other garden inmates. It kept constantly green and growing, and as sunlight increased its mantle of miniature muskets thickened, till now it represents a model numbrigeous tree, with boughs so succulent and heavy that a rough shake or breath would seem to shatter them. Associated with *Oxalises*, *Mabernia verticillata*, *Petunias*, and a few others, it made January look like May. A great addition to this kitchen window in mid-winter was the festooned drapery of the Madeira Vine.—"Gardener's Monthly."

NOTES OF THE WEEK.

BARBEROUS HORTICULTURE.—The "carpet bedding" which now does duty for flower gardening in so many places requires a good deal too much attention for its importance. In the London parks now men may be seen in the early morning armed with shear-like soissors, with which some of the poor little plants are clipped when they show themselves above the desired "carpet" level. Others will not bear clipping without suffering, and these the men have to mutilate with the finger and thumb. The result is sometimes described as "splendid," &c., but it is not gardening.

SPANISH MELONS.—Some of the usually despised Spanish Melons now sold so cheaply in our markets are really of a fine and peculiar flavour, which is distinct from that of our Melons, or from that of the deep-ribbed Paris Melon, being as rich as either and yet having a coolness and piquancy which is delicious to those accustomed to the often flat flavour of our Melons. It is noticeable that these Melons are out while green, and some of the most deliciously-flavoured of them that we have tasted were as green about the junction of stalk and fruit as a young Crab Apple.

A LOST BEAUTY REFOUND (*Milla biflora*).—This fine plant, long lost, is now in cultivation in a Continental garden, whence we hope it will some day again be distributed. The plant will not bear being handled at the bulb, nor being kept long out of the ground. It is a stately and lovely plant with pure white flowers.

BOUVARDIA HUMBOLDTI CORYMBIFLORA.—This large-flowering form of the well-known *B. jasminiflora*, so extensively grown for the London markets, is fast gaining favour with both florists and private growers. It is a free-growing plant, which yields clusters of handsome blossoms almost equal, as regards scent, to those of the well-known *Stephanotis*, for several months in succession, provided it is kept free from insects and has occasional applications of liquid manure supplied to the roots while it is in flower.—S.

SATYRIUMS.—Two interesting and novel representatives of this family of hardy Orchids are now in bloom in the Tottenham nurseries, *S. carneum* and *S. aureum*. The first-named has flowers of a delicate rose, and is a handsome plant. *Leucojum autumnale*, *Lilium Leichtlini*, *Hyacinthus candicans*, and many other good hardy plants are also in flower in the same place.

A NEW BALKAN PLANT (*Haberlea rhodopensis*).—This is a beautiful hardy plant, a native of Kalifer in the Balkans. In habit it resembles a *Ramondia*, the individual flowers being somewhat like those of the *Catalpa*, but of a bluish-lilac tint, and with a yellow throat. The plant has somewhat the appearance of a miniature *Gloxinia*, every rosette of leaves throws up from one to four flower-stalks, each with from two to four flowers. It blooms at the end of April in the open air, and is a fine plant for the rock garden.—M. L.

PLANTING IN HYDE PARK.—"I would respectfully recommend the following extract from an American work to Mr. Gerard Noel. It occurs in an account of Hyde Park in the 'American Cyclopædia,' under the heading 'Parks':—'The old trees are disappearing more rapidly than the young ones are brought forward; the turf is not well kept, and to avoid its destruction in many parts iron hurdles are placed along the walk. It is thus gradually losing its beauty as a park, for which its streaks of fine gardening here and there offer no compensation.' Really, I am afraid there is a good deal of truth in our American critic's remarks. Hyde Park is hardly kept up as it ought to be, and is by no means increasing in beauty."—"The World." [There is some truth in this so far as the trees are concerned. There is no attention paid to annual planting of fine trees and shrubs in our parks, parks which, on the other hand, are having a mad race with each other in the building of villages of glass houses for the subtropical and other plants which help to make up the evanescent bedding in autumn. This need not be done away with wholly, but ought certainly to be made subordinate to preparations for the permanent planting of the parks and for features which improve with time.]

THE LAVENDERS.—The Lavender (*Lavandula vera*) is now in full perfection. The fragrant blue flowers are arranged in axillary cymes, most of which are so close together as to form an uninterrupted spike. The floral leaves or outer bracts are rhomboidal and tapering, of a brown colour; those under each flower much smaller and narrower, but of the same colour. The calyx is nearly cylindrical and ribbed, with many veins, but is only furnished with one small tooth, which may be seen at the back of the flower; the corolla is two-lipped and of a deeper tint on its inner surface than on its outer. The lower verticillasters are often somewhat widely separated. In the *Lavandula spica*, which yields the oil of spike, there are very few characters by which it can be distinguished from *L. vera*. It

has, however, a denser habit and whiter aspect, and the spike is shorter and less interrupted, and it is more susceptible of cold, extending less far north than *L. vera*. As cultivated in botanical gardens in this country, its odour is scarcely to be distinguished from that of *L. vera*, and the inferiority of the oil of spike or essence d'aspic is probably caused by the use of the whole plant in distillation.—"Pharmaceutical Journal."

CANNA VIRIDIFLORA.—Herr Max Leichtlin informs us that this plant (recently alluded in THE GARDEN) requires to be kept growing all the winter in a warm house. In Germany (Manich), as in Paris, it flowers well in the open air.

WRECK OF THE POTATO CROP.—The Potato disease has followed the track of the thunderstorms and heavy rains which we have lately had, and the result is total destruction. There has been no attack so swift, so general, so complete for twenty or more years. Large plots of Potatoes, sound and healthy to-day, are converted into masses of rotten stems and putrid tubers to-morrow. It seems as if the lightning, of which there has recently been so much, had run across the Potato field, and scathed and destroyed the plants utterly, root and branch. A month or two ago the Potato crops never looked finer or better; now they have never been so bad. Unless the rain ceases and the sun shines forth with power this autumn-tide, it seems as if Potatoes must be wholly lost. We have had almost a month of intermittent thunderstorms and pouring rain, with a few most severe tempests—all favouring disease, and nothing but an intense drought, of which there is at present no sign, will save a mere remnant of the best Potato crop of modern times for seed. The prospect is gloomy in the extreme, and even within the last twenty-four hours enough rain has fallen to half wash the Potato crop out of the ground. The advice to store early is too late now. After the disease is abroad in such force, the Potatoes rot as fast after they are taken up as before. There seems nothing to do but to collect the diseased tops, where any are left, and burn them, and wait for fine weather to harvest any tubers left sound.—D. T. FISH.

FLORAL DECORATIONS AT THE AGRICULTURAL HALL.—Flowers when associated with music, as is now the case at the Agricultural Hall, afford perhaps the most efficient means of diffusing a love for them amongst townspeople. With this view floral arrangements on a liberal scale have been made in connection with a series of musical concerts held in the Hall just named. Mr. B. S. Williams and Mr. Wills furnished large collections of valuable Palms, Crotons, and other fine-leaved plants intermixed with Lilies, Orchids, Pitcher-plants, and other showy subjects, which were in some cases edged with a carpet of Club Mosses, in which were inserted choice cut flowers. We also noticed groups of *Gladioli*, around the bases of which were arranged Maiden-hair and other Ferns. Mr. Charles Turner, of Slough, contributed a fine collection of *Liliums*, effectively intermixed with fine-leaved plants, which by gaslight showed themselves off to good advantage. Mr. Ley, of Croydon, and Mr. Peed, of Norwood, also exhibited good collections of plants. Garden fountains and other ornaments were supplied by Messrs. Dick Radclyffe & Co. As in all other displays of this kind, there was room for improvement; but on the whole the arrangements were good, except that in the place of coloured flags which were suspended in great numbers from the roof, there might have been substituted a few hanging baskets of plants, if only of a common character. Semi-circular raised beds covered with turf were formed in various places on the floor of the Hall, and in these were tastefully and happily disposed light and elegant, fine-foliaged, and attractive-flowering plants, among which in some cases were introduced Pine-apples in fruit, and Grapes, Figs, Peaches, and other fruits in dishes. The prizes amounted to about £300, the principal one being £50.

Pentstemon lætus.—The number of blue-flowered *Pentstemons*, though much increased by recent introductions, is still sufficiently restricted to render acceptable any desirable addition to their ranks. The present plant is a close ally of *P. azureus* and *P. heterophyllus*, and like them is of dwarf branching habit, with linear-lanceolate to spatulate foliage, and blue flowers in terminal raceme-like panicles, but differs also from both the above species in the greyish glandular pubescence with which it is clothed, more especially the young growth. The foliage is also more fleshy, and occasionally toothed. The corolla is about 1 in. long, of an agreeable light blue, the lower lip being usually marked with two conspicuous white lines. It grows about 1½ ft. high, and blooms in July and August. It is a native of California, and is probably as hardy as most of the species from that region.—W. THOMPSON, Ipswich.

NOTES ON OUTDOOR PLANTS FROM EDINBURGH.

OWING to the long rains and almost sunless summer which we have had, rain falling frequently and more or less nearly every day during the last seven weeks, summer bedding plants, as well as those employed for perennial herbaceous borders, have this year been a comparative failure; of rock garden plants even, which are generally gay at this season, comparatively few are now in a free-blooming state, but they are generally in a healthy, though perhaps over-vigorous condition, in consequence of the moisture. With the exception of some late-flowering Liliums, such as *L. auratum*, *Humboldtii*, *Bloomerianum*, *Michauxii*, and others, the hardy autumn-flowering Heaths, *Dabæcias*, *Andromedas*, *Gaultherias*, and *Yuccas*, together with others recorded in the following list, at the present time only 126 species and varieties, exclusive of duplicates, can be counted in bloom. The list includes kinds selected for observation as to their yearly periods of flowering, and may be useful to those choosing plants to flower on their rock gardens during the month of August.

<i>Androsace lanuginosa</i>	<i>Linaria alpina</i>
<i>Arcebia echinoides</i>	<i>Lithospermum fruticosum</i>
<i>Bellis rotundifolia cœrulea</i>	<i>Meconopsis Wallichii</i>
<i>Calochortus luteus</i>	<i>Nertera depressa</i>
<i>Campanula isophylla alba</i>	<i>Orobanchi rubra</i>
<i>Campanula turbinata</i>	<i>Papaver alpinum album</i>
<i>Campanula turbinata alba</i>	<i>Papaver alpinum croceum</i>
<i>Cyananthus lobatus</i>	<i>Pterocarpus Parnassi</i>
<i>Dianthus alpinus</i>	<i>Santolina Chamæcyparissus</i>
<i>Dianthus deltoides</i>	<i>Schizostylis coccineus</i>
<i>Dianthus dentosus</i>	<i>Sedum cyaneum</i>
<i>Disa grandiflora</i>	<i>Sedum denticulatum</i>
<i>Eriogonum aureum</i>	<i>Sedum ibericum</i>
<i>Funkia lanceolata alba</i>	<i>Sedum kamtschaticum</i>
<i>Gaultheria nummularifolia</i>	<i>Silene Schaftæ</i>
<i>Gentiana asclepiadea alba</i>	<i>Teucrium pyrenaicum</i>
<i>Gentiana gelida</i>	<i>Thymus alpinus</i>
<i>Gentiana ornata</i>	<i>Veronica alpestris</i>
<i>Gentiana Wallichii</i>	<i>Veronica maritima alba</i>
<i>Gladiolus Pottsi</i>	<i>Veronica spicata</i>
<i>Gypsophila arenaria</i>	<i>Yucca angustifolia</i>
<i>Itea virginica</i>	

Royal Botanic Gardens, Edinburgh.

JAMES M'NAB.

ARRANGING OUT FLOWERS.

MANY who have flowers do not at all know how to arrange them so as to produce the best effect, while others seem born with a knack for doing such things in just the right way. Taste cannot be taught, but there are a few rules and principles on the subject so simple that any one can understand and follow them, and if people will keep them in mind when they have flowers to arrange, I think they will find them helpful. Just as flowers are the most beautiful decoration which any house can have, so the proper management of them is one of the most graceful of arts, and everything which makes home prettier and more attractive is worth study and pains.

1st. The colour of the vase to be used is of importance. Gaudy reds and blues should never be chosen, for they conflict with the delicate hues of the flowers. Bronze or black vases, dark green, pure white, or silver, always produce a good effect, and so does a straw basket, while clear glass, which shows the graceful clasping of the stems, is perhaps the prettiest of all.

2nd. The shape of the vase should also be considered. For the middle of a dinner table a round bowl is always appropriate, or a tall vase with a saucer-shaped base; or if the centre of the table be otherwise occupied, a large cunch shell or shell-shaped dish may be swung from the chandelier above, and with plenty of drooping spray and feathering green made to look very pretty. Delicate flowers, such as Lilies of the Valley and Sweet Peas, should be placed by themselves in slender, tapering glasses; Violets should nestle their fragrant purple in some small cup; and Pansies be set in groups, with no gayer flowers to subdue their soft, velvety hues; and—this is a hint for summer—few things are prettier than Balsam blossoms, or double variegated Hollyhocks, massed on a flat plate, with a fringe of green to hide the edge. No leaves should be interspersed with these; the plate should look like a solid mosaic of good colour.

3rd. Stiffness and crowding are the two things to be specially avoided in arranging flowers. What can be uglier than the great tasteless bunches into which the ordinary florist ties his wares, or what more extravagant? A skilful person will untie one of these, and, adding green leaves, make the same

flowers into half-a-dozen bouquets, each more attractive than the original. Flowers should be grouped as they grow, with a cloud of light foliage in and about them to set off their forms and colours.

4th. It is best, as a rule, not to put more than one or two sorts of flowers into the same vase. A great bush with Roses, Camellias, Carnations, Feverfew, and Pelargoniums growing on it all at once would be a frightful thing to behold, and the same remark applies to a bouquet made up of all these flowers. Certain flowers, such as Heliotrope, Mignonette, and Myrtle, mix well with everything; but usually it is better to group flowers with their kind—Roses in one glass, Geraniums in another, and not try to make them agree in companies.

5th. When you do mix flowers be careful not to put colours which clash side by side. Scarlets and pinks spoil each other; so do blues and purples, and yellows and mauves. If your vase or dish be a very large one, to hold a great number of flowers, it is a good plan to divide it into thirds or quarters, making each division perfectly harmonious within itself, and then blend the whole with lines of green and white, and soft neutral tints. Every group of mixed flowers requires one little touch of yellow to make it vivid; but this must be skilfully applied. It is a good practice to experiment with this effect. For instance, arrange a group of maroon, scarlet, and white Geraniums with green leaves, and add a single blossom of gold-coloured Calceolaria; you will see at once that the whole bouquet seems to flash out and become more brilliant.

Lastly. Love your flowers. By some subtle sense they always detect their friends, and for them they will live longer and bloom more freely than they ever will for a stranger. And I can assert from experience that the sympathy of a flower is worth winning, as will be found out when people grow older, and realise that there are such things as dull days which need cheering.—“St. Nicholas.”

Water Chestnut (*Trapa natans*).—This interesting aquatic plant, of which you have given an illustration (see p. 193), has white flowers with purple claws that float on the surface of the water among the foliage, the petioles being inflated similar to those of some of the marine Algae. The fruit, which is about the size of a Filbert, is very farinaceous. In the south of Europe, where it is abundant, it is made into bread; in France it is known as *Chastaigne d'Eau*; it is sold in the market at Venice as *Jesuit's Nut*, and is eaten after the manner of Chestnuts. It is sometimes called *Water Caltrops*, from the resemblance which the fruit bears to the spiked iron instrument (*calcestrata*), which was used in ancient warfare for strewing the ground to impede the progress of cavalry. It is only an annual, but still it can be grown in many parts of this country, and I have no doubt naturalized, and as it is exceedingly pretty when in bloom, it is well worth trying everywhere. It will grow in water 2 ft. to 3 ft. deep, and I should think wherever the *Aponogeton distachyon* would grow the *Water Chestnut* would succeed.—A. P.

Spent Bark for Covering Flower Borders.—This material, extensively used in some places for many years past, is invaluable to those whose gardens are liable to suffer from drought. I have a border here, under a wall, the soil of which is light and sandy, and where, during the hot days, we have been obliged to water plants and young trees, sometimes twice a day, to keep them alive. Lately I had nearly the whole of it first well watered, and then covered with about 3 in. of well-rutted spent bark. After about three or four weeks' almost daily exposure to a burning sun, I had it uncovered in several places, and found that the soil was still thoroughly moist, though no rain had fallen, nor had it been once watered. After a free use of it for some time, I am convinced that about three-fourths of the labour of watering is saved by the mulching, and the appearance of the beds is improved. I would strongly recommend 2 in. at least being used, more if possible, as it not only keeps the ground moist, but prevents weeds to a great extent from growing. The bark should be well rotted, even to soil, as was advised by a writer in THE GARDEN some months since.—C. F., *Merlwood, Parkstone*.

Green Crops for Orchards.—Mr. Yeomans, of Walworth, N.Y., enriches the land of his extensive and successful orchards by sowing Rye in the autumn, and when in full green head, ploughing under, following with sowed corn, to be ploughed under late in the season.

Cultivated Peach Orchards.—A correspondent of the “Michigan Farmer” mentions a strong case showing the advantage of placing Peach orchards on elevated ground, and away from frosty valleys. At Paw Paw, 25 miles east of Lake Michigan, and beyond what is termed the “fruit belt,” no Peach buds have escaped the frost of the past winter on level ground. On all elevations of 50 ft. or more all are alive; lower down the tops of tall trees have a few buds that have escaped. On the range of hills in that region, all the trees were loaded with blossoms from top to bottom.—“Country Gentleman.”

THE INDOOR GARDEN.

PROPAGATING CENTAUREAS.

ALLOW me to supplement Mr. Groom's remarks on this subject (see p. 155) with a little of my own experience in this matter. I know that the method described by Mr. Groom is a good and simple one, having practised it myself to a considerable extent. It often happens, however, that a considerable quantity of this plant is required, and that but a limited stock of it is possessed from which to propagate, and as the shoots available for cuttings during the summer are comparatively few, it follows that the process of working up a good stock is somewhat slow. Some years ago, when the great demand for these white-leaved plants set in, and when *C. candidissima* was hardly procurable in any quantity, the following method of increasing it was adopted, and found both easy and expeditious. Some good strong plants, well established in 8 $\frac{1}{2}$ -in. pots, were introduced into gentle heat in January; these plants possessed each some half-dozen shoots, the ends of which were removed with a sharp knife, and some of the old lower leaves were cut away close to the stem. The result of this treatment was that a number of very small shoots were produced up the stem; these, coming quite green, were free from that woolliness which characterises the plant, and which is the great obstacle to success as regards propagation. The cuttings, as they were taken off, were inserted in thumb-pots and placed on a brisk bottom-heat, where they quickly rooted at the rate of 95 per cent. This method of propagation may be continued several months, as if the plants which furnish the cuttings be kept in health fresh shoots will be formed in succession to those removed. I have since on several occasions employed this method of working up a quantity of *C. candidissima*, the species to which my experience has been mainly confined, but the other kinds may doubtless be similarly treated. If I had a good stock from which to cut, I should, I must confess, prefer treating them according to Mr. Groom's instructions, but in the case of those who possess but a few plants, and who are nevertheless desirous of making the most of them, I would say pot them now so that they may be firmly established before winter. As the cuttings root they should be carefully shifted into 3-in. pots, and when established removed to a cool house. I have remarked that these young plants are characterised by a very free after-growth.

Byfleet.

J. CORNHILL.

KENTIA CANTERBURYANA (VEITCHI).

FEW Palms are more handsome than this, and being of moderate growth, it is suitable for pot culture. It is a native of Lord Howe's Island; it is not an overquick grower, especially if somewhat confined as regards root-room, and consequently can be kept for a considerable time within the limits of a medium-sized house: neither does it require a strong heat, another important consideration with many who are desirous of cultivating Palms, but have not the convenience of a house wherein so much heat can be kept up as is needed by many of these exquisitely beautiful plants. Like most other Palms, it will grow in either peat or loam intermixed with broken crocks or charcoal and sand, so as to maintain the porosity

rendered necessary by the liberal applications of water required by it, especially during its season of growth. It should have a little shade in very bright weather, or the leaves are apt to become somewhat yellow, a circumstance which impairs their beauty. It forms a good centre plant for a moderate-sized house, contrasting as well with flowering as with other fine-leaved subjects.

T. BAINES.

CAMPANULA PYRAMIDALIS IN CONSERVATORIES.

THIS is by no means an ineffective plant for conservatory decoration, and its requiring no extraordinary amount of skill or space for its development ought to be a sufficient recommendation for its more general cultivation. It also forms beautiful beds by stopping the leaders when about 1 ft. high, and associates well with sub-tropical plants. Seeds of it sown during the months of June, July, and the first week of August will be sure to make fine plants, suitable for any of the above-mentioned purposes, during the ensuing summer and autumn months. The seeds being small, it is not easy to sow them as regularly as might be desirable; therefore, as soon as they have vegetated and formed one or two of their small but perfect leaves, they will require thinning, at the same time removing carefully Grasses or any other seedling weeds that may chance to make

their appearance among them. Although a hardier and more easily-grown plant than the Chinese Primrose or herbaceous Calceolarias, I treat the seed and seedlings in the first stage of their growth after the manner prescribed for these, sowing on the surface of previously-watered sandy loam and covering it with a piece of glass until germination has taken place; when fit to handle, the young plants are pricked off singly into soil of a similar character in small pots, which are then placed in coal ashes in a frame pretty close to the glass (within 6 in. or 8 in.), kept close for a day or two, and shaded if necessary, after which air and light are admitted freely. They must be afterwards well attended to as regards watering and repotting. The soil I find most suitable for subsequent use is a good fibry loam. If not naturally open, it should be made so by the addition of sharp river sand, leaf-mould, and well-decomposed hotbed or cow manure, the quality of the whole being regulated to suit the plant and size of shift required. Fre-

quent applications of manure-water will greatly benefit early-raised plants both now and on the return of spring, when they should receive their last shift. By following that course, I find that 9-in. pots are large enough in which to grow specimens with large leaves, which completely hide the pots from view, and beautifully-furnished flower-spikes from 8 ft. to 9 ft. high. Those planted out during the last week in May are equally tall and well furnished, but the flowers are not so large or so brilliant as those indoors. After the last shift, and when the future flower-spikes have lengthened from 9 in. to 12 in., if checked by removing the top, the plants will become very compact, and can be advantageously used in many ways out-of-doors during the summer and autumn months.—“Gardeners' Record.” [The white variety of this *Campanula* is one of the most desirable plants for the conservatory or greenhouse at this season. Its tall, white spikes, looking so cool and beautiful, are as fair as the costliest plants that may be grown for indoor decoration.]

Sweet Peas in Spring.—These, if sown now in 6-in. pots and moved under glass before frost occurs, will make useful early decorative plants for the greenhouse, or for supplying cut flowers.—E. HORNBY.

Finely-flowered Peristeria elata.—A plant of the *Peristeria elata*, or Dove Orchid, so well represented in *THE GARDEN* last week (see p. 153), is now in flower in the Birmingham Botanic Garden, where it is bearing about forty-five flowers and buds on two spikes.—W. B. LATHAM.

Kentia Canterburyana (Veitchi).

THE FLOWER GARDEN.

TUBEROUS-ROOTED BEGONIAS FOR BEDDING PURPOSES.

NO ONE who has not seen these most beautiful and invaluable plants, either bedded out in masses in circular beds slightly raised in the centre, or as single specimens each in the centre of a small round bed edged with a good Lobelia, or in a narrow border in front of a greenhouse, each plant framed in a ring of the ornamental *Polemonium variegatum*, can form any adequate idea of what a brilliant and continuous display of colour they provide during the whole of the three summer months from the middle of June to the middle of September. Then they may be lifted with good balls of earth, and without the slightest check put into pots for the decoration of the late autumn conservatory, where most of them will continue to bloom for another six weeks or two months, many of them not going to rest for the winter till the middle of November. Another great and conspicuous merit possessed by these plants is that even when in full bloom they are almost insensible of the heaviest rain, as torrents, which would knock every blossom off a bed of Zonal Pelargoniums, do not cause a single bloom to drop before its time, merely making the plant foot-stalks bend their heads to the storm, raising their lovely blossoms in all their brilliancy and beauty on the reappearance of the sun when the storm has passed. They are also of exceedingly quick growth, and should the bed become too crowded from having had too many plants put into it when they were in a small state, those that are in excess and interfering with the others may be moved into another bed, even when in full bloom and in the height of summer without undergoing the slightest check or interruption from the move, a good watering immediately after lifting has taken place being all that is required to establish the plant in its new position. They have also but few faults worth mentioning, the chief ones being that some of the varieties drop all their male blossoms (which, being invariably finer, larger, and of more perfect shape than the females, are a great loss) in a bud state unopened. Specially remarkable for this great drawback are Van Houtte's varieties, Mlle. A. Zimmermann of 1876 and Léon Plisson of 1875, and M. Deleuil's fine-foliaged and otherwise charming and novel-coloured variety *carnicolor*. Other fine varieties drop about half of their male blossoms unopened and expand the remainder; as an instance of this mitigated fault may be cited M. Fontaine's fine and brilliant Mons. Bienaimé. The tubers also, though apparently quite sound, sometimes refuse to start into growth when the season comes, nor can they be made to do so, artificial or bottom heat being of no use whatever for this purpose, and usually, when applied, merely resulting in causing the tuber to decay. The tubers when at rest are also unfortunately subject to the attacks of a white larva or grub of some kind, the eggs of which seem to be deposited in the earth of the pot, and the grub, if not discovered and removed in time, usually eating its way through the tuber and causing it to decay; the pots should therefore be got out, and each tuber carefully examined two or three times during the winter for the removal of these insect pests. The best and most distinct-coloured varieties now in cultivation are as follow, sent out by the well-known house of Van Houtte, at Ghent, in the present year:—James Backhouse, Laurent Desconrs, Baronne Hruby, and Notaire Beaucarne; in 1876 Madame Oscar Lamarche; in 1875 Paul Masurel, F. Lecomte, F. Siesmeyer, and Massange de Louvrex; and in 1874 Charles Raes by M. Victor Lemoine, of Nancy, France; in the present year Jules Janin, and W. E. Gumbleton; in 1876 Diamant, Oriflamme, Monsieur Marcotte, El Dorado (valuable as being the only real yellow as yet in cultivation); and in previous years Wilhelm Liebnicht, Rubens, Etna, Velours, and Corail Rose. To this raiser is also due the credit of sending out all the double-flowered varieties as yet in cultivation, most of which are very beautiful, though, as may not be known to many, only the male blossoms are double, the female being invariably single only. First and most beautiful of these stands Gloire de Nancy, on which the number of male blossoms produced largely preponderates over the females, consequently the very large majority of blossoms are double. This extra fine variety is

followed in order of merit by Lemoinei, Louis Thibaut, Louis Van Houtte, *Salmonia-plena*, *Balsaminiflora*. M. Fontaine, gardener to a private gentleman in the neighbourhood of Paris, has also raised and sent out through Messrs. Thibaut & Retteleer, the well-known nurserymen at Sceaux, the following beautiful varieties:—Monsieur Bienaimé, Lelia Hébé, and Mons. Piguy; a still more beautiful variety not yet sent out has also been raised by M. Fontaine, and named Exposition de Sceaux. M. J. B. Deleuil, of Marseilles, has also sent out Petrarque, Bayard, and Cleopatre. M. Vincent, of Bougival, has sent out a most beautiful and free-flowering cream-coloured variety, named Reine de Bougival. From Messrs. Veitch, of Chelsea, we have the fine varieties Acme and Kallista, sent out last year, and Vesuvius in 1875. M. Otto Friebe, of Zurich, has sent out the only pure white variety we have yet seen, under the very appropriate name of Mont Blanc.

W. E. GUMBLETON.

— Since Fuchsias were first taken in hand by hybridists, and the usefulness of the many fine varieties raised both for outdoor and indoor decorative purposes proved, it is a question if we have had any plants equal to them, unless it be the new race of tuberous-rooted Begonias, in which such advances have been made during the last few years. We have been so accustomed to associate the name Begonia with plants that almost all require considerable warmth, that many who have heard of, but not seen, the tuberous kinds grown in the open air, are slow to believe how well they succeed under such treatment; the fact is, that heat spoils them completely, and they are as much superior out-of-doors to what they are even in a cool greenhouse as they are in the temperature of the latter over that of an intermediate house or stove. Of this I felt more than ever convinced the other day, on looking over Messrs. Veitch's collection of seedlings at Chelsea; here they may be seen in every shade of colour, from the palest flesh to the deepest crimson; and in form varying from the large, broad, stout-petalled varieties, to the long, narrow, more elegant, drooping forms, clothed with a profusion of brilliant blossoms, the colours of which are intensified by open-air cultivation to an extent that would scarcely be credited by those who have not seen them. In addition to this, the other important point gained is a much closer, compact condition of growth, the leaves being, as might be imagined, much smaller, showing the flowers off to better advantage. For cool greenhouse decoration, the length of time they continue to bloom, their adaptability for cutting, and easy culture, commend them to all who grow flowers for such purposes. When grown out-of-doors, one great advantage they possess over most other plants is that no amount of wet appears to have the slightest influence in damaging their flowers, which they go on producing until cut off by frost. In the most favoured localities the roots, if left out through the winter, will sometimes survive, but it is better to take them up. For planting on rockwork, these Begonias have few equals.

T. B.

AMPELOPSIS VEITCHI.

AMONGST the great numbers of new plants that yearly make their appearance often with highly pretentious characters, it must be confessed that there are many more blanks than prizes in the shape of novelties that by their real merits are entitled to supplant established favourites. This holds good as regards both outdoor and indoor subjects, and it makes the majority of people cautious as to giving preference to any new comer until it has fully proved its superiority. As a plant for covering walls, draping verandahs, balconies, or any similar purposes, especially in towns where anything to be of use must have a free, vigorous habit so that it can succeed under adverse conditions of both soil and climate, the old Virginian Creeper (*Ampelopsis hederacea*) has long stood unrivalled; but from what I have seen of the more recently introduced *Ampelopsis Veitchi*, I feel convinced that it is destined to supplant the old species; in rapidity of growth under equal conditions, *A. Veitchi* appears to outstrip the old kind completely, the leaves having a more glossy and pleasing appearance; but the greatest advantage it possesses is that it requires no training, clinging to the bare

wall as fast and with more certainty than Ivy. It may be seen from Messrs. Veitch's Nursery, Chelsea, on some of the houses adjoining, closely clinging to the walls, yet withal hanging in graceful festoons from the eaves of three or four storey buildings, in some cases making its way on to the slates, and completely enveloping the chimney-pots. I have been told by a person who has it growing over the south side of his house that he never before experienced so much comfort in his bedroom during hot weather, as it effectually wards off the rays of the sun, and owing to the rapidity of its growth little time elapses before it covers a large surface. In autumn its leaves, like those of the common Virginian Creeper, acquire a brilliant colour, and I have no doubt that, when better known, it will become employed in such places and for such purposes for which the old Virginian Creeper has been almost exclusively used.

T. B.

MACLEAYA (BOCCONIA) CORDATA.

THIS, as will be seen by the annexed illustration, is a handsome herbaceous plant, now and then grown in English gardens, and

Macleaya (Bocconia) cordata.

a native of China. The foliage is large and graceful, and the feathery panicles of flowers possess a peculiar charm at this season of the year. For the wild garden it is one of the best plants with which I am acquainted; it has also a fine appearance isolated on lawns. It is, however, hardly adapted for the herbaceous border unless precaution is taken to pull up every year such shoots as stray away from the main plant; if this be done it can be kept from interfering with its neighbours, and that portion which remains is thereby strengthened. If very fine specimens be desired, the plant itself even should be thinned by pulling out all weak shoots when about 6 in. high. It is quite hardy, and appears to be passing under several names, but the one given above is the correct one. *B. frutescens*, a shrubby species from the West Indies, is very handsome in pots, but not hardy.

A. P.

Iridescent Moss.—There is near Portsmouth, Lancashire, a narrow tunnel, made by miners for the purpose of working the coal. This tunnel is many years old, and its sides are covered with a very minute Moss, which, when seen from the mouth of the tunnel, has a very delicate green metallic lustre. On going into the tunnel (about 5 ft. high) this lustre is not seen, and the Moss itself is nearly invisible. Its botanical name is *Schistostega pennata*.—T. WATSON, in "Science Gossip."

THE LIBRARY.

