In the old Lily House is a very fine specimen of *Arundo mauritanica*, a fine Grass with many stems (10 ft. or 12 ft. high) surmounted by large panicles of flowers. Where grown under favourable conditions as to space, moisture, &c., this makes a very fine object. *Osmanthus fragrans*, in the Economic House, has little white flowers, which emit a wonderful scent. This plant is much valued by the Chinese, who, it is said, use the flowers for perfuming the higher class teas. Any ordinary greenhouse treatment suits it. The large, orange flowers of *Linum trigynum*, and the orange-scarlet of *Aphelandra aurantiaca*, are very showy in the stove. A beautiful *Eranthemum*, *E. aspersum*, nearly allied to *E. tuberculatum*, has a long, slender, corolla-tube; the limb is white, curiously speckled with purple, the middle lower lobe being nearly all purple. This species is a native of the Solomon

Islands, and was first collected by Mr. John Veitch during his Australian voyage. Itambé is the varietal name given by Van Heute to one of his *Nagelias* sent out last year; it has fine green foliage and very large yellow and vermilion flowers. *N. incendie* has white corollas, finely spotted with fiery-red. *Cyrtodeira fulgida* is a dwarf New Grenadan Gesneriad, with very bright red flowers and dark green, bulbous leaves, inclining to coppery in a young state; this species has been in bloom for some months. A Brazilian *Malvaceous* plant, *Pavonia Wietii*, introduced to cultivation three years ago by Makoy, of Liège, has a dull purple corolla and bright blue anthers, the great beauty of the plant being, however, in the very numerous bracteoles which compose the epicalyx; these are of a fine red, long, narrow, and ciliated; the leaves are long and strongly toothed; the flowers borne in sub-terminal corymbs, and a strong specimen is hardly ever out of bloom. A very beautiful Chilean evergreen shrub, *Azara integrifolia*, is at the present moment very attractive in the narrow border by the wall of the Orchid-house; the flowers are very freely produced, about a dozen in each short, dense raceme; they are apetalous, but the four sepals, being yellow, unite with the brighter yellow of the stamens, and produce a very pleasing effect. Some species of the genus, the present one included, are remarkable for having, in the normal state, geminate leaves, somewhat differing in size, the lesser one being frequently stipuliform. There is a variegated form of *A. integrifolia*, which is well worthy a place in any collection of wall plants. The Natural Order *Flacourtiaceæ*, with the exception of *Ilexia polycarpa* (see *THE GARDEN*, July 21, 1877), and different species of *Azara*, does not contribute much to the decoration of the outdoor garden.

Among the Orchids there is little to note that is novel, unless it be *Catasetum macrocarpum*, which, as yet, we have been unable to find in any trade list. This species is more showy than many of its congeners, the petals being greenish-yellow, thickly spotted with reddish-brown, and the border of the very thick, fleshy hood, formed by the upper petals, being margined with deep yellow. *C. cristatum* is uniformly green, except the crested white labellum. For full description and explanation of the wonderful structure of the flowers of this genus, see Mr. Darwin's "Fertilisation of Orchids." *Eria odoratissima*, from Moulmein, is perhaps the prettiest of all the *Erias*. The large flowers are borne on long, drooping racemes, and are pure white in colour, with the exception of a rosy-purple bordering, and a streak or two of the same colour at the base of the lip; their scent is very powerful. G.

Large Tulip Trees (see p. 481).—We have an old Tulip tree which has a bole 12 ft. or 13 ft. in height, the smallest girth of which is half-way up, viz., 14 ft. It is much larger at the base, the tree during its growth having raised there a mound of considerable size. It is also much larger where its huge limbs fork off from the stem. Its height is between 80 ft. and 90 ft., and the spread of the branches the widest way is 70 ft. Unfortunately it was planted too close to the house, being within 20 ft. of it, and had to be pruned away from the windows from time to time, or its general size and spread would have been much larger. It had a great quantity of small and medium sized branches broken off in the recent gale. The bark has a rough, corded appearance which is very ornamental. It is annually covered with flowers, but I have never noticed that they were sweet scented. This tree forms a welcome shade in summer for lawn parties.—JOHN GARLAND, Killerton, Exeter.

Peas in November.—We have gathered from G. F. Wilson Pea during the last fortnight several dishes of Peas, of which I send a fair sample; also some blossoms. Should there be no frosts, we expect to gather many more during the following week, the two rows which we have being full of pods.—A. S. RAINE, *Fernhurst, Southboro', Tunbridge Wells*.—[A good sample, bearing a profusion of blooms and pods, and quite free from mildew.]

Kerosene Stoves.—Has any reader of *THE GARDEN* had any experience with regard to these stoves for keeping out frost in fruit-rooms, in which Apples and Pears are kept through the winter? If used in this way would they in any way deteriorate the flavour of the fruit? Information on this point would greatly oblige.—G. NOAKES, *Mountfield Court, Sussex*.

The Common Brake.—An impression prevails in this neighbourhood (Gainsborough), that the Brake, or Eagle Fern will die if cut at the fall of the leaf two or three years in succession. Will any of your correspondents kindly oblige me with their opinion on the subject.—R. C.

Parsnips Rotting at the Crown.—At this time of the year, when Parsnips are left in the ground, many of them are apt to decay at the crown. This arises chiefly from the leaves rotting and then infecting the root. We always remove most of the leaves when the first of them begins to decay, and the roots, when lifted, hardly show a decayed spot.—CAMBRIAN.

ROSES.

CLIMBING ROSES ON GRASS.

THERE are remedies for some of our garden troubles if people will only try to find them out. There are few more unprofitable and tedious labours than that of eternally pruning and training climbing plants. In many positions we can never avoid this in a modified degree; in others we can avoid it, and get a much more beautiful result in doing so. For example, many vigorous trailers and climbers are more beautifully planted out on banks of turf and let alone than under the most careful training. The accompanying little woodcut, drawn by M. A. de Bar, and engraved by Mr. Hyde, shows the result of planting a free-growing Rose by itself on the Grass and leaving it alone. Such effects are, of course, most suitable for the wilder and more picturesque parts of gardens; but in a modified degree they may be carried out in any part of the

Climbing Rose isolated on Grass.

garden. By this is meant that climbing Roses might be allowed to grow naturally, and be at the same time so thinned out and otherwise attended to that they would not become weak in flower or growth.

FORCING MARECHAL NIEL ROSES.

THOSE who are desirous of keeping up a good supply of cut Roses during the winter and spring months should get some standard *Maréchal Niel*s, and also dwarf plants of that Rose, to grow on for another winter. *Maréchal Niel*, although one of the finest Roses for cutting purposes, is, nevertheless, not one of the most showy varieties for decoration in pots, inasmuch as the flowers hang down, and are hidden, to some extent, by the foliage. It is, therefore, best as a standard, but it is only in the form of cut flowers that I can recommend it. No Rose forces better than *Maréchal Niel*, and it is always much admired when used for decorative purposes. Plants of it potted now will furnish a few flowers during the spring. When June comes, those that have done flowering should all be shaken out of their pots and re-potted, so as to give them time to make growth for the following winter's forcing. I have cut fine flowers of this Rose at Christmas and on New Year's day, but that was from plants the wood of which was strong and well-ripened—important points in the case of Roses that are forced early. In order to ripen the wood well, the plants should be placed in a warm, dry spot out-of-doors, watering very sparingly during the months of September and October, and replacing them under glass in November, or somewhere free from frost. When started for forcing, they should be plunged in a bottom-heat of from 65° to 70°, giving top air for the first fortnight, so as to keep the

tops of the plants cool, in order to check their breaking too quickly and feebly. If pushed on too fast, we do not get a good break, and this Rose generally produces its blooms on the strong shoots. As the buds swell, the heat should be increased from 55° to 60°. In Rose forcing, a strong top-heat should be avoided, as the flowers become drawn and sickly, and will often damp off before opening. Syringing, too, must be stopped, as water blackens the flowers and causes them to damp off. As soon as the blooming period is over, the plants should receive a slight pruning, and as soon as they begin to make a second growth—about the latter end of May or beginning of June—they should be carefully examined and potted, removing most of the old soil; if any plant looks sickly, wash the roots clean, and then repot it in a compost consisting of half loam, one fourth rotten cow-manure, one fourth one-year-old leaf-soil, and plenty of sand, and a small portion of soot, mixing all well together. The plants should then be plunged and grown in a humid atmosphere during the months of June, July, and August, watering occasionally with a little weak manure water, and syringing night and morning till they have made their growth. Sickly standards, as well as dwarf Roses, should be treated in this way, and as soon as they have made or finished their growth they should be removed out-of-doors and set in some warm corner. I have grown plants of *Maréchal Niel* with shoots from 10 ft. to 14 ft. in length in one season, and plants of it in 18 in. pots have produced from sixty to seventy blooms during the forcing season. Standards also flower well; they do not last more than three years in pots, but good strong plants of *Maréchal Niel* are so very cheap now that one does not mind the loss of a few plants. I find that *Marechal Niel* on the Brier, and on its own roots, do best for pot culture as well as for other purposes. It grows very strongly on the Manetti stock, but two or three fine plants of it have gone off with me at the graft or bud. The Brier in my opinion is the best stock for it, if we wish to obtain its Roses in perfection. In selecting standards for pot culture, see that they are budded on good clean healthy growing stocks, for if the stock be soft and sappy they will not succeed in pots. Rose growers should always lay up in autumn some good rotten cow-manure, and keep it until the following season, so as to have plenty for potting purposes, as this material forms an important item in the soil for pot Roses if used in proper proportions.

H. G.

LATE-BLOOMING ROSES.

ALTHOUGH we have varieties of the Rose which are said to be perpetual bloomers, yet we all know, pretty well, that the principal Rose season is June and July, extending in very late districts to August. After that time, if the season be favourable, many varieties continue to produce flowers, on the secondary growths, till late in autumn. Of these, the *Gloire de Dijon* is a good example, for it continues to flower until the frosts kill the buds; and *Souvenir de la Malmaison* is another. In fact, the nurserymen's catalogues enumerate a great number of what are called "autumnal Roses" in all the classes, but the sorts which are particularly disposed to bloom late or a second time—producing tolerably fine flowers—are not so very plentiful, and a reliable list of those which do would be highly serviceable. Owners of gardens who live in London during the season—that is, from the beginning or middle of May till August—never see their Roseries in perfection, and many are the regrets expressed on this head when they return to their country seats in autumn. True! they can have the flowers sent to them in London, in basketfuls if required, but they miss the charm of seeing them growing and gathering them fresh as often as they want them. Something may be done, however, by planting late-blooming varieties, and retarding the bloom of others when desirable. I knew a garden in Scotland where the gardener was very successful in keeping the flowers back to September and October, by simply pinching off the first buds at a certain stage. There was a general and extensive collection of Roses on the place, and he seemed to have operated on all in this way, for when I saw them at the end of September, there was quite a display of Roses on the beds, and very fine flowers the most of them were. The gardener informed me that it was his general practice, every year, to pinch the buds off when they were pretty well advanced, but before they began to expand, and that he then pinched pretty well back to where the wood and foliage were tolerably good, and the second breaks were all the stronger.

C.

Othonna crassifolia.—This is a remarkably interesting and peculiar plant, with flowers like a Daisy in shape, but of a pure canary yellow, and fat, small leaves like those of a *Mesembryanthemum*. It trails down so as to form a useful basket or shelf plant; it is now in bloom in various places about London.

NOTES OF THE WEEK.

Protecting Christmas Roses.—The large-flowered variety of *Helleborus niger*, the blossoms of which, until last week, were the most attractive amongst hardy flowers in London gardens, has suffered severely from the heavy rains and hailstorms which we have lately experienced. Valuable and hardy, therefore, though this plant is, it becomes necessary to protect the blossoms in some way during stormy weather, and the best plan of doing this which we have seen is to place spare lights over them, so as to allow of a free circulation of air about the plants. Hand-lights or bell-glasses will do, but if kept at all close, the expanded blossoms, as well as the buds, are very liable to damp off.

Cheilanthes elegans from Seed.—This Fern is not so common as it should be, on account of its being somewhat difficult to raise from seed; Mr. Ley, of Croydon, has, however, been fortunate enough to raise some 5000 or 6000 plants of it in that way, and when seen massed together in 4-in. pots, they have a most interesting appearance.

Jasminum grandiflorum as Standards.—A quantity of plants of this sweetly-scented white-flowered Jasmine, grown in the form of standards, are just now very attractive in the Pine-apple Nursery. They are grafted on stocks of the common free-growing kind at the desired height, and when well furnished with bloom, as we here find them, they are most useful for decorative purposes.

New Azaleas.—The new Azaleas, obtained from crossing *A. amœna* with the large-flowered kinds, are now in flower in Mr. Williams' nursery. In habit they resemble that of *amœna*, whilst their flowers are larger than those of that variety, and embrace various shades of colour. For forcing, these Azaleas will be very valuable, in proof of which, the plants in question have been flowering for some time past, although only subjected to ordinary greenhouse temperature.

Alnwick Seedling Grape.—Good examples of this new Grape may now be seen exposed for sale in Covent Garden Market. Its bunches are well formed, and the berries large and black; whether it possesses as good keeping properties as the Black Alicante we are yet unable to say, but the flavour is better than that of the Alicante, and the appearance nearly, if not quite, equal to it.

Finely-flowered Bignonia venusta.—I have recently seen this plant in the neighbourhood of London much finer than ever it has been my lot to see it before. Its shoots were trained up the rafters and sashes, from which depended hundreds of drooping racemes of large, tubular, amber-coloured flowers, forming such a blaze of floral beauty as can scarcely be conceived. This Bignonia is certainly the finest autumn-flowering climber for an intermediate house that any one can possess.—W. H. G.

Sophranitis grandiflora in Winter.—The bright scarlet flowers of this beautiful winter blooming Orchid are now enlivening the Orchid houses in the different nursery establishments round London. Either in pots, baskets, or on dead stumps of Tree-ferns, this little Orchid is equally interesting, and it will succeed well even in an intermediate house. For coat bouquets, the blooms are much prized, on account of their bright colour and lasting properties.—S.

Androsace sarmentosa.—This is a pretty little rosette-like plant with silvery-green leaves. It will prove useful for planting on rockwork, and probably also for carpet gardening. It is as yet scarce, but, judging from examples of it in Messrs. Rolliassons' nursery, it is a good plant, and therefore one the stock of which will doubtless soon be increased.—G.

Griffinia hyacinthina.—This is a useful plant at this season of the year. Its flowers, like those of other Amaryllidaceous plants, are produced from leafless bulbs; but, when associated with small Ferns or Palms, this defect is remedied, and the bright blue and lilac-tipped blossoms are shown off to increased advantage. Isolated plants of it in the Fern-houses in the Holloway Nurseries are just now very attractive.

Ipomœa Horsfalliæ.—This old but attractive stove climber is not nearly so frequently met with as it should be, considering the ease with which it may be grown, and the attractive character of its blossoms, which are produced in profusion during the winter months, and which last longer in good condition than those of many kinds of *Ipomœa*. A large plant of it, trained under the roof of one of the plant-houses in Messrs. Veitch's nursery, will shortly be one mass of bloom.—S.

Plants Unseasonably in Bloom.—Owing to the mildness of the season, a greater number of out-door plants may now be met with in bloom than is usually the case at the latter end of November. In the Hale Farm Nursery, at Tottenham, may now be seen in flower *Narcissus Onisi*, *Bulbocodium vernum*, and several kinds of *Crocus*, *Lithospermum prostratum*, *Scabiosa caucasica*, double *Primroses* (six varieties), *Helleborus niger maximus*, *Aubrietias*, *Schizostylis coc-*

cinea, *Stokesia cyanea*, several varieties of *Cyclamen*, *Iris alata*, *Sternbergia lutea*, and several *Asters*, the best at the present time being *A. grandiflorus*. There are also many other plants more or less in flower, but these are amongst the most showy. In other places we have noticed the tall-growing *Aster Novæ Angliæ*, and its variety, *rosens*, conspicuously in bloom; also, French *Marigolds* in abundance, and common *Nasturtiums*.

Pteris Leyi.—For button-hole bouquets this Fern will be found to be one of the most useful, its long leadlets being formed in such a manner that, if a few flowers be placed against a single frond, they become, as it were, enclosed within its long, claw-like divisions.

Cymbidium Mastersi.—A good variety of this beautiful Orchid is now finely in flower in Messrs. Rolliassons' nursery. The flowers, though considerably smaller than those of *C. eburneum*, are borne in much greater numbers. They are ivory-white, and are chaste and invaluable in small bouquets.

Palms and Calanthes.—A pretty combination is sometimes made at this season of the year with Palms, *Aralias*, and Ferns, interspersed with the various forms of *Calanthes* in flower; their white and rose coloured blossoms, set closely on gracefully drooping spikes, harmonise well with such associates, and edged with variegated *Panicum*, an arrangement of this kind has a fine effect.

Orchids in Flower at Chelsea.—A good variety of the beautiful *Lælia autumnalis* is now finely in flower in Mr. Bull's nursery; *Odontoglossum Rossi majus*, too, growing and flowering freely on small blocks, forms a good companion for it. Large-flowered varieties of the beautiful *Miltonia candida*, together with the peculiar leopard-spotted *Odontoglossum* (*O. Insleyi leopardiolum*), and other attractive kinds, are also in good condition.

Veronica Andersoni.—This is one of the best of the larger-growing Speedwells for winter flowering in pots, and its deep blue blossoms are invaluable in a cut state, or on the plant they supply a colour in the conservatory by no means plentiful. In mild winters it sometimes lives out-of-doors near London.

Pompone Chrysanthemums.—The neat little plants of this section, now to be found in the London markets, are the produce of cuttings inserted in cold pits or frames, or under hand-lights in June. These cuttings are obtained from old plants grown in some stray corner for the purpose. They are planted thickly in sandy soil, well watered, and kept shaded until rooted, when air, light, and sun are freely admitted to them. When well established, they are transplanted in an open border of sandy soil, 18 in. apart. Stopping the shoots is practised sometimes twice, the last time being just before they show bloom-buds. They then make dwarf bushy plants, which are lifted and potted in 5-in. or 6-in. pots, as soon as the buds are set, and placed in a half-shady situation until frost appears, when they are taken under cover until they come into flower.—S.

Dendrobium bigibbium superbum.—Numbers of plants of this Dendrobe, which is distinct in habit from any other kind, are now flowering beautifully in the Holloway Nurseries. The flowers, which are borne freely on long, slender, gracefully drooping stalks, are of a rich lilac-purple, or rose colour. It comes from Torres Straits, whence Mr. Williams has just received a large importation. We also saw several hundred plants of this Dendrobe in Mr. Bull's nursery, which had just arrived from the same place.

Three Good Dracœnas.—In a large collection of new and old kinds of these popular decorative plants, in Messrs. Rolliassons' Nursery, we lately had an opportunity of selecting three of the most useful kinds for table decoration. These were *D. elegantissima*, a kind with narrow leaves of a glossy bronze colour, margined with deep claret colour; *Guilfoylei*, white, crimson, and green; and a rich orange crimson-leaved, kind named *D. salmonica*. These are all graceful habited kinds, with narrow drooping leaves, and which can be grown into large plants in very small pots.

Floral Decorations at the Norfolk Wedding.—The decorations on the occasion of the Duke of Norfolk's wedding, on Wednesday last, surpassed anything hitherto attempted. On entering the church, large *Camellia* trees were seen in the distance, right and left of the altar, literally covered by hundreds of pearly-white blossoms. The trees, which were 12 ft. high and 10 ft. through, filled the centre places in groups of fine-foliaged plants, graceful Ferns, and choice Orchids. A little lower down within the sanctuary the eye rested upon some groups of plants, the centres of which were composed of marvellous specimens of Pitcher plants (*Nepenthes*), some of which were nearly 10 ft. high, and one of them (*N. Rafflesiana*) had over sixty finely-developed pitchers on it; miniature Ferns and graceful Palms, amongst which were assorted the lovely spikes of the *Odontoglossum Alexandræ*, with numerous little white *Hya-cinth*s peeping out amidst green Moss and Maiden-hair Ferns, rendered the floral display on the occasion complete. Mr. Wills, to whom these decorations were entrusted, informs us that nearly 3000 white *Camellia* blooms were used in them.

THE INDOOR GARDEN.

FICUS ELASTICA.

(ITS PROPAGATION AND TREATMENT ON A NEW PLAN.)

THE India-rubber plant is too well known to need description. It is one of those plants which is extremely serviceable for all the year round decoration of apartments; and were not its price in a great measure prohibitory, it would doubtless be still more extensively employed for that purpose. Those who possess sufficient convenience for its propagation and after growth, should at once see to the working up a stock of it. If cuttings of it be inserted between now and January, they may be easily grown on into plants from 2 ft. to 3 ft. high by next autumn. To obtain handsome plants in small pots, they must be grown quickly, and nine months are quite sufficient for the purpose. Plants that run into the second year are apt to become naked at the bottom just where they should be best furnished with foliage. Many possess plants which have become leggy or too large for general decorative purposes. These may be cut into pieces, leaving one leaf to each cutting. Before taking off the cuttings, the plants should be thoroughly washed, as the welfare of the future plant will much depend upon the maintenance of health in the cutting leaf. Each cutting should be inserted singly in a small pot in good sandy peat. The soil should be made very firm around them, and a small stick inserted therein, to which the cutting leaf should be attached. If the pots be plunged in gentle bottom-heat and covered with a handlight or cloche, roots will be formed in about six weeks, when the plants may be removed to a more airy position in the house. In the course of a week, they may be shifted into 3 in. pots. By the beginning of April, they will have come fairly into growth. They should then be placed in 5 in. pots, and, when fairly established therein, they may, if required so large, be transferred into 6 in. pots. A warm, moist atmosphere, with liberal supplies of moisture to the root, must be maintained during the growing season. Shading should only be afforded in very hot weather, and discontinued as soon as the sun begins to decline in power. In fact, the greater the amount of solar heat they can receive consistent with their well-being, the greater solidity will the tissues acquire, and the plants will consequently be better able to resist those alternations of temperature to which they must later necessarily be subjected. The best plants I ever grew were planted out upon a slight bottom-heat in frames in May. They were gradually hardened off, so that, when fairly in growth, the lights were entirely removed. The summer was, as is generally the case in Switzerland, intensely hot, and they were saturated with water occasionally, no shade being given. In September they were potted and placed in a close house for about a fortnight. This open-air treatment I could not recommend in England; the average of seasons is not warm enough, but under glass they may be planted out, and will form plants immeasurably more handsome than the best pot culture can effect. I would recommend those who would desire to see this *Ficus* at its best, to give this system a trial. The leaves acquire a development which those of a pot plant can never attain; and, if carefully lifted, they will experience no check. Those who possess sufficient glass accommodation, should keep a plant or two for the especial purpose of affording cuttings.

The terminal shoots make the best cuttings, as they start, when rooted, more freely into growth. The darkest corner in the stove will suit them very well; and a large, full-headed India-rubber is no mean ornament to a plant-house, and will be found very serviceable if large plants be required for decoration. I may add that E. Chauvieri may be treated in the same manner, and will be equally benefited by the same generous treatment. It forms, in fact, a capital companion plant to the ordinary India-rubber, and, where one is grown, the other should also find a place. J. CORNHILL.

Byfleet.

PRITCHARDIA GRANDIS.

THIS Palm is well named *grandis*, being undoubtedly one of the noblest fan-leaved Palms of small or medium growth yet introduced. It comes from the South Sea Islands, and consequently will require a high temperature in order to grow it satisfactorily. Its leaves, which are of a deep, shining green, are massive yet elegant in their arrangement on the plant. It would be difficult to imagine a better contrast than this plant makes growing in close proximity to the slender *Cocos Weddelliana*. It is a species that will evidently be in general

Pritchardia grandis.

request as soon as there is stock enough of it in the country to admit of its distribution. It is one of those plants to which no illustration can do justice, as regards conveying a full idea of its beauty. Being apparently a slow grower, it will be years before it gets too large for even a comparatively small house. Its cultivation will, no doubt, be similar to that of other heat-requiring Palms. It will need efficient drainage, plenty of water, and attentive shading in order to prevent the leaves from being scorched in bright sunshine. It has been introduced by Mr. Bull, but the name *Pritchardia* must be taken as provisional, as there is yet no certainty to what division of the Palm family it belongs. The leaves of these Palms are stated by Seemann to be

used as fans and umbrellas in the Feejee Islands. In a shower of rain they are so worn on the back of the head as to throw off the water behind the wearer. T. BAINES.

Jasminum Sambac.—Allow me to endorse "W. W.'s" remarks (see p. 377) respecting this Jasmine. Our plant of it covers part of the back wall of a plant stove, where it is allowed to run at liberty. We only thin out some of the weak growths in order that the stronger ones may get more light and air, as, if the wood be not strong and well-ripened, the quantity of flower is greatly diminished. We have had abundance of bloom for several weeks, and the plant still promises to keep on flowering for some time. With us it stands well in a cut state, and is invaluable for button-hole bouquets and lady's hair, the perfume being very delicate and sweet. Mr. Spelman (see p. 460) cannot, I think, be in possession of *Jasminum Sambac*, from the account he gives of it. I never remember seeing *Jasminum Sambac* doing so well as he says it does under greenhouse treatment, nor yet growing and flowering so freely in a pot as when planted out. —R. GREENFIELD, *Priory, Warwick.*

Tropæolum Ball of Fire as a Standard.—Plants of this *Tropæolum* come in very usefully at this season of the year, and they produce their brilliant scarlet blossoms in abundance all through the winter; in fact, by striking cuttings of it at different times, they may be had in bloom all the year round. For winter decoration, I

insert a number of healthy cuttings in small pots in August, giving them a little bottom-heat; they strike in a few days, and are soon ready for a shift into 6-in. pots, a neat stick 4 ft. long being at the same time applied to each plant. By keeping them in a temperate-house they soon reach the top of this stick, and are ready for a final shift into 8-in. pots. Some neat umbrella-shaped trainers are now obtained, about 2 ft. in diameter and 4 ft. high; these are firmly fixed to each plant, the young growths of which are neatly trained round them till the whole surface is covered. Laterals will be produced freely, and, with a little care, a well-formed head will be the result, and blossoms will make their appearance by hundreds. Such plants have a charming effect in the conservatory when other brightly-coloured flowers are scarce.—H. HARRIS.

Sonerilas as Winter Flowers.—The following three varieties, viz., *S. Hendersoni*, *S. marmorata*, and *S. argentea*, were grown by me this season as a test, because I had previously considered them to be all alike; but I find them to be distinct. They are planted in rough peat and sand in 6-in. pans, and have grown freely. Of the three, *S. argentea* is the best, having larger flowers, and of a deeper pink than those of the others; the next best is *S. marmorata*. All three are now, and have been for these last six weeks, in profuse bloom, and they look as if they would keep for some time yet in flower. When at Kew, I used to grow *S. margaritacea* on hillocks on a tan bed, on which they grew well. As beautiful little Alpine stove plants, nothing can be better than these *Sonerilas*. They are easily propagated, and might be grown in any quantity in any stove.—J. CROUCHER, *Sudbury House, Hammersmith.*

Hyacinths and Tulips for Winter-flowering.—These, as well as *Narcissi* and other bulbs, are now being forced for market by thousands, one grower alone using as many as 80,000 bulbs yearly. They are potted in 6 in. pots as soon as received from Holland in autumn, and are placed in square beds out of doors, and thickly covered with Coco-nut fibre. This, being light, can easily be removed in order to select the most forward bulbs from time to time for placing in heat. In order to discover which are ready for forcing, they are turned out, and if well rooted are taken indoors, plunged in a gentle bottom heat, and kept dark until their flower heads show themselves; light being afterwards gradually admitted to them until they will bear full exposure. The first batch of Hyacinths and Tulips is sent to market the day before Christmas, if possible, and a succession is henceforward kept up until they come into flower naturally out-of-doors. Roman Hyacinths are also grown in considerable quantities. They bear rapid forcing, and come into flower from October to Christmas, when flowers are scarcest. They are forced as a rule in shallow boxes, and potted four or five bulbs in a 6 in. pot just before they come into blossom. They are also largely used in baskets and vases, but their chief value is for making bouquets, as, on account of their sweet-scented pure white pips, they can be used for such purposes, with the certainty that they will be appreciated.—S.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Jacaranda filicifolia.—Of this elegant plant, so difficult to propagate, there is now a number in the Victoria Nurseries. It should be more frequently used than it is, as a dwarf Tree Fern might be, among choice hothouse plants. It also makes a lovely table plant.—H.

Convolvulus mauritanicus as a Basket Plant.—This *Convolvulus* makes a beautiful basket plant in winter if liberally treated. The best way is to obtain established plants of it in 6-in. pots, and in autumn to place them in wire baskets filled with Moss. Thus situated, the slender branches droop gracefully over the edges of the baskets, and, if placed in a light position near the glass, yield a profusion of pretty blue flowers all the winter.—S. C.

Remarkable Growth in England.—Some of us may have heard of the vigorous growth of certain trees in the Tropics, and the following instance of growth in England may be worth recording:—A Bamboo growing in the conservatory at Syon House sent up a shoot in August, which is now about sixty feet high and 24 in. round the stem. The Bamboo is *Bambusa arundinacea*, or one of its forms.

Goodyera Rollissoni.—Will "S." (see p. 449) kindly say under what conditions of winter and summer heat he has grown *Goodyera Rollissoni*, as it is new, and I have been unable to learn anything about it?—H. B. [*Goodyera Rollissoni*, one of the most robust-growing members of the genus to which it belongs, was exhibited for the first time in 1876 by the Messrs. Rollisson, of Tooting. The conditions under which it is grown at Tooting are very simple. The plants are potted in a mixture of peat, Sphagnum Moss, and sand, and grown in a small stove which is moderately moist and not very hot; when removed into a house with a drier atmosphere, they are covered with a bell-glass. Under these conditions they grow vigorously, and break into beautiful variegation.—S.]

ORCHIDS.

SEASONABLE NOTES.

In purchasing Orchids care should always be taken to select the best varieties obtainable, the numerous variations from the original types being truly surprising. The genus *Cypripedium* contains many beautiful kinds suitable for decoration at this season of the year. Amongst these the best are *C. insignis* and its variety *Maulei*—kinds specially valuable for amateurs, as they may be grown successfully in an ordinary greenhouse. *C. venustum*, too, with its pretty marbled leaves and gay, slipper-like flowers, is also a desirable variety. Amongst stove kinds now in flower may be mentioned *C. Sedeni* and *C. Harrisonianum*, both garden hybrids, and, like all hybrid Orchids, of vigorous and robust constitutions—a remarkable fact, which has led us to infer that, in a state of Nature, these plants must be, to a great extent, self-fertilised, and, consequently, much bred in, by which their constitution does not attain that vigour which is brought about by cross fertilisation. *Zygopetalum Mackayi* is an old but useful winter plant; in flowers of it now opening its blue and white labellum is very large and attractive, and with care its blooms will remain in perfection until Christmas. Amongst white-blossomed plants *Cymbidium Mastersi* is producing many-flowered racemes, and by the time the beauty of this plant is over *C. eburneum* will be ready to succeed it with large, Tulip-like, ivory-white blossoms, which are also long-lived; these plants are often ignored in small collections, but at this season really have few rivals. Another white-flowered Orchid of a different stamp is *Pilumna fragrans*, a kind which possesses a delicate perfume. *Laelia anceps* is now opening its rich, rosy-lilac and purple flowers, which are invaluable at this season of the year, and the variety called *Dawsoni*, with pure white sepals and petals, makes a lovely companion to it, but, unfortunately, too rare at present to be enjoyed by all. The pretty *Oncidium cucullatum*, now in flower, is essentially an amateur's plant, which may even be grown along with Ferns in a Wardian case. In a wild state it is found growing at from 6000 ft. to 14,000 ft. elevation—a fact which at once indicates the low temperature in which it will succeed. *Phalaenopsis Schilleriana* is just beginning to open its beautiful moth-like, mauve and white flowers; an individual bloom of this Orchid for a lady's hair or button-hole bouquet is quite unrivalled. It is sometimes said that ornamental-leaved plants do not produce fine flowers, but here we have the dark green leaves transversely banded and blotched with white, and yet the plant produces many-flowered racemes of lovely bloom; moreover, it is the most vigorous grower in the whole genus. *Phalaenopsis* are somewhat difficult to cultivate; their leaves are large and fleshy, and they are entirely destitute of pseudo bulbs, so that during winter great care must be exercised in watering them, or the result may be rotting at the heart. They succeed best in baskets or on blocks of wood, as under pot culture too much moisture is retained about their roots. Of curiosities amongst Orchids may be mentioned *Restrepia antennifera*, which is now quite a little gem. It is dwarf in habit, and produces reddish crimson and purple flowers in abundance, the narrow clubbed petals standing out in front like the antennae of an insect. *Saccolabium* are mostly spring and summer blooming plants; but some few species produce their gorgeous wreaths of wax-like flowers in winter, and these should be looked after by those who do not yet possess them. *S. giganteum* is one of the best, and at the same time a strong grower; *S. violaceum* is less robust, but very beautiful, and the wreaths of bloom of *S. Harrisonianum* are pure white. *Vanda tricolor* and its varieties, usually looked upon as out of season now, are in many instances delighting us with their large, chaste, and fragrant blossoms, which last a long time in perfection; they should not, however, be allowed to remain too long, but should be removed from time to time as flowers are required. If this be done the same plants will produce fresh buds, and flower again in spring. *Dendrobium bigibbum*, a species from North Australia, has been long known to us as a rare and beautiful Orchid, and, thanks to collectors, the plant is now in the market in tolerable abundance, and proves to be a perfect gem at this season. Coming, as it does, from the hottest point of Australia and New Guinea, at no great elevation, we should recommend its being placed in the East India House. Those on the outlook for novelties should watch for the arrival of the small-growing, new white *Vanda*, called *undulata*; it is now showing flower-spikes, and should these open it will be for the first time in Europe. The flowers, which are numerous, are pure white, the petals being beautifully waved at the edges; the lip is also white, stained with lemon. It grows at considerable elevations, in company with *Pinus Khasyana*, where it sometimes becomes covered with snow; it should, therefore, be an acquisition in the cool Orchid house. *Colax jugosus* cannot be called a purely winter-blooming plant, because it is continually throwing its lovely blos-

soms; but just now it is most interesting, the pure white of its flowers being beautifully contrasted with rich purple stripes and spots. To those who like to have white flowers in a cut state in winter, we say grow quantities of *Goodyera discolor*. It is a free grower, and when well established, every shoot will produce a fine spike of fine white flowers, which are admirably adapted for the decoration of the drawing-room or boudoir, or for bouquet-making.

W. H. G.

ROLLISSON'S UNIQUE PELARGONIUM.

THIS is one of the most distinct, beautiful, and useful of the whole family of Pelargoniums; and yet, strange to say, but few people grow it. Of its origin, all that is known is that it came up amongst some seedlings of other Pelargoniums about forty

Rollisson's Unique Pelargonium.

years ago in the Tooting Nursery. It is, therefore, probably not a hybrid, but a seedling from the old *P. glorianum*, which it much resembles, and which about that time was extensively grown as a decorative pot plant. Be that as it may, however, "Unique" still maintains its name, for there is nothing like it, and for covering a back wall or pillars in a greenhouse or conservatory it cannot be surpassed. It grows freely and blooms profusely, and its leaves are delicately fragrant; even during the winter months dozens of its beautiful purplish-crimson trusses of flowers may be cut for indoor decoration, whilst as a bedder the effect which it produces is striking in the extreme, if the shoots be kept pegged down. Indeed, in whatever situation it is used, it is sure to give satisfaction.

W. H. G.

THE FLOWER GARDEN.

TROPEOLUM SPECIOSUM IN SCOTLAND.

THIS is a plant for everybody who will take the trouble to put it in the right place, and that is on the east, north, or west walls of a house. I do not know which is loveliest, its flowers, its seeds, or its leaves. The flowers are so numerous that the exquisite foliage seems jewelled with reddest rubies; the seeds are blue gems in carmine settings. Growing up Mr. Gossip's house, in his nursery at Inverness, is the grandest example of this plant I ever saw—a fit companion to *Clematis Jackmani*. It was finest there on the north and east sides of the house, but it had rambled all over evergreen bushes, producing a striking effect. This *Tropæolum* is perennial, and forms long underground roots, any 1 in. of which will make a good plant by being potted and grown under glass during the winter. Next April plant them out in good loam where they are to remain. From one plant myriads might be propagated. Mr. Gossip (formerly Howden & Co.) has sent out many thousand plants of it during the last few years, and this is probably the reason why it is so common in Scotland. People think it cannot be grown well in England, but, if half the trouble were taken about hardy plants that is taken about hothouse invalids, none of these gems would be so uncommon. Probably it likes the moisture of Scotland, coming, as it does, from the wet regions of the Andes; at Edinburgh, however, I saw no good plants of it, though I believe it is well grown at Perth. In my own county (Nottinghamshire) it has been very successfully grown. At Richmond-on-Thames, Mr. Kinghorn grows it as it should be grown; perhaps he will give us some advice about it, as I cannot see why it should not be the companion plant to *Clematis Jackmani* all over the kingdom. Plenty of moisture, plenty of shade, but no tree-drip, are requisites. Leave it alone when once established, and give it something to catch old of. Another superb hardy plant is the golden *Tropæolum polyphyllum*, which requires a warm sunny border and plenty of room to trail about. I have not yet bloomed *Tropæolum pentaphyllum* and *T. tuberosum*.

FRANK MILES.

Bingham, Notts.

MY TOWN GARDEN.

IN addition to the plants which I mentioned in my last paper (see p. 414), I propose now to describe a few others which we have, and which I consider specially adapted for a suburban garden. Foremost amongst these may be named the early flowering varieties of *Chrysanthemums*, of which I have a dwarf variety with white flowers, changing to lilac, 3 in. in diameter, and very double. *C. Precocite*, a kind with golden-yellow flowers, very double, and of medium size; *C. Scarlet Gem*, a sort with bright crimson flowers, very double, and also of medium size; *C. Delphine Caboché*, with purplish-rose flowers, and very double; and *C. Illustration*, with light pink flowers, and of medium size. The flowers of these varieties are borne in great profusion, and keep the garden bright and cheerful from June to December; they grow about 18 in. in height, and, being neat and compact in habit, are desirable and effective in the mixed border.

Tall *Lobelias* constitute a very showy class of plants, almost sub-aquatic, and therefore require to be kept moist, especially in dry weather. They grow from 2 ft. to 3 ft. in height, and succeed very well in the open border; but, as they are somewhat tender, they require care during the winter. I get on very well, however, with the following two varieties, namely, *L. Boule de Fen*, a kind with deep rich scarlet flowers, of good substance; and *L. Dazzle*, which has a splendid spike of rich crimson blossoms, the foliage and stem being blood-colour, and very handsome. In the autumn, I throw two or three spadeful of ashes over their roots, and in spring lift the clumps bodily up and divide them, putting them singly into small pots; I then take them indoors for a month or so until the frosty nights have gone.

Dianthus hybridus is a small, but desirable class of Pinks, amongst which the best are *Highclere*, scarlet-crimson, and very double; *Lucy Ireland*, large, rich

crimson, and fine in form; Marie Pare, pure white, and fine in form; Multiflorus, a scarlet kind, free flowering and vigorous; Quetieri, dark crimson, and fine in form; Rosette, pink, a fine distinct flower; Stratiflorus, a very striking striped variety; and Superbus, dark crimson, large and fine. These are perpetual-flowering varieties, blooming freely from early summer until December, and harmonise well with other plants in the front of the mixed border. Some are beautifully scented, and useful for cutting. They do very well in ordinary garden soil, with a slight mulching or sprinkling of fine rotted manure placed over their roots.

The Campanulas, or Bell-flowers, are useful plants, and easily cultivated in ordinary garden soil. The kinds which we grow are, *C. carpatica*, bright blue, 9 in. high, one of the showiest; of this there is a beautiful pure white variety. *C. glomerata*, deep purple or violet, 2 ft. high, and *C. glomerata alba*, pure white; *C. grandiflora*, deep blue, and *C. grandiflora alba*, white, both handsome autumn-flowering plants that grow about 1½ ft. high, and that have flowers from 2 in. to 3 in. across. *C. Van Houttei* has dark blue flowers, upwards of 2 in. in length, on stems about 2 ft. in height. *C. persicifolia* is blue, and very handsome, and *C. persicifolia alba*, white; of these there are also double varieties; height from 2 ft. to 3 ft. *C. rotundifolia* (the Scottish Bluebell) is 1 ft. in height. *C. turbinata* is a beautiful dwarf, rigidly-tufted plant, which produces large, openly-bell-shaped flowers of a dark purple colour; *C. turbinata hybrida*, a beautiful variety of the last-named, is more vigorous in growth, and flowers more profusely.

Of Antirrhinums, there are many named varieties; but, without resorting to cuttings, their distinguishing characteristics cannot be maintained. As thousands of seedlings spring up every season from self-sown seed, I pick a number of them up, and plant them out in a nursery bed, and, as soon as they show for flower, I select those that are not desirable, and throw them away. When thus grown, the flowers will be various, and while some are bad, it is equally certain that many will be good.

As regards Wallflowers, their cheerful appearance and delightful odour make them favourites with every one. They have been cherished plants for centuries, and will, no doubt, ever remain favourites with all lovers of sweet-scented flowers. As they sow themselves, and spread in all directions, they may be propagated in the same manner as Antirrhinums, and every spare corner may be planted with them at comparatively no expense.

Of *Anemone japonica* (a fine stately plant 2 ft. or 3 ft. in height, with rose-coloured flowers) and its white variety, or *A. Honorine Jobert*, too much can hardly be said. The latter resembles *A. japonica* in habit, but has large, pure white flowers, which are produced in great abundance until quite late in the autumn. Both kinds are easily propagated by division of the roots, and both should be cultivated in quantity where large supplies of cut flowers are required late in autumn or early in winter.

Ranunculus aconitifolius fl.-pl. (Fair Maids of France or Bachelor's Buttons), is an old and well-known border plant, and one which enjoys a liberal share of the patronage of amateurs throughout the country, but it is not often seen in gardens of large extent. It grows about 18 in. high, and bears a profusion of beautiful pure white double flowers. *Ranunculus acris* fl.-pl. (Yellow Butcher's Buttons) grows about 18 in. high, and bears numerous panicles of bright yellow flowers, which are very double. It is a free and continuous-blooming plant. Both these *Ranunculuses* are worthy of a place among the most select mixed border plants. They may be propagated by division of the roots in autumn, winter, or spring.

The European Globe-flower (*Trollius europæus*) is a handsome border plant, which grows about 2 ft. high, and bears large, lemon-coloured, very globular flowers. It is propagated by division, and is a plant which likes good, rich, loamy soil.

Common Double White Rocket (*Hesperis matronalis alba-plena*) is one of the most beautiful of herbaceous plants. It has white flowers, similar to those of a fine double Stock, and very fragrant; and they are borne on large, branching spikes, in great profusion. If allowed to remain permanently in the ground without transplanting they will certainly die, but by

transplanting and parting the roots, say every second year, they will last long without any renovation from cuttings. The soil in which they attain their greatest luxuriance and beauty is a rich, deep loam, well drained.

Lychnis chalcedonica fl.-pl., a vigorous-growing plant, attains a height of about 3 ft., the flowers being brilliant scarlet, and borne in dense crowded heads. *L. Haageana* grows about 1 ft. in height, and is remarkable for its striking flowers, which are nearly 2 in. across, and of almost every shade of colour, from a brilliant scarlet to a pure white. Of the Chalcedonian *Lychnis* there are six distinct varieties. *L. Bungeana* is a very handsome brilliant scarlet kind, which grows from 1½ ft. to 2 ft. high; and *L. fulgens* grows about 1½ ft. or 2 ft. high, and has large, brilliant scarlet flowers two or three together, which appear throughout the summer. These *Lychnises* will grow in any good garden soil, well drained but moist, but are all the better for being removed into fresh positions every two years.

Morina longifolia is one of the most beautiful of border plants, and one which is highly ornamental both as regards foliage and flower. The foliage is about 1 ft. in length, bright green, slightly undulated and spiny; the flowers, which are arranged in whorls set closely together in the axils of the upper leaves, are white in the bud, and when expanded are of a pretty rose colour. It flourishes best in light rich loam, of considerable depth, being a tap-rooting plant. It may be increased by division in spring; but, if doing well, it should not be often disturbed.

L. E. X.

Are *Geranium cinereum* and *G. argenteum* Identical?

—When in the Pyrenees, this autumn, I found the *G. cinereum* of Lavanilles growing in fair abundance in the moraine deposited by the glacier torrent in the Cirque de Gavarnia. The plants seem to me as if in constant struggles with the elements of this wild and desolate tract. The stem was very short, and tufted; the root thick, woody, and fusiform, plunged itself deeply into the silt and stones; the petals were as large as those of our *G. sanguineum*, pale and ashen, with deeper prominent veins. *G. argenteum* is like it in so many particulars that one feels inclined to view it as a variety influenced by climate and local circumstances. The colour of the flowers may have led to the divergence in the matter of specific identity—but this is a hazardous test. Dr. Persoon describes it, I believe, under the name *varium*. Reichenbach omits it altogether. Woods queries *cinereum* under the name *argenteum*.—PETER INCH-BALD, Hovingham Lodge, York.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Delphinium nudicaule.—This has been blooming very beautifully with us for these last few weeks. The young plants were wintered in a cold pit in the seed-pan, and planted out in May in light rich soil.—J. WHITTAKER.

Maurandya Barclayana in Ireland.—This lived out-of-doors with coal-ashes over the root through last winter, on a trellis against the house; it is now about 10 ft. high.—C. M. O.

Packing Plants in Damp Material.—I have received a great many different packages of plants from distant parts of the country lately. Some of them were on the road for eight or nine days. Both rooted plants and cuttings always come in very much better condition in dry packing than in moist. The latter soon ferments and causes the plants to rot, and it should never be used where it has to be in contact with the plants for more than twelve hours.—CAMBRIAN.

Winter Crocuses.—Now, when Colchicums are over, the smaller flowers of the Crocus are among the most attractive of outdoor blossoms. These, if mild, dry weather prevails, will continue in perfection till Christmas. Even near London these autumn Crocuses in many places are in great beauty, especially where growing on light, well-drained soil. *C. serotinus*, *C. sativus*, and *C. byzantinus* are among the most showy and distinct; and, if well planted, they will bloom for months in succession. They are seen to the best advantage on Grass, on the edges of shrubberies, and similar places. The Grass prevents them from being spoiled by soil-splashings during heavy rains.—S.

The Collection of Show Tulips, formed by that veteran cultivator, Mr. Charles Williams, of Holloway, will be offered for sale, at the Mart, Tokenhouse Yard, on Monday, the 28th inst. In addition to all the best named varieties at present in cultivation, the collection includes a large number of breeders, from which some beautiful flowers have broken, and the sale in consequence will possess something more than the usual degree of interest. The cabinets, which are sufficient for the storage of the entire stock, will also be sold at the same time.

CANON KINGSLEY'S GARDEN AT EVERSLEY.

WHEN Canon Kingsley was made Rector of Eversley, in 1844, he found the garden at the Rectory in as unsatisfactory a state as the rest of his parish; but it had capabilities, and these capabilities he used to the utmost. On the sloping lawn between the house and the road stood, and still stands, a noble group of three Scotch Firs, planted at the same time that James I., who was just building the grand old house at Brainhill, hard by, as a hunting-box for Prince Henry, planted the Scotch Firs in Brainhill Park, and the isolated clumps on Hartford Bridge Flats, and Elvetham Mount, which have covered hundreds of acres with their self-sown descendants. Next to the Firs stood a Birch and Arbor-vitæ, growing so close that their stems almost touched—a lovely pair; but in the Royal Charter gale they fell together, and though the gap they left at first caused great grief to the inhabitants of the Rectory, it was found afterwards to let in

tana, Wistaria, Gloire de Dijon and Ayrshire Roses and variegated Ivy, hid the rest of the wall with a veil of verdure and sweetness. In front of the study window, on the lawn, grows an immense plant of Japanese Honeysuckle, trained over an iron umbrella. This was given to the Rector by Mr. Standish—a small plant with only six leaves, in a pot—a year or more before he distributed it to the public, and carefully the little treasure was nursed and well it thrrove, being covered every summer with sweet flowers, and with bright purple berries for autumn decoration. Next to this, the pride of the study garden lay in its double yellow Brier Roses. These grew very freely, and in June the wall of the house and garden was ablaze with the vivid golden blooms, and the rooms were always decorated for two or three weeks with dishes of the yellow Roses, mixed with darkest purple Pansies on a ground of green Ferns. The Rector was never able to afford himself a greenhouse, so only a

Canon Kingsley's Garden at Eversley.

more light and air to the front of the house. A fine *Acacia*, and twin *Arbor-vitæ*, 30ft. high, completed the trees on the lawn. Most of the garden consisted then of a line of ponds from the glebe fields, past the house, down to the large pond behind the garden and churchyard. The Rector at once became his own engineer and landscape gardener. The ponds were drained, with the exception of three in the field, which were in course of time stocked with trout; Plane trees, which threatened in every high gale to fall on the south end of the house, were cut down, and masses of shrubs were planted to keep out the cold draughts of air, which even on summer evenings still stream down from the large bogs a quarter of a mile off, on the edge of Hartford Bridge Flats. What had been a wretched chicken yard, in front of the brick-floored room the Rector used as his study, was laid down in Grass, with a wide border on each side, and the wall between the house and stable was soon a mass of creeping Roses, scarlet Honeysuckles, and Virginian Creeper. Against the south side of the house a *Magnolia* (*M. grandiflora*) was trained, filling the air and all the rooms with its fragrance. *Lonicera flexuosa*, and *Clematis mon-*

few plants were kept for bedding in a little pit; and, owing to the poor soil and the late and early frosts, which were peculiarly destructive, from the low, damp situation of the rectory, none but the hardiest and most common plants could be grown out-of-doors: but the borders were always gay with such plants as *Phloxes*, *Delphiniums*, *Alyssum*, *Saxifrages*, *Pinks*, *Pansies*, and, above all, *Roses* and *Carnations*, which grew, without the least trouble, in the greatest profusion. One bay in front of the house was well covered with *Pyracantha*, in which a pair of white throats built undisturbed for many years; the further bay was, up to 1860-61, covered by a single plant of *Jaune Desprez Rose*, but the severe winter of that year killed it, and its place was taken by hardier climbers; over the glass porch at the front door *Clematis Jackmani*, white cluster *Roses*, and *Pyrus japonica* were woven in inextricable confusion. *Rhododendrons* grow in the greatest profusion, and the neighbours always came to see the Rector's garden when two beds, on either side of the front gate, were in blossom. An ancient Yew tree, and a slight hedge of *Laburnum*, *Hollies*, *Lilac*, and *Syringa*, divide the

rectory garden from the churchyard, and here, again, the rector turned his mind to making the best of what he had. The church, a plain red brick structure, was gradually covered with Roses, Ivy, Cotoneaster, Pyracantha, &c.; and, in order that his parishioners should look on beautiful objects when they assembled in the churchyard for their Sunday gossip before service, the older part of the churchyard was planted with choice trees, flowering shrubs, Junipers, Cypress, Berberis, and Acer Negundo, and the Grass dotted with Crocuses where it was not carpeted with wild white Violets. Of one curious fact it would be interesting to have some explanation. The wild Violets in the churchyard, which were all white, and those in a hedge adjoining the garden, which were all blue, grew and spread freely, always keeping true to their colour; every Violet (except the Russian) which was planted in the rectory garden, not half-a-dozen yards from either of these spots, was certain, in the course of two or three years, to turn a muddy reddish colour. They grew luxuriantly and kept their sweetness, but their colour was sure to change. The flora of Eversley is extremely interesting; the bogs and moors produce many rare and curious plants, and every hedge, wood, and meadow is covered in spring with all the common wild flowers in the greatest profusion, with the exception of Cowslips, which grow nowhere in the parish. *Drosera rotundifolia*, *Narthecium ossifragum*, *Habenaria alba*, *Lycopodium Selago*, *L. clavatum*, *L. selaginoides*, *Ophioglossum vulgatum*, *Botrychium Lunaria* are not at all uncommon in this district; and last, but not least, the beautiful *Gentiana Pneumonanthe*, which, owing to enclosures of common land, is becoming scarcer every year, and was guarded with jealous watchfulness by the Rector. R. K.

Winter Treatment of Auriculas in Pots.—Auriculas are now subsiding into their winter rest. Owing to mild weather, enlivened with frequent gleams of bright sunshine, they have kept active much longer than usual, and many have pushed up autumn trusses. It is well not to allow these to remain, as, if they expand, they will prove unsatisfactory, and it is best to pinch out the buds, leaving the stalks to decay at leisure. But little water is necessary, especially so, as sharp frost may set in at any time. It is a good plan to stir the surface soil and add a little top-dressing where required; the plants derive much benefit from this when they commence to grow. Small slugs are apt to secrete themselves in the drainage holes at the bottom of the pot, which should be examined occasionally, for during mild nights in winter, the slugs sometimes venture out and do much mischief. As the humid character of the atmosphere will give sufficient trouble in the way of damp, no rain or drip from the lights must be allowed to fall on the plants, and the lights ought to be raised, back and front if possible, during favourable weather, as there will be a certain exhalation of damp from the soil, which requires to be carried off. During severe frosty weather, especially what is known as black frost, when attended with brisk, drying, easterly or northerly winds, the frames should be kept close; but in mild, foggy, weather they may be opened. When the soil becomes very dry, advantage should be taken of open weather to give a little water.—D.

Philesia buxifolia.—I saw a fine plant of this in bloom last September at Glasnevin, near Dublin. The flowers are like small *Lapageria* blooms, rich red, and exquisite in shape and colour. It is a shrubby plant, with Box-like leaves. The *Philesia* comes from Valdivia, in Chili, from the same country whence our *Lapagerias* were brought some thirty years ago. The climate of Valdivia is somewhat similar to that of the Island of Chiloe, the native habitat of *Escallonia macrantha*—perpetual rain, but little frost or snow. Wherever, therefore, the *Escallonia* is hardy, probably the *Philesia* would prove hardy too. At Glasnevin it has stood 14° of frost. It is from this lower region of the Andes that we may expect many new and beautiful hardy plants. The *Philesia* requires a bog soil: moist peat and sand suit it admirably. There is a plant of it in the winter house at Kew, which might be advantageously studied by London cultivators. For any moist climate, where *Fuchsias* do well, I am sure this plant will be a glorious acquisition.—FRANK MILES, *Bingham, Notts.*

Manure to be Efficient, must be as close to the surface as possible, in order that the nourishment afforded by it may be within easy access of the rootlets of the plants. If dug in too deeply, several years may elapse before it is decomposed.

SCENT-YIELDING PLANTS.

By G. W. SEPTIMUS PIESSE, Ph.D., F.C.S.

Geranium, Citronella, Patchouly, Verbena Grass.

GERANIUM.—Several varieties of the Natural Order Geraniaceæ bear scent-yielding leaves, but although these plants were introduced into Europe from the Cape of Good Hope so far back as 1690, it was not until 1847 that the *Pelargonium capitatum* began to be systematically grown for the purpose of extracting its scent-yielding principle, known in commerce as the Otto of Rose-leaf Geranium. This was first done by M. Demarson, of Paris, and since that time its cultivation has vastly increased in France, particularly at Montfort-Lamaury, in the Department of Seine-et-Oise, and it has even more rapidly spread in Algeria, Mr. Monk, an Englishman, and M. Chris pushing its production extensively. The same kind of culture is also carried on in Spain, by Senor Robillard, of Valencia. The propagation of the Pelargonium by means of

Scent-yielding Geranium (*P. capitatum*).

slips is too well known to need description. One ton weight of leaves will yield by distillation an average of two pounds weight of Otto, the lowest wholesale price of which is, say £6. Senor Robillard has about fifty acres of Rose Geranium under tillage, more or less, according to the demand. He strikes the cuttings from September to October, and puts them out in April; the plants have to be replaced every three or four years at longest, the land being well manured annually. About 3000 plants are required per acre.