THE FERN WORLD.*

THIS is an elegantly got-up book, beautifully printed, and illustrated with a Woodbury-type frontispiece, three full-page engravings, a few woodcuts in the text, and twelve nature-printed coloured plates of the Ferns, to the glorification of which this work is devoted. Some of these last are very pretty, others, such as plate vi. which contains no fewer than seventeen distinct figures, cannot be so characterised; they are weak, and the eye is confused by the multiplicity of forms which is simultaneously presented to it. Mr. Heath says "it would have been opposed to the object of this work to illustrate it by mere drawings of Ferns—for the best drawing is frequently but a poor imitation of nature." This of course is true enough; but on the other hand a drawing of many of the species, if executed with moderate care, would give a far better notion of the plants represented—their mode of growth, habit, &c., than can be gained from the diminutive scraps which represent the Wall Rue (*Asplenium Ruta-muraria*), the Rusty-back (*Ceterach officinarum*), and the Forked Spleenwort (*Asplenium septentrionale*), on the plate to which we have already referred. Such a representation is, indeed, a libel upon the species supposed to be depicted; and we do not think these small and unattractive figures are at all calculated to bear out the glowing description which Mr. Heath gives of the plants they are meant to represent. Others of the plates, however, offend less in this particular; but all strike us as rather cramped and artificial in their arrangement, and in many cases the fertile portion of the fronds is not shown. As Mr. Heath himself is responsible for the collecting and grouping, we may say without offence that they are scarcely as satisfactory as might have been expected from one who is so thoroughly an enthusiast in his subject.

The author tells us that "the object of the present volume is twofold—it seeks to inculcate a love for the study of Nature, and to do this by making the reader better acquainted with that world of beauty—the world of Ferns." But other works, not a few, have been written with precisely the same object in view, and we cannot discover that Mr. Heath's book is better than (if as good as) some earlier volumes upon Ferns, though it is certainly a far more attractive-looking volume.

With regard to the growth of Ferns on rockeries, Mr. Heath shows fairly correct taste; but we cannot say as much for his chapter on their culture in pots, which is illustrated by a curious little figure resembling a bridal bouquet on a stand with a Fern shooting up through the middle, which is really intended for a Fern-pot. The author grows quite poetical on the subject of a Fern-pot. "Art may be exhausted," he says, "in the attempt to create chaste and fanciful contrivances for holding individual Ferns in so small a space. The receptacle may be cut in the most delicate forms of crystal; it may be moulded in the most elegant styles of majolica, terra-cotta, or after the most approved designs in silver—nay, or even in gold. We cannot condemn the taste which would seek to surround the charmingly-fronded child of the woods with the most costly productions of man's art." Notwithstanding this, however, and many passages of a similar character, there is a good deal of information in the book which is certainly an improvement on the author's earlier work on the same subject. If there are still to be found those who are unprovided with a book on British Ferns—for Mr. Heath's "world" is very circumscribed in its area—and who do not mind a little extra expense in procuring an elegant volume to lie on the table, this work will just suit them. It has chapters on the growth, classification, structure, uses, distribution, and folk-lore of Ferns, and on their culture and collecting, with detailed and rather verbose descriptions of each British species, and a flowing account of "some rambles through Fernland," i.e., Devonshire. We see no new feature in the book which calls for special criticism or commendation; nor can we discover that it differs materially from many of its predecessors in the same field.

JAMES BRITTEN.

Fossil Plants.—Under the title of "Fossil Plants and their Testimony in Reference to the Doctrine of Evolution," Mr. Carruthers has reprinted the two addresses which he delivered to the Geologists' Association in his presidential capacity at the opening meetings of the last two sessions. A lengthy and able summary of the evidence for and against, from a palæontological point of view, is carefully given, and the summing-up of the whole is strongly opposed to the views which are now so generally held by the leading scientific school. "The whole evidence supplied by fossil plants," says the

* "The Fern World." By Francis George Heath. London: Sampson, Low, & Co., 1877.

author—and we know of no one more capable of pronouncing an opinion on the matter—"is opposed to the hypothesis of genetic evolution, and especially the sudden and simultaneous appearance of the most highly-organised plants at particular stages in the past history of the globe, and the entire absence among fossil plants of any forms intermediate between existing classes or families." He considers, however, that facts testify to development and progression from lower to higher types.

Pollen.*—Most persons who have examined flowers under the microscope with any degree of minuteness are probably aware that the pollen of different species varies very greatly in the size and shape of the grains of which it is composed. The subject has of late years occupied a good deal of attention abroad, and has been taken up also in this country; and Mr. Edgeworth has brought together and epitomized the researches of previous observers, adding to these the result of his own investigations. A large number of figures are given in illustration of the subject, which amply show the great variety to be found even in so apparently trifling a detail of the economy of plant life. Although somewhat roughly executed, these figures will doubtless prove useful to workers in the same limited field of observation.

Popular British Fungi.†—This little work brings together from various sources a good deal of information with regard to our larger British fungi. The more interesting species are popularly described: the experiences of the various fungus-eaters as to the merits and demerits of the edible species are summed up: and there is a mass of information with regard to what may be termed the legendary lore connected with fungi—such matters as fairy-rings, witches' butter, Jews'-ears, and the like, being duly discussed. Although mainly devoted to British fungi, a few of the more interesting and remarkable exotic species are referred to at some length. The book does not profess to be a scientific treatise, but contains a considerable amount of information about fungi which is put together in a pleasant and readable form.

THREE NEW FERNS.

Pellaea Ornithopus var. Brachyptrium.—The original type of this beautiful and distinct Californian Fern, *Pellaea Ornithopus*, has been awarded a first-class certificate by the Royal Horticultural Society, which it well deserved. The variety is, however, even more interesting than the type. Its fronds are from 9 in. to 12 in. in height, erect, and of a glaucous green colour; the arrangement of the pinnules represent the claw of a bird.

Polypodium Scouleri.—This is also a Californian Fern, the fronds of which vary from 9 in. to 15 in. length; they are leathery in substance, having more the stout texture of *Lomaria Boryana* than of any other Fern with which I am acquainted. The creeping caudex is stout, and about 1 in. in circumference, of floury whiteness, and presents a striking contrast to the dark glossy green foliage. It is a Fern which is sure to be appreciated.

Polystichum munitum.—As a hardy evergreen Alpine Fern this bids fair to be one of the best in cultivation. It resembles a large *P. Lonchitis*, with fronds 9 in. (or more) wide, in noble plume-like tufts or crests, measuring 4 ft. or 5 ft., or possibly 6 ft. across. Even the half-grown fronds were unaffected by frost during the winters of 1874 and 1875.

W.

Sanders's New Dwarf Iberis (*I. coronaria pumila*).—The Rocket Candytuft, as is well known, grows in good soil some 12 in. to 16 in. high or more, and is therefore unfit for the smallest beds. The present variety is described as so dwarf that it can hardly fail to be useful both as an edging plant and for entirely filling small beds. It is said to grow from 4 in. to 6 in. high, and to form spreading tufts from 12 in. to 16 in. in diameter, which become covered with large, clear white flower-heads, the blossoms composing which are of good substance, and resist the changes of weather better than some other annuals. It is of easy cultivation, requiring only to be sown thinly where it should bloom, but may be transplanted while young.—W. THOMPSON, Ipswich.

THERE is a man who is said to be so fond of green Peas that he goes down to Algeria every January to meet them, and he follows the growth until he winds up at Aberdeen in the autumn. A pursuit of Strawberries would be more worthy of such devotion.

TREES AND SHRUBS.

THE CALIFORNIAN BUCKEYE.

(*ÆSCULUS CALIFORNICA*).

THIS dwarf, handsome-flowering tree was introduced into this country from California about twenty years ago. Its white and

Fruit of *Æsculus californica*.

slightly scented spikes of blossom are produced in profusion during July, and it may sometimes also be seen in bloom as late as the early part of August; indeed, I saw a fine tree of it nearly 20 ft. high beautifully in blossom in the first week of August this year. I was informed that it was budded on a

Unshelled fruit of *Æsculus californica*.

stem of *Æ. sanguinea* upwards fifteen years ago. It presented a striking appearance, having a well-balanced head covered with hyacinth-like spikes of flowers, more particularly so as they occurred at a season when most trees have done flowering. This tree is, I have no doubt, to be had in the trade; but it is either not known or not appreciated half so much as it

ought to be by planters. For a lawn, pleasure ground, or even a park, it is one of the most beautiful low-growing ornamental trees which we possess. It succeeds best in a rich, loamy soil, and in a dry, airy, sunny situation where its young growths can be well matured, thereby enabling them to withstand severe frosts. In damp low-lying situations it is apt to grow too late in autumn: by using a judicious selection of the different varieties of *Æsculus* a succession of their beautiful blooms may be kept up from early in May to the beginning of September. *Æ. rubra* and *flava* are the earliest bloomers, and *Æ. macrostachya* is the latest, the latter being not yet in bloom (August 20) with me. They have also highly coloured foliage in autumn, varying when it is dying off from reddish to yellowish-brown. The best and quickest method of propagating them where trees are wanted is to "work" them on the common Horse Chestnut, and they may also be reared from layers and seed, but by these processes it takes many years to get them up sufficiently to form trees—by the last-named method, however, new varieties may be obtained; and if they be intended only for forming flowering bushes, plants raised from seed or layers answer the purpose well enough, especially if they be cut close to the ground and afterwards allowed to form stools. Thus treated they will be found to grow much quicker into large bushes than if they were allowed to grow from the original seedling stem; when grown in the form of shrubs, they make beautiful flowering bushes on dressed lawns where there is room sufficient for them to fully develop themselves. Thus situated their spreading branches have a strong tendency to layer themselves, and by a little attention to pegging the outer growths down, plants covering a considerable surface may easily be obtained in a few years. If the soil in the situation selected for them be poor, it should be deeply turned up and good loam or other enriching material mixed with it before planting; a thick mulching of manure should also be spread over the surface above the roots after the operation of planting is finished. I may add that plants of it in Mr. Wheeler's nursery at Warminster look this year as if they would ripen seeds.

GEORGE BERRY.

Longleaf.

DESCRIPTION.—*Æsculus californica*, Nutt. Leaflets four to seven, usually five, smooth, oblong-lanceolate, acute, obtuse at base, slenderly petiolulate, serrulate, 3 in. to 5 in. long: flowers in a close finely pubescent thyrse which is 6 in. to 12 in. long: calyx two-lobed, the

lobes scarcely toothed: petals slightly unequal, white or pale rose, half-an-inch long or more: stamens five to seven; anthers orange-coloured; ovary densely pubescent; fruit unarmed, usually one-seeded; seed 1 in. in diameter.—Torr. & Gray, Fl. i. 251; Nutt. Sylva, ii. 69, t. 64; Newberry, Pacif. R. Rep. vi. 30, fig. 1; Hook. Bot. Mag., t. 5077. From San Luis Obispo to Mendocino Co. and Mt. Shasta, and in the foot-hills of the Sierra Nevada. It is usually a shrub 10 ft. to 15 ft. high, but sometimes in the valley, particularly between Monterey and Clear Lake; it is a widely branched tree, the base much expanded and occasionally 6 ft. in diameter, the trunk half as large and branching low, the main branches 1 ft. to 2 ft. thick, the whole forming a dense head 25 ft. to 40 ft. high and of still greater breadth. In May, when in full flower, it is a beautiful tree, but the leaves often fall before midsummer, so that for much of the year it is bare. Usually only two or three flowers in each thyrse perfect their fruit, often but one. The wood is soft and brittle.

—"Botany of California."

Flower-spike of *Æsculus californica*.

MR. MEEHAN ON TREES IN ENGLAND.

MR. MEEHAN, who has lately been in England, writes as follows to one of the Philadelphia papers:—"American trees grow much taller and have larger trunks than the English, which are all inclined to have low, spreading heads. The short, chubby stems of the English trees, however, often attain huge dimensions, and seem to attain a great age. In Buxted churchyard, in Sussex (the church one of the oldest in England), I measured a Yew tree which I have little doubt is over a thousand years old. The trunk was 23 ft. in circumference 4 ft. from the ground, it was 59 ft. high, and the horizontal diameter was 75 ft. As we regard the Yew as little more than a bush, I thought this the most wonderful tree I had ever seen. On the estate of Col. Vernon Harcourt, near this is a Beech tree, which is another wonder to me. The woody base of the trunk at the ground formed a circle of 39 ft., but it tapered up rapidly to 2 ft. from the ground, where it measured 23 ft. round, making a good straight trunk to some height, when it made numerous massive branches. I never before appreciated a majestic sight as applied to a tree till I looked up among these huge arms. The head covered a circle

of ground very nearly 100 ft. in diameter. On the same estate Elm and Ash trees from 12 ft. to 17 ft. in circumference were common. American trees—planted artificially, of course—are not common in England; and this is remarkable, as the few which I saw were generally doing well. In Battersea Park I was pleased to find a few of our Silver Maples. Catalpas are occasionally seen in the parks. At the Duke of Northumberland's, at Syon, are some fine Cypress trees, knees and all. In Mr. Hibberd's grounds, in Essex, I found a surprisingly large Pin Oak (*Quercus palustris*); and there are, here and there, a few Pin Oaks and Red Oaks in the gardens. At Kew are some magnificent Black Walnut and Tulip trees, but the Walnuts do not perfect the nuts well. It must be indifference to new introductions that makes American trees so scarce, as they seem to do well

in England generally. The Locust tree (called here *Acacia*) is common and does well. The American papers a few months ago gave extensive circulation to figures regarding the immense size of the first one introduced into Europe by Robin, after whom the plant was named Robinia. I measured it in the "Jardin des Plantes" a few weeks ago, in company with M. Neuman, the director, and found it be 9 ft. 2 in. round, and said to have been planted in 1601. A few days ago, with Mr. Smith, the curator, I measured the largest at Kew, and it was 12 ft. 10 in. round, or nearly $3\frac{1}{2}$ ft. more than its French and more famous rival.

I have referred to the planting of a tree in connection with the birth of a son, and I find the gardens at Osborne House, Isle of Wight, are full of memorial trees. The visit of the Emperor Napoleon in 1857 was commemorated by planting a beautiful example of *Abies nobilis*. It is now about 16 ft. high and is bearing beautiful cones. Its companion, *Abies Pinsapo*, planted by the Empress, had done better and was a very fine tree. There are some beautiful trees planted by the Crown Princess of Prussia (when she was but one year old) in 1841. One of the grandest trees on the grounds is one of our Pacific-coast trees, *Abies bracteata*, planted by the Princess Helena in 1855. It must be 33 ft. high now. Its branches are close to the ground, and these are 18 ft. in diameter. Poor Maximilian planted a tree here in 1871, and the one chosen is the yellow Cedar of our Pacific coast (*Cupressus Nutkaensis*). It is now about 18 ft. high, and has about 7 ft. spread of branches. Another very beautiful American tree—the *Libocedrus decurrens* of Torrey, about 25 ft. high—was planted in 1866 by the Princess Hohenzollern of Portugal. The names of the numerous planters and dates and the occasions are neatly painted on labels and placed by each tree. Those who think they may never "live to see trees grow" may take heart by the multitude of beautiful trees here, all planted by Prince Albert or the Queen. How rapidly trees may grow is also illustrated by the Oak planted by the poet Byron at Newstead Abbey. This he set in 1798. This tree I found to be 6 ft. 9 in. round. A propos of memorial trees I may note that the twin Beech tree, famous in the life of Byron as that on which he carved his name and that of his sister, on the last and memorable visit of the poet to his home, is still standing, but the branch on which his own was cut, has long since decayed away, the sister branch now having covered the whole stump. It must have been dead for some years, for it is only 2 ft. 6 in. round, while Augusta's branch is 5 ft. 2 in.

Mortality amongst Chestnut Trees.—The "Courrier de Bayonne" mentions that in the neighbourhood of Baigorry numbers of magnificent Chestnut trees have been completely dried up this year without any one being able to account for the singular occurrence. The sight which these trees present wholly deprived of foliage is most dismal; and what alarms the peasants more than anything else are the ravages caused by this new kind of plague, which has been also seen on a much larger scale in the district of Espelette. Even if the visitation should only continue for a short time, the fine clumps of Chestnuts in the ravines of the Pyrenees will be entirely swept away, the produce of which is one of the principal means of existence and prosperity of the peasantry. Some attribute the cause to insect work underground.—M.

The Trees of Judæa.—Judæa, once renowned for the number and variety of trees which grew within its borders, is now poorer than any other country in this particular. Mr. W. J. Martin, in his work on the East, says:—The only trees one meets are the Olives, which, however, are by no means plentiful in Judæa, and mostly old and stunted-looking. In Samaria we saw several considerable plantations of them, but yet that country is also sadly deficient of trees. Where now is the Oak tree on which Absalom hung by his bushy locks? There is, I believe, only one remaining sufficiently large for this; and yet we read that the "Wood of Ephraim," where he was defeated, destroyed more men than did the sword. And where is the Sycamore tree upon which Zachariah climbed? I doubt if there be one such within many miles; and yet we know that Jericho was once richly clothed with trees and verdure, and called the "City of Palms." Indeed, that Palestine generally was once extremely fertile, and rich in woods and verdure, is evident from the meaning of many of the Scripture proper names. . . . There is along almost every little water-course a number of what are called trees, but they are generally Willows of mere copse or brushwood. A tree of any description, of size sufficient to make an ordinary beam for building purposes, is quite a rarity—such are only to be found miles apart. The Vine, so much alluded to in the Bible, is somewhat rarely to be seen; but that it was extensively grown is evident by the traces of terraces upon the steepest hills still abundantly visible. Then as to the flowers—"The Rose of Sharon" and the "Lily of the Valley"

cannot be found. There are many wild flowers certainly, but generally they grow out of a "dry ground," and have, with very good blossom, almost no green foliage. "Thorns and Briars" are abundant, but with very little foliage also, and seem useful only for burning. The Fig trees are even few and far between, and the Orange, Apricot, and Almond still more so. The fields are not enclosed, except in some rare cases, where a wise husbandman has gathered the loose stones into piles around his border. Hedges are rare, but when seen they are generally formed of large Cacti covered with dust, having in the twilight a somewhat weird look.

INFANT HAWTHORN IN FLOWER.

THE annexed is a full-sized representation of a Hawthorn in flower. It was found in a bed of seedlings in our nurseries here. I have

never seen anything of the sort before, and think it may be interesting to your readers.

Dundee.

WILLIAM STEWART, JUN.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Gravity of Woods.—Those heavier than water are Dutch Box, Indian Cedar, Ebony, Lignum Vitæ, Mahogany Heart of Oak, Pomegranate, Vine; the lightest are Cork and Poplar. Lignum Vitæ is one-third heavier, Pomegranate rather more. On the other hand, Cork, having a specific gravity of .24 and Poplar, .333, are the lightest woody products.

Laurus Sassafras.—I recently met with a very large *Laurus Sassafras*. It is growing on a farm rented by Mr. J. Gaul, on Cox's Lane, near the Island Road, in the lower part of Philadelphia. The circumference of the trunk at 3 ft. from the ground is over 12 ft. The tree itself is about 50 ft. or 60 ft. in height. The first branches are about 12 ft. from the ground, and where they leave the trunk are curiously flattened, being about 9 in. thick to 2 ft. wide.

Spiræa cæspitosa is a low-growing shrub found in the south-eastern part of Nevada on limestone rocks, in Southern Utah and Northern Arizona on sandstone, and about Mount Nebo, in the northern part of Utah, on limestone ledges. It is perfectly hardy, evergreen, growing to the height of 2 in., hugging the face of the rock. It throws up flower-stems 4 in. to 5 in. high, with very small white flowers. This shrub often covers 7 square ft. from a single root.

Rhododendron californicum.—Among the many plants of California, there are none more deserving of cultivation than *Rhododendron californicum*. It is a shrub, growing from 3 ft. to 8 ft. high, according to situation; in general outline it resembles the well-known Eastern *Rhododendron catawbiense*. The leaves are about, when full grown, 5 in. long, in shape broadly lanceolate or oblong; in colour they are a bright shiny green. The flowers, like those of all *Rhododendrons*, are very handsome. They are borne in umbels. The florets (or separate flowers) are about 2 in. in diameter. The flowers are broadly campanulate in shape, the lobes or divisions being undulate; in colour they are of a rosy-purple to a clear, almost violet, purple; they vary with age; the upper lobes are yellowish or cream colour, spotted within. The stamens are shorter than the corolla, the filament being incurved.

Chilanthus californicus.—I found a single plant of this growing on a ledge of limestone in the Beaver Dam Mountains, S.E. Nevada, two years ago. It was then in full leaf. In September following I found the same bush in flower, and sent you blooms of it. I have since found it growing amongst the rocks on the Saven River, about forty miles from its source. Its finely cut foliage and hardness will make it a desirable shrub, if not already introduced. As it seeds abundantly, it will be easily disseminated. At the same time that I found the above shrub in flower (September, 1875), I found in a stream lead-north from the Rio Virgin, *Chilopsis linearis* in full bloom, and it was truly very pretty.—"Gardener's Monthly."

TROPICAL ARUMS AT KEW.

PERHAPS the untravelled can obtain no better idea of the deep, glossy green, the extraordinary luxuriance, and the strange and varied forms of the vegetable kingdom in tropical forests, than by visiting the Aroid house at Kew. This house, as its name implies, is principally devoted to the Arum family, of which the common Lords and Ladies or Cuckoo Pint of our hedge-banks is a familiar example. It contains the finest collection in existence. Next in importance comes the Imperial collection at Schönbrunn, near Vienna, founded by the late Dr. Schott, the learned and enthusiastic monographer of the natural Order Aroideæ. Although we find the most wonder-

A Tropical Arum.

ful diversity in size, habit, &c., the structure of the inflorescence unites about 400 plants in a naturally very well-defined botanical group. In our present paper we propose to confine our remarks to some of the climbing species to be seen by any of our readers who have the means of getting to Kew. Their great size and rapid growth will always prevent them from being commonly cultivated, but where space is not so much an object, or where walls and pillars require quickly hiding by varied and graceful forms, the following species will always be a source of true pleasure to every one who knows how to appreciate the beautiful apart from a mass of glaring colour. Little trouble and skill are demanded in the successful management of all we shall name. They grow on shelves, under which run the hot-water pipes for heating the entire structure. A little sandy loam and peat are thrown among a few pieces of stone or brick, and the plant is placed in the centre of the little cone. The trunk of a small tree with the branches not lopped off too short is held upright at a distance from the woodwork by means of iron brackets, and the adventitious roots of the plants tightly embrace every part of the stem. Until recently they were allowed to climb up the woodwork at the front and ends of the house, but on the removal of the sashes some year or two ago, the tree stems were fixed as above described, and the innovation, both from an economical and æsthetic point of view, is a good one. The Mexican *Monstera deliciosa*, also known as *Tornelia fragrans*, is, apart from the beauty of its leaves, worth growing for the sake of its succulent fruits, which have somewhat the flavour of a Pine-apple. From the Kew report for 1876 we learn that the first and only plant of this Aroid received in Australia

was sent from Kew; that the climate suits it admirably; that it has fruited with great success at Bowen Park; and that it is pronounced by the most competent judges to be, as its specific name implies, a really delicious fruit.

Rhaphidophora decursiva is climbing up one of the pillars, and its leaves, as seen from underneath, exhibit a great resemblance in texture and general appearance to those of some Cycads. *Philodendron squamiferum* is one of those which will well repay being kept in a small state. The leaves are curiously five-lobed, the terminal lobe being the largest, and the petioles are densely clothed with jagged and torn squamæ, deep vinous red in a young state, greenish-white when older. The peculiar leaves and petioles of this species render it a very desirable acquisition, even in select collections of stove plants. The next three possess much in common, all of them having cordate or sagittate leaves, which in *P. erubescens* are suffused with red on the under surface when young; the bracts, too, when first developed, are very nicely coloured. *P. Imbé* is larger in all its parts, and *P. sagittæfolium* is much larger still. *Pothos scandens* is from India (all those previously mentioned are from the New World), and has jointed leaves and winged petioles not much larger than, and like those of, the Orange; it is a vigorous grower and makes wonderful, long, whip-like shoots in a very short time. The leaves, thanks to the joints just spoken of, can bend themselves without trouble to any angle in order to catch any ray of light, no matter in what position the branches may be. When we consider the dense upper growth of vegetation in the jungles where the *Pothos* grows, the advantage of this arrangement to the plant in the struggle for existence is very obvious. The names of *Philodendron tripartitum* and *P. lacerum* will give some idea of their respective appearances; the latter has peculiar lobed

A Creeping Giant Arum (*Monstera*).

leaves. *Tornelia dilacerata* has beautiful, pinnate, arching leaves on long foot-stalks, and is not so stiff and formal as *Monstera deliciosa*, which it resembles. *M. dimidiata*, with entire, strongly-nerved, wavy leaves, is an extremely fast grower. This sometimes makes long, rope-like shoots more than 20 ft. in length in a single season. *Philodendron crassinervium* has long, narrow, strap-shaped leaves on short stalks, the median nerve being very much developed. The upper surface of the entire wavy leaves of *P. Lindenii* is a fine, velvety, dark olive-green, with the nerves shaded light green; the under surface is light green with maroon-coloured blotches between the veins. The petioles are thickly covered with long, green processes. This, with *P. squamiferum*, is extremely handsome and deserves to be more generally known. With the exception of *Pothos scandens*, it has smaller leaves than any of the kinds we have noted. We will conclude our list with *Philodendron giganteum*, the largest of all the group. The very large, light green, waved leaves are from 2 ft. to 3 ft. long by $1\frac{1}{2}$ ft. to $2\frac{3}{4}$ ft. broad, on stout foot-stalks 3 ft. to 4 ft. long. Nearly all the species mentioned, and we have intentionally selected them as

representing different types, send out roots from the very summit of the branches, which roots quickly reach the damp flags, and then, not before, unless injured, begin to branch. At the base of some of the pillars there is quite a large mass of roots on the naked stonework. As a final recommendation we may observe that when once these Aroids are established, it requires a considerable amount of neglect to make them look shabby. They are admirably adapted to take good care of themselves. Few plants are more easily propagated, heat and moisture being nearly all that they require.

Square-stemmed Bamboos.—The accompanying illustration represents portions of two square-stemmed Bamboos selected from an interesting work in the possession of M. Sisley, published in Miyako, Japan, in 1829, by a society of artists, and entitled a "Collection of Fine-foliaged Ornamental Plants and Trees." The drawings in this work are said to have been faithfully copied from Nature, and executed in the primitive Chinese and Japanese manner, viz, simply in black and white without any shading. One represents

Square-stemmed Bamboos.

a 'stalk entirely without leaves; the other has some foliage and evidently is intended to show the part where, with the leaves, the rudiments of bloom are to be seen. The stem is variegated with yellow like a chess-board. There can be no doubt that the plants are real Bamboos, as they bear either sprays, or the commencement of such, at the nodes. They were introduced into France about the latter end of 1876. Their appearance and foliage are most graceful, but the most remarkable part belonging to them is their four-cornered stems.—COMTE DE CASTILLON, in "Revue Horticole." [We have seen a small plant of this curious Bamboo in cultivation, and hope it will soon be plentiful in our gardens.]

Deep Soil.—The soil of Nebraska, according to President Furnas, is of a remarkable character, three-fourths of the whole State resembling alluvion, varying in depth from 5 ft. to 150 ft.—rarely less than 40 ft. deep. Four-fifths of its ingredients are fine silica, and the remainder consists largely of carbonate and phosphate of lime; requiring little or no drainage, and at the same time so retentive of moisture as not to be affected by drought.

PLATE LXXXIX.

DOYENNE DU COMICE PEAR.

Drawn by H. HYDE.

VARIETIES of the same fruit are so much alike that only remarkable merit can justify their being represented in colour in our columns. The fruit now figured well meets this condition, for it is pronounced by good judges to be the best Pear introduced to our gardens from abroad during the past twenty years—and this after long trial. Mr. John Garland, who sent us the fruit to figure, has furnished the following particulars respecting its growth at Killerton:—"This excellent Pear, which was raised in the garden of the Comice Horticole, at Angers, well deserves the attention of fruit growers. A young pyramid tree of it, sent by the late Mr. Brock, of Guernsey, to the late Sir T. D. Acland, was planted by me in the autumn of 1858. It grew well, and soon formed a shapely specimen of good but not coarse or robust growth. It has throughout borne so freely that the growth has been partly regulated by the crops of fruit, which should always be thinned to get them satisfactory in size and flavour. I first showed this sort in November, 1864, at the Devon and Exeter Horticultural Show, where it was awarded a prize as a new variety, and for three years in succession it was awarded first prizes at the autumn meetings of the Royal Horticultural Society in the class set apart for any sort of Pear; the second year, twenty-seven dishes were set up in competition against it, and the third year twenty-one dishes—the prizes being awarded in those two years to my Doyenné du Comice. One specimen blown down by the wind in October, and sent to one of the Royal Horticultural Society's meetings, weighed 1½ lb. I consider it to be the best November Pear in cultivation, taking all its good qualities in consideration. To prolong its season I have grafted some trees on the walls with this sort, which I allow to hang netted as late as possible. These succeed those grown on the pyramids, which also require to be put into bags, to protect them from birds—those made of newspaper being as good as any. The original tree here is grafted on the Quince stock, and is still very healthy and bears well. It is probably the parent of some thousands, as grafts of it were freely given to several of our leading nurserymen and others some years before they were distributed by ballot among Fellows of the Royal Horticultural Society. It is, I should think, one of the best market Pears in cultivation, as the late Mr. Jno. Taylor, of Messrs. Webber & Co., Covent Garden, told me they could not get enough of it. It should be grown in the most select collections."

The Sacred Basil.—Dr. George Birdwood writes in the "Academy":—"The most sacred plant in the whole indigenous materia medica of India is the Tulsi or Holy Basil (*Ocimum sanctum*), sacred to Krishna, and called after the nymph Tulasi, beloved of Krishna, and turned by him into this graceful and most fragrant plant. She is indeed the Hindu Daphne. The plant is also sacred to Vishnu, whose followers wear necklaces and carry rosaries (used for counting the number of recitations of their deity's name), made of its stalks and roots. For its double sanctity it is reared in every Hindu house, where it is daily watered and worshipped by all the members of the household. No doubt also it was on account of its virtues in disinfecting and vivifying malarious air that it first became inseparable from Hindu houses in India as the protecting spirit or Lar of the family. In the Deccan villages the fair Brahmin mother may be seen early every morning, after having first ground the corn for the day's bread and performed her simple toilet, walking with glad steps and waving hands round and round the pot of Holy Basil, planted on the four-horned altar built up before each house, invoking the blessings of heaven on her husband and his children—praying, that is, for less carbonic acid and ever more and more oxygen. The scene always carries one back in mind to the life of ancient Greece, which so often is found still to live in India.

Lilium Wallacei.—This is a new Japanese Lily, and one of the most distinct and beautiful ever introduced. It is, in the opinion of Mr. Baker, a garden hybrid, and probably a cross between *Lilium Leichlinii* and *L. Thunbergianum venustum*, having the foliage, tall-growing habit, and beautiful spotting of the former, with the bright colour of the latter; it is very floriferous, each bulb throwing up from four to six flowering stems. Evidently an attractive variety, judging from specimens sent us by Dr. Wallace.

PEAR DOYENNE DU COMICE.

LONGEVITY OF VARIETIES.

At the last meeting of the Michigan Pomological Society, upon the subject of "Longevity of Varieties and Races," Professor W. J. Beal, of the Michigan Agricultural College, had something interesting to say on this subject:—"To begin with, let us consider the question, what is a variety and what is a race? The seeds from one plant may not all produce plants quite alike, especially if they be sown in different places and treated differently as to light, heat, moisture, richness, and texture of the soil. The seeds of these plants after a year or more of such diverse treatment will or may produce individuals so distinct from each other that some or all of them may be called distinct varieties. All varieties of plants, using the term in its accurate signification, can only be propagated by removing some part of a plant and placing it where it may continue to grow; that is, it is grafted, budded, increased by cuttings, runners, layers, offsets, tubers, &c. Examples of these are, all our Apples, Pears, Cherries, Gooseberries, Strawberries, and Potatoes. A variety can never reproduce itself by seeds, for as soon as it reproduces itself with a considerable degree of certainty it is no longer a variety but a race. Races are obtained from varieties and hybrids by constantly selecting seed from those having the peculiarities desired, and planting them apart from other varieties. In this way, after a time, varying with the variety, it will come in time to seed, as we say, and nearly or exactly reproduces itself. In this way we have obtained most of our present races of garden vegetables, as all our different Cabbages, kinds of Lettuce, Radishes, Turnips, Beets, Cucumbers, Onions (those from seeds), Squashes, Indian Corn, Oats, and Wheat. Some Peaches will nearly always come true from seed—they are ceasing to be varieties, they are becoming races. We are getting new races every year. No doubt, with time and care enough, any variety may become a race, even any of our Apples, Pears, Pelargoniums, Verbenas, and Potatoes. Among animals we have examples of races in the different kinds of cattle, as Shorthorns, Devons, Herefords, and Galloways. The Berkshires constitute a race of swine, the South Downs a race of sheep, the Light Brahmas a race of fowls. In speaking of the longevity of varieties, we must make a distinction between these and what are termed races. There may be some reasons why a variety may degenerate while a race may not degenerate. In the case of most animals, new individuals are produced by fertilized eggs. Some of the lower forms are also reproduced or multiplied by buds or offshoots, which become independent individuals. These lower animals which often bud and branch like plants, are also occasionally, at least, reproduced by fertilized eggs. Our plants are multiplied in two ways—by budding, branching, &c., and by seeds or spores. Some of our lowest water plants consist of a single microscopic cell; this cell has a way of rapidly increasing in numbers by repeated division. We see no reason why this process might not go on for ever without degeneracy, but all plants some time or other under their normal condition produce seeds or spores—fruit in some form or other. Even in cases of these minute one-celled plants of which I spoke, once a year perhaps two of them approach each other and meet. The cell walls break away or disappear in certain places; the contents of one cell are all poured into and mingle with

the contents of the other. This mingled material forms two new walls about itself, escapes from the old shell, and floats away to begin a new growth the same as before. In some cases two rows of cells meet in this way, the contents of two cells being used to make a single new one. In other cases, three cells are united to form one. This blending of cells is a process answering to fertilization. It cannot, of course, go on continually without other ways of propagation, as there is a loss of 50 or 66 $\frac{2}{3}$ per cent. for every such spore which is produced. Why should the higher plants resort to the mode of reproduction by seeds if this mode be not necessary in some way to the well-being of the plant? Why should these lower plants blend two or three into one to fertilize and begin anew if the process be not of some advantage to the species?—"Prairie Farmer."

Campanula macrostyla.

—This is stated by Boissier in his "Oriental Flora" to be an annual, and to come from the shores of Lake Isauria near Mount Taurus in Asia Minor. It has flowered freely in the gardens of M. Godefroy-Lebeuf, at Argenteuil, and is really a pretty plant, even prettier than our engraving shows it to be, which scarcely does justice to the beautiful reticulations that exist in the inside of the flower. To M. Godefroy-Lebeuf we are indebted for the accompanying illustration. The plant has been freely grown in this country in various gardens of late, and will no doubt for the future find a place in our lists of good annuals.

Asteriscus mauritanicus.

—This is a dwarf, half-hardy, perennial Composite, allied to Bupthalmum, and producing an abundance of deep yellow flower-heads, about 1 $\frac{1}{2}$ in. in diameter, throughout the summer. It forms a dense tuft not exceeding 1 ft. in height, the foliage being obovate-spatulate, entire and somewhat fleshy, and of a glossy green. The flower-heads terminate all the shoots, and are about 1 $\frac{1}{2}$ in. across, each head lasting some time in perfection. It is closely allied to the *A. maritimus*, and may possibly be only a form of that plant, but it is horticulturally distinct, the foliage being of a more lively green and almost free from pubescence, and the flowers are of a deeper yellow. It is of easy cultivation in any soil, but should have a sunny exposure, and will flower most profusely when a year old. As its name implies, it is a native of Northern Africa.—W. THOMPSON, Ipswich.

Mauve Beauty Stock.—I

have a bed of this Stock now in bloom in front of my door. It belongs to the Wallflower-leaved section, and has the early blooming character of the Ten-week, with the perpetual habit of the East Lothian. It comes wonderfully true, both as regards colour and habit of growth, and produces a large proportion of double flowers. This Stock will suit "M. S. H." (see p. 196), or any one else who likes sweet-scented flowers of a soft, pleasing colour, and lasting character. The seeds should be sown about the end of February or early in March in gentle heat, and the young plants should be pricked off into pans or boxes, or potted singly into small pots, but they must not be allowed to become starved or pot-bound before being planted out. If well hardened off they may be planted out in April.—E. HOBDAY.

Kew Gardens.—Warm enthusiasm and concord characterised the proceedings at the public meeting held the other night at Kew, to consider the advisability of opening the Botanic Gardens at an

Campanula macrostyla.

earlier hour than at present, and also of removing what was justly termed the "unsightly" wall—a wall as melancholy as that which surrounds Clerkenwell prison—that now hides the grounds from the Richmond Road. This is not surprising; indeed it would be marvellous if any men besides those who are responsible for the blunder could be found to approve of such a selfish policy as to shut up from those who pay for it that which is bright and beautiful within a hideous, patched-up wall, and to keep the public outside except for a few hours each day. It is not to be expected that the public will consent to a serious and galling partial exclusion from an establishment of this kind, for the maintenance of which they pay more than £20,000 per annum, only to receive admittance when it pleases those whom they have put in charge to graciously open the portals of this Palace Beautiful. The public are its lawful owners; they have all along had to find the money, and it is monstrous in principle and practice to keep them outside at reasonable times, as was the case with several thousands last Bank Holiday, when they could be admitted without any injury to the gardens, or, indeed, to the scientific work of which so much spurious capital seems to be made. The resolutions adopted the other night were so clear and decisive that no one can mistake their meaning. Yet they were sufficiently moderate, for it is only asked that the gardens, and not the houses, may be opened at ten instead of one o'clock, and that a style of fence similar to that in use in the London parks and elsewhere may be substituted for the obnoxious and unnecessary wall.—"Richmond Times."

SCENT-YIELDING PLANTS.

By G. W. SEPTIMUS PIESSE, Ph.D., F.C.S.

Orris-root.

IRIS FLORENTINA is the plant which yields the Orris-root, everywhere so much esteemed. Even the peasant girls in Italy and in those countries which fringe the Adriatic possess a few hanks of Orris beads. M. Grazzini, a turner near Florence, produces more than two tons of Orris beads annually; beauty they have none, but their fragrance, like that of Violets, is lasting and always fresh. The Orris-root, having been slowly and perfectly dried, is cut with circular saws into cubes which are then converted into beads. Some hundredweights of chips and shavings result from this work, to the value of which I shall presently advert. The Iris florentina or Orris plant, for commercial purposes, is mostly farmed about Pontassieve, in Tuscany. The root harvest for each plantation takes place but once in three years, so that of necessity there are plants always on the farm in three stages of growth. The harvest takes place in spring, before the Iris begins its annual growth. The roots are dug up and the flags cut back, as shown in the annexed illustration; each root is then decapitated at a point indicated by the arrow A A; the head is then replanted and grows with great vigour, making in the course of three years numerous off-shoots in the form of fresh roots. This Iris flourishes best in a soil that is somewhat marshy and stony, a kind of land not often found except at Pontassieve, where it exists in perfection; it is, in fact, a poor soil, but notwithstanding that, the plants require no manure. The Iris florentina is of larger growth than the common Blue Flag of English gardens, and the flowers far less numerous, and of a very pale blue; moreover, it does not come into blossom when first transplanted into British soil until five or six weeks later than its naturalised English ally. In spring, when the roots are dug up, they are spread out to dry and ripen in the open air; each root is then trimmed by women with a short sharp knife into the shape in which it is found in the market. It is also at the same time sorted into the various qualities under which it is sold. The dark-coloured sorts are often bleached by means of the fumes of burning sulphur, an operation, however, which is very detrimental to them, as far as perfumery purposes are concerned, but for bead manufacture they are improved by being whitened.

For scent-yielding purposes the Orris-root is used in two forms; one in powder, the other as a spirituous tincture. For producing the powder or flour of Orris, the root has to be perfectly dried; it is then crushed under millstones, and finally reduced to powder in a drug mill. The Orris powder thus produced is mixed with dry Wheat starch in the proportion of 2 lb. of Orris to 12 lb. of starch powder; after being sifted and blended they are allowed to remain together for a

time, when the starch becomes fragrant, and the product is the well-known "Violet Powder" of the shops. In this way many tons weight of Orris flour are used. Almost all tooth powders contain about one-quarter of their weight of Orris-root flour. Shakespeare thus chides the Violet—

Whence didst thou steal thy sweet that smells,
If not from my love's breath?

When Orris flour is tied up in cushions or bags (sachets), and distributed among the clothes in a wardrobe, it gives to the linen a most delightful odour.

The tincture or essence of Orris is made by intermixing 1 gallon of rectified alcohol and 8 lb. of broken Orris-root; or better still, the chips and shavings from an Orris bead turnery. These ingredients should remain together in a glass or copper vessel for about a month. When drawn off, the tincture will be quite bright, and it is then ready for use. This extract enters largely into the composition of many of the most celebrated "bouquets," but it is never sold pure because its odour, although grateful, is not sufficiently sweet to win public favour on its own merits. It possesses little aroma itself, but

Root of Iris florentina.

it has the power of strengthening the odour of other fragrant bodies. The celebrated Ess Bouquet consists of one-third of its volume of extract of Orris, as does also the equally-famed Jockey Club Bouquet. The Iris florentina could be cultivated in several of the English colonies, more particularly the Cape of Good Hope, and that, too, with considerable profit.

Hughenden House, Chiswick.

Standard as to the Size of Nursery Trees.—The recent Convention of American nurserymen at Chicago came to the following conclusions as to the size, &c., of the trees for sale by them. Apples—two years, first quality, shall be 3½ ft. to 5 ft. in height, pyramidal in shape; clean trunks for at least 18 in. from the ground, and in good healthy condition: three years, first quality, shall be 4 ft. to 6 ft. in height, 10-16ths of an inch and upwards in diameter, 2 in. from the ground, and in healthy condition. Cherries—two years old, No. 2, shall be 3½ ft. to 4½ ft. in height, ¾ in. and upwards in diameter at 2 in. above the bud, and well branched: two years, No. 1, shall be from 4 ft. to 6 ft. in height, not less than ¾ in. in diameter 2 in. from the bud; well branched with clean trunks not less than 18 in. from the ground. Pears—first quality, two years, shall be from 4 ft. to 6 ft. in height, free from forks, and well branched: two years, No. 2, shall be from 4 ft. to 5 ft., well branched and free from forks. Plums shall be classed and graded as for Pears; shall be measured from the collar to the terminal bud, or main stem, and carefully dug. No claims for damage not made within ten days from receipt of stock shall be entertained.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 180).

Violets.

- (1) *Queen.* The Violets, Cowslips, and the Primroses,
Bear to my closet.
Cymbeline, act i., sc. 6.
- (2) *Angelo.* It is I
That, lying by the Violet in the sun,
Do as the carrion does, not as the flower,
Corrupt with virtuous season.
Measure for Measure, act ii., sc. 2.
- (3) *Oberon.* Where Oxlips and the nodding Violet grows.
Midsummer Night's Dream, act ii., sc. 2.
- (4) *Salisbury.* To gild refined gold, to paint the Lily,
To throw a perfume on the Violet,
To smooth the ice, or add another hue
Unto the rainbow, or with taper-light
To seek the beauteous eye of Heaven to garnish,
Is wasteful and ridiculous excess.
King John, act iv., sc. 2.
- (5) *King Henry.* I think the king is but a man as I am; the Violet
smells to him as it doth to me.
Henry V., act iv., sc. 1.
- (6) *Laertes.* A Violet in the youth of primy nature,
Forward not permanent, sweet not lasting.
The perfume and suppliance of a minute;
No more.
Hamlet, act i., sc. 3.
- (7) *Ophelia.* I would give you some Violets, but they withered all when
my father died.
Ibid., act iv., sc. 5.
- (8) *Laertes.* Lay her in the earth,
And from her fair and unpolluted flesh
May Violets spring.
Ibid., act v., sc. 1.
- (9) *Belarius.* They are as gentle
As zephyrs blowing below the Violet
Not wagging his sweet head.
Cymbeline, act iv., sc. 2.
- (10) *Duke.* That strain again. It had a dying fall;
O, it came o'er my ear like the sweet south
That breathes upon a bank of Violets,
Stealing and giving odour.
Twelfth Night, act i., sc. 1.
- (11) *Song of Spring*—When Daisies pied and Violets blue, &c.
(See Cuckoo Buds).—*Love's Labour's Lost*, act v., sc. 2.
- (12) *Perdita.* Violets dim,
But sweeter than the lids of Juno's eyes
Or Cytherea's breath.
Winter's Tale, act iv., sc. 4.
- (13) *Duchess.* Welcome, my son—Who are the Violets now
That strew the green lap of the new-come spring?
Richard II., act v., sc. 2.
- (14) *Marina.* The yellows, blues,
The purple Violets and Marygolds
Shall as a chaplet hang upon thy grave
While summer days do last.
Pericles, act iv., sc. 1.
- (15) These blue-veined Violets whereon we lean
Never can blab, nor know not what we mean.
Venus and Adonis.
- (16) Who when he lived, his breath and beauty set
Gloss on the Rose, smell to the Violet.
Ibid.
- (17) When I behold the Violet past prime,
And sable curls all silvered o'er with white,
Then of thy beauty do I question make
That thou among the wastes of time must go,
Since sweets and beauties do themselves forsake
And die as fast as they see others grow.
Sonnets, 12.
- (18) The forward Violet thus did I chide;—
"Sweet thief, whence didst thou steal thy sweet that smells,
If not from my love's breath? The purple pride
Which on thy soft cheek for complexion dwells,
In my love's veins thou hast too grossly dyed."
Sonnets, 99.

There are about a hundred different species of Violets, of which there are five species in England, and a few sub-species. One of these is the *Viola tricolor*, from which is descended the

Pansy, or Love-in-Idleness (see Pansy). But in all those passages in which Shakespeare names the Violet, he alludes to the purple sweet-scented Violet, of which he was evidently very fond, for all the eighteen passages tell of some point of beauty or sweetness that attracted him, and which is said to be very abundant in the neighbourhood of Stratford-on-Avon. And so it is with all the poets from Chaucer downwards—the Violet is noticed by all, and by all with affection. I need only mention two of the greatest. Milton gave the Violet a chief place in the beauties of the "Blissful Bower" of our first parents in Paradise—

Each beauteous flower
Iris all hues, Roses and Jessamin
Reard' high their flourisht heads between, and wrought
Mosaic; underneath the Violet,
Crocus and Hyacinth with rich inlay
Brodered the ground; more coloured than with stone
Of costliest emblem.

Paradise Lost, Book 4.

and Sir Walter Scott crowns it as the queen of wild flowers—

The Violet in her greenwood bower,
Where Birchen boughs with Hazels mingle,
May boast itself the fairest flower
In glen, in copse, or forest dingle.

Yet favourite though it ever has been, it has no English name. Violet is the diminutive form of the Latin *Viola*, which again is the Latin form of the Greek *ῥῶν*. In the old vocabularies *Viola* frequently occurs, and with the following various translations:—"Ban-wyrt," i.e., Bone-wort (eleventh century vocabulary); "Clœfre," i.e., Clover (eleventh century vocabulary); "Violē, Appel-leaf" (thirteenth century vocabulary); "Wyolet" (fourteenth century vocabulary); "Vyolytte" (fifteenth century nominale); "Violetta" Ace, a Violet (fifteenth century pictorial vocabulary); and "Cleape, Ban-vyrt" (Durham Glossary). It is also mentioned in the Anglo-Saxon translation of the Herbarium of Apuleius in the tenth century as "the Herb *Viola purpurea*"; (1) for new wounds and eke for old; (2) for hardness of the maw" (Cockayne's translation). In this last example it is most probable that our sweet-scented Violet is the plant meant, but in some of the other cases it is quite certain that some other plant is meant, and perhaps in all. For Violet was a name given very loosely to many plants, so that Laurembergius says:—"Vox *Viola* distinctissimis floribus communis est. Videntur mihi antiqui suaveolentes quosque flores generatim *Violas* appellasse, cujuscunque etiam forent generis quasi vi oleant" (Apparat. Plant., 1632). This confusion seems to have arisen in a very simple way. Theophrastus described the *Leucojum*, which was either the Snowdrop or the spring Snowflake, as the earliest-flowering plant; Pliny translated *Leucojum* literally into *Viola alba*. All the earlier writers on natural history were in the habit of taking Pliny for their guide, and so they translated his *Viola* by any early-flowering plant that most took their fancy. Even as late as 1693 Samuel Gilibert, in "The Florist's Vade Mecum," under the head of Violets, only describes "the lesser early bulbous Violet, a common flower yet not to be wasted, because when none other appears that does, though in the snow, whence called Snowflower or Snowdrop;" and I think that even later instances may be found.

When I say that there is no genuine English name for the Violet, I ought perhaps to mention that one name has been attributed to it, but I do not think that it is more than a clever guess. "The commentators on Shakespeare have been much puzzled by the epithet 'happy lowly down,' applied to the man of humble station in Henry IV., and have proposed to read 'lowly clown,' or to divide the phrase into 'low lie down,' but the following lines from Browne clearly prove 'lowly down' to be the correct term, for he uses it in precisely the same sense—

"The humble Violet that lowly down
Salutes the gay nymphs as they trimly pass,"
Poet's Pleasance.

This may prove that Browne called the Violet a Lowly-down, but it certainly does not prove that name to have been used by others for the Violet. It was, however, the character of lowliness and sweetness combined that gave the charm to the Violet in the eyes of the emblem writers: it was for them the readiest symbol of the meekness of humility. "Humilitas

dat gratiam" is the motto that Camerarius places over a clump of Violets. "A true widow is, in the church, as a little March Violet shedding around an exquisite perfume by the fragrance of her devotion, and always hidden under the ample leaves of her lowliness, and by her subdued colouring showing the spirit of her mortification, she seeks untrodden and solitary places," &c. (S. Francis de Sales). And the poets could nowhere find a fitter similitude for a modest maiden than

A Violet by a mossy stone
Half hidden by the eye.

Violets, like Primroses, must always have had their joyful associations as coming to tell that the winter is passing away and brighter days are near, for they are among

The first to rise
And smile beneath spring's wakening skies,
The courier of a band
Of coming flowers.

Yet it is curious to note how like Primroses also they have been ever associated with death, especially with the death of the young. I suppose these ideas must have arisen from a sort of pity for flowers that were only allowed to see the opening year and were cut off before the full beauty of summer had come; and so they were looked on as apt emblems of those who enjoyed the bright springtide of life and no more. But however it arose, the feeling was constantly expressed. Shakespeare expresses it in the collection of "purple Violets and Marygolds" which Marina carries to hang "as a chaplet on the grave" (No. 14), and again in Laertes' wish that Violets may spring from the grave of Ophelia (No. 8), on which Steevens very aptly quotes from Persius' Satires—

e tumulo fortunataque favilla
Nascentur Viola.

In the same spirit Milton gathering for the grave of Lycidas—

Every flower that sad embroidery wears,

gathers among others "the glowing Violet;" and the same thought is repeated by many other writers.

There is a remarkable botanical curiosity in the structure of the Violet which is worth notice: it produces flowers both in spring and autumn; but the flowers are very different. In spring they are fully formed and sweet-scented, but they are mostly barren and produce no seed, while in autumn they are very small, they have no petals and (I believe) no scent, but they produce abundance of seed.

I need say nothing to recommend the Violet in all its varieties as a garden plant. As a useful medicinal plant it was formerly in high repute—

Violet an erbe cowth
Is knowyn in ilke manys mowthe,
As bokys seyn in here langage,
It is good to don in potage,
In playstry to wondrys it is comfortyf,
Wh^o oyer erlys sanatyf.

Stockholm MS.

And it still holds a place in the Pharmacopœia, while the chemist finds the pretty flowers one of the most delicate tests for detecting the presence of acids and alkalies; but as to the many other virtues of the Violet I cannot do better than quote Gerarde's pleasant and quaint words:—"The Blacke or Purple Violets, or March Violets of the garden, have a great prerogative above others, not onely because the minde conceiveth a certaine pleasure and recreation by smelling and handling of those most odoriferous floures, but also for that very many by these Violets receive ornament and comely grace; for there be made of them garlands for the head, nose-gaies, and poesies, which are delightfull to looke on and pleasant to smell to, speaking nothing of their appropriate vertues; yea gardens themselves receive by these the greatest ornament of all chiefest beantie and most gallant grace, and the recreation of the minde which is taken thereby cannot but be very good and honest; for they admonish and stir up a man to that which is comely and honest, for floures through their beantie, variety of colour, and exquisite forme, do bring to a libell and greatte manly minde the remembrance of honestie, comelinesse, and all kinde of vertues. For it would be an unseemely and filthy thing (as a certain wise man saith) for him that doth looke upon and

handle faire and beautifull things, and who frequenteth and is conversant in faire and beautifull places, to have his minde not faire but filthie and deformed." With these brave words of the old gardener I might well close my account of this favourite flower, but I must add George Herbert's lines penned in the same spirit:—

Farewell, dear flowers, sweetly your time ye spent,
Fit, while ye lived, for smell or ornament,
And after death for cures;
I follow straight without complaint or grief,
Since if my scent be good, I care not if
It be as short as yours.

Poems on Life.

Walnut.

- (1) *Petruchio*. Why, 'tis a cockle or a Walnut-shell,
A knack, a toy, a trick, a baby's cap.
Taming of the Shrew, act iv., sc. 3.
- (2) *Ford*. Let them say of me, as jealous as Ford, who searched a
Walnut-shell for his wife's leman.
Merry Wives of Windsor, act iv., sc. 2.

The Walnut is a native of Persia and China, and its foreign origin is told in all its names. The Greeks called it Persicon, *i.e.*, the Persian tree, and Basilikon, *i.e.*, the Royal tree; the Latins gave it a still higher rank, naming it Juglans, *i.e.*, Jove's Nut. "Hæc glans, optima et maxima, ab Jove et glande juglans appellata est" (Varro). The English names tell the same story. It was first simply called Nut, as the Nut *par excellence*. "*Juglantis vel nux, knutu*" (Ælfric's Vocabulary). But in the fourteenth century it had obtained the name of "Ban-nut," from its hardness. So it is named in a metrical vocabulary of the fourteenth century—

Pomus Pirus Corulus nux Avelanaque Ficus.
Appul-tre Peere-tre Hasyl Note Bannenote-tre Fygge.

and this name it still holds in the west of England. But at the same time it had also acquired the name of Walnut. "*Hec avelana*, A^c Walnot-tree" (Vocabulary fourteenth century). "*Hec avelana*, a Walnutte and the Nutte" (Nominal fifteenth century). This name is commonly supposed to have reference to the hard shell, but it only means that the nut is of foreign origin. "Wal" is another form of Walshe or Welch, and so Lyte says that the tree is called "in English the Walnt and Walshe Nut tree." "The word Welsh (wilisc, woelisc) meant simply a foreigner, one who was not of Teutonic race, and was (by the Saxons) applied especially to nations using the Latin language. In the middle ages the French language, and in fact all those derived from Latin, and called on that account *lingue romane*, were called in German *Welsch*. France was called by the mediæval German writers *daz Welsche lant*, and when they wished to express 'in the whole world,' they said, *in allea welschen und in tintschen richen*, in all Welsh and Teutonic kingdoms. In modern German the name *Wälsch* is used more especially for Italian" (Wright's "Celt, Roman, and Saxon"). This will at once explain that Walnut simply means the foreign or non-English Nut.

It must have been a well-established and common tree in Shakespeare's time, for all the writers of his day speak of it as a high and large tree, and I should think it very likely that Walnut trees were even more extensively planted in his day than in our own. There are many noble specimens to be seen in different parts of England, especially in the chalk districts, for "it delights," says Evelyn, "in a dry, sound, rich land, especially if it incline to a feeding chalk or marl; and where it may be protected from the cold (though it affects cold rather than extreme heat), as in great pits, valleys, and highway sides; also in stony ground, if loamy, and on hills, especially chalky; likewise in cornfields." The grand specimens that may be seen in the sheltered villages lying under the chalk downs of Wiltshire and Berkshire bear witness to the truth of Evelyn's remarks. But the finest English specimens can bear no comparison with the size of the Walnut trees in warmer countries, and especially where they are indigenous. There they "sometimes attain prodigious size and great age. An Italian architect mentions having seen at St. Nicholas, in Lorraine, a single plank of the wood of the Walnut, 25 ft. wide, upon which the Emperor Frederick III. had given a sumptuous banquet. In the Baidar Valley, near Balacava in the Crimea, stands a Walnut tree at least 1000 years old. It

yields annually from 80,000 to 100,000 Nuts, and belongs to five Tartar families, who share its produce equally" (Gardeners' Chronicle.)

The economic uses of the Walnut are now chiefly confined

great value, as it allows the artist as much time as he requires in order to blend his colours and finish his work. In conjunction with amber varnish it forms a vehicle which leaves nothing to be desired, and which doubtless was the vehicle of Van

dyck, and in many instances of the Venetian masters, and of Correggio" ("Arts of the Middle Ages"—Preface). In mediæval times a high medicinal value was attached to the fruit, for the celebrated antidote against poison, which was so firmly believed in, and which was attributed to Mithridates, King of Pontus, was chiefly composed of Walnuts. "Take two dry Walnut kernels, as many Figs, of Rue twenty leaves, stamp all these together into one mass with a grain or corn of salt. Whosoever accustoms himself to eat of this confection in a morning next his heart, there shall no poison hurt him that day" (Phillips).

Walnuts are still very popular, but not as poison antidotes; their popularity now rests on their use as pickles, their excellence as autumn and winter dessert fruits, and with pseudogypsies for the rich olive hue that the juice will give to the skin. These uses, together with the beauty in the landscape that is given by an old Walnut tree, will always secure for it a place among English trees; yet there can be little doubt that the Walnut is a bad neighbour to other crops, and for that reason its numbers in England have been much diminished. Phillips said there was a decided antipathy between Apples and Walnuts, and spoke of the Apple tree as—

Uneasy, seated by funereal Yew
Or Walnut (whose malignant touch
impairs

All generous fruits), or near the bitter dews
Of Cherries.

And in this he was probably right, though the mischief caused to the Apple trees more probably arises from the dense shade thrown by the Walnut tree than by any malarious exhalation emitted from it.

Warden (see Pears).

H. N. ELLACOMBE.

(To be continued).

Agave Celsiana.

to the timber, which is highly prized both for furniture and gun-stocks, and to the production of oil, which is not much used in Europe, but is highly valued in the East. "It dries much more slowly than any other distilled oil, and hence its

and when fully grown is from 1½ ft. to 2 ft. in height, and 2½ ft. in diameter. It generally flowers when about the age of seven or eight years, and belonging, as it does, to the Spioate group, it makes new heads again after flowering, which may be taken off and struck, which they readily do if set on soil and kept dry for a time. The

Agave Celsiana.—This Aloe, named in honour of the late M. Cels, of Paris, a large grower of succulent plants, is well suited for purposes of decoration, on account of the distinct glaucous green colour of its foliage, which is about the same shade as that of *Echeveria glauca*. It is of a moderately strong habit,

marginal teeth are soft, and the apex, unlike that of most Agaves, is also soft, as is, indeed, the whole plant. When raised from seed the young plants vary a little, some being more and some less glaucous than the parent, and these seedlings have been introduced into collections under the names of *A. Oasselghemiana*, *concianna*, and *glauca*.—J. CROUCHER.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

September 3.—Sowing Mignonette in pots; also a large plot with Spinach for winter use. Putting in cuttings of Heliotropes to furnish blooms in winter. Potting batches of Pelargoniums and late-struck Fuchsias. Clearing off Onions, and placing them in fruit-cleared Vineries to dry ready for roping. Renovating the linings round Cucamber and Melon frames. Gathering Williams' Bon Chrétien Pears, and putting stakes to all fruit trees which require them, in order to prevent wind-waving.

Sept. 4.—Sowing Mustard and Cress in succession; also Red and White Turnip Radishes. Putting in cuttings of bedding Pelargoniums; also Ageratums and Lobelias. Taking up and storing away whilst perfectly dry Paterson's Victoria Potatoes. Earthing up Celery and Cardoons; also putting a little soil round Leeks. Forking over the surface of the ground between late-planted Cauliflowers, in order to admit the rain. Giving Peach and Nectarine trees on open walls a good washing with the garden engine to keep them free from red spider and other insects. Gathering Lord Suffield Apples and ripe Tomatoes. Watering carpet beds and other flower borders that are dry.

Sept. 5.—Thinning Turnips and Spinach. Planting out Coleworts from July sowings to come into use in winter. Making Mushroom beds and spawning others at a declining temperature of 85°. Forking the surface of the ground between newly-planted Cabbage and Broccoli plants. Stirring the soil between late Peas, Spinach, and Turnips. Clearing off Peas and Broad Beans, and preparing the land for other crops. Potting a batch of Carnations and Picotees; also Czar and Neapolitan Violets for early blooming. Tying Chrysanthemums and watering them with guano water. Gathering Summer Thorle, Golden and Kerry Pippin Apples and Pond's Seedling Plums. Watering Lettuce, Endive, and other salad crops in order to keep them growing and render them crisp.

Sept. 6.—Cleaning and roping Onions while the weather is wet. Picking over Potatoes and sorting out seed and bad ones. Washing shelves and pots. Cutting shreds, labels, and pegs. Cleaning out the fruit rooms ready for storing away fruit.

Sept. 7.—Sowing a batch of Osborn's Early Forcing French Beans in pots for a supply at Christmas. Putting in Ageratum and Heliotrope cuttings for winter blooming. Rolling gravel walks after rain. Removing runners and weeds from Strawberries in pots which are intended for forcing, and placing them further apart, so that they may be fully exposed to air and sun, and their crowns become more hardened. Thinning Turnips and July-sown Carrots; also late-sown Mignonette. Digging borders ready for planting with Cauliflowers and Lettuces. Shifting a portion of Cinerarias and Primulas to warmer quarters. Earthing up Celery. Gathering Coe's Golden Drop and Kirke's Plums; also Williams' Bon Chrétien Pears. Watering Pines and inside borders of late Vineries.

Sept. 8.—Planting Lettuces and Endive in borders so that they can be conveniently covered with spare frames during winter. Pruning Laurels and other shrubs which require it. Stripping leaves from Cabbage stamps, in order to get sprouts for the winter. Making a new Mushroom-bed and turning more manure for others. Gathering Louise Bonne of Jersey and Jersey Gratioli Pears. Fruit in use for dessert—Pines, Melons, Grapes, Peaches, Nectarines, Pears, Apples, and Plums.

THE AMATEUR'S GARDEN.

[By THOMAS BAINES.]

Plant Houses.—Whatever requires to be done to plant houses, pits, and similar structures in the way of repairing the glass and painting should be immediately carried out before the plants now standing out-of-doors are brought in, as at no other time of the year can this work be accomplished with less inconvenience. It is a great mistake to allow several years to elapse without re-painting glass-houses, for not only does the woodwork perish much sooner through this cause, but in a house where the whole surface of wood and brick-

work is clean and white there is much more light reflected to the plants during the dull winter months than where all is dark and dirty. Where no painting has to be done, the glass, rafters, sash-bars, shelves, and stages should be all well scrubbed before the plants are got into their winter quarters, and any repairs, alterations, or additions necessary to the heating apparatus completed. All winter-flowering plants that require artificial heat, and that may have been during the summer grown in pits by the aid of solar heat alone, such as *Eranthemums*, *Plumbago rosea*, *Euphorbia jacquiniæflora*, *Poinsettias*, *Thysanacanthus rutilans*, *Sericographis Ghiesbreghtii*, *Begonias*, and others, should no longer remain in structures where they cannot receive a little warmth should the weather suddenly become cold; for though it frequently happens through this month that the days are hot, yet during the nights the temperature falls very low, in which case the above-named and similar plants become chilled so far as to injure them seriously. All plants of this character should receive plenty of air during the middle of the day when the weather is bright, which will have the effect of stopping the shoots from extending, and secure the solidifying and hardening process which it is now desirable they should undergo; they should not be shaded, as full exposure to the sun will promote their flowering capabilities—for this reason where the glass has been smeared with whitening, to break the force of the sun's rays, this should be washed off. *Gloxinias*, *Achimenes*, and *Tydas* that have bloomed through the summer should now be gradually induced to rest, but this should not be brought about too quickly, as is sometimes done by withholding water, through which the tops will die off at once instead of undergoing a more gradual decay. Another mistake is frequently committed at this time of the year by moving them to a cool house or pit, or allowing them to remain in one whilst their shoots and leaves are yet green. When so placed, and the soil allowed to get quite dry, it will cause the tops to die down; but this is not the natural ripening process to which they should be subjected—their shoots become weakened, and the plants cannot be wintered successfully. In place of such treatment they require to be stood where they can receive a fair amount of warmth, with a drier atmosphere, and the soil kept sufficiently dry to check all leaf growth, yet not so as to cause them to flag for any length of time. In this way the tops will die down naturally, and the roots ripen in such a manner as to ensure their vigorous development in spring. Deciduous stove plants, such as *Allamandas*, *Bougainvilleas*, and *Clerodendrons* (excepting such of the latter as have flowered late and have been proportionately late in making growth), should during this month be kept in a house where there is only a slight diminution in the temperature, having the atmosphere much drier, and with no more water to the roots than will prevent the leaves shrivelling; the plants, however, may be allowed to flag slightly before water is given, and it should then be applied in a smaller quantity than when the plants are in full growth; they ought to have more air during the day, and no shade. The above is the only treatment that in any way approaches the conditions under which such plants exist naturally.