THE STILL.—As so many odours are obtained by means of distillation, the still becomes an important instrument to the cultivator of plants for their scent. The saleable products of the year can, by its aid, be quickly put upon the market; on the other hand, he can dry and stack the products, and distil them at his leisure when labour is not elsewhere required. The accompanying illustration shows its general construction pretty clearly:—*A* is the alembic or boiler; *B* is the still-head; *C* is the junction of the steam tunnel with the worm pipe in the tub *D*; *E* is the Otto separator. Assuming that Patchouly is to be stilled, the still-head wants to be taken off at the joint shown by the ring on the top of the alembic; the boiler would then be filled with as much herb as it would hold, together with as much water as would about half-fill the interstitial space; the still-head would then be replaced and joined to the worm; the tub *D* is kept full of cold water. Fire would then be applied; and, when the water boils in the alembic, the steam

collects in the head and travels down the tunnel into the worm pipe, carrying with it the Otto of the plant; here, the worm being surrounded with cold water, condenses the vapour into a liquid form, from whence it trickles into *E*. Water, being heavier than the Otto, falls to the bottom, and finds an exit from the separator, as seen in the cut; the Otto accumulates in the separator, and is decanted when necessary. If the worm-tub be too small in proportion to the still, the water in it quickly becomes hot, and so ceases to condense the vapour;

A. The Alembic; B. The Still-head; C. Junction of Worm-pipe in the Tub D; E. Otto Separator.

in such a case cold water has to be supplied by the funnels, the tube of which reaches nearly to the bottom of the tub; the hot water, being lighter than cold, flows away by the tap, as seen at the top side of *D*.

PATCHOULY.—This is one of the most unique of scent-yielding plants. It is a Labiate, stated by some authors to be a native of Silhet, a district of Bengal, some 120 miles from Decca; it is now, however, known to grow in Java and Ceylon, and also

Pogostemon Patchouli.

on the Malay coast, and one must say in China, because its odour is very clearly defined in the Black-stick Ink, commonly called Indian Ink, that comes from that country. Deccan Indian shawls were known in Europe as really of Indian manufacture by their peculiar odour, which was due to their being packed for exportation along with Patchouly, a favourite scent-plant of the district. About the year 1850, Patchouly began to be imported into this country in bales of 2 cwt. each, and some few adventurous dealers distilled it, and obtained

small portions of Otto, but at a great cost; the herb being badly harvested, and stacked too damp, become mouldy in transit. Europe, however, now obtains Otto of Patchouly from the fresh herb. A bale of good dry Patchouly will yield about 3 lb. of Otto, worth about £14. The consumption of Patchouly in the perfumery trade of Europe is something beyond belief.

VERVAIN.—An exquisite scent is derived from the *Aloysia citriodora*, or Lemon-scented Verbena. This plant, as a scent-yielder, is only cultivated, so far as I am aware, by Senor Robillard, of Valentia. He offers the Otto for sale to the trade at 20s. the pound weight, a fact which indicates that the plant grows better in Spain than in England, where it will only live out of doors on walls; but we have no specific information to give as to its cultivation.

LEMON GRASS (*Andropogon citratus*) is cultivated for the scent which it yields, to a large extent in Singapore and Ceylon, also in the Maluccas; it affords its otto freely by distillation. Lemon Grass Otto, or, as it is sometimes termed,

Verbena Grass
(*Andropogon citratus*).

Citronella
(*Andropogon Nardus*).

“Verbena,” on account of its similarity of odour to that of the *Aloysia citriodora*, is cultivated by Mr. Winter, of Ceylon, who produces annually about 1000 lbs. weight of it. Mr. John Fisher, of Singapore, distills even more.

CITRONELLA GRASS (*Andropogon Nardus*) is cultivated both by Mr. Fisher and by Mr. Winter, its Otto being obtained by means of distillation. The importance of the trade in this one article in Ceylon alone may be estimated at £15,000 annually. At Gaylang, Singapore, there are about 1000 acres under Citronella, Lemon Grass, and Patchouly. Geranium Grass Otto is obtained from the *Andropogon Schœnanthus*. This Grass, sometimes called Ginger Grass, is a wild plant of Central and Northern India; its otto is produced by distillation, but it has not much reputation out of India.

PLATE CI.

HARDY PRIMROSES.

(WITH FIGURES OF IMPROVED VARIETIES.)

Drawn by Mrs. DUFFIELD.

THE accompanying illustration depicts, much more forcibly than words can express, the extreme beauty to be found in some of the more recently-raised garden varieties of the hardy Primrose. All who have had the opportunity of seeing the lovely forms of Primroses exhibited at South Kensington early in spring, will admit that, in regard to this particular flower, varieties have been raised of late years of singular richness of colour and excellence of form, while the same robustness of constitution and free habit of growth that characterise the common variety of our hedgerows has been preserved. It may be long before our woods and hedgerows are decorated and beautified with such gems as these, but it is at least possible that in wild gardens, and semi-cultivated spots that lie just outside the garden proper, we may yet see seedling forms of these Primroses in their varied hues of crimson, red, purple, violet, mauve, white, yellow, and other tints, thus bringing into the midst of the wild flowers of spring colours to which we have hitherto been strangers, thereby enhancing the beauties of Nature by the addition of such charms. It would prove an impossible task to endeavour to trace out from the first the origin of high-coloured Primroses; for, although rarely found in woods in a state of Nature, yet we have long been familiar with red, pink, and lilac tints amongst the semi-wild forms often found growing in shrubby borders or by the sides of woodland walks, and in places where the Primrose had been brought into contact with the pollen of some of the old garden Oxlips or varieties of the Polyanthus. None, however, have their history or origin so little known as the fine old double forms, of which there are probably a dozen kinds perfectly distinct in colour, and yet showing indications, both by leafage and habit, that they have resulted in sports from others. It is a curious fact that the deeper the hue in the double kinds the less robust the plant, and both the rich crimsons and deep purples are most difficult to cultivate in ordinary summers; but, in the extreme north, where the climate is at once temperate and moist, they grow almost with luxuriance. The climate of Ireland also favours them considerably, but in the south and midland districts it is found necessary to afford them shade and abundant moisture during summer, and the protection of glass generally from the effects of continued frosts and rains in the winter. The white, lilac, and sulphur kinds are, on the other hand, very hardy, and appear to stand our summers and winters, if established, with impunity. The double crimson, of which there are two diverse shades, bears

strong evidence of close relationship to that most charming single variety, *Auriculæflora*. In colour, in habit, and in leafage the likeness is most marked, and if, as is sometimes assumed, these doubles originated from seed through the agency of some of the old florists of the eighteenth century, it is not unlikely that the single *Auriculæflora* sported from the crimson double, just as we have seen a very beautiful single lilac form that had sported from the double of that colour. It is worthy of note that the production of double flowers of the *Primula* family seems to run in cycles; and perchance we may yet see other new double forms developed out of the beautiful single kinds now so largely being produced. The Chinese Primrose is an illustration of this, as many of the finest kinds that have been put into commerce originated some years since at certain establishments near to Southampton, where the seed-strains for several years invariably produced a good percentage of double flowers from seed saved from single ones; at length, however, in spite of all possible care, that curious quality died out, and now not a single double

flower is produced. That the quality is not entirely lost is, however, evident, as we now and then see, as in the case of Mr. Gilbert's Primroses, some recently-raised doubles of great excellence, thus showing that there is a sort of eccentricity about their production which admits of but a doubtful explanation. I find the purple and salmon double hardy Primroses to be closely allied in character; so also are the white, lilac, and blush; and, again, the sulphur and the early purple, so that it is just possible that if there be any of them originated from seed in remote days, they may have extended their kind, probably one-half or more, by means of sports. Whether

Weeping and erect-growing trees on the margin of a small lake. Drawn by A. de Bar, March, 1877.

sport or species, or garden variety, however, the beautiful *Auriculæflora* has proved to be a most valuable pollen parent, as regards the production of a lovely progeny. Equally valuable is that charming kind which has so long been known in commerce as *Primula altaica*, but which Mr. Niven has told us, is but *Primula vulgaris grandiflora*. Whatever may be its correct designation, it has, because of its lovely hue and colour, robust habit, and large pin-eyed flowers, proved a specially fine seed parent; and this, fertilized with the pollen of *P. auriculæflora*, a thrum-eyed kind, and therefore specially suited to make a pollen parent, has produced some of the most beautiful of the newer coloured Primroses. *Primula auriculæflora* is in itself one of the most perfect of flowers, and its intensely rich crimson hue, clear yellow centre, and thrum-eye are points that can hardly be excelled. That it is so perfect, however, affords no reason why these excellent points should not be turned to good account, and the examples illustrated show to what good purposes they have been put. Rosy Morn, deep rosy red; Gem of Roses, rosy pink; Queen of Violets, deep purplish violet; Crimson Banner, deep maroon-

VARIETIES OF THE COMMON PRIMROSE. (PRIMULA VULGARIS)

crimson; *Viola*, pale purple; *Fairy Queen*, pure white with good eye, and *Sulphurata*, large sulphur colour. These are some of the earliest progeny of the cross we have mentioned, and very beautiful varieties they are. Of more advanced form and greater substance of petal are *Virginia*, a very pure white of excellent form; *Brilliant*, a very fine variety, in colour rich vermilion-red and of the finest form and substance. *King of Crimsons*, rich massive crimson; *Violetta*, a very beautiful violet-purple; and *Lustrous*, very deep coloured crimson, with small perfect lemon eye. These are some of more recent production that indicate beauty and excellence, almost amounting to perfection. The propagation of these kinds, as well as of all the perennial *Primroses*, is necessarily slow, except where they can be reproduced true from seed. A seedling plant may produce two others the first year after blooming; these may again produce six or eight the next year, and thus it will take several years to work up 100 plants, a fact which shows that some patience must be exercised ere the newest forms can be circulated largely. Amongst growers of hardy flowers the production of forms from seed, even from the best kinds, is not so satisfactory as might be desired. No doubt flowers specially fertilised will generally produce some good results, but, such seems to be the inevitable tendency of the *Primrose* to return to its pristine form, that it is by no means uncommon to find even the very best flowers producing a large proportion of comparatively inferior kinds. Of course these are of varied and rich hues; but, perchance, lacking the other qualities that go to make up a first-class flower. Then there is also a possibility that the seed crop may be at times almost *nil*; this year, for instance, owing to the many spring frosts that occurred, and from other causes, not one-twentieth part of the flowers have produced seed; indeed, as a crop, it is a very short one. It is well that this should be known, because it illustrates how difficult it is to secure an abundance of productive material from select varieties of these things, and thus to bring them within the reach of all classes. Of all the *Primula* family none can excel these early *Primroses* in loveliness and freshness; and, with the exception of the tender Chinese *Primrose*, they are the earliest of all to flower.

The specimens from which our plate was prepared were furnished by Mr. Dean, of Bedford.

A Few of the Best Chrysanthemums.—In a large display of *Chrysanthemums*, arranged in the *Camellia-house* in Messrs. Veitch's nursery, a good opportunity is afforded for selecting the best and most effective flowers in the various sections. The Japanese kinds are generally admitted to be the most graceful, and among them are now many kinds possessing colours previously unknown in *Chrysanthemums*. The kind named *The Cossack* bears narrow-petalled flowers of a brilliant flame colour; these contrast effectively with the snow-white, cushion-like blossoms of *Elaine*, the deep claret-coloured *Gloire de Toulouse*, and the bright purple, light, and graceful flowers of *Purple King*. Perhaps, however, one of the most elegant of all is *Gold Thread*, the petals of which are, as the name denotes, slender and thread-like, and of a bright golden-orange colour. Among incurved or show varieties, the bronze and yellow varieties of *Jardin des Plantes* still hold a foremost place; *Prince Alfred* is the best purple-crimson kind, and the white and golden *Queen of England* are both bold and effective flowers in their respective colours. *Alfred Salter*, an old but excellent kind, with delicate pink-tinted petals, is much thought of; as is also one similar to it in colour named *Pink of Perfection*. *Empress of India* is an excellent large white, and *Guernsey Nugget* is still the best sulphur-coloured kind. Among *Pompoees* the most striking sorts are perhaps the dark magenta-coloured *Progne*, the most sweetly-scented of all *Chrysanthemums*, and one which should be largely grown for furnishing cut flowers, being devoid of that unpleasant smell to be found in many kinds of *Chrysanthemums*.—S.

Aucubas for Market.—Small, compact plants of the various forms of *Aucuba*, when well furnished with berries, are much valued in London during winter for window decoration. The way in which they are chiefly obtained is by fertilising old-established plants with male pollen, and then layering in light sandy soil, good-sized branches with bushy heads being selected for the purpose, and pegged down. In a short time they strike root, when they are severed from the old plant, and in autumn are lifted, potted, and placed indoors to colour their berries. Standard plants are obtained by grafting on the common *Aucuba*.—S.

THE GOLDEN LARCH OF CHINA.

(PSEUDO-LARIX KÄMPFERI).

THE Larch, represented by the accompanying characteristic, catkin-bearing twig, is generally believed to have been discovered by Kämpfer; but it was certainly re-discovered by Fortune, on the mountains of the Province of Che-Kiang, in North-eastern China, at an elevation of 3900 ft. above the sea, and was introduced by him into British gardens in 1852. As yet, however, it is only represented here and there by a few plants. This scarcity is principally owing to the difficulty experienced in procuring seeds, and the fact of it being difficult to propagate by other means. The best plants of it with which I am acquainted—one being 20 ft. high—are growing vigorously in light sandy loam, making from 1½ ft. to 2 ft. of growth annually; but not one of them has a continuous or uninterrupted stem, in consequence of the immature points of the shoots being injured by the untimely frosts of early autumn. Independent, however, of such checks, the annual increase of the trees in height is considerable, though we need never expect this Larch

The Golden Larch of China (*Pseudo-larix Kämpferi*).

to attain in England 120 ft. the height which Mr. Fortune found it to reach in China. Nevertheless, it is well worthy of a place in the *Pinetum* or pleasure-ground, on account of its beautiful pea-green colour in spring, its rich dark green in summer, and, as the English name implies, its golden-yellow foliage in autumn. While seeds of it cannot be procured, the best means of increasing it is by cleft grafting it on short, stout pieces of its own roots about the end of January or beginning of February. The after success will greatly depend on the amount of moisture kept in the propagating case, which must be regulated so as never to accumulate on the scion.

GEO. SYME.

Slow Growth and Durability of a Coniferous Tree.—A remarkable instance of this is recorded in the "Transactions of the New Zealand Institute," by Mr. John Buchanan. The tree in question is *Podocarpus epicata*, the *Matai* of the Maoris, a common forest tree almost throughout the island of New Zealand. Mr. Buchanan describes a prostrate trunk, which was pointed out to him in a valley near Dunedin. He calculates that the tree must have lain where he saw it at least 300 years, from the fact that its trunk was enfolded by the roots of three large trees, which must have grown from seed since its fall. The three trees seated upon it and rooting in the earth on both sides, thus holding it in their embrace, are all *Grielinia littoralis*, with trunks 3 ft. 6 in. in diameter. They were recently felled, and the growth rings count over 300, thus approximating 300 years.

THE FRUIT GARDEN.

GROWING GRAPES ON BACK WALLS IN LEAN-TO HOUSES.

ALLOW me to furnish a few remarks about growing Grapes on back walls, a plan which has answered satisfactorily at Castlehill. I do not mean to assert that Vines have not been grown on back walls to stand for a time until the permanent ones covered the entire roof. When this is the case the supernumeraries are invariably removed; for, if both be left, those on the back wall only exist in a state of debility. It is a well-known fact to all practical gardeners that, after the roofs of Vineries are covered with foliage, the interior of the house below the trellis becomes useless for any other purpose from want of light and sun; this also may be said of back walls. Deliberating one day how to make the most of space, a thought occurred to me that by leaving a portion of the roof free from leaves, the back wall might be also utilised as well as the greater portion of the front roof. The next thing to be considered was the best means of getting the most light and sun without decreasing too much the front roof space. After mature consideration I found that the best means to obtain the largest space for training Vines was to cover one-third of the lower part of the front roof all over, then from this point to leave a space of about 2 ft. free from leaves between each Vine to the top of the house, so that the small sacrifice of space made in the front roof trellis would give ample light and sun to the back wall, which would thus also become available; this would more than compensate for the slight decrease of front roof space by a clear gain of one-fourth more total trellis space. This is not the only advantage, for the whole of the house below the Vines becomes available for growing any sort of fruit trees in pots, or any of the numerous varieties of Palms, or any other kinds of fine-foliaged plants; any of these, judiciously disposed, tend much to enhance the appearance of a range of Vineries, provided a clean selection of plants be made so as not to contaminate the Vines. To grow Vines on this system, the front Vines must be planted wider apart than usual, say two instead of three; this would be about one Vine to every one and a half rafter. The two end Vines should be planted at the two extreme ends, in the usual way; care must be taken to have the back wall trellis at a distance of 15 in. from the wall, in order to prevent the bunches from rubbing and to give room for development. The unsightly back walls are hidden with green leaves and fruit, which, together with the plants above mentioned, greatly improve the appearance of the Vinery. Some may be inclined to think this mode of growing Vines may not answer, as the bunches are more exposed to the direct rays of the sun, and that consequently scalding might ensue, especially at the stoneing season, with Muscats and Lady Downe's Seedling. But this is easily obviated by leaving plenty of foliage over the bunches to shade them during that critical period. I have taken ample time to test this mode before publishing these facts; and I may say that I have not only got greater weight than before from the same house, but that the quality is as good. I will give a proof of this by stating that I this year exhibited bunches grown on this system in my collection of twelve varieties of fruit, two sorts of Grapes, black and white, and I was awarded the first prize, a silver cup. The show was held in Taunton, on August 16th, open to all growers, and that show is generally admitted to be one of the best in the west of England. I have been asked by many noblemen visiting here, who are interested in Grape growing, and highly pleased with the results in the fruit, and the improved appearance of the houses, to give publicity to this plan in one of the leading garden periodicals. This I have now done; and I think any of your readers who determine to try this mode will be satisfied with the results in both respects.—D. WILSON, *Gardener to the Right Hon. Earl Fortescue.*

— I write, at the request of my gardener, Mr. Wilson, to corroborate the account which he has given you of his plan of Grape-growing. He tried it for the first time, with my full approval, three years ago here, and has continued it with the excellent results which he has faithfully described. From the explanations which he gave me of it, I expected it to succeed,

but the results have exceeded my most sanguine hopes, both as regards the quantity and quality of the Grapes, and the number of other plants kept in perfect health in my Vineries. *Castlehill, North Devon.* FORTESCUE.

FIELD CULTURE OF HARDY FRUIT TREES.

(Continued from p. 476.)

Keeping up an Orchard.

WHEN we have planted and reared a tree as a careful grower should do, and when the growth, both of the stem and the crown, has received the requisite amount of attention, a great step in advance has been made. But a large amount of work still remains behind, which is required by all trees, whether they are healthy or sickly. On the one hand, they must be protected against outward accidents, and vicissitudes which frequently endanger the success of an orchard; and on the other, we must fight against insects and other dangers by which the trees may be attacked. These little matters are generally only too much neglected, just for the very reason that growers look on them as being so insignificant as not to merit notice. But in fruit culture there are no little evils. First of all, we must give the tree the support which is necessary for it; first, in order to give the stem the proper direction if it be inclined to grow crooked; secondly, to prevent the young branches of the crown from being damaged by the wind; and, lastly to protect it against the effects of accidents from men or cattle. In the first case a strong stake is planted at the same time as the tree at a few inches from the stem. The young tree is attached to the stake by means of a withy, taking care to place a quantity of Moss or Hay between the withy and the tender young stems, so that the bark may not be injured by the swaying of the tree backward and forward. If the tree be inclined to grow crooked, it requires to be attached to the stake by several of these ligatures. When there is a difficulty in straightening a crooked tree, a number of longitudinal incisions should be made in the hollows of the curved portions, carrying them upwards and downwards a little beyond the curve. At the same time that the stake serves for straightening the tree or for preventing it growing crooked it is useful for training the crown. For this purpose it should be from 18 in. to 30 in. taller than the subject to which it is attached. Where young trees are sufficiently strong and straight to need no stake, a special stake is used for the crown (see p. 474). Growers are as a rule very neglectful in training their young subjects. Under the pretence that fruit trees are not grown for ornament but for use, and that a crooked tree will give as good fruit as a straight one, growers plant either crooked trees, or let those which are naturally straight twist themselves in any direction, without in the least caring about their future. A curved stem which departs from the perpendicular will infallibly bend lower and lower as years roll by. As a matter of fact, in a tree like that in fig. 42 the lower part (a) grows healthfully, while the upper, (b) is always sickly. This being the case the crown becomes top-heavy and bends the stem nearer the earth every year. All this is easily avoided by early training by means of stakes. When the evil has not gone too far, it may be remedied by the use of strong stanchions and struts, as shown in fig. 40 (p. 473). The straightening of bent or crooked trees is a matter of great importance, especially in the case of Apple trees; the great breadth of their crowns and of their roots rendering them liable to become uprooted. If the trees grow crooked on account of the prevalent winds, they may be straightened by means of a short stake driven in the ground obliquely, on the windward side of the tree, at a few feet distance from the root. To this a galvanised wire, provided with a raidisseur, may be attached, the other end being fastened to the upper part of the stem of the tree. By gradually tightening the raidisseur, the tree may be kept perfectly straight. It is a great mistake to suppose that the training stake, properly so-called, which has just been described, is sufficiently strong to protect the tree against the effects of the wind. It is not merely necessary to provide against trees being uprooted by the wind, but in the case of newly-planted young trees, we must guard them against even the slightest movement; otherwise, the young rootlets and

fibres, which play so important a part in nourishing the tree, are destroyed by the continual shaking. We must, therefore, distinguish between stakes which are used to train, and those which serve the purpose of props. A large number of expedients have been invented for supporting trees; one of the most effective and simple of which is shown at fig. 40. We plant round the stem, in an oblique direction, three or four short, strong stakes, at about 16 in. to 20 in. from the root of the tree; they are then tied firmly to the tree by means of osiers, cord, or wire, a piece of cloth being interposed to prevent chafing. They may be joined at their lower extremities by cross bars, which will add much to their firmness, and Thorns, Brambles, or Furze, may be thrust in between the tree and its supports to ward off the attacks of cattle or sheep upon the young bark. This kind of support has many advantages. The struts effectually prevent the trees from being shaken by the wind, no matter how strongly it may blow; the trees are never disturbed by the attacks of cattle, and the soil round the roots is protected from being trodden down, which is a great advantage. Besides this, we avoid the use of straight stakes for training the tree, which always, more or less, injure the roots, on account of its being necessary to insert them close to the tree itself. Besides this, a straight stake, except it be exceptionally strong, can never keep a tree perfectly immovable. Care should be taken to provide supports of this sort for all trees, whether they have training stakes or not. It is easy to keep cattle from rubbing themselves against the trees when they are planted in pastures, by surrounding the stems with lathes, into which several sharp nails have been driven.

Newly planted trees are also exposed to numberless other vicissitudes. The sun and wind dry and split the bark, and harden it so as to check the circulation of the sap. This evil may be at any rate diminished by anointing the tree at the time of planting with a kind of paste, composed of cow-manure, clay, and a little chalk. The whole should be bound with straw placed lengthways, and not twisted round the stem. If large numbers of gnawing animals, such as hares, rabbits, &c., are in the neighbourhood, twisted straw may be rolled round the first layer on the lower part of the stems, as high as is necessary to ward off their attacks. If the stem has already felt the effects of strong sunshine, two longitudinal incisions ought to be made in it before covering it up. The straw ought to be removed every three years, if it be found necessary to protect the stems beyond this time. Generally speaking, the straw may be stripped off during the September of the second year, and the stems well whitewashed. The roots also suffer from too much sun, as well as from too much cold, especially in dry and sandy situations. It is therefore necessary to cover them at least during the first year with a layer of straw, or, what is better still, long stable manure. This covering may be changed every year about the autumn. If stable manure be used, it will protect roots against frost, and if dug in as the spring comes on, it will favour the growth and fructification of the tree. If the trees are old, and the roots spread a long way, the manure should be buried in the place where it is supposed that the extremities of the roots are to be found. Liquid manures and perhaps spent rape cake may also be used in the same manner. These are the best manures to give to fruit trees of this kind. As soon as the leaves begin to appear they should receive the first watering, which should be renewed several times during the summer, whether they are young trees in full bearing or whether they are in a weakly condition. Attention must be paid to the way in which the trees are, whether with plain water or liquid manure. The liquid manure ought to be spread as far round the tree as possible, the amount being greater in proportion as the tree is older. A channel or hole cut near the stem for the reception of the liquid would only lead to mischievous results. Nature ought in this case to serve as an example, the crown of the tree acting as an umbrella, which keeps the soil dry for a certain distance round the trunk; in fact, it confines the rainfall to the exact place where the rootlets of the tree are waiting for the refreshing and fertilizing shower. In old orchards which are ramified in all directions by tree roots, a layer of farm-yard manure should be spread about in the autumn, and allowed to remain until the spring, when the remaining straw may be taken away, the soil having

absorbed all the soluble material. In the winter, the whole of the orchard may be well watered with liquid manure, and afterwards dressed with good soil from a meadow, or the compost described in the section on planting. It will seem strange to many growers that the roots require air for their nourishment, as well as water and manure. We must, therefore, in planting be careful to keep the roots as near the surface as possible, so that the air may take effect on them. We must also keep the earth well stirred from time to time, and in new orchards clear all weeds and Grass away for the first three years. By this means we also destroy great numbers of insect pests. These operations should be performed once or twice a year according to the consistency of the soil. It is hardly necessary to remark that these operations must be performed so as to avoid any injury to the roots themselves. Many growers neglect these matters, and it is for this reason that so many young trees die off or take two or three years to establish themselves. Young trees in nurseries receive all these attentions, but when once they are planted in the orchard they receive no more attention.

DISEASES.—By strictly observing the above directions, many diseases may be avoided; but, in spite of all possible care, the trees are always liable to accidents, on account of their living, so to speak, under artificial conditions. This is not so much the case with fruit trees, which are less frequently attacked by disease than others. It would be useless to detail all the futile remedies applied to sickly trees. One of the most common causes of disease is the bad state of the soil, which frequently induces a kind of jaundice. Trees attacked by this disorder, although they increase in size somewhat slowly, produce pale yellowish leaves. If the evil be not attacked at once, it becomes worse every year. The disease is the result of several causes—a damp, cold soil, for instance, in which the roots do not fulfil their proper functions, and absorb too much water, and become covered with a white mould. Good drainage and planting on mounds are the best preservatives against this fatal disease. The second cause results from the contrary state of things; that is to say, very high or sandy situations, which dry to a great depth during the summer, or which are too much drained by the lower ground. Another fruitful cause of the evil is found in heavy, clayey soils, into which the air cannot penetrate, may be also placed in the same category. The remedies to be adopted in all three cases are too evident to need description; they are drainage where the soil is damp, cold, and heavy, and the copious application of stable manure, straw, and frequent watering where it is too dry and porous. In the third case, the soil should be opened from time to time, and the surface kept clear of weeds and Grass, so as to favour the passage of the air to the roots. If the leaves do not speedily re-assume their natural tint, they may be watered with a solution of green copperas (sulphate of iron) of the strength of 1 oz. to a pailful of water. The solution must be made fresh and fresh, as it loses part of its properties by keeping.

CANKER.—This disease causes great ravages to pipped fruit trees, especially to Apples. In stone fruit trees this disease is known under the name of gumming, and does serious mischief if not checked. It is generally caused by the soil being too damp, and manifests itself first in the roots, and then in the branches, upon which scars and crusts make their appearance, and increase rapidly. The best remedies consist in ameliorating the condition of the soil by trenching, or any other method of drainage. Here again we must insist on the advantages of shallow and mound planting. The disease is often the result of wounds, too abundant pruning, or the injuries inflicted by insects. When the branches or stem of a tree are wounded, the dead wood should be cleared away, and the part well covered with either grafting wax, or some similar composition. Grafting wax would be too dear for large work. The following is an old English receipt for a cheaper composition:—Cow manure ten parts, plaster of Paris ten parts, firewood ashes ten parts, and sand one part. This composition hardens, completely resists damp, heat, and frost, and may be prepared by any one for a mere trifle. A tree may, however, be so deeply cankered or wounded as to render recovery almost hopeless, from the difficulty of closing the wound. In such cases it should

be cut slanting both upwards and downwards, thus— \wedge as the new wood will grow better when treated in this manner. \vee It is as well to cover up the composition with straw. If the trees be very valuable, wounds may be closed by inserting two large grafts between the bark and the stem, both above and below the wound, at $\frac{3}{4}$ in. apart. This method is recommended by M. Fooney, Professor of Arboriculture at the Jardin des Plantes, and although it has not yet been extensively tried, it seems to promise success. Trees which are completely hollow should be well cleaned out, the aperture filled up with rubbish, the whole being covered up with the composition described above. Some people use coal tar for stopping bleeding shoots and for covering wounds, but it is not to be recommended, especially for young trees. Large numbers of Poplars and other soft-wooded ornamental trees have been killed by its use; it should only be employed for hard-wooded forest trees. It may be used, in case of necessity, for Apples, Pears, Walnuts, and Chestnuts, but only on wounds which have resisted all other modes of treatment. Even as a last resource it is better to use ordinary oil paint, made very thick, which will often succeed when all else fails. Besides these diseases, trees are also attacked by other disorders, some of which originate in old age or premature decay, while others result from the numerous accidents to which trees in orchards are liable. We may instance failing vigour, which causes the leaves to fall before their proper time, as well as rotteness, which is due to the same cause. This disease consists in the drying up of the extremities of the branches. Cutting back to the healthy wood, manuring, or renewing the soil are the best remedies for this disease, provided it is not caused by natural decay.

INSECTS.—It would be impossible to describe the infinite number of insects which attack trees. The best means of prevention or cure are applied with difficulty when the orchard is on a large scale, and are often insufficient, and even useless. We will therefore only speak of those insects whose ravages are to be dreaded, and against which we may protect orchards more or less effectually. *Coccus* or *Chermes*.—These are as large as a grain of Wheat, but flatter, and the eggs are covered with a conical shell; they attach themselves for part of their life to the bark of Pear and Apple trees, suck the sap, and give rise to rottenness and canker. They should be destroyed when in their dormant state, for, if the eggs are allowed to hatch, the insects escape and form fresh broods. Before the sap begins to rise, the branches attacked, which are generally within arm's length, should be cleaned with a stiff brush, after which they should be well washed with a solution of soft soap and lime mixed with Tobacco water, a decoction of Alder or Walnut leaves, or gas liquor. Trees planted in close situations are the most subject to this plague; this insect is met with much more frequently in gardens than in orchards. *Woolly Aphis*.—This fly is the most destructive of all; it collects on the trees in woolly patches, having the appearance of white Moss. They principally attack the Apple tree, giving rise to nodosities which develop into canker. The best mode of destroying them is by cleaning the bark with a stiff brush dipped in a solution of potash, to which a few drops of petroleum have been added. When there is reason to believe that a new plantation has been attacked by these pests, the roots should be well soaked with a solution of potash mixed with lime water, as the new generation of these insects is always found in the roots. This destructive plague seems to increase year by year, and now-a-days few orchards are free from its depredations. Trees planted in an open situation, and in a good soil, are less liable to the attacks of this insect than others. *Caterpillars*.—The different species of caterpillars are simply endless. In spring the cocoons, which shelter the pupa, should be destroyed wherever seen. Several species cover themselves and the bnds of the tree with a web; they may be destroyed with coal tar under the precautions given above, or removed by means of the *supprime échelle*. Once the caterpillars are hatched, they must be caught and destroyed, either by syringing the trees or by beating them into a sheet spread upon the ground for the purpose, destroying them by crushing, or, better still, by burning them. *Maggots*.—The most destructive of all maggots is the white worm or grub of the cockchafer; these pests gnaw the root-bark of young trees, and commit fearful havoc on both fruit and forest trees. The

worms should be dug up wherever suspected, and the perfect insect should be destroyed during the summer. Beetle grubs are also very destructive to the wood and bark of fruit trees, hollowing them out secretly and doing great damage before they are discovered; even the strongest trees yield to their attacks. Removal of the bark as far as they have penetrated, and a plentiful application of milk of lime, are the best remedies. The magpie is the natural enemy of these worms, and should be encouraged. Mole crickets are also great plagues to the orchardist; happily, on this side of the channel, they are less frequent than on the Continent. The strongest allies which the orchardist possesses are to be found amongst the feathered creation, and will often rid him of a number of pests which he is otherwise powerless against. He should therefore do all he can to encourage such true friends as the linnet, the sparrow, the thrush, the starling, the goldfinch, and a number of other birds who feed greedily on insects. There are other members of the animal kingdom which do good service, and which should be protected and encouraged by the orchardist, such as lizards, frogs, toads, bats, hedgehogs, moles, spiders, gold beetles, dragon flies, &c. Ignorant persons are often in the habit of destroying certain useful animals, either through not knowing better, or through repugnance, or because they do some small amount of damage which is counterbalanced a thousandfold by the good they do. Some insect destroyers, such as the sparrow, become destructive when they breed in too great quantities; such doubtful friends should be thinned, but not entirely destroyed. The mole, for instance, is pursued by most cultivators with relentless cruelty, but it must be remembered that he helps the growth of trees by the tunnels which he burrows amongst their roots, as well as by destroying immense quantities of grubs, white worms, mole crickets, &c.; he can do but little harm and much good in the fruit garden and orchard. It is an erroneous notion that the mole gnaws the roots of fruit trees.

(To be continued).

Preserving Grapes in Bottles of Water.—I have often thought that if those who recommend this mode of keeping Grapes throughout the winter would not give such elaborate instructions about the "Grape-room," more of us would be induced to try the system. We have no finely fitted-up Grape-room here, although there is a suitable house and plenty of material at hand, and yet we keep Grapes, even tender-skinned ones, successfully in bottles of water. The place in which we keep them is an ordinary room, round the walls of which are several shelves about 9 in. wide, and to each of these is fixed an upright board about the same width. Along the top, every 4 in. apart, is cut a notch 1 in. wide and 1 in. deep. Quart wine bottles are set along the shelves as closely as they can sit; each bottle is filled with water, into which are put a few pieces of charcoal, and laid in a slanting position, with the necks in the notches just alluded to. This is a simple way of erecting a Grape stand, but it answers admirably. Each bunch of Grapes is cut off the Vine with about 6 in. of wood attached to it; the end of this wood is inserted into the neck of the bottle so as to be about 2 in. in the water, and the bunch hangs over the front of the upright board. The mouths of the bottles are not stopped, and the water is never changed, but filled up as it evaporates; no fire-heat is used in the room, but daylight is admitted as in the case of an ordinary dwelling. During damp, sunless days, the windows are never opened, but at other times air is freely admitted. We have had some scores of bunches of Black Hamburgs out and bottled in this manner since the beginning of October, and not more than two berries in each have decayed during that time, all being plump and fresh, while some of the bunches left in the Vinery have lost half of their berries, and others are shrivelling; so that the advantages of bottling are very apparent. I may state that the room is kept at no given heat, but fluctuates with the outside temperature; frost must, however, be excluded.—CAMBRIAN.

Pot Vines.—When visiting the Messrs. Veitch's Nursery, at Chelsea, a few days ago, I was astounded at the immense numbers of Pot Vines which I saw there, with canes from 6 ft. to 8 ft. long, extra short-jointed, and thoroughly ripened, being of a beautiful nut-brown colour. I have an antipathy to pot fruit culture of any kind, but the sight of such Vines made me long to have a batch of them to deal with next spring. Is it too much to ask the Messrs. Veitch to make us acquainted with their mode of culture?—W. W. H.

THE TOOTH-PICK CACTUS.

(ECHINOCACTUS VISNAGA).

THIS is one of the noblest of the genus to which it belongs; its bold port unmistakably asserting its individuality. Its flowers, which are produced in profusion on the woolly apex, are straw coloured, their base or ovary being densely clothed with wool. The spines, which are in sets of from eight to ten, are very strong, and 1 in. or 1½ in. long, flat, and ribbed, and make very good and perfectly harmless tooth-picks. Besides this there are also other Cacti, to which the name tooth-pick has been given by the natives, many of them producing spines fit for that purpose. The plant in question grows freely in rough

* Echinocactus Visnaga.

sandy loam, and is moderately hardy, but I have never known seedlings of it to live out-of-doors more than a few weeks in this country. It varies in ribs from six to sixty, according to age.

Sudbury House, Hammersmith.

J. CROUCHER.

THE GEOGRAPHICAL DISTRIBUTION OF PLANTS.

(Continued from page 479).

Climate of the United Kingdom.

GENERAL REMARKS.—If we first of all examine the climatal conditions of the country in which we live, and study the general features of its flora, we shall be in a position to profitably extend our observations, for purposes of comparison, to other countries enjoying a similar or dissimilar climate. The amount of heat and the rainfall vary very much in different parts of even this small kingdom, but it is not necessary to enter into details respecting the climate of a number of different points. Moreover, there are so many quite local modifying influences at work, that an attempt at anything more than a general sketch would involve us in an unintelligible maze of figures. It is, however, very essential that in practice nothing should be taken for granted, and that a study of local diversities of heat and rainfall in connection with the soil, aspect, &c., of the land should be the basis of all operations. The United Kingdom extends through nearly ten degrees of latitude, and in the northern part there are mountains whose summits reach a height of more than 4000 ft. In round numbers the average annual temperature decreases in Central Europe one degree of Fahrenheit's thermometer for each degree of latitude, as we travel northwards, and it is also diminished by about one degree for every 300 ft. of elevation. But in Britain the rate of decrease is considerably modified by influences explained below.

MEAN TEMPERATURE.—Perhaps it will not be out of place here to explain how average mean annual, quarterly, monthly, weekly, or daily temperatures are obtained, and upon what, besides a correct and uniform system of observation, their value depends and increases. The mean temperature of a day is the highest and lowest reading of the thermometer in the twenty-four hours added together and divided by two; thus, if the maximum were 80° and the minimum 60°, the mean would be 70°. For certain purposes, and where greater exactitude is required, the highest and lowest temperature during every hour of the twenty-four is taken, and the mean deduced by dividing the sum of the readings by the number of observations. In practice it is found that the mean obtained from the absolute highest and lowest temperatures approaches very closely to that obtained from hourly observations. To get the mean temperature of a week we have only to add the means of each day and divide by seven, and the same method of procedure applies to the means of months and years. Little reflection is necessary to convince ourselves that one mean, whether for a day, month, or year, is of little value beyond fixing the temperature for the particular period in question, because it may have been exceptionally hot or exceptionally cold; but if the observations are repeated year after year, we get some insight into the range of fluctuations, and, by the arithmetical process described above, we are able to ascertain the average temperature for the year, or for any given day, in the locality where the observations are made. An average of three years would obviously be of less value than an average of ten years, but the latter would pretty well cover the whole range of variation a climate undergoes. This may be proved by comparing the averages of successive decades, which will also show whether there is a decided tendency to a real change in the climate. It should be stated that all readings for this purpose are taken from thermometers protected from the direct influence of the sun, and at a certain distance from the ground. In the extreme south-west of England and Ireland the average annual temperature is 52°, with a difference of about 20° between the averages for July and January, and a difference of about 15° between the three winter months, December, January, and February, and the three summer months, June, July, and August. The average annual at Chiswick for twenty years (1852 to 1871) is 48°·7, and the average for Greenwich is about 49°, with a difference between January and July of 25°, and between summer and winter of 20°. The average winter temperature of the north-east of (mainland) Scotland is 37°, of the south-west of England 43°, and the July temperature for these localities respectively is 56° and 64°. It will thus be seen that a table of mean temperatures of Britain, constructed from the means of different parts, is of an

French Vegetables and Fruits.—M. Berenger, President of the Second Section of the Customs' Commission in France, has addressed a report to the Minister of Agriculture, calling renewed attention to the serious decrease in the exportation of early vegetables and fruits from the country. Only a few years ago France enjoyed a monopoly of this trade to North Germany, Austria, and Russia, while in 1874 the value of the exports had fallen to 30,340,000 francs; in 1875 to 18,634,000 francs, and last year it barely exceeded 13,600 francs. The principal cause of this decline is traced to the greater competition offered in foreign markets by Italian produce, which has been greatly favoured by contracts effected with the German railway companies for conveyance of such goods at special rates, and by a considerable reduction on freight on the Italian lines. The president calls attention to the unwise policy of the recent increase in the tariff of the French companies, and bespeaks the assistance of the Government, so far as practicable, to restore this important industry to its former state of prosperity.

use whatever to the practical cultivator, unless he knows how it is constructed.

Lines of Equal Heat.—The extreme figures just given will afford the cultivator some clue, but a clearer idea of the distribution of heat in this and other countries may be given by a plan devised by Alexander Von Humboldt, one of the founders of the science of the distribution of plants. It is simply connecting on a map by lines all those places enjoying the same annual or winter or summer temperature. Such lines he termed isothermal lines or lines of equal heat. If we trace the isothermal lines in Britain for summer and winter respectively, we find that they take quite different directions; thus, the winter isotherm of 37° runs from the north-east, southward down the eastern side of the island into England, receding gradually from the coast, until it reaches its south-eastern limit, then striking the midland counties, and returning northward a little west of the centre of the country, enclosing a tract of country of about the same temperature; but, continuing the line to the north-west of Scotland, it becomes 38° and 39° as it approaches the north-west coast. The general direction of the isotherms of 40° , 41° , 42° , and 43° , is from north to south on the west side of the island, bending to the south-east in their southern part, each higher degree being nearer the coast. Comparing the general direction of the summer isotherms, we see that they cross the winter at right angles, running from south-west obliquely north-east, so that the eastern side of the island is warmer for latitude in the summer than the western, whilst the contrary obtains in the winter. In the winter there is a central coldest area, extending from north Scotland to the south-midland counties of England, and in the summer there is a central area of greatest heat in the south-midland counties. In Ireland the isotherms take much the same direction, but the lowest winter is 39° , and the highest summer 62° .

Modifying Influences on Climate.—The cause of these climatal conditions is not far to seek. Proximity to the ocean engenders an equable climate, its warm currents softening the rigours of winter, and its breezes moderating the heat of summer. The North Sea modifies the climate of the eastern coast in winter, but its influence is less potent in summer.

Extreme Temperatures.—Before leaving the subject of temperatures, a word may be said respecting extremes, although extremes affect very little the profitable cultivation of plants, for which the average annual amount of heat is sufficient to bring them to maturity. But severe winters, such as we experienced in 1860-1, when the extremes of cold were very great, play sad havoc among ornamental trees and shrubs which bear our average winters without injury. Usually the vicinity of the ocean is sufficient to overcome even the extremes of cold, or to greatly modify them. For example, on the 25th Dec., 1860, at Hurstpierpoint, a little north of the Downs in Sussex, and less than seven miles in a direct line from the sea, the temperature fell to 3° of Fahrenheit, whereas at Worthing, on the coast, it did not go below 17° , and at Helston, in Cornwall, the lowest was 32° . On the 29th of the same month, in the same year, the minimum at Hurstpierpoint was 5° , at Worthing 33° , and at Helston 28° . On the other hand, the lowest temperature at Helston in October, 1859, was 32° , and at Truro and Worthing it was down to 30° .

Distribution of Moisture.—We now come to the consideration of the distribution of atmospheric moisture, precipitated as rain or otherwise. The extremes of the average annual fall of rain in different parts of the kingdom are much greater than in the temperatures. In the south-eastern part, in Essex, not far from the centre of the greatest summer-heat, and where there is a maximum quantity of sunshine, the average annual fall does not exceed 22 in.; at London, it is about 24 in.; at Manchester, 36 in.; and at Seathwaite, in Cumberland, as much as 140 in.; and on the opposite eastern coast of the same county it is only 20 in. But it is not so much the quantity of rain that falls as the proportion of sunny days that influences the maturation of grain and seeds. Our average autumn weather, except in a few favoured places, is not favourable to the profitable production of many kinds of seed, which ripen freely and with little care in the same latitude on the

Continent. General comparisons with the climates of other countries will be made when treating of the plants of the different zones.

Vegetation of the United Kingdom.

Definition of a Flora.—The vegetation of almost all countries, which, collectively, is termed the flora, consists of two elements—an indigenous, and an introduced. This fact should always be kept steadily in view in studying the distribution of plants, especially in countries like our own, where the cultivation of exotic, useful and ornamental plants, has been practised for centuries. It is necessary to distinguish between the agencies which have effected the existing conditions, and to define which are to be regarded as natural, in opposition to the artificial. Any species owing its existence in a certain country, or region, to the voluntary or involuntary interposition of man, is an exotic introduced by an artificial agency, whether it be wild and flourishing as well or better than species belonging to the aboriginal vegetation, or whether it be directly under cultivation. The indigenous species, on the other hand, include all the rest, whose presence may be due in the country either to creation, migration step by step, conveyance by wind, birds, or animals of any kind—in short, whose presence is due to any natural cause whatsoever. This definition would be open to criticism, of course, if by aboriginal or indigenous vegetation we limited, or attempted to limit it, to those species actually created in the country. It has the advantage that it involves us in no speculations as to the origin of species, and leaves us to consider their presence independently of all theories. Probably the flora of no other country in the world presents so many difficulties to the botanist, who seeks to refer its components to their respective categories of indigenous and exotic; but by studying the general distribution, as apparently uninfluenced by man, of each species, one is able to arrive at the probabilities of its nativity or otherwise. Most botanists agree in regarding the common Elm (*Ulmus campestris*) as an introduced tree, and the circumstance that it never (?) ripens seed in this country supports this view, though it does not prove it.

Number of Species.—The indigenous flora of the United Kingdom numbers, according to a moderate view of what constitutes a species, about 1428 species; but Mr. Beatham, at one extreme, admits only 1285, whilst Professor Babington at the other, raises the number to upwards of 1700. This greater number is mainly owing to the fact that numerous forms of the Water Buttercup, Bramble, Rose, Hawkweed, Willow, and a few other things are regarded as species. In this, as in all other figures given, the lower Cryptogams are excluded. Taking the number of 1428 as our standard, we find they belong to 463 genera, and 90 Natural Orders. The following are the Natural Orders most numerous represented:—Compositæ or Aster family, 120 species, belonging to 42 genera; Gramineæ (Grasses), 100 species, 43 genera; Cyperaceæ (Sedges), 75 species, 58 of which belong to the genus *Carex*; Cruciferae (Wallflower family), 70 species, 24 genera; Leguminosæ (Pea family), 65 species, 17 genera; Umbelliferae (Parsley family), 62 species, 34 genera; Scrophulariæ (Antirrhinum family), 50 species, 13 genera; Labiatae (Salvia family), 48 species, 17 genera; Caryophyllæ (Pink family), 44 species, 12 genera; Orchideæ, 37 species, 17 genera; Ranunculaceæ (Buttercup family), 34 species, 10 genera; and 40 Ferns, belonging to 17 genera. These twelve Natural Orders include 257 genera and 745 species, or more than half of the total numbers, and may be termed characteristic groups.

Proportion of Woody Plants.—The proportion of woody to herbaceous species in our flora is remarkably low, numbering only about 100, including every species that has woody, persistent branches, no matter how small it may be, such as Rock-rose, Milkwort, Whortleberry. Upwards of thirty of them, indeed, are under shrubs, or quite dwarf shrubs; about forty are larger shrubs, or quite small trees; and thirty are trees of moderate or large size. At least a third of the woody species are rare, or only locally abundant, and very few extend to every county in the kingdom. Three species of Heath, *Erica Tetralix*, *E. cinera*, and *Calluna vulgaris*, are amongst the most ubiquitous.

ous of shrubs, covering large tracts of uncultivated land from north to south, the first and second ascending to above 2000 ft., and the third to 3000 ft., in the highlands of Scotland. The Blackberry, in some of its innumerable variations, is common almost everywhere; several of the Willows, too, are common and widely spread; and the only indigenous evergreen climbing shrub, the Ivy, is pretty general. The Dog Rose, and some other forms, extend from north to south; and, finally, Furze or Gorse, is a characteristic shrub on waste ground in all, except the coldest, parts of the kingdom. The most widely and generally dispersed of trees is the Oak.

ENUMERATION OF TREES.—The deciduous trees are:—One Alder, 1 Ash, 1 Blackthorn, 1 Birch, 1 Beech, 1 Cherry, 1 Elm, 1 Elder, 1 Hawthorn, 1 Hazel, 1 Hornbeam, 1 Lime, 1 Maple, 1 or 2 Oaks, 2 Poplars, 5 species of *Pyrus* (Crab, Mountain Ash, &c.), and 6 Willows. The Lime and some others are rare in a wild state, and doubtfully indigenous; and several, as the Hazel and the Thorn, rarely form trees. To these may be added five evergreen trees, namely, *Arbutus* (locally in Ireland), Box (possibly indigenous to Surrey, very rare elsewhere in an apparently wild state), Holly (the only common species of the five), Scotch Pine and Yew (both rare in a wild state now). Among noteworthy shrubs we may name the only deciduous climber, *Clematis Vitalba*; the solitary twiner, Honeysuckle; the only shrubby parasite, Mistletoe; and the only indigenous Monocotyledonous shrub, Butcher's Broom.

ANNUALS.—The herbaceous vegetation includes a considerable number of annuals, more or less abundant in cultivated grounds, which may or may not be indigenous. Among familiar examples of annual plants may be named the Poppy, Papaver Rhæas; Charlock, Brassica Sinapistrum; Shepherd's Purse, Capsella Bursa-Pastoris; Chickweed, Stellaria media; Shepherd's Needle, Scandix Pecten-Veneris; Mayweed, Anthemis; Cotula; Knotgrass, Polygonum Aviculare; Goosefoot, Chenopodium album; and Black Grass, Alopecurus agrestis. The desire to keep these articles within reasonable limits compels us to omit many interesting details of the distribution of some of the rare perennials. How some are limited to almost a single locality, others to two or three isolated and distant spots, and so on. We may, however, before bringing this part to a conclusion, quote some statistics from Mr. Watson's works on this subject.

ANALYSES OF THE FLORA.—This gentleman has devoted almost a lifetime to the study of botanical geography, and more particularly to the elucidation of the laws of the distribution of British plants. He divides the whole of Britain into six zones of heat, depending upon latitude and altitude. In the three lower zones cultivation of cereals and Potatoes is general or practicable. The upper boundary of the third zone has much the same climate as the Arctic circle at the level of the sea; and there is a comparatively small area of surface in Britain above this, it being limited to the peaks and ridges of the mountains in the north. Taking these zones in the order of the greatest to the smallest amounts of heat, the number of species in each is—Inferagrarian zone, 1225 species; Midagrarian, 1070 species; Superagrarian, 760 species; Inferarctic, 293 species; Midarctic, 244 species; and Superarctic, 111 species. Of the total number of species found in Britain, 532 are generally diffused at sea level from north to south; 606 do not reach the northern latitudes or ascend into the mountains; 238 are of a northern or mountain type, and 49 are too local in their distribution to be referred to either class. On the summits of the highest mountains in the north, the vegetation is of a purely Arctic or Alpine character, and in the milder parts of the south-west of England and Ireland are found several species characteristic of the south-west of Europe. Some of the plants characteristic of a warmer climate are *Trichomanes radicans*, *Trichonema columnæ*, *Erica vagans*, *E. ciliaris*, *E. mediterranea*, *Arbutus Unedo*, *Neotinea intacta*, *Daboecia polifolia*, *Saxifraga Geum*, and *Pinguicula lusitanica*.

NUMBER OF SPECIES ON A SMALL AREA.—After having given the total number of flowering plants for the whole kingdom, it may be interesting to give the number found on a small area, that has been very carefully botanised by three or four different persons, and on which the writer of this spent nearly two months. In Rothamsted Park, Herts, Dr. Lawes has had

about 7 acres of meadow land, divided into about a score of plots, under experiment for upwards of twenty years. On the whole area about eighty different species occur, a fourth of which are comparatively rare. On one of the plots, $\frac{1}{4}$ acre in extent, which has received no manure during the whole period of the experiments, sixty of these species occur; and on an adjoining plot, highly manured with artificial manures every season, and which yields a quantity of Hay equal to at least 5 tons per acre annually, the number has been reduced to eighteen. This is interesting and instructive in its aspect of a struggle for existence. The number of different Grasses found on the experimental ground is only eighteen, and they all occur on several of the plots.

NO PLANT LIMITED TO THE UNITED KINGDOM IN ITS DISTRIBUTION.—In conclusion of this part, and as introductory to the next, it may be mentioned that not one Natural Order, not one genus, and not even a single species—in the sense that we understand a species—is endemic or limited in its distribution to the United Kingdom. With few exceptions, they occur in Continental Europe, and many of them have a very extensive area of distribution. One of the exceptions is *Eriocaulon septangulare*, a plant of the Sedge family, which is a North American species, that has not been found elsewhere in Europe.

GEOGRAPHICAL RANGE OF SOME SPECIES.—The following common British plants are examples of those found in very distant parts of the world:—*Ranunculus aquatilis*, nearly all temperate regions; *Barbarea vulgaris*, north and south temperate regions; *Cardamine hirsuta*, nearly everywhere in temperate and cold regions; *Montia fontana*, temperate and frigid regions both in the north and the south; and Duckweed, cosmopolitan. A long list of such plants might be drawn up, but it seems sufficient to mention the fact and give these examples.

INCONSPICUOUS FLOWERS.—There is one fact connected with the woody element of the vegetation of the United Kingdom which cannot fail to have struck anybody who has visited other temperate countries, particularly in the southern hemisphere, or had opportunities of gaining some knowledge of the vegetation of other countries. It is this—the almost invariably small, greenish, inconspicuous flowers. Excepting the Heaths, Furze, Viburnum, Cornus, and Lonicera, almost all have inconspicuous flowers. This characteristic applies particularly to temperate Europe, and less decidedly to the whole of the north temperate regions. Already in the warmer parts of China, Japan, and North America; whence we obtain hardy plants, as well as in the Mediterranean countries, the proportion of shrubs and trees with large, coloured flowers is much greater.

DISTRIBUTION OF THE ARBORESCENT GENERA.—The distribution of the genera to which our principal large, undoubtedly indigenous, trees belong, offers many curious anomalies. *Fraxinus* (Ash) consists of about thirty species, scattered over the temperate and sub-tropical regions of the northern hemisphere; *Ulmus* (Elm) comprises about a dozen species, confined to the north temperate zone; *Populus* (Poplar) about a score of species in the temperate regions of Europe, Asia, and America; *Salix* (Willow), a large genus, including upwards of 150 species, widely dispersed, but most numerous in the temperate regions of the northern hemisphere, especially in the Old World; several species, however, extend to the Arctic regions, and *S. reticulata*, which is indigenous to some of the higher mountains of Scotland, reaches the northern limits of Arctic vegetation; a few species are widely dispersed in South America, one, at least, nearly to the extreme south; in South Africa, too, there is one or more species having a wide range of distribution; there are some others in the mountains of tropical Asia, but the genus does not occur in Australia, New Zealand, and the Pacific Islands. *Quercus* (Oak), a genus of some 250 species, dispersed over the temperate and sub-tropical regions of the northern hemisphere, extending to the southern hemisphere in the mountains of Java, and perhaps also in America; *Fagus* (Beech) consists of about fifteen species, the distribution of which has already been explained in the introductory remarks; *Betula* (Birch) is a genus of about twenty-five species, which inhabit the temperate and frigid countries of the northern hemisphere; *Alnus* (Alder), fourteen species,

dispersed over Europe and Asia, from the Himalaya Mountains northwards, North America, and Andes of South America southwards to Chili; and Pinus (Pine or Fir) comprises upwards of 100 species, found in the temperate and sub-tropical regions of the northern hemisphere, from Borneo and Mexico to the Arctic circle. One noteworthy fact in connection with the distribution of the genera of British timber trees is, that only one of them—*Salix*—reaches the mountains of tropical Africa and the temperate regions of South Africa.

W. B. HEMSLEY.

PROTECTING HALF-HARDY PLANTS.