Mushrooms.—Many amateurs are deterred from attempting Mushroom culture on account of their not having houses especially constructed for the purpose, and also through the crop being, under the most favourable conditions as to the structure in which they are grown, somewhat precarious; but these reasons should not have sufficient weight to prevent any one trying to grow them. It frequently happens that an outbuilding of any description that can be spared for the purpose will answer as well or better for the growth of this vegetable than houses that are built expressly for it. For amateurs to succeed in the cultivation of Mushrooms it is necessary to reflect a little upon the natural conditions of their growth. As every one connected with rural affairs is without doubt aware, Mushrooms grown in the open fields are not equally plentiful every year. In seasons when they are the most abundant it will invariably be found that it is when the earth has been warmed to a considerable extent by a long continuance of hot, dry weather before August, with a copious rainfall during that month: this produces in the heated ground something almost approaching to fermentation, as will easily be ascertained by plunging the hand during a hot season in loose earth a day or two after it has been well moistened by rain. The heat and moisture thus combined start the spawn (which in some land is always present in quantity) into action, and should the atmosphere be still and moist and cloudy weather follow, then there is an abundance of Mushrooms out-of-doors. This at once points to the conditions necessary to be observed when they are to be grown in houses. From the present time to the close of the year they may be produced with the greatest facility and certainty; they can be grown in a very small building, but the larger the internal space, within reasonable limits, the less fluctuations there will be in the temperature, especially in changeable weather—a condition of great importance to success. An empty stable, or any similar place

on the ground-floor, will generally be found to answer; if there be an apartment above, all the better, and a thatched roof is much to be preferred to either slate or tile, for the variations in the weather will have less influence upon the internal temperature than if the roof be covered with slates or tiles. Manure in quantity proportionate to the space at command, or the size of the bed to be made, should at once be procured; this may consist of from a few wheelbarrows full up to an ordinary cart-load or more; let it be fresh, and such as has not been saturated by rain, or has previously fermented to any considerable extent. Shake out all the long litter, leaving nothing but the droppings and short bits of straw; throw it together in a heap, either in an open shed or in the place where the Mushrooms are to be grown; do not allow it to remain so long as to ferment violently—to avoid which turn it over two or three times at intervals of four or five days; by this time it will have discharged the superabundant moisture, and can be at once made up. The bed or beds may be made altogether on the ground-floor or can be constructed in the form of wide wooden shelves, two or three above each other, with spaces between of 3 ft. or 4 ft.; but where there is room I should recommend their being made altogether on the ground-floor. Shake the manure well together, and beat it solid with the fork as the work proceeds to the thickness of about 1 ft., making the whole smooth with the back of the spade. Insert a thermometer in the middle of the bed, and as soon as the temperature falls a few degrees under 80° put in the spawn, which should previously have been broken into pieces about the size of a small egg and thrust in just below the surface 8 in. or 10 in. apart. It will be safer not to soil the bed for a few days until the heat appears to be declining; the depth of soil used varies considerably with different cultivators, some using several inches, others being equally successful with only a couple. I have generally found, when the greater depth is laid on, that the beds are longer in coming into bearing, as it takes more time for the spawn to run. The soil (any ordinary loam) must be of a medium moisture, neither too dry, nor so wet as to be adhesive; beat it quite firm, and cover at once with dry hay. In the course of a month the Mushrooms should make their appearance—about which time examine the bed, and if it be too dry, which will be indicated by the buttons not swelling freely, give it a moderate moistening with tepid water applied through a rosed can, after which replace the hay on the surface. When the bed has been in bearing for some weeks and the growth of the crop begins to slacken, soak it moderately with tepid water, which will often have the effect of inducing a further production. Of course I am supposing that the building is not provided with any heating medium. As the autumn months advance other Mushroom beds may be made up, and the warmth given off by the manure for these will keep up the requisite temperature for the growth of the Mushrooms. Towards the close of the year, when the weather becomes cooler, a little more covering may be used to the beds; the door in all cases should be kept shut, and any windows or other apertures through which the external air can get in quite closed. Mushrooms can also be grown successfully in an ordinary garden frame; in fact, it frequently happens that a crop will spring up spontaneously without being spawned or any other preparation after the bed has been used for Cucumbers or Melons; but when intentionally grown in a bed of this description I have frequently at this season cleared out the exhausted Cucumber and Melon plants, levelled the soil, and inserted a brick or two of spawn in the soil in the usual way; previous to which, if over dry, moistening it moderately with water, allowing a day or two to settle before putting in the spawn, covering with 6 in. of hay. If the thermometer did not indicate a bottom-heat of 75°, I applied back and front moderate linings of warm manure, and covered the glass with 3 in. or 4 in. of litter, tacking down mats to keep it from being blown away. This covering is necessary, as the weather is frequently so bright through this and the beginning of the next month that the heat from the glass, if uncovered, would be too much for the Mushrooms, without admitting air in such quantities during the day as would make the atmosphere too dry. Beds so treated, moistened with tepid water as required, and kept warm by an occasional lining, have continued bearing freely up to the end of November.

Hardy Flowers.

ABUTILONS.—Though not quite hardy, these can nevertheless be grown in the open air with excellent effect during a good portion of the year, and in favourable situations like Heckfield some of the varieties will even stand out all the year round. Abutilons make good summer-flowering plants, especially in the sub-tropical garden, where a bed of mixed varieties forms a fine feature. Such a bed I saw at Heckfield a few days ago. In the centre was the strong-growing Duc de Malakoff, with its large, bold flowers, and around it were the fine white Boule de Neige, *Sellowianum variegatum* (the

finest variegated variety for outdoor work), and the charming yellow Lemoinei; the last-named a few days ago received a first-class certificate from the Royal Horticultural Society. Boule d'Or and probably Buisson d'Or are the same, only that the last-named is represented as having flowers of a brilliant golden-yellow, and if this be true, they are of a much deeper hue than those of Lemoinei. One of the most useful of Abutilons is Boule de Nieve; it is in bloom all the year round, and therefore supplies an abundance of cut flowers at certain seasons. When at Heckfield Mr. Wildsmith cut out the corolla of one of the flowers and reversed the petals, when it looked like a finely-formed, recurved *Convolvulus*, and in this character made an excellent subject for a button-hole. There are several varieties of Abutilons, such as Le Liliput, with bright mauve flowers; Le Nain, clear mauve; Lilaceum album, white shaded with soft lilac-mauve; Mons. Louis Marignac, soft rose colour; Perle d'Or, clear canary yellow; and Simon Delaux, soft chamois colour shaded with purple. It would be an instructive lesson were examples of these in bloom to be shown at one of the meetings of the Royal Horticultural Society.

ANEMONE JAPONICA.—Of this hardy perennial we have three fine forms, viz., japonica, japonica alba, and japonica hybrida. The former has rosy-carmine flowers of good size, but a little ragged in the outline; the second, large and finely-formed white flowers; the latter blossoms of fine form, of a pale salmon-rose hue. They are all of robust growth, and when well established, flower with great freedom, especially the white variety; and, indeed, it would be difficult to name another plant of greater value for cutting from at this season of the year. It is surprising that these fine plants are not more generally grown than they are. When once obtained, it is not difficult to increase them, for towards the end of the summer, small suckers are thrown up from the roots, and if these be taken off and put into small pots of rich soil, they soon establish themselves, and can be planted out in spring. They would make fine conservatory objects grown in pots and fed with liquid manure at the time of flowering. As the plants grow from 3 ft. to 4 ft. in height, when well established, they should have ample space in which to grow.

CALCEOLARIAS.—Seedling plants will now require to be taken from the seed-pans and pricked out in other pans or shallow boxes. This is absolutely necessary, in order to give the plants space, and prevent them becoming drawn. The pans or boxes should be well drained with crocks, and some rough peat or fibry turf placed over the layer of crocks. The soil best suited to the plants during the winter months will be one part loam and one part leaf-mould, silver sand being liberally used. They require to be pricked off about 3 in. each way, and from the store boxes they can be eventually potted. Any cuttings of Calceolarias that may have been taken from fine varieties should be potted off as soon as rooted.

FRANCOA.—This is a genus of hardy herbaceous perennials, amongst which some are of great value as decorative plants for cultivation in pots in a cold greenhouse. This is how they are grown by Mr. Bruce Findlay, in the Botanical Gardens at Manchester, and most effective they are. There are two species, viz., *F. appendiculata*, having long racemes of purple flowers; and *F. ramosa*, having white flowers. Both bloom with great freedom, the latter especially, and quite small plants in pots will throw up fine heads of bloom. When grown in the open ground, a rather dry, sandy loam, and a somewhat sheltered position suit them best, and that is why they are cultivated in pots in unfavourable localities.

PHYSOSTEGIA IMBRICATA.—This is one of a few members of a genus of hardy herbaceous perennials that are now only very rarely met with. *P. imbricata* is a tall and handsome perennial, growing 3 ft. and 4 ft. in height, and bearing numerous spikes of pale purple flowers, with a white lip, not unlike those of *Heath* in appearance. I met with this at a country show a few days ago, where it was a conspicuous feature in a collection of bunches of cut flowers. It should be planted in a good sandy loam. It is one of many fine old plants of great beauty that have become almost lost to gardens, but which can happily be found in a few old-fashioned borders. It is so beautiful that it sadly needs re-introduction. D.

A Valuable Orchard.—Mr. Stickney gave a description of the orchard of Mr. Whitney, of Franklin Grove, Ill. It occupies 160 acres, 100 of which are in bearing. In 1876, it bore 25,000 bushels. Mr. Whitney cultivates to heed crops while the trees are small; afterwards the ground receives occasional ploughing, or is pastured with sheep. He gives no quarter to insects, and last year expended £200 in destroying the canker worm. The result is fine fruit, while others who neglected their orchards have had their crops ruined. His remedy for the canker worm is whale-oil soap. He dissolves 6 lb. of the soap in 40 gallons of water, using about one gallon to a tree. His sheep do no injury to the trees when a large range is given, and he has taken effectual care of the Codlin moth.

THE FRUIT GARDEN.

STRAWBERRIES IN SEPTEMBER.

ALTHOUGH the weather has been anything but propitious for the last three weeks, yet we have a very promising show of Strawberries for this month. They are ripening fast, and the

crop on the whole is abundant, though the swelling process is irregular, a circumstance to be attributed to the rapid changes in the weather we have had; irregular swelling has, however, its advantage, inasmuch as it prolongs the season during which the fruit is fit for use. The only variety which we try in this way is Vicomtesse Héricart de Thury, a most accommodating Strawberry for any purpose. The plants now bearing a handsome crop of fruit are those from which we gathered our supply last April. Partial shelter is necessary in order to harden them a little before they are turned out-of-doors. In planting, the most favourable aspect with a high elevation should be chosen in order to insure a maximum of sunshine and light; a light dry soil is also an advantage in the case of autumn crops, as the sun's rays penetrate more freely through porous soils than stiff ones. The plants should be kept at least 2 ft. apart each way, and the fruit should be thinned out to a regular crop and propped up with Birch twigs so as to secure every advantage as regards giving flavour. They must be netted immediately the first symptoms of colouring show themselves, otherwise our ever-watchful friends, the birds, will soon deprive us of our fruit; they seem to have a particular liking for anything that is not over-plentiful. Those plants in pots that have been top-dressed and that had their drainage

seen to two months ago, will soon require to be removed from behind north walls into a more genial climate preparatory to being brought forward gently later in the season. All flower-spikes may yet be removed, but it will not be safe to interfere with them after the middle of September. Autumn and winter Strawberry growing differs from spring forcing materially; spring work is done rapidly by successional batches whilst

autumn crops may be prolonged by inducing the same plants to produce a succession. W. HINDS.

PEAR TREE ROOTED ON BOTH SIDES OF A WALL.

THE tree of which the annexed is an illustration was planted against

Pear Tree rooted on both sides of a Wall.

a western aspect wall, in sandy soil, in 1851. It is in perfect health, the branches measuring on either side 21 ft.; about five years ago the two principal stems had attained sufficient length to be turned over the top of the wall and placed in the ground, where the two branches cross one another under the surface. The eyes in the ground threw out strong roots, and those out of the ground furnished shoots which have been trained, as will be seen, obliquely, and are already close upon 16 ft. in length. When first carried over the wall the buds naturally pointed towards the ground, and it was supposed that they would ultimately turn upwards, but up to the present time such has not been the case. On the downward stems all the buds, which are few, grow with their points in the direction of the ground, a circumstance doubtless occasioned by the sap furnished by the original roots on the western side of the wall being so much more abundant than that supplied by the roots on the eastern side. It is possible that the case might be otherwise if the branches which unite the two trees were severed on the top of the wall. M.

New Melon from Khiva.—I have lately fruited a new Melon raised from seeds sent to me by Messrs. Carter & Co., and brought from Khiva by Captain Burnaby. I find it to be an oval-shaped, very early fruiting, green-fleshed variety, with a flavour something like that of the old Egyptian Green-flesh. The fruits of it when young have a hairy appearance, and are quite different from those of any other Melon with which I am acquainted. The fruit has the fault

of being small, but it will be useful on account of its flavour for crossing with some of our larger sorts. Owing to the sunless summer which we have hitherto had, Melons in general have not been so good in flavour as in some years. I have, however, found Mann's new Hybrid Green-fleshed to be one of the best; Gilbert's Green-fleshed has likewise been excellent in flavour. Amongst the scarlet sorts, Sutton's new Scarlet-fleshed and Carter's Bloxholm Hall Scarlet-fleshed are all that could be desired.—WILLIAM TILLERY.

A NEW WAY WITH RASPBERRIES.

THE little cost incurred in cultivating the Raspberry, and the remunerative price which the fruit always fetches in the market, render it one of the most profitable fruits to grow either by the amateur, cottager, or market gardener. Two things connected with the cultivation of the Strawberry deserve particular attention, viz., its aptitude for rooting near the surface, and the necessity of having it always well supplied with moisture. Where the soil is of a sandy character it is a good plan to make trenches 3 ft. wide and about 15 in. deep. In these place a good layer of rotten manure, and mix it well with the soil; on this plant the canes, spreading out the young fibres at full length, and covering them with 2 in. of soil and a good coating of rotten manure. This keeps the ground moist and encourages surface-roots, which form the chief points in securing success. If the weather should be dry at the time when the fruit begins to swell, liquid manure should be freely given, as it improves both the size and flavour of the berries. Neither hoe nor spade should ever be used on the surface, inasmuch as they bruise the roots and cause a quantity of suckers to spring up. In strong, heavy, rich soil, trenches are not required; the ground should be worked up two spades deep, mixing in with it as the work proceeds plenty of rotten manure, vegetable refuse, leaves, or anything of a similar character, and as soon as the young plants can be handled they should be thinned out to five or six suckers, according to their strength. As soon as the crop is gathered cut out all the old wood, so as to give the sun full power to mature the young canes and plump up the buds. Planting, which may be done at any time between October and the end of March, may be performed in different ways, and with about the same results. I prefer planting in rows 4 ft. apart, and 1 ft. asunder in the row, tying the canes to a couple of wires stretched along the row, on stakes. Thus managed, they have a neat appearance, and room is afforded for free admission of light and air. A less expensive plan, however, is to plant three canes together 4 ft. apart in straight lines each way, and to arch the young canes by tying them together every year; this leaves every alternate row open for gathering the fruit and cleaning the ground. In pruning, the canes should be left at different lengths—the strongest at full length, the medium ones shorter, and the next shorter still. By this system a crop is furnished from the bottom, and a succession is kept up to the middle of November. A bed of the autumn-bearing variety should be cultivated, as it is the most profuse bearer of the whole. It should be treated as follows:—The young canes should be planted 2 ft. apart not later than the end of March; about the middle of April, cut off the young canes close to the ground, and as soon as the young shoots can be handled, thin them out to 5 in. or 6 in. apart. When they have made 18 in. of growth, pinch out the points of about a third of them, a second third at 30 in., and allow the remainder to grow to their full length. By this system of pinching a regular succession may be maintained from the beginning of August to the middle or end of November, according to the season. This variety should not grow on the same ground more than two years in succession. If fine fruit is to be maintained, it is better to plant a succession every year. As this variety bears on the annual wood, it requires yearly to be cut close to the ground. As regards varieties, some of the newer sorts are very fine, but for this part of Lancashire the Red Fastolf and Yellow Beehive are most suitable, and the Double-bearing for autumn.

JAMES SMITH.

Waterdale.

FRUIT FROM BEYOND THE SEA.

THE summer of 1877 promises to be a great fruit season. The trees are all hanging full. Apples will be at least in average abundance; Peaches are growing in extraordinary quantity; Grapes and Pears promise well, according to the latest reports. It is apparently a bearing year, and orchards and Vineyards will swell the gains of the farming community considerably. A large crop of fruit was once not a blessing to this country, at least not to the producers, owing to the limitations of the market, and the consequent fall of prices and unprofitableness of gathering the fruit. Prices are better sustained, and a

greater proportion of the crop is gathered and sold, when the yield is an average one. It was not unusual to see £3,000,000 worth of fruit go to waste in this country in a great fruit year, because it did not pay to market it. This year, however, will differ from those which have preceded it in an interesting manner, and there is reason to believe that the whole crop of fruit may be harvested and utilized this season, no matter how large it may turn out to be, without upsetting the market and putting prices down disastrously low for producers and dealers. Invention was very much occupied last year in devising and perfecting means to utilize large crops, and the result is that this year the machinery has been created for securing a more thorough and rapid distribution of Apples, Peaches, Pears, &c., to all parts of the country, and to Europe, than ever before known. The market for fresh fruit has thus been immensely enlarged, and there is a probability that a very much larger quantity of fruit will be disposed of at remunerative prices than in any previous year. There have also been perfected some capable inventions in the way of fruit driers. Some of them of large capacity are to be set up in the Peach districts or immediately adjacent thereto, and a number of small ones will be tried in the Apple districts. Preparations for canning on an unprecedented scale are also going on, and between the drying and canning the promise is now that an uncommonly large proportion of the surplus crop will be saved and put into shape for distribution and exportation after the fruit is out of the way. Some of these appliances for transporting and drying have yet to go through their first serious trial of a busy year, and may, perhaps, still be regarded as experiments; but they have been tested on a small scale and have worked well. The one feature of the situation which is worth speaking of at length is the foreign demand for American fruit. The past season has demonstrated the fact that Europe and Australia are prepared to take pretty much all the fruit, fresh and dried (dried Peaches excepted), which the United States can land in their markets in good condition. England prefers the fresh fruit. Of Apples since last October she has taken 396,000 barrels from the United States, beginning with the latter part of October at the rate of 8,000 barrels a week, increasing in four weeks to 17,000 barrels. In December they averaged over 20,000 barrels a week, once running up to 28,525. These Apples were mostly Baldwins, Greenings, Russets, and Newtown Pippins. The English like a red Apple and one with a high flavour, and varieties answering this description found a ready sale. Sound Baldwins and Russets generally realised 14s. a barrel. Greenings fluctuated from 10s. to 16s. a barrel, according to quality. Newtown Pippins and the other remarkably good Apples ranged from 24s. to over 40s. a barrel, big shipments having been made from this port at the latter price, especially towards the close of the season. Apples are always sold in England at auction on the wharves, and prices have therefore depended to a certain extent on the amount of arrivals in port; but the market showed remarkable steadiness in the heaviest months, and shipments were always disposed of at remunerative rates. Circulars recently issued from Liverpool state that as a result of the season a preference for American Apples has been established in England, and that hereafter, whether the English crop is large or small, large supplies of well-selected fruit are likely to find there a good market. During a season of scarcity, like that of the last year, England can certainly take an average of from 12,000 to 15,000 barrels a week for the whole market year of nine months.

With reference to dried fruit, the market abroad is peculiar, but its capacity to take a vast quantity of the article has been demonstrated over and over again, and in a later and emphatic way by the experience of the season just closing. For dried Peaches there is no sale abroad at present. Possibly a demand for them may be created by the recently-invented evaporators, which dry fruit rapidly and in large quantities. If these machines succeed in bringing down the price of dried Peaches to a point low enough to tempt the working classes to buy, it will probably build up a sale. There is little hope of a foreign demand springing up unless the fruit is cheapened, for this matter of cost is all important. Our customers for dried fruit abroad are the working classes of Germany, and the miners and working men of Australia principally. The poor people of

England and Russia buy to a limited extent; and France is also a buyer, though exactly why is not clearly understood in this country, the impression being that France buys for the purpose of distillation, but no responsible authority is willing to certify to it, and little is known about it. The buyers of nine-tenths of the American dried fruit exported are the working men of Europe and Australia. As long as dried Apples can be exported from New York at 2½d. per lb., or even at 3½d., these people will buy all we can spare. If the price rise above that limit the sales fall off at once. Now Peaches cost at least 7½d. per lb. to export, and that fact alone prohibits their sale to the consumers of dried fruit abroad. Before they can be exported the price must come down 50 per cent. at least. Of dried Apples, however, there is an immense sale. Within the last eleven months over 13,800,000 lb. have been exported, and the demand has kept up longer than ever before known. Usually it ends with February 1; this year it has been steadily maintained to the present time. It is important to farmers to understand the cause of this demand, in order that they may reap the full advantages of the foreign market in the future. It is due, in the first place, to the price. At 2½d. per lb., or even 3½d., exportation goes on briskly. Dealers believe that the whole of the surplus of the crop of Apples converted into dried fruit can be marketed abroad every year at these rates. The manner in which the fruit is prepared also enters into the question. Sliced fruit will not sell abroad at all. Our customers want it cut up in pieces as large as possible, the larger the better; in halves, if possible. Sliced fruit was a failure this year, and all who traded in it lost money. Fruit raisers should understand this. Size in the cut fruit is as important an element as cheapness. Sliced fruit is perhaps better in point of fact than cut fruit, and a taste for it may yet be created, but this article is dealing only with the experience of the trade so far, and the fact is as stated. One peculiarity of the foreign sale of dried Apples is the size of the packages. Europe prefers them in barrels, the larger the better, and would rather have them in hogsheads. Australia, on the other hand, will not take packages as large as barrels; the stuff must be put up in 55-lb. and 100-lb. kegs, suitable for placing on the back of a mule for transporting up into the mountains. Venezuela requires small packages also. Canned fruit, Peaches especially, is now entering into exportation in a marked manner. The amount sent abroad within the last ten months is £140,600 worth. It is in cans that Peaches find their way to foreign countries principally at present, and the growing demand for them in this form is very encouraging. Dealers are unanimous in the opinion that Peach raisers will do better to turn their attention towards canning their surplus crops this year than in attempting to dry it. The market for the dried article is yet to be educated and built up. The market for canned fruit exists already and is a lively one.

Exportation of fruit from this country to Europe has been going on more or less for forty years, but it was never very large until 1865. That year was very prolific, and a few shipments of Baldwins, Spitzenbergs, and Greenings were made to Europe to try the market. They were fairly successful, and the business has continued in an intermittent way since. In 1873 it became a good business, and now appears to be fairly established. The figures for the last sixteen years are as follows, the years severally ending July 1.

1861	£53,800	1870	£108,400
1862	47,600	1871	101,300
1863	72,800	1872	160,800
1864	173,300	1873	340,600
1865	200,200	1874	198,000
1866	98,400	1875	326,600
1867	70,000	1876	165,400
1868	81,200	1877 (11 months) .	566,200
1869	61,200		

The high figure now reached cannot be maintained unless the Apple, Peach, and Pear crops are good. But the fact that there is now a market abroad for the surplus fruit of the country, as well as for the surplus cotton, grain, and provisions, would seem to be an inducement to farmers and fruit raisers to take better care of their orchards, and not only to have no fear of a big year, but to do what they can to make the crop as large as possible.—“New York Tribune.”

MYSTICAL PLANTS.

THE evil reputation of the Mandrake procured it subsequently the name of *Atropa Mandragora*, by which our oldest botanists distinguish it; a name borrowed from the most terrible of the Fates, *Atropos*, and since transferred to its relative, *Atropa Belladonna* (Dwale, or Deadly Nightshade). So potent and valuable were the medical uses of the root at a time when few anodynes were known, that the ancient Romans made it the subject of a weird ritual, without which they would have deemed it impious to have taken it from the earth. The operator stood with his back to the wind, drew three circles around the root with the point of a sword, poured a libation on the ground, and, turning to the west, began to dig it up. Saturnine and poisonous plants were those most affected by necromancers and witches—plants dwelling in shady groves, or on wild heaths, like the potent Moonwort, which opened locks and unshod horses; or amidst solitary churchyards and old ruins, like the deadly Nightshade and fetid Henbane, Hound's-tongue, and *Digitalis*, plants with dusky or sad-green leaves, and lurid-coloured flowers for the most part, and an ill-favoured soporific scent. Nature herself distinguishes Hemlock from all others of the umbelliferous tribe by the pink or purplish spots with which its tall smooth stem is variegated. It grows by hedgerows and in waste places; its large-winged, finely-cut leaves and white umbels of flowers give no indication of its dangerous nature; but its speckled cuticle betrays it, and prevents its being rashly meddled with by rustic herb-gatherers and children. Wolf's-bane or Monk's-hood, an herb of Saturn, sacred to Hecate, and which has since figured in the floral calendar of witchcraft, had its first name from the use the Anglo-Saxons made of the juice, in which they dipped their arrows and literally kept the wolf from the doors of their wattle huts. It was, and is, a brave herb for all evil purposes. Its root resembles the tail of a scorpion; its flowers, of a lurid purple, have the form of a helmet; features significantly significant for those who sought such dangerous simples. The very scent of the flowers on some sensitive persons has produced swooning and loss of sight for several days; others it has deprived of speech; and there are instances on record of persons who have eaten of the root being seized with all the symptoms of mania. Imagine such powers in the hands of a reputed witch, malevolent enough to exercise them for reward or malice, in days when medical science itself was not without faith in magic! Dreadful as are its proved effects, the Monk's-hood is a common plant in cottage gardens, where we have seen it flourishing 3 ft. in height, crowned with its handsome spikes of purplish flowers, and little children playing with them. Black Hellebore had also a place in the category of mystical plants; the Romans removed the root with the same ceremonies as were observed in taking up the Mandrake, with this distinction, that prayers were humbly offered to Apollo and *Æsculapins* for permission, and the operator turned to the east instead of the west on commencing to dig it up. No way-side plant is more simple in appearance than the Vervain, the “holy herb” of so many nations. Its pale lilac spike of minute flowers scarcely attracts attention, except from those who know its ancient history. In the sun-worship of the ancient Persians, their magi carried branches of Vervain in their hands when approaching the altar. So did the pagan priests of ancient Greece and Rome, and ages subsequently the Druids in the forest temples of Gaul and Britain. With the Greeks and Romans it was never absent from their religious rites. The plant was long considered to be good against witchcraft and the bite of venomous creatures; and being under the dominion of Venus, was a great beautifier. It were “perhaps well,” as Lord Bacon would say, to notice the agreement between various writers as to the cephalic virtues of the plant, and remedial efficacy in taking away headache and the “pin and web,” or clouds and mists which darken the optic nerve. From medical to magical uses was but a step in those days, sometimes a very short one; and accordingly we find a spray of Vervain used as a charm to keep horses and persons from harm, and especially from evil spirits and witchcraft. A relic of the latter superstition lingers in the rhyme—

Vervain and Dill
Hinder witches of their will.

St. John's Wort, by virtue of its dedication to the saint whose birthday, according to the religious calendar, is the anniversary of the summer solstice, was said to have the power of putting to flight ghosts, demons, and even Satan himself. Nowadays, the Mistletoe generally affects old Crab and Apple trees and the boughs of Beech and Ash; but in so-called Druidical times it appears to have flourished in the Oak groves, which these strange worshippers are said to have made their temples, and under the name of the “All-heal plant,” was, we are told, severed from these trees with solemn ceremonies. The mystery of its appearance—its aerial place of growth—the pale green antlered branches, putting forth their pearly berries in honour, as it were, of the high festival of the winter solstice, “the mother of the

nights"—probably conduced to render it a miraculous plant. Long after Druidism was but a name, the plant retained its healing and protective properties for the populace, whose teachers strengthened superstitious reverence for it by calling it *Lignum Sanctæ Crucis* (Wood of the Holy Cross). Amulets were made of it and worn round the neck to defend the wearer from enchantment and other dangers, and in more modern times as a charm against the falling sickness and the plague. The Yew, like the Oak, was sacred to the Druids. Branches of it were anciently carried by the mourners at funeral processions, and were thrown into the grave before the coffin was lowered. The awe in which it was originally held is traceable in the traditions yet extant of its dangerous and even deadly properties. The Mountain Ash or Rowan tree has for ages been endowed with mystical properties in Scotland. The custom of carrying sprigs of it in the pocket still obtains in the Isle of Man, where it is extensively grown and cherished for warding off demons, witchcraft, and the evil eye. Not such the reputation of the Lunaria, described by Chaucer, Spenser, and Drayton, as one of the most powerful of vegetable charms, and an ingredient in the most subtle spells of night hags and enchanters; this, the homely Honesty of the cottage garden, the Satin-flower that our grandmothers cherished, is a plant than which none more apparently harmless is to be found in the floral calendars of herbmen and gardeners. But in days when plants were supposed to bear witness in many instances to their own attributes, when certain features were sought for and believed in, as affording a key to the sympathies and properties of herbs, its round, flat, silvery pods showed it to be under the dominion of the moon and endowed with magic influences.—"Chambers's Journal."

FRUIT, FLOWER, AND VEGETABLE TRIALS AT CHISWICK.

ZONAL PELARGONIUMS, of which a large collection is planted out this season at Chiswick, were examined on this occasion by the Floral Committee. Many of the sorts have suffered severely from the recent heavy rains, but the following varieties, being in excellent condition, were deemed worthy of first-class certificates—viz., *Excelsior* (Denny), scarlet, with distinct white eye; Charles Smith (Pearson), dark scarlet; Mrs. Huish (Pearson), magenta scarlet; Portia (Denny), magenta scarlet; Mabel Eden (Pearson), light magenta; Lais (Denny), magenta scarlet; Mrs. Holden (Pearson), rosy pink; Mrs. Lancaster (Pearson), rosy pink; Lord Giffard (George), bright scarlet. Among the older varieties *Triomphe de Stella*, *Golden Harry Hieover*, *Vesta*, *Rose of Summer*, *Claude de la Meurthe*, *Arthur Pearson*, *Princess of Wales*, *Mrs. Turner*, *Christine*, *Cleopatra*, *Lady Emily*, and *Snowdon* were conspicuous. The collection of Pelargoniums, consisting of all the newer varieties which have this season been grown under glass, was then examined, and the following being considered very suitable for pot culture were awarded first-class certificates—viz., *Miss Wakefield* (Pearson), orange scarlet; Louis (Pearson), rosy purple; Lustrous (George), very bright scarlet; Lady Eva Campbell (Pearson), salmon; Mrs. Pearson (Pearson), bright orange scarlet. Among other varieties *Thisbe*, Charles Smith, Miss Strachan, Lizzie Brooks, Rebecca, Blanche Gordon, and Lord Zetland were especially noticeable. The double Pelargoniums, consisting of a selection of the best varieties of last season and new sorts received during the present year, were examined, and first-class certificates awarded to the following—viz., *Député Anselon* (Lemoine), deep magenta rose, and *Le Nord Est*, bright scarlet. Madame Thibaut, Noemie, C. Gligm, Auguste Villame, Meteor Flag, Mrs. Trevor Clarke, and Madame Amilio Baltet were also very fine.

A large collection of Asters now in full bloom was next examined, and the following were highly commended as being excellent stocks—viz., *Pompone* (Dippe Bros.), of erect, moderately-bushy habit, producing very close, compact heads of flowers; *Diamond* (Haage & Schmidt), a larger and more vigorous variety of the *Pompone*; *Dwarf Chrysanthemum-flowered* (Dippe Bros.; Carter & Co.), is perhaps the best variety of any for general use, never exceeding 10 in. in height, and yielding in great profusion very large and well-formed flowers; *Victoria Aster* to all appearance seems to be a tall-growing variety of the *Chrysanthemum-flowered*; *Betteridge's Exhibition Quilled* is a very distinct and pleasing variety, throwing the flowers well up, and, being of a hardy constitution, does not seem to be affected by rough weather. A full report on these will appear in the Society's Journal.

Of *Dianthus*es, a large collection has this season been grown, and on examination the following received first-class certificates, viz., *Heddeewigi hybridus fl.-pl.* (Benary), *Heddeewigi laciniatus* (Benary), *Heddeewigi hybridus atro-purpureus* (Benary), *Chinensis fl.-pl.* (Benary), *Imperial fl.-pl.* (Benary), *Heddeewigi plenissimus splendens* (Haage & Schmidt), and *Heddeewigi* (Benary).

The collection of Tomatoes grown in pots under glass was examined by the Fruit Committee. It is represented by over sixty differently-named varieties, two plants of each being grown. These the Committee had arranged into classes as distinct in appearance, amounting in all to thirty-one, which number may, however, be still further reduced or increased when further examined in comparison with those growing in the open air. These Tomatoes at the present time are most interesting and well worthy of inspection. The smallest variety is represented by *Red Currant*, of about the same size as a Currant; the largest is *The Trophy*; the earliest is *The Early Gem*, and the latest, *De Lave's*, which is of little value. First-class certificates were awarded to *Little Gem* (Bliss), a medium-sized, round, deep red, very free-fruited kind, and very early; to *New Improved* (Vick), a large, smooth ovate variety of a distinct rosy crimson colour, free-fruited; to *Vilmorin's Large Red*, a very large, slightly-ribbed variety, and a wonderful cropper; to *Trophy* (Carter & Co., Veitch, Wheeler), an exceedingly large, nearly smooth red variety, of fine appearance, and late. *Hathaway's Excelsior* was found to well merit the certificate awarded to it some time ago; also *Green Gage* (Carter), as being by far the best yellow variety. *Conqueror*, *One Hundred Days*, and *Portsmouth* amongst the new varieties were greatly admired.

The collection of cordon-trained Peaches and Nectarines on the open walls was next examined. These trees, which have this season done good service, are in perfect health, and many of them are bearing heavy crops. Prominent amongst all others stands the *Lord Napier Nectarine*, which was awarded a first-class certificate. The fruit is very large, roundish-oblate, of a deep, dark purplish colour; the flesh is pale throughout, of rich and excellent flavour, having a dash of the *Stanwick* in it. It is of fine constitution, and a free bearer.

Turnips were next examined. Of these a very extensive trial has been made. The earliest varieties were found to be the *American*, *Strap-leaf*, *White* and *Red-topped*. This is an exceedingly fine Turnip, and completely takes the place of the old *White Dutch*, which seems to be almost worn out; at least, no true or good stocks of it have been grown at Chiswick. Following these come the *Early Red Top*, the *Red Globe*, and the *Early Six-weeks* or *Snowball*, which has numerous synonyms. This is the main-crop garden Turnip, and the finest of all. Of others—all good enough in their season, but including no novelties—were noted a very good stock of the *Long Vertus*, pointed-rooted, which comes in very early, and is much used in France, although not in this country; the *Round Black* or *Chirk Castle*, an excellent autumn sort; the *Yellow Finland*, *Yellow Malta*, *Orange Jelly*, &c. The whole of those dry-fleshed Turnips—as the *Teltauer* and others, so esteemed in some parts of the Continent—proved a failure, as well as many of the varieties generally grown for field culture. A later sowing of Turnips has been made, which will be examined in due course.

The collection of Savoys, it may be mentioned, is now nearly ready for inspection.

Robbing Birds' Nests.—A lecture was recently delivered in which an estimate was formed of the damage to crops by the robbery of a nest of five eggs. It was stated that during the first month each young bird eats on an average about fifty-eight flies or other insects in a day. The aggregate, multiplied by thirty for the months, makes 7,500 insects to every nest. Every insect eats daily from blossoms and leaves an amount equalling its weight until it reaches maturity.

Vegetarians in Germany.—The vegetarians of Germany have founded a pension and a colony for people of their way of thinking at Gernsbach, in Baden, where also orphan children committed to their care will be brought up on vegetarian principles. A roomy mansion known as *Thalysienhof* was purchased for the purpose, together with extensive fruit and vegetable gardens, and here its new occupants intend to prove by demonstration to their carnivorous neighbours how health may be attained at infinitesimal cost without animal food.

Old Pollen.—As an instance of the length of time that pollen, if secured from damp, will preserve its fertilizing properties, M. Carrière states that M. Houlet collected some pollen of *Ceratostamia mexicana* in the gardens of the Museum in 1877. With this he fertilized some female flowers of *C. mexicana* in 1872, the result this year being an abundant crop of the drupaceous fruit of this plant. Pollen, indeed, would probably keep even much longer than this.

For the Love of it.—Ward Beecher, it is said, last year raised about 15,000 bushels of Onions on his Peekskill farm. They cost him 4s. 10d. a bushel, according to estimate, and as the market price was 4s., any one can see how much he made. Mr. Beecher can send beef to the New York market at 2s. per lb., and can raise Oats at as low a mark as 8s. a bushel. His butter is reckoned at 5s. per lb., and his eggs at 5s. a dozen. He made £3,000 by lecturing last winter, and if he maintains such an income he will be able to continue farming and gardening.

AMONG THE ROSES.

IN BULGARIA.

"Owing to the devastating war in Bulgaria, total ruin and annihilation have overtaken the Rose crop in the valley of Kazanlik and the neighbouring districts. . . . All these places are devoted to this peculiar and beautiful husbandry; the Roses are grown by the field-full."—*Our Own Correspondent.*

FAIR Flora stood upon the trampled ridge
Where erst her myriad Roses wooed the eye,
Now reddened with a deeper dye—
The ghastly crimson of ensanguined feet
Which flying beat
In headlong haste across War's brazen bridge.
She stood, pale horror on her tender lips,
Her bright eyes dim and dark with pain's eclipse,
While the smoke smouldered westward on the wind
That bare Bellona's hoarse, far-echoing shout
Harsh on the ears of startled humankind.
Where'er she gazed, the wreck of hideous rout
Blotted her ancient pleasures. The earth,
Of old heaped high with sweet Rose-petals, now
Was piled with mangled dead. From Flora's brow
Had fled the winning smile of summer mirth,
As, lifting eyes of horror to invoke
Help out of Heaven, the sad Flower-goddess spoke:

"How serve a race that stains my loveliest gift
With fierce Bellona's blond-dye? Here indeed
The ministries of Beauty and of Thrift
Were late united. But War's harpies heed
Nor labour's gain nor loveliness's dower.

Alas! my well-loved flower!
Broken thy charm, thine augury belied,
Before the ruthless storm of hate and pride.
Crescent or Cross, methinks, had fitter wreathed
Its ensign with the blooms that lately breathed
A sweeter incense than the Churches know
O'er all these ravaged homesteads night and day,
And made these fields with brighter blossoms gay
Thou deck the altars where great organs blow
Praise to the God of Peace.

Your fruitless flutings cease,
Ye pipes with mouths of gold! What music now,
Save War's shrill trump and hollow drum?

All instruments but these be dumb,
Whilst Christian hate with Moslem fury closes
In murderous conflict 'midst my trampled Roses.
And which the most accursed? Furious man
Has made a Golgotha of Gullistan,
Till fiends among my Roses might laugh loud,
Taking my wreaths of red and white to shroud
War's hideous horrors and Hate's helpless prey.

And yet but yesterday
They made the land like Benlah with their blooms,
And not a purer, sweeter air perfumes
The Vale of Cushman than late breathed among
These squares of fragrant husbandry, now flung
A prey to battle's never-satiate maw.

What wounds were those you saw,
Ye blue skies, and bright waters, and pure blossoms,
In men's hearts, children's limbs, and women's bosoms?
No more! I must away

From where Bellona shares with Belial sway!
He holds a girl's fair tress in bloody hands;
Her mailed foot on a crushed Rose, she stands.
With that foul pair sad Flora may not cope.

But flies in far-off hope,
When this dread Carnival of Carnage closes,
Once more to dwell with Peace among the Roses.

IN BRITAIN.

I sat among the Roses. Row on row
Their blossoms clustered, in the golden glow
Of English August, round a garden nook
Whence, in the midday hush, glad eyes might look
O'er sweeping slopes of Corn-land, stretching far
To where in the bright east the azure bar
Of circling ocean gleamed against the sky,
A silent witness of security.

Couched at their Sage's feet
A troop of English maidens clustered, sweet
As their own Ruses, and as gay
As the light dancing in the leaves' glad play.

With them mild age and manly youth together
Basked in the light of home and harvest weather,
Until I sighed, and said—

"Yon eastward skies
Look clear, my maidens, as your orbs of blue;
But cover that which if those orbs but knew
By startled onlook, it would something dim
Their frolic sparkling. Boys, your length of limb,
Stretched lazily, would leap at the black work
Among the Roses, yonder, where the Turk
Red-handed grapples his red-handed foe.
Well that these balmy breezes do not blow
Echoes from those far Rose plots to our own!
For Childhood's shriek and outraged Woman's groan
Would mar our Summer music. Yet, perchance,
Some thought of poor Bulgaria may enhance
Our stolid, silent British thankfulness
For long immunity from battle's stress,
For peace, and pleasant hours, and happy love
Amidst our English Roses here; may move
Unpartisan Compassion to its task
Of even-handed helping. Here we bask
In sunny safety; there the smoke of war
Sweeps o'er the bloody track of battle's car,
Whose ruthless course is over homes and hearts.
Here, as the breeze yon leafy screen disparts,
Sweet pink-flush'd petals, shaken from the bough,
Fall on the close-coiled tress that crowns your brow,
My fair-hair'd beauty, like a soft caress
From lips I need not name; but there,
Where through wrecked Rose-fields woman-slaughters
press,

The severed blossoms fall on bosoms bare,
Leaving a stain of redness not their own.
Poor Flora, lately flown
From that so desecrated Paradise,
Looks in on us, methinks with mournful eyes,
Pleading with her more favoured children here,
Safe screened from lust's assault and battle's fear,
For pity and for help. Eternal shame
If party war-cries, in whatever name,
Deafen our ears to that appeal!
Prove we that no one-sided clamour closes
Our hearts to the large kindness which can feel
For sufferers of whatever race and creed,
That we can spare them help and pitying heed
From our blest homes of peace among the Roses."

—"Punch."

NOTES AND QUESTIONS—VARIOUS.

Keeping Mushroom Spawn.—This is the best month of the year for making Mushroom beds, and with good spawn and the proper temperature in the bed success ought to be certain. I am convinced that many beds fail through using spawn that has been badly preserved. Many, on receiving their stock of spawn, pack it away together in heaps; in that way it naturally generates damp; the white filaments or threads begin to run, and the spawn for all practical purposes is ruined. The best way to keep Mushroom spawn is to spread the cakes out thinly in a dry, warm place.—E. HOBNAV.

Salt not a Remedy for Mildew on Vines.—Having tried the plan (see p. 160), recommended by a French writer, for preventing mildew on Vines by sprinkling a handful or so of salt at their base, I am sorry to say that it has proved a failure. I tried the experiment on two outdoor Vines (one facing the south, the other south-east) about sixteen or twenty days ago; the disease, which was then only just appearing, has extended seriously. Can any one else, who has tried the remedy, give us the result of his work?—C. F., *Merlwood, Parkstone.*

Dahlias Unlifted.—It is not a common practice to allow Dahlias to remain in the ground all the winter, but where land is well drained it answers well. The plants grow much stronger, and the flowers are larger, and the great strength of the stems is in their favour when exposed to wind. When the plants begin to shoot up, the stems may be reduced to one or more as desired, a quantity of manure may then be forked into the surface, and the stakes placed in position, one to each plant, and with the exception of tying the stems securely, there is little more trouble necessary. A small mound of ashes placed over each crown as protection in winter, generally keeps the roots safe and sound. We have known them in the midland counties of England and Ireland to stand ordinary winter without any protection whatever.—"Florist and Pomologist."

Notice to Correspondents.—Various correspondents are reminded that we never name plants or fruits unless the full name and address of the sender be given.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

BRINGING PLANTS FROM ABROAD.

To introduce tropical plants to this country successfully, care should be taken to time matters so that the vessel should not reach English waters during the winter season. Many instances could be quoted of fine specimens having borne a long voyage and arrived in the English Channel in good order, but the cold there had absolutely killed everything. Similarly, it is extremely unwise to send out cases of tender plants from England during the winter months, unless such cases can be very carefully tended and sheltered until the vessel reaches warmer latitudes. A cheap and perfectly efficient plant-case is represented by our woodcut. It is strongly made of good deal or some other wood which does not readily warp. One side of the upper portion is fixed, the other marked A B C D can be wholly removed, and represents the front of the case. Half-a-dozen gimlet-holes should be made in the bottom, which must be covered with an inch or so of any good draining material. A quantity of moist earth is placed over this, and all is ready for receiving the plants, which may or may not be in pots. Before actually placing these, however, it is better to nail firmly a strong strip of wood all along the back, just above the level of the soil; then pack in the plants in rows so as to allow battens to be easily fixed between these rows. After planting give a moderate watering, and let the whole stand for a day or

Case for Conveying Plants.

so in order that the soil may settle and the superfluous moisture escape. Non-success is often attributable to the too wet condition of the soil. A batten is now put between each row, with one end under the long piece already in position; all that is now wanted is another long piece to hold securely the near ends of the short cross-pieces. If this be done properly (and too much care cannot be expended on these details) the case will stand all the knocks and rough handling in transit without injury to its living contents. The width of the cross battens must be determined by the size, &c., of the plants or pots packed. In order to effectually exclude the air, the lid is screwed down on a layer of putty; each side should be glazed with crown glass (three squares will be found quite sufficient for an ordinary-sized case), and a very strong close piece of wirework should be fixed on it; this serves the primary purpose of guarding the glass from breakage, but also is of great use in somewhat subduing the light. The case should always stand upon feet so as to allow the salt water to run freely away underneath whenever a wave comes on board. We are aware that there are patent cases with special contrivances for ventilation, &c.; such a one as figured can, however, be made cheaply by any carpenter, and if the conditions we have defined be well adhered to, no one need wish for anything better. It is often advisable to place seeds in the soil of the case. From Seemann's "Popular History of Palms" we learn that "when Allan Cunningham was in New Holland he sent a case with living plants to the Royal Gardens at Kew, which on being disturbed was found to have, instead of the crocks usually placed at the bottom of such cases for drainage, seeds of a Palm, nearly all in process of germination. Cunningham's attendants, too indolent to look for the crocks, had substituted the seeds of the *Livistona australis*, which happened to be

more handy. These young plants were carefully nursed, and one of them has now become one of the gems of the collection of Palms at Kew. The discovery that the seeds of Palms could be introduced most effectually by being in their native country at once placed in mould was not overlooked by Mr. John Smith, ex-Curator of Kew Gardens; he made it widely known, and to its diffusion more than to any other circumstance must be mainly ascribed the great increase of the collections of Palms in our horticultural establishments." Seemann availed himself of the knowledge thus accidentally obtained, and was in this manner enabled to introduce several rare species into our gardens. As every one knows, some seeds retain their vitality but for a very short period, and, in many instances, the plants producing these are of vast commercial importance. We will instance two—the Liberian Coffee (*Coffea liberica*), and one of the India-rubber-yielding plants (*Hevea brasiliensis*). So short a time do the seeds retain the power of germination, that it may be looked upon as next to impossible to introduce the species by means of seeds to many of our distant colonies. Here the plant case helps us out of our difficulty, for by its means living plants are easily transmitted, thus saving time, expense, and anxiety. Owing to the diseases which have caused enormous damage to the Coffee plantations in some countries, the Liberian Coffee—a stronger and altogether more robust plant than the older species (the Arabian Coffee), and which is expected to withstand the attacks of both animal and vegetable parasites much better—has excited the hopes of Coffee planters in all parts of the world to the highest degree. As its seeds, however, do not always germinate here on their arrival, even after much care has been spent on their collection and quick transport, it is unnecessary to add that the chances of their growing in a distant colony are very materially lessened. From Kew we learn that out of 70,000 seeds of *Hevea brasiliensis* only little more than 3 per cent. grew, although no pains had been spared in gathering, packing, and bringing them to England with all despatch. One thousand nine hundred plants, part of the produce of these seeds, were transmitted in thirty-eight plant cases to Ceylon, and of that number 90 per cent. arrived at their destination in perfect condition. Had the seeds been sent direct to Ceylon instead of to England, where every attention was bestowed on them from the moment of their arrival, total failure must have been the result. Now it is reasonable to hope that the cultivation of the *Hevea* in India may succeed. If it does, the Rubber will become, as Quinine already has, a most important and valuable article of commerce. Prior to the introduction of glazed cases, the difficulty experienced by collectors was very great. Of course, the mass of their plants were packed in the hold of the vessel, and were killed by the exclusion of light. Menzies, on his return from his last voyage round the world with Vancouver, lost the whole of his plants from this cause. Other botanists, who managed to place their living specimens on deck, always lost an enormous proportion owing to the salt spray and the extremes of temperature to which their plants were forced to submit. In the passengers' cabin on board ship, there is but little room for plants; nevertheless, by dint of careful watching, rare plants have often been kept alive during long voyages without further shelter than that afforded by the cabin itself. In 1717 Mons. de Clieux was put in charge of several Coffees for Martinico. The voyage was long and the weather unfavourable, so all the plants died but one, with which, when the crew were put on short allowance of water, Mons. de Clieux shared his portion. His self-denying care deservedly met with success; for the plant thrived and was the parent stock whence the neighbouring islands were supplied. Q.

INDIAN AZALEAS AT MESSRS. ROLLISSONS'.—There may now be seen a very interesting phase of the culture of Azaleas in the Messrs. Rollissons' nurseries at Tooting. For several years the young stock, and even numerous specimens, have been planted out in the open ground, and with the best results. They are of course in beds of prepared soil, and are potted and removed indoors in autumn, and planted out again in early summer. The growth being made out-of-doors is clean, healthy, and firm. The beds of Azaleas treated in this way are now well worth a visit.

ALPINE FLOWERS AT HOME.

WHEN I wrote of the flowers of the Riffel, I overlooked two which had every claim to mention, from their intrinsic merits and their abundance—*Androsace glacialis* and *Draba aizoides*. The former of these seems to have a limited range in respect of altitude, growing, I believe, within pretty much the same limits as *Eritrichium nanum*, seldom, if ever, below 8000 ft. or 9000 ft. above the sea-level, and necessarily soon stopped in its upward course by the absence of all needful conditions of vegetation. No flower can well be more beautiful than it is when closely inspected, almost more gem-like than resembling ordinary blossoms, scarcely raised above the snow-trodden grit where it finds a home, showing next to no leaf, and itself of unruffled regularity in point of form, though the little stiff petals partake of every shade of colour, from pure white to the brightest rose. I have tried more than once to cultivate it, but with so little success that this time I could not bring myself to lay sacrilegious hands on it again. *Draba aizoides* is a stouter, more ordinary plant, and though probably its Swiss luxuriance is not likely to be attained by many cultivators, it will make itself contented on our lowlands. Around the Riffel it helped *Androsace Vitaliana* to sprinkle the moist hollows with patches of bright gold. In thus singling out those which I have, I wish it to be understood that I found my selection on such beauty as qualifies its possessor to become a subject for horticulture, and also on its general occurrence. Several rare plants only occurred in single specimens, or were chiefly of interest to the scientific botanist, which I have consequently made no mention of. The village of Zermatt stands on what may loosely be described as the meeting point of no less than four glaciers, the two more considerable ones debouching more or less northwards from Monte Rosa and the Matterhorn, and the intervening chain; the other two eastwards and westwards respectively. The one which flows westwards (for glaciers are frozen rivers, flowing as steadily as the Thames or Severn, if more slowly) is called the Findelen glacier, and has some plants of its own in the valley to which it gives its name. They are, so far as I could ascertain, for the most part, rather botanical than horticultural, if my distinction be admissible. A few of the latter deserve special notice; and the first which has prominently fixed itself on my memory, from its soft, tender beauty, is *Anemone Halleri*. I must leave to others to speak of its aptitude for cultivation, for as to this I know nothing whatever, having never seen it in any garden, nor having been able to find it in any gardening book which has fallen in my way; but it is a very distinct and beautiful species, and I found it in considerable abundance round and near a little tarn by the glacier side, just emerging (with that graceful, bashful bend which is so characteristic of some of the higher Alpines) from its winter mantle, its thick, downy, much-divided leaves harmonizing with the pale mauve of the interior of the corolla. I could only wonder what had hindered so striking a plant from establishing a home amongst our naturalized treasures. The other plant which I have in my mind is one which an ordinary flower-gatherer might possibly pass by as only a free-growing *Myosotis sylvestris*, which, by some freak, had left its usual haunt on the sunniest pastures for out-of-the-way holes and corners more or less in the shade. But a closer inspection, especially of the seed-vessels, which were little, oblong, prickly nuts (whence its name, *Echinosperrum deflexum*), would soon reveal its true character, and add another distinct plant to our collections, which, so far as appears, may be as capable of cultivation as its congeners of the *Myosotis* family. The highest pastures on the north side of the Findelen Valley, just under the Little Rothhorn, offered specimens of a very interesting family of plants (the habits of which under cultivation I shall be glad to learn more about), in the shape of *Oxytropis cyanea*, *lapponica*, and, I believe, *uralensis*. A very minute botanical distinction separates these from the *Astragalus* family, of which I before mentioned *A. monepessulanus* as quite a feature of the main Zermatt Valley, and may now add *A. aristatus*. *Phaca alpina*, another kinsman, is to be found very commonly in the high, moist pastures, and, if in cultivation it prove as graceful as in its untrammelled freedom, will be amongst the chief ornaments of our rockeries. I must not leave these regions—"Alps" as they are technically called—by which is meant not mountains, but mountain-pastures, where

cattle feed in the short summer—without alluding to the *Potentilla* family, which were well represented. *P. grandiflora* was very handsome on the sunny slopes, *P. frigida* grew above the Riffel, and *P. nivea* is also, said to do so though I did not succeed in finding it. The first of the three should have a place in our collections, and ought to have its wants supplied without much trouble. I should like to notice, while the subject occurs to me, the tendency that exists amongst Alpine plants—at any rate, in their higher habitats—to put forth white flowers. My explorations this summer were necessarily very short, but in the course of them I came several times—as, indeed, I mentioned before—on white *Viola calcarata*; at other times on *Linaria alpina*, *Campanula barbata* and *rhomboidalis*, *Primula farinosa*, and *Gentiana verna*, if not on others which I have forgotten, exemplifying this pretty variation. Has the shortness of the summer, and the consequent strain laid upon vegetation, to enable it to go through its allotted functions, anything to do with the phenomenon? Certainly there is nothing like the same amount of albinism in the flowers we raise in our gardens. I must reserve for another number some other Zermatt flowers, which it would be sheer injustice to omit.

CANONICUS.

LATE GOOSEBERRIES AND CURRANTS.

AS ADDITIONS to the dessert these are highly appreciated, more especially during such a season as the present, when stone fruits are, as a rule, very scarce. I find medium-sized Gooseberries, with a firm and rather thick skin, to be the best for hanging late, as the large, thin-skinned varieties that are preferred during the ordinary Gooseberry season are sure to split during heavy rains; the sweet kinds when over-ripe also lose their flavour, and are decidedly surpassed by those which, when moderately ripe, have a sharp acid flavour. Red and White Currants are also both very useful, for although as a rule the flavour of the White kind is preferred, the mixture of the two has a pretty effect, the Red variety being very bright under artificial light. Although they may be preserved on ordinary bushes by means of netting, they are best on walls with a north aspect, on which few crops are more prolific or certain, and in such positions they can be easily protected from birds. We usually plant them about 3 ft. apart, and train up the required number of shoots about 6 in. apart, spurring them in quite closely in winter. During summer the shoots of the Currants are pinched in to three or four leaves, for if left at full length the foliage at the base of the shoots gets overgrown and falls off, whereby the keeping quality of the fruit is injured. When once the trees are fully furnished with spurs they only require an annual pruning of the simplest kind, and let the season be what it may, I have never known those on walls to fail in producing an abundant crop. Of Gooseberries we find the Warrington, Rumbullion, and Smooth Yellow, and of Currants the Red and White Dutch, and Warner's Grape to answer best.

J. GROOM.

Henham.

The Brighton Aquarium Fernery.—This fine example of Mr. Pulham's handiwork improves in appearance as it gets older. The only fault to be found with it—if fault it may be called, and that not Mr. Pulham's—is its scantiness of verdure. True, there are a few Tree Ferns, Indian Rubbers, and other vegetation, but not nearly enough. Mr. Pulham's bold, natural-looking rockwork, with its waterfalls and dripping caverns, needs skilful draping, not with the view of concealing the rocks, but for the purpose of setting them off to increased advantage. This ought to be easy enough, considering the great wealth of plants which we now possess for that purpose. The roof or terrace garden is better planted; its beds of *Lobelias*, *Alternantheras*, and other low-growing plants at the base of the vases, divided into compartments by means of terra-cotta divisions, are very pretty, and the vases themselves are well filled with showy plants. These vases, which are made of terra-cotta and graceful in design, Mr. Pulham informed me will withstand frost without injury, as will also the neat terra-cotta edgings that keep the boundary fringe of *Enonymus* in its place. This shrub stands the salt spray with impunity, and soon grows into a large bush, which, along with the Tamarisk, forms the staple shrub vegetation of Brighton. The fish caves, so well constructed by Mr. Pulham, that are filled with sea Anemones—flowers of the ocean, as they have been called—deserve a word of praise. They are the best specimens of the kind which I have seen under artificial conditions.—M.

NOTES OF THE WEEK.

NOTES FROM DUBLIN.—It may interest some of the readers of THE GARDEN to know that in an exposed position facing the sea, in Sir Francis Brady's garden at Dalkey, *Diosma ericoides* has proved itself to be perfectly hardy, having now been out-of-doors for three severe winters. In the same garden I noticed a plant of *Erica McNabiana* in full flower, which had also overcome the hardships of three winters. *Romneya Coulteri* has now fairly established its claim to be placed amongst half-hardy plants; in spite of incessant rain and cold, it flowered very well on a south border at Glasnevin, one bloom measuring $4\frac{1}{2}$ in. in diameter. At the last show of the Royal Horticultural Society of Ireland some very fine plants were exhibited, two of the most interesting being a fine specimen of *Lapageria alba*, with over fifty blooms on it, and a good example of *Philesia buxifolia* in full bloom. Messrs. Rodger McClelland & Co., of Newry, staged a very good collection containing several new and interesting plants, conspicuous among which was a fine *Croton* called *Etna*, with very bright leaves, something in the way of those of *C. Veitchi*, but superior. From the same firm also came seedling tuberous *Begonias*, which were pronounced by Mr. Gumbleton, an authority on such subjects, to be the finest he had ever seen.—F. W. MOORE, *College Botanic Garden*.

THE INTERNATIONAL SHOW AT CARLISLE.—This opened on Thursday last, and had many attractions. Hothouse plants generally were well represented, and shown in very large tents. Our principal London nurserymen, such as Messrs. Veitch, Williams, and Bull, showed large and remarkable groups of new and rare plants. There was also a very fine show of fruit and vegetables, dinner-table decorations, &c. Out-of-doors there were fine collections of Conifers shown by Messrs. Little & Ballantyne, Barron, Dickson & Turnbull, and others. Mr. Colman, of Eastnor Castle Gardens, won the first prize for a collection of fruits, Mr. Johnson the second, and Mr. Ingram the third, the whole of the collections being remarkably good.

THE GOLDEN CHESTNUT IN SCOTLAND.—We have received from Messrs. Dicksons & Co., Waterloo Place, Edinburgh, specimens of this Chestnut in flower and fruit, the latter well guarded by reddish, brown-tinged spiny husks. The leaves, which are not unlike those of a Myrtle, are glossy green above and golden beneath. The plant from which these specimens were sent, Messrs. Dicksons state, is 3 ft. 9 in. high and 2 ft. 9 in. through. It has been planted out in the Redbraes Nursery for the last nine years, and is a very perfect specimen—quite the finest we have seen. It has flowered for the last three years, but the seed has never come to perfection.

COCHLIOSTEMA JACOBIANUM.—The large plant of this in the Holloway Nurseries, which was noticed in THE GARDEN as being in flower early in June, is still flowering freely, and to all appearance will continue to do so for some time yet to come. Such effective plants as this, which yield brilliant flowers in succession for so long a period, cannot well be too highly prized for decorative purposes.—C. S.

POTATOES PRODUCED FROM A POUND OF SEED.—We have received the following report concerning the produce of our six new sorts of Potatoes grown this year near Dartford. One pound of each was planted, and the results are that Centennial yielded $26\frac{1}{2}$ lb.; Covent Garden Perfection, 38 lb.; Superior, $48\frac{1}{2}$ lb.; Success, 46 lb.; Lady Webster, 23 lb.; and Improved Peach Blow, 77 lb., being 259 lb. from 6 lb. of seed.—HOOPER & Co., *Covent Garden*.

PEAR BEURRÉ DE L'ASSOMPTION.—We have received some good specimens of this Pear from Mr. Rivers, of Sawbridgeworth. This is a somewhat new variety, obtained from seed by an amateur, Mons. Ruillé de Beauchamp, at Gropillière, near Nantes. It is remarkably fertile and vigorous, and grows perfectly on the Quince. It forms regular, well-furnished pyramids. The flesh is white and soft, juicy and sweet, and it is slightly but delicately perfumed; the fruit is rather gritty towards the centre. It is a Pear of the first quality, and is with us at maturity from August to September.

EFFECTS OF THE WET ON HARDY PRIMROSES.—The rains which we are now having are inducing a luxuriant leafy growth in the case of all hardy Primroses and Polyanthes, and thus giving promise of a rich yield of blossom next year. With this new leafage come many new crowns, and strong plants may be lifted next month and be hand-divided, replanted, and yet in the spring produce good heads of flower. As evidence of what may be done with a hardy Primrose, I may say that early in the spring I lifted from the open ground a strong seedling plant with a single crown. This was exhibited two or three times at South Kensington, was then divided into four, and repotted. They remained in their pots all the summer, and I have now just redivided them into thirteen good strong plants. This is the result of keeping the plants cool and constantly growing. Hardy Primroses should have no summer rest, but may remain quiescent during the

winter until excited into growth and flower by the advancing spring. *Primula denticulata* and *purpurea* have done remarkably well, and although their foliage flagged greatly during hot sunshine, yet they seem to be none the worse for it, and the present moisture has brought about a complete revival. Less robust kinds, such as *P. nivalis*, *intermedia*, *Munroi*, *marginata*, and others, have thriven remarkably well both in and out of pots.—D.

LUCCULIA GRATISSIMA IN FLOWER.—Last spring I obtained a plant of this from the nursery (in a 6-in. pot, and planted it in a new house and in a newly-made border consisting of light loam, peat, and leaf-mould. The plant has made growths upwards of 2 ft. in length, several of which are now in flower, and have each four lateral shoots close below the flower-truss. These will probably flower in the winter with the other shoots. Its being in bloom now is probably the result of its robust growth.—JOHN GARLAND, *Killerton, Bæter*.

CRATHEA BURKEI.—This is one of the most graceful of tree Ferns of recent introduction. Its stems, which are stout and erect, are surmounted by large heads of deep green fronds of a gracefully pendent habit. Succeeding as it does in a moderately warm conservatory, this Fern may be classed as one of the most useful of its kind. Large importations of it have lately been made by Mr. Williams, of Holloway, in whose nursery may be seen some fine examples of it.—S.

THE COLORADO BEETLE STAMPED OUT.—The "Cologne Gazette" says that all fear of ravages by this wearisome insect in the neighbourhood of Mulheim seems now to be past, thanks to the energetic measures taken by the authorities of the district. Since the discovery and destruction on July 30 of the last brood, sixteen men have been constantly engaged in examining all the Potato fields in the place. Dr. Harenstein, of the Poppelsdorff Academy, the Government Commissioner, who has weekly inspected the fields, has now declared the danger past.