EXTREMES of temperature act in various ways upon different plants. Those whose natural home is on the mountain side, suffer more from damp than cold or frost, when moved to moist valleys; hence the importance of knowing as much as possible the conditions under which all new reputedly hardy exotics exist in their native countries. Many a hardy shrub and plant has been lost from a want of this knowledge, and a little intelligent attention until it had become thoroughly established. I have known instances in which a small potful of dry Fern over the roots and collar of a plant turned the scale between life and death, in favour of the former, when put on just at the right time. Many plants of whose hardiness in any particular locality we may have doubts, if planted on a well drained elevated site, with a little light protection over their roots for two or three winters after planting, would there become acclimatised and do well. Perhaps with recently planted shrubs or plants there is nothing more important or necessary than temporary shelter from cutting winds; too often this is left till the leaves begin to drop and turn back; but to be thoroughly effective the shelter should be put in operation when the planting is finished; and the simple expedient of lacing a few branches through stakes driven upright in the ground, on the windward side, is generally as effective as anything. Shelters need not be wind-proof, if they break its force, sift it as it were, they will answer the purpose better than if quite close. Hollyhocks of choice valuable kinds, growing in cold positions, should be taken up, potted, and placed in a cold pit, or they may be laid in closely together in some warm corner where they can be sheltered with a few branches, when the frost and snow comes, and which, according to the weather prophets, we are to have this winter. Fuchsias and Dahlias may be covered and kept safe with cones of ashes. I have sometimes lifted them and preserved the roots in a mound of ashes, and planted them again in spring, dividing the Dahlia roots to one eye each. Cannas keep better in the ground covered a foot deep with leaves and litter. In dry soils, tuberous Begonias may be wintered in the same way. Many of these, before their proper culture was understood, were killed by being kept too dry and warm in winter.

In cold situations, it is best to take up Tea Roses carefully and plant them thickly in some sheltered border, laying them in sideways, when they can easily be protected, or have some old lights placed over them. In the event of a severe winter, they will be secure, and this will give an opportunity to have the beds or borders manured and trenched up, which will be of immense benefit to them when planted again in March, or when the weather is settled. It is never desirable to begin protecting anything too soon. Protection should always be looked upon as a necessary evil, but still as an evil nevertheless. A few degrees of frost never hurts anything that is capable of standing our climate at other times, and there are always some premonitory signs, giving notice of the approach of a severe frost, which are well enough known to those who are in the habit of closely observing the state of the weather. It is after the first night's frost has dried up the damp surface and made locomotion cleanly, that protection should have attention, by setting all available hands to work, and having all things made safe and comfortable. I am speaking now more especially of plants that are fairly hardy. Dahlias, Cannas, and Begonias had better be made secure at once, and so must Tea Roses if it be intended to lift them. I need not say that the protecting material should be ready somewhere handy when wanted. Fern, if it be available, should have been cut and stacked ready. Reeds or Rushes make excellent protection,

because they do not altogether exclude air; branches or cuttings of evergreens are also useful, and dry leaves, if their tendency to blow away can be overcome, are equal to anything.

In the vegetable and fruit departments, many things will require attention on the approach of frost—Celery, Artichokes, Broccoli, Endive, &c. Freshly-planted fruit trees, and, indeed, all fruit trees the roots of which are close to the surface, will be benefited by having a slight mulching placed over them. The roots of a plant are of a softer nature than the branches, and, if frozen through, the vessels or cells may be ruptured, circulation stopped, and the tree or plant receive serious injury from their inability to perform their natural functions. When plants have been covered or sheltered on the approach of severe weather, defer the uncovering for a day or two after the weather has finally broken up, in order to avoid sudden changes.

E. HOBDAY.

THE GOAT MOTH.

(*COSSUS LIGNIFERDA*.)

THIS insect, there is little doubt, continues to spread in the neighbourhood of London—a whiff of the strong goat smell, to which it owes its name, striking the sense in very many plantations in the western suburbs. We may note that the more we know of it, the greater the number of trees we find it attacks. In an article on it (see Vol. III., p. 203), we noted

The Goat Moth and Caterpillar (natural size).

the various trees that it attacks, and among these the Oak. The cases, however, in which the Oak suffers are comparatively rare, and we therefore mention a striking instance of a whole row of bleached and barked dead Oak trees which we saw sometime since in a field not very far from Red Hill, which owed their death entirely to the attacks of this insect, as was evident from scars on the wood. They were pointed out to us by Mr. John Clutton, on whose property they stood; and he was good enough to cause another to be cut down at some distance, which was also dying under the attacks of this insect.

A. M.

Preserving Turnips in Winter.—Severe frost injures the tissues of almost all vegetables, and, with one or two exceptions, spoils their flavour and destroys their keeping properties, when thawed again. When Turnips are grown in drills, and have room enough, it is a good plan to draw a little earth up over the roots with the hoe on each side the rows, but this need not be done till just before frost of a severe character is expected. This will, in a great measure, prevent that alternate freezing and thawing that does so much injury, as the plants may be pulled up intact just before frosts sets in, and be laid in shallow trenches, just burying the bulbs. They will keep in good condition for a long time in that way. A few should, however, always be stored away in some cool place to be at hand in bad weather.—E. H.

RERODUCTION OF LILY BULBS.

THE act or process of reproducing that which has been destroyed is, with respect to the cultivation of the Lily, well worthy of the careful consideration of all Lily growers; more especially, as we see at the present time, that opinions differ most widely with regard to the wonderful operations of Nature in the reproduction and increase of these deservedly-popular plants. We are told that a new bulb, whether grown from seed or from bulblets, takes not less than three years, under the most favourable circumstances, before it develops a flower-bearing stem. We are also told, that raising seedling Lilies is a long process, as one must wait from three to ten years ere they bloom. And we are, moreover, taught to believe that it is the very same seedling, or bulblet, that grows year after year, larger and larger, until it becomes a flowering plant, and that the bulb then goes on living for an indefinite number of years, sending up each year a flower-stem from its centre. This may appear to many to be a very plausible doctrine; but how it has become the belief of so many Lily growers is difficult to understand. If we lift a clump of Lily bulbs, we often find a whole colony of small bulbs, popularly, but without discrimination, called offsets. When we carefully examine them, however, we find they are not all real or genuine offsets, but that they consist of offsets, and the offspring of offsets, properly called successional bulbules. A genuine offset is not furnished with all the characteristics of a fully-developed bulb, but, though deficient in some respects, it is possessed of this important function, namely, the power of generating a successor in the shape of a bulbule or small bulb. With respect, therefore, to the powers of reproduction, it is important to bear in mind, that plants, no more than animals, come into existence without a parentage. An offset no larger than a Pea, may, during the ensuing summer, send up above the soil a slender stalk a few inches in length, bearing what may be called a seed-leaf. But this identical offset will never send up another stalk. This becomes the duty of its offspring—the successional bulbule. Nature causes this operation to be repeated, season after season, each successional bulbule growing larger than its progenitor, until a fully-developed flowering bulb is the result. If any of the successional bulbules be carefully examined, it will be seen that the stalks or stems of the preceding season did not emanate from them. De Candolle has said:—"If we desire to know more of plant life in its higher bearings, we must live with, and observe the cycle of plant growth in all its stages, from the germination of the seed to the full development of the fruits." For myself, I can truly say, that I have almost literally complied with this injunction. For many years I have lived with, and have been in the habit of watching the underground life of the Lily, from the most minute seed-bud and the smallest offset, to their full development as flowering bulbs, and even after that. In order to do this satisfactorily, I have planted, from time to time, in distinct places, hundreds of offsets, as well as fully developed bulbs, and have watched their progress, winter and summer, by taking up a portion now and then for examination by dissection or otherwise. The result of this has been to me full confirmation that no individual offset, bulbule, or fully developed bulb lives for another season, after having once sent up a stalk or a flowering stem. Take a bulblet in the autumn, that has been produced on a bulb-bearing stem, and carefully cut it open. At the very core will be found a seed-bud, in every respect similar to one that will be found in a flowering bulb, in the axil formed by the inner scale and the base of the flower-stem. In the case of the bulblet, it will take more than three years before its successional bulbule is sufficiently developed to throw up a stem that will bear even one flower. In the other case, the seed-bud, which is contained within the flowering bulb, will take not more than twenty months before it blooms, possibly more perfectly than its parent did before it. How is this? The seed-bud in the fully developed bulb is nourished by that bulb as its parent, and its growth is consequently so stimulated that in eight months from its germination it is shooting down strong, healthy roots, 3 in. or 4 in. in length, mixed up with those of its parent, and through these its own roots, it receives additional nourishment, while the parent bulb continues still to nourish its offspring for some time longer. All this time

the little bulblet is left to starve or provide for itself. What can it do, for it is still alive? In order to preserve its life, Nature directs it to send down two or three slender feelers in the shape of thread-like roots, in search of such food as the soil can supply, and such as is fit for it in a young state. Its further progress until—not it, but its successional bulbule has arrived at a state of full development—I have already described when treating on the progress of an offset; for an offset, if carefully dissected, will also be found to be possessed of a similar seed-bud. It is from a careful study of this part of the subject that we learn that an offset or bulblet has to go through a distinct and different stage or transformation every year for a length of time before it can arrive at the stage of being a fully developed flowering bulb, whereas the seed-bud in the flowering bulb, which is generated in the autumn, will, in eight months, be sending down strong roots; in two months more it will be nearly of adult size; and in six weeks from this time it may safely be detached from the decaying remains of its parent, and transplanted, if necessary, where it will bloom next summer. The rapidity of growth in the new bulb is not generally known, and has therefore given rise to very mistaken notions on the part of those who dip little deeper than the outward appearances of the bulb.

If I thought that I was making the columns of THE GARDEN a medium for the promulgation of erroneous doctrine—mere fancies of my own—I would never write another word on the subject of the Lily. When, therefore, giving the result of my experimental researches for the use of those who may be inclined to adopt or test them, it is not very encouraging to be told, as I have been, by the author of "Notes on Lilies and their Culture" (p. 268, April 7), that "though it is impossible for him either to deny or accept my statements as facts, he thought I could hardly expect many Lily cultivators—out of some hundreds who are interested—to sacrifice some dozens of bulbs in the pursuit of science." Why not? I am, myself, but a mere amateur investigator, and they, according to his own account, who would not sacrifice a few bulbs for the sake of science, number some hundreds! The author, who is himself a cultivator on a large scale, as a matter of commerce, and besides a teacher of Lily culture, might surely have considered it a duty to sacrifice a few bulbs in the pursuit of a science which is so intimately connected with his profession. But no! Instead of doing this, he laid down for me a most inconsistent and impracticable programme. He said:—"I want to know, is 'Dunedin' right or wrong? The onus of proof lies on his shoulders; I therefore propose to him to prove it thus to the horticultural world. Let a series of preparations, sections of bulbs showing the seed-bud in its several incipient, semi-developed, and fully-developed stages (in fact, the life history of the 'seed-bud'), be put up in spirit or some other antiseptic fluid that will keep the specimens in a fresh, undecomposed condition for months at least, by 'Dunedin,' or under his supervision and labelled with clear descriptions, so as completely to illustrate the views advanced, and let these be exhibited before the Royal Horticultural Society, and there explained by 'Dunedin,' and afterwards be on view for a time in London, or be presented to the Museum at Kew, so that all interested may have an opportunity during the summer of familiarising themselves with the appearances on which these new views are based. Typical bulbs from each of the various groups of Isolirion, Eulirion, Martagon, and Auxilirion, in their various stages of development, should be exhibited, as these groups materially differ in their appearance, growth, and treatment under cultivation." To all this, he added:—"If 'Dunedin' will do this, he will render a great service to science as well as to Lily cultivation."

As these unique instructions for my guidance were published in THE GARDEN on April 7, I trust they will again be permitted to appear on this occasion, simply as a setoff to the views I have continued since that time to make public. To show, further, that I am actuated by no unkind feelings, I propose to bring this paper to a close by attempting to clear up one or two passages in his "Notes on Lilies," in reference to which he himself seems to be somewhat doubtful. At p. 5 the author says:—"Lilies may get their stems eaten off, injured, or destroyed in various ways, or from some cause may lie over [or 'remain dormant,' as amended by "F. W. B.,"] and not emit

shoots; but are the bulbs damaged? Not so; the roots at the base of the bulb are put forth as usual, and the bulbs grow—perhaps even the more so, because there is no stem to draw nourishment from them.” In a note, at the foot of the page, he adds:—“We could relate an instance of this where no growth was made aboveground, but the bulbs which had been supposed to have perished (having made no sign), were in the autumn found much finer [“much larger,” as amended by “F. W. B.”] than when planted.” Now these two passages, though written by the author of “Notes on Lilies,” and afterwards amended by “F. W. B.,” rest upon mere theory without a single experimental fact to support them! At p. 349, Mr. Baines very truly remarks that the common White Lily should not be removed in October, “as it will be making active growth, and, if the roots be disturbed, it will have the effect of wholly or partially preventing its flowering next year.” We have here a case in point. If the White Lily be removed in October, the green tufts of leaves which it then produces will, in a great majority of cases, flag and die down; but the bulb will not “lie over,” or “remain dormant,” as the author and “F. W. B.” supposes. A Lily bulb is never dormant; for, if not entirely dead, it is either growing or decaying. Those who believe in the dormant theory, can know very little indeed about the underground life of Lilies. From the moment the seed-bud is generated until it has bloomed it is always in a growing state; when it has bloomed the object of its growth is accomplished, and it forthwith begins to decay, and ultimately dies—stem, bulb, and roots all certainly perish, the same bulb never flowering but once. As the bulb and stem are parts of the same structural organization, one cannot be destroyed without destroying the other. If the stem be “eaten off, or destroyed,” as the author of “Notes on Lilies” remarks, the bulb, of which it is a part, will inevitably die; but in general, not before it has nourished the new young bulb within it, sufficiently to enable that bulb to grow and become, in its turn, a flowering plant. This is the interregnum which the author designates as “lying over,” and which “F. W. B.” erroneously calls “being dormant.” The parent bulb, that is, this bulb which was destined to flower during the season, having been destroyed through the destruction of its flowering stem; and as a Lily bulb flowers only once during its short existence, this identical bulb cannot now flower again, and thus a season is lost; but the off-spring of the destroyed bulb will flower the year after that; all new bulbs taking about twenty months from the time the seed-bud [is generated until they become flowering plants. We have seen that the author remarks that Lilies may get their stems eaten off, or destroyed, or from some cause [unknown to him] may lie over and not emit shoots; and then he asks:—“But are the bulbs damaged?” He answers this himself, by saying:—“Not so, the roots at the base of the bulb are put forth as usual.” It is much to be regretted that he should have answered his own question in so positive a manner, as he is altogether wrong. If he had made a careful examination, before publishing such a statement, he would have found that the roots were not put forth from the base of old bulb, but from the base of the new bulb, the off-spring of the bulb whose stem was destroyed; and that this new bulb, is often found to be “much finer,” and “larger,” than the parent bulb had been before it. The author of “Notes on Lilies” has said: “I want to know, is ‘Dunedin’ right or wrong?” I think the best way to convince him that I am right, is to point out how he can prove to his own satisfaction that he himself is wrong.

DUNEDIN.

Tomatoes and Coal Ashes.—Both Tomatoes and Potatoes are good this year where they have a monopoly of the soil—very good on manured lands, and phenomenally good on rich soils, which have been farther enriched by coal ashes. Having casually observed the effects of coal ashes to be, as I thought, something out of the common on Tomatoes—increasing not so much the growth of the plants as the size, smoothness, and number of the fruit produced—a market gardener of experience confirmed my suspicion, and last spring I accepted his directions for their use, which were to throw out a wheelbarrow load of earth where each plant was to stand, and then fill with half soil and half coal ashes, and therein set out the plants. I did so, and the result was quite surprising, the dozen plants thus treated bearing nearly double the fruit of others, and smoother and larger; but Tomato plants so set, will, in case of drought, require water oftener, and more of it, than those growing in common soil.—Country Gentleman.”

THE KITCHEN GARDEN.

SELECT VEGETABLES.

AMONGST many kinds of vegetables which we have grown for trial, the following proved to be the best:—Among autumn Broccolies, Veitch's Self-protecting is now (middle of November) turning in for use in excellent condition. Carter's Fern-leaved Parsley is the best which I have ever seen; at a little distance off it looks like a well-grown Lycopod, and it answers unusually well for garnishing; indeed, as an ornamental culinary plant, it stands in the foremost rank. Veitch's Autumn Giant Cauliflower, raised from the remains of a packet of seed which I had last year, is unusually fine at present, and has been so for weeks; but from seed which I had this year the case is altogether different. Purchasers of seeds of this, as well as of other choice vegetables, should therefore be sure that they get them genuine. Among Brussels Sprouts, the Roseberry beats all comers, being unusually fine. Osborn's and Williams' French Beans have been the most serviceable this untoward season. Lettuces last summer were the best I ever had; the kinds were Alexandra White Cos and the true old Bath Cos, from seed which I had from a neighbour, who has saved it from his own stock for many years. This kind (Bath Cos) I cut finely blanching from the open ground the whole of last winter and as late as June; along with Batavian Endive, these were greatly valued and much in demand. The Alexandra White Cos was the largest Lettuce I ever saw; it grew hard, very crisp, and white, and nutty in flavour; it was grown on very rich ground that was heavily manured. Veitch's Red Globe Turnip has been extra fine this autumn; some samples of it, before me while I write, being very beautiful to look at, and, when cut, they are as white as snow, crisp, tender, and juicy. The best Celery, which is this season larger than we really care to have it, is represented by Turner's Dwarf White Incomparable, the seed of which was also given to me by the same grower who saved the Cos Lettuce. He has saved it for many years, and, though it has often appeared under new names, we find nothing to equal it, if from the stock which was sent out twenty years ago. M. TEMPLE.

Impney Hall.

Potatoes in Worcestershire.—I have this season been more unfortunate with my Potato crops than I ever remember to have been before; in fact, the whole of the late ones were useless, and none were left for seed, all and sundry having the “dreaded mark” on them. The very earliest kinds were harvested in tolerable safety, but when the disease appeared, some time in August, it carried out its work of destruction amongst other sorts quickly and without mercy. Our collection was a good one, including some of the best sorts recommended by those much better skilled in Potato lore than I am; now they are all gone, I would be glad if some kind friend would, in the pages of THE GARDEN, recommend me a few good kinds suitable for a strong heavy soil, moderately rich. Last year the ground was freshly broken up Grass land, and the crops were heavy, and the quality excellent, but we lost nearly all of them. I find in this locality that Myatt's Ashleaf is a favorite, that it has stood well this year, but it is hardly white enough for what is generally desired.—M. TEMPLE.

Mushroom Culture without Manure.—It is not always that one can secure the horse manure and other necessities to grow these esculents in the way recommended by some writers on Mushroom growing. This autumn I wanted to have some fine crops in a new Mushroom-house which we have, but could not get any horse manure. I therefore collected a quantity of turfy soil, the result of thin cutting; with this I mixed a quantity of old, rotted straw and some green Grass, and threw the whole into a large heap, until it heated violently. It was then turned and well mixed, and, when still warm, was wheeled into the Mushroom-house, beaten firm, and the spawn inserted in the usual way. The result is an excellent crop of good Mushrooms. When the crop seemed well-nigh exhausted, we dusted a sprinkling of salt over the bed, and watered it with tepid water, and shoals of fresh Mushrooms speedily made their appearance. Last year, among many makeshifts to secure Mushrooms, we used rotten sawdust mixed with a little horse manure, but with only moderate success. In the open ground, tolerable crops were obtained late from heaps of soil mixed with Grass; but the best was from a quantity of manure very wet, in fact drenching, from a manure hill. This was placed 1 ft. thick, well beaten, and pieces of spawn inserted, wrapped in a good handful of Hay. They were covered

over with rich earth, and the crops were all that could be desired.
—M. TEMPLE, *Impney*.

THE OCHRA.

This plant, the *Hibiscus* or *Ahelmoschus esculentus* of the botanist, is indigenous to the West Indies, where the pod or seed-capsule goes by the name of the Ochra, Ochro, or Gombo, and forms the chief ingredient in the famous West Indian dish Gombo soup, which is said to have very nutritious properties. Like the fruit of all the *Malvaceæ*, the Ochra contains a large amount of mucilaginous matter, which gives it a great value as a culinary vegetable. For cooking purposes it is used in the green condition, being gathered when in a tender state, before the woody fibre has begun to be formed; it is also used in the dried state. In the West Indies the Ochras are gathered while green, the hard calyx being cut off; they are then sliced and exposed to the sun on trays or mats, and turned now and then until they are perfectly dry. In Greece and Turkey, where, both in the green and the dry state, they form one of the principal ingredients in the native *pot-au-feu*, they are plucked when only about 1 in. long, threaded on strings, and allowed to dry spontaneously. The chandlers' shops in Constantinople and Athens are always hung with festoons of dried Ochras. The fresh green Ochras, stewed with collops of lamb or mutton, Onions, and Tomatoes, form one of the favourite dishes of Turkish dinner-tables. When dried they will keep

Pod of the Ochra.

for any length of time, and would form a valuable addition to the seaman's diet-table as a preventive of scurvy. The fresh Ochra is also served as a vegetable alone, when it is simply boiled in salt and water and flavoured with salt, pepper, and a little good stock. They are very mucilaginous, and have a slightly bitter flavour, somewhat resembling that of the English Turnip-top. In France a sweetmeat has been made of them, which is said to be a better remedy for affections of the throat than the famous *pâte de guimauve*. The seeds contain 16 per cent. of oil, which, owing to its bitter flavour, is useless in the kitchen; it contains a large amount of stearin, and, if obtainable in large quantities, the oil would be valuable for soap making. The oil-cake contains notable proportions of nitrogenous matter and phosphorus, and would form a very nutritious food for cattle. In Africa, the natives roast the ripe seeds and use them as a substitute for coffee. The mature stalks of the plant contain large quantities of woody fibre, and M. Bonjon, a French engineer, has commenced its cultivation in Algeria as a paper-making material. At the exhibitions of 1867 and 1873, Dr. Riddell showed excellent specimens of paper and cordage made from the fibre of the Ochra plant. The Ochra is moderately hardy, and ought to thrive in this country if sown in heat and planted out; in fact, it will grow under the same circumstances as the Tomato. The Ochra has long been naturalised in India, West Africa, the south of France, Greece, Turkey, and the Southern States of America. The French know it under the name of Gombo, or *Cornes Grecques*; the Greeks and Turks as the *Bamiya*; while our own countrymen in India and West Africa have given it the pretty name of Lady's-fingers.

C. W. QUIN.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Winter and Spring-flowering Plants.—Amateurs who make a point of furnishing their dwellings with flowering plants during summer, and who have no glass accommodation except ordinary garden frames, often feel much at a loss in winter for material wherewith to maintain their indoor decoration; but, by the use of a good-sized frame, say three or four lights, the length of time during which they may enjoy these flowering subjects may be greatly lengthened by always having something in bloom from the latter part of winter through the spring, provided the right plants for the purpose are selected. It must be borne in mind that I am now treating of such plants as will only require protection from frost, with no artificial heat whatever; and, therefore, it is essential that the subjects employed are all but proof against damp, as in a hard winter it frequently happens that the frame will require to be kept closed, or almost closed, for several weeks together, the lights being covered with a thick coat of Fern, litter, and mats, and the sides also surrounded with as much litter as will keep out frost. Amongst the first plants that I should recommend for this kind of treatment are the different varieties of *Primula cortusoides*, than which nothing can be more beautiful early in spring; their flowers, which are produced in profusion, vary from white to the deepest lilac, almost approaching crimson; these *Primulas* will live in the open ground in favourable spots, but they never flower so finely as they do when grown in pots; 6-in. or 8-in. pots are large enough for them; they should be well drained, and good loam should be used with a little leaf-mould and sand. The Japanese *Primula* (*P. japonica*) is suitable for associating with them; this, in proportion to the size of the plant, should have plenty of root-room, the soil, too, should be well enriched with rotten manure, and manure water should be applied freely when the plants are in vigorous growth. Thus treated they will make leaves as large as the hand, with flowers proportionately strong; the whole plant, indeed, will be so different from what it is usually seen when confined to small pots with insufficient sustenance, as to assume quite another character. Some of the laced forms of *Polyanthus* will form suitable companions to these, making handsome window plants, as do also the common double white and lilac *Primroses*; different varieties of *Myosotis*, of which *distiflora* is one of the best, also succeed well under similar treatment; the pots for these need not be larger than from 4 in. to 6 in. in diameter. *Hepaticas*, naturally early flowerers, will come into bloom in a cold frame a month or six weeks earlier than in the open ground; the beautiful double blue and pink varieties are two of the best, their flowers lasting long in a cut state. *Dodecatheons* (*American Cowslips*), of which there are several beautiful kinds—white, lilac, and violet—likewise do well in cold frames, and are amongst the most distinct and beautiful flowers which one can possess. *Campanulas*, though not early bloomers, should likewise have a place in this frame of specialities. The elegant drooping *C. fragilis*, both blue and white, are amongst the very best plants that can be grown for a window, blooming, as they do, in such profusion as to almost hide the leaves of their pendent shoots, and, when their principal flowering season is over, still giving a succession, though less in quantity, up to late in the autumn; 6-in. or 7-in. pots are large enough for them. The stately *C. pyramidalis* is a perfect contrast in every way to the foregoing, its flower-spike forming an elegant pyramid, that, when well grown, with plenty of pot room, will attain a height of from 6 ft. to 10 ft.; there is no plant grown that is more effective in a hall or on a staircase, and during the time of its blooming, for several weeks, it will do with less light than most plants. Both the blue and the white varieties should be grown; they require liberal pot-room, say pots from 9 in. to 13 in. in diameter, according to the size which the plants are required to attain. These are biennial, and, if propagated from suckers in spring, or raised from seed, as previously recommended, they will come in most usefully next summer. In the case of these, as well as the other sorts of *Campanula* just named, care should be taken to pick off the capsules as the flowers fade, otherwise they are sometimes liable to communicate decay to the advancing buds; good ordinary loam answers best for them. A few of the better varieties of *Pansies* I would also recommend, but they should consist of the best and most distinctly-coloured show kinds, which are vastly preferable to the magpie-coloured fancy sorts. Although naturally early-flowering plants, when grown in pots they come in some weeks sooner, and, not being exposed to the beating rains and cutting winds of spring, have a fresher appearance than those seen at that season out-of-doors; another advantage is that where the flowers, which are serviceable for cutting, are so required, their stems, when grown in this way, are considerably longer than those of outdoor blooms. As a matter of course, *Violets* should be included, the *Czar* and the *Queen* of *Violets* being two of the best

Culverwell's Telegraph Pea.—Mr. Tillery speaks of this (see p. 484) as a late crop Pea. In order to prevent others from treating it only as such, I write to say that it should be used as a second, or general, crop Pea, coming in, as it does, a little earlier than *Champion* of England. Mr. Tillery further says that its height is from 4 ft. to 5 ft. If well grown, however, its height should be from 5 ft. to 6 ft., and under such conditions the pods, as regards size and quantity, are unequalled.—W. CULVERWELL, *Thorpe Perrow, Bedale*.

for the purpose; they succeed well in ordinary loam, with some manure and leaf-mould; Pansies thrive most satisfactorily in fully one-half vegetable mould mixed with loam; in both cases, enough sand should be added to ensure porosity; 5-in. pots for the Violets, and 7-in. or 8-in. for the Pansies will be found to be sufficiently large. As regards *Dielytra spectabilis* and its white variety, if moderate sized roots are now taken up and placed in 8-in. or 9-in. pots, they will bloom several weeks before those out-of-doors, producing their handsome drooping sprays unscathed by spring frosts. The pendent blooms of this plant are never seen to greater advantage than when hanging from the sides of a vase mixed with other flowers. To these should be added *Scillas* (including *S. sibirica*, *S. bifolia*, *S. campanulata* and its white variety) and *Dog's-tooth Violets* (both white and rose-coloured kinds). *Hyacinths*, *Narcissi*, *Crocuses*, and *Snowdrops*, as a matter of course, should receive attention, as many of them being grown as the frame or frames will hold. The whole of the above plants should be plunged in a bed of ashes inside the frame. Thus managed, they will require less attention in the way of watering, and be much less liable to suffer through the effects of frost, should any mishap occur so as to cause its getting inside the frame, which should stand in a sheltered place, but, above all, thoroughly exposed to the light, and under the full influence of all the sunshine that at this dull season can be got; to still further admit of the solar rays exerting an influence over the growth of the plants, the frame ought to be well raised at the back, so as to make it slope abruptly to the south; 18 in. of straw should be packed round the outside, and kept in its place by stout stakes driven into the ground; dry litter ought also always to be at hand to lay over the glass. In covering frames in winter, I have found it best during severe weather to first lay mats on the glass, then 6 in. of litter or Fern, and another thickness of mats on the top, and if light wooden shutters or light frames, on which have been nailed some ordinary asphalted covering, be laid on the top of all, the whole will be kept dry, which is a great desideratum, as when covering material is dry it wards off double the amount of frost it is capable of doing when wet; by laying mats under the litter in the way described, the glass is kept much cleaner than it otherwise would be—an important matter, as the more light the plants get the better. Air in abundance should be given on all favourable occasions, and care should be taken to keep the ashes in which the pots are plunged as dry as possible. From a frame such as that just described, with the plants fairly attended to, a great deal of pleasure, as well as a good supply of flowers, may be had, that will go far to while away the dreary months until blossoms are more plentiful out-of-doors.

Bedding Plants.—The principal stock of these should now be looked well over, and, if yet in frames, should at once be removed to a house or pit where there is sufficient heating power to protect them from frost and expel damp. Store pots of *Pelargoniums*, *Lobelias*, *Verbenas*, *Ageratums*, and everything of a similar character ought to be from time to time gone over, removing all decayed leaves, or these will quickly affect those that are sound; give just enough water to keep the soil in a healthy state, and the plants growing slowly. On the first appearance of mildew on *Verbenas*, which are very subject to it, dust them over with sulphur. Shrubby *Calceolarius*, cuttings of which were put in some weeks ago as recommended, will now be rooting, and should have more air given them by tilting the lights freely, or drawing them off altogether on mild days, which will make the plants stout and strong—the best preparation for withstanding severe weather. Where *Echeverias* are grown in damp, low localities, they should be wintered in a frame planted as thickly as they will stand; the soil should be kept rather dry, and the frame protected with litter and mats in frosty weather; in the southern parts of the kingdom, they will do in the open ground, but they should occupy a sloping bank in a dry, sheltered position; in both instances this applies to the smaller varieties of the *secunda* section, the large *E. metallica* will require warmer quarters. *Alternantheras*, *Iresines*, and *Coleus* must be kept in a house where there is continuous warmth; from 55° in the night, with 5° or 10° more by day, will be sufficient for them.

IMMORTELES OR EVERLASTINGS.

THE Immortelle (*Helichrysum orientale*) is principally cultivated in warm situations on the shores of the Mediterranean, where it flowers in June, or at the earliest in the end of May. It generally thrives better in barren, dry soil than in that which is rich and fertile. It produces little seed, and, therefore, it has to be propagated by means of cuttings, which are secured in the month of July. These are inserted closely together in well-prepared, shady ground, and afterwards moderately watered. From fifteen to twenty days afterwards, they begin to develop roots and new leaves. In the following spring they are transplanted, after all danger from frost is over. The ground is

prepared for their reception by being dug about 3 in. or 4 in. deep, very little or no manure being added. With a view to getting the plants well established, the flowers are not gathered the first year. In harvesting the crop, the heads are cut off before the buds open, each head containing some twenty flowers; well established plants pro-

The Immortelle (*Helichrysum orientale*)

duce sixty or seventy stalks, and a plantation will continue productive from eight to ten years, the flowers being only gathered once in two years. These flowers dried, and dyed sometimes green, red, and black, are much used on the Continent for crowns and wreaths for the decoration of cemeteries.—M. L.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

November 26.—Getting in another lot of Ashleaf Kidney Potatoes in pots. Making up a hotbed for Asparagus with manure and leaves that had been previously well turned and mixed. Veitch's Autumn Self-protecting Broccoli still in good condition. Planting out the last batch of Coleworts, and stirring the soil amongst those previously planted.

Nov. 27.—Potting herbaceous *Calceolarias*, and fumigating *Cyclamens* to kill green fly. Cutting down Jerusalem Artichoke stems and clearing them away, and covering up a portion of the roots with long litter to keep the frost from them. Adding to late Celery a little more earth whilst the soil is dry and in workable condition.

Nov. 28.—Sowing a three-light frame with Radishes. Potting a quantity of *Echeverias*, and filling a number of boxes with them. Covering up Endive and Lettuce to blanch. Getting all Peach and Nectarine trees unnailed. Finishing tying Raspberry canes and giving a good coat of well-rotted manure between the rows.

Nov. 29.—Sowing 100 pots of French Beans and earthing up those previously started. Clearing out decayed vegetables and dead leaves amongst growing crops. Making up a new hotbed for forcing Asparagus. Rolling lawn tennis ground and other turfed surfaces. Pruning third Black Hamburgh-house.

Nov. 30.—Getting a few more *Cinerarias* and *Primulas* into gentle heat to bring them forward. Giving second early Vinery a top-dressing inside, and afterwards a good watering. Looking over Cauliflowers, turning down leaves where required, and removing those that are most forward to an open shed. Plenty of Pears fit for use just now of the following sorts, viz., *Beurré Diel*, *Beurré Clairgeau*, *Duchesse d'Angoulême*, *Doyenne du Comice*, *Huyshe's Victoria*, and *Broom Park*.

December 1.—Clearing up leaves and otherwise putting the pleasure grounds in order. Rolling down all gravel walks firmly. Looking over fruit-room, and clearing away fruits that are beginning to rot. Looking over Pines, and watering such as require it; tying up fruit where necessary. Fruit in use for dessert—Pines, Grapes, Apples, Pears, Medlars, and Nuts.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

A DESTRUCTIVE SAW-FLY

(*LYDA CLYPEATA*).

A WEEK or two ago (see p. 439) we gave a figure of one of those web-forming, semi-social insects that disfigure and injure our fruit trees, viz., the small lepidopterous species called *Hypnomenota cognatella*. We now figure a similarly-gregarious species belonging to the Hymenopterous Order, and endowed with similar bad qualities. It is one of the saw-flies, called *Lyda clypeata*. During the past summer it occurred in considerable abundance in the neighbourhood of London (Isleworth, &c.), infesting the Thorn and kindred plants. On the Continent it occurs in greater numbers, where it is also said to be sometimes injurious to the Pear tree. Its larva is of an orange-yellow colour, with a black head. The shade of yellow differs in different individuals, being in some a fine maize colour, and in others a dirty straw-yellow. The texture is dull and opaque, which is due to a very fine transverse wrinkling. The larvæ form a small society of from eight to twenty, and spin a small tent at the termination of the branches, as shown in the accompanying

A Destructive Saw-fly (*Lyda clypeata*).:

figure. They become full fed about the middle of August, and then come out of their tent or web, and descend to the ground by the help of a fine thread, like the spiders, and bury themselves in the ground, where they spin a small cocoon, in which they pass the winter. They are transformed into a chrysalis in spring, and into the perfect insect in the month of June. The perfect insect is a small black saw-fly, about the size of the *Hylotoma rosarum*. It is black, with the abdomen marked on each side by from three to six small white spots, and a yellow patch on the scutellum. The base of the antennæ and the legs, as well as a spot on the upper lip, are pale yellow. When their webs are seen on the trees, Boisduval recommends that they should be swept away by coarse besoms and destroyed, a plan that is equally efficacious for the webs and larvæ of the other species of *Hypnomenota*. ANDREW MURRAY.

The Goat Moth (*Cossus ligniperda*).—The ravages of this insect are noted in your number for Nov. 24 (see p. 504), but not their remedy. I have found the following a simple and efficacious check:—At any time during the summer, when the stains which they cause on the bark of trees infested by the caterpillars are more readily observed, and at a greater distance than the offensive smell

declares itself, pour spirits of turpentine into the highest perforation which can be reached, using a handful of moist clay to secure a cap around and under the perforation, to prevent waste of turpentine, and to secure its entering the timber; the insects will soon be driven out, and can be easily destroyed, one by one, as they appear. If the tree has many perforations, I have found it necessary also to cut off with a chisel and light mallet the surrounding bark, under shelter of which a nest of young caterpillars will often be found, and can easily be disposed of. The bark will soon heal over. If the Moth appears the following year on the same tree, repeat the process. In case of trees out of the sight of drives or walks, coal tar, mixed with benzoline, or any animal oil, is perhaps a cheaper remedy, but is necessarily disfiguring. Neither remedy does any injury to the timber. I have used both for several years successfully. Oak and Ash are the only trees I find infested here; but in the neighbourhood of London the Elm suffers most, so far as I have observed.—JOHN J. ROGERS, *Penrose*.

RENOVATING AND IMPROVING THE TURF ON EXHAUSTED LAWNS.

THE chief cause of the wearing out of the Grass on lawns is the continual removal of the produce from it by almost constant mowing and sweeping, and bringing nothing back to supply the waste. No crop could long stand the wear of this system without showing signs of deterioration and exhaustion. Of course, where the land has been well prepared and deepened before being laid down in Grass, the period of exhaustion will be longer in occurring, but come it none the less surely will, unless some assistance be given in the way of top-dressings. There are two principal modes of improving worn-out lawns—one, by taking up the turf, manuring and improving the soil underneath, and relaying it as soon as the work can be properly done; the other, by giving rich top-dressings. The former usually answers best, but much improvement may be effected by top-dressings in February over the surface of the Grass, to be followed by sowing a few fine Grass seeds, and about 2 lb. per acre of white Clover. If the Grass be not much worn, the Clover seeds alone will be sufficient. White Clover is an excellent plant for dry soils, as it roots deeper than most Grasses, and, consequently, maintains its colour and stands drought better, but it will not grow under trees. We are accustomed to look upon earth worms as a nuisance, but, were it not for the annual top-dressing which they gratuitously bestow, the condition of many lawns would be worse than it is. The best way of improving lawns that are worn and weedy is to take the turf up, improve the soil, and re-lay it. If new turf can be easily obtained, free from weeds, a preference should be given to it; but if, in cutting up the old turf, it is cut very thin, most of the weeds, such as Plantains, Daisies, &c., being strong-rooted, will be cut through and perish, as the main part of their roots will be left in the ground. When such work is done before Christmas, the turf, even when cut thin, has plenty of time to get well established before drying weather sets in in summer. As the season advances, and the Grass, from having been closely shorn, loses its first vigour, it is a good plan to remove the collecting-box from the mowing machine, and allow the Grass to be distributed over the surface for a few weeks. It is astonishing how soon the cut Grass withers and disappears, and, if continued for a month or so, it forms such a mulch over the roots of the Grasses as effectually screens them from the blazing sun when drought sets in. There are places in which this plan might be objectionable; but the eyesore is really very little. If the Daisies be numerous, the scattering of the Grass mowings should be deferred till they have exhausted their blooming capacity, or some of the flowers may produce ripe seeds, which will grow and still further increase their numbers. A sprinkling of soot and salt mixed with wood-ashes, will be beneficial as a top-dressing in February or March for all lawns on which the Grass is weakly. Five or six cwt. of salt may be used to the acre with safety; the soot and ashes may be used liberally, and will be most beneficial in strengthening and improving the colour of the Grass. Lawns that are kept in good order are seldom infested with Moss to an injurious extent. Of course, where Moss does become established, it ultimately masters the finer Grasses; but, where the mowing machine and roller are regularly used it seldom gets unsightly. E. HORDAY.

NOTES OF THE WEEK.

Viola Munbyana.—This is likely to prove almost as valuable as *V. cornuta*, probably more so in some soils. I have lately (Nov. 23) seen a large mass of it in good bloom in M. Vilmarin's garden at Verrieres. It has now been in bloom for ten months. Very healthy plantations of the Japanese Primrose, in the same garden, are now throwing up strong flowering stems.—V.

Chamedorea Ernest-Augusti in Bloom.—Examples of this well-known ornamental Palm may now be found in bloom in Messrs. Carters' nursery at Forest Hill. They produce strong forked flower-spikes, 4 ft. or 5 ft. in length, of the brightest crimson colour, conspicuously dotted with dark spots. Associated with the glossy green leafage, these have a striking effect.—S.

Dried Natural Flowers.—Everlasting flowers dried naturally, or dyed to vary their colours, have of late years been much used for decorative purposes; but such flowers as Asters, Chrysanthemums, Pæonies, Roses, Pansies, and Delphiniums have, until lately, escaped such attentions. The other day, however, we had an opportunity of seeing many dozens of bouquets in Messrs. Dixon's nursery at Hackney, ready for sending away, composed of such flowers, which, together with dried Grasses, were very effective, and would, if kept free from damp, last in good preservation for years.

St. Paul's.—We are glad to hear that the efforts which have been made to secure to the people of London the ground round St. Paul's Cathedral have been successful, and that an agreement will shortly be entered into between the Dean and Chapter and the Corporation for this purpose. The contemplated improvements include lowering the railings, remodelling the ground, planting trees, and making the necessary pathways.

Phalænopsids at Chelsea.—There will shortly be a fine display of these beautiful white-flowering Orchids in Messrs. Veitch's nursery. The varieties of *Phalænopsis*, although very beautiful, are, in comparison with other Orchids, but few. As yet no hybrids have been raised amongst them in this country, though many attempts have been made in that direction. Good seeds have been often saved from them, but they have, under all conditions to which they have been subjected, failed to germinate satisfactorily.—S.

A Beautiful New Tree (Phellodendron amurense).—This, a native of Siberia and Mandschouria, is just now a beautiful object in my garden. My specimen of it is about 12 ft. in height, and has a tall pyramidal crown of from 3 ft. to 6 ft. The form of its foliage, which is deeply lobed, gives it a singular appearance, and the colouration of the leaves, which are bright red, is very fine. It is also all the more valuable on account of its keeping its foliage much longer than other deciduous trees, which hereabouts have shed their leaves a fortnight ago. It has a spongy bark, and is called the Siberian Cork-tree.—MAX LEICHTLIN, *Baden Baden*.

Cypripedium Boxalli.—Hundreds of plants of this Lady's slipper will shortly be in bloom in Messrs. Low's nursery at Clapton. It is a free and distinct species, robust in habit, and having hairy leaves and flower-stalks. Its blossoms, which are freely produced, even on small plants, are peculiarly distinct from those of any other species, the upper sepal being pale yellow or green, blotched and spotted with dark purple. When better known, it will, doubtless, be largely cultivated.

Roses and Veronicas in November.—We have here a combination that could hardly be surpassed at this season, for we have been specially favoured in the matter of weather lately, so that I never saw such really good November Roses—in this part of the midlands, at least. The shrubby Veronicas are also strikingly beautiful. Of Blue Gem and Andersoni we have bushes 5 ft. or 6 ft. high, and as much through, full of flower, contrasting with clumps of *Tritoma grandis*, whose grand torch-like heads of bloom shine with nowonted brilliancy this fine sunny autumn; also *Schizostylis coccinea*, and small bushes of the silver variety of the broad-leaved *Enonymus*, combine with flowering Roses, such as *Gloire de Dijon*, *Madame Falcot*, *Xavier Olibo*, *La France*, and *Souvenir de la Malmaison*, to make one forget that it is mid-November.—E. H. W.

Chrysanthemums at Hackney.—The Chrysanthemums in Messrs. Dixon & Co.'s Amburst Nursery, Hackney, have been very fine during the last few weeks, and, although the best of the blooms are now over, there is still a good display. Among the newer kinds now in flower may be mentioned Mrs. Barnes, a Japanese variety, with large lemon-coloured blossoms; Ethel, a pure white one; and Red Gauntlet. The best of the incurved kinds are Princess Teck, a variety with large globular flowers, the petals of which are white tinted with pink; John Salter, and a pink kind named Hero of Stoke Newington. A creamy-yellow form of Mrs. Geo. Rundle is also

much valued on account of its perfectly-formed, handsome blossoms. As fast as the plants go out of bloom they are cut down, in order to induce strong outtings to be emitted from the bottoms, for it is considered one of the most important points in the production of large flowers to get the cuttings in early.—S.

Sweet-scented Odontoglossums.—One of the most sweetly scented of Orchids is *Odontoglossum madrense*, a kind with white flowers, set off by a brown and gold-coloured centre. Its perfume in the morning resembles that of the Hawthorn. It is now in flower in several nurseries about London.—S.

Cypripedium vexillarium.—This is one of the prettiest of the Lady's-slippers. It is the result of a cross between *C. barbatum* and *C. farrieanum*; its lip is brownish-crimson backed up by rich purple-striped sepals and petals.—S.

White Hoop Petticoat Narcissus.—This is now in flower with Mr. P. Barr, and very large and pure white it is. It is a lovely hardy flower, which it is to be hoped will become much less rare in our gardens than it is at present.

Oncidium Rogersi.—Mr. Broome, of St. Peter's Square, Manchester, has sent us some unusually large blooms of this *Oncidium*, which is really a magnificent Orchid, and so free-flowering that some spikes of it are said to have borne as many as 170 flowers. Amongst plants now in bloom it is one of the showiest.

Gift of a Public Park by the Queen.—At a special meeting of the Heywood Local Board it was announced that the Queen had presented to that town 20 acres of land for the purposes of a public park. The money required for the purchase of the land has been set apart by the Queen out of a sum exceeding £10,000 which fell to her as Duchess of Lancaster through the death, without heirs, of Mr. C. M. Newhouse, of Heywood.

Odontoglossum cirrhosum.—Few Orchids have become so abundant in so short a time as this, and, considering its beauty and use for so many purposes, it is satisfactory to know that almost any quantity of it may now be found in all the London nurseries, and hundreds of plants of it are coming into flower at Clapton. It will, no doubt, eventually be largely grown for supplying cut blooms alone, Mr. Wills having already a large number of plants of it devoted to that purpose.

Decorative Plants at Clapton.—Numerous large houses, containing thousands of Heaths and *Bouvardias* of various kinds, each to be brought into bloom for Christmas, may now be seen here. Among the Heaths was noticeable a new form of *Erica hymenalis*, which was sent out two years ago by Messrs. Low. It is named *E. h. superba*, and possesses a freer-growing habit than the old form, and its flowers, which are much larger, are of a bright rose colour. The uniform appearance of the Heaths in this nursery is almost as interesting as the flowers themselves, and the plants, which are remarkably dwarf and bushy, being arranged on flat stages, represent miniature meadows of deep green spray.—S.

Cattleya exoniensis.—A specimen of this *Cattleya*, in Messrs. Veitch's nursery, is now bearing nearly twenty fully-expanded blossoms, and there are many buds yet to open. The flowers, individually, are among the handsomest to be found in the fine genus to which the plant belongs; but, when seen in quantity, as on the plant alluded to, the effect is striking indeed.

"Breeze" as Hothouse Fuel.—We have been for the last four months testing breeze, i.e., washed cinders from furnaces, as a fuel for a saddle boiler. It costs in use less than half as compared with small coal, does not choke the flues, is practically free from sulphur, and holds a steady fire longer than any fuel we have used. This fuel should be better known than it is at present.—F. F.

Summer-Flowering Chrysanthemums.—These belong to the *C. indicum* section, in which one or two are very handsome. The fact alone of their flowering in the open air in June, July, and August, before any of the varieties of *C. sinense* have made their appearance, is sufficient to bring them prominently into notice. *C. indicum nanum* is, without doubt, in every respect the best of this group. It is hardy, of a dwarf, neat habit, being more than 2 ft. high, very free-flowering, and the flowers are of good size and striking in colour. Under glass, the flowers are white, but in the open ground they are tinted with rose at the margins. As a border perennial, I can strongly recommend it for almost any soil or situation; give it plenty of manure when it is planted, and divide annually or increase it by cuttings in the ordinary way. It gets too large and unsightly if left alone for two or three seasons. I find the divided plants to flower much more freely and earlier than those from cuttings, but the blooms are not so good.—A. P.

A WEST INDIAN BOTANIC GARDEN.

CHARLES KINGSLEY, whose pretty house and garden at Ever-sley we engraved in last week's GARDEN, was a passionate lover of flowers, and his descriptions of trees and plants—where they occur—always bear the stamp of keen observation and excellent descriptive power. This is fully seen in many passages in various works, but particularly in "At Last," from which we extract the accompanying passage and illustration:—"But what would—or at least ought to—strike the new comer's eye with most pleasurable surprise, and make him realise into what a new world he has been suddenly translated—even more than the negroes, and the black vultures sitting on roof-ridges, or stalking about in mid-street—are the flowers which show over the walls on each side of the street. In that little garden, not 30 ft. broad, what treasures there are! A tall Palm—whether Palmiste or Oil-palm—has its smooth trunk hung all over with Orchids, tied on with wire. Close to it stands a purple *Dracæna*, such as are put on English dinner-tables in pots: but this one is 20 ft. high; and next to it is that strange tree the *Clavija*, of which the Creoles are justly fond. A single straight stem, 15 ft. high, carries huge

from the great heat and moisture, runs too much to wood. But the roots, especially the different varieties of Yam, were very curious; and their size proved the wonderful food-producing powers of the land when properly cultivated. The road—and all the roads round Port of Spain, thanks to Sir Ralph Woodford, are as good as English roads—runs between the Savannah and the mountain spurs, and past the Botanic Gardens, which are a credit, in more senses than one, to the Governors of the island. For in them, amid trees from every quarter of the globe, and gardens kept up in English fashion, with fountains, too, so necessary in this tropical clime, stood a large "Government House." This house was some years ago destroyed; and the then Governor took refuge in a cottage just outside the garden. A sum of money was voted to rebuild the big house; but the Governors, to their honour, have preferred living in the cottage, adding to it, from time to time, what was necessary for mere comfort; and have given the old gardens to the city, as a public pleasure-ground, kept up at Government expense. This Paradise—for such it is—is somewhat too far from the city; and one passes in it few people save an occasional brown nurse. But when Port of Spain

A Botanic Garden in the West Indies (Port of Spain).

oblong leaves atop, and beneath them, growing out of the stem itself, delicate panicles of little white flowers, fragrant exceedingly. A double blue Pea (*Clitoria Ternatea*, which should be in all our hothouses) and a purple *Bignonia* are scrambling over shrubs and walls. And what is this which hangs over into the road, some 15 ft. in height—long, bare, curving sticks, carrying each at its end a flat blaze of scarlet? What but the *Poinsettia*, paltry scions of which, like the *Dracæna*, adorn out hothouses and dinner-tables. The street is on fire with it all the way up, now in mid-winter; while at the street end opens out a green park, fringed with noble trees all in full leaf; underneath them more pleasant little suburban villas; and behind all, again, a background of steep wooded mountain a thousand feet in height. That is the Savannah, the public park and race-ground; such as neither London nor Paris can boast. The flowers seen at a flower show here were not remarkable, save for the taste shown in their arrangement, till one recollected that they were not brought from hothouses, but grown in mid-winter in the open air. The Roses, of which West Indians are very fond, as they are of all "home," *i. e.*, European, flowers, were not so good as those of Europe. The Rose in Trinidad, though it flowers three times a year, yet,

becomes, as it surely will, a great commercial city, and the slopes of Laventille, Belmont, and St. Ann's, just above the gardens, are studded, as they surely will be, with the villas of rich merchants, then will the generous gift of English Governors be appreciated and used.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Cupressus macrocarpa Submerged.—In the autumn of 1875 I planted a *Cupressus macrocarpa* on a small eyot in the River Barrow. It was submerged that winter, and stood the ordeal well, appearing none the worse the following year. Last winter, though actually from 2 ft. to 3 ft. deep in water for two months continuously, it has, to this day, a beautiful rich green colour, and is growing fast. This tree seems to flourish well in almost all soils.—J. H. W. THOMAS, Belmont Carlow.

The Strawberry Tree (*Arbutus Unedo*).—Both large and small specimens of this handsome evergreen shrub are very effective at this season; viewed simply as an evergreen shrub, it is worthy of a place in even the most select collection, but when covered with large clusters of white pendent flowers intermixed with handsome Strawberry-like fruit, it is especially attractive. It is not planted so largely as it deserves to be, for it will grow almost anywhere, and is especially adapted for sea-side planting. Its contour is improved by just a little shortening back of the long shoots in March.—E. H.

ROSES.

Tea Roses.—The trade done in Tea Roses from France is now nearly at an end, English growers being able to compete, on equal terms, with French raisers. Rose-growing is considered, in favourable seasons, a profitable undertaking. The plants are grown in good sandy loam in pots varying in size from 8 in. to 10 in. in diameter, and some growers have plants in large tubs. The plants are grown in the form of pyramids, by tying the main shoots to an upright stake placed in the centre of each pot. Treated in this way, they have a neat and uniform appearance, and do not take up so much room as bushy plants would do. In spring, when the plants are out of flower, they are potted, if found necessary; but the plants frequently remain in the same pots for several years, unless the drainage becomes defective. Pruning is seldom adopted, except to remove over-luxuriant growths, which are very seldom produced, on account of the quantity of flowers each plant is made to furnish. The best kinds are Niphetos (white), Isabella Sprunt (yellow), and Duchess of Luxemburg (pink). In forcing Roses, market gardeners always avoid subjecting their plants to a high temperature until their bloom-buds are formed, at which period the heat is gradually increased until 65° to 70° is arrived at. Frequent fumigations with tobacco and daily syringings with tepid rain water keep the plants free of insects, and a succession of bloom is obtained for several months from one batch of plants. Each day, when the buds begin to expand, all the plants are gone over, and each bud ready for market has a piece of soft matting tied round its petals to prevent them opening, they are then cut and placed in boxes and sent to market three times a week.—S.

Planting and Pruning Roses.—Now is the best season of the year to plant Roses. When the plants are procured from the nursery it should be stipulated that they are to be lifted with as many roots as possible. Through the carelessness of the workmen employed to take them up, the plants are frequently sent without a root adhering to them, the Erier stock having just the knob at the end of it that it had when dug up out of the wood or hedgerow, and looking like a walking-stick more than anything else. The consequence is that many good plants die before the winter is over; the roots are simply torn off in lifting. Autumn-planted Roses should not be pruned till spring, otherwise they are much more likely to suffer from frost. In planting, wide and deep holes should be made for the roots, unless the border has been recently prepared and enriched, and plenty of good loam given, or, failing that, well-rotted manure mixed with the soil, and afterwards the roots should be well mulched. As regards the pruning of the Rose, the problem is, which is the best season—autumn or spring? Were we sure of a mild winter and a genial spring, autumn would assuredly be the best time; but, should the winter turn out severe, the work might be advantageously left till spring. The danger of waiting till the latter season is that the buds at the points of the shoots, should the weather prove mild, are apt to push, and such growth, being removed at the spring pruning, represents a considerable loss of vigour. On the other hand, Roses pruned in November are also apt to break away too soon and get injured by late frosts. Perhaps the best plan is to wait till the turn of the year, say January or February, and then prune, choosing open mild weather for the work; but, as a rule, all weak varieties or feeble plants may be left till later in the season. I am quite sure that all pruned plants suffer worse from severe frosts than unpruned ones, and this is particularly noticeable in the case of the Rose.—C.

FROM KEW.

THE pearly white, Mistletoe-like berries of *Rhipsalis Cassythæ*, in the Cactus house, claim our attention; they are seated on the blunt, cylindrical, cord-like branches. In the West Indies this Cactaceous plant is an epiphyte, and hangs down from the branches of trees in tufts from 1 ft. to 6 ft. in length. *Astelia Banksii*, from New Zealand, is both in flower and fruit; the branched panicles are half-hidden by the densely-tufted, Sedge-like leaves, and are not at all showy; but the lilac-coloured, berry-like fruits are pretty. The genus *Astelia* belongs to the Natural Order Juncaceæ, and is restricted to the islands of the Southern Ocean. *Crassula lactea* is one of Masson's introductions from the Cape of Good Hope; it is a very close-growing, free-flowering species, and blooms during the winter months. The flowers are white, and a well-grown plant is a very pretty object.