GODETIA LADY ALBEMARLE.—A mass of this *Godetia* in Messrs. Osborn's nursery is just now very attractive. Its flowers, which are large and of a brilliant crimson colour, are produced in profusion for several months in succession. Amongst hardy annuals, this is one which should have a prominent place. It is also a valuable plant for pot culture.—S.

A LATE-FLOWERING GENTIAN (*Gentiana septemfida*).—We are indebted to Mr. E. Farrer, jun., of Petygards Hall, for a pretty coloured drawing of this fine hardy Gentian, which he finds to thrive better than most others, and to be a very beautiful late-flowering kind. "It flowers well on either the heavy clay or light loam, still those who can obtain the latter for it will be amply rewarded. It seems to prefer a sunny spot, and to be able to open well its blossoms and show the beauty of their colour; but to me the best points in its character are that it flowers at a time (July and August) when dwarf perennials are scarce, especially blue ones; and it does not so readily or so soon close up at evening as the rest of the family. I purchased it under the name of *G. gelida*."

OTHONNA CRASSIFOLIA.—This 'succulent plant of recent introduction has a pendulous habit and Mesembryanthemum-like leaves, and when grown in small hanging-baskets or in pots placed on pedestals, it is both useful and ornamental, being generally beset with small yellow flowers. It might be grown successfully as a window plant. We saw a quantity of it in the Victoria Nurseries the other day growing in pots and drooping over the sides, not only of them, but over the shelves on which they were placed with good effect.—S.

BATTERSEA PARK GARDEN.—Notwithstanding a singularly unfavourable season, this is now very beautiful in the main. The carpet beds are protected at night by canvas stretched over hooped sticks, giving the place in the early morning somewhat the appearance of an encampment. The best of the so-called carpet beds are those with stately plants—like *Dasyliirius*—in them; in such cases the carpet takes its true place as the representative of the small plants that often carpet the ground beneath trees and shrubs. *Spiræa Lindleyana* is very beautiful by some of the quiet, grassy-margined shrubberies here.

ARCHDEACON DENISON ON POTATOES.—Archdeacon Denison's harvest home, which took place last week, was of the usual pleasant character. The Archdeacon in the course of some observations said he had entirely abandoned the planting of Potatoes, as they only rotted in the ground. He recommended his hearers to sow Beans, Peas, and Beet, and plant Greens in their place. The Archdeacon is perfectly right: the Potato fungus is a pest which rushes from leaf to leaf freely when the Potatoes are sheeted with water; hence it is absent or not injurious in dry countries. There are regions perfectly suited to the Potato and extensive enough to supply many times more than the present demand. Obviously it is wisest to grow in a wet country vegetables not destroyed through rain, but rejoicing in it.

A NEW METHOD OF PROPAGATING PLANTS.

OUR correspondent, Mr. Peter Henderson, fully describes in the "American Agriculturist" a new and very successful method of propagating Geraniums and many other plants, which is an improvement made by him on an earlier process known as "layering in the air." This consisted in tonguing the shoot to be used as a cutting half through with a knife, as in the ordinary layering; the shoot so treated formed granulations, or "callus," on the cut surface, and was in a condition to form roots immediately on being detached and put into the earth. In the new process, instead of tonguing the shoot to be used for a cutting, it is merely snapped short off, at a point where the condition of the shoot or slip will make it hang on to the plant by the merest shred of bark. Slight as this strip of bark appears to be, it is sufficient to sustain the cutting, without any material injury from wilting, until it forms the "callus," or granulated condition, which usually precedes the formation of roots. The cutting or slip may be detached in from eight to twelve days after it has been broken in the manner described, and then potted in 2-in. or 3-in. pots. If watered and shaded rather less than required by ordinary cuttings, it will form roots in eight or twelve days more, and not one in a hundred will fail, even of plants of the Tricolor Geraniums, which are difficult to root under the ordinary modes of propagation, particularly in hot weather. Of the success of this method, and the classes of plants to which it is applicable, Mr. Henderson says:—We last autumn propagated in this way nearly 10,000 plants of the Tricolor class, with a loss of 1 per cent., had we adopted the ordinary method, even with the plants in good condition, our experience has been that a loss of at least 50 per cent. might have been expected. This plan is applicable to many other plants as well as Geraniums; we are now using it with excellent success on the new double Poinsettia. The following plants may be also propagated with great certainty by this method, using the young, unripened shoots:—Abutilons, Begonias, Carnations, Crotons, Cactus of all kinds, Heliotropes, Lantanas, Oleanders, Petunias (double), Pelargoniums or Geraniums of all kinds, together with nearly all plants of a half-woody or succulent character. Besides the absolute certainty of having the cuttings root by this method, it has another most important advantage. All propagators know that many kinds of plants, when cut back for cuttings, become weakened so much that if not carefully handled they may die; also that if two or three crops of cuttings are taken off as they grow, the "stock plant" becomes permanently injured. By this method of breaking the slip, so that it hangs by a shred to the parent plant, the roots have to use their functions for its support nearly the same as if it remained entirely attached to the plants. This results exactly as we wish, in causing the parent plant to strike out shoots below the broken slip, and these again in their turn can be so treated. This process will be useful not only to florists but to amateurs, as it is both easy and sure, and we have no doubt that many of our readers will be interested in trying it.

Gentiana americana.—This *Gentiana*, an annual of sterling merit as a garden flowering plant, a native of Arkansas and Texas, is a comparative stranger in cultivation. It is described by Dr. Gray as from 1 ft. to 2 ft. high, but the plants now growing in our garden are 4 ft. high. They are stout-stemmed, rather sparingly branched as compared with their size, but every branch and branchlet are terminated by a flower-head, of which from fifteen to twenty-three decorate each plant; the open heads are from 3 in. to 5 in. across, of a pale purple colour, and very showy. They begin to bloom about the middle or 20th of July, and go on flowering till September. In spring we raise and otherwise treat them as we do Stocks, Asters, Zinnias, or Drummond Phlox, and towards the end of May transfer them to the garden plots in clumps of three. At night, and after being cut and kept in a shady place, the flowers close up, the heads then looking like a painter's brush. These brushes, whether on the plants or as cut flowers in the house, open as beautifully as ever ere sunrise next morning. *G. americana* var. *Halli* (according to Mr. Falconer, in "Rural New Yorker") only differs from the typical plant in having the flowers of a deep rich purple colour, and perhaps a little fuller and more compact. Nor does it close up so noticeably

or quickly as does the true americana. It is not a garden-raised variety, but is a native of Texas, where it was collected and disseminated by Mr. Hall, in compliment to whom it was named.

Exhibitions of Wild Flowers.—The following, cut from a local paper, shows how much a gardener may do in the study of native plants, even within the limits of a country seat. A great feature of the exhibition which took place the other day at Henley-on-Thames was a collection of 228 varieties of wild flowers, all found near Henley, contributed by the Botanical Class of Park Place, which is conducted in connection with the Science and Art Department of South Kensington by Mr. Stanton, gardener to Mr. Noble. The arrangement of this large number of flowers was most artistic and effective, and must have involved no small amount of labour.—G. S.

Tree Carnations Planted out.—These are yielding a fine crop of flowers that are highly esteemed in a cut state, and which carry on the season of Carnation blooms from the time when the ordinary outdoor varieties of Cloves, Picotees, and Carnations are over until the winter supply from spring-out plants is ready under glass. These, after supplying cut flowers during the winter and spring, are usually set out-of-doors during April, as they become denuded of flowers, and after being hardened off in a sheltered position, are planted out in May either in mixed borders or in beds in the reserve garden, where, if attended to as regards moisture during periods of drought and tying up the flower-spikes as they approach maturity, they invariably well repay that attention by an abundance of blossoms.—J. GROOM.

The Dove Orchid (*Peristeria elata*).—In your last issue (see p. 201) reference is made to a plant of this in the Botanic Garden, Birmingham, which is bearing two flower-spikes on which are forty-five blossoms and buds. We have here a plant which has had ten spikes upon it, another that has had five, and a small one that has had two spikes. On these I have counted as many as seventy flowers open at one time, and some of the strongest spikes have borne about thirty flowers and buds. These *Peristerias* have been growing amongst ordinary stove plants; though not showy, they are great favourites with many, and as they flower at this comparatively dull season as regards indoor plants, they merit more attention than they generally receive. Single flowers of them when mounted are well adapted for bouquet-making; they also last a long time in a cut state, and emit a delicious perfume. The pseudo-bulbs of this plant are unusually large, some of them here measuring upwards of 9 in in circumference.—ROBERT MACKELLER, *Abney Hall, Cheadle*.

The Potato Crop.—On reading Mr. Fish's article (see p. 199) on this subject, I notice a great difference between the time of the Potato ripening in his locality and in this, the western part of Co. Cork. The disease attacked Potatoes in this neighbourhood as early as the 28th of May, and many kinds had lost all their leaves and stalks by the end of June. All my Potatoes to be saved for seed have been out of the ground since the end of July, and are spread out separately on the wooden floor of a loft, having open skylights in the roof. I find this to be the best way in which to keep Potatoes to be used for planting, as they remain very firm, and are always well sprouted by planting time. I grow ten varieties, and of these Rivers' Royal Ashleaf, Extra Early Vermont, and Berkshire Kidney, when dug out, were found to be almost free from disease. Flounders, Lapstone Kidney, Snowflake, and American Red, were nearly all of them bad; and Eureka and Brownell's Beauty were a mass of rotteness. The only kind I have which has withstood the disease is a local one called Hero; it is a large pink-skinned Potato with deep eyes, and is a very heavy cropper. In this neighbourhood Potatoes are much smaller than usual this year, and are, as a rule, badly diseased. The weather has been dreadfully wet for some weeks past.—JOHN CLARKE, *Cork*.

Garden Churchyards in London.—The Rev. W. Abbott, the rector, and the churchwardens of St. Luke's, Old Street Road, applied to the Chancellor, at the Consistory Court, on the 21st ult., for a faculty to convert the closed burial ground of the old parish church of St. Luke's into an ornamental place for trees and flowers. There was no opposition to the plan, and the inhabitants were in favour of the proposed improvements. The rector explained that it might be necessary to remove some of the memorial stones but no remains. At a recent vestry a resolution was unanimously passed to effect the required alterations, and £500 had been voted for the purpose. The Chancellor said the faculty would be given in a few days.

Mountain Ash-tree Berries.—A girl, four years old, named Campbell, has died at Grennock from the effects of having eaten a quantity of Rowane or Mountain Ash-tree berries.

TREES AND SHRUBS.

THE LAWSON CYPRESS AND ITS VARIETIES.

To the inhabitants of the North Pacific coast this Cypress is better known as Port Orford Cedar, Port Orford, on the Oregon coast, being one of its native habitats. It was, however, originally discovered in the Chasta and Scots Valleys in Upper California by Mr. W. Murray, of San Francisco, who, twenty-three years ago, sent a small consignment of its seeds to Messrs. Lawson & Sons, of Edinburgh, who offered them for sale at the rate of £5 a single seed. No better proof of its qualifications as an ornamental evergreen tree can be given than when I say that in Britain it is annually raised from home-grown seeds by the million, and that it is to be met with almost everywhere, in place and out of place, in the gardens of the poor as well as in those of the rich—here as a single specimen of almost unrivalled grace and beauty, there in groups, or adding variety to the mixed shrubbery; and often, but as yet not too often, forming beautiful and ornamental hedges. So accommodating is it as a stock, that not only are all its own distinct varieties grafted on it, but also other species of Cypress and members of very distinct but, of course, of cognate genera. Singular however as it may appear, it will have little or nothing to do with what botanists consider its nearest blood-relative—*C. Nutkaensis*. They suggest to one the truth of the old adage, "Friends agree best when separate." *Cupressus Nutkaensis*, as a scion, unites kindly with *C. Lawsoniana*, but the union is not a happy one and very soon comes to an end through the death of the scion. It may interest some to know that *C. Nutkaensis* makes a perfect and lasting union with *Juniperus virginiana* and *J. communis*. Mr. Murray found the Lawson Cypress a handsome tree, in some instances 100 ft. in height, with a trunk 2 ft. in diameter. In this country it has already attained a height of from 20 ft. to 30 ft.; but although its timber is said to be good and easily worked, it will never, I fear, excel as a timber tree with us in Britain. Its proper place is as an evergreen decorative plant, and as such it has, at least among Cupresses, few if any equals. Being perfectly hardy, and not too particular as to soil, it luxuriates almost everywhere, but prefers a heavy, damp soil to a light or dry, sandy one. In the latter it is subject to premature sickening of the leaves, and, ultimately, defoliation. But this Cypress, like the majority of Coniferous plants, is less fastidious as to soil than it is to climate; it delights in shelter rather than exposure to cutting winds. As

a cheap, effective, and ornamental hedge plant it has few equals. Its shade of green is more cheerful than that of any other plant at present devoted to such a purpose; and its gracefully recurved feather-like branchlets form a pleasing relief to the rigid shoots of the Holly and even the Yew. Plants of large size may be advantageously used for this purpose, but small ones, say from 18 in. to 4 ft. in height, are preferable, as they can be clipped and headed back until a proper base is formed on which to build the superstructure. A distance of from 12 in. to 18 in. apart (according to the size and habit of the plants) will be found sufficient; but of course a greater distance is requisite where large specimens are required to screen unsightly objects. About the beginning

or not later than the middle of September, and again in spring when the shoots show signs of new life, are good times for clipping; but of the two early autumn is probably the better time, as the shoots then clipped are not so liable to be displaced and bent down by snows in winter, which would, were the shoots left untouched, give the hedge an irregular and ragged appearance. Plants of this Cypress are sometimes to be seen of a sickly hue and in a partially defoliated state; and people very naturally attribute such a condition to the occurrence of some constituent in the soil that does not suit the plants. It will, however, generally be found that mishaps of this kind are the result of poverty at the roots, and will in nine cases out of ten disappear after a generous top-dressing of well-rotted manure. Many plants, when under diverse cultivation, present a greater or less degree of variation from the normal type, and particularly is this the case with the Cypress under consideration. In the short space of time during which it has been under cultivation in Europe,

many very distinct varieties in habit and colouration have been obtained, and are now extensively cultivated. But, unfortunately, all the varieties named in trade lists do not deserve the consideration of planters; I shall, therefore, briefly describe a few of the best.

[Synonyms—*Cupressus fragrans* (Kellogg), *Chamaecyparis Lawsoniana* (Parlatore), *Chamaecyparis Boursieri* (Carrière).]

Green Varieties.

Cupressus Lawsoniana erecta viridis.—This is an erect, tapering tree of moderate growth, thickly and closely inlaid from base to top with compressed twiggy branches and branchlets of the richest green; indeed, it is quite unique as regards beauty, and never needs pruning and clipping.

C. L. argentea.—In this we have a dense, oval shrub of a sil-

The Lawson Cypress (*Cupressus Lawsoniana*).

very, bluish-green, with the points of its branches gracefully recurved. It is of moderate growth, and doubtless never will attain any great size: it is therefore a suitable subject for planting in fore-court gardens.

C. L. gracilissima.—This has the same habit of growth as the preceding, but is characterised by thinner and more twiggy branchlets; it is also of moderate growth.

C. L. nana.—This form has been in cultivation almost as long as the species, and yet is seldom to be seen over 2½ ft. in height. It is of an ovate shape, with stiff, erect, flattened branches and branchlets. It is represented by two distinct seedlings, the one bright green and the other bluish-green; the latter is the best.

[Synonym—pygmaea]

Self-coloured and Variegated Varieties.

C. L. lutea.—Although this has only been in existence some five or six years, it has already received several names. Its peculiarity is its colour, which is throughout the growing season a rich golden yellow, and even in the autumn and winter months it is only slightly subdued into greenish yellow. It is of good form and vigorous, and indeed all that can be desired for relieving the monotonous green of our shrubberies; but to do it justice, it is necessary that it be fully exposed to the sun. There need be no fear of it being scorched, for it is as immutable as the parent species.

[Synonym—aurea.]

C. L. pyramidalis alba spica.—This is a dense, pyramidal small tree, with the bark and leaves of the vegetating shoots of a chalky whiteness. Although of good colour when exposed to the sun, it will, unlike golden variegated Conifers generally, be improved by being planted in shady positions.

C. L. alba variegata.—This is of an upright habit, without ever reaching to any great height, with branches almost regularly blotched and striped with yellowish-white. It is consequently rather pretty and a most befitting subject for enlivening a shrubbery.

C. L. aurea variegata.—This differs from the preceding in its branches being loosely spreading, and in the variegation being of a golden yellow.

There are other very promising varieties in cultivation, but they are of recent introduction, and consequently not yet fully tested.

J. R. W.

Bedfordshire.

Californian Buck-eye (*Æsculus californica*).—I am glad to see attention directed (see p. 205) to this ornamental lawn tree. Surely no better proof of its merits as a handsome flowering tree need be given than that you, who have seen it forming one of the most striking details of the scenery of the valleys and foothills of California, should endorse all that Mr. Berry has said in its favour. I first made its acquaintance in the neighbourhood of Monterey about the beginning of November, 1866. By that time it had long been denuded of its foliage, but the large, smooth, pear-like fruit still depended from its numerous erect branches. Subsequently I met with it at intervals from Monterey, north-west throughout the broken coast range to Clear Lake, either growing singly or in small groups in the valleys as round-headed, middle-sized trees, or on hill-sides as large shrubs, which were, when in leaf but particularly when in flower, the most striking objects in the more immediate landscape. It is quite true of this tree, as is quoted from the "Botany of California," that "the leaves often fall before midsummer," and no wonder, considering that the uncultivated soil of the districts in which it grows is entirely dried up by that time; but from this drawback the people of damp-soiled, rainy Britain have nothing to fear.—**GEORGE SYME, Elveston Nurseries, Borrowash.**

Lilliputian Rhododendrons.—IN THE GARDEN of July 28, 1877, there is an interesting account of a new method of inducing Rhododendrons to flower at a very early age. A similar method of grafting in August with flower-buds that will thus bloom during the following spring has also been much practised by Messrs. S. B. Parsons & Sons, of Flushing, New York. Last June, at the exhibition of the New York Horticultural Society, this firm showed a fine collection of the choicest varieties of Rhododendrons treated in this manner. I would only suggest, as an improvement on the directions given for propagating, that the pots containing freshly-grafted plants be plunged in a cold frame during the winter, where roots, branches, and buds will retain more dormant and normal conditions than in an ordinary greenhouse. If forced Rhododendrons be desired, it is always advisable to select such varieties as possess most of the East

Indian, ponticum, or caucasicum nature, the Catawbiense, and still more the maximum, kinds being less fitted for such work on account of their late season of blooming.—P. S.

Influence of Temperature on the Germination of Pine Seeds.—Some experiments were recently made by M. Veltin, of the Vienna Academy, with a view to determine the influence of a previous warming on the development of Pine seeds. The latter were kept in darkness and sown in shallow glass vessels, the bottoms of which were covered with wide-meshed nets. The seeds were heated four hours to 40°, 45°, 50°, 55°, . . . 100° C, and then left to germinate. Seeds gathered in 1872 in a locality in which the Fir thrives well, first showed that the greatest number capable of germination occurs in the case of unheated seeds—that, with raising the temperature the germinating power gradually diminishes, and that through one hour's heating to 80° C, the nil point of germinating capacity is almost reached. The heated seeds nearly always germinated more slowly than the unheated; but a quarter of an hour's heating had hardly any influence. The germinating force also showed a decrease with rise of temperature, and gradually approached the zero point. In a second series of experiments seeds of Pine cones collected in another region, in the autumn of 1875, showed that a heating to 40° had hardly any influence on the germinating power. On raising the temperature to 70°, however, the germinating number was observed repeatedly to rise, but without reaching that of the unheated seeds. The germinating force, on the other hand, presented, as in the former case, a gradual decrease, with raising of the temperature. Further experiments were made, in which the previous heating of the seeds was continued longer, the lower the temperature; and, lastly, experiments were also made with like seeds at different times after they had been gathered. The following deductions were arrived at:—(1) The germinating percentage, as well as the velocity of germination, gives no certain indication as to the germinating force of the seeds; and the converse also holds good. (2) The heating of the seeds may have a favourable or an unfavourable influence on the germinating capacity and the germinating force, according to the physiological condition in which the seed is. (3) The duration of heating of the seed is of essential influence on its development, inasmuch as long heating at lower temperatures can produce the same effect as short heating at higher temperatures.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Carolina Prunus.—This for a Southern American tree thrives uncommonly well in London. It is seldom seen out of Kensington Gardens. It is very glossy in foliage and has a good habit. It is *P. Caroliniana* (Aiton), the Mock Orange, Wild Peach, &c., of the Southern States.

Griselinia lacida and Eurybia corymbosa.—Although the first-named of these is not quite hardy, it is a very effective evergreen shrub, and is well worth planting in sheltered situations. The *Eurybia* bears beautiful Aster-like flowers, which are also very showy. Any one who will give these two shrubs a trial will, I feel sure, be satisfied with them.—W. S.

Acer dasycarpum.—In 1843, Mr. Emerson measured a tree of this species, growing in the town of Stockbridge, Mass.; when at 3 ft. from the ground, it girthed 12 ft. In October, 1876, the same tree was measured by Mr. W. R. Robinson, who reports that its circumference at the same height was then 15 ft. 9 in., showing an annual average increase of circumference during the last thirty-three years of a little over 1·38 in.—"American Naturalist."

Abies Engelmanni.—The English papers continue to discuss the differences between *Abies Engelmanni* and *A. Menziesii*. Some say that "because it pushes out earlier than *Abies Menziesii*, *A. Engelmanni* is unfitted anywhere for the north of Europe." We know of a specimen which is undoubtedly *A. Engelmanni*, because it was taken from an altitude of some two miles up the mountain, where *A. Menziesii* does not grow, and which we examined in company with Dr. Parry himself recently, and which we are satisfied is hardy enough for any part of Europe.—"Gardener's Monthly."

The Oriental Plane.—An unjust prejudice may have worked, more or less, against the Oriental Plane by confusing it with the American Plane (*Platanus occidentalis*), a tree vastly inferior in outline, durability, and health. The Oriental Plane tree is entirely hardy, and quite valuable to the landscape gardener for the creation of his larger and more prominent effects. Our list of popular shade trees is too limited. Everywhere we see little else but Maples and Elms. A very agreeable variation of this sameness might be made by more extended employment of this well-tried Plane tree, and the diversity of effect accomplished would prove perhaps a stimulant to the taste for larger collections of fine Oriental trees. [So writes Mr. S. Parsons, of Flushing, in the "Cultivator," and that one so experienced in trees should say it makes these statements the more remarkable. In England generally, the American Plane is by far the finest tree.]

THE FLOWER GARDEN.

NOTES ON THE BEST PYRETHRUMS.

A GREAT improvement has been effected during the past few years in this family, principally through the exertions of the late Mr. Salter and others. The old *Pyrethrum roseum*, for instance, has been so improved that we have flowers equalling the finest of the French Asters, but with the additional advantages of being perennial, hardy, and producing abundant bloom at a time when flowers are comparatively scarce. They are in perfection in May and June, and, with the Iris and Pæonies, form a glorious group, which ought to be well represented in every garden. They are also invaluable for autumn decoration, for if cut down after flowering in June, they flower again in autumn. They are easily propagated by division of the root and by seed, but the latter mode I would not recommend, as the proportion of good flowers from the best of seed is remarkably small. A good rich loam suits them best, and the more well-rotted manure is incorporated with the soil the better the plants grow, and the more luxuriantly they flower. Mulching, especially in dry soils, is very advantageous, as it keeps the ground moist and cool. The following comprise the best of this family:—*White and White Shaded*—Boule de Neige, delicatum, Madame Billiard, Nancy, niveum plenum, Olivia, Argentine, Prince de Metternich, and Ne Plus Ultra. *White*

Pyrethrum roseum.

with *Yellow Centre*—Bonamy, Impératrice Charlotte, La Belle Blonde, virginale, and Voie lactée. *Purple and Red*—Mrs. Dix, rubrum plenum, Mons. Barrel, Brilliant, and Wilhelm Kramper. *Crimson*—Michel Buchner, Miss Plincke, Modèle, multiflorum, Prince Teck, Progress, Emile Lemoine, and Marquis of Bute. *Carmine and Pink*—carminatum plenum, Charles Ballet, floribundum plenum, Gloire de Stalle, imbricatum plenum, Nemesis, fulgens plenissimum, Haage et Schmidt, and Iveryanum. *Yellow*—sulphureum plenum, Solfaterre. *Lilac and Rose*—Comte de Montbrun, delicatissimum, Dr. Livingstone, Gaiety, Galathée, Hermann Stenger, Lady Blanche, Lischen, Minerva, Uzziel, and roseum plenum. A. P.

AN OLD-FASHIONED COTTAGE FLOWER GARDEN.

ALLOW me to describe a delightful old place to which I had free access some years ago, where the effect produced was always pleasing, although the expense of keeping was next to nothing, as the occupier did most of the work himself. As a matter of course, although the garden was full of flowers at most seasons of the year, and weeds and litter were always promptly removed, there was no attempt at what may be called fine gardening. There had originally been Box edgings to the paths, but these had been removed and in their place were wide, low masses of Sedums, Saxifrages, Cerastiums, Aubrietias, Arabis, and similar plants of low, spreading growth, all along the front of the borders. These were not often cut in or other-

wise interfered with, and, as a consequence, after meeting they spread out here and there over the edges of the paths in a wavy sort of outline that had a somewhat picturesque effect, especially in spring, when the bulbs that had been planted amongst them pushed up through the dense carpet. White and Provence Roses formed good-sized bushes in this garden, and the old-fashioned Monthly Rose was nearly always in flower. There were, too, good-sized bunches of Southernwood, Rosemary, and Lavender; these formed, so to speak, some of the more permanent features of the place, but there were, in addition, many interesting plants and bulbs, some modestly peeping out from under spreading branches of Roses or Lavender, others standing boldly forth challenging notice and admiration. Beyond all these, moreover, there were distinct phases which the occupier called, for want of a better name, his flower shows, three of these being his Wallflower, Larkspur, and Michaelmas Daisy displays. The Wallflowers in spring certainly were lovely, and the atmosphere around seemed loaded with their fragrance. There was no attempt at formal planting in this garden; indeed, many of the plants were self-sown, and bloomed where the seed fell, now growing singly out of masses of Sedum, and further on gathered together into a bold mass or group. The same occurred in the case of the Larkspur, which was the common single variety, and both these and the Michaelmas Daisies, which flowered in autumn, were sufficiently numerous to give a character to the garden during the time when they were in flower. When borders are planted altogether on the mixed principle at regular distances apart, there is a tameness and formality about them which these showy phases relieve. Thus, after the Wallflower display in spring, there comes a quiet resting time, and one is better able to appreciate the scattered beauties amongst the mixtures before the Larkspurs burst forth. The latter require little or no trouble or care, either to sow or plant, and there is an airiness and grace about their erect and slender flower-stems that is pleasing in a garden of this kind; even the seeming carelessness or want of method in their arrangement sets them off to better advantage than if they were planted by means of line and rule. I do not mean to assert that all gardens should be like this, but what I plead for is that all who have gardens, if they really wish to derive the greatest amount of pleasure from them, should, instead of copying from others, think and act for themselves. There is, I have reason to know, a large amount of latent enthusiasm connected with gardens and gardening; it is only necessary to touch the right chord to draw it forth, and then gardening will become a necessity to the many as it is now to the few. It is not a question of means, but one of "loving care." Gardening can be learned and practised during times of leisure, and, comparatively speaking, almost without cost. It has been said that many old-fashioned plants, about which many are inquiring now, cannot be obtained, that they were thrust on one side to make room for the favourites of the hour, and have through neglect perished, but in a commercial country like ours, when a demand arises for anything it is sure to turn up, and it must not be forgotten that with many kinds of hardy plants we are far better supplied now than we were twenty years ago. The Phloxes, Pentstemons, Pyrethrums, Pæonies, Potentillas, Delphiniums, and many other good subjects, have undergone a great improvement at the hands of the hybridist, and much yet remains to be done. Take the Michaelmas Daisies or perennial Asters, for instance, how rare they have comparatively become! and yet I remember that they were common enough in every country garden thirty years ago. These and similar plants must again come to the front, and those who cater for the public wants would do well to be working up a stock of them.

E. HOBDAV.

PLANTING HARDY BULBS.

As the season for planting the majority of bulbs is now fast approaching, a few remarks on those which I have found most satisfactory as permanent occupants of beds and borders may not be unacceptable to those who have positions where they can be allowed to grow undisturbed. Give them a situation well prepared at first; plant them with due consideration as to their future development, and they will every succeeding season

come up with increased strength and vigour. Amongst positions in which I have seen Lilies, Gladioli, Narcissi, Hyacinths, and similar bulbs grow most luxuriantly, are beds of such shrubs as Rhododendrons, Azaleas, Kalmias, &c., or permanent Rose beds or banks on which the spade is never used, or herbaceous borders backed up and sheltered by shrubs. There need be no fear that the soil will not suit them, for if the ordinary occupants of such beds flourish, and the ground has been previously deeply cultivated and enriched, even small bulbs will soon be found to increase in size both as regards blossoms and bulbs. Beds containing Rhododendrons and similar evergreen-flowering shrubs planted in an ordinary mixture of peat and loam, will not only suit Lilies and Gladioli admirably, but the blossoms of such bulbs intermixed with the shrubs will set them off to advantage when they are not in flower. I have planted scarlet Gladioli in such positions, and between rows of standard Roses, for yielding spikes for cutting, and they have annually increased in strength and effectiveness, while amongst dwarf Roses and on the edges of herbaceous borders the whole race of dwarf early spring-flowering bulbs succeed admirably, the shelter afforded by the Roses being decidedly advantageous in breaking the force of the wind. Lilies do well in borders, and when cut flowers are in request during summer, they well repay any attention that may be bestowed upon them; and even a small collection will yield a long and varied supply of exquisite flowers. Those bulbs, however, which are easiest of culture, the hardiest, and which yet yield the most delicate blossoms in even the poorest soil, are the Narcissi and Jonquils. Both are such strong-rooting plants that even when robbed at the roots and overgrown by stronger and statelier vegetation, they will continue for an indefinite number of years to throw up foliage and flowers that can scarcely be surpassed by any plant in existence, and only equalled by some of the choicest exotics.

Henham.

J. GROOM.

NOTES FROM IRELAND.

Romneya Coulteri.—The first estimate of the value of this interesting stranger as a hardy flowering plant has been more than realised. We had recently an opportunity of seeing it at Glasnevin, and the first glimpse of it with numbers of its flowers open did not fail to draw forth an expression of surprise and admiration. The Glasnevin specimen, though only struck from a cutting in the spring of last year, is now some 6 ft. high, 4 ft. or more through, and every branch and branchlet are terminated by a flower or flower-bud. The expanded flower is fully 6 in. across, quite flat, delicate in texture, and pure white in colour; from the centre rises a great ball of gold, formed by the close globular aggregation of anthers innumerable, forming with the petals a brilliant and beautiful contrast of white and gold. The flowers remain perfect for three or four days, and there is a constant succession of them open. The protection afforded the plant during the past winter was of the most trivial kind, namely—a bit of bast mat thrown over two or three stakes. It is doubtful if even this be absolutely necessary, a slight protection over the roots, we apprehend, being all that is really required, perhaps not even that. The present cold, unless, wet summer was by no means best calculated to bring out its grand flowers in the quality and profusion seen under Californian light and sunshine. Nevertheless, here we have it now blooming freely and profusely for some weeks, and likely to continue to do so for some weeks to come. In regard to it, therefore, three things are, we think, fairly established—firstly, its perennial character; secondly, its hardiness; and thirdly, its early flowering and very striking and highly ornamental aspect. To the botanist, *Romneya Coulteri* is a very interesting plant, as being the connecting link between the Orders Papaveraceæ, Nymphæaceæ, and Sarraceniacæ; to people in this country it is also interesting, by reason of the genus being founded by our distinguished countryman, the late Dr. Harvey, and the name of the genus being given in honour of another distinguished Irishman, Dr. Romney Robinson, of Armagh, and further, the specific name commemorating the name and memory of Dr. Coulter, one of the most eminent professors of the Royal Dublin Society.