The warmer compartments of the new range contain some very interesting plants. *Aphelandra Porteana* is a handsome species of one of the most beautiful genera included in the large Natural Order Acanthaceæ. The flowers are more brilliant than those of *A.*

aurantiaca, and the leaves are not only larger, but of a much more decided metallic hue. *Dædalacanthus paniculatus* is another Acanthad, of neat, dwarf habit; its pleasing lilac flowers are produced in great abundance. The splendid blue of *Clitorea ternatea*, one of the prettiest of the climbing Legaminoæ, is very striking, and the more so by reason of the blotch of white at the base of the standard. This very fine old plant should certainly be more frequently seen in gardens. The singularly-distorted stems and branches of the gouty-stalked *Jatropha*, *J. podagrica*, together with the large cyme of rich, orange-scarlet flowers, are very curious. The scars of the fallen leaves are large, and are rendered conspicuous by the persistent, fringed, and glandular stipules. This peculiar Euphorbiaceous plant flowers at almost all seasons of the year; but its place is more in the botanic garden or in the stoves of the curious than in general collections of warmhouse plants. It hails from Santa Martha, in New Grenada. Peculiar as are the strange and varied forms assumed by the flowers of many of the tropical Orchids, perhaps none present a more remarkable appearance than those of *Cirrhopetalum Medusæ*; the flowers, taken individually, are small, but are numerous, and two of the three sepals are so very much lengthened as to give the short, dense spike the semblance of a head with very long, diebevelled hair; this induced Dr. Lindley to call the plant the Medusa's-head Orchid; Singapore is its native country. The flowers of the Brazilian *Epidendrum variegatum* emit an odour somewhat like that of the Lily of the Valley. This species is very subject to variation; the Kew plant has sepals and petals marked with reddish-brown blotches on a pale green ground. *Masdevallia polysticta* is a charming species from the temperate region of the Andes of Northern Peru; it is one of Roelz's discoveries. The flowers are white, speckled with purple; and, measuring from the top of the dorsal to that of either lateral sepal, are about 1½ in. in diameter.

The following may be seen in the Palm house—*Aechmea glomerata*, is a handsome plant, very effective at a season when conspicuous plants are somewhat deficient in most stoves. This and many other Bromeliads are of very easy cultivation. The present species has rigid, spinescent foliage, and a stout scape bearing brilliantly coloured, blood-red, branched panicles of large bracts studded with small violet flowers; the rachis is green, tinged with red, and the floriferous branches, with the dense bracts, form broad, ovoid masses. It was first brought to this country (some twelve or fourteen years ago) from Bahia, in Brazil. *Plumbago zeylanica* has white flowers, and is not such a showy plant as either *P. rosea* or *P. capensis*. It has a wide geographical range, extending as far north as 30° N. lat. in the Indian Plains, and as far south as Port Jackson, in Australia. When first received in England, it was treated as a half-hardy shrub. The fresh roots bruised, act as a very severe blistering agent, and Dr. Royle says that the natives of India call it by "all the names of fire." The only European species, *P. europæa*, possesses similar properties, and, though no longer used in medicine, is employed by beggars to cause artificial sores. *Alyxia ruscifolia* is a small shrub with rigid, glossy leaves, and small white flowers, which smell like Jasmine. The pretty red baccate fruits contrast well with the neat, dark green foliage; a well-fruited specimen being extremely ornamental. This plant belongs to the Periwinkle family, Apocynaceæ, and is particularly interesting on account of its berry-like fruit; it grows in tropical Australia, and also in dense woods near Moreton Bay. It will do well in a cool-house. *Pancratium caribæum* is a very handsome white Amaryllid from the West Indies. The corona is formed of the dilated bases of the filaments. *Grinnm ornatum* is another very beautiful member of the same family. A most remarkable fact connected with the geographical distribution of this Order is, that the genera without a corona to the perianth are very rare in Europe and North America, while they abound in South Africa and trans-Equatorial America. G.

Cycas Intermedia.—Cycads generally are prized for conservatory decoration, but few of them are more graceful than this. Its fronds are of a lively green colour, very bright and elegant, and on well established stems attain a length of 7 ft. or 8 ft. We lately saw a specimen in Mr. William's Nursery, at Holloway, which had a stem from 10 ft. to 15 ft. high.—C. S.

Variegated Habrothamnus.—The variegated leaved form of *H. elegans*, though comparatively little grown, makes a good subject for small pots or pans in winter. It possesses a compact habit, and is beautifully variegated with white and green. It succeeds well in an intermediate house.—C.

Christmas Roses.—These are flowering well this year, and I note a curious thing respecting them—that though the season of 1877 has been throughout a month or more behind hand, yet the Christmas Roses of 1877-8 are quite a month or more in advance of the usual time. How is this to be explained?—H. N. ELLACOMBE, *Bitton*.

THE ENGLISH GARDEN SIDE OF THE PETIT TRIANON.

THIS charming little peep of the Petit Trianon well shows the superiority of simplicity and a carpet of Grass, as compared with the very different materials often seen before houses. There are some noble trees among those shown, notably a very fine spreading *Sophora*. The open glade of Grass allows the forms of the trees to be seen and enjoyed, and the effect is charming, especially in spring, when our view was taken. The Grass is somewhat rougher and more tossed in appearance than it really seemed, but that is M. de Bar's fault—artists not liking shaven surfaces.

Tropæolum speciosum, *T. polyphyllum*, and *Philesia buxifolia*.—Allow me to supplement Mr. Miles' notes on these three plants with a few words of caution. He strongly recommends them, and no one who knows them will think his glowing descriptions too strong; but first as regards *T. speciosum*. This is not by any means the easy plant to cultivate that Mr. Miles supposes; I have tried to grow it in every aspect and in every sort of soil, and have failed in all. It is one of those capricious plants that will grow without any trouble in some gardens, but which no amount of labour will induce it to grow in others. My first plant came, many years ago, from Mr. Veitch, of Exeter, and, by his direction, I planted it in a north aspect in soil mixed with a large proportion of dry hedge clippings; but though I never succeeded with it, I still continue to try it. It seems specially to like Scotland. I have seen it at Inverness, and at Bowhill, near Selkirk, but I think I never saw it in greater beauty than I did last year trained up the front of the Police Station at Buckden, at the upper end of Wharfedale in Yorkshire. With *T. polyphyllum* the case is different; I believe that will grow anywhere, and it spreads rapidly. The objection to it is that it goes off immediately after flowering, and in a very untidy manner; it does very well on rock-work. *Philesia buxifolia* is certainly not hardy. I have tried it more than once, but without success, and should not try it again. Mr. Miles thinks it would be hardy, because it comes from the same region as *Escallonia macrantha*, but that is no guide. There are many tropical plants that we can grow out-of-doors, and there are many from temperate regions which we cannot grow. The subject of hardiness is very curious and interesting, but too long for this note.—HENRY N. ELLACOMBE, *Bitton Vicarage, near Bristol*.

Flowers and Fruit of the True Paradise Stock.—This stock, of which so much has been said of recent years, is seldom seen in flower or fruit. The cuts which we now publish (see pp. 514 and 515) were drawn and engraved for us during the present year from specimens kindly furnished by M. Carrière, of the Garden of Plants.

Begonia Frœbeli.—I obtained a packet of seed of this last spring; it was sown in March, and the young plants commenced to bloom in August. They are now one mass of flowers, each measuring over $3\frac{1}{2}$ in. in diameter.—J. CLEWS, *Headfort, Kells*.

THE FRUIT GARDEN.

CULTURE OF THE GRAPE VINE.

It may be said that more than enough has been written on this subject; nevertheless, if we take up a book containing anything about the Vine, it is the first to arrest attention. Grapes are the first fruits that attract the eye in a dessert and the most useful and highly appreciated in a sick room. If only for the benefit of the latter, therefore, Vine culture ought to receive every attention, in order that Grapes may be brought within the reach of everybody.

Site for the Vineries.

The situation in which a Vinery is erected should not be too high, as elevated gravelly subsoils are difficult to keep moist during severe droughts, and a low position must be equally avoided, unless the water can be drained off 2 ft. or more below the bottom of the border, as nothing is more inimical to the successful cultivation of the Vine than stagnant water. A gentle slope to the south is desirable, and it should

be well sheltered from the north and east winds; but the shelter, if of trees, should not be too near the Vineries. In order to produce Grapes by the end of March, April, or May, a lean-to house is most suitable, as it affords the greatest amount of light during the dark months, presenting the whole surface of glass to the south, and maintaining a uniform temperature, which is necessary to insure success in early forcing. In the construction of the roof, no more wood or iron should be used than is necessary to secure strength and durability. The front wall should be built on arches or pillars. The back wall should be plastered and whitewashed. The training wires should be stretched length-

ways, 10 in. apart and 18 in. from the glass; for, if nearer, vigorous-growing shoots are apt to get chilled by coming in contact with the cold glass before it is safe to tie them down. The heating power should be on a liberal scale, so that a sufficiently high temperature can be maintained without overheating the pipes, and which, in the end, is the cheapest, less fuel being required. In an early Vinery 16 ft. wide and 14 ft. high, eight rows of 4-in. pipes are not too many in cold, wet northern counties. Arrange the pipes so as to distribute the heat equally throughout the house, and keep them as far from the floor as circumstances will allow. When placed against a front wall, the heated air ascends direct from the pipes, and, coming in contact with the cold glass roof, loses part of its heat before reaching the top of the house, a fact which explains why Grapes over hot-water pipes are ripe a month before those at the top of the house. As regards ventilation, it is necessary that it should be ample, both at front and top. Early Vineries, in which Grapes are cut in March or April, require every means to be used to keep them cool in summer, and so prevent a second growth in August or September; the front lights should open with a rod and lever, and the angles, instead of

The English garden-side of the Petit Trianon. Drawn by A. de Bar in April, 1877.

being riveted, should have a small bolt or nut, so that when the Vines are at rest the nut can be unscrewed and the lights opened to their full extent. For late Grapes, a span-roofed Vinery, 24 ft. wide and 18 ft. high, answers very well. It should stand north and south; in that way it gets the full benefit of the sun longer than a lean-to house, as the east side gets the morning sun as it rises, and the west side until it sets; besides a span-roofed Vinery contains a larger volume of air than a lean-to one, thus maintaining a more uniform temperature, which is beneficial, not only to the well ripening of both wood and fruit, but as regards the improving the flavour and keeping qualities of the Grapes during the damp, dark autumn months.

Construction of the Border and Planting.

The first consideration in making a Vine border is the drainage, for however great the care afterwards may be, good results cannot be attained if the young roots made in summer are destroyed in winter by ineffective drainage. The character of the drainage must be arranged according to the position of the Vinery. But few situations occur in which Vines derive any benefit by being allowed to run into the subsoil, so that, as a rule, it is safest and cheapest in the end to concrete the bottom, which should have a slope of 1 in. in the foot from the Vinery to the extremity of the border. If the subsoil be damp and retentive, take out the surface soil to the depth of 18 in. or 2 ft., and fill in with refuse brick or stone, covering the whole floor with 4 in. or 5 in. of concrete, and allowing it to get thoroughly dry before introducing the drainage. Run a main drain parallel with the border, 10 in. below the concrete; and to make sure of perfect drainage in case of spouts running over, lay a row of 2-in. drain tiles, at distances of 6 ft. apart, at right angles with the main drain, filling in between with refuse brick or stone, to the depth of 9 in., and finishing off with finer material; over the drainage place fresh turf, with the Grass side downwards. In making borders for Vines, care should be

taken to have them of a permanent character, avoiding rank manures and a too retentive soil, which destroys the active roots in winter, producing long-jointed wood, and shanking the following season. Under good treatment, Vines will continue in a healthy bearing state for a great many years. The best material for borders is a good, strong, fibrous loam, of a calcareous character, with plenty of fibre in it, taken not more than 3 in. deep from an old pasture. First mow off the Grass and stack the thin turves for a month or two previous to using them; although, if the turf be in a dry state, it may be used at once. Fibrous turf, being often difficult to procure, is, however, fortunately not the only material in which Vines can be grown, for fair Grapes may be obtained from Vines in any good ordinary soil, mixed with a few $\frac{1}{2}$ -in. bones, broken brick, or lime rubbish, with rich top-dressings of manure. In forming the border it is a mistake to make it the full width at first, as a great portion of it must be unoccupied with roots for some time, while the fibre is decomposing to no purpose. Make it piecemeal, as every addition throws fresh vigour into the Vines. Get a quantity of waste bricks, according to the size of the border, and break them up similar in size to stones used for macadamising. I prefer broken bricks to lime rubbish, particularly in the case of early forcing, where the borders have

to be kept dry during the months of July and August. The roots, coming in contact with the pieces of brick, throw out rootlets that completely envelop them, and, even if the border be dust dry, I find these rootlets quite fresh, being preserved by the moisture contained in the brick. There is no necessity for going to a great expense for materials, inasmuch as broken bricks, a few $\frac{1}{2}$ -in. bones, and some good fibrous loam, with perfect drainage, are all that is required. Such a mixture is always sweet and lasting. Manures of any kind should always be applied on the surface, the water from rains and otherwise conveying it to the roots by degrees, as required by the Vines, thus keeping the border sweet and healthy. The drainage being complete, let the border extend 5 ft. from the front wall, both inside and out, making, together with the arch, about 11 ft. To every five or six barrowfuls of chopped turf, add one or so of broken bricks, according to the character of the loam; beat all well down, with the back of a four-pronged fork, to the depth of 3 ft., sloping to the front, where there should be a dry wall of single bricks, to keep the materials in their place, and to induce any roots that come in contact with them to throw out laterals or rootlets, and protect them from the weather. Additions of not less than 3 ft. should be made

to the border every year, until it is completed. If the soil surrounding the border be of an unfavourable character, it is best to cut the roots off from it by means of a wall. The following are the best Vines for forcing, to cut in March, April, or May, viz., Black Hamburgh, Foster's Seedling, Madresfield Court, and Muscat of Alexandria. Muscat of Alexandria should be planted at the hottest end, and given less air than the others. Late Grapes, for use in the winter months, should consist of Muscat of Alexandria, Alicante, Lady Downes, Gros Colman, and many other useful varieties might be added. In selecting Vines for planting, those that are one year old are perhaps the best in the hands of the inexperienced; and, to make sure of being free from the Phylloxera, it is best for all growers to raise their own Vines. I prefer Vines raised from eyes in spring, on the turf system, as they are easily transplanted,

without interrupting the growth. At pruning time, select the best ripened short-jointed prunings with plump eyes, tie them in a bundle, label them and lay them in the soil by the heels, in a cool greenhouse, until, say the beginning of February. In preparing the eyes, cut the shoots with a sharp knife into lengths of 2 in., the eye being in the centre; cut away the wood on the upper side within a $\frac{1}{4}$ in. from the eye, in a slanting direction. Cut rather more than the number required of fibrous turves, 6 in. square and 2 in. thick. Cut a niche in the centre, and place in it the eye, covering it over with fine soil, and packing the turves closely together on slates; then give a gentle watering with tepid water, and place them on a bottom heat of from 70° to 75°, with a moist atmospheric temperature of from 60° to 62° at night, and from 70° to 75° in the daytime, with plenty of light. When started in a low temperature, the buds lose vitality, which weakens the growth. As soon as the roots begin to show themselves through the sides of the turf, prepare for a shift, by cutting double the number of turves you require, 12 in. square, and 2 in. thick, placing one on the other, on separate slates, and cutting the centre out of the uppermost 6 in. square. Select the most promising young Vines, and carefully place them in the turf, which should fit exactly, cutting off first, with a sharp knife, the

Flower of the true Paradise Stock. Drawn from nature, and engraved by A. Thiebault.

points of the strong roots round the edges of the turf, an operation which causes them to throw out more lateral roots and strengthens the growth of the weaker rootlets, closing the union with a little fine soil; then give a gentle watering and replace them in bottom-heat, which must be maintained. Give ventilation only when the weather is favourable, and, if all goes well, they will be ready for planting out in a month or six weeks. The border being ready, a hillock, 5 in. or 6 in. higher than the intended position at which the Vines should stand, should be made against the front wall of the house, to allow for subsiding. This keeps the collar of the roots well up, and allows plenty of room for top-dressing. Vines should never be allowed to root up the stem through earthing them up. Being on separate slates, the plants may be carried and placed in their positions on the slates, slipping them from under the Vines without the least check, and filling up with the compost. Give a gentle watering, and tie each plant to a small stake, until it has reached the wires. If it be intended to grow plants beneath the Vines, they should be planted 3 ft. 6 in. apart, but if for Vines only, 2 ft. 6 in. After planting, cover the borders with half-rotten stable manure to the depth of 3 in. or 4 in;

this protects the surface, and water carries down the manurial properties into the border. The Vines being planted, the chief object is to obtain the largest possible amount of well-ripened wood and roots. On these depend future productions. Keep the day temperature at from 70° or 75°, or 5° more with sun-heat, and from 60° to 65° at night, paying strict attention to ventilation, and shutting up early in the afternoon. Sprinkle every part of the floor and inside border with water. Tie the leading shoots to the wires, allowing the laterals to grow freely; and, if any should take the lead, pinch out the centre, so as to keep

them equally balanced, allowing them to cover every inch of the roof. In proportion to the foliage which the house contains will be the number of roots in the border. When they reach the top of the house, train them down the other side, *i.e.*, if the house be span-roofed; but, if a lean-to, train them on the back wall. It is frequently the case that fruiting pot Vines are placed between the permanent ones, but this, in the long run, is no saving. Watering with tepid water must be regularly attended to as the Vines get into rapid growth. When the house gets well filled with foliage and the wood begins to ripen, admit air freely, and, to some extent, withhold moisture. To prevent red spider, mix sulphur with milk, and paint it on the hot pipes; take care to keep the foliage healthy until the wood gets brown and solid, when the ventilators may be opened to their full extent. As soon as the leaves are down, prune at once, heading the Vines back to a foot or so below the rafters, as the buds at the base rarely break if the shoot be left long. When the wounds are dried up, rub a little painter's knotting over them, young Vines being liable to bleed. Cover the outside border with litter and wooden shutters to protect the roots from rain and

frost, keeping the inside cool until the time to start again has returned. In the case of late Grapes, the Vines should be allowed to break into growth without fire-heat, which they generally do about the end of April; but, if for early fruit, close the Vinery the first week in February. Wash the glass and wood-work with soft soap and water; whitewash the walls with new slacked lime mixed with a handful of sulphur; paint the wires with white lead and turpentine, or as a substitute paraffin; in fact, it is the best plan to give a coat of paint inside every year at starting time, an operation which both destroys the eggs of insects, and preserves the wood. All the spent manure on the surface of the borders, both inside and out, must be carefully taken off when the Vines are started into growth, removing all the loose bricks against the front of the borders, and any roots tending downwards must be reversed. Then add 3 ft. more to the border, replace the loose bricks, and over the whole spread 3 in. of half-rotten manure, with 8 in. or 10 in. of litter, covered with wooden shutters. Commence with fire-heat the last week in February, syringing the Vines three times a day, and filling the evaporating pans. Maintain a night temperature of from

45° to 50°, and in the daytime from 55° to 60°, according to the state of the weather. As the growth begins to push, the temperature may be increased, and the same attention in every way paid, as directed for the first season. At the end of April remove the shutters and litter from the outside border, only leaving the manure. Pay every attention to watering the inside border, as the Vines will grow rapidly this season, and any check from over dryness should be prevented, it being almost impossible to give a young growing Vine too much water, if the border be well drained. When the leading shoots get half up the rafter, pinch out the centre

Fruit of the true Paradise Stock. Drawn from nature, and engraved by A. Thiebault.

and also the top of the laterals, allowing the others to grow until the leading bud breaks again, when the laterals may be pinched to three leaves. This strengthens the buds at the lower part of the Vine, which are to bear fruit next season. Allow the leader to grow to the top, where it should be stopped, thus causing the rod to thicken and the buds to swell. Allow the laterals to grow freely, as they encourage root action; if the season should be very dry, see that the outside borders receive plenty of water. As the wood begins to ripen, give more air and less moisture, cutting the laterals to one leaf, which plumps up the buds. Keep down red spider, and proceed as previously directed.

Third Season.

It will now be necessary to say a few words with regard to temperature, as the next is the first fruiting season, and, with respect to heating, considerable latitude must be allowed, as the cultivator must be regulated by certain conditions as regards weather. In early forcing a vast amount of injury has been done to Vines by keeping the night temperature too high. Vegetable life, as well as animal life, requires

rest at night, to fit it for work next day. Always, therefore, avoid exciting influences in the absence of light; true, shoots will lengthen as much by night as by day; but no new material is added, the result being merely an extension of tissue formed during the day. I have repeatedly had early Muscats at 55° at night, when in full bloom, setting as freely as Hamburgs. This, no doubt, may be attributed to the vigorous growth obtained under a low night temperature, with a rise as early as possible in the daytime to the usual height. The details of treatment for the third season will be equally applicable to subsequent years. Let us suppose the Vinery closed the first week in January. Wash and clean according to former instructions. Scrape off the loose bark, and paint the canes with Fowler's Insecticide, in the proportion of four ounces to the gallon of water; and, in order to induce the regular breaking of the buds, tie the points of the Vines down to the border, and carefully clear off all the spent manure, if any be left, as it is liable to generate fungi. If any roots should have run into the manure, comb it out with the fingers, covering the roots with fresh loam. Add a second 3-ft. addition to the front of the border, and cover as directed for the last season, enclosing the natural summer's heat, preserving the surface roots, and encouraging an upward tendency. Apply fire-heat the last week in January; give a gentle watering at 75° to moisten the surface, and five or six days afterwards give a thorough watering to moisten the border throughout, maintaining a night temperature of from 50° to 55°, raising it 5° or 10° with sun-heat in the daytime, until the buds begin to swell, when it may be raised gradually from 60° to 65° at night, according to the severity of the weather, with 70° in the daytime, or with sun to 85° or more. It is opposed to Nature in early forcing to open the ventilators and let sun-heat out and cold air in; always supply moisture according to the weather. As the Vines come into leaf, cease, by degrees, filling the evaporating pans, so that all may be empty by the time they come into bloom. Damping in the morning may be dispensed with until about ten o'clock, when each Vine should be given a sharp tap with the hand on the main stem in order to disperse the pollen; then damp every part of the floor and walls to produce a genial growing atmosphere. On dark, dull, cold days, keep the temperature low, with less moisture, and make up for the loss on bright days by running the temperature up to 85° or 90° with sun-heat. This produces short-jointed wood, clean foliage, and plenty of substance, an important item in finishing off the fruit satisfactorily and in preparing the Vines for a full crop next year. Never use a syringe after the buds have broken, for, however clear the water may be, it always damages the bloom, which is so highly appreciated. I have an early Vinery 56 ft. long, in which I commenced to cut the third week in April, and it has not an evaporating pan in it, nor is the syringe used from the time when the Vines begin to push until the Grapes are ripe, and this Vinery always produces the heaviest crop, and the foliage is freer from insects and warted leaves than that in any other house. Keep the fire-heat up when the sun shines until April, and, as the sun gets more powerful, more air is required. Give ventilation whenever the weather is favourable, and, as soon as the Grapes are fairly set, give a good watering to the inside border at 75°, and keep the atmosphere in a good growing condition. Early forcing cannot be carried out successfully by dry rules; the cultivator must adapt his practice according to circumstances and the condition of the weather.

Disbudding and Thinning.

In disbudding, leave the side shoots of young Vines from 12 in. to 15 in. apart. Stop the fruit-bearing shoots two leaves above the bunch, and, if a growth shows more than one bunch, pinch the worst off. The Vine being pruned back to one third its length, should not be allowed to carry more than four bunches, which are generally large in the case of young Vines, weighing from two to three pounds or more according to the variety. No bunch should be left on the leading shoot, which must not be stopped until it has reached the top of the house; pinch the laterals to one or two leaves, always keeping the strongest the most pinched in, as it throws more strength into the weakest, and maintains an equal balance of growth. Allow

every leaf plenty of room to expand, a great number of large well developed leaves, being much better than a large quantity in a crowded state. Take care to tie in the young shoots by degrees, merely keeping the points from touching the glass, until the young growths get matured, as they are apt to snap off from the main stem, leaving a blank on the Vine that is not easily repaired. As soon as the shoots are hidden underneath the wires, thin the bunches to the number directed, except in the case of "shy setters," which are better left until they are set, as the strongest shoots and bunches are apt to set the worst. It is recommended by a great many Vine cultivators to commence thinning the berries as soon as they have attained the size of a pin's head, but I never found any advantage to occur from doing so. I prefer allowing them to attain the size of early Peas, when it is easily perceived which berries are taking the lead, and when the bunches can be thinned finally at once, which is preferable to going over them a second time. To keep the bloom in perfection and the bunch compact, the less the berries are handled the better. With a light wooden peg in the left hand, and a pair of clean Grape scissors in the right, the operator should begin at the bottom and work to the top, easing the shoulders with the peg, and thinning out all the small and innermost berries, being careful not to rub them with either the peg or scissors. More than half of the berries, as a rule, require cutting out, leaving plenty of room for those left to swell; but discretion must be used in accordance with the variety. Sufficient, however, must be left to make a compact bunch when finished, as nothing looks worse than a bunch of Grapes, when laid on a dessert dish, spreading all over it. It should lie as compact in shape as when growing on the Vine. About the first week in June, the Grapes will commence their second swelling, and the inside border must have a thorough watering with weak liquid manure at about 75°. As the fruit begins to colour, give more air by degrees and less moisture, until it is ripe, when plenty of ventilation and a cool, uniform temperature will be all that are required. Next year the Vinery may be shut up on the 1st of January; in the season after that, on the 1st December; and the next after that, the first week in November, when the Grapes will ripen in April. This is the earliest period at which Vines should be started, for, after being forced two or three seasons, they may be had ripe by the third week in March. About the middle of February give the inside border a good watering with weak liquid manure at 75°, as the fruit commences its second swelling, and in ten days or so it will begin to colour, and swell more rapidly than at any other time. Open the front ventilators a little on every favourable opportunity; it keeps the air in motion, retaining both heat and moisture, which, if ventilated at top, would escape, rendering necessary more fire-heat, which creates a parched atmosphere, thus checking growth and rendering the foliage more liable to red spider. As soon as the Grapes are ripe, take the shutters and half the litter off the outside border, and when the fruit has been all cleared out give the inside a good watering with weak liquid manure to encourage growth and plump up the buds. Maintain a growing atmosphere for a month or so, as it prolongs the growth and preserves the buds from breaking in the autumn. Remove the remaining half of the litter carefully, as the roots will, no doubt, have run into it; if so, comb it out with the fingers, and cover the roots with two or three inches of fresh loam, and the same with half-rotted manure. The Vines being in full leaf, the roots will take hold of the loam at once, and accumulate vigour for future crops, keeping them from pushing into growth in August and September. This is the most difficult part with which an inexperienced hand at very early forcing will have to contend; for, if care be not taken, every bud on the Vine will push into growth if ripened in March; whereas, if not ripened before the middle of April, they will merely push a few of the terminal buds, which should be rubbed off as fast as they grow, for if allowed to go on they weaken the Vines for the following season. If inclement weather occurs in the early part of July, put the shutters on the outside border (placing a brick on edge at each end) to protect the border from rain, and at the same time to admit a free circulation of air, which keeps the roots dry and quiet. About the middle or end of September, according to the state of the weather, take off the shut-

ters, and remove the bricks. If leaves be plentiful, but not ready until the end of October, put on 6 in. of litter, covering it with the shutters, to preserve the sun-heat in the border; but when the leaves are ready, and in a dry state, push the litter into a row at each end of the border, and fill in between to the depth of 15 in. with the dry leaves; then cover with the shutters; the litter at each end will prevent the leaves from blowing about, and will keep in the natural heat of the summer. Late Grapes require the same treatment as early ones, as far as regards temperature, but as little fire-heat as possible should be used. Ventilate early and close in early the sun's heat in the afternoon, as nothing invigorates Vines so much as such treatment. In wet, cold seasons a little fire-heat is beneficial, particularly in regard to finishing off the fruit, and ripening the wood, as well as keeping the Grapes.

Pot Vines.

There is not now the same necessity for these as there used to be, as summer Grapes can now be kept so late. Still, they are useful to bring in before the permanent Vines, in March and April, and they are also very useful when Vine-borders

RUST.—This is scarcely a disease, though a disfigurement. It is generally caused by over-heating the pipes, or sulphur left on them from the previous season, or cold draughts when the berries are setting.

WARTS OR EXCRESCENCES.—These occur on the undersides of the leaves; some contend that they do no harm, but I prefer being without them, as the leaves cup and are arrested in their growth. They are caused by the atmosphere being over-charged with moisture and by insufficient ventilation.

SCALDING.—To this some Grapes are more subject than others; it occurs at stoning time. Early ventilation and a cool atmosphere are the best preventives.

INSECTS.—The most formidable insect that attacks the Vine is the Phylloxera, and the best preventive in my opinion is raising one's own Vines.

RED SPIDER.—This, if neglected, soon spreads all over a house, destroying the foliage and weakening the Vines. A want of root action and a dry atmosphere encourages it; in guarding against it, cleanliness, and painting the hot pipes with sulphur

The large-leaved Panicum (*P. plicatum*).

have to be removed, or for placing at the end of a stove or warm greenhouse in summer. Their cultivation differs in no way from that for permanent Vines, except that they should stand on a bed of leaves, or bark, which furnishes a gentle moist heat, and after the pots get well filled with roots, they should be fed freely with weak liquid manure.

Diseases and Insects.

MILDEW.—Vines are liable to both diseases and insects, and in both cases prevention is better than cure. Mildew is a very destructive disease if neglected. In our heavy soil we have never the least signs of it, although in light soil I have seen it affect Vines badly. Painting the hot-water pipes with fresh slacked lime and sulphur soon destroys it; the best preventive is well-drained borders and a sweet healthy atmosphere.

SHANKING.—This is another disease which often causes disappointment at the finish, as it attacks the stalks of the berries as the fruit begins to colour, arresting the ripening, and eventually causing the berries to drop off. In some cases it is caused by the roots being in an uncongenial soil, or getting into a wet subsoil, to prevent which I always prefer concreting the bottom of the border. A good preventive is well ripening both wood and roots, thus preventing rank growth, the fruit on which is most liable to shank.

and milk, or with new slacked lime is best, but such mixtures are difficult to clean off the pipes.

MEALY BUG AND THRIPS.—These are often introduced into Vineries through growing plants in them, and if once they get a footing they are difficult to get rid of until the foliage drops. If the bug get into the bunches, take a light peg, with a small piece of sponge tied to the end of it, dip it in spirits of turpentine, and merely touch the insect; this will destroy it.

Waterdale, St. Helens, Lancashire.

J. SMITH.

THE LARGE LEAVED PANICUM (*P. PLICATUM*).

THIS, like many other of the more ornamental forms of Grasses, has come much into favour of late years for mixing with flowering plants in stoves and conservatories; to have it in perfection it requires some warmth, especially in winter. Although it will live and thrive out-of-doors in a warm summer, it will be found to be most generally useful grown as a specimen plant in a pot. It is of the easiest possible culture, succeeding well in any kind of soil that is sufficiently porous to allow water to pass freely through it, and with water it must be plentifully supplied, as from its free rooting character it naturally needs a fairly moist soil. It may be increased by division.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Ground Work.—I would urge the necessity of no time being lost in getting on with any new work or alterations in shrubberies and pleasure grounds that may be contemplated. Where everything of this sort can be finished before the close of the year, it makes a full season difference in the growth that trees and shrubs make that are thus early planted, over others that are put in late in the spring after a protracted winter's frost. Undoubtedly, the best time for planting evergreens is considerably past, yet, with young stock that has been well prepared for removal by frequent transplantings, such as are usual in the best nurseries, there need be no hesitation; but, in the case of large evergreen shrubs, especially Hollies, that have stood for many years without removal or preparation by their principal roots being shortened back within the last twelve months, I should recommend their not being moved until the spring is considerably advanced, or, still better, as soon as may be after the middle of the ensuing August. No doubt large shrubs can be, and are, frequently moved under the most adverse conditions as to time, without any preparation, and, in time, recover from the effects of the severe ordeal to which they are thus subjected; but, under such treatment, immense numbers die outright, or remain for years in a stunted state. In the case of all trees and shrubs that have already been moved, they should be gone over to see that their supports are efficient—the recent storms which we have had will show any defects in this matter, and, if not at once remedied, the roots will be seriously injured. Where new lawns, bowling greens, or croquet grounds have to be made, or worn-out turf replaced on those already in existence, if such work be carried out forthwith, instead of being deferred until spring, the result will be immeasurably more satisfactory, and the labour involved less. Where turf-laying is deferred until late in the spring (as it must needs be in the case of a severe winter), no matter how much attention may be given it, the Grass never looks well the first summer, and all the beating and rolling that it is possible to give in a dry season will not prevent the unsightly openings that become apparent where the turves are jointed together. Wherever new gravel has to be laid on to any great extent, now, when the leaves are all fallen, and comparatively little sweeping will be required through the winter, is the best time to do it. It may be urged that by deferring it until spring, it will have a fresher appearance through the summer; but, as against this, spring, with its numberless calls in any garden large or small, furnishes matters enough that demand attention, without the interference of works of a permanent kind. In respect to gravel walks, I would again urge that however good the quality of the gravel, in both texture and colour, may be, it will never look well long, or be comfortable to walk upon in wet weather, unless the under drainage be efficient.

Herbaceous Borders.—Where anything like a good assortment of herbaceous plants is grown, it is essential, except in the most favoured localities, to afford some slight protection to many of them, for, although they may not be killed outright in our severest winters, still it often happens that they are injured to an extent which has a weakening influence. The old flower-stems of all that are decayed, for mere appearance sake, should be partially cut away, but in thus denuding them of their tops it is well to bear in mind that we deprive them of the ability to protect themselves, as those dead stems not only have a considerable influence in warding off frost from the crowns and buds already formed for next year's growth, and which lay thickly immediately below the surface, but, being often hollow, when cut away they at once act as receptacles for water, holding it in a position in which it is most likely to be injurious. For these reasons it is well to sacrifice something in appearance, and not cut away these decayed stems so close as is usually done. As regards protecting material, there is nothing more effectual than the leaves of deciduous trees, especially those of a hard nature, such as those of Beech and Oak; but, where these are used, to avoid the continuous litter they make by being blown about, they should have a thin layer of half-decomposed stable litter scattered over them. This will retain them in their places and keep the plants snug for the winter; moreover, the fertilizing elements from the manure will be washed down into the soil, and in this way invigorate the plants. Early in spring the whole of this covering should be forked into the ground a few inches deep, without disturbing the roots. Where leaves are not to be had, Fern, or where procurable, Furze, cut in small pieces and strewed over the ground is one of the best materials that can be used for protective purposes. These failing, it is necessary to resort to ordinary litter, but where this is employed it should be thrown together in a heap for a few days to partially ferment, in the same way as if intended for hotbed making. By this treatment it acquires a dark colour, thus doing away with the objectionable straw-like appearance which it has when used quite fresh; a

couple of inches of such material laid over all bulbs will be an advantage to them.

Frames.—Carnations, Picotees, and summer-struck Phloxes, and Pentstemons should have the lights kept completely off them except during severe frost, or when extremely wet, as it is not well to let the soil get saturated, for if it becomes frozen in that condition the roots are more liable to get injured, hence it will be obvious that the drier the soil is when severe frost occurs the better.

Kitchen Garden.—Where Rhubarb is required early, some roots of it should now be put into a little warmth; this is requisite, as it will not come on so soon with mere protection in the way that it will when we get some weeks into the new year; if the roots for forcing were dug as soon as the leaves were decayed, they will push up with the application of less artificial warmth than if got up at the time when they are wanted to be put in for forcing. A bed of leaves, similar to that which has been recommended for Seakale, will answer well for the Rhubarb; the objection to forcing Rhubarb in a Mushroom house—although often practised—is that the fumes given off by the fermenting manure always communicate a disagreeable flavour to it. A little more Seakale should be put in; it is much better to start as much as will be required once a fortnight or three weeks, than to put in more at one time, as if the produce be not used when ready it gets long and tough. Where any weeds have sprung up amongst winter Spinach, Onions, Lettuce, and Endive, these should be removed by hand, the ground being too wet now to effect their destruction by hoeing; as even if cut with the hoe and allowed to remain, they very soon take root-hold again; but, after this hand-weeding, it will be an advantage to hoe the surface over, selecting a dry day for the purpose.

Cabbages.—The earliest planted should have the soil drawn close up to their stems as high as the under leaves; this is the more necessary where the action of the wind has loosened the plants, the effect of which is, that if left in this state and the soil becomes congealed by frost, the stems chafe against the frost-hardened soil, and in this way they get killed. Half the losses that are experienced with young Cabbages during severe winters arise through this cause.

Winter Spinach.—Where the plants of this are too close in the rows, they should be immediately thinned out to something like 4 in. apart; if allowed to remain too much crowded, they are naturally weakened thereby, and get destroyed if a severe winter ensues. It is well to bear in mind that it is now advisable to take every precaution to insure the well-being of all winter and spring crops; the more than usually wet, mild weather which we have had has kept everything in a soft-growing state up to the present time, rendering them more than ordinarily susceptible to destruction, should we have a hard winter.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

December 3.—Getting shelves in early Peach-house filled with Keen's Seeding Strawberries. Cutting down old trees, grubbing up their roots, and trenching the ground ready for large specimens. Washing Vinery lights ready for painting. Finishing pruning, and nailing Plums and Cherries on north walls.

Dec. 4.—Cutting all the bunches of Grapes in the Mrs. Pince house, and putting their stems in bottles in the Grape-room. Giving early Peach-house a good watering. Covering up a small piece of Parsnips to keep the frost out. Moving large shrubs from nursery to pleasure grounds. Getting another bed of Seakale covered up with pots. Getting all prunings and rubbish burned up.

Dec. 5.—Looking over all seed Potatoes and removing any that are going bad. Tying mats ready for covering. Making labels and pegs. Cutting shreds, and pointing nails. Sorting Peas. Cleaning seeds. Looking over Onion store, and removing any that are bad.

Dec. 6.—Sowing Mustard and Cress. Getting a few more Hyacinths into gentle heat to get them forward. Commencing pruning and nailing Pears on east and west walls. Getting some large Apple and Pear trees, growing too grossly, root-pruned. Getting manure on to land whilst the weather is favourable.

Dec. 7.—Putting in 100 pots of French Beans. Making a new Mushroom bed. Clearing up flower-borders, forking them up, and planting them with bulbs and spring flowers. Pruning Gooseberry and Currant bushes. Turning up together leaves and long manure for hotbeds. Getting on with deep trenching as fast as the weather will permit. Looking over all the Pines, and giving them a little water where required.

Dec. 8.—Looking over Grapes in bottles, taking out any bad berries, and filling up the bottles with water where required. Looking over fruit-room and removing all fruit that is beginning to rot. Fruit in use for dessert—Pines, Grapes, Pears, Apples, Medlars, and Nuts.

THE INDOOR GARDEN.

CHIRITA SINENSIS.

THIS is an evergreen, herbaceous, Chinese Gesnerad, the leaves of which spread not unlike those of a Gloxinia; the flowers, which are blue, are also somewhat similar in shape to those of a Gloxinia, but they are produced in bunches on the extremities of erect stalks, that rise well above the foliage, and, as these are thrown up freely, the plant has a very effective appearance. It blooms in summer, and is a useful subject for conservatory decoration. It thrives well in a mixture of peat and loam, to which has been added a little leaf-mould and sand; when in active growth it must not be allowed to want for water, or the advancing flowers will be injured. After blooming it should be kept somewhat drier at the root, but, owing to its evergreen character, it must not be allowed to get so dry as to cause the leaves to flag. It does best in a moderate temperature. There

Chirita sinensis.

is also a variegated form of this plant, the leaves of which are handsomely marked. B.

WINTERING BEDDING PLANTS.

I NEVER had bedding plants in better condition at this time of the year than I have them now, and I never had plants that were less coddled. With the exception of a few odds and ends, all our stock of these plants are in boxes 2½ ft. long, 1 ft. wide, and 3 in. deep. Each box has six holes in the bottom, large enough to put the finger through. In the second week in August, a piece of crock was put over each of these holes; the boxes were filled with a mixture of loam, leaf-soil, and sand, and then about fifty cuttings were put into each. As soon as the cuttings were put in, each box was watered and set outside, fully exposed to sun and air. Here they remained until the middle of October, when they were shifted into a Vinery, from which the Grapes were just cut, and there they are now. Through being so much exposed to the air, the plants are not drawn up; on the contrary, every one of them is dwarf and bushy, and although there are thousands of them, there is not a single blank amongst them, and no dead leaves have yet been gathered from them. A little artificial heat is admitted two or three times a week, and the top and bottom ventilators are open night and day, unless it is extremely cold. They are not watered oftener than once a week, sometimes not so often. It is not the hardiest of green-leaved Pelargoniums that are thus treated, but many choice variegated ones as well. Alternantheras are often found to winter badly; hundreds of them were put in boxes like the Pelargoniums; they were rooted in a close frame, and then hardened off. They are now along with the Pelargoniums, and so luxuriant that not a particle of soil can be seen, looking down through the plants, and they are so

bushy that the little branches are hanging over the sides of the boxes. Mesembryanthemum cordifolium is equally healthy under the same treatment, and so are the different kinds of Iresines. I attribute all this chiefly to growing them hardy at first, and afterwards not putting them into any close place to make them tender before the winter had set in. Last year most of our Pelargoniums were rooted and wintered in small pots, and it took four times as much space to accommodate the same number of plants in that way as in the boxes, and I find that they keep much better in the latter than in pots. In March the Pelargoniums will be potted into small pots, and the Alternantheras given more room in the boxes in which they are now growing. CAMBRIAN.

Lycopods on Tree Stumps.—Pyramids of Lycopods are usually made by placing pans or flower-pots of different sizes one above the other, but good effects in this way may also be obtained by procuring good big stems of dead Trees. Ferns, or of other trees which have a loose bark that will hold moisture. They should be potted, a small pan being secured on the top of the stump in which to plant the Lycopod; the margin left between the pot and the stump may be planted with Ferns, and a plant of the graceful *Nephrolepis exaltata* may be placed in the middle of the pan; on the top any of the free-growing Selaginellas may be employed in this way, or Ferns with creeping rhizomes may be used with excellent effect.—S.

Bouvardias Planted Out.—By planting out Bouvardias during summer in good, rich garden soil, and keeping them well supplied with weak liquid manure, much better plants can be obtained for winter-blooming than by growing them in pots. In the Pine-apple Nursery we lately saw a large house full of plants which had been thus treated, and which will soon make a fine display. They were struck in February, planted out in June for the summer's growth, and potted up during the first week in September; they were then placed in a cold frame for a few weeks until re-established, when they were removed to a lean-to house, where a little heat can be given them to assist in opening their flowers. All the varieties may be treated in this way with the best results.

Stephanotis as a Basket-plant.—Among the many plants used for conservatory baskets, the *Stephanotis* is seldom or never employed in that way. It has, however, occurred to me that it might be made one of the best of basket-plants. It would, in the first place, be necessary to obtain plants of it with several good shoots rising from the bottom; these must be trained up stakes inserted in the pot, for the plants would perhaps be best grown in pots until they began to flower, when they could be set in the baskets. In order to insure the plants flowering freely, the wood must be thoroughly ripened by being exposed to sun and air during the summer-time, either near the glass in a cool house, or trained on a south wall out-of-doors. The baskets in which they are to be placed should be prepared previously by having a pot, of the same size as that in which the *Stephanotis* is grown, placed in the centre. This should be packed round with lumpy peat and Sphagnum, and planted with Ferns and Lycopods, so as to hide the outside of the baskets. When all is ready, the empty pot can be replaced by the one in which the plant is growing. The branches of the *Stephanotis* might be arranged so as to droop equally all round the sides; and, when in full bloom, plants thus treated would have a striking effect in a moderately warm conservatory, where they would last in beauty for a long time. I have never seen the *Stephanotis* tried in this way, but I see no reason why it should not succeed.—S.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Hibiscus Lambertii.—This is one of the most useful of winter-flowering stove plants; it has large, deep green leaves, and brilliant scarlet double blossoms, which are very valuable in a cut state.—S.

Fern-leaved Capania (C. filicifolia).—This is one of the best green-leaved plants for dinner-table decoration that can be grown. Its fronds are large, graceful, and spreading; and, although bushy plants of it cannot be obtained, straggly plants, cut closely down, will throw up an upright shoot, and thus make handsome specimens.

Standard Epacris.—These are seldom met with, but grown in this way, Epacris when in flower have an attractive appearance. We lately saw some in the Exotic Nursery, Chelsea; they had upright stems 18 in. in height, and large bushy heads. When once formed, they require no other training or tying, and when in flower the branches quite droop under the weight of blossoms which they produce. When used for vases or table decoration, for which they are very suitable, the surface of the pots should be hidden by mixing a few Ferns with small flowering bulbs, such as Lily of the Valley, Squills, &c., or cut flowers might be used for the same purpose.—S.

PLATE CII.

CHINESE PINKS—EASTERN QUEEN AND CRIMSON BELLE.

Drawn by H. NOEL HUMPHREYS.

DURING the past autumn, Messrs. Carter, of Holborn, sent us some beautiful Chinese or Japanese Pinks, plants which, in such forms as we figure, well deserve culture. Mr. Noel Humphreys succeeded in catching some of their beauty for us, and the plate we now publish, after his water colour drawing, will give some idea of their charms. It is, however, even with this aid, very difficult to give an idea of the singular beauty of colour in the form with the flakes across the petal. As regards their production, Mr. Robert Gardiner, Messrs. Carters' manager at St. Osyth, writes to us as follows:—Many years ago I took great interest in the cultivation of *Dianthus Heddwigi* as a charming flower worthy of great care in keeping it true to name. As we grew it largely, I had a good opportunity of noting all its variations, and I discovered a tendency towards two distinct and very beautiful forms, which I lost no time to improve by careful and continued selection. It was several years, however, before I met with complete success in reaching that which I aimed at, and in establishing their respective characters; Crimson Belle and Eastern Queen are the result of my efforts. Their cultivation is very easy. Sow under glass in February, with very little or no bottom-heat, give air freely during open weather, and plant out in April in well-cultivated soil; but it is not necessary that it should be rich. Place the plants from 9 in. to 12 in. apart each way, and they will form compact tufts, which will be quickly covered with blossom. Encourage the formation and growth of laterals by pinching off decayed flowers, and the result will be a mass of blossom through the whole summer, probably till November. Some sow the seeds in autumn, and winter the young growing plants in frames, or under hand-glasses, hardening them off by degrees in spring, until they have become fully established.

Rivina humilis.—This pretty berry-bearing plant is largely grown in the gardens at Hatfield for decorative purposes; and, considering its easy culture, it might be grown much more extensively in other places than it is. For market purposes, too, it would doubtless be a good plant, for, when well furnished with its bright scarlet berries, few plants are more effective for room decoration. Strong cuttings of it should be inserted early in spring, potting them on when rooted, and always stopping the shoots, allowing them to break again before each shift. 5-in. or 6-in. pots are the best sizes in which to grow them, and the soil should be sandy loam and leaf-mould. A warm temperature is needed until the plants have fruited. —C.

TREES AND SHRUBS.

CLEMATISES ON TREES.

THE accompanying illustration is drawn and engraved from a photograph, taken last May, showing an old and vigorous plant of the handsome and hardy *Clematis montana* allowed to have its own way to some extent. This climbing shrub, of which the large-flowered variety called *grandiflora* is grown here and there on walls, is most precious for those who wish to garland trees and stumps and hedges with lovely flowers. It is as hardy and free as the common English *Clematis Vitalba*. The sketch will also suggest to many various ways in which hardy climbers may be used to produce similar beautiful effects. Other families of climbers might be named as equally useful, but the Clematises are so numerous, so hardy, so beautiful in flower, and so singularly varied in the colour and form of their blossoms, that whole wild gardens of beauty may be formed of them alone.

Clematises on trees in May.

YEWS—THEIR USES.

THE Yew ranks with the Holly as an evergreen shrub, only that the varieties of it are hardly so numerous, though they present, perhaps, a greater diversity of aspect. Like the Holly, too, most of the varieties are very accommodating subjects for forming hedges and specimens, and even dwarf edgings, submitting to the shears for many years—though the partial clipping of the trees, or training them in fantastical shapes, is not to be recommended, except when they are used in geometrical flower gardening, as at Harewood and other places, where the plants are shaped like pyramids and cones, necessitated by the highly artificial but questionable disposition of the flower beds and architectural adjuncts of the garden. The fine old Yews in the old garden beside the river at Hatfield are a very interesting sight; their growth has not been much restricted or interfered with, but marvellous pains have been taken to form and preserve the shadowy aisles and nooks that penetrate their undergrowth in all directions. Altogether, the wilderness there is a very pleasing retreat, and presents an aspect differing totally from the stiff and formal topiary work which is still a feature of some old gardens in this country. For general planting, the common English Yew is still the best, as it grows fast and furnishes quickly. Like all the other Yews, it delights in a good deep but well-drained soil, and attains great age under such conditions. On thin and very dry soils, the tree is less luxuriant, and soon gets thin at the top, unless top-dressing is resorted to, to provide the roots with food and sufficient moisture. We have known old trees renovated in this way. The Yew is not a good town tree, nor does it thrive in smoky districts. In some of the colliery and manufacturing districts of the north we notice that mostly all the old trees are in a dying state, and few young trees are planted. If the hand is rubbed upon the

foliage it is soon blackened with soot, which, no doubt, is the destroying agent in this case. The common variety makes a good hedge if planted thick enough at first. The plants should not be cut in too much for a year or two till they form a bottom, when they may be clipped in a little—top and sides—annually, taking care to keep a straight and even surface. In cases where the hedge faces the spectator chiefly from one side, as when it is placed between the wood or fields and the garden, or to hide unsightly objects, the hidden side is that too frequently neglected and allowed to grow, while the garden side is clipped regularly. Now the consequence of this neglect is that the vigour goes to the hidden side, and the clipped side becomes thin and unsightly. To keep such hedges in good condition, they must be regularly clipped on both sides. Of characteristic varieties of the Yew, the Irish Yew is one of the most ornamental and best known. It is very suitable for planting on lawns or in shrubberies; but the plants in any case should be tied to a short stake or iron rod at first to keep them straight, and the branches should be tied with a piece of band to keep them from straggling. In a good soil this Yew attains a great bulk and a good height. There is now a golden variety, of the exact type of the Irish Yew, raised, a number of years ago, at Hansworth Nurseries. It is a good companion to the green variety, and an equally good grower. The variegation is of a fine, bright golden colour; and, altogether, it is a great acquisition. At the same nursery there are also many hundreds of seedlings of the golden variegated type, numbers of which have not yet found their way into commerce. In all of them the variegation is of a bright golden hue, and hardly any two seedlings are alike in habit, some resembling the Irish Yew, some bushy, and some pyramidal in shape; but all are more or less vigorous, and suitable for ornamental planting. Among other named sorts of the variegated kind must be mentioned *Taxus argentea* and *elegantissima*, both silver-striped and very ornamental; and the deep green *T. adpressa*, which affords an excellent contrast to the others, and is in itself very ornamental. Other good sorts for planting in mixed shrubberies are *T. Dovastoni* (weeping), *epacrioides*, *ericoides*, and *japonica* (both bushy), *pyramidalis*, and yellow-berried (these are green). The variegated varieties not already named are *Dovastoni variegata*, *elegantissima*, *elegantissima fœmina* and *superba*, *Washingtoni*, golden striped, and a variegated variety of *pyramidalis*. S.

A Columnar Cypress.—This curious form of the common erect Cypress is figured by M. Carrière in the "Revue Horticole." Its branches are all transformed into branchlets and so closely growing together that they quite conceal the stem, and form a dense narrow column of vegetation. M. Carrière calls it the *Cereus*-formed Cypress, and states that it was raised by M. Ferrand, of Cognac (Charente). Plants of it are also in Messrs. Thibaut & Keteleer's Nursery at Sceaux, and, for all we know, may be in some of our own nurseries. It is stated to come true from seed.

Large Tulip Trees.—Referring to this subject, allow me to state that there are several Tulip trees in the pleasure grounds at Margam Park, the largest of which is 13 ft. in girth, and close upon 100 ft. in height.—A. P.

HYBRIDISATION OF PLANTS.*

HYBRIDISATION has received so much attention of late years, principally through the efforts of Mr. Darwin and a few others, that it is difficult to turn up a trade catalogue or trade advertisement without finding every seedling plant described as being the result of careful cross-fertilisation. So much is this the case that one is apt to come to the conclusion that the whole vegetable kingdom will soon become an indescribable mass of confusion. It is therefore necessary to bear in mind that two distinct classes will not cross-fertilise each other, that bi-generic hybrids are very scarce, and that the offspring of distinct species, when crossed, are, like bi-generic hybrids, generally self-impotent. Although in this latter respect they are no worse than some varieties, nevertheless, the above is the general law. This, however, is very often neglected, or mistaken by horticulturists for the well-known law of variation, to which plants are liable under cultivation; so plastic are some plants when cultivated that they are often mistaken for hybrids. This is well illustrated in the case of the Hollyhock, which, although, so far as is known, has never been crossed by any other species, has yet produced, in the hands of such men as Mr. Downie, Mr. Chater, Mr. Wm. Paul, and others, as many distinct and beautiful varieties as can be found in any class of florists' flowers. The Dahlia, also, may be instanced as the descendant of one original species. The Phlox—of which we have two distinct species cultivated by florists, namely, the *P. suffruticosa*, or early flowering, and the *decussata*, or autumn flowering, both from North America—has produced numerous and distinct varieties; yet we have it recorded, on the authority of Mr. John Downie, who was about the first to raise improved varieties, that no intercrossing of species has taken place in their production, each being the pure descendant of either species. The modern Pentstemons are derived from seminal varieties of *P. gentianoides*; and so on. Unfortunately, the history of the great majority of cultivated plants is unknown, but sufficient has been said to show the necessity of being careful in crossing plants, to remove all the stamens from the flowers to be used as the female a few days before they open, and afterwards protecting them from insects. If this be not attended to, the whole becomes a mere matter of chance. Indeed, without this care, we may be retrograding, for the offspring may not be so good, as if the very best flowers were marked, as the most of skilled florists do, and the result left to the inherent variability of the plant, and methodical selection when the seedlings are in flower, a circumstance which has hitherto done more for the improvement of florist-flowers than has been accomplished by hybridising. Mr. Darwin observes:—"When animals or plants are born with some conspicuous and firmly inherited new characters, selection is reduced to the preservation of such individuals, and to the subsequent prevention of crosses; but, in the great majority of cases, a new character, or some superiority in an old one, is at first faintly pronounced, and is not strongly inherited; and then the full difficulty of selection is experienced. Indomitable patience, the finest powers of discrimination, and sound judgment must be exercised during many years, and a clearly predetermined object must be kept steadily in view. Few men are endowed with all these qualities, especially with the powers of discriminating any slight differences. Judgment can only be acquired after long experience, but if any of these qualities be wanting, the labour of a life may be thrown away."

Variability.

With regard to variability as distinguished from hybridism, numerous instances could be given, such as the Peach having produced the Nectarine, the various kinds of Gooseberries in cultivation, Plums, Cherries, and the numerous varieties of Apples and Pears, all of which have been obtained by careful methodical selection. It is also well known that in a single bunch of Grapes may be found white and black Grapes. So variable a subject, therefore, requires both care and patience. I find Mr. Thomson, of Clovenfords, has recorded the fact that in order to raise four good sorts of Grapes he had to fruit 400 plants, the seed parents of which he had carefully fertilised with distinct varieties. Time and disappointment are often saved by being careful. In making experiments with *Lilium auratum* and *L. lancifolium*, by placing the pollen of the one on the stigma of the other, and excluding insects, I never got a single capsule to swell; not only so, but I found that pollen from *L. lancifolium* acted like a poison on the stigmas of *L. auratum*, so that in about eight hours the stigmas had a blackened appearance, and the flowers began to fade long before they would have done if self-fertilised; the same thing occurred in trying to cross *Primula japonica* with many species and varieties of *Primula*; I did not observe the poisonous results as in the last case, but I never was able to get a single capsule. In the genus *Passiflora*, the swelling of seed-capsules is no sure indication

Read by Mr. Robertson Munro at a recent meeting of the Scottish Horticultural Association.

A Columnar Cypress.

that the seeds will be fertile; for, in attempting to cross such hybrids as *Impératrice Eugène*, *Comte Nesselrode*, *floribunda*, and others, with pure species, I found capsules freely produced, but in no case did they contain good seed. In some, as in *P. floribunda*, the outer walls of the ovary were alone developed, while, in the case of *Impératrice Eugène*, in addition to the outer walls, the albuminous substances, with rudimentary seeds, were freely produced when pollen of *P. alata* was applied. It not unfrequently happens in some classes of plants that the anthers discharge the pollen before the flowers open, a fact which I first observed in reference to a plant which has, so far as I am aware, baffled hybridisers, namely, *Rhododendron Edgeworthii*, which may account for the fact that this plant has never been crossed with any of the species, although its pollen has been found effective in numerous instances in fertilising other species. R. Thomson I found to emit pollen for days before the flower expands, and from the viscid orifice of the stigma to which pollen was seen adhering, I would infer that it must be generally fertilised with its own pollen. It is from considerations like these that I would advise every one to exercise the greatest caution as regards receiving loose statements about hybridising, which will not bear close investigation; and this is equally applicable to a kindred subject, namely, graft hybrids.

Grafting Potatoes.

A subject which created some interest a few years ago, and which still crops up, was the grafting of Potatoes, from the fact that some Potato growers asserted that they had by this means raised hybrids or Potatoes intermediate between the scion and stock. With the view of testing the accuracy of such statements, I obtained through the kindness of Mr. Syme all the varieties in Messrs. Lawson's extensive collection. I selected thirty-four distinct sorts, and began by placing the most distinct varieties together. I first took all the eyes out of the one that was to be the stock, and cutting various pieces out with a sharp knife, I took a corresponding piece out of the one that was to be used as the scion. These were fitted together as neatly as I could by tying; but, previously to that, I passed a piece of wire through both so as to hold them the more firmly together. After doing about a hundred in this way, it occurred to me, in order to make doubly sure, to ask Mr. James Cooper, who for upwards of thirty years acted as budder and grafter to the Messrs. Lawson and Sons, and who is well known as one of the most successful grafters in the kingdom, to graft some of these Potatoes for me; but, after doing thirty-six tubers, he threw them aside saying that it was all nonsense. Some of these were potted and placed in a sharp bottom heat, others were placed in suitable soil in a cold frame, and some were planted in the open border. Those in heat were examined after they had made about 6 in. of growth; those in the cold frame, as well as those in the open border, were allowed to mature their tubers, but in no single instance could I trace the least change, nor yet could I find that the scion and stock had united; and this was also the case when I cut the eyes out of the one-half of a single tuber, cutting it in two, and tying the two halves together, so that there could be no misfitting of parts. I found in numerous instances that eyes had been formed on the so-called stock, but in such instances the young tubers were the same as the stock.

Graft Hybrids.

In reference to other forms of grafting, I never did much. Mr. Cooper, however, informs me that during the time he was in the Messrs. Lawson's nurseries, he grafted every year upwards of 45,000 stocks, which in thirty years is upwards of 1,350,000, and yet he never observed a single instance in which the scion exerted any influence on the stock, or conversely the stock on the scion, beyond the well-known fact that the scion sometimes grows more rapidly than the stock. I think this worth recording, more especially as Mr. Cooper had every opportunity of observing any changes, if such took place. I do not, however, dispute the existence of graft hybrids to a limited extent; the fact that the variegated *Abutilon*, when grafted on a green *Abutilon* has exerted sufficient influence on the stock to produce, from the eyes below the union, variegated branches, as well as the case of the well-known *Cytisus Adami*, would seem to indicate the existence of such hybrids; but, judging from such a statement as that made by Mr. Cooper, it must be of rare occurrence. Seminal hybridisation is not so restricted. Dean Herbert, Mr. Isaac Anderson Henry, and others showed long ago that hybrids between two distinct species could easily be produced; but to Mr. Darwin is due the credit of being the first to point out the beautiful adaptations furnished by Nature for the express purpose of providing that cross-fertilisation will take place. Of this no class of plants will give a better illustration than the Orchids usually cultivated in our stoves; from the construction of some of their flowers it is a physical impossibility that they can be

fertilised without insect or other agency; and this is not all, for I found, on placing the pollen of many of them on the stigmas of the same flowers, that they would not produce capsules, yet the pollen was good, for with it I could fertilise other flowers on distinct species; their ovaries were good, for they could be acted on by pollen from another species. Three species of *Oncidium* in the Edinburgh Botanic Garden were found to be self-impotent, yet capable of being intercrossed in various ways. I have fertilised hundreds of flowers of *Oncidium flexuosum* with its own pollen, and no capsules were produced; but, when fertilised with pollen from *Oncidium divaricatum*, another self-impotent plant, it produced plenty of capsules full of apparently good seed, and this was also the case when fertilised with such distinct species as *Oncidium Papilio*. *Maxillaria atro-rubens*, also a self-impotent plant, could be fertilised with *Oncidium sphacelatum*. Orchids have, however, been considered by some to be an exception, but many other plants are found to be self-impotent, and yet capable of being self-fertilised by pollen from other species. *Lobelia fulgens* and some species of *Verbascum* have been found to be in this predicament. A very remarkable case in reference to this came under my own observation. *Passiflora alata*, a self-impotent plant, in the Edinburgh Botanic Garden, was for many years fertilised with its own pollen by Mr. James Munro, Mr. J. Scott, and others, but could not be induced to yield a single fruit. Mr. Donaldson, gardener at Keith Hall, Aberdeenshire, when foreman in the gardens at Taymouth Castle, had also a plant of this same *P. alata* under his care, but no fruit was ever produced. He grafted a plant of it on another species, probably *P. quadrangularis*, and ever after it produced fruit in abundance. After Mr. Donaldson went to Keith Hall he was anxious to try how seedlings from the Taymouth plant would behave, and procured some; but, after growing them for some years they failed to produce a single ovary. Pollen from the Keith Hall plant was tried on the plant in the Edinburgh Botanic Garden, and after some failures it produced a single pod full of good seed. The seedlings raised from this were, however, as self-impotent as the mother plant, but pollen from these seedlings was effective in every instance in fertilising the mother plant. Mr. Darwin says, in reference to this, "I have met with no case in regard to plants which shows so well as this *P. alata* on what small and mysterious causes complete fertility or complete sterility depends. I have fertilised *P. alata* with *P. racemosa*, and also with *P. macrocarpa*. Hybrid plants from these unions were distributed by the Messrs. Lawson and Son, and Mr. B. S. Williams. One of the male parents, *P. racemosa*, was self-impotent in the Botanic Garden, but when fertilised with *P. alata* or *Tacsonia mollissima* it produced fruit, but in no case did it yield good seed. These are extreme cases, the species being self-impotent, but there are other causes which render it necessary that the flowers must be fertilised by the pollen of other flowers, or of distinct varieties." In *Pelargoniums*, the anthers discharge the pollen, and in the scarlet and crimson varieties it falls off twenty-four, and in some cases forty-eight, hours before the stigmas are in a fit state to receive it. The pink and white varieties, such as *Christine* and *Madame Voucher*, are exceptions, and this should be taken into account by those who send out new varieties, for it will be found that when planted out those in which the anthers fall off before the stigmas are developed last much longer in flower, and have less of the seedy appearance constantly observed in *Christine* than some others, and it is a remarkable fact that *Christine* and *Madame Voucher* will generally reproduce themselves true from seed. I have observed many species of *Campanulas* in which the anthers fall off in the same way, and Mr. J. Grieve who has cross-fertilised a number of species, informs me that he has also remarked the same fact. Mr. Bennet has mentioned several others, so that, in such cases, the sexes might as well be in separate flowers so far as fertilisation is concerned, and yet the male and female elements are quite capable of performing the functions of fertilisation. I seldom failed, on placing the pollen of any of the bronze kinds, such as *Tricolor Pelargoniums*, on the stigmas, in effecting a cross which was in nearly every instance apparent on the cotyledons, which showed a speck of yellow or white, or, in some instances, came too yellow or too white, and in such the seedlings quickly perished if the cotyledons were not closely observed; the second leaves frequently showed no signs of a cross having been effected, and it was sometimes a year after before the seedlings gave any indication of their hybrid origin. I may observe that I was not nearly so careful in crossing the *Tricolor* and *Bronze* on the green-leaved sorts as on the *Zonal* varieties, but capsules were produced, and the seedlings were nearly all yellow or white, that is, the colours became diffused throughout the leaves; this was particularly noticed in regard to such as *Trentham Rose* and *Frogmore Scarlet*.

Crossing Primulas and Auriculas.

Large numbers of plants are rendered more or less infertile by having their pistils and stamens of unequal length. This was first observed by Mr. Darwin in the genus *Primula*, to which he gave the

name dimorphic and trimorphic; but they are better known under the names of pin-eyed and thrum-eyed. In pin-eyed flowers, the stamens are very short, and the reverse is the case in thrum-eyed kinds. Mr. Darwin made numerous experiments with *Primulas* and *Linums*, and found that, in order to render *Primulas* perfectly fertile, it was necessary to fertilise the long-styled or pin-eyed form with the short-styled or thrum-eyed form; and this he called a legitimate union. When the short-styled or thrum-eyed was fertilised with the long-styled or pin-eyed, less seed was produced. This he called an illegitimate union. I never myself made any experiments with the view of testing the relative fertility of the two forms when legitimately or illegitimately fertilised; but from one or two instances which have come under my notice, I find that they are capable of producing more good seed when illegitimately fertilised than Mr. Darwin's experiments would have led me to infer. I had a good yellow *Polyanthus*, which I wished to propagate by means of seed. It was long-styled or pin-eyed, and I had no other *Polyanthus* with long stamens and the colour equally good. I therefore fertilised the flowers with pollen from its own short stamens, and I had two fine capsules full of excellent seed, which I did not count; but I have, after some deaths, fifty-four seedling plants. In another case I had a plant of a yellow *Polyanthus* named *Golden Gem*, also a long-styled form; it had altogether four flowers, two of which I fertilised with its own pollen, and two with pollen from the long-styled form above mentioned. The two fertilised with their own pollen proved abortive; but the other two produced two capsules full of fine plump seed, the produce of which is now germinating. These operations were carried on under glass, and far from the beds of *Polyanthuses*; so there could be no interference in the way of foreign pollen. In the spring of 1875, I had upwards of 200 *Primulas* and *Auriculas* in one house, which I tried to cross in various ways, but the result was disappointing. I effected a cross on some of the Alpine forms of *P. Auricula*, such as *P. intermedia* fertilised with a border *Auricula*, but I never could get a cross between the two sections. I see in Mr. Darwin's new work, on "The Forms of Flowers," that Mr. J. Scott crossed *P. Auricula* with *P. verticillata*; I have tried to cross the two several times, but never could get a single capsule. I was also unsuccessful with *P. cortusoides amoena*. I tried it in various ways with *P. sinensis*, blue *Polyanthus*, *P. verticillata*, and the common *Primrose*, as well as with its own pollen, but I never got a single capsule. Most *Primulas* seed freely under glass; I never got *P. nivalis*, however, to seed, but Mr. Lindsay informs me that the plant of *P. nivalis* on the rock garden in the Edinburgh Botanic Garden has produced seeds. With regard to *Primulas*, they must, I think, be grown in the open air when trying them, as the least sunshine under glass makes them flag, and hence failure, in all such cases, will be the result.

Changing Seed.

In the case of the *Brassicaceæ*, the difficulty is to keep the different tribes from being cross-fertilised, and this is also the case with the different varieties of Wallflower, while the closely allied genus, *Mathiola*, the East Lothian Stock, for example, seldom gets intercrossed with other varieties. I have grown five distinct varieties of this Stock for 6 years, and although no care was taken to separate the plants, which were all grown in a single row, yet their seedlings have never failed to come true to colour, showing that even colours may become as constant in closely allied varieties as if they were distinct species. I think this is also of some importance in reference to the breeding in-and-in of plants, of which, until Mr. Darwin's work on "Cross-fertilisation" appeared, we were quite ignorant, or at least we had no record of any well-conducted experiments, although gardeners and farmers changed their seeds occasionally, with the view of improving their crops. Mr. Darwin has grown plants from ten distinct genera for ten successive years. From one set of them insects were excluded, so that they became self-fertilised, while another set was freely exposed and therefore became liable to get fertilised from distinct plants. Seeds from the two sets were placed on opposite sides of the same pot, and a careful record of their progressive development kept each day until they arrived at maturity, and Mr. Darwin forcibly sums up thus:—"If all the men in a country were on an average 6 ft. high, and there were some families which had long and closely interbred, these would be almost dwarfs, their average height during ten generations being only 4 ft. 8½ in. It is, however, difficult to see how these East Lothian Stocks are not constantly self-fertilised, unless colour is of more specific importance than is generally supposed. Instead of farmers changing their whole seed, it has occurred to me, looking at these experiments, that it would be better, as well as more profitable, to get a small quantity only, and use it at the time of sowing with the old seed. In this way they would, in the second year, have all the advantages which a change of seed can effect by the small quantity brought from some

situation where it was grown under slightly different conditions becoming effective in cross-fertilising the old variety. New and improved varieties would undoubtedly be raised; and, by careful selection, kinds better suited to the particular locality would be obtained than by changing the whole stock. Time will not permit me to enter into the great advantage to be derived from hybridisation when performed with the view of improving the breed. From the crosses effected in *Passifloras* we find that tender kinds can be cross-fertilised with comparatively hardy ones; the brilliant colours of the Himalayan *Rhododendrons* are retained in their hybrid offspring. Even odours are capable of being transmitted, as in the case of a hybrid named *Mimulus Harrisoni* obtained between the common *Musk* and a border *Mimulus*. A wide field is therefore open to all who have time and opportunity, and the subject is so interesting that one never tires, although often baffled and disappointed.

ORCHIDS.

SEASONABLE NOTES.

Those who are desirous of having good cut flowers during the dull months should pay special attention to obtaining winter flowering kinds of Orchids, and foremost amongst them may be named *Ansellia africana*, a robust growing plant which produces from the apex of each growth a long, somewhat lax-flowered, drooping raceme, the blossoms on which are yellow, spotted and barred with cinnamon-brown. They are thick and waxy in texture, and therefore they last long in beauty. In the variety called *lutea*, the colour is plain yellow, and consequently not so attractive as that of the type. Being African plants, growing in low situations, they require the warmth of the East Indian House.

Angræcums.—These belong to an African genus which contains an immense number of species, but the majority of them produce very diminutive flowers. A few fine species having large, singular-looking handsome flowers, are however, included in it. Of these some are now opening their flowers, and they have broad, two-ranked (distichous) leaves, which render them beautiful ornaments to a plant house even when not in bloom. *A. sesquipedale* is perhaps the very largest of the genus, and although few plants of it are to be found now in full flower, some are commencing to unfold, and will continue in bloom for two or three months. Some *Angræcums* naturally bloom towards the end of spring and beginning of summer, and these are highly prized by exhibitors, being showy and telling plants in collections; the flowers are thick and fleshy in texture, ivory-white, with a spur often a 1½ long. *A. eburneum*, another species has an erect spike, bearing smaller ivory-white flowers, furnished with a shell-like labellum. This is a stronger growing plant than the preceding, and one which bears longer leaves. *A. pertusum*, a native of Sierra Leone is a small compact kind, somewhat rare in collections, but well deserving of more extended cultivation on account of the elegance of its long, pendulous many-flowered racemes of blossoms, which are pure white, having an appearance of shells set upon a string. *A. bilobum*, another winter-blooming species from Cape Coast, bears charming white flowers, each of which has a long spur; these plants should all be grown in Sphagnum; the two last named succeed well in baskets, but the others are too large for anything but pot culture. The pots should be well drained as they like a liberal supply of water, and must be carefully guarded against the attacks of red thrips, which, if allowed to establish itself, will greatly disfigure them.

Dendrobium speciosum has acquired the character of being a shy-blooming plant; and, consequently, has not found that favour with amateurs which it deserves; flowering, as it does, all through the winter, and requiring but little attention, it gives a large return for a small outlay. Its stout pseudo-bulbs bear two or three thick, dark green, leathery leaves, and from buds near their apex the raceme of flowers is produced, in length from 12 in. to 18 in., and densely crowded, the blossoms being yellowish-white and slightly fragrant. It begins to grow soon after the blooms are over, when it should have a little heat and plenty of water; and, in order to insure a rich harvest of bloom the following season, let it be placed in the open air all the summer, and supply it very sparingly with water; indeed, unless the pseudo-bulbs show signs of shrivelling, the less water it has the better. *D. Hilli*, a species of more recent introduction, somewhat resembles *D. speciosum*, and requires the same treatment. It may, however, be readily distinguished by its much longer and less robust pseudo-bulbs; the raceme of flowers is also much longer and pendulous, whilst the blossoms themselves, though very numerous, are set farther apart. Taking it all in all, *D. Hilli* is a very desirable plant.

Stanhopeas find little favour with the majority of Orchid-growers, their flowers being very fugacious. They are, however, valuable on account of the delightful aromatic fragrance which they diffuse through an Orchid-house, independent of the grotesqueness of their blooms. The flower-spike grows downwards, and therefore basket-culture is the proper system to adopt with such plants, a few of which should always be grown in a collection, and the less they are disturbed, the more abundantly will their flowers be produced. A somewhat dark, cool place suits them best, and, when growing, they enjoy a liberal supply of water; very little will, however, suffice afterwards.

Oncidium Barkeri, better known perhaps by the name of *O. tigrinum*, is a beautiful species, its large, rich yellow, fragrant flowers being most welcome at this season of the year; it is, moreover, a cool house species, and consequently doubly valuable. *O. Papilio* is best known as a summer-blooming plant, but those who possess well-established specimens may always have a supply of its singularly beautiful blossoms. The long flower-stem should never be cut away until it is quite dead, as it develops fresh buds from the apex for a very long time. Just now many plants of it are extremely gay. It thrives best upon a block of wood. Some few years ago, it was announced that a white-flowered variety of this species had been introduced; unfortunately, however, it has not yet made its appearance, but still remains a desideratum.

Maxillarias, although at one time largely cultivated, are now little better than outcasts; nevertheless, amongst them there are still several very fine kinds that would undoubtedly receive more attention did they not belong to this family. Amongst those now in bloom, *M. grandiflora* should not be overlooked; it is easily managed, and is dwarf and compact in habit; its thick waxy, flowers are large, pure white, and last long in beauty. Amongst older kinds, *M. picta* deserves notice; it has small, yellowish-white flowers, variously streaked and freckled with brown, and produced in great profusion. They have been found very serviceable in a cut state for mixing with other flowers in vases, for, though not very beautiful, they diffuse a grateful spicy odour throughout the apartment in which they are placed.

The genus *Lycaste* furnishes many fine species, which at this season (and, indeed, all through the winter and spring), supply us with large and beautifully-coloured flowers. All of them thrive best under cool treatment; indeed, some of them may be grown all the year round in a dwelling-house; but where this expedient is not resorted to, they may nevertheless be used as indoor ornaments for a long time without diminishing the beauty of their flowers, or injuring their constitutions. Foremost on the list is *L. Skinneri*, a kind which has bold, well-expanded, thick, waxy flowers that vary in colour from pure white, through all the gradations of white and rose, pure rose, white and crimson, to crimson-purple, all being equally lovely. *L. Harrisonia*, with its large white and rosy-purple flowers, is also a grand species; but, unfortunately, it was introduced many years ago, and therefore lacks novelty, which is too often substituted for sterling worth. *L. Deppei*—another old species, producing flowers variously marked with white, orange, and brown—is very attractive, and is now being sought after; but, owing to neglect, has become rare.

Odontoglossum Roezli is at once a novelty and a very fine winter-flowering plant, its large flowers being both attractive on the plant and in a cut state. Of this plant there are numerous varieties; it thrives best with a little more warmth than is required for the majority of the family.

Dendrochilum glumaceum cannot be said to have large or gaily-coloured flowers; but its pendulous white or pale straw coloured racemes present a very graceful appearance, hanging, as they do, outside of the dark green leaves, and they yield, in addition, a grateful perfume, somewhat resembling that of Almonds, altogether rendering it a very desirable plant.

In *Leptotes bicolor* we have a beautiful Orchid for a Wardian case; its dark green terete leaves contrast beautifully with the pure white of its sepals and petals and the violet-purple of the lip.

During the dull wet weather which we are now experiencing, Orchid-growers should guard against a superabundance of moisture in the atmosphere; such a condition is not only liable to start the plants into growth prematurely, but to cause the flowers to become spotted, and to fade much sooner than they otherwise would do.

W. H. G.

Odontoglossum Andersonianum.—A plant of this beautiful Orchid, growing in Mr. Williams' nursery, is now bearing twenty-one flowers on one spike; it is one of the best varieties which we have seen of this comparatively rare *Odontoglossum*.

A FEW STAPELIAS.

STAPELIAS are succulent, leafless plants, the branches of which are generally four-sided, toothed, and covered over with dark tubercles, which give the plants a grotesque appearance. Their singular and often beautiful flowers, which spring from uncertain points of the stems, exhibit a variety of colours, forming exquisite marked or dotted patterns, and, notwithstanding the repulsive carrion-like odour which almost all the varieties possess, they are extensively cultivated because of their beauty.

S. glauca.—This is a form of *S. mutabilis*, from which it differs in being rather dwarfier and more glaucous. It is a free-growing kind, and has dark brown flowers without hairs, with the exception of a fringe on the margin of the petals; the stem is quite glabrous. The

Stapelia glauca.

odour of the flowers, though but slight, is, nevertheless, sufficiently strong to induce flies to visit them. It is a native of the Cape of Good Hope.

S. Thureti.—This is a very dwarf, singular little plant, which has pale brown striped flowers that are quite glabrous. Its stems have a curious habit of burrowing in the ground, and then rising again. Plants possessing this habit are called *Huernias* by some but I am of opinion that *Stapelia* is the best name for them, as the general appearance of the plants shows them to belong to one and the same section.

S. tubata.—This is quite a gem in its way; it is compact in habit, and nearly related to *S. campanulata*. Its flowers, which are produced freely, are densely clothed inside with glandular hairs, which give them a singular appearance. The stems are glaucous, and quite smooth. With those who are fond of plants more interesting than showy, this will prove a favourite.

S. variegata.—This, the most common kind of *Stapelia*, may be easily cultivated in any greenhouse, and for beauty of colouring and finish of structure few plants surpass it, especially when seen under the microscope, and were it not for its bad smell it would, doubtless, be a general favourite.

Stapelia (Huernia) Thureti.

Stapelia variegata.

Stapelia tubata.

Stapelia grandiflora.

S. grandiflora.—The "survival of the fittest" surely cannot apply to this plant, for its smell is so much like that of carrion that flies congregate on it in quantities. The hairs on the flowers, which are velvety-brown, are very soft, and the stems pubescent. It requires more heat than most species.

All *Stapelias* are natives of South Africa; therefore, a greenhouse temperature suits them best; but the lightest and warmest part of the house should be selected for them. They should be grown in light sandy loam; cuttings, taken off in June or July, strike freely.

Sudbury House, Hammersmith.

J. CROUCHER.

THE GEOGRAPHICAL DISTRIBUTION OF PLANTS.

(Continued from page 504).

Vegetation of the United Kingdom Compared with that of other Insular Countries.

INSULAR FLORAS.—Comparing the flora of the British Isles with the floras of other islands or groups of islands in different latitudes, and at various distances, usually much greater from the nearest continents, we are struck with the fact that our own flora, as an insular flora, is almost alone in possessing no endemic species—a fact which seems to indicate that these islands were connected, at no very remote period in the history of the world, with the mainland of Europe. Generally speaking, the more distant an island is from the nearest mainland, the more distinct its vegetation, and the greater the number of endemic species. The vegetation of Japan, of New Zealand, of the Galapagos, of St. Helena, and of the Azores, is in each case of a more or less distinct character from that of the nearest land.

THE FLORA OF NEW ZEALAND COMPARED.—The flora of New Zealand, including the Kermadec, Chatham, and Auckland islets, furnishes excellent material for comparison. The area of the islands of New Zealand collectively is not much less than that of the United Kingdom, and its loftiest mountain peaks are nearly thrice the altitude of our highest. The general mean winter temperature, in 1874, of South Island (middle Island of some books) was 43°.7; the lowest mean, 37°.2, being from Queenstown; and the mean summer for the whole islands, deduced from observations taken at seven stations in different parts, was 60°.3. Thus the winter temperature is about the same as that of the warmest parts of England and Ireland, with a somewhat lower summer temperature. The general mean summer temperature of the North Island for the same year was 65°.1; and, for the winter, 50°.6. The extremes in the amount of rainfall are nearly as great as in England.

NUMBER AND DISTRIBUTION OF THE SPECIES.—The total number of species of flowering plants and Ferns hitherto collected in New Zealand is about 1025; but it is probable that future explorations may add another hundred or two. They represent 89 Natural Orders and about 340 genera. None of the Natural Orders are peculiar to New Zealand, but about 27 of them are not represented in Britain, and these, for the greater part, occur in the warmer regions of New Zealand only. Upwards of 30 of the genera and 700 of the species are peculiar to the country, in striking contrast to the absolute absence of endemic types from our flora. Of the remaining genera, 115 extend to Europe, about 265 to Australia, and 175 to America; and about 230 species are Australian, and half that number South American.

BRITISH PLANTS INDIGENOUS IN NEW ZEALAND.—The British species found in New Zealand, and believed to be indigenous, are—*Nasturtium palustre*, *Barbarea vulgaris*, *Cardamine hirsuta*, *Spergularia rubra*, *Montia fontana*, *Geranium dissectum*, *G. molle* (?), *Potentilla anserina*, *Geum urbanum*, *Callitriche verna*, *Taraxacum Dens-leonis*, *Picris hieracioides*, *Sonchus oleraceus*, *Convolvulus Sepium*, *C. Soldanella*, *Solanum nigrum*, *Veronica Anagallis*, *Chenopodium glaucum*, *C. urbicum* (?), *Suaeda maritima*, *Atriplex patula*, *Polygonum minus*, *P. aviculare*, *Typha angustifolia*, *Sparganium simplex*, *Lemna minor*, *L. gibba*, *Potamogeton natans*, *P. heterophyllus* (?), *P. gramineum*, *P. pectinatus*, *Ruppia maritima*, *Zannichellia palustris*, *Juncus communis*, *J. maritimus*, *J. bufonius*, *Luzula campestris*, *Scirpus maritimus*, *S. lacustris*,

S. triquetus, *Carex stellulata*, *C. teretiuscula*, *Alopecurus geniculatus*, *Agrostis canina*, *Deschampsia cespitosa*, *Koeleria cristata*, *Festuca duriuscula*, *Hymenophyllum tunbridgense*, *Cystopteris fragilis*, *Pteris aquilina*, *Aspidium aculeatum*, *Gymnogramme leptophylla*, *Ophioglossum vulgatum*, *Lycopodium Selago*—in all 54 species. It is possible, and even probable, that some of the foregoing plants were originally introduced by man; but there can be no doubt that most of them, which are cosmopolitan species, are really indigenous. In addition to this already considerable list, some 200 or more British species have been intentionally or unintentionally introduced, and are now more or less naturalized in different parts of the islands. This circumstance will receive further consideration under the head of the "influence of man on the present distribution of plants."

NATURAL ORDERS CHARACTERISTIC OF THE BRITISH FLORA IN NEW ZEALAND.—Taking the same Natural Orders enumerated above as characterising the British flora, the number of genera and species in New Zealand belonging to the same Orders are:—*Compositæ*, genera 24, species 143, including many singular densely-tufted species, and 40 shrubby ones; *Gramineæ*, genera 26, species 61; *Cyperaceæ*, genera 14, species 69; *Cruciferae*, genera 7, species 13; *Leguminosæ*, genera 5, species 13; *Umbelliferae*, genera 10, species 45; *Scrophularinæ*, genera 10, species 62; *Labiatae*, genera 2, species 2; *Caryophyllæ*, genera 4, species 12; *Orchideæ*, genera 17, species 38; *Ranunculaceæ*, genera 4, species, 27; and *Filices* (Ferns), genera 31, species 123. These twelve Orders contain 154 out of 340 genera, and 608, or considerably more than half of the total number of species. The remarkable features here are the paucity of *Leguminosæ* (including only the genera *Edwardsia*, *Clanthus*, *Swainsona*, and two curious genera of almost leafless shrubs), *Labiatae* (one Mint and one *Scutellaria*), and *Cruciferae*; and the large proportion of Ferns, *Compositæ*, *Umbelliferae*, and *Scrophularinæ*, which, collectively, make up considerably more than a third of the whole flora.

PROPORTIONS OF WOODY PLANTS.—Counting 9 species of Tree-Fern, 1 Palm, and 4 *Cordylines*, the total number of woody species, shrubs and trees, amounts to 322; another feature in which the flora differs from our own. *Myrtaceæ*, *Compositæ*, *Laurinæ*, *Coniferae*, *Araliaceæ*, *Scrophularinæ*, and *Ericaceæ*, contribute largely to the woody element. To go more into detail here would be wearying to the reader, and it is quite unnecessary, because many of the ornamental species are enumerated under the heads of geographical distribution of the hardy and cool conservatory exotic plants cultivated in this country. There is, however, one or two more features of the New Zealand flora worthy of comment.

GENERA REPRESENTED BY MANY SPECIES.—One is the relative proportion of large genera. Thus, there are 20 species of *Ranunculus*, 12 of *Pittosporum*, *Metrosideros* 10, *Epilobium* 17, *Hydrocotyle* 10, *Ligusticum* 12, *Panax* 10, *Coprosma* 24, *Olearia* (shrubby composites) 20, *Celmisia* 24, *Cotula* 13, *Raoulia* (singular-tufted composites) 12, *Gnaphalium* 15, *Senecio* 20, *Dracophyllum* 11, *Veronica* 40 (32 of which are shrubby), *Pimelea* 10, *Juncus* 12, *Uncinia* 10, *Carex* 23, *Agrostis* 10, *Hymenophyllum* 15, *Lomaria* 14, *Asplenium* 12, and *Polypodium* 10. These 24 genera average 16 species each, and, collectively, constitute 386 species in a total of 1025.

MONOTYPIC GENERA.—In opposition to this, the number of genera represented by single species is very large, no fewer than 170 being restricted in these islands to one species each.

ORDERS REPRESENTED BY ONLY ONE SPECIES.—Another peculiarity of the flora is the number of outliers of tropical orders and genera; and the following orders are represented by only one species each: *Magnoliaceæ*, *Elatinæ*, *Linææ*, *Meliaceæ*, *Oleaceæ*, *Stackhousiæ*, *Anacardiaceæ*, *Passifloræ*, *Cucurbitaceæ*, *Primulaceæ*, *Sapotææ*, *Gesneriaceæ*, *Nyctagineæ*, *Amarantaceæ*, *Paronychiææ*, *Chloranthaceæ*, *Balanophorææ*, *Hypoxidææ*, *Pandaneæ*, and *Palmeæ*, and many others are represented by two or three species only. Finally, there are eight indigenous *Loranthaceæ*, shrubby parasites, belonging to three distinct genera; and there are six species of *Drosera*, some of them very handsome.

GENERAL REMARKS ON OTHER INSULAR FLORAS.—Having described so fully the vegetation of New Zealand, a few general remarks respecting other insular floras must bring this part to a close.

FLORA OF JAPAN.—The Japanese Islands, somewhat similarly situated as the British Islands, with regard to proximity to mainland, and enjoying in the northern and central part a climate similar to the English climate, presents a flora having many features in common with our own, associated with a much greater variety of trees and shrubs, both evergreen and deciduous. The richness of this flora, particularly in shrubs with showy flowers, may be gathered from the enumeration in a succeeding paragraph. With many peculiar species, it has a large proportion of species common to the mainland of China, and, as the country stretches through some 20° of latitude (from about 30° to 50° N. lat.), and some of its mountains rise to an altitude exceeding 12,000, it includes types characteristic of cold, temperate, and sub-tropical regions.

FLORA OF ST. HELENA.—One of the most remarkable insular floras in the world is that of St. Helena. This speck of dry land in the midst of the vast Atlantic Ocean is only about a third the size of the Isle of Wight, and it is 1200 miles distant from the coast of Africa, and 2000 from America. Unfortunately, much of the aboriginal flora was destroyed before this interesting spot was thoroughly botanized. When the country was discovered, many of the valleys were covered with forests, but these have now quite disappeared, and the original vegetation is being supplanted by introduced species from various countries. Excluding Mosses, Lichens, &c., the indigenous flora consisted, so far as botanists have been able to determine, of less than seventy species, whereof more than fifty have never been found elsewhere. It is possible, however, that some of the endemic species were extirpated before any botanist thoroughly explored the island. One or two, or perhaps more of the species no longer exist in a living state in the island itself, though they are in cultivation in this country. *Pelargonium cotyledonis*, a species with peltate leaves, appears to be in this critical situation. The affinities of this singular flora are decidedly South African, though the species and some of the genera are quite distinct.

FLORA OF THE ISLETS OF THE SOUTH INDIAN OCEAN.—The voyage of H.M.S. "Challenger" was the means of contributing some interesting particulars of the vegetation of the islets of the Indian and South Atlantic oceans. Kerguelen's Land, Marion Island, Yong Island, and several others were visited, and the fact established that the vegetation of these islands, although they are very remote from each other, is essentially the same. (Marion Island is about 2000 miles from Kerguelen's Land, with only the Crozet group intervening. That most interesting plant, *Pringlea antiscorbutica* (Kerguelen's Land Cabbage), described by Sir Joseph Hooker on his return from the Antarctic Expedition, and which proved so serviceable to the crews of the ships forming the expedition, was discovered by the naturalist to the "Challenger" in Marion Island; and it has also been collected in the Crozet Islands. Several other plants were found to be common to the three groups.

IDENTICAL SPECIES OCCURRING IN VERY DISTANT ISLANDS.—Amongst several European species, probably introduced by the sealers, who sometimes visit these remote islands, were *Montia fontana*, *Limosella aquatica*, and *Hymenophyllum tunbridgense*, which cannot be regarded as introduced plants. One more instance of the same species being found in distant islands. The genus *Phyllica* is a large one, whose species, with few exceptions, are South-African. One of these exceptions is *P. arborea*, a native of Tristan d'Acunha, where it forms an important part of the woody vegetation; and until a few years ago it was supposed to be confined to this island. But three or four years ago the lamented and unfortunate Captain Goodenough landed on Amsterdam Island, which is about 5000 miles distant from Tristan d'Acunha, and brought away a specimen of the only kind of tree seen. This proved to be no other than *Phyllica arborea*.

GALA PAGOS ISLANDS.—The still imperfectly explored Galapagos Islands, immediately on the Equator, and about 600 miles from the western coast of South America, have a flora very distinct as to species from that of the mainland.

POLYNESIA.—In many of the islands of Polynesia it is difficult to distinguish between indigenous and introduced plants, and none of them exhibit a peculiar flora. The Bread-fruit tree and Cocoa-nut Palm are almost universally dispersed, and exist both in a wild and cultivated state.

AZORES.—Coming nearer home, to the Azores, which are about 800 miles distant from the opposite coast of Portugal, we find a flora essentially that of the Mediterranean region, arguing a not very remote separation. The total number of species is 480, whereof 40 are endemic, 400 extend to Europe, and 320 to North Africa.

COMPARISON WITH CONTINENTAL FLORAS.—We have given instances of insular floras of the most diverse composition. The vegetation of large Continental tracts presents similar peculiarities in different parts. Thus, in the northern hemisphere, more particularly in the Old World, speaking generally, plants have a wide area of distribution, whereas in South Africa and in Australia the species are numerous, and many of them very local.

Distribution of Exotic Plants Hardy in the United Kingdom.

DEFINITION OF THE TERM "HARDY."—The term hardy is here employed in its widest sense, and includes, at least, three different categories of plants, namely—(1) Such as are quite at home in the climate, summer and winter, flowering and bearing mature fruit in ordinary seasons; (2) such as grow and flourish and receive no injury, or little injury, from the cold of our ordinary winters, but either do not flower, or, if they flower, do not produce perfect seed; and (3) such whose period of life or growth lasts only for a few months, but whose seeds or root-stocks retain their vitality in the open ground. Of course no hard and fast line can be drawn, nor is it necessary in the definition of the term hardy, because a plant that is hardy in one part of the kingdom may require shelter in another part of the kingdom; but no plant can be considered as hardy which, from some climatal cause or other, must be sheltered, or renewed, or replaced every season.

ARCTIC AND ALPINE PLANTS.—Taking this definition, we should exclude such Arctic or Alpine plants as are unable to withstand the heat of our summers and the wet of our winters, under the most favourable conditions we can provide for them. Practically, the number would be small, though governed by the skill of the cultivator in choosing situations in accordance with the natural requirements of his plants.

MEAN ANNUAL TEMPERATURE OF COUNTRIES WHENCE WE OBTAIN HARDY PLANTS.—Therefore, we include under this head the vegetation of the Arctic and Alpine regions, where the mean annual temperature ranges between 30° and 40°, and where the winter temperature is exceedingly low—though vegetation is rarely exposed to its full influence, on account of its usually being covered with a more or less thick layer of snow—and also that of all countries and regions enjoying a mean annual temperature of 40° to 60°. The last temperature, or upper limit given, may appear rather too high; and so it is in some respects. The plants from the warmer regions within our limits are hardy only in the southern and western parts of the kingdom, and belong, many of them, to the second and third categories enumerated above. But, just as in different parts of this kingdom, the mean annual temperature is the result of a very equable climate, or a higher summer or lower winter temperature, so the climate of other countries enjoying the same mean annual temperature exhibits similar and much greater variations. In round numbers, we may put the mean annual temperature of the southern half of the kingdom at 50°, made up by an average of 40° for the six colder months, and an average of 60° for the six warmer months.

COURSE OF AN ISOTHERM, DENOTING A MEAN ANNUAL TEMPERATURE OF 50° IN THE NORTHERN HEMISPHERE.—Now if we take a map showing the isotherms, drawn up from observations made in various countries, and trace the mean annual of 50° around the world in the northern hemisphere, we shall find that its course is by no means determined by latitude. Starting from the west coast of Ireland, in about 54° N. lat., in a westerly direction, the isotherm of a mean

annual temperature of 50° bends gradually southward as it approaches the eastern coast of America, past Newfoundland and Nova Scotia, and enters the American Continent in about 44° N. lat. It still tends a little more to the south, sufficient to clear the lakes, and then bears northward, as it approaches the western side, and traverses Vancouver's Island. In the Pacific Ocean it reaches, in about 160° west longitude, the same latitude it has in Ireland, and then curves southward nearly to the fortieth parallel before entering Japan. From thence it bears a little northward until it reaches Central Asia, and then a little southward, skirting the north shore of the Caspian and Black Seas. After leaving the Black Sea, the course is through Holland to England and Ireland. The description of the course of this one annual isothermal in the northern hemisphere will give some idea of the general distribution of heat in this part of the world, except that successive lines of smaller

Black Seas through Asia Minor, and the south and west of Europe, it enters England.

COURSE OF ISOTHERM OF 60° FOR JULY IN THE NORTHERN HEMISPHERE.—Now note the difference in the direction of a line of equal heat of 60° for the month of July; the curves are nearly all through their course southward where they were northward, and the reverse, for the equal January temperature. Thus, the isothermal line of 60° runs from the north-east of Scotland through the south-west of Ireland, and a little southwards across the Atlantic, entering America below the fiftieth, and running northward to beyond the sixtieth parallel of latitude, at some distance from the north-west coast. As it approaches the coast it takes a southerly direction, issuing from the continent in about 54° lat., and reaching about 40° in mid Pacific, then, turning northwards, and entering Asia in about the same latitude it leaves America, it gets up to 65° in

A Garden in a sun-burnt land.

amounts of annual temperature show increasingly larger curves to the north in the oceans, and successive lines of higher annual temperature gradually smaller curves.

COURSE OF AN ISOTHERM OF 40° FOR THE MONTH OF JANUARY IN THE NORTHERN HEMISPHERE.—Before concluding this part of the subject, it will be instructive to show the course a line of an equal temperature of 40° for the month of January and one of 60° for the month of July. The mean of 40° for January, after passing through the south-west of England and west of Ireland, runs northward in the Atlantic beyond the sixtieth parallel, a little to the west of Iceland, and then gradually curves southward until, in the centre of North America, it is below the fortieth parallel; in fact, near the thirty-fifth. As it approaches the western coast it runs farther north, and in the Pacific Ocean still further, but never beyond 50° . Descending again, it enters Asia about 40° , and in the centre of this continent it is as low as 35° , passing south of the Caspian and

Asia and Europe, and runs down the coast of Norway to Scotland. Anybody taking the trouble to trace on a map the lines of equal heat which we have roughly indicated, will see that the same modifying influence—water—which we know affects the climate of this country so much, is equally active in other parts of the world.

CONTINENTAL CLIMATES.—In the centres of large continents, the extremes of heat and cold for latitude are much greater than in islands and in countries bordering the sea; and the Atlantic makes its influence felt much further to the north on its western side than on its eastern, and much further north than the Pacific. These differences are attributed to the direction taken by streams from the equatorial regions. As an instance of an extreme climate in the latitude of London, a few figures relating to Nertchinsk, in eastern Asiatic Russia, will give some idea. It should be mentioned, however, that this place is situated about 2250 ft. above the level of the sea.

The mean temperature of the winters of two years, deduced from hourly observations, was 47° of frost, or 15° below zero, and the mean for December was $19^{\circ}.6$ below zero; on the other hand, the mean for July was $64^{\circ}.2$, for June $58^{\circ}.5$, and for August, $60^{\circ}.9$, or a sufficient amount of heat for ripening any of the cereals cultivated in this country, and for raising many other summer crops.

COURSE OF ISOTHERMS IN THE SOUTHERN HEMISPHERE.—Turning from the northern hemisphere to the southern, a glance at a map of the world is sufficient to enable one to appreciate the vast difference in the proportions of land and water and the little land there is in high southern latitudes. The isotherm of a mean annual temperature of 50° —almost the coldest passing through land, with the exception of the extreme south, where no vegetation has been seen—touches the southern extremity of New Zealand, and includes a considerable portion of Patagonia, besides a few small islets. Here temperature for latitude, at sea-level, is nearly uniform.

CONCERNING COUNTRIES HAVING A MEAN ANNUAL TEMPERATURE HIGHER THAN 50° , BUT THE PLANTS OF WHICH ARE HARDY.—So far, we have limited ourselves to pointing out the course of the isotherms of a mean annual temperature of 50° , because that will give a general idea of the extent of country whose vegetation is perfectly hardy in this country. But, owing to the mildness of our winters, plants from countries enjoying a higher mean temperature, even up to 60° , will succeed in the south-west, though, as has already been mentioned, some of these do not get sufficient heat to produce flowers, or flowering, fail to ripen their seed. This applies more especially to those countries in which the mean temperature is considerably higher than 50° on account of the high summer temperature. The variety of ornamental plants from which we can choose is thus considerably increased; but the number of useful plants, especially those whose uses depend upon their perfect development, is not materially increased. It extends the area of country in the northern hemisphere, in the parts less open to the influence of the oceans, down to 35° N. lat., and in some places even a little further south. In the southern hemisphere it adds very little, because the mean there is made up of a very narrow range of temperature. W. B. HEMSLEY.

GARDENS IN SUN-BURNT LANDS.

WE, who have to endure excessive wet and so often long to see more of the sun, are perhaps much more happily situated than people in some brighter countries. The heat and drought are often so excessive that it is with the greatest difficulty that any plants at all can be grown. In Brazil, for example, the gardens in many places are formed of little covered walks with climbers which will stand the sun, and in the shade of which they try to grow a few plants in pots, which would have no chance of thriving in the open sun. Edgings are formed of shells or stones, which cause the gardens to have an arid appearance. In the large vase-like pots a few favourite plants may be grown. Even without going so far, the gardens in Southern Europe are often fearfully scorched in summer time, and the only plants to be seen are a few in vases on a walk, as in this case. We are inclined to think, however, that, owing to the wonderful variety of vegetation which exists, there are few places for which some plants would not be found to thrive. To ascertain this, however, many plants have to be tried and many experiments made.

THE ADULTERATION OF SEEDS ACT.

THOMAS STRANGEWAYS, a wholesale seedsmen, carrying on business in the Mile End Road, appeared before the Lord Mayor, at the Mansion House, the other day, to answer two summonses issued against him for having sold a quantity of killed seeds for the purpose of adulterating genuine seeds. It was explained that the offence imputed to the defendant was that he had sold twenty-eight bushels of Charlock seed, for the purpose of mixing with Swede and other Turnip seed, and this was generally done in equal proportions, so that a purchaser who made use of the killed seeds was defrauded of one-half of the value of the seed which he bought. The defendant had boasted that the operation was so profitable that he did not care for the penalty fixed by the Act, which was £5 for the first offence, and £50 for the second.—A witness named

Francis proved the negotiation for the purchase of two different parcels of the killed seeds on the 26th and 27th of October, and he also proved that the defendant assured him the seed he sold him was all dead, and that he was careful in seeing that not a single seed was left in the sack when it was emptied into the kiln to destroy its germinating power. Three pounds of Turnip seeds were usually sown to the acre. Twenty-eight bushels (the quantity of seed purchased from the prisoner) would sow 460 acres, and 24 bushels about 430 acres. If dead seed was mixed in the proportion of half and half, that quantity would sow about 1,700 acres. Mr. Charles Sharp, of Sleaford, deposed that Charlock was worth 3s. 6d. a bushel, and was crushed for oil and manure. When killed it had no proper agricultural purpose, nor was it an article of commerce. Swede Turnip seed varied in price from 7s. to 8s. a bushel. Killed seed had no value whatever. It was only sold for mixing purposes. If the seed was not killed, it would betray the fraud. The defendant urged that what he had done was not with any intention to defraud. The Lord Mayor fined the defendant £5 for the offence of killing the seed, and £5 for that of selling the killed seed, and £5 5s. costs. The money was paid.

THE KITCHEN GARDEN.

KITCHEN GARDENING MADE EASY.

FOR these nine years past, the greater part of our kitchen garden has not been dug more than once in two years. I find too much digging not only hurtful to many vegetables, but very expensive; I therefore try to serve our *chef* and make the garden pay its way. To illustrate the method which I adopt, I will begin with early Peas on a south border, which, contrary to many, I always sow early in November; but let me remark that by rolling the seeds in red lead, the mice do not touch them; and, when they appear above ground, a small coating of coal ashes keeps them warm, and in a great measure wards off the slugs; and, lastly, when well above ground, I stretch three lines of worsted along each row, a plan which keeps off the birds. When the Peas come off, which is generally by the 1st of July, I stir up the ground with a tool which we call a cultivator. I then set the line, making holes with a crowbar, and drop into them Brussels Sprouts, giving them a good watering when planting is completed. These stand until March; we treat them to a mulching of long manure from the stables, which keeps them moist all the autumn. The first week in April we again cultivate the land, and all the long manure being now rotten, we mix it with the soil. Again we set the line, draw drills 3 in. deep, and plant Veitch's Ashtop Potatoes. These we take all up when ready, level the land with a wooden rake, and sow Carrots in the middle of July, making the fourth crop, without the use of a spade. The Carrots are not all lifted before February, as we take them up as required. These Carrots are very different from those sown early in spring; they are young, tender, and delicious. When all are off, the border is then manured heavily and dug deeply, preparatory for another campaign. R. GILBERT.

Burghley.

DANDELION SALAD.

AT a time when materials for salad-making are somewhat scarce, it may not be amiss to direct attention to the Dandelion for this purpose. It may be found in abundance in almost every part of the country, and, therefore, easily obtainable in excellent condition from November to March. It is highly esteemed by the French, and may be seen in their markets for sale; it is really delicious as a salad, and one that can be used almost daily without tiring the appetite. The French attribute to it excellent medicinal qualities, with what truth I am unable to say. I feel confident, however, that the plant is most wholesome as well as agreeable to the palate. The great drawback to its general use in this country is the want of knowing how to treat it. I may mention, however, that it is one of the simplest salads to make, as it requires nothing whatever except oil, vinegar, pepper, and salt; it would, in fact, be spoilt by any interference with it in the shape of adding other ingredients besides those just mentioned. In gathering Dandelions, an ordinary table-knife is required to cut the roots just below the crown, choosing those with narrow leaves, which will be found the most tender and best flavoured, the large-leaved kinds being somewhat coarse. In preparing them, a small portion of the root should be allowed to remain attached to each crown, for the double purpose of holding the leaves together and for flavour; they should, in fact, be trimmed similar to roots of Celery for market. Care should be taken to remove old or

decaying leaves, Grasa, or other matter, cutting off just the tips of the leaves if decayed. The trouble of preparing them is perhaps one of the reasons why they are not more generally eaten, as certainly some little patience is requisite to clean them, but I can guarantee that the labour will be well repaid. Nothing remains after this to fit them for the salad bowl except giving them a thorough washing, particular care being taken that no grit is left. They should also be dried in a towel, for it is impossible to make a good salad unless the materials of which it is composed are thoroughly dry; inattention to this I believe to be the cause why many persons dislike salads, as water spoils the vinegar, and prevents the oil from becoming properly incorporated with the salad. In mixing it, a wooden spoon and fork are necessary; salt and pepper, according to taste, being placed in the spoon, pour on them enough vinegar to make a thin sauce, which pour equally over the salad; then add more vinegar, and lastly the oil; mix all thoroughly, *i.e.*, turn the materials over and over until the oil and vinegar are evenly distributed; however insignificant these simple details may appear, I assure those who make salads that their goodness or badness depends in a great measure upon these directions being attended to or neglected, although the proportion of oil to vinegar may depend upon taste. I have found the following agreeable to most persons, *viz.*, three tablespoonfuls of vinegar to two and a half of oil. I may here mention that I allude to French white wine vinegar, the English not being nearly so suitable for salad-making, and the oil should be the best obtainable, as nothing is more calculated to spoil a salad than indifferent oil. After mixing, no vinegar or oil should remain at the bottom of the bowl. I venture to think that, if the above suggestions be strictly observed, some of your readers who have never tried Dandelion salad have still a treat in store.

CHARLES DENNIS.

Southwark Park.

Early Peas Under Glass.—Unheated glass structures, no matter what form they may have, are most efficient aids in forwarding early produce; and those who have abundance of such conveniences stand in a far better position than others whose means are limited. Peas of Tom Thumb, Blue Peter, Multum in Parvo, or any other of the dwarf growing kinds, sown now in boxes or pots, and placed under glass in a light position, will yield a good and certain crop earlier than could, under the most favourable circumstances, be obtained from an unprotected border. In the open border I find wire protectors to be great conservators of warmth, more so than any one would believe who had not tested them side by side with rows unprotected, and they also, during the early stages of growth, which are generally the most critical, protect them from the depredations of sparrows.—E. HOBDAY.

Mushrooms in a Fruit-room.—My fruit-room is built on the ground floor, at the back of a late Vinery, and is paved with common bricks, but not heated. Thinking that a slightly moist atmosphere would prolong the keeping of the fruit this season, I determined to try to grow Mushrooms under the first shelf by enclosing it, and so far the result is very satisfactory, both as regards the keeping of the fruit and the growing of Mushrooms, for at present the bed is covered with Mushrooms in all stages of growth. I prepared the bed in the usual way, and spawned it on September 18 with, I must say, very doubtful spawn. About a fortnight afterwards, finding some Mushrooms on my Rhubarb bed, I removed 1 in. in depth of the soil, and discovered a large patch of good spawn, with which I spawned my bed again, and from this I obtain my Mushrooms. In growing Mushrooms it will therefore be seen, as Mr. Groom says (see p. 483), that upon the quality of the spawn success more depends than on the kind of structure in which they are grown.—JAMES SIMMONS, *Calverton Hall, Notts.*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Dalmien Brussels Sprouts.—These are by far the best that I have ever grown. We have a large batch of them now ready for use; each plant is about 18 in. high, and from four to five dozen large hard sprouts are clustered round each stem. Scrymger's Giant, which is generally well spoken of, has failed to fold its sprouts, and I will not grow it again.—CAMBRIAN.

The Best Winter Lettuce.—We grow a good many varieties of Lettuces for winter use, including the hardy green Hammersmith, All the Year Round, Tom Thumb, &c., but the best of all is Stanstead Park. We have one large plantation of this ready, and others are coming on to succeed it. Those which we are cutting average 20 in. in circumference. They are hard and crisp, and self-folded into a ball, with the exception of three or four leaves on each plant.—CAMBRIAN.

Mr. W. BULL is forming a supplemental nursery near the King's Road, in which eighteen large hothouses are now being built for the accommodation of new plants.

SOCIETIES AND EXHIBITIONS.

MESSRS. SUTTONS' READING ROOT SHOW.

At this show collections of vegetables were limited to twelve kinds, and, as there were sixteen competitors, the display was a remarkably good one. Mr. W. Wildsmith, gardener to Viscount Eversley, at Heckfield Place, was placed first; his collection contained Brussels Sprouts, Dwarf Curled Savoys, true R-sette Coleworts, handsome Masters' Prolific Cucumbers, Suttons' selected Parsnips, Pink Celery, handsome Reading Onions, Dark Red Beet, Excelsior Round Potatoes, Autumn Giant Cauliflowers, Intermediate Scarlet Carrots, and Red Stone Turnips, all very effectively arranged on a ground of leaves of the Curled Kale, making a group as to the merits of which there could be no doubt. The second prize was taken by Mr. Higgs, gardener to Mrs. Crawshaw, of Caversham Park, Reading, whose collection included both Asparagus and French Beans, but the Savoys, Brussels Sprouts, Celery, Victoria Potatoes, and Cabbages were, perhaps, rather too large and deficient in quality. The third prize was taken by Mr. Neal, gardener to P. Southby, Esq., of Bampton, in whose collection were some singularly beautiful examples of Suttons' Golden Globe Savoy, the hearts being of a rich yellow tint. The fourth prize went to Mr. Moss, gardener to C. Eyre, Esq., of Welford Park, Newbury, and several other collections were highly commended. The class for collections of Potatoes, of an indefinite number, brought a large competition, the first prize being taken by Mr. Bellis, gardener to Major Thoys, of Sulhamstead, who had twenty-five kinds, about one-half of which were fairly good samples, but the remainder were poor; the large number of sorts shown by this exhibitor probably influenced the decision, as the second prize lot, consisting of eighteen dishes, shown by Mr. Wildsmith, was certainly the best as regards average quality and table excellence. The third prize was taken by Mr. Higgs, whose collection was rough and uneven, and far below the best exhibition standard. Mr. Tegg, gardener to John Walter, Esq., M.P., Bearwood, was placed fourth. Several commendations were given in this class. For eighteen tubers of Magnum Bonum Potato Mr. Tegg was placed first, amidst a remarkable number of competitors. The Onion class was a singularly good one, Mr. Southby being first with some very fine bulbs of great size and beauty; Mr. Penny, gardener to His Royal Highness the Prince of Wales, at Sandringham, was second; H. Verey, Esq., Troxford, third; and Mr. Wildsmith, fourth. Parsnips were shown very large, perhaps mostly too large for table use, and in great quantities. Carrots were also a great feature, and excited considerable competition. Amongst subjects of garden interest not placed for competition was an interesting collection of Potatoes from Mr. Robert Fenn, Sulhamstead, and which included some fine samples of his new Anglo-American seedlings, produced from a cross between the American Willard and the English Bountiful. Of those exceptionally good, were Sulhamstead Seedling and Anglo-American, both very handsome, long, white kinds; and Weighwell, C. P. Pringle, and Robert Fenn, red kinds; there were also excellent samples of International Kidney, Early White Kidney, Rector of Woodstock, Early Market, and a fine pile of the new Woodstock Kidney, a fine late white kind, the stock of which has passed into the hands of the Messrs. Sutton. This firm also staged a fine collection of some fifty or more kinds, and had, likewise, large heaps of their late Kidney Magnum Bonum, a very fine main crop Potato. The show was, moreover, enriched by the presence of a very fine collection of Apples and Pears staged by Mr. Fowle, gardener to Sir Henry Mildmay, Dogmersfield Park, Odham; amongst them were Alfriston, Blenheim Orange, Cox's Pomona, Wellington, Mere de Menage, &c., in kitchen kinds; and rich-coloured samples of Ribston Cox's Orange Pippin, Court of Wick, the Wax Apple, Scarlet Nonpareil, and others amongst the dessert sorts. There were some good dishes of Pears. Mr. Davidson, gardener to Mrs. Marson, Highfield House, Heckfield, sent a quantity of bunches of a new Grape Tomato, the produce of a cross between the Red Currant Tomato and Hathaway's Excelsior, giving bunches 6 in. long, and fruit larger than Cherries. It is a very robust grower, and is yet in full fruit on a wall, merely sheltered by mats at night.