Panocratum (Ismene) calathinum Flowering in the Open Border.—This beautiful Amarylloid has flowered finely this season in the open border at Glasnevin, where it has grown and flourished without the least protection for the last five years, but did not flower till the present one. It is, moreover, now swelling seeds. When planted out it was only a single bud, now there are several

and quite a tuft of strong and vigorous foliage. Here, then, we have another and rather unlooked-for addition to our hardy bulbous plants.

Eucalyptus globulus at Killarney.—One of the handsomest and most promising specimens of *Eucalyptus* that has come under our notice is that growing at Dinas Island, Killarney, facing the Tore or middle lake. It is now some 50 ft. high, perfectly symmetrical, and apparently quite at home in that fairy and favoured region. There is a second one growing within a short distance of it, and about the same height, but not so evenly furnished.

Limncharis Humboldti in an Open Tank.—It is to be regretted that this lovely and most floriferous aquatic is not more availed of for outdoor work. It is one of the most effective plants for a tank or quiet bit of water. The small outdoor tank near the Victoria-house at Glasnevin is nearly monopolised by this plant, and at this season few features of the garden are more attractive to visitors. The tank is only about 10 ft. or so in length and 3 ft. in breadth, and in this circumscribed space we counted the other day over 160 flowers floating on the surface.—“Irish Farmers’ Gazette.”

LAYERING CARNATIONS IN LEADEN CUPS.

It is in cups of well-rolled lead, according to the “*Fleurs de Pleine Terre*,” that the celebrated cultivator of Carnations, M. Gonthier, of Pierrefitte, has so successfully practised their propagation by layering. The lead used for these cups is rolled out to the thickness of strong paper, and then cut into triangular bands. These are

formed round the finger to a shape somewhat like a small sugar paper. The soil employed is fine, and the same as that used for culture in pots; threads serve to support the cups in position, and a pin thrust through helps to secure them and keep the layer in position.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Rudbeckia bicolor.—I can quite endorse everything which Mr. Thompson of Ipswich says (see p. 178) about this new annual. The yellow-rayed flowers are set upon a bed of green undergrowth like an Aster—the dark centre being surrounded when in full bloom by a margin of yellow fringes, making it altogether one of the prettiest of our annuals. I am trying what autumn sowing will do for it. We amateurs who despise the absurdity of ribbon and carpet bedding should be grateful to Mr. Thompson who has given us two such flowers as *Rudbeckia bicolor* and *Helianthus cucumerifolius*.—W. H. C., Kensington.

The White Betony on Hampstead Heath.—It is interesting to learn that Hampstead Heath still possesses a curious flower. John Gerarde published in London, in 1597, “*The Herball, or General Historie of Plantes*,” and therein, speaking of Betony (*Stachys betonica*), he alludes to having found a white-flowered one “in a wood by Hampsteeds, near Master Wade’s house.” This pretty flower, now to be seen plentifully on West Heath, is usually a reddish purple.

Shearing Gardeners.—With reference to the expression “shear-like scissors” in the note on “Barber-ous Horticulturs” in last week’s *Garden*, allow me to say that the instrument in question is really the common sheep shears. I met three young men armed with them the other morning, and traced them to their “atrocities” committed on some beds of *Alternantheras*, &c. They set to work mutilating, shearing, and nipping these, enpointed on a plank placed over the bed. I may add that it was not in the extensive grounds surrounding Bedlam where I witnessed this.—Q.

THE FRUIT GARDEN.

MINIATURE MELONS.

MELONS are appreciated by most people during the hot days of summer and early in autumn, but many attempt their culture who do not meet with the success that their efforts merit, while many are deterred from attempting their culture from fancied difficulties that lie in the way, and which only exist in the imagination. Failures arise from ignorance of a few simple facts. The essentials of success in Melon growing are: First, a bottom-heat ranging from 75° to 85°, and a top-heat of from 65° to 90°, and this is easily commanded during summer with a common garden frame and one square yard of any kind of litter that will ferment slowly. A few barrowloads of stable manure and an equal amount of tanner's bark make a good hotbed; but littery straw with leaves, sawdust, or even part of an old hotbed mixed with it to moderate the stable-yard manure or straw is a good thing, and in favoured districts success is often attained without any fermenting material. Second, the variety is of some importance to those who have only a spare frame or so to devote to Melon culture; and this is another fact often lost sight of by many who are possessed of the best appliances, and who venture to instruct those who are otherwise situated. Little Heath is a good Melon for amateur

Miniature Melon-plant in pot.

cultivators who have little space, as it is hardy and is not a shy setter, while its flavour is good, although second-rate as compared with some of our finer white and green-fleshed sorts. There is another Melon, which we have grown for a few years under the name of Golden Queen, but it differs a good deal from the one under that name in commerce, inasmuch as it is a small grower, and requires, therefore, little space; it is an excellent Melon, good in flavour, and is the hardiest and best bearer with which we are acquainted, Little Heath not excepted. Soil, too, is a main point with most writers on Melon culture, and that generally recommended—a good loam—is undoubtedly the best. But with a free-fruited variety, this is of less importance than when the varieties grown are what are called shy setters. A good medium garden soil, to which a little bone dust has been added, contains all the essential elements necessary to produce a good crop of Melons, especially if some guano or similar substance be mixed with the water given them when growing. The training and pinching is a somewhat important affair, as by being properly trained they are so regulated that crowding is guarded against, and when properly pinched, the food which the leaves elaborate is diverted into the formation of fruit. In writing for the instruction of others, it is often difficult to apply the instruction given so as to suit all cases. Perhaps a description of the way by which we successfully raise a fine crop of Melons annually in a very small pit might meet the case of many who have similar places, and so be the means of furnishing many

a table with a good supply of Melons from odd corners which may be thought too small for the purpose. Having a pit, not originally intended for the cultivation of Melons, along the front of a stove of the width of 3½ ft., which would be idle in summer, it is devoted to Melon culture. As there is a pipe along the front, and as a barrowload or two of fermenting material is added to serve as bottom-heat, and a board between this and the pipe to keep it clear, the space is reduced to 2 ft. Nevertheless, in this small space several varieties are grown; but during the present season we have discarded all except the one just described, which is truly a miniature Melon. The plants are prepared in the usual way, stopping them in all cases when they have made two rough leaves. This causes them to throw out two or three shoots, which are reduced in number, leaving two only as nearly equal in strength as possible. A plant is put in at every 4 ft., and when the shoots have pushed 1½ ft. they are stopped. By this time the laterals are pushing, and, in the case of the above variety, are showing fruit at the first joint on every lateral. All laterals are pinched at one joint beyond the fruit, and all further growths are rubbed off. If planted in a good depth of soil (with no manure except bone meal), and if they be afterwards fed with manure-water (after the roots are in possession of the soil), every fruit will set and swell. Most varieties will not do this with the growth restricted to such miniature dimensions as they are in my case; indeed, few would show fruit in so small a state. Even Little Heath is shy when so restricted. But when all that set are fairly swelling up, they are reduced to six or eight, and these come to be fine-flavoured Melons of about 1 lb. each—a useful size for an amateur's table, much better perhaps than one large one weighing 8 lb., and which would be more than half lost. In a common frame we would plant two plants, prepared by pinching as above, one within 1 ft. of the back of the frame, and one fully 2 ft. from that nearer the front of the frame; and we would pinch and train in the same way, and would feel sure of obtaining from 16 lb. to 24 lb. of fruit from a common frame. We never allow crowding of foliage, but we do not thin it; we prevent it forming by judicious pinching, and fill every inch with leaves. We expose fully to the sun and give air whenever possible. Heat, by means of the pipe in front, is seldom or never applied during the summer months—and this in a cold, exposed district, some 400 miles north of London—and yet we are very successful.

In conclusion we may add that we have this year grown a few varieties in 6-in. pots, and have fruited every one of them. Of course one fruit to a plant was all that was allowed to set, and that when fully grown was necessarily small in each case. The experiment has convinced us that a good quantity of fine fruit could be grown in a very small space, although we do not recommend the use of such small pots for Melons. The plants were kept small by pinching. The seedlings were pinched whenever they had made rough leaves. The plants then threw out from three to four shoots, which were in their turn pinched to one joint; and on the laterals which issued from this joint the fruit appeared at the first joint, at which all the growths were finally pinched, and any further growths were kept rubbed off and only one fruit was allowed to swell, although on several plants two set. The experiment was made to ascertain what is the smallest-sized pot in which a Melon can be induced to fruit in perfection when fed on proper food. The above is our experience so far as regards growing miniature Melons.—“Field.”

EXPERIMENTS IN VINE-GRAFTING.

I HAVE for a considerable number of years experimented with the view of proving what influence certain Vines, as stocks, produced on others grafted on them, and *vice versa*. So far the results have been both instructive and interesting. In grafting Gros Guillaume on the Muscat, and not allowing the stock to make any growth, not even to develop a single leaf, the result was bunches somewhat more compact than the general run of Gros Guillaume bunches, more regular and larger-sized berries, and a colour exceeding in density that of any other Grape, except the best finished examples of Black Alicante. This variety, grafted on the Muscat, and allowed to develop itself in the proportion of one to two rods of the Muscat on which it is grafted, has been very much increased in fruitfulness, and

bears freely on the short-spur system of pruning. The shape of the bunch has, however, been entirely changed; the large shoulders characteristic of Gros Guillaume when well grown being wanting, the bunches having assumed a long tapering shape. The colour of the berries has not been nearly so dense—in fact, they have been more of a grizzly colour, some berries colouring to nearly black on one side and grizzly on the other. The flavour has been appreciably improved, and the wood of the Vine ripens very rapidly and perfectly. On the other hand, the effect of one strong limb of Gros Guillaume on the two limbs of the Muscat is to deteriorate them, as well as to influence the character of the foliage considerably. As compared with other Muscats on which no other Grape has been grafted, the limbs are weak, there being a tendency to shank in the bunches, and the foliage goes off early in the season with streaks of straw colour, much the same as Gros Guillaume goes off streaked with claret and crimson. The two Muscat limbs are also much more subject to scorching from intense sunshine than are the Vines entirely Muscat. These effects are distinctly realised, and are very conspicuous at the present moment: an entire Muscat being beautifully green in foliage, and the Vine next to it with two Muscat rods and one of Gros Guillaume, with the Muscat portion of the foliage going off into straw-coloured streaks, like the Gros Guillaume. The fact is the latter is deteriorating the character of the Muscat, while the Muscat stock and limbs are exerting a most marked influence on the Gros Guillaume.

Gros Guillaume grafted on the Black Hamburgh comes very fine in berry and colour for about three years, after which it deteriorates, becoming less fruitful and much smaller in bunch and berry. On one Black Hamburgh grafted with Gros Guillaume we have allowed a spur of the Black Hamburgh to grow on each side of the stock, about 6 in. or 8 in. below the union of the stock and scion. This was allowed in order to see the effect of a large spread of Gros Guillaume foliage on the small amount of Black Hamburgh stock growth. Last year, as it happened, there were two bunches on the Black Hamburgh spurs, and there was no appreciable effect on the fruit, but the leaves assumed the shape of those of Gros Guillaume, and went off in autumn with exactly the same crimson colouring of that variety, while no other Hamburgh foliage in the same house did so. This season there is just one bunch on the Hamburgh spurs (they having apparently become less fruitful); but that bunch, although hanging over the hot-water pipes, has just, like those of Gros Guillaume on the same Vine, begun to colour, while the Hamburgh bunches round about it are black. The berries are also much less in size than the other Hamburghs. The foliage on the two portions of the stock are this year again much more cut and pointed, and will no doubt change, like those on the main limb of Gros Guillaume, into crimson as they ripen.

In the case of Muscat Hamburgh, it has been found that grafted on Black Hamburgh, and the stock and scion allowed to develop in nearly equal proportions, the bunches set better, form more compactly, colour better, and are less subject to shanking than when it is grafted on the same stock and no growth allowed on the stock: the result, in the latter case, being large formed bunches, with more stoneless and shanked berries. Duke of Buccleuch on a Muscat stock, with also a limb of Gros Guillaume, does not succeed well at all. The berries shank very much. In fact, the fellow scion robs and cripples it. On the Black Hamburgh the Duke does well, with the stock allowed to develop itself in equal proportions; but from an eight years' experience of this Grape, we conclude that it does on the Muscat stock, the Vines being allowed to grow in equal proportions. The Vines on which it was thus grown were, however, destroyed. This Vine does very well on its own roots when properly established. The Grizzly Frontignan has done best on the Muscat stock, the latter being also allowed to make growth in about equal proportion. Trebbiano grafted on Muscat, and grown in the proportion of one rod to two of the Muscat, does better than on its own roots; but from its very robust habit it has proved injurious to the Muscat. From our experience, we conclude that any Grape grafted on a given stock derives very little, if any, benefit or harm from the stock after a very few years, if the stock be not also allowed to make growth.—"The Gardener."

completely covered with small, white threads, these being the mycelium or spawn of some fungus which has generated from decaying vegetable matter that has got into the border. The most fertile agents are pieces of wood, or the broken stems or branches of trees, or it may be the stump of a Vine that has been cut down and left in the border. Therefore, these should all be rigidly excluded in the formation of Vine borders. If once fungus be introduced, its growth is very swift, and the fine threads of the mycelium will soon permeate the whole border, and choke the action of the roots. Fungoid growth may also be introduced into the border through heavy top-dressings of leaves or stable manure. Where its presence is detected, every bit of soil in the least affected should be taken out, and the roots of the Vines washed, sprinkling the remainder with quicklime, so as to destroy every vestige of its existence.

Shanking of Grapes.—Of all the perplexing maladies that affect Grapes this is the worst; other agencies may destroy a crop, or even the plants, much more speedily and completely, but there is no ill pertaining to Vines the true causes of which are so difficult to estimate and to grapple with as this. The term shanking is applied to denote the drying or withering up of the stalks of the bunches and berries of Grapes. Sometimes it is only a berry or two that shanks, at other times it is the whole bunch, and in extreme cases it may be the entire crop. The period when shanking commences is just as the berries begin to change colour or to ripen, and it continues more or less in action until they are ripe. The berries that thus shank or lose the vitality of their stalks never colour or ripen, but they become intensely sour, and they soon decay and require to be cut out. In many cases all that the eye can detect is a minute black speck, or a ring round the stem or stalk of the berry; in other cases the whole stem is quite blackened. It may be noted that shanking is far more prevalent amongst late Grapes than amongst early-forced ones, and again, that it is but seldom seen amongst outdoor Grapes, while some varieties—those of the Frontignan class to wit—are far more subject to shanking than others, such as the Royal Muscadine. As to the causes of shanking, many and varied opinions have been given; it is not so much, we believe, the result of any one special cause, as of a variety of concurrent causes. In a broad or general sense shanking seems to be the result of some overstrain, some bad condition or injury to the feeding or respiratory organs of the Vine. Either the foliage has been in some way injured, or prevented from performing its proper functions, or the roots have got into bad condition and cannot perform theirs, or, it may be, a combination of both these causes may exist. As to the immediate or leading causes of shanking, we shall briefly call attention to some of the principal:—

(1) **Overcropping.**—The crop of fruit must be regulated according to the strength of the plant, and this may nearly be estimated by the amount of properly developed leaves, so that an over-crop of fruit is just tantamount to a scarcity of leaves, an over-straining of the power of the plant, and the result is shanking to a very serious extent. (2) **The destruction of the foliage by red spider, burning, or other causes,** which, again, is equivalent to a scarcity of leaves. (3) **A stripping-off a great quantity of fully-developed leaves at one time,** as is frequently done by those who neglect timely stopping, which interference with the foliage affects in a corresponding degree the action of the roots, and so on. (4) **The roots getting into a cold sub-soil, or the border becoming sour and soddened,** whereby the young spongioles of the roots are destroyed. (5) **Borders composed of too rich materials,** containing too much organic matter, in consequence of which the Vines may grow with great luxuriance, but seldom ripen the wood well. The roots formed, although plentiful, are very soft and spongy; they do not acquire firmness, but rot and decay during the winter season, and consequently the next season a fresh supply of rootlets has to be produced; then, when the strain upon the energies of the Vine by the advancing fruit crop takes place the roots are not in a proper condition to meet it, and as a result shanking begins. This late production of roots, their decay in winter, and the subsequent shanking, may go on year after year. (6) **Excessive dryness at the roots,** such as to cause injury to these organs. If the border be allowed to get dry whilst the Vines are in full growth, and be then deluged with water, the young roots will as a consequence be certainly destroyed. These, then, are several of the causes that directly or indirectly lead to shanking, acting either singly or in combination; yet when a case of shanking appears it may be very difficult to trace it to its true origin, or to apply a remedy. Many of the above-named causes may be avoided by good management, as indeed they all should; but where the roots are at fault, either through being in a too rich or a too wet sour border, the only remedy that can be adopted is to take them up carefully, remake the border thoroughly, taking care if in a low or damp locality to use a greater proportion of porous materials than before so as to secure good drainage, and replant them.—"The Florist."

Fungus on Vine Roots.—This is not of frequent occurrence, yet it is of very serious import where it does find a footing, and should be carefully guarded against. The difficulty of dealing with it is the want of knowledge of its existence until the Vines are perhaps killed through its effects. The healthy Vines of one season may in the next, when in the fullest vigour, suddenly droop and flag and die, when upon examination of the roots it is found that they are

GRAPE SPORTS.

For a white Grape to produce a cluster of fruit partly white and partly black is by no means a common occurrence; but the annexed woodcut shows a case of the kind in a Vine which, until this happened, always produced fruit true to colour. The size and form of the berries were in both cases the same, but the flavour was slightly different. This shows that if it be desired to propagate any particular variety, it is absolutely necessary to mark the shoots destined for that purpose during the time when the Grapes are on them, as

Grape Sport.

without such precaution it is possible that shoots may be taken which have degenerated, or which do not possess the qualities desired to be perpetuated.

L. M.

Apricot Disease.—Moor Park Apricot, in some situations, is apt to be affected by canker in different parts of the tree, thereby occasioning a partial loss of its limbs. When this takes place in old trees, it is too late to apply a remedy; but its occurrence might be prevented by taking up the young tree after it has been trained three or four years, cutting off close those roots which have taken a perpendicular direction and spreading out the others horizontally, and replanting it again, taking care that the part where it had been budded be kept 6 in. or 8 in. above the surface of the ground. If this be carefully performed, without shaking the mould off the roots, the progress of the tree will be but little impeded by the operation. At the end of three years more this should be repeated in the same manner, after which it will rarely happen that any of those local injuries will take place.—B., Watford.

Viburnum plicatum.—I see that nurserymen say this plant (the new Snowball) is very difficult to propagate; I have not found it so. I raised three fine plants from one small layer; but I think it was a two-year-old shoot which I laid down, and my impression is that no shoots came up till the second year. I think if two-year-old shoots were laid down, or if any shoot remain layered for two years, well-formed roots will result. A neighbouring nurseryman tells me he has had like experience.—T. M.

The Golden Age Restored.—Young Lady (through passenger, at West Riding station): "What's going on here to-day, porter? Has there been a fête?" Porter (astonished): "Bless thee, lass, there's nae feichtin' noo-a-days; 'tis agin t'la-aw. Nobbut a flooer-show."

WINTER TREATMENT OF LOBELIA FULGENS.

This truly handsome herbaceous plant is but seldom seen in thoroughly good condition. Its bold erect habit and strikingly brilliant flowers render it eminently adapted for situations where bright colours and effect are desirable. Planted in masses, backed up by, or in the near vicinity of evergreens, it has a gorgeous effect. Its most congenial situation is amongst the lower shrubs in a border, as sufficient space being allowed for its development, it receives just that amount of shelter which is necessary to ensure its flowering in perfection. I do not think that it is for a due want of appreciation that this plant is comparatively seldom seen, but that few persons have any idea of what it really is when thoroughly well grown. The principal reason probably why it is not so much in general cultivation is that in many localities it is very liable to rot off during the winter, while in a more than usually damp season it is not uncommon to hear complaints of the whole stock disappearing. There are, in fact, very few localities where it may be depended upon to do well from one season to another. Now the great enemy, to the insidious attacks of which this Lobelia is liable, is a kind of rust, which fastens on the main fleshy roots when the plants are gone to rest, and, quickly eating them away, thoroughly rots them, and they eventually disappear. This disease, working as it does from the bottom at a time when growth is at a standstill, is not perceived in sufficient time for its ravages to be checked, and the whole collection, much to the grower's disappointment, will in the course of two or three weeks be completely ruined. This state of affairs is of course very discouraging, and it is not surprising when the same thing has occurred several times, that its culture is renounced in disgust. Having myself experienced much vexation in losing the greater portion of a fine stock in this manner, and clearly seeing that no reliance could be placed upon the plants standing uninjured during the winter in the ordinary way, I was induced to adopt a system for their preservation which I invariably found to succeed, and can now always depend upon having a good stock of healthy vigorous plants with which to work in the spring.

There are perhaps many cultivators who may have been troubled to get and keep any quantity of this fine Lobelia, and who would gladly take a little pains to ensure a good stock of it. I will therefore briefly describe the method which I follow. The disease which attacks the roots, and which ultimately destroys them makes its appearance towards the latter end of October or beginning of November, especially if the weather at that time should set in cold and wet. The plants should then be carefully taken up, preserving as much of the roots as possible, the soil shaken from them, and the roots well washed. If the disease be present it will be readily discovered, as it comes in the form of rusty-looking spots which eat their way into the roots. Wherever these are perceived they must be cut out with a sharp knife, as if only a small portion be left it will suffice to destroy the vitality of the plants. When the plants are thus examined they may be either potted or laid in a frame in some free sandy soil. Very fine specimens are obtained by potting and plunging in a slight bottom-heat, keeping the top quite cool. In about a fortnight they will have made fresh fibre, and this is the great object to be attained, as when once a new root is formed all danger of rotting is past. They may then be placed and kept in a cold frame during the winter, to be planted out where desired in spring: a very fine display may be thus secured. The bottom-heat, however, is not at all indispensable; they will succeed very well indeed if carefully and but sparingly watered after potting.

Although the main object is to secure the plants against the perils of a wet winter, yet they will in any case amply repay for the slight trouble they have given by a greater vigour and more abundant bloom. I once saw a bed of this plant grown for seed at Mr. Benary's nursery at Erfurt some 6 in. in width and about 50 ft. long, protected by a glass span-roof; the sides being open, the effect of this flowering mass was, it is needless to say, truly magnificent. I have occasionally seen this Lobelia flourish and grow like a weed year after year, but I know that in many places it is impossible to get it to do so satisfactorily unless some extra precautions be taken.

Byfleet.

JOHN CORNHILL.

THE TONQUIN BEAN.

CONSIDERABLE interest attaches to the plant represented in the accompanying illustration—the Tonquin or Tonga Bean (*Dipteryx odorata*), inasmuch as it is one of only eight species included in the genus, all of which are large forest trees of Brazil, Guiana, and the Mosquito coast. The genus is also remarkable for being one of the few belonging to the natural Order Leguminosae, that have drupaceous or single-seeded, indehiscent pods. The Tonquin Bean acquires in the

Branchlets of Tonquin Bean Tree.

forests of British Guiana an average height of about 60 ft. It has alternate leaves composed of from five to seven alternate leaflets. The flowers are borne in racemose panicles, and the fruit, as will be seen, is of a somewhat oval form, consisting of a thick fleshy substance which becomes when mature of a hard, woody character, and encloses a long, almond-shaped, shining black seed. This seed has a powerful odour, resembling that of newly mown hay. At one time, when snuff-taking was much more general than at present, a Tonquin Bean was

Tonquin Bean and Section.

generally kept in the snuff-box for the sake of the agreeable fragrance which it imparted to the snuff. Now, however, the uses of Tonquin Beans are mostly confined to the preparation of perfumes either for fluid extracts for handkerchiefs or for sachet powders. They are often, moreover, to be seen in hosiers' shops, where they are sold for placing in drawers with linen. For these purposes they are imported into this country to the extent of a few hundredweights per annum. The Creoles fully appreciate the fragrance of these seeds, and make use of them not only for their perfume, but also for putting in chests or drawers for the purpose, they say, of

driving away insects. A closely-allied species of *Dipteryx*, namely, *D. eboensis*, a native of the Mosquito country, bears a fruit and seed almost identical in appearance with those of *D. odorata*. It has, however, no perfume, but contains a quantity of thick oil or fat, which is extracted by the natives, and used as a hair oil. It was at one time said that this oil formed the basis of a much-advertised hair-restorer, known as "Balm of Columbia," but of this I am unable to give any opinion. With regard to cultivation, the species of *Dipteryx* are said to grow best in a loamy soil. They are easily raised from ripened cuttings planted in sand, with a good moist heat, and covered with a hand glass.

J. R.

PLATE XC.

CHOISYA TERNATA.

THE annexed coloured illustration represents a pretty Mexican shrub well deserving of cultivation. It is found to be hardy in warm, sheltered situations in most parts of the country, and when well grown is very ornamental, producing, as it does, abundance of blossoms during several months in spring and early summer. Even in cold districts it is well worth attention as a pot plant, for where it can have the advantage of a cool house or pit its flowers are produced at a time of year when every spray of white blossom is an acquisition. It may also be used with good effect for conservatory decoration, its glossy leaves of a peculiar tint of green, and panicles of white blossoms forming a pleasing contrast. As a wall plant, either indoors or out, it is likewise valuable. A good example of it used to be found on a south wall in the Wellington Nurseries, St. John's Wood, where it flowered freely every year. Its blossoms resemble in general appearance and scent those of the Orange, for which when the plants are forced they form good substitutes. On the Continent, where it is more plentiful, its flowers are largely employed in a cut state for decorative purposes, and there can be no reason why they should not be so used here, provided the plants were properly prepared for the purpose, and forced like *Daphnes*, *Dentzias*, and similar shrubs which yield flowers of no greater value. It would succeed perfectly in a mixture of sandy loam and peat, and, whether grown in pots or planted out, it must have good drainage. It may be increased by means of cuttings made of the half-ripened wood and struck on a gentle bottom-heat.

S.

Propagating Centaureas (see p. 201).—I have found these to strike readily in autumn, treated as follows:—Remove from the old plants good stout cuttings with as much stem attached to them as can be had; strip off the lower leaves and clear off the woolly substance, after which dip the stalks in silver sand, which will absorb the moisture; then place two cuttings in 4-in. pots, one at each side, using soil of a stiff, loamy character, liberally intermixed with sand. To each cutting place a small stick, to which tie the leaves in order to keep them from getting entangled with each other and loosening the cuttings, which should be inserted in the soil as firmly as possible. Plunge the pots up to their rims in damp ashes, in a wooden frame facing the north; keep the lights closed for the first few days, then gradually admit air during the night, but keep all close in the daytime. Little water will be required until the plants are struck, and then it should only be given when the soil is nearly dry, and on a fine day when the lights can be left off for an hour or two to dry up the moisture. When well rooted, which they will be in a few weeks, the cuttings may be removed to a rather warmer situation, or the frame may be surrounded by a lining of ashes or straw, and further protection should be given when necessary during the winter, always admitting air on all favourable occasions.—W. S.

Celtis occidentalis at Home.—A very old specimen of this tree is growing in an exposed situation close to the shore near the Squantum Beach Hotel in the town of Quincy, Mass. Its size is worthy of record. At the ground it has a circumference of 11 ft. 4 in., and at 5 ft. from the ground, just where its short stem is the smallest, it girths 7 ft. A still finer specimen stands in the city of Lowell, and this at 4 ft. from the ground girths 7 ft. 6 in. This is the tree of which a photograph appears in Emerson's "Trees and Shrubs of Massachusetts," second edition, where it is called *Celtis crassifolia*, although in foliage and fruit it is identical with the form of *C. occidentalis* common in the Eastern States.—"American Naturalist."

CHOISYA TERNATA

THE CASUARINAS.

CASUARINA, so called by Rumphius on account of the similarity of its foliage to the plumes of the Casar or Cassowary, is the only genus of the natural Order Casuarinæ, and is represented abundantly in tropical Australia. In the East Indies, the islands of the Indian Ocean, and in Madagascar, the species are far less frequent. These very peculiar plants have scarcely any affinity except with the Myricaceæ, from which, however, they differ considerably in habit, and in having a woody, cone-like fruit. They are shrubs, or even large trees, much resembling the Ephedras and Equisetums (Horse-tails). Their branches are whorled, jointed, and furrowed, and instead of leaves have striate, many-toothed sheaths surrounding the nodes. The flowers are diolinous or unisexual, the males, each with a single stamen, being produced in spikes at the termination of the

Fruit-bearing Branch of Casuarina.

branches, and the females collected into dense axillary heads. The hard and heavy wood is used by the savages in the construction of their canoes, &c.; they prefer it, too, for their clubs, lances, and other arms. Living plants of several species may be seen in the temperate house at Kew; their strange and graceful habit make them somewhat conspicuous. Their cultivation is by no means difficult; they prefer a light soil, a mixture of peat and loam perhaps suiting them best, and require a moderate supply of water during the growing season. In favoured places in the open air on the south-west coast probably several kinds would succeed pretty well. *C. equisetifolia* is perhaps the best known; it is a large tree, and is found in the South Sea Islands and India. *C. torulosa* is a medium-sized tree with nearly tetragonous, channelled branches covered with corky bark; *C. quadrivalvis* attains a height of 6 yards; *C. stricta* has upright branches and altogether a much more rigid style of growth; *C. distyla* is larger than *C. quadrivalvis*, and, with that and *C. stricta*, is a native of Australia. For the cool conservatory all are desirable. Plants raised from seeds make much better specimens

than those struck from cuttings; they like a little fresh soil every year. *C. tenuissima* is perhaps the prettiest of all, and would form a beautiful and elegant living screen that would charm the heart of every plant lover and artist. G.

THE PLANT-LORE OF SHAKESPEARE.

(Continued from p. 213).

Wheat.

- (1) *Iris*. Ceres, thou bounteous lady! thy rich leas
Of Wheat, Rye, Barley, Vetches, Oats, and Peas.
Tempest, act iv., sc. 1.
- (2) *Helena*. More tunable than lark to shepherd's ear,
When Wheat is green, when Hawthorn buds appear.
Midsummer Night's Dream, act i., sc. 1.
- (3) *Bassanio*. His reasons are as two grains of Wheat hid in two bushels
of chaff—you shall seek all day till you find them, and when you
find them, they are not worth the search.
Merchant of Venice, act i., sc. 1.
- (4) *Hamlet*. As peace should still her Wheaten garland wear.
Hamlet, act v., sc. 2.
- (5) *Pompey*. To send measures of Wheat to Rome.
Antony and Cleopatra, act ii., sc. 6.
- (6) *Edgar*. This is the foul fiend Flibbertigibbet. . . . He mildews
the white Wheat, and hurts the poor creatures of earth.
King Lear, act iii., sc. 4.
- (7) *Pandarus*. He that will have a cake out of the Wheat, must tarry
the grinding.
Troilus and Cressida, act i., sc. 1.
- (8) *Davy*. And again, sir, shall we sow the headland with Wheat?
Shallow. With red Wheat, Davy.
2nd Henry IV., act v., sc. 1.

I might perhaps content myself with marking these passages only, and dismiss Shakespeare's Wheat without further comment, for the Wheat of his day was identical with our own; but there are a few points in connection with English Wheat which may be interesting. Wheat is not an English plant, nor is it a European plant; its original home is in Northern Asia, whence it has spread into all civilized countries. For the cultivation of Wheat is one of the first signs of civilized life; it marks the end of nomadic life, and implies more or less a settled habitation. When it reached England, and to what country we are indebted for it, we do not know; but we know that while we are indebted to the Romans for so many of our useful trees, and fruits, and vegetables, we are not indebted to them for the introduction of Wheat. This we might be almost sure of from the very name, which has no connection with the Latin names, *triticum* or *frumentum*, but is a pure old English word, signifying originally *white*, and so distinguishing it as the white grain in opposition to the darker grains of Oats and Rye. But besides the etymological evidence, we have good historical evidence that Cæsar found Wheat growing in England when he first landed on the shores of Kent. He daily victualled his camp with British Wheat (*frumentum ex agris quotidie in castra conferebat*); and it was while his soldiers were reaping the Wheat in the Kentish fields, that they were surrounded and successfully attacked by the British. He tells us, however, that the cultivation of Wheat was chiefly confined to Kent, and was not much known inland—"interiores plerique frumenta non serunt, sed lacte et carne vivunt" (*De Bello Gallico*, v. 14). Roman Wheat has frequently been found in graves, and strange stories have been told of the plants that have been raised from these old seeds—but a more scientific inquiry has proved that there have been mistakes or deceits, more or less intentional, for "Wheat is said to keep for seven years at the longest. The statements as to mummy Wheat are wholly devoid of authenticity, as are those of the Raspberry seeds taken from a Roman tomb" (Hooker—"Botany" in "Science Primers"). The oft-repeated stories about the vitality of mummy Wheat were effectually disposed of when it was discovered that much of the so-called Wheat was South American Maize.