The Common Brake.—"R. C." (see p. 486) need not apprehend that the common Brake will perish, if cut over at the fall of the leaf two or three years in succession, nor for twenty years. Near to where I write is a rabbit-warren of several hundred acres, covered to a great extent by Brake. The more accessible parts of it have, to my personal knowledge, been cut down annually for ten or twelve years, and I believe previous to that for time out of memory. The parts so cut yield just as strong a growth as those not cut. The farmers in the neighbourhood use it extensively for litter and bedding for cattle in the winter months, for which purpose it is an excellent substitute for straw. It is cut early in October, when partly green, or not so far dried as to become brittle. I use it to protect Celery and other garden crops in hard frost; it is not so unsightly in a garden, nor so liable to be carried about by the wind as straw.—J. E., *Llangefni.*

Artificial Clouds.—If you could give full details as to how the French produce artificial clouds, it would, perhaps, be of great use to me as a means of producing valuable fruit, and to other subscribers of *THE GARDEN*.—JOHN MARTIN. [Probably Mr. Martin alludes to the practice of burning pitch or tar in Vineyards.]

GREEK AND ROMAN PLOUGHS.

THE history of ploughing and ploughs, from the primitive instruments mentioned in the Old Testament down to the most recent inventions

Drawing of ancient Greek Plough.

and improvements which have taken place since the application of steam to so many practical purposes, would furnish material for a

Drawing of ancient Roman Plough.

very comprehensive sketch. The ancient Egyptian implement, which was formed entirely of wood, can hardly be considered more than a modification of the hoe, and in some cases, indeed, consisted of

scarcely more than a pointed stick, which was forced into the ground as it was drawn forward. The earliest kind of Greek plough, which was known as the antogon, consisted simply of the trunk of a small tree, having two opposite branches; of these branches one formed the share and the other the handle, while the pole or beam was furnished by the trunk. A later form of Greek plough, the pekton, was very similar to that still in use in Mysia. The Romans, as might have been expected from so practical a people, made great improvements in the plough, as may be seen from the accompanying figure, where we observe that the coulter and mould-board have been added, as well as the wheels which are attached to the beam to prevent the share from going into the earth to too great a depth. It was reserved for our own country, either at home or in the colonies, to bring the plough to the high state of efficiency to which it has now attained.

BOTANIC GARDEN, HOBART-TOWN, TASMANIA.

AFTER a long and tedious voyage from England, the approach to Hobart-Town, situate on the river Derwent, just where it widens out into its estuary, excites the utmost admiration in the lover of Nature whose tastes lie chiefly in the direction of gardens and scenery. This is not a journal for recording Alpine ascents or mere scenery, beautiful in their way though they be, so I will only say that the coast is rocky, with bold mountains rising steeply but a short distance from the sea-shore. Vegetation on the banks of the Derwent is scanty, the low-lying ground having been cleared by fire to allow of cultivation, but the mountains which rise on both sides of that river are densely clad with virgin forest, whose sheltered recesses are rich in Tree Ferns and other vegetation that delights in the cool, damp south wind that blows in so constantly during the summer months from the cold antarctic seas. Our point of interest is the botanic garden, which is beautifully situated at some distance from Hobart-Town, and close to Government House. From thence the view looking northwards, over the clear blue lake-like waters of the Derwent, towards Mount Wellington, which rises to a height of 4200 ft. only a few miles off, is worthy of comparison with any view, however famous, on the northern shores of the Mediterranean. In this hemisphere a north aspect is the sunny and sheltered situation, so on entering the garden, *Bougainvillea glabra* in flower on the walls, and Norfolk Island Pines growing on the sheltered slopes, surprise a visitor who finds from records kept for some years that the summer temperature does not exceed that of the south of England; absence of any severe frost, the hot sun of lat. 44, and a dry summer climate, account for such apparent anomalies as sub-tropical plants and English temperature. Among beautiful evergreen trees, *Balfouria Pittosporoides* deserves particular notice, laden, as it is, with clusters of large Jasmine-shaped flowers, shading from pale lemon-yellow in the opening bud to apricot colour in the fading flowers. Its scent, recalling that of its near ally, *Pittosporum Tobira*, fills the air; its leaves are large, smooth, and rich green, so, altogether, it is a most desirable small tree for those who can grow such things. Where the New Zealand *Metrosideros* thrives, the *Balfouria* would, I think, succeed. On every side brilliant colours sparkle in the glowing sunshine and keen bracing air, and *Cantua dependens*, entirely covered with its rose-crimson, pendent flowers, causes one to stop and admire it. Here, this shrub flowers for several months in the year, and rivals the most gorgeous *Azalea* in the mass of its blooms. Surely this plant deserves more attention than it has hitherto received in England. Like many other gems whose culture has not been properly understood, it has been pushed first into the background, and then thrown away, to make room for novelties not nearly so beautiful. I must not forget to mention that beds of Cape *Statice*s and divers garden hybrids, such as *S. Holfordi*, make, with their feathery heads of rose or lavender-blue blossom, quite a new effect, which I recommend to bedders-out. But what is that lovely hedge of blue and white? A closer inspection reveals to us that it is composed of the single *Macartney Rose* (*R. bracteata*) with its large, white, *Cistus*-like flowers almost hiding its glossy, dark leaves, alternating with bushes of *Sollya heterophylla*, whose bright blue, starry blossoms, on wire-like stems, and whose pointed, pale green foliage, make together a line of beauty indeed, although the hedge itself is but a straight one. This *Rose* thrives on a light, warm soil in the south of England, and

a dry, sunny bank would suit it thoroughly; but I fear that *Sollya heterophylla* declines to thrive out-of-doors, even under such conditions. A striking feature also is the number of hybrid Passion-flowers, some of them raised by Mr. Abbott, the energetic curator, who, despite the great scarcity of labour and slender funds set aside for the maintenance of the gardens, contrives to find time for patient hybridization. New Zealand *Cordylines* are, of course, abundant, as are also many other trees from that island. *Xanthorrhoeas*, or Grass trees, of divers sorts here assume a beauty unknown in their wild state, their feathery leaves and blue, glaucous bloom combining the grace of a *Dasylium* with the colouring of the Aloe; their flower, however, is not remarkable for beauty, being in colour and shape almost exactly the model of a large kitchen poker! But among so much beauty and interest, it would be endless to describe all that deserves attention, so we recommend all those who can to go there and judge for themselves. E. H. W.

THE LIBRARY.

VAN HOUTTE'S FLORE DES SERRES ET JARDINS DE L'EUROPE.

THE second instalment of the twenty-second volume of this beautifully and profusely-illustrated work has just reached us, and gives further evidence of the desire and intention of the new editor, Professor J. E. Planchon, of Montpellier, to keep up the work entrusted to him to the high standard of excellence to which it was brought by its founder, the late M. Louis Van Houtte, of Ghent. The triple part now before us, which completes the first half of the volume, contains beautifully-executed double-page portraits of the following plants, viz., *Cypripedium Harriianum*, *Alstroemeria Pelegria*, and the pure white form of the same plant; the cone and separate seed nuts of the beautiful Norfolk Island Pine (*Araucaria excelsa*); the free-blooming, white-flowered *Daphne Blagayana*, which we do not think quite true to Nature, as, so far as we know, this variety blooms before the leaves appear, the bunches of bloom appearing with great freedom, but at the ends of bare stems, whereas, in the plate before us, the plant appears in full and simultaneous foliage and bloom. Single-page portraits are also given of *Rhodanthe Manglesii* maculata, an introduction of Mr. Thompson, of Ipswich, very pretty, and quite distinct from the type; *Statice Bourgeani*, from the Canary Islands; *Salvia leucantha*, from Mexico; *Limnolobos rosea* superba, a lovely rose-coloured Orchid, from Moulmein; *Lisaria triornithophora*, a beautiful form of this family, and a native of Portugal, also known as *Lisaria lusitanica*; *Adiantum candatum*, a distinct and beautiful Fern from the East Indies—also known under the various names of *A. incisum*, *A. vestitum*, *A. hirsutum*, *A. flagelliferum*, *A. capillus gorgonis*, and *A. ciliatum*; *Linum pubescens* Sibthorpianum, a beautiful pale pink-flowered hardy Flax, also known as *L. piliferum*, *L. decoloratum*, and *L. hirsutum*; *Scyphanthus elegans*, also known as *Grammatocarpus volubilis*, a beautiful golden-flowered trailer, from Chili, somewhat resembling *Tropaeolum polyphyllum* in colour and habit of growth; three fine double-flowered *Fuchsias* named *Missi*, *Tatlo*, and *Remor*. *Cælogyne Scillerisana*, a small Orchid, from Moulmein; *Crinum Brachynema*, from Hindostan; *Hepatica angulosa*, from Transylvania; *Eucomis punctata*, a dull-flowered bulb, from the Cape; *Orchis foliosa*, from Madeira; *Pentstemon centranthifolius*, from South California, with scarlet flowers; *Dipladenia crassinoda*, from Rio Janeiro; *Trillium sessile*, from North America; *Helipterum eximium*, a curious white, woolly-leaved plant, with rose-coloured, Amsrantes-like blossoms, from the Cape; and *Blandfordia flammæa* var. *priiceps*, perhaps the handsomest variety of this family yet introduced. W. E. G.

WE have received the "Annales du Jardin Botanique de Buitenzorg," published in Batavia, by H. M. Van Dorp & Co. It contains good figures of a variety of Palms grown in the garden, and is altogether a most creditable publication for a botanic garden in such a country. A good many new plants of New Guinea are described in it, and there is an interesting account of a journey in that country by the director of the garden.

THE new paper named "Brief," though unconnected with gardening, deserves a word of commendation on account of the brief way in which it deals with matters. It aims at being a reliable record of facts, dates, and opinion. No need now for those, whose outdoor claims upon their time are great, to get lost in the columns of their morning papers, to be bewildered by the verbiage of one-sided city articles, and to winnowing the penny-a-liner's chaff from the grain of fact. Here are at once both sides of all questions—political, social,

and economical—presented to view. "Brief," in a word, makes a necessary literary labour shorter, the time for our various other pursuits longer.

Mr. Murray has just published a second edition of Mr. Cooke's "Leaves from My Sketch Book." It forms an elegant volume, comprising sketches from Venice, Naples, Pompeii, Pristum, and many from the banks of the Nile, in which interesting land Mr. Cooke has spent a long time and made several thousand sketches.

Plant-lore of Shakespeare.—Many of our readers will be pleased to learn that the Rev. Mr. Ellacombe's papers on this subject in THE GARDEN are being reprinted (with additions and alterations) as a book on the subject. We believe Mr. Ellacombe was the first that ever seriously took the subject in hand, and who was at the same time, fitted to deal with it from long familiarity with the flora of our open air gardens, both now and in past times.

IDESIA POLYCARPA.

THE accompanying little drawing of this interesting tree was made from a specimen sent to us this season from Mr. Luscombe's richly-

Idesia polycarpa.

stored gardens at Combe Royal, near Kingsbridge. It is described at some length in THE GARDEN for July 21 of the current year (see p. 55).

Vines on Back Walls of Vinerias (see p. 498).—There is nothing new in this. I began gardening more than five-and-thirty years ago, with that famous old English gardener, Mr. Elworthy, at Nettlecombe Court, in Somersetshire, and one of the things which I remember so well was my first start at training Grapes on a back wall of a Vinery, which was afterwards converted into a greenhouse. The Grapes on this wall ripened up to such a size in berry that I have never forgotten them; but Mr. Elworthy, if I remember rightly, adopted the method of growing a single rod to each rafter. This house was made available for a great variety of plants, including Orange trees of great age, which the late Mr. Loudon, when there, pronounced to be the very acme of perfection. I have followed out this system in a Vinery at this place with wonderful success, and Mr. Wilson would no doubt improve the quality of his fruit by adopting the single rod. He would then have more light for the fruit on the rafters, as well as throw all the light on the back wall. I could name many places in this district where the back wall is made use of either for Vines, Figs, or Peaches. If the border be properly made, and the Vines carefully planted, success is certain; failure as regards inside borders generally occurs through an insufficient supply of water during the growing season.—WILLIAM CULVERWELL, *Thorpe Perrow.*

MR. GEORGE MAW, to whose many extensive journeys our gardens are so largely indebted for new, and particularly for hardy, flowers, has lately been robbed in one of the Ionian Islands. The authorities, however, afterwards succeeded in recovering the money, and punishing the offenders.

WE learn that a seat at the Board of Directors of the West London Commercial Bank, Chelsea, rendered vacant a week or two back by the death of one of its oldest members, has been unanimously voted to Mr. Geo. Deal, an active member of the firm of Messrs. J. Weeks & Co., Horticultural Engineers, Chelsea.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

Oranges and other Citronworts at Combe Royal, S. Devon.—The interesting description of trees of the Citron tribe in a recent number of THE GARDEN, reminds me of those growing here; and I venture to think you may be gratified by seeing specimens of the fruit produced at this place. My trees are growing on south and east walls, and protected only by wooden or reed frames, which are closed at night and partially by day in very severe weather. The Citrons are not good specimens, as they have often been 17 in. and 18 in. in circumference, and one or two, some years ago, measured 19 in. I could have gathered very many more, and yet not have denuded the trees of their golden glory. Oranges and Lemons have, for a long series of years, flourished at Combe Royal, and one Seville Orange tree we know must be nearly, if not quite, two centuries and a half old; it is vigorous now, as the fruit (which I have marked) will testify. From another tree more than 300 Oranges have recently been gathered.—*JOHN LUSCOMBE.* [This was a varied and most interesting collection. The heavily-laden branch of the Seville Orange clearly showed it to be still in vigorous health. The Sweet Lime, in the same collection, was very like *Citrus japonica*, of which good specimens were also sent.]

Winter Flowers.—Are amateurs generally aware how easily Roman Hyacinths may be got into bloom in the first week of November without any forcing whatever? I potted some on August 14, and took them from the ashes on September 18; they came out quite naturally in the greenhouse on November 8. Cyclamens came out late in October, and the Paper Narcissus is nearly out—all entirely without heat. It is astonishing how many amateurs one finds quite ignorant of the existence of useful flowers like Roman Hyacinths, that cheer us at this dead time of the year. Fuchsia planted out in summer, and lifted the first or second week in October, furnish a very useful lot of blooms in the greenhouse at this season, as do also Veronicas similarly treated. Roses here are still furnishing good blooms.—*P. P., Shrewsbury.*

American Apples.—Messrs. Ellwanger & Barry have sent us, from their noble and beautiful nursery at Rochester, in Western New York, specimens, large and bright in colour, of that fine Apple, the Northern Spy. This Apple Downing describes as "the most delicious, fragrant, and sprightly of all dessert Apples. It ripens in January, keeps till June, and always commands the highest market price. The tree is of rapid, upright growth, and bears moderate crops. It originated on the farm of Heman Chapin, of East Bloomfield, near Rochester, N.Y. The trees require high culture, and open heads to let in the sun, otherwise the fruit is wanting in flavour, and apt to be imperfect and knotty. Young shoots dark reddish brown. The tree blooms late, often escaping vernal frosts." The specimens sent were very high in colour, and fine in flavour. A number of them weighed nearly twelve ounces each.

The Cape Gooseberry (*Physalis peruviana*).—Walking down Oxford Street the other day, we noticed in a shop window some wicker-covered jars labelled "Cape Gooseberry Jam." As it is quite likely that this new preserve may become a recognised adjunct to our breakfast tables, a few words about the plant which produces it may be of interest. In spite of its name, the "Cape Gooseberry" has nothing to do with the ordinary Gooseberry of our gardens; it is a member of the Nightshade family (*Solanaceæ*), and a near ally of the Winter Cherry (*Physalis Alkekengi*). It is described as a robust, diffuse herbaceous plant, covered all over with a greyish down, with sharp-pointed ovate, entire, or wavy membranous leaves, and small, short-stalked yellowish flowers, with a dark purple centre. The pale yellow calyx increases greatly in size after the expansion of the corolla; it is at first only a $\frac{1}{4}$ of an in. long, but attains as much as 2 in. in length, with an inflated tube; this encloses a globose, yellow edible fruit, to which the name of Cape Gooseberry is applied. Originally a native of Chili and Peru, this plant has spread throughout the warmer regions of the world. It was originally cultivated for its fruit in India, New South Wales, and the Cape, but is now completely naturalised in the two last regions. It established itself in suitable localities with very great rapidity; Drummond, who planted the first example in the Swan River Colony, states that it

was perfectly naturalised there in the short space of ten years, and it is now widely spread throughout Australia. In New South Wales it was held in great esteem by the earlier colonists, and was indeed the chief fruit which they possessed; whether eaten raw or made into pies, puddings, or preserves, the Cape Gooseberry met with general approval. In Mauritius and Rodriguez it is well established, and is completely naturalised throughout the Cape district; it is found in the Sandwich Islands and is common throughout Fiji. In the Sandwich Islands (where it may possibly be indigenous) two varieties occur, one with a berry as large as a Hazel-nut, the other in which it is about as big as a Pea; both are employed in making pies and tarts by the colonists. It is also naturalised in Madeira, Java, the Philippines, the Canaries, and many parts of India, and is, or has been, established in parts of central Spain, and in the Island of Sicily. It was cultivated in Kew Gardens exactly a hundred years since; and is figured (under the name of *P. edulis*) in the "Botanical Magazine," t. 1068.—*B. J.*

Epiphyllums.—Mr. Speed sends us from Chatsworth some beautiful seedling varieties of these, some purple kinds being particularly remarkable. These useful, winter-flowering plants are exceedingly well done at Chatsworth, and we know of none more worthy of attention; their graceful habit, easy culture, and now charming variety of delicate colours all especially recommending them to our notice.

A Welcome Gift.—The rich garden of the late M. Thuret, of Antibes, which contains such a valuable collection of plants, will now be exclusively devoted to State uses, and form a branch of the Museum of Natural History. M^{me}. Louise Fould has given £8000 for the purchase of the property for this purpose, and the Minister of Public Instruction has been authorised to accept the noble gift.

Orchids Effectively Arranged.—In one of Mr. Ball's Orchid-houses, I noticed, the other day, well-flowered plants of *Ocidium Barkeri* and *O. ornithorhynchum* associated with *Odontoglossum Bictonense* and *O. crispum* in such a way as to be very effective. Other combinations consisted of a mixture of the flowers of *Calanthes* with those of *Odontoglossums*, *Sophranitis*, and *Lælias*, the whole being set off by a groundwork of *Cypripedium insigne*, the flowers of which were produced in great profusion. In the same house were also in flower *Cypripedium Stouei*, the richly-spotted *Vanda tricolor* and *V. t. insignis*, a beautifully-marked variety of *Odontoglossum Insleyi* *Leopardianum*, and the waxily-flowered *Colax jugosus*.

Plants in Flower in the York Nurseries.—At this, the duldest time in the whole year for Alpine and herbaceous plants, it may be interesting to note what plants are now in flower, or even partially so. The following are a few which I noted on the rock-work at York, viz.:—*Erodium Manescavi*, *Pyrola rotundifolia*, *Veronica amethystina*, *Helleborus niger*, *H. r. maximus*, *H. lividus*, *H. orientalis*, and *H. foetidus*, *Aubrietia græca* var. *superba*, *Polygala Chamæbuxus purpurea*, *Iberis Babiani*, *Colchicum autumnale* fl.-pl., *Primula acaulis*, *Arabia procurrens*, *Botryanthus pallens*, and *Veronica rupestris*.—*R. P.*

Meconopsis nepalensis in Winter.—There is a quantity of this noble and singularly beautiful Poppywort growing in the herbaceous grounds at the York Nurseries—some of them in the open peat beds, where they are very vigorous. The leaves are produced in a circle radiating from a common centre—the lower or larger leaves lie close upon the ground, while the younger and smaller ones are erect or sub-erect, and beautifully and densely clothed with long hairs, causing them to resemble, when dry, leaves made of lamb's wool. The crowns are from 12 in. to 18 in. in diameter, and with from sixty to eighty leaves to each. It flowered in the York Nurseries last summer, and was very pretty; but I consider it is equally beautiful in its present state.—*R. P.*

Pampas Grass and Arundo conspicua.—In Mr. Fraser's work on trees, he speaks of the Pampas Grass coming into flower in July, which, I think, must be a mistake. Here, in the north of Ireland, it rarely flowers till November, and this year it is later still, as my plants, although well sheltered, are only now (December 3) showing the inflorescence. The lateness of the flowering of the Pampas greatly detracts from its value for decorative purposes, as its appearance is disfigured, and its culms broken by the rains and winds of November and December. As an ornamental plant I give a decided preference to the *Arundo conspicua*, which flowers with me about the end of July, and is even now in considerable beauty. A group of three or five of these plants placed on a lawn in front of a Pine, Cypress, or other dark-foliaged tree or shrub, has a grand effect, the slender, plume-like panicles being in constant graceful motion stirred by the slightest breeze. This *Arundo* is easily raised from seed, is quite hardy, and deserves a place in every collection of ornamental plants.—*WILLIAM VALENTINE, Glenavna, Whiteabbey.*

Waste Lands and Fruit Culture.—The French Société d'Encouragement offers a prize of 1000 francs (£42) for the best plan for utilising waste lands in fruit culture. Essays must be sent in by 31st December next.

Prizes for Plans of Flower Gardens are offered by Mr. John Downie, to be competed for by under gardeners, members of the Scottish Horticultural Association. The plans are to be sent in to the secretary of the association by Feb. 1, 1878.

Another Park for Birmingham.—Mr. Marnock has been called in to lay out another park in Birmingham. It is at Small Heath, and was presented to the city by Miss Ryland. It is about 40 acres in extent and valued at £30,000.

A New Lapageria.—Mr. Bull exhibited, at South Kensington, the other day, a spray of *Lapageria rosea superba*, from 15 in. to 18 in. long, bearing twenty large richly-coloured blossoms. This will make a good addition to the red and white kinds already in cultivation.

Lasiandra macrantha floribunda.—This Melastomad, which is now flowering freely in several of the London nurseries, is one of the best plants which can be grown for greenhouse or conservatory decoration in winter. Bushy plants of it in 6-in. pots, if well grown, will yield an abundance of large bluish-purple blossoms for many weeks in succession.—S.

Two Good Primulas.—In a collection of double-flowered Primulas in Messrs. Lee's nursery at Isleworth are two kinds which should be largely grown for conservatory decoration, and also for furnishing out flowers. One, named Prince Arthur, has bright pink flowers, and the other, which is called *alba magnifica*, has pure white ones. In both cases the colours are decided, thus rendering these varieties more valuable than kinds having streaked and spotted blossoms.—S.

Fuchsia Dominiana.—This is one of the best Fuchsias which can be grown for conservatory decoration in winter. It is robust in habit; its leaves are large, and of a healthy bronzy-green colour; and its flowers, which are produced freely, even during the duldest part of the year, are rich rosy-scarlet in colour. Several good specimens of it may now be seen in Messrs. Veitch's nursery at Chelsea, where it was raised, being the result of a cross between *F. spectabilis* and *F. serratifolia*.

Pansies in Scotland.—As a proof of the mildness of the season in Scotland, we are exhibiting, in our winter gardens, Pansy blooms, consisting of both show and fancy sorts, cut from the open border; many of the blooms would not disgrace a stand in June. The other day we filled a stand of thirty, and could easily have furnished 100 such blooms.—DOWDIE & LAIRD, Pinkhill Nursery, Corstorphine.

A Large Fruit Cargo.—The steamer "Discoverer," which arrived in the Mersey a few days since from the Spanish ports of Valencia, Almeida, and Malaga, brought the largest cargo of fruit, it is believed, ever imported into the port of Liverpool, and probably the largest ever carried in one vessel. The cargo in question consisted of 22,559 boxes of Raisins, 21,940 barrels of Grapes, and 6443 boxes of Oranges, &c. The combined cargo weighed 1600 tons, of which the Grapes alone weighed upwards of 800 tons.

New Public Park for Wishaw.—This, the gift of Mr. J. Houldsworth, of Coltness, is situated to the east of the town, at the foot of the rising knoll on which stands the parish Church of Cambusnethan. It is exactly eight acres in extent, and is being laid out with considerable taste; excellent pathways have been made through it, and in time it will be stocked with plants and shrubs and trees suitable for its embellishment. A skating and curling pond, situated at the east end of it, has been diminished on the east side and enlarged on the north, so as to increase the size of the park. In addition to presenting the ground, Mr. Houldsworth has spent over £2,000 in making it suitable for the purpose for which it is intended.

A NOVEMBER ROSE.

O late and sweet, too late, too late!
What nightingale will sing to thee?
The empty nest, the shivering tree,
The dead leaves by the garden-gate
And cawing crows will for thee wait,
O sweet and late!

Where wert thou when the soft June nights
Where faint with perfume, glad with song?
Where wert thou when the days were long,
And steeped in summer's young delights?
What hopes thou now but cheeks and slights,
Brief days, lone nights?

—"Atlantic Monthly."

FROM KEW.

SEVERAL plants of considerable interest and beauty are now to be seen in flower at Kew, in spite of the very unfavourable weather. *Dombeya Burgessiae*, a Byttneriaceae shrub, from South Africa, has large, fragrant, white, rosy-disked flowers. The genus *Dombeya* is a very beautiful one, almost peculiar to Tropical Africa and its eastern islands. A very large-flowered Rubiaceae plant from Sierra Leone, *Randia longiflora*, has yellowish blossoms about 1 ft. long. *Randia* is nearly allied to *Gardenia*, and the present species has flowers very similar in shape and size to some of the largest-flowered *Gardenias*. A deep blue Indian *Acanthad*, *Eranthemum nervosum*, is certainly worth a place in a select collection of stove plants; its colour is very taking. *Cratogeomys ligustrinum*, from China, belongs to the St. John's-wort family, and has opposite, glossy leaves and terminal panicles of white flowers. *Pancratium speciosum* is a very handsome West Indian Amaryllid, often confounded with *P. caribaeum*. From the latter species, however, it is abundantly distinct, and is easily recognised by its long-stalked leaves (the leaves in *P. caribaeum* are not stalked). The large umbel of pure white flowers is extremely ornamental and very fragrant, especially in the evening; the dried blossoms retain their scent for many months. The tropical American *Pitcairnia fulgens* has narrow arching leaves, and panicles of bright red flowers. All the *Pitcairnia*s are desirable stove plants. *Strelitzia ovata* has now several blooms expanded, and *S. Reginae* will be in flower very soon. Both are strikingly handsome plants, and are among the most splendid members of the Natural Order Musaceae. The latter species was introduced to Kew by Sir Joseph Banks in 1773, and the former is recorded as having been introduced four years later. The long-stalked, glaucous leaves are about 4 ft. long; the flower-stalk is about the same length, and is crowned by the obliquely-placed, spathe-like bract, within which are the flowers. These are very gorgeous, the three outer perianth segments being bright glossy orange, and the three inner azure-blue; the two inner lateral ones are united into a sort of tube which encloses the stamens. The two species, both of which come from the Cape of Good Hope, will do well under greenhouse treatment, but, in that case, flower some months later. The above are selected from the Palm-house.

In the stove are several pots of a very pretty bulbous plant, lately imported by Mr. W. Bull, from the mountains of the province of Bogota, in New Grenada; it is *Calliphurria Hartwegi*, and is the only known species of the genus. From the rosette-like tuft of neat, bright green, glabrous leaves, springs a scape, about 1 ft. long, surmounted by an umbel of six or eight pure white flowers; the tube of the perianth is about 1 in. long, and the diameter of the almost horizontally-spreading segments is the same.

Masdevallia melanopus is similar in habit to *M. polysticta*, noted last week, and is about as floriferous as that species, though much inferior to it as a decorative plant. *Oncidium cheiroporum* has bright, sparkling yellow flowers, and neat, narrow leaves. From the letterpress accompanying the figure in one of the later numbers of the "Botanical Magazine," we learn that it was discovered by Warscewicz, on the volcano Chiriqui, in New Grenada, at an elevation of 8000 ft., flowering in December, with the thermometer some few degrees above the freezing point. It is a very charming little species, and possesses the extra merit of being sweet-scented. The tall stems, somewhat like a sugar cane in habit, and the drooping panicles of large flowers, render *Ansellia africana* very attractive; this Orchid was first discovered growing on Oil Palm trees, near Fernando Po, by Mr. Ansell, who accompanied the Niger Expedition, and after whom it is named. It, however, does not seem to require epiphytial treatment under cultivation; the waxy flowers are yellow, blotched with reddish-brown, and last a long time in perfection. *Angraecum eburneum*, and its variety *virens*, though boasting neither brilliancy of colour nor fragrance, are very noble and desirable plants; the former has a large, ivory-white lip, the remainder of the flower being green; the latter has a greenish-white lip, and is not nearly so handsome as the former. These two plants are from that exceedingly rich and comparatively little-explored store-house of botanical treasures, the island of Madagascar. The Mexican *Laelia furfuracea* has one-flowered scapes, the flower being of a fine, warm rose colour. *Angulosia Clowesi* has very thick, waxy, yellow, sweet-scented flowers, and is a very distinct and beautiful Orchid.

In the greenhouse (No. 4) is an almost forgotten Rosaceous plant from China, *Raphiolepis salicifolia*; it has terminal panicles of white flowers, which last a long time, and answer well for bouquets. Mons. Carrière states that this pretty shrub forces readily. We have not heard of its growing in the open air, but as *R. ovata*, also from China, is certainly hardy in the south of England at least, there is a probability of the other species being so. *R. ovata* bears good-sized purple berries, which are said to make good tarts and preserves. A pretty, Rosemary-like Labiate from Australia, *Westringia eremicola*, is also in bloom; it is a neat-growing shrub, with narrow whorled leaves, and pale-blue flowers.

THE INDOOR GARDEN.

DORYANTHES EXCELSA.

THIS strong-growing Amaryllidaceous plant from Australia consists of a number of long, stout, lanceolate leaves, somewhat erect in growth, from the centre of which springs a tall, straight flower-stem, partially clothed with bracts. The flowers, which are each about the size of those of the common white Lily, are borne in a bunch on the top of the stem, and are of a bright scarlet colour. It is one of the most gorgeous plants in cultivation, and one very easily managed, requiring simply ordinary greenhouse treatment. As regards soil, it does well in a sandy loam, and, owing to its vigorous habit, it needs a good-sized pot, in order to enable it to attain sufficient strength

Doryanthes excelsa.

to exhibit its true character. It should have plenty of water while in active growth; but, during the dormant season, the soil in which it is growing should be kept in a tolerably dry state. B.

Luculia gratissima in America.—This is one of those plants which could not be obtained in this country a few years ago. We imported it from Europe several times, but it was found, on its arrival, to be dead. At last, however, two plants of it were alive, one of which I planted in the Camellia-house and the other went to California; that was three years ago. Last year we had on our plant upwards of fifty fine heads of bloom; this year there are over 100 heads on it, and we have a good stock of young plants obtained from cuttings during the summer. Some consider that this plant requires stove heat, but I find when it is grown in heat that insects are troublesome, while, in a cool house, they are easily kept in check. This is no new discovery, for I planted two plants of it in the Camellia-house at Chatsworth some years ago, and they grew and

flowered profusely; but, in the moist, dull climate of England, the flowers do not last so long as they do here, and in a very cold house, I think, they are not so sweet scented. The *Luculia* is not fastidious as regards soil; I have grown it in a mixture of two parts loam and one part peat, giving it, when thoroughly established, a mulching of good horse manure, and also a good soaking of manure water when in full growth. It is, I may add, a very thirsty plant, and requires an abundance of water at all times when in active growth. It should be cut well back after flowering, an operation which encourages the production of both foliage and flowers from bottom to top, and it will make shoots of 6 ft. or more in length in one season; therefore, if not cut back, it requires a very lofty house to accommodate it. Green fly is rather troublesome, especially when it is making young growth, and, later in the season, thrips attack it, but either fumigation or syringing with Tobacco-water will be found to be a sure remedy.—JAS. TAPLIN, *South Amboy, New Jersey.*

JAPANESE CHRYSANTHEMUMS.

It is worthy of remark that, while the Japanese Chrysanthemums have generally been regarded as blooming much later than the ordinary kinds, they have this season flowered quite as early, and, indeed, in many instances earlier. While the lateness of the season has affected, in a remarkable degree, the varieties of one type, the varieties of the other have not shared the general retardation. At the Chrysanthemum shows that have recently taken place, the Japanese varieties have been exceedingly attractive, and, on the whole, very fine; and, in addition, they present so much variety of form, such uncounted and eccentric shapes, and such brilliancy of hues, that it is not to be wondered at they are so much admired by the general public. I noticed at the recent Chrysanthemum exhibition at the Royal Aquarium, that by far the greatest pressure of visitors gathered round the stands of the striking Japanese Chrysanthemums. Of the newer varieties which have been distributed during the past few years, the following have proved very fine:—Diamond, bronze, shaded with orange, a large, full, very distinct-looking flower; Peter the Great, lemon-yellow, of great size, and very showy; Red Gauntlet, dark crimson, quite a new colour, very fine indeed; Sarnia, pale lilac, of a very delicate tint, distinct and very pleasing; Mr. Barnes, rich buttercup-yellow, flowers large and full; and R. T. Biggs, rich deep crimson, very attractive indeed. Some other fine varieties will be found in Jupiter, pale magenta-pink; Soleil Levant, clear yellow; Royal Soleil, orange-crimson; Baron de Prailly, clear pink, very good; Emperor of China, pale blush, nearly white; Bronze Dragon, Golden Dragon, and Red Dragon; Magnum Bonum, clear lilac, very fine; Fulgare, bright purplish-lilac, very good and distinct; and, of those more generally grown, such flowers as Comte de Beauregard, very fine; Dr. Masters, Chang, Elaine, Fair Maid of Guernsey, Garnet, a very rich crimson hue; Grandiflorum, golden-yellow; James Salter, very fine; Mons. Chas. Hubert, reddish-chocolate, very fine; Oracle, Plantagenet, yellow shading to orange, very fine; The Cossack, The Damia, and Viceroy of Egypt, rosy crimson. Of varieties not yet distributed, but which will be put into commerce next spring, the most remarkable are Fulton, fine golden yellow, very rich in colour and very showy; and La Nympe, delicate pink, with pale lemon centre, very distinct and attractive. Nora, To Kio, Nnit d'Hiver, and Emperor Nicholas, are also very promising. The Japanese varieties should be grown against warm, sunny, south walls, or under glass, as they are undoubtedly late, and cannot be expected to succeed in the open air. Nor is it of much use to plant Chrysanthemums in the open air with a canvas covering for protection when frost or bad weather threatens. The flowers come on very slowly indeed, and there is nothing like glass over them in autumn.

To have a good succession of Japanese Chrysanthemums, both for house decoration and cutting from, some good cuttings should be taken in February, struck in a little heat, and grown on as vigorously as possible, but in a cool temperature, to keep them vigorous. The best specimens for flowering are made when the plants are 2 ft. or so from the ground; they break out into three or four leading shoots, and bloom at the points. The earliest varieties should have the side buds taken out, leaving the centre ones, as these will bloom quickly. For successional blooming, take out the centre bud, and the result will be that three or four buds will be thrust out on either side, making two stems, 3 in. or 4 in. in length. These flowers will not be so fine as those formed by the centre bud, but they will be of great service for decorative purposes. Many Chrysanthemum plants are nearly ruined from want of attention during the summer; they are allowed to languish for want of water; the plants make a spare growth, lose their leaves, and cannot be expected to do well. It is because there is so much necessity for keeping the roots cool and moist while the plants are growing vigorous, that it is the usual practice to plunge the pots in ash beds during the summer. Copious

waterings overhead are also of great value; and, indeed, the Chrysanthemum is a great lover of moisture in whatsoever way it may be administered. Manure water is also indispensable at the time the buds are in course of formation. That recommended by Chrysanthemum growers is made by putting into a large tub or tank a barrow-load of fresh cow manure, on this a quantity of hot water is poured, a barrow-load of soot is added, and then rain-water enough to fill the vessel; the whole should be well stirred for a few days, and it should be allowed to settle before being used.—D. [We hope efforts to raise "Japanese" Chrysanthemums, devoid of the picturesque aspect of those originally introduced, will not succeed in destroying these really precious additions to our autumn flowers. The ideal of a ball might well be forgotten in their case.]

STORING SOIL FOR POTTING.

As this is the season when a supply of good turfy soil for potting purposes is required to be got in for storing, it may be noted that in most places there is great difficulty in procuring it. Cultivators in numerous instances have to put up with most unreasonable shifts in getting a supply, although they are expected to produce first-rate plants and fruits in due season. The fine "turf loam" and "fihry peat" has often to be procured by stealth, and this only in quantities enough to grow a few plants of the rarer kinds. The policy of compelling cultivators to take what soil they can get, and prohibiting them from taking a supply of that which is proper, is not at all profitable to their employers. They will not allow the gardener to take a few cartloads of turfy soil from a field, for fear the land will be permanently deteriorated, even though he says he will replace it with a richer and better Grass-producing soil. A method of getting some good fibry soil from a meadow containing it is to mow the Grass off very closely, and then skin the turf off as thin as to bear handling; then to take about 3 in. of the maiden loam beneath, and fill up the space with rich garden soil, relaying the skin of turf on the surface, and rolling all well down. Next summer this patch will produce richer and earlier Grass than the rest of the field, if it be well solidified by rolling, and by sowing the seeds of some permanent Grasses thickly on it. In thus pointing out the groundlessness of the notion that cultivators deteriorate the value of Grass land by skimming off the turf on the surface, it is yet but right on their part to be as sparing as possible in regard to the supply. A great deal more use might be made of charred refuse, and of the soil shaken out of the pots and consigned to the rubbish-heap from the potting benches. If this were sifted out and stored into a heap, it would be found very useful for mixing with fresh soils. As peat soil is only found good for potting purposes in a few localities, it is requisite to be as sparing of it as possible, and only to get a supply to supplement any sandy or leafy soil that can be procured on the place.—WILLIAM TILLERY, in "Florist."

Cyclamen Sports.—Last year one of my Persian Cyclamens produced three flowers on a stem, and this year the same bulb or corm has thrown up about 100 flower buds, and on one stem there are three flowers, and three leaves at the top of it; the stem is about 2 in. long, and the leaves and flowers are just showing. Is this usual?—A. LOWERY, *Blakesley, near Toncaster.*

Jasminum Sambac (see p. 489).—Perhaps Mr. Greenfield is correct; my plant may not be *J. Sambac*, though so named, as I thought, on good authority. It has been for the last four months in a cool house; it is in perfect health, and promises to flower profusely in a couple of months. I would feel greatly obliged if Mr. Greenfield would let me have a bloom off his plant.—THOS. SPELMAN, *Derry Castle, Kil'atloe, Co. Clare.* [The plant sent is *Jasminum Sambac*.]

Goodyera Rolissoni.—"S." says (see p. 490) that this *Goodyera* was exhibited for the first time in 1876, but that is a mistake; *G. Rolissoni*, which is the same as *G. Veitchii*, was raised by Mr. Dominy at Messrs. Veitch's nursery some eighteen years ago, and was sent out by that firm. It is a cross between *G. discolor* and *Anacochilus Veitchii*, and was named *Goodyera Veitchii*. How it comes to be sent out by Messrs. Rolisson it is impossible for me to say. Is it possible that the same plant has been raised in two different establishments? Be that as it may, I feel sure that Messrs. Rolisson would be the last to deprive Mr. Dominy of the honour of having raised it.—J. SPEED.

They are now converting the Square Notre Dame into a garden. In the course of necessary excavations many remains of ancient buildings have been found.

The executors of the late Dr. Welwitsch have placed the following inscription on his tomb in Kensal Green Cemetery:—"Fredericus Welwitsch, M.D., Botanici eximius, Floræ Angolensis investigatorum Princeps. Nat. in Carinthia, 25 Feb., 1806; ob. Londini, 20 Oct., 1872." The inscription is surmounted by a *Welwitschia* plant carved in relief.

IMPROVED CATERPILLAR-NEST DESTROYER.

If towards the end of June, or somewhat later, we walk through any extensive fruit-growing district, we can scarcely fail to come here and there upon a tree partly denuded of its leaves, the harer portions being festooned with a web-work that serves as the encampment of a numerous army of caterpillars. Supposing that it is an Apple tree which is thus attacked, closer examination of the assailants will probably show them to be caterpillars of the Allied Ermine Moth (*Hyponomeuta cognatella*), and, unless the culturist takes prompt and radical measures to ensure the destruction of the insects, every tree presenting the above appearance will, in all probability, be completely defoliated, and yield little or no fruit. One of the commonest remedies adopted consists in cutting off the affected parts with a pair of shears; but, in some instances this

Fig. 2.

Fig. 1.

Improved Lamp for Destroying Caterpillar-nests.

would entail the loss of too much fruit-bearing wood, and recourse is then frequently had, especially in the case of the higher branches, to a lighted lamp or torch; a calm, fine day being selected for burning the caterpillars and their nests. Of the different so-called "caterpillar lamps," specially constructed for this purpose, one of the most practical is that represented by the annexed illustrations; fig. 1 shows the wick and burner, fig. 2 the complete apparatus. The height of the latter (including the hollow stand or holder) is about 15 in., whilst the oil reservoir has a diameter of 2½ in. The holder is made hollow so as to allow of a rod or handle being fixed into it; the chief advantage of this over Mader's and other lamps of the kind, is that the reservoir remains upright and does not permit the oil to escape when the rod is held in a slanting direction. To Mr. Frank, of San Michele, in the Tyrol, we are indebted for the above improvement in construction.

T. S.

New Double White Violet.—A new double white Violet, named *Belle de Chatenay*, has lately been introduced from France, and will form a good companion to the Neapolitan. It is now flowering freely in Messrs. Lee's nursery at Isleworth, where there is a good stock of it. The plant is a profuse bloomer, and comes into flower at Christmas with very little forcing. Its flowers, on established plants, are very double, and about the size of a shilling. In the bud they are of a delicate mauve colour; but, as they expand, they become pure white. For button-hole bouquets this Violet will be invaluable.—S.

THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

(Continued from page 529).

MOUNTAIN FLORAS.—There is one more source from which we obtain many plants, namely, the mountains of the sub-tropical and tropical countries; in the former, broadly speaking, those growing at an altitude of more than 5000 ft. are hardy in this country, and, in the tropics, those found above 10,000 ft. Of course, these figures, like most of those given here, are the approximations, and about the extreme limits, as no such thing as a leap of 5000 ft. occurs in Nature.

EXTENT OF COUNTRY FROM WHICH WE OBTAIN HARDY PLANTS, AND NUMBER OF SPECIES.—Altogether more than a third of the surface of the dry land, which is estimated at 52,000,000 square miles, comes within our region of hardy plants; and the number of species it supports must be upwards of 25,000. In a certain restricted sense, the region of plants hardy in Britain—excluding, of course, the Arctic zone and the mountain heights of corresponding climate—coincides with the region in which the cereals—Barley, Rye, Oats, and Wheat—can be profitably cultivated, though all of them, but especially Wheat, are cultivated in sub-tropical countries, where the crop is harvested during the cooler season. Wheat is not a profitable crop in countries where the mean summer temperature is below 60°, and it is only sparingly grown above 60° N. lat. in Western Europe. It is most productive in the warmer part of the temperate zone bordering the sub-tropical. Barley and Rye are much hardier, and are cultivated in the exceptionally favourable (for latitude) climate of North-western Europe up to 70° N. lat., or at some distance within the Arctic circle.

NUMBER OF SPECIES FOUND WITHIN THE ARCTIC CIRCLE.—Within the Arctic regions, about 800 species have been collected, and they are chiefly remarkable for their wide range in distribution; only 1 per cent. of them have not been found beyond. Flowering plants have been found in almost the highest northern latitudes trodden by the foot of man; and, in Spitzbergen alone, upwards of 100 species have been detected.

NO PLANTS FOUND WITHIN THE ANTARCTIC CIRCLE.—Although we often read of Antarctic vegetation, and there are cultivated plants named antarctica, as *Dicksonia antarctica*, there is no zone of vegetation in the southern hemisphere corresponding

to that of the Arctic in the north, for not a single plant has been discovered within the Antarctic circle. Of the numbers of strictly Alpine species not found also in the Arctic regions, it is difficult to form an estimate; but they number several thousands; and those of the northern hemisphere are, for the greater part, different from those of the southern.

DEFINITION OF ALPINE AND ARCTIC.—The word Alpine or Arctic is properly restricted to those plants which do not occur in a wild state outside of those regions in which the amount of heat is insufficient to ripen our hardest cereals. The Alpine plants in cultivation are chiefly European, and are almost, without exception, herbaceous perennials, or dwarf shrubs. Indeed, monocarpic or annual plants are exceedingly rare in

frigid regions. It would unduly extend this part to no useful purpose, to enter more into detail respecting Alpine plants; but the plants of the temperate regions, being the most interesting and important of all, a few more particulars will not be out of place. Food plants will be treated of elsewhere. The others will be treated of generally, according to their native regions. The lists given below are by no means exhaustive; but they include most of the characteristic plants of each region, and give at a glance something approaching a true picture of the manner and extent in which different countries have contributed to our parks, shrubberies, and flower gardens. Half-hardy annuals and other herbaceous plants employed for summer embellishment are purposely excluded, as they more properly find their place among greenhouse plants.

BRITISH PLANTS CULTIVATED.—Before reviewing the exotic cultivated hardy plants according to their regions, let us take a glance at the indigenous cultivated forms. Although, as

Geographical Distribution of Garden Plants: Palms naturalised in Southern Europe.

already stated, there is not a single distinct species of plant, native or growing wild, in the United Kingdom, which is not found elsewhere, our indigenous vegetation has contributed a large number of useful as well as ornamental forms and varieties, now cultivated in gardens.

ORNAMENTAL NATIVE SPECIES.—They consist of double-flowered varieties of various plants, as: *Ranunculus acris* (Buttercup), *Papaver Rhæas* (Poppy), *Viola odorata* (Violet), *Spiræa Filipendula* (Dropwort), *Ulex europæa* (Furze), *Cratægus Oxyacantha* (Thorn, of various colours), *Bellis perennis*, &c. Of water plants, as: *Nymphæa alba* (White Water Lily), *Nuphar lutea* (Yellow Water Lily), *Hottonia palustris* (Water Violet), *Sagittaria sagittifolia* (Arrowhead), *Butomus umbellatus* (Flowering Rush), *Typha* (Reedmace), large-growing Sedges,

&c. Of variegated, coloured, or cut-leaved, or weeping varieties of trees and shrubs, as: Ash, Oak, Beech, Elm, Lime, Willow, Alder, Elder, Birch, Box, Holly, Ivy, Yew, &c. A very few are cultivated on account of the beauty or odour of their flowers; amongst them *Aquilegia vulgaris* (Columbine), *Geraniums* (various), *Viola odorata*, *Saxifraga umbrosa* (London Pride), *Centaurea Cyanus* (Blue Cornflower), *Achillea Millefolium* (Yarrow), *Lysimachia nummularia* (Creeping Jenny), *Myosotis sylvatica* (Forget-me-Not), *Digitalis purpurea* (Foxglove), *Armeria vulgaris* (Thrift), &c.

USEFUL NATIVE SPECIES.—In addition to the foregoing indigenous plants, the following have long been cultivated as vegetables, &c.: *Anthemis nobilis* (Camomile), *Apium graveolens* (Celery), *Crambe maritima* (Sea Kale), *Cichorium Intybus* (Chicory), *Daucus Carota* (Carrot), *Foeniculum vulgare* (Fennel), *Humulus Lupulus* (Hop), *Inula Helenium* (Elecampane), *Marrubium vulgare* (Horehound), *Nasturtium officinale* (Water Cress), *Pastinaca sativa* (Parsnip), *Sinapis alba* (Mustard), *Taraxacum Dens-leonis* (Dandelion), and *Valerianella olitoria* (Corn Salad). It is also possible that some of the varieties of *Brassica oleracea* (Cabbage, &c.) and *B. campestris* (Turnip, &c.) are indigenous, but this is very uncertain, and almost beyond proof now. Nevertheless, our flora includes a good proportion of useful plants, and, doubtless, the number might soon be increased should occasion arise. We leave out of the question trees and shrubs planted for their timber, &c.

Cultivated European Species.

GENERAL CHARACTER OF THE FLORA.—This region is characterised by the relatively small number of different kinds of trees constituting its forests, and the large number of herbaceous plants. The Cruciferae (Cabbage family) and the Umbelliferae (Celery family) find their greatest concentration through Central Europe and Asia to China. Being nearer than any other part of the world to us, many of the species enumerated below were amongst the earliest exotic plants introduced; and this, with the Mediterranean region, contributed a large proportion of our hardy food plants. According to Gerard, the Laburnum was in cultivation in this country in 1596.

Garden Plants from the Mediterranean Region.

DESCRIPTION.—This region comprises, for our purpose, all the countries bordering the Mediterranean Sea, that is to say, the South of Europe, North Africa, and Asia Minor. Doubtless some of the plants enumerated below have migrated from countries eastward of Asia Minor; but it is now very difficult to determine where they are really indigenous. It was from this region that the more northern parts of Europe obtained the cereals—Barley, Rye, Oats, and Wheat—and most of the fruit trees, and where, possibly, they are, or were, indigenous. The accounts of travellers on this point are contradictory and unsatisfactory, and can only be regarded as opinions of unequal value. The countries of the Mediterranean region, at sea-level, enjoy a mean annual temperature of nearly 60°; and, therefore, few of the plants are really hardy, except in the milder parts of the kingdom. But the majority of the species we obtain from this, the southern limit of a temperate climate in the Old World, inhabit the mountains and colder parts. On the other hand, some descend to the sea level, and are, at the same time, able to brave our winters.

THE SOURCE OF THE FIRST EXOTIC EVERGREEN SHRUBS INTRODUCED INTO THIS COUNTRY.—From an examination of the following lists we learn that it was these countries which first enriched our gardens with ornamental evergreen trees and shrubs, many of which are still very highly cherished, and some are almost universally planted, though they have to compete with numerous more recently-introduced rivals from Japan, North America, and other parts of the world. It will be seen, also, that many of the most highly-esteemed herbaceous plants, the old favourites, came to us from the shores of the Mediterranean. Some of them, it is true, have been replaced by less worthy occupants in our gardens, but others remain. Here and there in this region Palms and other tropical and sub-tropical plants are naturalised with great success, and in many places afford effects even more striking than those of the native flora, as, for example, the Palms at Bordighera, as shown in our illustration (see p. 537).

CHARACTERISTIC FEATURES OF THE FLORA.—Characteristic features of the vegetation of the Mediterranean region are the predominance of evergreen trees, of shrubs belonging to the Leguminosæ (Broom family), Cistineæ (Gum Cistus family), of herbaceous plants belonging to the Labiatae (Salvia family), to the Caryophyllæ (Pink family), and to the Compositæ (Aster family). Of the last family alone there are nearly 2000 species belonging to about 150 genera. The dates, or approximate dates, of the introduction of some of the trees, shrubs, and herbaceous plants which are now to be met with at almost every turn, and which have, to a great extent, metamorphosed the face of park and garden scenery, being of great interest in the history of gardening, are appended, in order to enable the student to appreciate the degree to which they have taken possession of the soil, or rather, have been put into possession of the soil, in a given time. In many cases it is impossible to fix the dates with any degree of certainty. It is assumed that the Romans introduced many useful and ornamental plants during the nearly 400 years they held sway over this country, and subsequent religious communities many others. Turner in his "Herbal," published more than 300 years ago, mentions the Almond, Apricot, Peach, Cistus salviæ-folius, Rosemary, Thyme, Fig, Plane, Elm, Sweet Bay, Mulberry, White Jasmine, Spanish Broom, &c.

W. B. HEMSLEY.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Two Useful Ferns.—For decorative purposes *Adiantum Flemingi* and *A. concinnum latum* will be found among the most useful. They require a little more heat than *A. cuneatum*, but their fronds, either on the plant, or in a cut state, are more elegant, and their culture for market purpose is becoming rapidly increased in consequence.—S.

Richardia maculata.—This variegated form of the well-known Aram Lily is now held in as high estimation for market purposes as the green-leaved kind. Its flowers, though much smaller, are very useful, whilst the plant, when out of flower, is equal in appearance to some of the *Dieffenbachias*, which are not so easily grown.—S.

Phyllanthus nivosus.—Few plants are more pleasing during the dull months of winter than this. When well grown, it assumes a bushy habit; each shoot terminates with pure white or blotched leaves, thus forming a striking contrast with the deep green of the under foliage.—S.

Ficus Parcelsi.—This is useful for associating with Palms, or similar plants in a moderately warm house. If well grown, its leaves attain a large size, their lively white and green blotches are very striking. It is employed for room decoration by the London florists on account of its fine appearance by gaslight.—S.

Lily of the Valley Forced Early.—At the Aigburth Nurseries of Messrs. Kerr & Son, I saw, on the 27th ult, good examples of early-forced Lily of the Valley. They consisted of single crowns imported from Belgium or Holland, potted thickly in 6-in. pots, plunged in a hot-bed in a stove, and covered about 1 in. deep with cocoa-nut fibre refuse. This covering keeps the crowns in an even and regular state, both as to moisture and temperature, and induces an even, regular growth. If it should happen that they start away irregularly, they are taken out and re-potted, the early ones being separated from the late ones. In this way capital pots of Lilies are obtained very early in the season. E. HODGKIN.

ROSES.

THEIR PROPAGATION AND CULTURE.

SEEDLING BRIER STOCKS.—To lovers of Roses who delight in working or propagating their own plants, the present season will be a busy one; for, not only is it the right time to start in earnest with such matters, but there are stocks to be thought of on which to bud next summer, besides Manetti cuttings to be made and put in for the same purpose, and also for grafting during the following winter. For standards, nothing yet supersedes the Brier. The finest and most vigorous plants I ever saw were some growing on Briers that had been raised from seed, instead of being grubbed out of the hedgerows in the ordinary way. The wonder is, considering how the country has been ransacked for stocks and how scarce they had become, that no one thought of, or at least put in practice, the natural mode of raising them from seed, till Mr. Prince, of Oxford, did so, and surprised Rosarians with his fine blooms. That seedling stocks are far superior to wildlings there cannot be a doubt, as the former, being raised in good soil, never receives a check, and becomes more fibrous-rooted; whereas, the latter have to struggle on under difficulties, and get nearly choked by the coarser vegetation around them. The hips being now ripe, should be gathered at once and sown in rows in sandy soil, in any open, sunny spot that may be available for the purpose; for the first season, all the attention which they will require is keeping them free from weeds, and seeing that mice or birds do not molest them, which, just as they are germinating, they are apt to do. There is a great difference even amongst common Briers as regards sorts and their suitability for Rose stocks; and in gathering the hips this should be borne in mind, and only the best chosen, the distinguishing characteristics of which are their clear, straight growth, and smooth grey-looking bark, almost, or entirely, free from spines about the lower portions of the stems. Such as these are always free, vigorous, and healthy, and well adapted to produce flowers of great size and substance, such as exhibitors delight in, as it is only these that have any chance now at shows, so strong has the competition become both amongst amateurs and growers for sale. As regards seedling Briers, the point is to entice them to make straight, upright rods as fast as possible; and the best way of doing this is to mulch with manure along each side of the row, and by removing the side shoots, to prevent them making any lateral growth till they get up to the height required for budding.