Willow.

- (1) *Viola*. Make me a Willow cabin at your gate.
Twelfth Night, act i., sc. 5.
- (2) *Benedick*. Come, will you go with me?
Claudio. Whither?
Benedick. Even to the next Willow, about your own business.
Much Ado About Nothing, act ii., sc. 1.
Benedick. I offered him my company to a Willow tree, either to make him a garland as being forsaken, or to bind him up a rod as being worthy to be whipped. *Ibid.*
- (3) *Nathaniel*. These thoughts to me were Oaks, to thee like Osiers
[bowed].
Love's Labour's Lost, act iv., sc. 2.
- (4) *Lorenzo*. In such a night
Stood Dido, with a Willow in her hand,
Upon the wild sea-banks.
Merchant of Venice, act v., sc. 1.
- (5) *Bona*. Tell him, in hope he'll prove a widower shortly,
I'll wear a Willow garland for his sake.
3rd Henry VI., act iii., sc. 3.
Messenger. [The same words repeated]. *Ibid.*, act iv., sc. 1.
- (6) *Queen*. There is a Willow grows ascant a brook,
That shows his hoar leaves in the glassy stream.
There on the pendent boughs her coronet weeds
Clambering to hang, an envious sliwer broke.
Hamlet, act iv., sc. 7.
- (7) *Desdemona* (singing).
The poor soul sat sighing by a Sycamore tree.
Sing all a green Willow;
Her hand on her bosom, her head on her knee,
Sing Willow, Willow, Willow.
The fresh streams ran by her and murmur'd her moans,
Sing Willow, Willow, Willow.
Her salt tears fell from her and softened the stones,
Sing Willow, Willow, Willow.
Sing all a green Willow must be my garland.
Othello, act iv., sc. 3.
- (8) *Emilia*. I will play the swan,
And die in music. [Singing] Willow, Willow, Willow.
Ibid., act v., sc. 2.
- (9) *Friar*. I must fill up this Willow cage of ours
With baleful weeds and precious-juiced flowers.
Romeo and Juliet, act ii., sc. 3.
- (10) *Celia*. West of this place, down in the neighbour bottom,
The rank of Osiers by the murmuring stream
Left on your right hand, brings you to the place.
As You Like It, act iv., sc. 2.
- (11) When Cytherea all, in love forlorn,
A longing tarrance for Adonis made
Under an Osier growing by a brook.
Passionate Pilgrim, 6.
- (12) Though to myself forsworn, to thee I'll constant prove;
Those thoughts, to me like Oaks, to thee like Osiers bowed.
Ibid., 5.

Willow is an old English word, but the more common and perhaps the older name for the Willow is Withy, a name which is still in constant use, but now more generally applied to the twigs when cut for basket-making than to the living tree. "Withy" is found in the oldest vocabularies, but we do not find "Willow" till we come to the vocabularies of the fifteenth century, when it occurs as "Hæc Silex, A^o Wylo-tre;" "Hæc Salix-icis, a Welogh;" "Salix, Welig." Both the names probably referred to the pliability of the tree, and there was another name for it, the Sallow, which was either a corruption of the Latin Salix, or was derived from a common root. It was also called Osier.

The Willow is a native of Britain. It belongs to a large family (Salix), numbering 160 species, of which we have seventeen distinct species in Great Britain, besides many sub-species and varieties. So common a plant, with the peculiar pliability of the shoots that distinguishes all the family, was sure to be made much use of. Its more common uses were for basket making, for coracles, and huts, or "Willow-cabins" (see No. 1), but it had other uses in the elegancies and even in the romance of life. The flowers of the early Willow (*S. caprea*) did duty for and were called Palms on Palm Sunday (see Palm), and not only the flowers but the branches also seem to have been used in decoration, a use which seems to be now extinct. "The Willow is called *Salix*, and hath his name à *saliendo*, for that

it quicklie groweth up, and soon becommeth a tree. Heere-with do they in some countres trim up their parlours and dining roomes in sommer, and sticke fresh greene leaves thereof about their beds for coolness" (Newton's "Herball for the Bible").

But if we only look at the poetry of the time of Shakespeare, and much of the poetry before and after him, we should almost conclude that the sole use of the Willow was to weave garlands for jilted lovers, male and female. It was probably with reference to this that Shakespeare represented poor mad Ophelia hanging her flowers on the "Willow tree ascant the brook" (No. 6), and it is more pointedly referred to in Nos. 2, 4, 5, 7, and 8. The feeling was expressed in a melancholy ditty, which seems to have been very popular in the sixteenth century, of which Desdemona says a few of the first verses (No. 7), and which concludes thus:—

Come all you forsaken and sit down by me,
He that plaineth of his false love, mine's falsder than she;
The Willow wreath weare I, since my love did fleet,
A garland for lovers forsaken most meet.

The ballad is entitled "The Complaint of a Lover Forsaken of His Love—To a Pleasant New Tune," and is printed in the "Roxburgh Ballads." This curious connection of the Willow with forsaken or disappointed lovers stood its ground for a long time. Spenser spoke of the "Willow worne of forlorne paramoures," and though we have long given up the custom of wearing garlands of any sort, yet many of us can recollect one of the most popular street songs, that was heard everywhere, and at last passed into a proverb, and which began—

All round my hat I wears a green Willow
In token, &c.

It has been suggested by many that this melancholy association with the Willow arose from its biblical associations; and this may be so, though all the references to the Willow that occur in the Bible are, with one notable exception, connected with joyfulness and fertility. The one exception is the plaintive wail in the 137th Psalm:—

By the streams of Babel, there we sat down,
And we wept when we remembered Zion.
On the Willows among the rivers we hung our harps.

And this one record has been sufficient to alter the emblematic character of the Willow—this one incident has made the Willow an emblem of the deepest of sorrows, namely, sorrow for sin found out, and visited with its due punishment. From that time the Willow appears never again to have been associated with feelings of gladness. Even among heathen nations, for what reason we know not, it was a tree of evil omen, and was employed to make the torches carried at funerals. Our own poets made the Willow the symbol of despairing woe" (Johns). This is the more remarkable, because the tree referred to in the Psalms, the Weeping Willow (*Salix babylonica*), which by its habit of growth is to us so suggestive of crushing sorrow, was quite unknown in Europe till a very recent period. "It grows abundantly on the banks of the Euphrates, and other parts of Asia, as in Palestine, and also in North Africa," but it was only introduced into England during the last century, and then in a curious way. "Many years ago, the well-known poet, Alexander Pope, who resided at Twickenham, received a basket of Figs as a present from Turkey. The basket was made of the supple branches of the Weeping Willow, the very same species under which the captive Jews sat when they wept by the waters of Babylon. The poet valued highly the small and tender twigs associated with so much that was interesting, and he untwisted the basket, and planted one of the branches in the ground. It had some tiny buds upon it, and he hoped he might be able to rear it, as none of this species of Willow was known in England. Happily the Willow is very quick to take root and grew. The little branch soon became a tree, and drooped gracefully over the river, in the same manner that its race had done over the waters of Babylon. From that one branch all the Weeping Willows in England are descended." (Kirby's Trees).

There is probably no tree that contributes so largely to the conveniences of English life as the Willow. Putting aside its uses in the manufacture of gunpowder and cricket bats, we may safely say that the most scantily-furnished house can

boast of some article of Willow manufacture in the shape of baskets. British basket-making is, as far as we know, the oldest national manufacture; it is the manufacture of which we have the earliest record of the value placed on British work. British baskets were imported to Rome, and it would almost seem as if baskets were unknown in Rome until they were introduced from Britain—for with the article of import came the name also, and the British "basket" became the Latin "bascauda." We have curious evidence of the high value attached to these baskets. Juvenal describes Catullus in fear of shipwreck throwing overboard his most precious treasures—"precipitare volens etiam pulcherrima," and among these "pulcherrima" he mentions "bascaudas." Martial bears a still higher testimony to the value set on "British baskets," reckoning them among the many rich gifts distributed at the Saturnalia—

Barbara depictis veni bascauda Britannis.
Sed me jam vult dicere Roma suam. *Book xiv., 99.*

Many of the Willows make handsome shrubs for the garden, for besides those that grow into large trees, there are many that are low shrubs, and some so low as to be fairly called carpet plants. *Salix Regiæ* is one of the most silvery shrubs we have, with very narrow leaves; *S. lanata* is almost as silvery, but with larger and woolly leaves, and makes a very pretty object when grown on rockwork near water; *S. rosmarinifolia* is another desirable shrub, and among the lower-growing species, the following will grow well on rockwork, and completely clothe the surface:—*S. alpina*, *S. Grahami*, *S. retusa*, *S. serpyllifolia*, and *S. reticulata*. They are all easily cultivated and are quite hardy.

Woodbine (see Honeysuckle).

Wormwood.

- (1) *Rosalind*. To weed this Wormwood from your fruitful brain.
Love's Labour's Lost, act v., sc. 2.
- (2) *Nurse*. For I had then laid Wormwood to my dug.
When it did taste the Wormwood on the nipple
Of my dug, and felt it bitter, pretty fool.
Romeo and Juliet, act i., sc. 3.
- (3) *Hamlet*. That's Wormwood.
Hamlet, act iii., sc. 2.

Wormwood is the product of many species of *Artemisia*, a family consisting of 180 species, of which we have four in England. The whole family is remarkable for the extreme bitterness of all parts of the plant, so that "as bitter as Wormwood" is one of the oldest proverbs. The plant was named *Artemisia* from *Artemis*, the Greek name of *Diana*, and for this reason:—"Verily of these three Worts which we named *Artemisias*, it is said that *Diana* should find them, and delivered their powers and leechdom to *Chiron* the Centaur, who first from these Worts set forth a leechdom, and he named these Worts from the name of *Diana*; *Artemis*, that is, *Artemisias*" ("Herbarium Apulæi"—Cockayne's translation). The Wormwood was of very high reputation in medicine, and is thus recommended in the Stockholm MS.:—

Lif man or woman, more or lesse
In his head have gret sicknesse
Or gruaunce or any werking
Awoyne he take wt. owte lettyng
It is called Sowthernwode also
And hony eteys et spurge stamp yer to
And late by yis drunk, fastined drinky
And his hed werk away schall synkyn.

But even in Shakespeare's time this high character had somewhat abated, though it was still used for all medicines in which a strong bitter was recommended. But its chief use seems to have been as a protection against insects of all kinds, who might very reasonably be supposed to avoid such a bitter food. This is Tusser's advice about the plant—

While Wormwood bath seed get a handfull or twain
To save against March, to make flea to refrain;
Where chamber is sweeped and Wormwood is shown,
No flea, for his life, dare abide to be known.
What savour is better, if phisic be true,
For places infected than Wormwood or Rue?
It is as a comfort for heart and the brain,
And therefore to have it, it is not in vain.

July's Husbandry.

This quality was the origin of the names Mugwort and Wormwood. Its other name (in the Stockholm MS. above), *Avoyne* or *Averoyn* is a corruption of the specific name of one of the species, *A. Abrotanum*. Southernwood is the southern Wormwood, *i.e.*, the foreign, as distinguished from the native plant. The modern name for the same species is *Boy's Love*, or *Old Man*. The last name may have come from its hoary leaves, though other explanations are given: the other name is given to it, according to Dr. Prior, "for an ointment made with its ashes being used by young men to promote the growth of a beard." There is good authority for this derivation, but I think the name may have been given for other reasons. "Boy's Love" is one of the most favourite cottage garden plants, and it enters largely into the rustic language of flowers. No posy presented by a young man to his lass is complete without *Boy's Love*; and it is an emblem of fidelity, at least it was so once. So Sir Francis de Sales applied it—"To love in the midst of sweets, little children could do that; but to love in the bitterness of Wormwood is a sure sign of our affectionate fidelity."

In England Wormwood has almost fallen into complete disuse; but in France it is largely used in the shape of Absinthe. As a garden plant, Tarragon, which is a species of Wormwood, will claim a place in every herb garden, and there are a few, such as *A. sericea*, *A. cana*, and *A. alpina*, which make pretty shrubs for the rockwork.

Yew.

- (1) *Song*. My shroud of white, stuck all with Yew,
Oh! prepare it.
Twelfth Night, act ii., sc. 4.
- (2) 3rd Witch. Gall of goat, and slips of Yew,
Slivered in the moon's eclipse.
Macbeth, act iv., sc. 1.
- (3) *Scroop*. Thy very beadsmen learn to bend their bows
Of double-fatal Yew against thy state.
Richard II., act iii., sc. 2.
- (4) *Tamora*. But straight they told me they would bind me here
Unto the body of a dismal Yew.
Titus Andronicus, act ii., sc. 3.
- (5) *Paris*. Under yon Yew trees lay thee all along,
Holding thine ear close to the hollow ground;
So shall no foot upon the churchyard tread
(Being loose, unfirm, with digging up of graves)
But thou shalt hear it.
Romeo and Juliet, act v., sc. 3.
- (6) *Balthasar*. As I did sleep under this Yew tree here,
I dreamt my master and another fought,
And that my master slew him. *Ibid.*

The Yew, though undoubtedly an indigenous British plant, has not a British name. The name is derived from the Latin *Iva*, and "under this name we find the *Yew* so inextricably mixed up with the *Ivy* that, as dissimilar as are the two trees, there can be no doubt that these names are in their origin identical." So says Dr. Prior, and he proceeds to give a long and very interesting account of the origin of the name. The connection of Yew with *iva* and *Ivy* is still shown in the French *if*, the German *eibe*, and the Portuguese *iva*. *Yew* seems to be quite a modern form; in the old vocabularies the word is variously spelt *iw*, *ewe*, *engh-tre*, *haw-tre*, *new-tre*, *ew*, and *iw*.

The connection of the Yew with churchyards and funerals is noticed by Shakespeare in Nos. 1, 5, and 6, and its celebrated connection with English bow-making in No. 3, where "doubly-fatal" may probably refer to its noxious qualities when living and its use for deadly weapons afterwards. These noxious qualities, joined to its dismal colour, and to its constant use in churchyards, caused it to enter into the supposed charms and incantations of the quacks of the Middle Ages. Yet Gerarde entirely denies its noxious qualities:—"They say that the fruit thereof being eaten is not only dangerous and deadly unto man, but if birds do eat thereof it causeth them to cast their feathers and many times to die—all which I dare boldly affirme is altogether untrue; for when I was yong and went to schoole, divers of my schoolefellows, and likewise my selfe, did eat our fils of the berries of this tree, and have not only slept under the shadow thereof, but among the branches also, without any hurt at all, and that not at one time but many times." There is no doubt that the Yew berries are quite

harmless, and I find them forming an element in an Anglo-Saxon recipe, which may be worth quoting as an example of the medicines to which our forefathers submitted. It is given in a leech book of the tenth century or earlier, and is thus translated by Cockayne:—"If a man is in the water elf disease, then are the nails of his hand livid, and the eyes tearful, and he will look downwards. Give him this for a leechdom: Everthroat, cassuck, the netherward part of fane, a yew berry, lupin, helenium, a head of marsh mallow, fen mint, dill, lily, attorlothe, pulegium, marrubium, dock, elder, fel terræ, wormwood, strawberry leaves, consolida; pour them over with ale, add holy water, sing this charm over them thrice (here follows some long charms which I need not extract); these charms a man may sing over a wound" (Leech Book, iii., 63).

I need say little of the uses of the Yew wood in furniture, nor of the many grand specimens which are scattered throughout the churchyards of England, except to say that "the origin of planting Yew trees in churchyards is still a subject of considerable perplexity. As the Yew was of such great importance in war and field sports before the use of gunpowder was known, perhaps the parsons of parishes were required to see that the churchyard was capable of supplying bows to the males of each parish of proper age; but in this case we should scarcely have been left without some evidence on the matter. Others again state that the trees in question were intended solely to furnish branches for use on Palm Sunday, while many suppose that the Yew was naturally selected for planting around churches on account of its emblematic character, as expressive of the solemnity of death, while, from its perennial verdure and long duration, it might be regarded as a pattern of immortality" ("Penny Magazine," 1843).

A good list of the largest and oldest Yews in England will be found in Loudon's "Arboretum."

The following was omitted in its proper place:—

Pinks.

Romeo. A most courteous exposition.

Mercutio. Nay, I am the very Pink of courtesy.

Romeo. Pink for flower.

Mercutio. Right.

Romeo. Why, then is my pump well flowered.

Romeo and Juliet, act ii., sc. 4.

The Pink or Pincke was, as now, the name of the smaller sorts of Carnations, and was generally applied to the single sorts. It must have been a very favourite flower, as we may gather from the phrase "Pink of courtesy," which means courtesy carried to its highest point; and from Spenser's pretty comparison—

Her lovely eyes like Pincks but newly spread.

"Amoretti"—Sonnet 64.

The name has a curious history. It is not, as most of us would suppose, derived from the colour, but the colour gets its name from the plant. The name (according to Dr. Prior) comes through *Pinksten* (German), from Pentecost, and so was originally applied to one species—the Whitsuntide Gilliflower. From this it was applied to other species of the same family. It is certainly "a curious accident," as Dr. Prior observes, "that a word that originally meant 'fiftieth' should come to be successively the name of a festival of the Church, of a flower, of an ornament in muslin called *pinking*, of a colour, and of a sword-stab." Shakespeare uses the word in three of its senses. First, as applied to a colour—

Come, thou monarch of the Vine,
Plumpy Bacchus with Pink eyne.

Antony and Cleopatra, act ii., sc. 7.

Second, as applied to dress in Romeo's person—

Then is my pump well flowered.

Romeo and Juliet, act ii., sc. 4.

i.e., well pinked. And thirdly—

There's a haberdasher's wife of small wit near him, that railed upon me till her Pink'd porringer fell off her head.

Henry VIII., act v., sc. 3.

And as applied to the flower in the passage quoted above. He also uses it in another sense—

This Pink is one of Cupid's carriers;
Clap on more sail—pursue!

Merry Wives of Windsor, act ii., sc. 7.

where Pink means a small country vessel often mentioned under that name by writers of that date.

"The Dismal Yew" concludes the list of Shakespeare's plants and the first part of my proposed subject, and while I hope that those readers of THE GARDEN who may have gone with me so far have met with some things to interest them, I think they will also agree with me that gardening and the love of flowers is not altogether the modern accomplishment that many of our gardeners now fancy it to be. Here are more than 180 names of plants in one writer, and that writer not at all writing on horticulture, but only mentioning plants and flowers in the most incidental manner as they happened naturally to fall in his way. I should doubt if there be any similar instance in any modern English writer, and feel very sure that there is no such instance in any modern English dramatist. It shows how familiar gardens and flowers were to Shakespeare, and that he must have had frequent opportunities for observing his favourites (for most surely he was fond of flowers), not only in their wild and native homes, but in the gardens of farmhouses and parsonages, country houses, and noblemen's stately pleasaunces. The quotations that I have been able to make from the early writers in the ninth and tenth centuries down to gossiping old Gerarde, the learned Lord Chancellor Bacon, and that excellent old gardener Parkinson, all show the same thing, that the love of flowers is no new thing in England, still less a foreign fashion, but that it is innate in us, a real instinct, that showed itself as strongly in our forefathers as in ourselves; and while we can show that such men as Shakespeare and Lord Bacon (to mention no others) were almost proud to show their knowledge of plants and love of flowers, we can say that such love and knowledge is thoroughly manly and English.

In the inquiry into Shakespeare's plants I have entered somewhat largely into the etymological history of the names. I have been tempted into this by the personal interest I feel in the history of plant names, and I hope it may not have been uninteresting to my readers; but I do not think this part of the subject could have been passed by, for I agree with Johnstone—"That there is more interest and as much utility in settling the nomenclature of our pastoral bards as that of old herbalists and dry-as-dust botanists" ("Botany of the Eastern Border.") I have also at times entered into the botany and physiology of the plants; this may have seemed needless to some, but I have thought that such notices were often necessary to the right understanding of the plants named, and again I shelter myself under the authority of a favourite old author—"Consider (gentle readers) what shifts he shall be put unto, and how rawe he must needs be in the explanation of metaphors, resemblances, and comparisons, that is ignorant of the nature of herbs and plants from whence their similitudes be taken, for the inlightening and garnishing of sentences" (Newton's "Herball for the Bible.")

I have said that my subject naturally divides itself into two parts, first, the plants and flowers named by Shakespeare; second, his knowledge of gardens and gardening. The first part is now concluded, and I go to the second part, which will be very much shorter, and which may be better entitled "The Garden-craft of Shakespeare."

H. N. ELLACOMBE.

Landscape Gardening.—The accompanying plan is one that has been specially taken for us, showing the disposition of the garden round the Tour St. Jacques, planted as it is during the present year. For a town garden it has considerable merit, mainly in the bold variety of its contents, which remove it at once from the too-numerous gardens with a few common trees and a few common flowers only. It has also some faults, which might be easily avoided in similar cases. The masses or beds of flowers are sometimes too large, though they are, as they ought always to be, simple in outline. The walks are too numerous; a bold walk around and one round the tower would have sufficed for all needs, and allowed much more space, affording fuller opportunities for a more favourable disposition of the ground. The walk that passes by the Red-leaved Peach and cuts a long plot in two is particularly objectionable, and quite needless. The details of the planting are printed in the plan.

GARDEN ROUND TOUR ST. JACQUES, AS PLANTED THIS SEASON.

THE KITCHEN GARDEN.

NOTES ON THE POTATO CROP OF 1876.

THE following Table shows the results of twenty varieties of Potatoes, grown in a good soil—sandy loam—at Marnham, East Notts, in 1876, and may be of some use for comparison with the crop now being lifted (of which, I fear, a woful account will have to be given). The Table is further intended to show the effect of change of seed, in the case of Nos. 9, 10, 11, 12, and 17, and with Nos. 6, 7, 8, and 11, the result of wider and nearer distances in planting. Nos. 1, 2, 3, 7, 8, 14, 15, 16, 18, and 19, and all marked (a) were grown from my own seed, carefully picked, thoroughly ripened, and very even; those marked (b) were from seed grown in a neighbouring garden (a light soil but very inferior to my own), from seed supplied by me in 1875; Late Rose (c) was from a friend's garden (from seed I had given him in 1875), a good, strong loam, but where the Potatoes are frequently heavily bit with disease; Nos. 4, 5, 6, 13, and 20, were altogether new seed. None of the varieties had been grown in this garden for more than four years without a change of seed. The early varieties were planted 6 in. deep (Nos. 1, 4, and 9), the rest 7 in. deep,

and none were earthed up at all. The ground was scarcely manured with anything after the previous crops; what was used was chiefly the ash from a slowly-burnt garden fire. The disease, as the Table shows, was merely nominal, and I attribute this to a great extent to the absence of anything like fresh or strongly stimulating manure, which, though undoubtedly increasing the yield, renders the crop much more liable to the disease as well as, in my opinion, tending greatly to weaken the constitution of the Potato. The season was by no means a very favourable one—dry and hot to nearly the end of August, then unduly wet the rest of the season, especially the end of September and beginning of October. This caused much disease in the neighbourhood generally, and with all late Potatoes, excessive super-tuberation. I had a few late sorts which produced heavy crops, but so spoiled by super-tuberation, that I could take no account of the yield. Among these also there was more disease, but still not to any extent; but experience seems very plainly to prove that it pays best to grow such varieties as mature early, by the end of August or beginning of September, especially as there are now several heavy cropping sorts, though not equal in all respects to some of our old late Potatoes. With such springs as we now so often have, it seems impossible to secure the advantages that we used to think were gained by early planting. All Potatoes that were above ground as late as even the middle of May, were this year very seriously injured, at least in this dis-

trict. With regard to change of seed, all will agree it is a good plan to have fresh seed as often as possible, provided it can be obtained of as good quality as the home-grown, and I have not found this as easy as it ought to be. In connection with this point I think the system of encouraging (with new varieties especially) unnatural production by the offer of prizes for the highest yield from a given quantity of seed, as bad a plan as could well be devised. The conditions of growth all tend to the weakening of the Potato, and the result is seed of a very poor quality. I can only attribute to this cause the comparative failure of Compton's Surprise and Brownell's Beauty (Nos. 5 and 13 in the Table) which I grew for the first time last year from newly imported seed. They were planted on a carefully prepared and fresh piece of ground, on which no Potatoes had been grown since 1872, and the crop was very poor in quantity and indifferent in quality, yielding less than eight-fold, while Late Rose (c) from seed which had only had one year's change from my own ground, yielded over twenty-fold. It will be seen by the Table that in the case of No. 9 the yield was slightly in favour of my own seed, but as I have already remarked, the soil on which all the seed marked (b) was grown is very inferior to my own, and in this case the seed was not as well sprouted. With regard to the distance apart of rows and sets the advantage of giving plenty of room is very marked, especially in the case of Nos. 7, 8, and 11 (c) and (b), and when the rows are 4 ft. apart, the ground is not all occupied by Potatoes, a row of Greens be set between each row of Potatoes, and they, too, give a proportionately heavy return for the abundance of room in which they revel. I have tried giving more space still, but have come to the conclusion that the above is about the happy medium.

E. C.

Over-ripe Seed Potatoes.—The term "over-ripe," as applied to seed Potatoes, is wholly a mistake, for no seed tuber will germinate and produce a plant until it is thoroughly ripe—that is, the germinating organs perfectly matured; and this maturity only results from long keeping. When a tuber is fit and starts its eyes into growth it is ripe as a seed tuber, and not before. Over-ripe tubers must, like over-ripe Apples, be rotten, or tending to that stage. It is equally absurd to assert that seed Potatoes, lifted before the haulm has decayed or ripened, are better for seed than are those that have remained longer in the ground; the strongest Potato plants invariably come from sets that have never been lifted, but have remained in the ground the entire winter. The danger that follows upon lifting Potatoes for seed too early is, that the sooner they are lifted the sooner do they start their eye-buds; and this is an undoubted evil, as it should at all times be the aim of the cultivator to keep them in check. The best check upon this form of precocity is to allow the tubers to remain in the cool soil as long as can be consistent with safety and convenience, and then the eyes will remain much longer dormant. There is a common form of belief that if tubers after the haulm is dead be allowed to remain in the soil, they are much more liable to be affected by disease: I hold this to be a simple error, and not supported by facts. When the haulm is struck the tubers are affected more or less almost simultaneously, and even if got up at once, the affected ones will rot as badly in the store as in the ground, whilst those that are sound in either case will remain so.—A. D.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Origin of the Jerusalem Artichoke.—I am not wise enough to decide who invented the Jerusalem Artichoke, but this I can vouch for, that they are found growing wild and in abundance on the banks of streams in this section, where none have ever been planted, where the virgin soil has never been touched by plough or any implement. They were here when the first white settlers arrived.—J. M. MILLER, Peabody, Marion Co., Kansas, in "The Rural New Yorker."

Herbs.—There is a lamentable ignorance of the use of herbs in American and English cookery. A writer in the current "Quarterly Review" says:—"The fact is, French cooks and French gardeners know what herbs for cooking are. A friend of ours happened to be in a country house the other day where there was much show, little science, and a large garden kept up at a great expense. At luncheon he volunteered to make a fresh salad, and forthwith proceeded to the garden to gather his materials. He asked for Lettuce, Chervil, Tarragon, and Borage: he only found the first. It is to the judicious use of herbs that French cookery owes half its merit."

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

September 10.—Sowing Red and White Turnip Radishes. Shifting a few Cinerarias and Primulas into pots for blooming early. Putting in cuttings of double Petunias, Lobelias, and Nierembergias. Cutting and bottling a few bunches of Black Hamburgh Grapes left from the second early house, and removing the lights off the same, in order to get the wood well ripened. Cutting off all heads of Globe Artichokes that are overgrown. Removing all young shoots from Tomatoes, in order to expose the unripened fruit to the sun, and gathering those that are ripe; also removing laterals from Vines, and cutting out bad berries from the bunches. Making new gravel walks and turning old ones. Watering newly-planted Endive, Lettuce, and Cabbage.

Sept. 11.—Potting Pelargoniums which have been struck in the open ground. Clearing off Strawberry runners from permanent plants, applying a good coating of rotten manure between the rows and forking it in. Dutch hoeing amongst Broccoli and all other growing crops, to kill weeds before wet weather sets in. Planting all spare ground with Cabbage plants to come into use in winter. Gathering Louise Bonne of Jersey, Jersey Gratioli, and a few Marie Louise Pears for dessert; also Victoria Plums from a north wall for preserving. Watering the Pines, late-planted Celery, Scarlet Runner Beans, and late Peas.

Sept. 12.—Potting a collection of Campanulas. Covering up dwarf Beans with spare lights to protect them from early frosts and heavy rains. Roughly digging and heavily manuring a piece of ground lately cleared of Peas for next year's Onions. Earthing up Celery and Cardoons. Pruning and painting the early Black Hamburgh Vines and washing the woodwork and glass. Emptying old Mushroom-bed and turning manure for another one. Pinching off all runners from Strawberries in pots. Weeding and hoeing amongst Asparagus-beds.

Sept. 13.—Pricking out Black-seeded Brown Cos and Stanstead Park Lettuce. Thinning out Spinach and afterwards hoeing between the rows. Cutting Grass edgings and turning gravel walks to give them a fresh appearance for the winter. Cutting off Strawberry runners and weeding and hoeing between the plants. Earthing up Celery whilst the soil is dry and friable. Spawning and soiling Mushroom bed. Watering the Pines all through, also Lettuce and Cauliflower plants.

Sept. 14.—Potting off cuttings of Colens and Alternantheras. Putting in cuttings of Heliotropes and Pelargoniums. Digging ground for August-sown Cabbage. Clearing off Peas and cleaning the ground for other crops. Thinning Turnips. Cleaning, weeding, and rolling gravel walks. Stopping all laterals on Vines. Placing stakes to Pines which are in fruit. Tying out Chrysanthemums. Gathering Yellow Ingestre, Cox's Orange Pippin, and Emperor Alexander Apples; also a few more Marie Louise Pears and Tomatoes. Watering indoor Peach borders.

Sept. 15.—Sowing Chervil. Thinning out Mignonette in pots; also Lettuce and Endive in seed beds. Dutch hoeing between all Cauliflowers, Cabbages, and newly-planted Lettuce and Endive. Looking over all Cucumbers and Melons, and stopping their shoots where required. Renovating manure linings round frames. Filling up Grape bottles and cutting out all bad berries from the bunches. Fruit in use for dessert:—Pines, Grapes, Melons, Peaches, Figs, Nectarines, Pears, Apples, and Plums.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Large-flowered Pelargoniums, cut down late, will have now made enough growth to be shaken out and re-potted; treat them similarly to the earlier plants by cutting away a portion of the roots and putting them into 6-in. pots, as it will be better to move them into others an inch or two larger later on than to place them at once in those in which they are to bloom. Insert them in a pit or frame where they can be kept comparatively close for a fortnight, during which time syringe overhead, but do not give them much water at the roots.

Lilies.—The different varieties of *L. speciosum* that flowered late should be supplied with water so long as the foliage keeps green. *L. auratum* and other species, the tops of which are dead, should have just enough water to keep the soil in a slightly moist state.

Calceolarias and Cinerarias, &c.—See that all soft-wooded plants, such as Calceolarias, Cinerarias, and Primulas, that are in pits and frames, are free from aphides; if any be affected with this pest, they should be now repeatedly fumigated or dipped in Tobacco water, so as to have them clean previously to getting them into their winter quarters. Herbaceous Calceolarias, sown about the end of July, will shortly be ready for pricking out; as soon as they are of a sufficient size to handle they should be put in large pans thoroughly drained and filled with loam, to which has been added a good portion of rotten manure and sifted leaf-soil in equal parts, and sand enough to form with the whole a light, open compost. Insert the plants 1½ in. apart, and range them on a moist surface, such as a broad shelf or flat stage, covered with coal ashes or sand; they must not be too far from the glass, or they will get drawn up weakly through the winter. If possible during the winter they should be in a temperature of from 40° to 45°, as they ought to keep on growing. As soon as they have made leaves 1 in. long, let them be transferred singly into 3-in. pots.

Primulas sown for late flowering in spring should now be moved into the pots in which they are to bloom. Give them a rich, porous soil, and encourage them to grow freely whilst there is yet a considerable amount of daylight, keeping them close to the glass in the pit or house they occupy.