STOCKS FROM CUTTINGS.—Being short of stocks last year, it occurred to me to try cuttings, which I did, and found them to succeed beyond my expectations; I would therefore advise others who may experience the same difficulty in getting stocks to do the same, as, if put in now, they will be ready to work next July, and will make very fine dwarfs or quarter-standards, according to the height at which they may be budded. Firm, ripe wood is necessary for forming the cuttings, which should be made 6 in. or 9 in. long, and be put quite into the ground, so as only just to leave the tip out, as then they do not shrivel and are sure to strike root. Manetti cuttings should be made in the same way, and be treated in like manner; but there is one thing to be observed with regard to both of them, and that is to cut out all buds except the one at the top, for, if left, they are a lot of trouble after, as they form others round their base that are not readily got rid of. By selecting ripe wood, and putting in Manetti now in the way just indicated, scarcely one in a hundred will fail; but if not well earthed up, a large percentage will do so, as the air and weather act in such a manner as to dry all the sap out of them if exposed to their influence.

HEDGE BRIER STOCKS.—In the case of Briers that have to be collected from woods and hedgerows, no time should be lost in getting the quantity required, as much of the success of next summer's budding depends on whether the stocks are thoroughly established; and, unless planted early, they cannot be had in that very desirable state. If expected to do really well, the ground where they are to be grown should at least be double dug, and if trenched, all the better, as then they will have plenty of root-room, and be able to ramify freely, which

GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS: TREES OF THE MEDITERRANEAN REGION: THE EASTERN PLANE (PLATANUS ORIENTALIS).

will render them comparatively independent of rain or artificial assistance during the summer. To afford room for budding, the rows should be 3 ft. apart, and the Briers 1 ft. asunder in the rows, a space which admits of any one passing between, and enables them to carry on the work in a convenient and comfortable manner. A thick mulching of manure spread over the ground will keep frost out, and enrich it, besides acting most beneficially in encouraging root formation by the way in which it intercepts evaporation, and maintains a uniform degree of heat in the soil.

TRANSPLANTING ROSES.—Not only is the present season the most favourable for collecting stocks, sowing seed, grafting, putting in cuttings, &c., but it is also the best for re-arranging and transplanting any Roses that may require it, or to get fresh ones from a distance; besides which, heavy top-dressings of manure among beds should not be forgotten, nor ample protection for Tea-scented kinds before sharp weather sets in, and catches them in the unprepared state they now are from having made such a late growth owing to the exceeding mildness of the autumn. For Perpetuals, as a winter dressing, there is nothing to equal good farm-yard manure that has been laid up and well rotted; and the same may be said as regards Teas, but with these latter, some littery material, such as dry Fern or half rotten leaves, should be placed round their collars in addition, as that is the vital part with them, and where they always suffer most; but with Perpetuals, a simple mulching will carry them safely through any winter, however severe it may be. Having a very light shallow soil to deal with, and which is consequently unsuited to the growth of Roses, I have been trenching in some blue clay rather freely before planting, and the result has been of such a satisfactory nature that I can most strongly recommend its use to any one similarly circumstanced. On lifting some to re-arrange them, I found they had sought out these nodules of clay, and had rooted around and through them in such a manner that they had the appearance of tubers, thus showing how greedily the plants had fed on the moisture and nutritive matter therein contained. In preparing the clay and working it in, the great point is to chop it up small, and mix it regularly with the soil well down below the surface, so that there is little, if any, in the top 6 in. or so, as then it does not get turned out in forking or cleaning the beds. Used in this way, it is surprising the quantity of water it will absorb during the summer, and from the slow manner it parts with the same, when buried away from the air, it affords a rich larder for the roots to which they soon direct their course, and avail themselves of its contents. The best manure for Roses in soils that are not naturally stiff, or such as have to be dealt with in the above manner, is that of a cow or pig, on account of being of a cooler nature than horse manure, the litter of which suits well as a mulching or for ground that is close and retentive.

GRAFTING ROSES.—Where an increase of stock is desired, it may now be obtained in two ways, the most rapid of which is by grafting on stocks or pieces of the large roots of the Manetti, Dog Rose, or, indeed, any of the strong-growing garden varieties. The former, however, are the most preferable, and may be bought of almost any nurseryman at about 6s. or 8s. per 100. If these be properly worked and attended to afterwards, scarcely one will fail; but, to insure success, the wood from which the scions are to be formed should be taken off the plants before severe frosts occur; otherwise the inner bark becomes injured, and, instead of callusing, turns black, which prevents the parts uniting. Before grafting, I find the best way is to lay in the Manetti stocks by the heels in some place where they can get a gentle warmth of about 65° or so, to give them a start and get them in advance of the pieces of Rose to be worked on them. A fortnight will be sufficient for this, when they can be taken out and have their tops cut away to within 3 in. of the roots, which will then leave sufficient length of stem to put the grafts on. There are many modes of doing this, but the simplest, and one that is quite effectual for Roses, is to make a slanting cut on both stock and scion about 2 in. in length, just as would be done in forming a quill pen. If these cut portions be then tied tightly together with soft matting, so as to bring them in close contact, they will quickly unite. The wood for the scions should be such as is firm and

short-jointed, as that which is soft and pithy is not so suitable, and rarely succeeds well at this season of the year. Grafts containing two or three eyes are the most suitable, and, in preparing them, they should be cut for one to be near the base and the other at the top, the object being to get dwarf plants with the shoots low down to the soil. To economise room, the plants, when worked, may again be laid in by the heels in any hotbed frame, where they can be kept perfectly close and dark, or placed under hand-lights in the same way in the stove; but, wherever put, light and air must be excluded from them till the parts are firmly attached, after which they are fit for potting, an operation that should be carried out with care, as, during the early stages of growth, any rough handling is sure to displace them. To obviate this, it is as well to leave the ties to rot away; and, as they do this before any rapid swelling takes place, there is no fear of them cutting the wood or otherwise causing any injury to either stock or scion. The advantages of grafting now are manifold, as a great number of Roses may be packed away in a small space, and any new varieties increased and got to a size fit for planting out in April or May, whereas, with budding, another year would be lost, as buds could not be put in till next July or August.

ROSES FROM LAYERS AND CUTTINGS.—In cases where they are desired on their own roots, the most certain way of getting plants is by means of layers, as every branch pegged down and covered with soil is sure to root, provided a slight incision is made at one of the joints, the same as is done in the case of Picotees and Carnations. So treated, they will make good plants within a year, and be fit for removal any time after next October. Cuttings, too, if put in at once, before sharp frost comes to injure the wood, will root freely; although, when propagated in this way, it ought to be done in August or September, when the growth is in a semi-ripe state, as they callus before the autumnal rains and cold weather set in, from the effects of which they are then safe. Being late with this work one winter, and requiring a quantity of plants the following spring for a special purpose, I made a lot of cuttings that had about three buds each, and buried the whole of them thickly in moist sand in pans and boxes, which I set in a Mushroom-house, where, after remaining a couple of months, I think, without a single exception, the whole of them had callused at the cut part both top and bottom, and if allowed to remain where they were, would undoubtedly have rooted at both ends, as they do when only a single eye is put in. Where there are no stocks at hand, and it is desired to make the most of the wood of any scarce or new kind, this way of propagating is the best that can be adopted, as if cut up in 1½ in. pieces, with a bud in the centre, each will form a plant. J. S.

Cheshunt Hybrid and Marechal Niel.—Being in search of a companion Rose to Marechal Niel for culture under glass, I was advised to try Cheshunt Hybrid, and have found it a very good one for the purpose so far. It is not such a lengthy traveller as the Marechal, perhaps; but it grows and forces well enough, and is a very handsome Rose, coming in about the same time as the other under greenhouse culture. A number of young plants, which I potted last winter in 10-in. pots, are now 7 ft. or 8 ft. high, and promise well for flower next spring. I prune them but sparingly, and rather prefer to twist the long shoots round a few stakes to cutting them back, and they then break and flower freely. I recommend Cheshunt Hybrid for trial, as, if I remember rightly, several inquiries have been made in THE GARDEN as to a good companion red Rose to Marechal Niel. By the way, the latter, I find, has a bad habit of dying off just when it gets established that is very provoking; and it is also a risky plant to lift. I have heard of numerous instances of this Rose dying quite unexpectedly, caused apparently by canker at the graft, or where the bark has been wounded in some cases, but in others through no visible cause.—S.

Gloire de Dijon Rose.—This Rose comes nearer to a perpetual bloomer than any other with which I am acquainted. It is growing on several walls here, one of which is well sheltered and faces the south. From this we cut blooms last April, and we have done so every month since up to the present time. Let it be good for exhibition or not, a Rose that will bloom like this, eight months out of twelve, deserves a place in every garden.—CAMBRIAN.

THE KITCHEN GARDEN.

KITCHEN GARDENING MADE EASY.

LET me start this week with the Strawberry, the land for which I have deeply trenched, and well manured; and, before planting, it will be well trodden down; my favourite time for planting is the first week in August. I plant at $2\frac{1}{2}$ ft. apart all ways, using plants that have been layered in pots. They therefore feel no check, and they are the produce of forced plants that have been selected, and marked with a X, showing that they bore good potfuls of fruit, so that our stock is always improving. The first year the fruit has only quality to recommend it, the second and last quantity. By the first week in August, as soon as the Strawberries are picked, we cut the runners close off with a spade, rake all the land, set the line, and plant, crowbar fashion, Watt's Excelsior Broccoli. The first year in which this was done here my old wallman says, "Ah! master, that won't do in this land." He however lived to see that it did do—for a finer batch of Broccoli than these Excelsiors were never grown in a garden. When they begin to grow, we keep the hoe or cultivator at work in order to keep down weeds and the surface of the soil open. In April and May we cut Broccoli to our heart's content, and the land in June comes in for Celery. The trenches are taken out 4 ft. apart, and the plants are set in double lines. The usual earthing up is carried on; of course, the soil is all loose, but, unfortunately, the crop stands so long that March sets in before the Celery is cleared away. When off the ground, we take lime and malt dust in equal quantities, and give the land a thorough dressing; again the cultivator is used instead of the spade, and in the first week in April we plant Potatoes, thus growing Strawberries, Broccoli, Celery, and Potatoes without digging the ground. Some may ask, but what kind of crops have you—good or bad? I answer, come and see.

R. GILBERT.

Burghley.

CLOCHES AS PROTECTORS.

ONE of the most characteristic features of French gardens at this season of the year is the number of cloches which are employed in them. Market gardeners use them extensively during the winter months for covering Lettuces, a purpose for which they are in every way admirably adapted, inasmuch as they can be easily removed, are drip proof, and effectually exclude the searching frosty winds. When thus employed they are generally placed in rows upon raised beds of old rotten manure, with a fall to the south or east, an arrangement which enables them to receive the greatest amount of light, and

Cloches as Protectors.

admits of their being easily covered. It is somewhat singular that Cloches should not be more largely employed in our gardens than they are, as their portability renders them extremely serviceable for many purposes, such as raising seeds or protecting tender, freshly put-out plants in spring. Amateurs would find them very useful for such kinds of work, as well as for purposes of propagation in the summer time.

J. CORNHILL.

Varieties of Tomatoes.—A collection of Tomatoes has been grown for trial purposes in pots under glass this year at Chiswick. The collection was represented by over sixty differently-named varieties, two plants of each being grown. The smallest variety was Red Currant, of about the same size as a Currant; the largest variety was the Trophy, the earliest the Early Gem, and the latest De Lay's, which is of little value. First-class Certificates have been awarded to Little Gem (Bliss), a medium-sized, round, deep-red variety, very free-fruited, and very early; to New Improved (Vio), a large, smooth, ovate variety of a distinct rosy-crimson colour,

free-fruited; to Vilmorin's Large Red (Vilmorin), a very large, slightly-ribbed variety, and a wonderful cropper; to Trophy, an exceedingly large, nearly smooth red variety, of fine appearance, and late. Hathaway's Excelsior was found to well merit the certificate that was awarded to it some time ago; also Carter's Green Gage, as being by far the best yellow variety. Conqueror, One Hundred Days, and Portsmouth, amongst the new varieties, were greatly admired. Stamfordian, one of the best varieties in cultivation, was, it appears, selected and grown by Mr. Jackson, at Case-wick, and was named and sent out at an earlier date under the name of Jackson's Favourite.—"Florist."

CHICORY.

CHICORY, or Succory, as it is sometimes called, does not appear to be very extensively cultivated now-a-days, a circumstance which may be accounted for by the fact that it has been supplanted by its near

Chicory—root and flowering top.

relative, the Endive, which, on account of its finer appearance and milder flavour, has become the greater favourite, both for market and general purposes. The Chicory possesses, however, many meritorious points, which should recommend it to more general attention than it now enjoys. It is of easy culture, is not at all fastidious as to soil, and may, therefore, be grown largely by those who cannot devote much time or attention to the culture of choice salading. Even where Lettuces and Endive are extensively grown, Chicory should find a place, as its addition to the salad bowl imparts a piquancy which cannot well be obtained by any other ingredient. It is largely used and is much esteemed as a winter salad in many parts of France, and, in common with the Dandelion, it there enjoys the reputation of possessing peculiar blood purifying principles. It is often, however, eaten alone, and liked by those accustomed to its use. It should, however, in a general way be mixed with Lettuces or Corn salad.

J. CORNHILL.

Early Peas Under Glass.—No crop is so useful or gives more satisfaction than a dish of early Peas; I therefore echo what Mr. Hobday said concerning them in last week's GARDEN, with the exception of the varieties recommended. I have tried many kinds in pots, but boxes are best; for a thorough gem give me Little Gem, which enjoys a singular immunity from mildew. I have fifty boxes of it, $3\frac{1}{2}$ ft. long, all up and doing well, and, if all goes as I expect, I shall pick Peas throughout April and May, from successional sowings.—R. GILBERT.

PLATE CIII.

EUCRYPHIA PINNATIFOLIA.

Drawn by H. HYDE.

THIS handsome shrub, recently introduced by Messrs. Veitch, from whose Coombe Wood Nursery we received the specimens figured here, is a native of South Chili, and will doubtless prove hardy in the south-west of England and Ireland; indeed it may be hardy enough to plant anywhere in the south and on the western coast to the north of Scotland. But plants from South America differ so much in constitution, according to the conditions of their native habitats, that it is advisable to advance by experimental steps with a new species. We get a plant from a known latitude, but unless we know at what altitude, or what aspect on the mountain slopes it grows, we have no clue to its relative hardiness. Temperate South America contains many floral treasures suitable at least for the milder parts of the kingdom, and some of them for general planting. This region is peculiarly rich in evergreen shrubs with showy flowers, just as Japan and North America are rich in handsome deciduous flowering shrubs. The number of different species from this region commonly planted is still very small, but most of them possess a special value of their own, and are practically indispensable. Thus the beautiful *Berberis*

Darwini, *Pernettya mucronata*, and *Araucaria imbricata*; the hardy *Fuchsias*, and the showy crimson *Geum coccineum*. *Buddlea globosa* is another very distinct and useful shrub from the same part of the world; and who can consider a garden complete without the Lemon-scented *Verbena* (*Aloysia citriodora*)? Several species of *Escallonia* are among the very best shrubs for clothing walls immediately facing and close to the sea in the south and west, and some of the singular, odd-leaved *Azaras* are

also very pretty for the same purpose. A tree which attains a large size, even in Magellan's Straits, an evergreen Beech (*Fagus betuloides*), as well as its deciduous congener, *F. antarctica*, should find a place in every exposed garden on the western coast, as they brave the roughest winds with impunity. Adding to the foregoing list only the unrivalled *Lapageria rosea*, and its variety *alba*, and what a wealth we have in this small selection! Several more names might be given, all belonging to highly ornamental plants, whether regarded as greenhouse plants for the colder parts of our country, or for the open air in the south-west. The plant before us is one of a small genus of singular geographical distribution. Altogether four species are known, two Chilean and two Australian; and, strange to say, one simple-leaved and one pinnate-leaved species occur in each of these two distant countries. The earliest publication in which we find any information respecting *Eucryphia pinnatifolia* is Gay's "*Flora Chilensis*," published in 1845. He says this beautiful little tree (*Este hermoso arbolito*) grows amongst the rocks at the foot of the Cordilleras in the Province of Concepcion, where, however, he found it only once on the steep rocky shores of the River Biobio. This was in the month of March, when it bore both fruit and flowers. It appears to be an exceedingly

rare plant in its native country, both on the evidence of Gay and the fact that few subsequent travellers have collected it. The beauty of this shrub or small tree speaks for itself, and Gay describes the flowers as agreeably fragrant. In general appearance the flowers recall those of the Mock Orange (*Philadelphus*), but the pinnate leaves at once distinguish it, to say nothing of peculiarities in the floral structure, which it is unnecessary to enter into here. The plant is not yet in commerce, but will, we believe, be sent out next spring. The other Chilean species, *E. cordifolia*, was introduced about a quarter of a century ago, but it is rarely seen in collections. This also is described by Gay as a beautiful thing in its native country, where it is much commoner than *E. pinnatifolia*, being abundant in the Island of Chiloe, and on the mainland at Valdivia and Arauca. It has opaque, very thick, oblong leaves, on short stalks, and white flowers, and is of a more dense habit of growth. The Australian species have, I believe, hitherto not been introduced into European gardens, though they are both very ornamental. *E. Billardieri*, the simple-leaved one, particularly is worthy of attention. It inhabits the mountainous districts of Tasmania, and is probably almost or quite as hardy as its Chilean congeners. It is described as a handsome tree, attaining a very large size in its lower habitats, becoming smaller and bushy as it ascends, and in very much exposed situations. The leaves are oblong, thick, and glossy,

like those of *Buxus balearica*, and vary in the different forms from 2 in. to $\frac{1}{2}$ in. in length, and are glaucous or whitish on the under surface. The flowers are white and very showy, the broad petals often 1 in. in diameter. *E. Moorei* has pinnate leaves, with nine to eleven leaflets, and rather smaller white flowers. It is a native of New South Wales, and less hardy than any of the others. The fruit or seed-vessel of this genus is a hard, woody capsule, and the position of the genus in the natural system debatable, it

Rocky Streamlet in Garden, with tufts of *Cotoneaster*, *Yucca filamentosa*, *Iris*, &c.

having been variously assigned to the Hypericaceæ, Rosaceæ, and Cunoniaceæ, and considered as the type of a distinct Order.

W. B. HEMSLEY.

The Compass Plant.—It has long been known that the western plant growing on the open prairies of America, and known as the *Silphium laciniatum*, has the property of turning many of its leaves nearly north and south, and hence the name "compass plant." It is also called "rosin-weed," from its copious resinous juice. In order to determine to what extent this alleged polarity exists, Mr. C. E. Bessey, of Ames, Iowa, has, says the "*Scientific American*," made a large number of accurate observations, which he reports in a late number of the "*American Naturalist*." Out of ninety-three observations, fifty-four were found which pointed more or less east or north, and thirty-nine more or less west. Of the fifty-four which pointed eastwardly, eighteen were within 5° of north, eight more within 10°, seven more within 15°, five more within 20°, and three more within 25°, leaving only fourteen leaves which diverged more than 25° from due north. Of the thirty-nine which pointed to the west of north, nine were within 5°, five more within 10°, three more within 15°, seven more within 25°, and seven more within 35°, leaving only eight which diverged more than 35° from due north. Its polarity is, therefore, fully established.

THE FLOWER GARDEN.

ANEMONE "ROBINSONIANA."

Of a numerous and very beautiful family, this is, to my mind, the undoubted queen. There is a gorgeous splendour about *A. fulgens* and *Pavonina*, and a dazzling beauty in *A. stellata* and *coronaria*; there is much delicate grace about *A. bracteata*, *trifoliata*, *apennina*, *blanda*, *sulphurea*, *alpina*, *nemorosa*, and *narcissiflora*; we all admire the purple and silk in which *A.*

Anemone "Robinsoniana."

Pulsatilla and *vernal* love to clothe themselves, and seldom tire of gazing at the golden sheen of *A. palmata* and *ranunculoides*; *A. japonica* and *vitifolia*, and their varieties and hybrids, have much pleasant autumnal brightness; but, to my mind, all fade before the simple and innocent loveliness of *A. "Robinsoniana,"* or, as it is perhaps more commonly called, *A. nemorosa cœrulea*. Botanists seem to agree that, though in many respects very distinct, it is a variety of the common British Wood Anemone, *A. nemorosa*. It is a much dwarfer plant, blooms later, and both leaves and flowers possess more strength and substance; but its distinguishing characteristic is the pure, pale, cœrulean blue of the inner surface of its

petals. I know of nothing more exquisitely lovely than a fully-expanded patch of this beautiful flower on a bright spring morning. It is a rare British wild plant; I know of its occurrence in Norfolk and Essex, and I believe it has also been found in Kent and Sussex. It has long been cultivated in the Oxford Botanic Garden and in a few other choice collections, but was practically unknown to the general public till a few years ago, when Mr. Robinson found it growing wild, and, struck with its marvellous beauty, so frequently spoke of its charms, that it became a general favourite, and, in compliment to its champion, took the name of *A. "Robinsoniana."*

H. HARPER CREWE.

Drayton-Beauchamp Rectory, Tring.

BEGONIA FRÆBELI AND OCTOPETALA ROSEA (?).

HERR OTTO FRÆBEL, of Zurich, writes to me to take exception to the above first-named Begonia, recently figured in THE GARDEN, being described as a winter-flowering variety, such as my continued experience of it has undoubtedly proved it to be; and has requested me to inform the readers of THE GARDEN that with him at Zurich (planted out in quantity in beds in the open air) it is in full blossom in the month of June, and that hence arose the assertion that this plant might be considered as a formidable rival to the old scarlet Zonal Pelargonium. It may be that the Swiss sun, being much more intense than anything we can hope for (at least in ordinary summers) in this country, has the effect of bringing the plant into bloom thus early, but certain it is that, when planted out by me in the sunniest part of my garden, it grew indeed, and sent up many beautiful velvety Gesneria-like leaves, but did not open a flower till towards the middle or end of October, after it had been lifted into a pot for the greenhouse, and, continuing in flower till the middle of January—fully earned in my opinion the name (to which Mr. Fræbel objects) of winter-flowering Begonia. It is now in great beauty in my greenhouse, and its brilliant colour is an immense acquisition at this dull and almost flowerless period of the year. Herr Fræbel also informs me that the name of the other variety of Begonia at the head of this paragraph with a query affixed to it is only temporary, as he considers this plant quite distinct from *octopetala*, though kindred or allied to it. It also comes from quite a different part of Peru, being indigenous to the extreme north of that country, whereas *octopetala* comes from the southern district—more than 100 leagues distant. He has merely given the plant the provisional name of *octopetala rosea* till the correct specific name is ascertained by some botanist learned as regards the Begonia family. This, Herr Fræbel allows, is distinctly altogether a winter-blooming variety, as its bloom-head is only now showing itself above ground, and if it has to grow to the height of the tall foliage, it will be some fortnight or three weeks yet before it can be expected to show what it is like. W. E. G.

CHRISTMAS ROSES OUT-OF-DOORS AND UNDER COVER.

Of all hardy plants, this is certainly one of the most serviceable, affording as it does an abundant supply of flowers for cutting, at a time when they are generally much in request, and not over plentiful. Not only is it of great use for the above purpose, but it is equally valuable for pots to use in the greenhouse or window recesses in rooms, for the latter of which positions it forms a charming ornament of great powers of endurance, owing to the thick texture of its leaves and the immense substance of its fine waxy-looking blooms; the stems, too, that support these, being large and porous, take up water freely, in which, when placed with flowers even in the bud state, they absorb sufficient to induce them to expand almost as well as if left on the plant. Although generally supposed to be slow to increase, I have not found that to be the case with *H. niger maximus*, which is by far the finest and best of all the species, as, after obtaining three clumps last autumn, I was enabled, by shaking them clear of all soil and carefully separating each crown, to increase them to twenty-five, only one of which failed to grow. The situation I chose to plant them in is a narrow border, at the sunny end of a greenhouse, a position that appears to suit them admirably, as they have all made fine crowns, and are producing a profusion of blooms. Here they get shelter, and can easily be protected by leaning some old lights over them on the approach of bad weather. So favoured, the flowers come with much greater purity of colour, and free from that disfigurement to the edges of the petals in the way they are generally affected when exposed to wind and wet, and allowed to take their chance. To

grow them well and strong, they require a light, deep, rich soil, and if of a peaty nature, all the better, as they delight in decomposed vegetable matter; and, if peat is not easily to be had, plenty of leaf-mould should be worked in instead, with a little road-scrappings or sharp sand, to keep the whole open and porous. In ground prepared in this way, and with occasional waterings during the summer, they will luxuriate and make plenty of foliage, on the free and full development of which much of the success in flowering these most useful plants depends. For pot work, it is best to take them up about the middle of October, and to put them under cover in cold frames, where they can be kept with plenty of air till they get well into bloom. It should be borne in mind that, hardy as they are, they are very susceptible of injury after being housed some time, as the leaves do not acquire that degree of firmness and leathery texture so characteristic of them when fully exposed to the weather. This being the case, any that are used as pot plants should not be turned out in open quarters as soon as their beauty is over, but be kept in some cool, light place till all danger of severe frosts is over.—S. W., in "Gardeners' Chronicle."

YELLOW PICOTEEES.

THE Yellow Picotees—"Golden Gems" as they are termed by some of the more enthusiastic of the old florists—are very rarely met with now, still they are grown, for in Mr. Turner's last spring catalogue he enumerates not less than twenty varieties. They must be in demand, and it is a fair inference that they are cultivated by somebody who has a fancy for these beautiful and distinct flowers. There is no class assigned to them in the annual exhibition at Manchester, of the National Carnation and Picotee Society, and they are not to be met with in any of the stands, the pure white-ground flowers being staged in preference; and also for this reason that they are more easily grown. There lies the secret. The yellow Picotees are not a robust class, capable of enduring, without protection, the vicissitudes of our climate; but they are a delicate race, extremely difficult of cultivation, and frequently rendered more so by unskilful treatment. In order to succeed with this lovely flower—for the yellow ground, in contrast with the richly coloured edge of the petal, makes it a charming floral object—it must be made a speciality, and have constant attention. The late Mr. W. R. Bragg, florist, of Slough, used to grow the yellow Picotee remarkably well, and raised some good varieties; Bragg's Beauty being still one of the best in cultivation. To grow Yellow Picotees with anything like success, a dry situation must be given to the frame, and air given on all favourable occasions; but the usually humid atmosphere prevalent during the months of November and December must be guarded against, and especially sudden and severe frost. The yellow Picotee has at best a delicate constitution, and precautions are necessary; but what a reward it is to the enthusiastic florist, after having safely guarded his plants through the shoals and quicksands of the trying autumn and winter months, to be favoured with fine blooms after so much care!

Two objections have been urged against the yellow Picotees from the strict florists' point of view—one a material imperfection, a notched or jagged petal; and the other the uncertain style of marking in the edge. Both of these can be improved by time, if the work of improvement be gone on with patiently and thoroughly; but it will take time to tone down these defects. Let it be remembered that the yellow Picotees are a restricted class, containing but few varieties, and that the advance in the direction of improvement is necessarily much slower than in the case of the much larger section of white-ground flowers. One of the foremost florists of the past generation—the late Rev. George Jeans—once laid down a course of action by which he thought the class of yellow Picotees might be materially improved, and his legacy remains to the present day, for the present or a coming generation to put into practice. A first-class yellow Picotee should have a clear yellow ground, as deep and fine in colour as possible, a rounded edge to the petal, and a regular and even margin or beading of rose. The serrated marking and irregular edge have to be got rid off before this can come, and the motley assemblage of colours, which often obscure and disfigure the edge, withdrawn and replaced by clear rose. This has been only partly brought about, and the completion of the work lies yet before the present race of florists. The following plan was laid down by the Rev. Geo. Jeans in one of the earlier volumes of the "Florist."—1. By saving seeds from yellow selfs hybridised with the yellow Picotee; and, for experiment's sake, reversing the parents when it will not have a tendency to reduce colour. 2. By saving seed from two fertilised yellow Picotees. 3. By saving seed from dark-coloured yellow selfs hybridised with the highest coloured white ground Picotees of the several classes of red, purple, and rose, using the pollen from those flowers which are particularly distinguished

by a steady style of marking, and not intermixing light and heavy edges. 4. By seed from yellow Picotees hybridised as in the previous recommendation. An important caution to raisers of seedlings is here necessary. The young plants always take on a vigorous growth in a young state and during the summer; but, as it wanes, the inherent delicacy of constitution in the yellow Picotee begins to assert itself. Then it is that great care is necessary, and it is best to lift the plants, pot them, and treat them during the winter as above recommended. Who will enter upon this work? In these days of floricultural enterprise, there should not be wanting some to devote themselves to so interesting a task. D.

THE GROWTH OF LILY BULBS.

"DUNEDIN'S" startling assertion that Lily bulbs are of annual growth, or at any rate are not true perennials, has excited great interest in the minds of many Lily growers, and has met with more than one opponent. We must remember that for forty years "Dunedin" has been studying Lilies; there are few growers who have his experience; but I am surprised that no one has confirmed his idea: for my own part I feel sure he is right. Suppose we plant in the autumn a Lily bulb; after it

Base of flowering stem of *Lilium giganteum*.
A.—Germ of new bulb. B.—Woody stem.

flowers, the bulb has done its duty, and either rots and disappears in the soil, or else passes the substance and tissue of its scales into one or more newer bulbs (formed on the basis of the corm) that were in process of formation while the flower-stalk was being thrown up. Whether it can therefore be said to be an annual growth or not is not clear to me; but I can well believe that it is annual, biennial, or triennial. Manifestly there must be a beginning to these new bulbs. "Dunedin's" doctrine of the seed bud of the new growth being formed close to the flower stem, near the centre of the bulb on the basis of the corm, I also hold to. In short, I believe Lily bulbs are in perpetual growth, never dormant, and therefore never require absolute rest, though, likely enough, they do not want as much water in the autumn as during their flowering period. I take it the corm of the bulb is the nurse to the future bulbs; the scales of the flowering bulbs are pushed aside by the newer growth in the interior. In the summer, this newer growth is sending up its flower-stems, and is in turn, as it becomes the old bulb, pushed aside by another growth, so that separate bulbs are formed. I believe the growth of *Lilium giganteum* to be common to other Lilies. None are true perennials; no part of the bulb, except, perhaps, the corm, is the same after being three years in the ground. Take the case of a large bulb of *Lilium speciosum*, with scales much separated, and no clean white growth in its heart; this was planted last September, and all the summer showed no signs of growth. In

the middle of the bulb, when I took it up this autumn, I found two small young growths touching each other and proceeding from the corm, being part and parcel of it, and not adventitious bulbs clinging to the scales; each new growth was about as big as a Walnut; it had no root at all. By the end of the next spring these two young growths will have entirely filled up the surrounding scales, from which scales, in conjunction with the corm, they derive their nutriment; when these outer scales have done their duty, and have fed with their tissue the new bulbs, they will decay and pass into the earth round the bulb. This can be constantly and continually seen in the case of Lilies of the auratum class newly imported. What vitality there is in them after their journey goes to support the already-formed flower-stem; but, at the same time (if they continue in good health) a new bulb is formed, and, if the bulbs are inspected in the autumn, all the old scales will be found rotten round the new bulb. Whether the germ of this new bulb is a season old or two seasons old, I trust we may learn from more experienced cultivators than myself. Lilies may certainly remain underground without showing any signs of growth aboveground for a whole season; some sorts do this continually—*Lilium Brownii*, for instance, or *L. Wallichianum*. In the autumn of 1875 I planted, in the open border, a small bulb of *Lilium concolor*; in the summer of 1876 it flowered well; in the summer of 1877 it made no sign of growth aboveground, so I carefully uncovered the bulb, and found that, though there was no root whatever, an entirely new and much larger bulb had formed, which will probably bloom well next year. I planted last winter the most gigantic bulb I ever saw of *Lilium auratum*, which the season before had thrown flower-stems 9 ft. high; there was no appearance of fresh growth in it, no white heart or feeling of newness—all seemed separated and parted. A tiny growth an inch high was all that showed this summer; but probably all the summer new growths have been forming in its heart from germs already a season old, feeding on the basis of the corm and on the old scales, and I confidently expect fine stems next season. Regarding the white garden Lilies (*L. candidum*) being evergreen, for two months after flowering no leaves appear, and the old ones are completely dead long before the new leaves arrive.

Bingham, Notts.

FRANK MILES.

White Hoop-Petticoat Narcissus.—Mr. Rawson has shown me two beautiful flowers of this Narcissus, or, as it is sometimes called, *Corbularia*, one of them as large almost as the yellow *Corbularia*; and now he sends me another, remarkably distinct in the length of the tube, but not so large as the previous one in the trumpet. Mr. Rawson has been more successful with this bulb than any one else. He informs me that he grows it in pots; when the foliage dies he places the pots on their sides, and there lets them remain till the autumn, without moisture. In the autumn he fresh-surfaces the pots, and then places the pots in a little water, and gives a gentle bottom heat till growth is induced; very soon they throw up their flowers, giving a succession. At the present time I have a wonderful display of foliage of these, produced by roots received during the summer from Algiers. I have never before been so successful, and anticipate that the great difficulty hitherto experienced with this bulb is now overcome.—P. BARR.

Double Pyrethrums.—Great progress has been made with these, and Messrs. Kelway & Son, of Southport, who have lately entered the field as raisers of novelties, own the following sorts, remarkable for their size, fullness, symmetry, and striking hues of colour:—*Amethyst*, pink, flushed with violet-blue, large, and striking in appearance; *Achilles*, rosy-pink, large, and very fine; *Captain Boyton*, cherry-red, a fine dash of colour, large and full; *Captain Nares*, soft magenta; *Ceres*, bright pink, deepening to rose on the ray florets, large, and very fine; *Cleopatra*, pure white, large, and full; *Duchess of Edinburgh*, pale pink, tinted with violet, and surfaced with silver, very pretty and attractive; *Galopin*, deep magenta, shaded with maroon; *Kreimhilda*, pale pink, a pretty hue of colour, large, and full; and *Queen Mary*, blush, flushed with pink. These Pyrethrums are most effective border flowers.—“*Florist*.”

Omphalodes Lucilia.—This pretty little plant has been in full flower in my rock garden for these last six weeks. I only got it last spring, and know nothing as to its hardiness or propagation. Will any correspondent of *THE GARDEN* kindly inform me in reference to these points?—D. Mc C. Mahony, *The Island, Rochestown, Cork*. [It may be increased by seed or division.]

THE FRUIT GARDEN.

TRAINING PEAR TREES.

HAVING read with much interest the remarks in *THE GARDEN* on the upright system of training (see pp. 393 and 429), I am induced to furnish an account of results obtained from the horizontal system, which will, I think, compare favourably with any mode of training or culture yet practised. The tree which I take as an example is a *Glou Morceau* on the Pear stock against a west wall; it covers a space 10 ft. high and 20 ft. wide. Over this space the crop was well distributed, and 460 fair-sized fruits were this season gathered from it, being a fraction over two and a quarter Pears to the square foot, or twenty to the square yard. Mr. John Wills, of Brompton, and Mr. A. F. Barron, of Obiswick, saw the Pear crop on the walls here the first week in August last, and both stated that they had seen nothing like it elsewhere. I allowed the tree in question to carry a heavier crop than usual this year, as pyramids with us this season have been a comparative failure, otherwise our fruits are generally thinned down to a fair but not too heavy a crop, and in that way we get larger size individually. From the *Glou Morceau* tree just named, I have gathered fruit of the following dimensions, viz., $12\frac{1}{2}$ in. in circumference the long way, and $11\frac{1}{2}$ in. in girth; weight, $16\frac{1}{2}$ oz. The tree has not been summer pruned, as it made only sufficient growths to keep the nets, for preventing the birds from picking the fruit, well off the wall. I plant my Pear trees on walls as much together as possible on this account, and let the fruit hang as late as I can before it is gathered; the season of ripening is thereby retarded. The branches are all three courses of bricks apart, and every portion of the wall is completely covered. The bark of the main stem, to the base where the tree is grafted, is as smooth and shiny as that of a sapling Oak, showing what a healthy growing state the tree is in, although planted eighteen or nineteen years ago. When trees are carrying such heavy crops, I make it a rule to well mulch and water occasionally. From a young tree of *Josephine de Malines*, growing by the side of the *Glou Morceau*, I have this season gathered 140 fine fruit; this tree is on the Pear stock, and was planted seven or eight years ago. It supplanted one of the same sort on the Quince stock, which did not thrive, and which was therefore removed. From a tree of *Winter Nelis*, covering a space of 10 ft. by 18 ft., I gathered one season some 900 Pears, but this was cropping much too heavily. I quote it, however, to show what horizontal training and good culture can do. I believe horizontal to be much better than upright training, as the growth throughout the tree is more equalised, whereas the upright system favours a gross overgrowth at the tops of the branches. I have tried upright training and also oblique with Peaches and Nectarines on open walls, but it tends to a strong coarse growth with very little fruit, even in seasons when the other trees trained in the common way have borne good crops of fine fruit. From the tree of *Winter Nelis* above alluded to, I showed at South Kensington on the 17th November, 1868, six fruit weighing together 2 lb. 11 oz., the average of each being 7 and one-sixth oz. I have often had them, however, upwards of $\frac{1}{2}$ lb. each, which I consider heavy for *Winter Nelis*. From the same tree I can gather this variety from October until the end of February; this is done by taking some early and placing them in a warm room a few days or a week before they are wanted for table, while others should be left hanging on the tree as late as possible. I consider *Winter Nelis* to be the best of all winter Pears. By planting young trees in good loam, and growing them strongly, they soon cover the walls; and, by notching the sides deeply to form the horizontal branches, five and six can be grown on each side in one season, and the second year afterwards I get fruit from the whole length of their first years horizontal growth. The branches of the young tree of *Josephine de Malines*, to which I have referred, extend 8 ft. on an average, and are well set with fruit-bearing spurs of not more than $1\frac{1}{2}$ in. long. I ought perhaps to state that this district is probably much milder as regards climate than many other parts, and that we have a choice of good loam which might be equalled but not surpassed. In pruning, I annually cut many of the spurs that have borne fruit well back to the main branch; they always break freely, and are thereby kept

short and close to the wall. We have now a good quantity of well ripened Chaumontels fit for dessert. They were grown on the Quincestock against a south wall. The following sorts of Pears were in season in October, viz., Beurré Superfin, Thompson's, Seckel, and Crassane. We have now Beurré Bose, B. Diel, B. Bachelier, and Doyenné du Comice. Second rate sorts of dessert Pears I find very useful for culinary purposes, any of them being fit for stewing, &c., although not equal in this respect to such sorts as Catillac and Bellissime d' Hiver.

JOHN GARLAND.

Killerton, Exeter.

VINES AND POTASH.

A CORRESPONDENT of a contemporary, who hails within 100 miles of the Carse of Stirling, and who, as is well known, has got a "bee in his bonnet" on the subject of manures, has lately been taking somebody to task for mentioning wood ashes from garden rubbish as a manure for Vines. As I happened to say in THE GARDEN of July 21 that I burnt our garden rubbish for such purposes, it is just possible I am the person referred to, and, as it appears from this correspondent's remarks, that grievous mischief might be caused by what I said, I hasten to say, for my own part, and for the peace of mind of my brother Grape-growers who may have been led to adopt the practice, that I have applied the wood-ashes from general garden rubbish—with which, also, as much clay as possible is always burnt—to our Vine borders for years without any more disastrous consequences than always having plenty of good Grapes for nearly twelve months in the year, and receiving not a few prizes at different times, and if I, or any of your readers, have erred by thus using such garden rubbish as cannot be used any other way conveniently, we have erred in good company, and under good advice, to wit—Dr. Lindley, Thompson, and others. The correspondent alluded to is actuated, he tells us, by a desire to guide our actions according to method, instead of in a vague way, for which I trust everybody is duly grateful; but, judging from the schooling to which he has himself had to submit in another contemporary, I should say his guidance is not of the safest description. It must be admitted that he has grown a crop of Melons which averaged some 2 lb. each, a feat which the grower himself has fully set forth in an article of closely-printed matter, about 1½ yards in length; but in future we trust he will give us more of his gardening and less of his chemistry, for surely he ought to produce something very sensational indeed, seeing he proceeds so methodically and so scientifically to work, and has got the chemistry of the garden at his fingers' ends. His instructions on Grape culture, however, savour just a trifle of the philosopher who was going to extract sunbeams out of Cucumbers. He may rest assured that gardeners are quite equal to the task of growing Grapes, without troubling themselves to analyse the contents of their Vine borders, or to serve up food to their Vines as a doctor does to a sick patient. To do our friend in the north justice, however, it appears he has so far succeeded in his mission as to be able to tabulate exactly the different elements that go to compose the structure of plants—fruit, flowers, and foliage—and he is probably now just casting about him for a way to stick them together, and make us independent of cultural processes altogether. I purpose paying our friend in the north a visit at the earliest opportunity; afterwards, I shall have much pleasure in publishing the astonishing results of his "methodical" practice in THE GARDEN.

J. S. W.

NOVEMBER AND DECEMBER PEARS.

IN continuation of my notes and illustrations of Pears, the following must be placed amongst the best that ripen during the months of November and December. Beurré Six (fig. 1) is a Pear of large size and handsome shape, with a smooth skin of a light green colour, somewhat after the style of Glou Morceau; and, like that variety, changing to pale yellow when quite ripe. The flesh is white, and of delicious flavour, being slightly aromatic, and the fruit will keep for a month after being fully ripe. The tree is of good habit, and a free grower, and is well worthy of extensive culture. Van Mons Léon Leclerc (fig. 2) is a well known Pear, and must have a first position either for dessert, market purposes, or for exhibition; it is also more hardy and free bearing than many other favourite kinds, for, during even this bad season, the crop with us is an average one. The flesh is sweet, buttery, and melting, sometimes, though very rarely, slightly gritty. It deserves to be grown on a wall, but does well in the form of a bush. Its fruit generally ripens about the middle of November, and keeps good about three weeks. Bergamotte Crassane (fig. 3) is a small but delicious Pear, valued by some for its highly perfumed flesh. In this respect, it partakes to some extent of the

character of Seckel, only that the flesh is more juicy than that of that variety. It requires a warm situation, and makes a fine pyramid. The tree, being a free-grower, frequent stopping is necessary, in order to induce the formation of fruit buds. It is most fruitful on the Quince stock. Beurré Diel (fig. 4) is one of the largest of all Pears, often weighing 1 lb. or more. I recently saw a fruit of it which weighed 22 ounces. It is also excellent in quality, a wonderful free bearer, and a Pear which deserves a wall, a position in which it grows very large; if grown as standards or bushes, it rarely exceeds medium size, and is always gritty. It ripens

Fig. 1.—Beurré Six.

Fig. 2.—Van Mons Léon Leclerc.

in November, and continues on into January, the long season in which it is in use being one of its chief merits. Fondante de Noel (fig. 5), although comparatively little known, is in all respects most excellent, being of large size, and first quality. It has a pale yellow and russety skin, and the fruit is uneven in outline, and not of the handsomest shape. It is a good keeper, its season being from the beginning of December to the end of January; Dr. Trouseau (fig. 6) is a very handsome-looking fruit, with a rough dark green skin, tinged with red on the side next the sun. Its flesh is rich, sugary, and highly aromatic. A most excellent Pear, and one well suited for cordon or espalier training. Triomphe de Jodoigne (fig. 7) is a large, fine looking fruit, but here it gets into bad repute on account of its deception, rotting at the core before it is fit for table. This fault is the more to be regretted, as it is a most profuse bearer in any situation, and under any mode of training. Local circumstances apparently are to blame for this fault, as I often meet it else-

Fig. 3.—Bergamotte Crassane.

Fig. 4.—Beurré Diel.

where in fine condition. Beurré Delfosse (fig. 8) is a good looking moderate-sized fruit, of but second rate quality; its greatest merits being its free-bearing properties, and the comparatively long time during which it remains fit for use. It is a fine stewing Pear. Nouvelle Fulvie (fig. 9) is one of the finest late Pears in cultivation. It ripens generally about Christmas, and continues in use till well into February. Its skin is green and russet, with red on the side next the sun; the fruit is uneven in outline, but by no means ugly, and its flavour is juicy, rich, and fragrant; altogether a most desirable kind to grow. Beurré Rance (fig. 10), is a well known late Pear, being especially good for stewing, and in some soils and districts

equally good for dessert; but southward it is only valued for stewing, as it rarely comes up to the dessert standard. In the south it is generally best flavoured when grown on bushes; if grown on a wall, it is mealy and gritty, and only fit for stewing or baking. It is a sure and free bearer, and as it seldom ripens till Christmas or February, it is a valuable late Pear. The tree is very hardy, and does well either on the Quince or Pear stock. Other very good kinds of December Pears are Comte de Flandre, Napoleon, Passe Colmar, Chaumontel, and Beurré de Aremberg.

W. W. H.

FIELD CULTURE OF HARDY FRUIT TREES.

(Concluded from p. 500.)

PARASITIC PLANTS.—There are certain vegetable enemies of fruit trees which require periodical removal, as they live at the expense of the sap of the trees. Amongst the most hurtful are the Mistletoe and different kinds of Moss. The

it forms a refuge for all kinds of destructive insects. In most cases the sickliness of the tree, caused by the poor state of the soil, is the cause of the appearance of Moss in the branches of young trees, the natural remedy being the improvement of the ground. When Moss appears on the decaying portions of old trees, it should be scraped off. In young trees, which might be injured by the application of an iron scraper, a stiff brush may be used. The operation should be performed in autumn, and the parts attacked should be covered with milk of lime as soon as the Moss is removed. This cleansing process should be practised frequently, experience having shown that it is favourable to the recovery of the weakly trees which, through the neglect of this and other precautions, are only too frequently found in our orchards now-a-days.

Fruit Trees in School Yards and on the Walls of Farm Buildings.

The object of these remarks is to treat of certain subjects in

Fig. 5.—Fondante de Noel.

Fig. 6.—Dr. Trouseau.

Fig. 7.—Triomphe de Jodoigne.

Fig. 8.—Beurré Delfosse.

Fig. 9.—Nouvelle Fulvie.

Fig. 10.—Beurré Rance.

Mistletoe (*Viscum album*) is a parasite that grows by preference on Apple trees, but is also found on certain forest and ornamental trees. It insinuates its roots between the bark and the wood, forming large bushy tufts, which drain the tree of its natural nourishment, and only dies when the portions of the branches on which it grows are decayed. As soon as it makes its appearance it should be destroyed by removing the bark beneath which it has insinuated its roots. The seeds are surrounded by a viscous substance, and are generally carried from one tree to another by birds. The appearance of Moss upon otherwise healthy-looking trees is a sure and certain sign that there is something wrong with the roots, and shows that the soil is either badly drained, or is of poor quality. In old trees, the decaying portions of the bark give rise to the growth of this parasite in accordance with the law of Nature, according to which everything that ceases to live becomes the prey of some other being. Moss on a tree prevents proper evaporation, and prevents the access of the air, besides which

detail which have already received general attention in the preceding portion of these articles. In one of the books published by the author, the part to be played by country schoolmasters in the spread of fruit tree cultivation has been treated of at length, and the question of growing tall-stemmed fruit trees in school yards and playgrounds has been discussed in a way which shows that not only can the schoolmaster's private garden be utilised, but also the scholars' recreation grounds. Fruit culture in these days of progress ought to spread beyond gardens and orchards, and extend to the roads and highways, the fields and meadows, according to the good example set by Germany and other Continental nations. This idea has, during the last few years, been alternately advocated and condemned by different authorities on the subject. Efforts have been made to plant fruit trees along the sides of railway lines, but M. Burvenich is of opinion that there is little to be hoped for in this direction for several reasons. First, because tall trees are inadmissible; and, secondly, from the numerous

obstacles placed in the way by the different railway companies. But this is no reason why fruit trees should not be planted in our meadows and hedges, and along the sides of country roads. The rising generation should be taught to respect private property as they are in other countries, or as they do in Cherry and Apple growing districts. However, this is a matter for the schoolmaster and not for the fruit-grower. As instruction spreads among the masses, children will become less greedy and destructive. To begin with, tall-stemmed fruit trees might be planted in school-yards and playgrounds with great benefit. The shade of the trees would be beneficial to the children, and the schoolmaster would find his slender resources increased by the sale of the fruit to the children or the public. The trees themselves, too, would afford interesting objects for lessons at all times of the year, and the children would pick up a few notions about fruit culture that would be useful to them in after life; or, in purely agricultural districts, they might serve for a complete course of fruit culture on a small scale. The teacher might begin by explaining how they are planted, why the ground is dug for so large a space round the tree to be planted, why they should be planted on rising ground or below the general level (according as the soil is damp or dry), why the ground is dug to a certain depth, and, lastly, why the soil immediately surrounding the tree should not be trodden down within a certain distance from the stem. The different operations described in the foregoing series of articles would all serve as lessons, such as the way in which the head of the tree is formed by grafting and pruning, how diseases and pests are fought against, all of which would bring out the powers of observation and reasoning. The children thus instructed need not all become gardeners or farmers, but the knowledge they would gain would be certain to be useful to them in after life, to say nothing of the mental training which a series of well connected, well-digested lessons on the general principles of fruit culture would give them. In rural districts, where every cottage has its garden, the children would repeat at home the lessons they learned at school, and thus become the unconscious propagators of correct information on the subject of fruit growing. It may be objected that the transformation of school playgrounds into orchards would divert them from their original use, by putting obstacles in the way of the children's games, and that their means of exercise would thus be curtailed. But this objection needs but little consideration. Conscientious schoolmasters, who teach in the playground as well as in the school-room, tell us that the boisterous games in which children are so prone to indulge do them much more harm than good, and encourage them in rudeness of manners. A judiciously planted playground need in no way interfere with a hundred different games in which active children take a delight. The boisterousness of their play would become healthfully moderated, and torn clothes and cut knees would become the exception instead of the rule. At first, no doubt, it would require some trouble to train the children. It is undoubtedly the nature of a healthy, active child to destroy something; but, once succeed in exacting from a child a proper respect for the trees in his playground, and a wholesome moral lesson has been inculcated. It is a well known fact that where children have a garden at home to which they have free access, they are infinitely less prone to destroy the flowers or pluck the fruit in the gardens of strangers. The country child has an innate respect for the productions of the fields amongst which he lives, whereas the town-bred boy is much more liable to take liberties, possibly from curiosity, and often from love of mischief or from not knowing the result of the wanton damage he inflicts. Let children be but accustomed from their earliest years to respect fruit and flowers, and they will have gained something infinitely more valuable than the general knowledge of the principles of horticulture which they have imbibed.

Schoolmasters in this country may well be encouraged by the excellent results which this system has produced in Eastern Flanders, where several playgrounds have been planted with fruit trees. There small orchards prosper wonderfully, and the children respect the trees and fruit. In Ghent itself, M. Vande Vyver, a schoolmaster of that city, has succeeded in growing excellent Pears in the middle of his playground. It must not be thought that the spirit of destruction is absent in the future burghers of that venerable city, for some of the

public plantations can tell a different tale, for, in spite of all protection, they are constantly being damaged. In this respect they seem to be far behind their London confreres, the damage done to public parks and gardens by their young frequenters being really insignificant. The experiment would therefore have a double chance of succeeding on this side of the water; and, if once tried, we might look forward to the time when school-yards and public highways would be planted with inviolated fruit trees.

In planting fruit trees in a playground, certain special precautions are necessary. The ground ought to be prepared in the ordinary way as already described, but the soil round the tree must not be walked on during the first three years. A light fence of iron or wood should be made round each tree at about 3 ft. from it. It may be thought that the surface of a much-used playground is too hard to allow trees to grow, but this is a mistaken notion. A school-yard which has been ten years in constant use has a hardened crust, but very little thicker than one which has only been used for a quarter of that time. The hard surface skin is comparatively thin, and there is plenty of soft soil at a very slight depth wherein the roots of trees may spread at their ease. As for the choice of trees, it is wrong to suppose that only Walnuts and Chestnuts will grow in ground that is continually trodden on. Except the playground be very extensive, neither the Walnut or the Chestnut should be planted. The Cherry and Plum, too, are not favourable for this mode of culture; the Apple and Pear succeeding best of all. Apples or Pears only may be planted, in a varying admixture of the two, according to the nature of the soil. In light deep soils, the Pear should predominate; whilst a heavy, compact soil, is more fitted for the Apple. Kinds which will yield grafts suitable to the locality should receive the preference. What a delightful change it would be if the millions of traditional Lime trees all over the country could be uprooted, and fruit trees planted in their stead!

M. Burvenich's experience in this matter is extremely valuable. Having been appointed by the government as instructor to the district schoolmasters of Eastern Flanders, he received orders to plant in the different playgrounds a complete collection of the best sorts of Apples and Pears, the list having been drawn up by the Belgium Arboricultural Club. By this means the best varieties have been spread throughout this part of the country, a striking proof of the part which the schoolmaster's fruit garden may play in the improvement of the fruit culture of a district. Much of the success attending M. Burvenich's efforts is due to the interest taken in the matter by M. Krevyn, the provincial school inspector, who from the first took the greatest interest in forwarding this useful movement. One country district formed a special fund for carrying out the project, thus setting an example well worthy of imitation. This is a step in the right direction, for schoolmasters are generally but ill able to afford even the small sum necessary for the purchase of the trees and tools necessary for starting. The schoolmasters applied to seem to have been almost unanimous in taking up the project, feeling that the time and labour devoted to their task would yield beneficial results in the future.

The Culture of Fruit Trees on the Walls and Gable-ends of Farm Buildings and Cottages.

This subject has already been fully treated of by M. Burvenich (see Vol. X., p. 111.). The amount of lost space which might be easily devoted to fruit growing, both in town and country, is something enormous. The information given by M. Burvenich, in his former work on the subject, may be summed up as follows:—Fruit trees may be trained against the walls and gable-ends of farm buildings, dwelling houses, barns, stables, coach-houses, and even against those of labourers' cottages. Everywhere a wall may be found which has a favourable aspect for one or other kind of fruit tree. Those positions which enjoy the benefit of the best aspect may be used for the profitable production of choice varieties. The utilisation of waste walls offers another advantage in being favourable for the growth of keeping sorts, of which there is always a great scarcity in the rural districts, owing to the difficulty of growing them in the open orchard. It is evident that such varieties can only be grown on walls having the best

aspect, those fronting the north and west being reserved for good early sorts. With rare exceptions, these useful walls are covered with a scrubby Vine, or a worn-out Pear or Peach.

Pears to be Cultivated on Walls of Different Aspects.

SOUTH.	WEST.
Doyenné d'Hiver	De Tongre
Passe Colmar	Bonne Louise d'Avranches
Beurré d'Hardenpont	Beurré Dumont
EAST.	NORTH.
Beurré Diel	Beurré d'Amanlis
— Sterckmans	Bon Chrétien, Williams'
Duchesse d'Angoulême	Beurré Hardy

These sorts should be grafted on tall stems on a free stock, so as to cover a large portion of the gable ends. Trees on tall stocks, trained as espaliers, are generally very prolific.

Details Regarding Particular Fruit Trees.

We have thus far explained generally in what manner the amateur ought to look after his orchard if he wishes to obtain the largest amount of benefit out of it; but, in order to render our explanation as clear as possible, we purpose entering into certain details respecting each particular kind, as regards the worth of the fruit, the soil, the situation, and the choice of varieties. Whoever plants an orchard does so with the intention of reaping the largest amount of benefit from the trouble and money expended. It is, however, much to be regretted that, either through indifference, or want of knowledge or attention, a bad choice of varieties is made in the first instance. Thus it is that, while we possess fine sorts of every variety, the great majority of orchards, with some rare exceptions, are filled with trees that bear fruit of an inferior quality, only fit for cooking. One reason for the comparative rarity of good fruit is the universal belief that very fine table fruit cannot be grown on tall-stemmed trees. We will try to combat these prejudices by observing that the best varieties require just the same care, and occupy just as much space, as those of medium or inferior quality. The choice of varieties may easily undergo modification, according to the purpose which the grower has in view. The soil and situation will also influence his choice. For instance, where the orchard is situated at a distance from a large town, and the fruit has to be delivered in one or two batches, the varieties ought to be restricted as much as possible. In all cases our choice should be founded, in the first place, on the quality of the fruit. Inferior qualities should never be planted by any one, be he gardener or orchardist. Secondly, we must consider the time of ripening, the varieties which come to maturity either very early or very late being the best. For orchards near town, stone-fruit trees are recommended, as they succeed each other during the whole of the summer, and just at the time of the year when pipped fruits are scarcest. Although the best fruits are generally those which ripen in autumn or about the beginning of winter, besides being easily transportable and saleable, we find orchardists too much given to planting summer varieties, in accordance with the old absurd routine. Thirdly, we should consider vigour of growth as an important item in deciding our choice. The large size to which the crown of a free-growing tree ought to be grown is a sufficient reason for rejecting slow-growing varieties, which produce weak wood and poor fruit, besides being subject to all kinds of diseases and the attacks of insects and other pests. Fertility is another quality that is important to be considered in choosing trees for growing in the open air, for the numerous devices for improving the fertility of dwarf trees are wholly inapplicable to tall trees growing in the orchard or garden. The firmness with which the fruit is attached to the stalk is another good quality which invites notice. Certain varieties of Pears and Apples drop their fruit at the slightest breath of wind, either through an inherent defect, or from the fruit being too heavy. This is a point deserving great consideration, and the general appearance of the fruit and its stalk may often help us in forming our opinion. In Pears of medium size, for instance, a long, thin, woody stalk is a good sign. Those varieties, too, which bear their fruit on longish shoots, instead of on short twigs, should be chosen, in spite of the stalks being somewhat short. To sum up, what we require for the orchard are varieties which yield abundance of good fruit firmly attached to their

branches, which ripen without passing away too quickly, and bear transport without injury. If one day we see our hedges and roads planted with fruit trees, as in Germany, we must be influenced in our choice by another series of conditions. In Germany, where this kind of plantation has been long in vogue, Pears and Apples are divided into three different categories. First we have street trees, the fruit of which is, for the most part, uneatable. These are reserved for planting by the sides of roads and highways, the fruit being used for making cider and perry. Then we have field trees, which are planted in fields and meadows, the fruit of which is used for drying or for making syrups and preserves, as well as for cooking; and, thirdly, we have garden trees, which bear choice fruit for the table, and which are grown in gardens or walled orchards. When the object of planting is the sale of the fruit, the number of varieties ought to be limited as much as possible; and equal circumspection ought to be exercised in the choice of the trees. Errors in this direction are generally disastrous in their consequences, being only perceived when

Large Bunch of Gros Guillaume Grapes.—A bunch of this Grape, grown by Mr. Roberts, at Charleville, Tullamore, Ireland, weighed, as recorded in the papers, 23 lb. 5 oz., and measured 24 in. in length, by 2½ in. across the shoulders. This is the heaviest weight recorded of any black Grape in this country; a wonderful weight, indeed, but not so wonderful to our mind as that a bunch of the dimensions given should have weighed so much. It cannot have tapered so very rapidly as the bunches of this variety always do; and, if we had been told the dimensions only, we should have guessed the weight at 16 lb. We hope that Mr. Roberts has furnished a photograph of the bunch to one or other of the garden papers, so as to hand down its portrait with other wonderful bunches of the present decade. If he has, our surmise as to the shape of it may be found correct.—“The Gardener.”

Rust on Grapes.—This is an affection or injury to the skin of the berries, giving them a rusty appearance. It is caused whilst the skin is young and tender, about thinning-time, and disfigures them even when ripe. When once it is produced there is no remedy. The best that can be done when it is observed is to cut out the affected berries. Many views have been entertained and many opinions have been held as to the causes of rust. Touching the berries with the hand, or with the hair of the head, is one. It is well, therefore, not to touch or handle the berries in any way; they are easily bruised and spoiled; but this is not the chief cause of rust. Cold draughts of air are also suspected. Avoid, therefore, cold draughts or currents of air whilst the Grapes are young; they are very injurious, even if rust be not caused by them. Rust is most common in early houses, where a good deal of firing is required, and especially in those where the old-fashioned flues are still in use. An extra-heated flue, with the inevitable dry, parched air, and the fumes of sulphur, will cause rust to a certainty; and so also will sulphur, when applied to hot pipes, as is frequently done in order to destroy red spider. It is good judgment, therefore, to avoid the use of sulphur whilst the berries are so young and tender. Later on, the skin becomes more hardened, and is not so easily injured.—“Florist.”

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Emile d'Heyst—a Good November Pear.—This, when ripe, is a very fine Pear—bright yellow in colour, with patches of cinnamon-russet, giving its fruit a rich and inviting appearance. Its flesh is tender, melting, and slightly perfumed. The fruit keeps well after it is ripe; much longer, indeed, than that of either Marie Louise or Louise Bonne of Jersey, which it succeeds.—A. H., Thoresby.

Willows for Tying Fruit Trees.—We tie all our Raspberry canes with Willow twigs, and also the stronger branches of wall trees, as well as Currant and Gooseberry stems to stakes, and so well do they answer for all these purposes that I intend tying all our Vine rods up with them this winter.—CAMBRIAN.

Pears on Pear Stocks.—These should be planted in soils in which those budded on Quince stocks do not succeed. This is a rare occurrence, but there are to a certainty some soils in which Pears on the Quince will not flourish, even when double-grafted.—F. R.

Flower and Fruit of the Paradise Stock.—Owing to an error in punctuation last week, the fact that M. Thiebauld both drew and engraved the beautiful illustrations of the flower and fruit of the true Paradise Stock was not clearly expressed.

THE PARAGUAY TEA.

THE plant of which we here figure a flowering branch yields one of the most important of the vegetable products of South America. The Maté or Paraguay Tea occupies relatively the same position in South America, which is filled in this country by the Chinese plant; and it is calculated that at least 8,000,000 lb. are annually consumed in that country. It is yielded by the leaves and young shoots of a species, or of several nearly-allied species, of *Ilex*, not very dissimilar to our ordinary Holly. It is a shrub or small tree with smooth, egg-shaped, irregularly serrate leaves, and axillary racemes of small white flowers, which are succeeded by berries as large as a Pea. Mr. Miers has described several species in his paper on "The History of the Maté Plant," all of which produce the herb, and are by most authors considered as forms of one species, *Ilex paraguayensis*. In the settlements of the Indians in Paraguay under the dominion of the Spanish Government, the preparation of Maté—or Yerba, "the herb," as it was called—constituted the principal branch of industry in the country. The plant is prepared in different ways; sometimes larger branches are roughly cut or torn from the plants, and placed on hurdles over a wood fire until they are sufficiently roasted, after which they are placed on a hard floor and beaten; this operation knocks off the leaves and reduces them to a powder, which is then ready for use. More recently, however, the leaves have been roasted in large cast iron pans set in brickwork, after the style in which Chinese Tea is prepared; and, when they are sufficiently dry, they are powdered by machinery, and then packed in bags. The Maté owes its refreshing properties, which seem to be very considerable, to the presence of a peculiar acid, as well as to theine, which has also been detected in it. The actual results of the use of Maté seem somewhat doubtful, for while some maintain that it will stimulate the languid, and, at the same time, calm the restless, others consider its use prejudicial to health. The Creoles of South America are especially addicted to the use of it, always taking a supply of the leaves with them in their travels, and drinking an infusion of them before each meal. In our figure is also represented the small-spouted vessel (which gives its name of Maté to the plant)

in which the leaves are infused; they will bear to be steeped two or three times, but fresh water must be used every time, and the infusion must not be allowed to stand, or it will become deep black. The tube above is called a bombilla; through this the hot infusion is sucked, the small holes preventing the escape of the soaked leaves, which float on the top. Specimens of these objects may be seen in the Kew Economical Museum.—B. J.

A CHINESE GARDEN.

LAST year I paid a visit to the Rev. W. Duffus, of Swatow, and, wishing to see something of the country, I made a short expedition into the interior. We went to see a garden belonging to a family that had once been very wealthy. The grounds are not large, but appear at one time to have been well kept, for there are still the remains of some very interesting things, such as miniature pagodas, rustic arches, ornamental ponds, &c. The whole aspect of the place is thoroughly Chinese, most of the flowers and shrubs being tortured into every imaginable shape, so as to resemble different animals, houses, ships, &c., a style of horticulture of which this strange people appear to be very fond. Opposite the front entrance was a huge lion, made of a Banian tree. The legs appeared as thick in proportion as those of an elephant, and the eyes were represented by two small baskets painted white, with a black spot in the centre. The optic nerve was a piece of cord fixed to a branch higher up, so that the eyes appeared to be dangling in the brute's head; and their movements in the breeze conveyed the impression that the onlookers were being strictly watched, and might at any moment be called to account for their conduct. Farther on we came to a gigantic frog, which seemed to be in the very act of leaping off his perch on to the walk; then an elephant, with a most wonderful looking trunk, but not fully developed. On the other side was a great crab with such lusty looking claws that one felt inclined to keep on the farthest side of the path. Then we came to a goose, a cock, a tiger, a fabulous animal whose name I forgot, and, last of all, the traditional Chinese dragon. All these figures were made of an ever-green shrub, called "Serissa," which is a great favourite with Chinese gardeners, probably because it bears twisting into all kinds of grotesque shapes. There were several species of Pine, apparently Japanese, that had a very venerable appearance, and we were solemnly assured that they were at least three or four hundred years

Maté or Paraguay Tea, with Implements Employed in its Preparation.

old, and were highly prized on that account. The trunks were so much decayed that one wondered how they could keep in life at all, some of them having only a few shreds of rotten-looking wood, not more than an inch in thickness, connecting the branches with the roots, while the trees themselves were 15 ft. or 20 ft. high. Some members of the family to whom this garden belonged were at one time most bitter persecutors of the Christians here; but, happily, it is so no longer, for the one who brought us to see the place frequently attends the services himself. While we were examining the different objects of interest we noticed that the head gardener, who had designed and executed the works of art already referred to, looked rather sullen, and kopt aloof, as if the presence of foreigners in his garden was anything but agreeable to him. A little honest praise of his garden, however, caused his face to relax into a smile, and he looked much more cheerful and resigned during the remainder of our visit.

JAMES LAMONT, Hong Kong.

A PRETTY PARASITE.

ON one of the walls in the Glasnevin Garden, devoted to half-hardy shrubs and other plants, there is a fan-trained specimen of the pretty yellow-flowered Forsythia suspensa. For some weeks past one half of the aforesaid Forsythia has been clothed with a beauty not its own, and presented an aspect pretty as it was novel. In fact, for some square yards of wall there was nothing to be seen but a dense entanglement of pearly-coloured, Lily-of-the-Valley-like flowers, smelling sweetly as Heliotrope, and very like it. We dare say not a few of the visitors to the garden were puzzled as to one side of the Forsythia being a mass of tiny flowers, and the other bare of anything of the kind, and turned away anxious to get the name of this novel, sweet-scented, late-flowering shrub. No doubt they were surprised when told that the mass of floral beauty they were so struck with and admired so much did not belong to the shrub at all, but to a grasping little stranger plant only introduced to it a few months since, and which, now holding its almost every branch and branchlet in its tight embrace, garlanded them with flowers as unlike as possible to their own, and at a season, too, quite different. Well, the plant which produced this wealth of flowers on the open wall at a period of the year when outdoor floral effects are scarcely to be looked for, and which, moreover, bore them in full beauty till the beginning of the present week or so, when a smart touch of some five or more degrees of frost spoiled their fair and gay aspect, is no other than that pretty American Dodder (*Cuscuta Cephalanthi*). The specific name was given it at a time when the erroneous opinion prevailed that each species of *Cuscuta* attached itself and confined its attachment to some particular plant; the present species being frequently found growing about St. Louis on *Cephalanthus*, it was thought right to thus specifically distinguish it. This species has long been a pretty and interesting object in the cool greenhouse at Glasnevin, where the little alien was clothing some plant with its pretty pearl necklaces; but it was only the present year it occurred to Dr. Moore to try it out of doors. This he did with the results just described. The flowers are produced in marvellous profusion, in clusters of ten or a dozen at short intervals all along the brown, fiddle-string-like, twining stems. Each flower is nearly the size of, and not unlike in shape, that of the Lily of the Valley, and as pleasantly fragrant. Though the frost has destroyed the beauty of the flowers, there is no occasion for apprehension that the Dodder itself will not come safely through the winter; and, if permitted to extend itself, clothe a much larger portion of the Forsythia with its clustering flowerets next and other years, till ultimately the supporting plant succumbs to the exhausting operations of this pretty vegetable vampire. The smallest bit of it will grow if attached to any exogenous plant or shrub, and we have no doubt Dr. Moore will be happy to give a morsel to any one caring to grow or experiment with it.—*Irish Farmer's Gazette.*

It is no fable, that the Duchesse de Galliera has made a present of her mansion in the Rue Varennes, to the Comte and Comtesse de Paris. It stands in a garden of eleven acres, on the grassy part of which Brittany cows graze. This is how the Duchess came to think of giving her town residence to the Royal pair:—They were regretting to her the impossibility of holding large receptions in the suite of rooms the Duc d'Aumale assigned them in the Hôtel Pond. Said the Comte de Paris, "What we want is a villa somewhere within the fortifications, standing in spacious grounds, in which we could give garden parties. The garden party is an admirable institution. Society has grown unmanageable. One can receive a crowd on a lawn, which would be insupportable in a drawing-room. With sunshine, flowers, and a musical band, a little light refreshment goes far. There is no degrading scramble at the buffet. One's health is not wasted by turning night into day."—*Truth.*

THE CAS CROM OR SKYE PLOUGH.

HAVING obtained a Cas Crom from a Skye man some years since, I forward a sketch of the same, as it appears to illustrate the Greek plough of your issue of Dec. 1 (see p. 531). In describing Skye, Anderson, in his "Guide to the Highlands," says the distinguishing feature of its husbandry is the use of the cas crom, or ancient crooked spade or plough, an instrument, to all appearance, most clumsy and unwieldy, yet a most suitable and efficient one under the circumstances in which it is used. The cas crom is formed either of a stout, obtusely angled knee of wood or two pieces bound together with iron; the upper handle, or limb, is 4 ft. or 5 ft. long, the lower about 2½ ft., and shod at the point with a sharp, flat piece of iron, which is driven into the soil by means of a lateral wooden peg (A), projecting from the angle on which the right foot acts. With this implement a man can turn over a great deal more ground than he could do with a fork or garden spade, and,

Cas Crom, or Ancient Crooked Spade.

though, of course, it turns over much less ground than the ordinary horse plough could do, yet it is much better adapted than the horse plough for the tillage of the small rock-encumbered patches of ground of which much of the small tenements consist.

C. ISHAM.

Lampart.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Fruit Trees.—The pruning of fruit trees, in common with all other operations connected with gardening, should never be delayed longer than necessary, inasmuch as where any work is put off beyond the time that it should be completed, it causes an accumulation that necessitates additional efforts to clear off—the results of which are not generally satisfactory; but, in respect to the pruning of fruit trees—with the exception of Peaches and Nectarines—there is an additional reason why the operation should be completed by the end of the year; pruning is chilly, uncomfortable work, and if delayed until the colder weather which we generally experience during the first months of the year, it makes it still more uncomfortable; and, in the case of hardy fruits, the work is quite as well done immediately the leaves are off as if deferred until later.

Pruning Gooseberries.—With respect to these, it is sometimes urged that it is better to leave the pruning until nearer spring, so that if the fruit buds are attacked by sparrows, finches, or tits, allowance can then be made for the buds thus destroyed by leaving the shoots closer. This is a poor way of reasoning, as the birds act indiscriminately in their attacks, not by any means doing their work regularly, often making a clean sweep of a portion of the branches, and leaving others untouched; any after-pruning regulated on such destruction would obviously render necessary a retention of branches in some parts of the trees so as to overcrowd, whilst others would require to be cut away that ought to be retained to maintain the requisite form and symmetry of the bushes; and it is a matter of no great difficulty to take means that will either scare the birds from touching the buds, or render them so unpalatable as to make them safe. It is not an easy matter in writing to give directions that will convey a clear idea how to prune successfully, nevertheless, for the guidance of those who have had little experience in such work, I may offer a few suggestions likely to be of use. Gooseberries bear not only from the old wood on which permanent fruit spurs are formed, but also from the preceding summer's shoots; in the case of young trees that have not attained the requisite size, a sufficient number of the strongest shoots, best placed for the future formation of the tree, must be retained, neither reducing their number so far as to make the trees too thin, or leaving so many as would cause overcrowding; the centre of each tree ought to be left the most open, so as to admit sun and air freely, without which the fruit

will never attain its requisite quality. All the short, weaker growths, as a matter of course, should be cut away, to leave room between the larger branches for the hand to pass freely in gathering the fruit; the young shoots ought to be slightly shortened back by cutting away one-fourth or a fifth of their points, which will have the effect of causing them to break out at the point severed, from which, in all probability, it will be necessary, at next year's pruning, to retain a couple of shoots so as to furnish the trees properly. Some difference in the use of the knife will require to be made between the erect-growing kinds and those of a drooping habit; with the latter, the under branches, that cling too close to the ground, will need to be removed, retaining more towards the middle of the trees; in the case of older bushes, that have attained a size sufficiently large, it is well each year to cut out from near where they spring a few of the older branches. If the trees be in good health, this will have the effect of causing them to make strong young shoots from the points where the branches are thus cut back to; by yearly following this up, the trees will be kept furnished with the necessary quantity of young wood springing from the base, a matter of importance in the cultivation of this fruit.

Red and White Currants also bear fruit from both last year's wood and from permanent fruit spurs, with which, on well-managed trees, the old wood is thickly studded; but it is on the latter that the greatest weight of fruit may be looked for. With young trees of these, as with Gooseberries, it is necessary to be guided in the shoots that are to be retained by the future form, shortening the young shoots that are kept a little. With old Currant bushes, of the Red and White kinds, I have always found it answer best to take out annually, near the bottom, a few of the branches, as advised for Gooseberries; by this means only can the trees be kept furnished with young wood from top to bottom. Immediately the pruning is done, I should advise means to be taken for the protection of the buds. The use of thick white cotton thread, wound from point to point of a portion of the branches, and allowed to hang in loose festoons, so as to move with the wind, will generally, but not always, be found a sufficient deterrent for sparrows; not so with bullfinches and tits, they take no more notice of it than if non-existent. Previous to stringing on the cotton, it will be much the safest to dress the trees with lime, soot, and water, mixed to the consistency of ordinary whitewash, and applied by a syringe furnished with a rose perforated with holes of considerable size. Choose a dry, windy day for the application, so that the mixture may get thoroughly dried on, when it will resist a good deal of wet weather without being removed; after this a little of the cotton wound on the trees as described, will be an additional safeguard. The whole of the work connected with this bud-protection need not occupy much time; a handy man will syringe on the mixture and put on the threads to a good number of trees in a few hours; and it is necessary to take this precaution, especially in small gardens, where birds are generally much more persistent in their attacks than in the large breadths under cultivation in market gardens. It is not only the current year's crop that suffers when the trees are stripped; but when, as is frequently the case, the fruit-spurs on the old wood are denuded of their buds, they generally die back, leaving the lower portion of the trees permanently unfruitful. Black Currants require comparatively little pruning, except an annual cutting out, near the base, of a few of the branches, from which will spring stout shoots to take the place of others that are cut away in after years; in addition to this, where the branches are too much crowded, the weaker ones ought to be thinned out.

Raspberries.—Some discrimination should be made in allowing considerable difference as to the length the canes are shortened back to; where they are very strong and vigorous, and trained in the form of arches by a portion of the shoots from each stool being bent over, and tied to others from the adjoining plant, 5 ft. will not be too long to leave them, as when bent, as this method of training involves, it assists the bottom eyes to break; the same holds good when the shoots are each trained in a slanting direction to strained wire supports at an angle of about 50°; this also assists the bottom eyes to break; and even if tied upright to stakes where they are strong and well furnished with roots, a much greater number of eyes will push bearing shoots, than where the plants are comparatively weak; but, when strong, do not be induced to retain too many shoots, the result of which is the production of a thicket of bearing wood impermeable to sun, which is more necessary to this soft fruit than many others.

Apples.—Bush-shaped trees are the best adapted for gardens, large or small, where culinary vegetables are grown near; in pruning young trees of this description, the operator should always look well ahead so as to leave such branches as are essential to the future balance of the tree, with a view to make it shapely in after years. Of the two extremes, it is better to err in cutting out to leave it a little too thin rather than maintain an overcrowded condition; after the

branches have attained the height of a few feet, and it is desirable to increase their number, such strong shoots should be cut back at the point where it is necessary they should branch out as will induce them to do so, but anything like severe pruning by cutting hard in the shoots collectively ought to be avoided; even in the case of such as possess undue vigour a too free use of the knife will only aggravate the evil by directing the whole energies of the tree to the production of wood growth in the place of forming fruit spurs. Pyramidal-shaped trees often have a tendency to push the greater portion of their growth into the leading branches, which, despite a free use of the knife, keep continually producing a number of gross shoots, leaving the lower side branches comparatively weak. Where this happens I have found it best to tie the strongest of these rank shoots out, bending them down in a horizontal position, leaving one somewhat weaker as a leader. Such other winter pruning as trees of this shape require is regulating the number of side shoots, so as to keep each sufficiently clear of the other, and slightly shortening back to keep the tree within due bounds. With standard Apples little is required besides keeping the branches thin enough to admit light and air, and not allowing the trees to stand so closely together.

Pears, restricted in size, are much more generally grown as pyramids than bush-shaped; but, in both cases, the pruning will require to be of a similar description to that advised for Apples, keeping in view the generally more erect growing habit of Pears; in such varieties that particularly exhibit this disposition, it is necessary to keep them well open in the centre, for, if at all crowded, the branches are lashed against each other as to knock off a good deal of the fruit.

Plums and Cherries, as a rule, need less pruning than Apples and Pears; as, from the fruit being less liable to be blown off, they will succeed fuller of branches; but young trees should have the knife sufficiently used to preserve a shapely outline. In the case of all these fruits on walls, fan-shaped trees for general use are the best; in pruning these whilst young, especially in the first year or two after their being obtained from the nurseries, it is necessary to be careful in not allowing a few strong branches, such as produced by many trees, to take the lead too far, as, if left unchecked, they absorb the greater portion of the strength, leaving the weaker branches completely behind; this can only be corrected by cutting such strong growths back freely considerably lower than the points of the weaker shoots, which, if performed timely and persevered with systematically, will restore the wanted balance. As the pruning of wall trees is completed, they should be at once nailed or tied, according to whichever method they are grown under, for, although pruning is cold work in cold weather, nailing is still worse, and when all operations of this kind are completed early, it allows leisure for seasonable works that are ever coming due.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

December 10.—Potting another quantity of Potatoes that has been previously started in the Pine stove. Pruning first Muscat-house, and washing the paint with soft soap and hot water. Finishing pruning and nailing Pears on east and west walls. Taking up Box edgings and re-making them.

Dec. 11.—Putting a few Herbaceous Calceolarias into their flowering pots. Getting more leaves into pot Vine pit, in order to increase the bottom-heat. Collecting horse droppings for Mushroom beds, and turning over a large heap to sweeten. Getting up a few more clumps of Mint for forcing. Veitch's Autumn Self-protecting Broccoli still in fine condition.

Dec. 12.—Shifting Campanulas. Putting into gentle heat a few plants of Dielytra and Deutzia gracilis. Painting Muscat Vines, lightly forking over the surface of the border, and adding a little more fresh loam to it. Fumigating Cinerarias and Cucumbers to kill green fly. Clearing all leaves and rubbish out of all the spouting; also all catch-pools, so that heavy storms may pass off freely.

Dec. 13.—Getting into the forcing-pits more Lily of the Valley, Hyacinths, Narcissi, Tulips, and Cyclamens. Covering up more Endive and Lettuce to blanch. Levelling ground in pleasure grounds, and laying down new turf. Looking over fruit room, and clearing away any fruits that are decaying.

Dec. 14.—Getting in 100 pots of Osborn's Forcing French Beans, and adding a little more earth to those already up. Forking up shrubby borders, and getting them filled with spring flowering plants. Getting a pit filled with leaves in which to plunge Strawberry plants. Getting on with trenching as fast as the weather will permit. Looking over the Pines, watering and tying up all that require it.

Dec. 15.—Clearing up pleasure grounds, and rolling down all gravel firmly. Looking over Grapes in bottles, removing any that are bad, and filling up the bottles where required. Thinning-out Mignonette, and tying up that which is in a more forward state. Fruit in use for dessert—Pines, Grapes, Pears, Apples, Medlars, and Nuts.

PODOCARPUS.

THIS interesting *Taxus*-like genus is but little represented in gardens, notwithstanding the fact that it contains numerous varieties, probably upwards of fifty, introduced into Britain from almost every quarter of the globe; the majority of them, however, are not sufficiently hardy to withstand our winters in the open ground, especially those from tropical climes. Nevertheless, there are a few from temperate regions that may be considered hardy in the south and west of England, and one of the very hardiest is *P. Koraiana*, a sturdy, dark-foliaged, dwarf tree from Japan, much resembling the Irish Yew, but having longer and stouter leaves. *P. chinensis* and *P. alpina* are

Podocarpus macrophylla.

also tolerably hardy in mild localities. The latter is a graceful plant, of slender habit; its foliage, too, is small and neat. *P. macrophylla* is a handsome variety, the leaves of which are about 4 in. long and about $\frac{1}{4}$ in. broad. A variegated variety of this, as well as of *P. chinensis*, is in the trade. *P. macrophylla* can scarcely be called hardy; it may, however, perhaps be able to withstand our winters in sheltered sites, near the sea, on the south coast. The best collection of *Podocarpus* with which I am acquainted is in the Lucombe Nurseries, Exeter, where they seem to thrive exceedingly well. G. B.

Colour from Leaves of Shrubs.—In grouping low-growing shrubs there is a beautiful feature that should be kept in view—the autumnal effects of foliage. Compared with trees, their varied hues are as bright and attractive, and the diversity of tints and colours quite as marked. We lately noticed just such a mass of showy leaves as pleases the eye of an artist, and the taste of every lover of plants. The *Spiræa prunifolia*, with deep crimson foliage, vied in tint with the Oak-leaved *Hydrangea*; golden yellow was supplied by *Forsythias*, and bright scarlet by the despised *Sumach*. Peeping out from this mass of bright colours, a single shoot of chance *Blackberry*, of the deepest magenta, made its presence acceptable for once, at least. A trailing *Ampelopsis*, loosened from support on a tree near by, had found its way to the group, and festooned its branches with regal splendor. A Sweet Bay (*Magnolia glauca*) made quite a contrast to the others, with its light glaucous, green foliage, and an imaginative person might easily fancy that the fragrance of its long-past bloom still lingered among its leaves.—“Tribune.”

Trees in Marylebone.—A letter was read from the inhabitants of St. Edmund's Terrace, North-gate, Regent's Park, stating that they proposed to plant Lime trees, 8 ft. or 10 ft. high, and 8 yards or 10 yards apart—fifty trees to be planted on each side, the expense to be defrayed by subscription, and asking the Vestry's permission.—Mr. G. Edwards moved that the application be granted.—Mr. Carr seconded, remarking that the terrace was a very suitable place for trees. [It is a pity better trees than the Lime were not chosen.]

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 4.

THIS meeting was in every way a satisfactory one, both flowers, fruits, and vegetables being shown in considerable numbers, and these, too, of an interesting description. The principal features were collections of flowering and ornamental-leaved plants from Messrs. Veitch & Son, and Mr. William Bull, Chelsea.

First-class Certificates.—These were awarded to the following new and rare plants:—

Croton picturatum (Bull).—A very distinct, highly-coloured variety from the New Hebrides. The older leaves are some 18 in. long and about 1 in. broad, somewhat irregular at the edge. The midrib is bright red, and the surface is marked in an irregular blotchy manner with clear yellow. The leaves have an oblong leafy petate base, from the back of which the costa is continued like an excurrent thread, at the end of which is appended another elongated leafy portion.

Chrysanthemum Golden Empress of India (E. G. Henderson).—A beautiful incurved flower, globular in form, and large in size; its colour is a rich creamy-yellow. Well worthy of a place in every collection.

Tropæolum Perfection (R. Dean).—A climbing variety, with brilliant dark scarlet flowers.

Cibotium pruinatum (Bull).—A distinct Tree-Fern, with elegant, broad, gracefully-drooping fronds, from 10 ft. to 12 ft. in length.

Pelargonium White Vesuvius (Cannell).—A white-flowered sport from the well-known scarlet *Vesuvius*, which it resembles in habit and general good qualities. For flower garden decoration, or for culture in pots for winter-flowering, this will prove one of the most valuable *Pelargoniums* which have been introduced for some time past.

Tree Carnation A. Alegatiere (Turner).—A kind remarkable for its good habit, and for producing an abundance of bright crimson flowers of good form and substance. One of the best winter-blooming kinds which we have seen.

Chrysanthemum Fulton (Jackson & Son).—A Japanese variety, the flowers of which consist of gracefully-disposed petals of a rich lemon-yellow colour.

Broccoli Self-protecting (Veitch).—The best new Broccoli which has been sent out for some time. It makes an excellent succession to Veitch's Autumn Giant, and comes in just before Snow's Winter White. The leaves grow over the curd in such a manner that frost is entirely excluded, and the flower kept firm and white.

Miscellaneous Subjects.—In Messrs. Veitch's collection were well-flowered examples of *Oncidium Barkeri*, *Lælia autumnalis*, the beautifully-marked *Oncidium Forbesi*, very fine specimens of *Cattleya exoniensis*, *Saccolobium giganteum*, *Calanthes*, and *Lady's Slippers*. The same firm also exhibited cut spikes of *Poinsettia pulcherrima rosea*, the bracts of which are broad and of good substance, and the colour dazzling rosy-scarlet. A basket of plants of *Bouvardia leiantha* was also shown by Messrs. Veitch. This is a dwarf-growing kind, and one which produces abundance of bright orange scarlet blossoms, exceedingly useful for cutting at this season of the year. Specimens of *Fuchsia Dominiana* were also shown in good condition as regards flower. *Rhododendron Arthur Potts*, a garden hybrid from Messrs. Veitch, was much admired on account of its bright orange-scarlet blossoms, which are produced in large clusters on every young shoot. A basketful of well-flowered plants of the sweet-scented *Daphne indica rubra* was also exhibited. In Mr. Bull's collection were stately plants of *Encephalartos villosus ampliatius*, *Cocos Weddelliana*; remarkably well-variegated plants of the graceful *Curculigo recurvata variegata*, *Anthurium Veitchi*, *Dracæna Goldiana*, and a pan full of small, well-flowered plants of the old, but now somewhat scarce, *Impatiens Jernonia*. These, together with one of the best-flowered branches of *Lapageria rosea superba* we have ever seen, and a plant of *Pilumna fragrans*, several Ferns and *Crotons*, and *Tillandsia Lindeni*, made this a very effective group. Mr. Cannell, of Swanley, sent, in addition to the white-flowered *Vesuvius*, other *Pelargoniums*. Mr. Chambers, Westlake Nursery, Spring Grove, Isleworth, contributed cut sprays of *Bougainvillea glabra*, being a third succession within 12 months. Messrs. E. G. Henderson & Son, of Pine-apple Place, showed cut blooms of incurved *Chrysanthemums*, and Messrs. Jackson & Son sent blooms of Japanese varieties. Mr. Moorman, gardener to the Misses Christy, Kingston, also sent a collection of *Chrysanthemum* blooms. Plants of the graceful *Asplenium viviparum* came from Mr. Chambers. Cut flowers of herbaceous plants were furnished by Mr. Parker, of Tooting; amongst them were blooms of *Helleborus altifolius*, *niger maximus*, *Tussilago fragrans*, *Gentiana acaulis*, *Pansies*, and *Tritoma grandis*. Mr. W. Paul showed good examples of *Picea nobilis*. A bank of double white *Primulas*, from the Horticultural Society's Gardens, was very effective. Mr. Mill, The Gardens, Rendlesham Hall, Woodbridge, sent a remarkably fine spike of *Oncidium æmulum*, measuring 12 ft. in height, and furnished with numerous chocolate-coloured blossoms. Mr. Ollorhead, gardener to Sir H. Peek, Wimbledon, sent flowering plants of *Centropogon lucianus* in good condition, showing its utility as a pot plant at this season of the year.

Fruit and Vegetables.—Mr. Wildsmith, gardener to Viscount Eversley, contributed good examples of *Barbarossa* Grapes, and Mr.

Miller, The Gardens, Combe Abbey, sent fine examples of Smooth Cayenne Pine-apples. From Mr. Muir, Margan Park, South Wales, came a good collection of Oranges, Lemons, and Citrons. Mr. William Skinner, Boughton, near Maidstone, sent a collection of Apples, consisting of thirty-four varieties. Among them were fine specimens of Stone's Apple, Blenheim Orange, Warner's King, and other good kitchen varieties; and among dessert kinds we noticed clean, well-coloured fruits of the King of the Pippins, Court Pendu Plat, and Cox's Orange Pippin. A good collection of Apples also came from Mr. Fenn, Sallaampstead, Reading. Mr. Ford, St. Leonard's Lee, Horsham, also sent a remarkably fine collection of Apples, amongst which were Devonshire Queen, Blenheim Orange, Winter Pearmain, Cellini, Golden Reinette, and others. From Mr. J. Atkins, gardener to Colonel Lloyd-Lindsay, Wantage, came fine examples of Mascat of Alexandria, Black Alicante, and Black Hamburgh Grapes, good both in bunch, berry, and bloom. Mr. Jones, Bentley Priory, sent remarkably fine examples of Veitch's Autumn Giant Cauliflower, in order to show its adaptability for winter as well as for autumn use. Good Cucumbers were contributed by Mr. Gilbert, of Barghley, who also sent good examples of Veitch's Autumn Giant Cauliflower.

SCOTTISH HORTICULTURAL ASSOCIATION.

The ordinary monthly meeting of this Association was held at 5, St. Andrew's Square, on the evening of the 4th inst. There was a large attendance of members. The President, Mr. Dann, Dalkeith Palace Gardens, occupied the chair. Fifteen new members were duly admitted, and seventeen new names were proposed and seconded for admission as members at next meeting. The subject proposed for discussion was the Kitchen Garden, by Mr. Lawrence Dow, Saughton Hall. At the outset he urged upon young gardeners the necessity of devoting great attention to the proper management of the kitchen garden, so as to keep up a constant supply of first-class vegetables; some were very apt to overlook this department, in their anxiety to have a fine display of greenhouse and bedding plants. He then in a practical and lucid manner described the different methods in which he had been most successful in growing Potatoes, Onions, Jerusalem Artichokes, Parsley, and Asparagus. Several members expressed concurrence with Mr. Dow's views as to the importance of the subject, and also as to the modes of culture pursued. Mr. Dow received the thanks of the meeting for his paper, and, at their request, agreed to continue the subject at a future time. A communication from Mr. James Morrison, Preston Hall, was read, advocating the autumn planting of the Potato, and also attaching great importance to the proper ripening of the seed tubers. A vote of thanks was passed to Mr. Morrison for his contribution. It was intimated, that the subject for next meeting was the Phlox and Pentstemon, by Mr. Jas. Grieve, Pilrig Park Nursery.

Potatoes Shown at Bingley Hall, Birmingham.—At the late Bingley Show, the Messrs. Hooper, Covent Garden, exhibited an interesting collection of American Potatoes, grown by the Messrs. Bliss, of New York. The best white kinds amongst them were Snowflake, Peerless, Climax, Early Dimmock, Sheldarne, and Burbank's Seedling, a white kind, of the Rose type and form. Of red sorts, the handsomest were Trophy, a new kind, having the beauty of Snowflake, with a bright red skin; Triumph, a handsome round kind; Ruby, early kidney; Manhattan, purplish-red skinned, an improved Compton's Surprise; Peach Blow, large, but somewhat coarse; Vermont Beauty, and Centennial, a new round sort. Mr. P. McKinlay, of Beckenham, was awarded first prizes in all the eight classes in which he exhibited, his samples being handsome, and of good size. Of thirty-four dishes exhibited by him, the finest white kinds were International, Climax, Schoolmaster, King of Potatoes, Model, and McKinlay's Pride, a new and handsome kidney. Of coloured kinds, Garibaldi, Grampian, Purple Ashleaf, Blanchard, Salmon Kidney, and Late Rose were exceptionally good. In the various seed trade stands there were some very fine collections of tubers, those shown by Messrs. Carter & Co., being exceptionally so, all the samples being so arranged as to display their size and quality to the best advantage. Messrs. Suttons, of Reading, had fine samples, &c., set up in baskets. Altogether, it will be the fault of the various exhibitors if the visitors do not take away with them the opinion that the many comparatively new kinds now being offered present many marked excellencies over older and less productive varieties.—D.

Vegetables and Water.—It is impossible to grow good vegetables in a dry season without some better means of obtaining and supplying moisture than are commonly met with at present. No doubt better cultivation, greater depth of soil, and a more frequent stirring of the surface with hoe and fork will do much to mitigate the effects of severe drought; but where it is possible to obtain a good supply of water for irrigating purposes, better crops would certainly be obtained. Wherever there is a pond on a higher level, a pipe laid from it through the gardens would give not only a good supply of water, but also the necessary pressure for its distribution; and in such cases the outlay, in proportion to the benefits derived, would be so small that scarcely any valid excuse can be urged for not adopting it. A small hydraulic ram by the side of a running stream or river, where the necessary weight of water could be dammed up, and where the waste water could get away on a lower

level, would insure an ample supply. By these and similar means the water that now finds its way through the drains and water-courses to the rivers, and finally to the sea, might be arrested in its course and passed through the parched soil again and again. And not only is this feasible, but it would also pay.—"Field."

An Odd "Discovery."—Dr. Taschamer, of Gratz, says the "Sanitary Record," has discovered that a fungus grows upon the skins of Apples and Oranges, which is precisely similar to the fungus which forms the peculiar germs of infection in whooping-cough. He writes that on Oranges and Apples which have been kept some time may be found dark brown and black specks which, when scraped off, appear as a damp powder. Under the microscope this powder is seen to consist of the spores of a fungus, identical with those of the whooping-cough fungus. Taking two of these specks from the skin of an Orange, Dr. Taschamer introduced them by a strong inhalation into his lungs. The next day tickling of the throat began, which gradually increased, until, at the eighth day, a thoroughly developed whooping-cough set in. Should the discovery be confirmed, there is an additional reason to see that children abstain from eating Apples with the skin on, and from chewing Orange peel, which many are so fond of doing.

A Centenarian Gardener.—On Thursday last, December 6, the Rev. Canon Beadon, rector of North Stoneham, near Southampton, reached the completion of his hundredth year, having been born December 6, 1777. There are still a few who can remember the Rev. Frederick Beadon, as an early exhibitor at the Southampton and Winchester horticultural exhibitions of nearly half a century ago, when such exhibitions were rare and of great importance to horticulturists in those days. Mr. Beadon's name was well known throughout Hampshire, and further as an earnest patron of horticulture, and with a thorough love for plants, as well as possessing a good knowledge of them, and this affection he has retained to the present time. In his library at North Stoneham is to be found a valuable collection of horticultural works, many of them very rare. In the rectory gardens many examples of rare trees, shrubs, and herbaceous plants are to be found, as well as some veteran Camellias against a south wall, and an old Azalea indica alba, out-of-doors, in the American garden, which rarely, if ever, misses having a good head of flowers.—"Gardener's Chronicle."

The Veitch Memorial Prizes.—The Veitch Memorial Trustees, at a meeting held on the 4th inst., confirmed their provisional resolution to place a Veitch Memorial Medal, with a prize of £5, at the disposal of each of the undermentioned societies, for the several subjects specified, it having been ascertained that the exhibitions of 1878 of the respective societies, will take place at a period of the year when these subjects can be produced:—*Manchester*, June 7—For the best specimen Orchid, in bloom. *York*, June 19 to 21—For three bunches of Black Hamburgh Grapes. *Clay Cross*, August 13—For a dish of Peaches and a dish of Nectarines. *Hereford*—For twelve cut blooms of the best new Rose, sent out within the last five years. *Exeter*, August 23—For a collection of twelve kinds of vegetables, distinct. *Brighton*, in June—For one bride and one ball-room bouquet. *Woodbridge*, July 11—For three stove or greenhouse plants, in bloom, distinct. *Reading*, May 23—For three stove or greenhouse plants, in bloom, distinct. *Dublin*, Royal Horticultural Society of Ireland, in August—For three bunches of Muscat of Alexandria Grapes. *Belfast*—For twelve cut blooms of the best new Rose, sent out within the last five years. The prizes are to be open to competition amongst *bona fide* gentlemen's gardeners, eligible to compete at the several shows; and the subjects exhibited, are, in all cases, required to display superior cultivation.

QUESTIONS AND ANSWERS.

Weeds on Walks.—My paths are perfectly infested with weeds and Grasses. How can I best eradicate them? Is not a layer of salt or a good sprinkling of brine a good check, and then a coating of gravel over it?—G.

Wintering Pelargoniums.—Will Pelargoniums, if taken up in the autumn, and hung up in a cellar, keep alive during the winter, and be fit for planting in the spring? I have read that such is the case, and want to know if it be true.—W. W.

Creepers Covered Fence.—Being compelled to surround an American garden with 115 yards of wire netting, owing to the destruction caused to young trees by rabbits, which this year have been unusually numerous. I should like to make the netting into an ornamental screen, with climbers bearing varied and beautiful flowers in the summer and autumn. The aspect is mild and sunny, and the soil peat mixed with sandy loam. What shall I plant?—CAMBRIDG. [Such a trellis will afford a home for many lovely plants, and on it they may be prettily arranged. Japanese Honeysuckles, Tropæolums, Clematises in great variety, Tea and other Roses, and Ivies of different kinds would all be suitable for a trellis, such as that described.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FALLACIES OF LILY-GROWERS.

IN continuation of my observations on the Reproduction of Lily Bulbs (see p. 505), I would here premise that a well-known Lily-grower has this year headed his Lily Catalogue with the following remark:—"There is hardly a situation in which more or less of the Lilies will not thrive, and yet how rarely do we see them grown." This is true enough, but it raises the important question, "Who is to blame?" Is it the buyers or the sellers—the amateur gardeners, or the professional Lily-growers themselves? There are thousands upon thousands of amateurs in the suburbs of London, and other large towns, who could spare time for the interesting and healthy exercise of gardening in August and September, but who could not spare a day, or even an hour, during the latter part of October; and yet, if they apply to nurserymen, they are told that Lily bulbs will not be ready for lifting before the end of that month! If they apply to Lily-growers in Holland, the answer is even more fallacious, for they are told that the Lily bulbs will not be "harvested" until the end of October; and that the best time for planting is from October to March! Others say, as an excuse for late planting, that Lily bulbs are not fully "matured" before the end of October. Now this is a fallacy, most hurtful to both buyers and sellers. No Lily bulb can be said to be fully matured until it has advanced to a state of perfection—that is, until it is in full bloom; this being its last and highest stage. In October, and onward through the winter months, Lily bulbs can only be said to be maturing; that is, approaching maturity. We are told by a writer on Lilies, that a Lily will flower better the second year after planting than the first. This, also, is a fallacy; but why? Too late planting! The growth of the first year is checked, while the growth of the new, or succession bulb, is undisturbed; consequently, that bulb blooms well the following year, leaving the parent bulb to decay and die. In some catalogues we are told that Lily bulbs should not be disturbed for three or four years after planting, as patches that have been undisturbed flower much better, and grow taller than those fresh planted. Why? For the same reason as already stated—too late planting in the first instance. It is said by some writers, "that imported Lilies often take a year to recover themselves after being planted." This is a fallacy, founded on the fact that many of those Lilies, after being planted, do not spring up again, but decay and die, leaving to their offspring, the successional bulbs, the duty of growing in their stead, and flowering the following year. There are hundreds of thousands of imported bulbs, which, by the time they are planted (their roots being decayed or cut off for the purpose of packing) have so far lost their vitality that they never again show a sign of growth. This is corroborated by a writer in a contemporary, who says:—"The continued importation of Lily bulbs is surprising. The sale of several thousands in one day by Mr. Stevens has for many years past been an ordinary occurrence. By this time no moderate-sized garden ought to be without them. But what is the fact? They are still unknown, except in the gardens of the few. Where, then, are the bulbs? Why, dead." Another reason why thousands of imported bulbs do not bloom the first year after planting, and that many do not bloom at all, is the fact, that they are not flowering bulbs; that is, they are not fully and sufficiently developed.

As regards the evils of late planting, I am borne out by Mr. Baines (see p. 349) in saying that it would be folly to attempt to transplant the White Lily (*Lilium candidum*) in October, "as it will then," as he says, "be making active growth; and, if the roots be disturbed, it will have the effect of wholly or partially preventing its flowering next year." This remark holds good with regard to all Lilies, with the exception of a

very few late-flowering ones. We see the green tufts of leaves shooting up from the White Lily bulbs before October arrives, and we can therefore imagine the activity that must be going on beneath the surface of the soil. With regard to other Lilies, we cannot see this; but experiments can lay open the mysterious underground workings of Nature, as plainly as the green tufts of leaves can be seen by the naked eye. At the end of June, 1876, I lifted and transplanted a number of White Lilies, and they bloomed as well during this last summer, if not better, than those which had not been disturbed. At the end of October, I lifted and transplanted a few bulbs each of five different sorts, including the White Lily. Only three stems, out of all I had transplanted, came up this last season, and even these did not show the slightest signs of bloom. So much for early and late planting. The method of reproduction is different in different plants; but, as a general principle, it may be stated that the parent bulb is charged with the function of liberating germs or seed-buds, which vegetate as soon as brought into a condition fitted for their growth; and this is in general, about eight or ten days after the flowers of the parent bulb have faded. It is very soon after this time that we are enabled, by experiment, to observe the phenomenon called "three generations in one;" that is, the parent bulb, now destined by Nature to perish; the new bulb within it, which is destined to bloom next summer; and the seed-bud within the new bulb (now cut open to observe it), which is destined to flower the year after that. From this it will be seen that a Lily is not an annual, nor is it a biennial, but a part of both, two years comprising the period of its existence from birth to death; it is certainly not a perennial, as some have called it. These seed-buds, as soon as they can be discerned, even by the aid of a magnifying glass, can, by a simple, though necessarily protracted, course of experiments, be followed in their growth distinctly until they become flowering plants, leaving no room whatever for those who are otherwise biased or prejudiced to theorise on the subject. There are some, however, who would rather indulge in mere theory than take the trouble to go an inch under the surface of the ground. A Lily grower, writing in the "Gardener's Chronicle," says "the stems in a healthy plant are generally from 6 to 18 in. in length, before the roots are emitted from the base of the bulb." This is clearly a fallacy, and very much calculated to mislead; for, on the contrary, the roots of the new bulb are generally 3 or 4 in. in length, before the stem is $\frac{1}{2}$ an in. above the apex of the bulb. It is then, at the time above-mentioned, namely, about eight or ten days after the petals have fallen, when lifting and transplanting can be done with the best prospect of a successful bloom during the next season. Nature has designed that there should be a reciprocity in action between the roots and the bulb. But man, thoughtlessly, or unknowingly, deranges all this. The new bulb, at this time, derives its principal support from the roots, as the parent bulb is now dead, or dying. At this time, also, the bulb and its roots approach nearer to a state of quiescence than at any other succeeding period of their growth. If, therefore, the roots be as numerous, as strong, and in as vigorous a condition as they are in October, the bulb itself and all that it contains would be forced into an unnatural state of excited action, so much so, as would soon entirely ruin the plant. On the other hand, by lifting and transplanting, indiscriminately, all bulbs in October, man destroys the reciprocity of action in the plant. The roots are disturbed, the flow of nourishment is checked, the damage, in fact, is as complete as if the young stem itself had been cut out of the bulb; having the effect, as Mr. Baines distinctly points out, "of wholly or partially preventing its flowering next year." There are some late blooming Lilies that may be transplanted in October; but this should not be taken as a general rule. The catalogues of Lily-growers show us, that, with a well-selected collection, Lilies may be had in bloom from June to October, embracing a period of five months. Here, then, we have a scientific guide, if we choose to follow it. It is a fact, which science has placed beyond a doubt, that, if Lilies do not all bloom at the same time, they should not be all transplanted at the same time. Beginning, therefore, eight or ten days after the Lilies which flower first, have shed their bloom, we go on lifting and transplanting, from time to time, until October; during the most agreeable part of the year, and during a period, too, when amateurs have

a good deal of spare time on their hands, which might be turned much to their own advantage, and, at the same time, to the advantage of our professional growers.

We now come to another fallacy, one of the most disheartening with which amateurs can have to contend; but as time and space both forbid my enlarging on the subject at present, I shall simply throw out a few hints for further consideration. In an advertisement which I have lately seen, a Lily bulb importer (not a nurseryman) announces that he expects shortly a shipment of *Lilium auratum* from Japan, and offers the bulbs "at the following prices:—Sizes No. 1, 6d.; No. 2, 1s.; No. 3, 1s. 6d.; and No. 4, 2s. each." Here we have no less than four different sizes of one sort of Lily offered to amateurs, without any guarantee whatever that they are flowering bulbs; I do not blame the importer, as it is a mere matter of business with him, and I know that he could not give a satisfactory guarantee, if he were ever so willing, that the bulbs offered would bloom. With a shipment of Potatoes we might be able to judge what they would be worth, but with Lily bulbs it is altogether different. It is within the bounds of possibility, that of the whole shipment there may not be a tenth part flowering bulbs, and these no one could point out. In fact, no man can tell this but he who overlooks and takes an interest in his Lily department. He sees his stock in bloom, and knows, or ought to know, that every bulb that blooms is at that time the parent of a new bulb—perhaps twin-bulbs, but rarely triplets—that will bloom the next season. But even he can go no further than this with certainty. Before the parent bulb bloomed for the first time, he could not have told that that was a flowering bulb. It has been supposed, that if a bulb shows a portion of the parent stem attached to it, this ought to be sufficient, but this is not an infallible test, for every bulb has a parentage even in a two or three-year-old bed of offsets, and consequently every bulb, large or small, flowering or non-flowering, has sprung from the side of a stem, some small offsets of a first year's growth, on the outer edges of some bulbs, excepted. This being the case, we need not be so much surprised that a vast number of Lily bulbs do not flower the first year after being planted. As regards imported bulbs, they are only fit to be planted out in nursery beds. The many that will die must die, and those that flower will (not always) leave behind them successional flowering bulbs to fill blank places in the ornamental beds or borders. I had written thus far, and was about to close, when my copy of THE GARDEN was placed in my hands. From it I am glad to learn that Mr. Frank Miles have taken this subject in hand. We may now hope to see, ere long, the underground history of the Lily made plain clear, and as intelligible as that part which grows in the light of day.

DUNEDIN.

Retinospora ericoides a Misnomer.—Is not Mr. Syme (see p. 404) mistaken when he charges M. Carrière with saying this "is a native of Japan"? I have too high an opinion of M. Carrière to believe he would ever say as a fact, what he could have no knowledge of. In these matters it is best to quote the exact language, with references, of the author charged with the statement. That the plant is simply *Thuja occidentalis*, and nothing more, and has no relation whatever to Japan, is well-known to every intelligent American, by whom not only the fact, but the biological law which induces the dimorphism, is understood. Those who wish to pursue this study further will find the explanation in the "Proceedings of the Chicago Meeting of the American Association for the Advancement of Science"; and later, in the excellent "Book on Evergreens," by Mr. Josiah Hoopes. In branches which I have from the same plant, the upper portion is the normal *T. occidentalis*; the lower, *Retinospora juniperoides*; the dingy-brown base of the tree forming a striking contrast with the green upper part. It does not get brown till cold weather sets in, of which we have had none yet. It seems strange to us over here that our friends in England should be so mystified over these things, which are old to us in America.—THOMAS MEEHAN, Germantown, Philadelphia.

Goodyera Rollissoni.—I cannot agree with Mr. Speed's assertion (see p. 536) respecting this plant. It is certainly not *G. Veitchii*, but an introduced plant, bought of M. Linden, in almost a dried state, under the name of *G. velutina*. The plant, however, figured by M. Van Houtte under that name is totally distinct, and this circumstance, combined with the fact that it was an introduced plant, and different from any other species, gave rise to the name under

which it was distributed by us. Had it been one of the Chelsea hybrids, Mr. Dominy is far too much respected here to be deprived of the slightest honour that may belong to him. In *G. Veitchii* the leaves are bronzy-red, ribbed with silver lines; in *G. Domini* the leaves are bronzy-black, striped lengthways with white lines, and transversely netted with fine lines of the same colour. Our plant is figured by M. Linden under the erroneous name of *G. velutina*.—W. GOWER, Manager, Messrs. W. Rollisson & Sons, The Nurseries, Tooting.

Tropæolum speciosum in Warwickshire.—Having made several attempts to grow this plant without success, it may interest your readers to know how I have succeeded, this season, in obtaining a very fine show of bloom. In the first week in April (the best time for planting), I had given me two small tubers, which I broke into bits, about $\frac{3}{4}$ in. long, and laid them on silver sand, in a stove, for a few days. When I could see them forming eyes I had a border prepared for them in the following manner:—It was dug out one foot deep and one foot wide; two inches of crocks were placed in the bottom for drainage, and then I filled up with a mixture of peat, sand, and charcoal, making all solid by treading. I then planted each bit of tuber about two inches deep and surrounded them with a little silver sand; they soon began to grow, and, after that, they were never allowed to get thoroughly dry, and the result has been a beautiful display of this *Tropæolum* all the autumn.—FREDERICK PERKINS, Leamington.

Panicum variegatum as a Pyramid.—It may not be generally known that this can be grown as a pyramid; but it is quite possible to grow it in that way if desired. Plants for such a purpose should be struck from cuttings taken in spring, and inserted in a compost consisting of equal parts of leaf-mould, peat, loam, and sand, and plunged in a good bottom-heat. When struck, the strongest plants should be selected and potted in loam and leaf-mould, with the addition of a little peat and sand. In the centre of the pot should be inserted a stake, up which the leading shoot should be led. The side shoots should be pinched in a little, and as soon as the plants have begun to grow, each shoot should be trained up the stake in succession until it is found that the plant is large enough. The leading shoot should then be stopped, when it will throw out side shoots in abundance. Thus treated, an excellent pyramid will be the result, fit either for indoor decoration, or for other purposes. Plants 3 ft. through, and proportionately high, may be grown in this way.—T. W. S.

Pelargonium inopinatum.—In editing the new edition of Maund's "Botanic Garden," shortly to be published, on reaching the last page but one, I find a *Pelargonium* mentioned under the above title (certainly a specific name new to me) that, on an examination of the accompanying plate, somewhat startled me, by the close relationship which appeared to exist between it and the perfectly modern breed of *Pelargoniums*, of which we may take Captain Ruikes and Queen Victoria as typical representatives. On referring again to the letterpress, I find its popular title to be Willmore's Surprise, a name which, though familiar to my mind, does not appear to associate with it the special form of plant there figured. The description of its origin as a garden hybrid—"found by Mr. Willmore, of the American Nurseries, Birmingham, growing amongst a bed of Hollyhocks, where it had stood the winter," and supposed to be an accidental mule between those plants and some unknown *Pelargonium*—at once excited my curiosity; not for one moment that I imagined the probability, or even the possibility, of such a hybrid origin; but in the figure we have plainly and pronouncedly stamped all the peculiarities which belong to the new race of *Pelargoniums* to which I have just alluded. We have irregularity in the number of the petals, and also in their marginal outline; the sepals are irregular in shape, the two or three outer ones having a marked tendency to become foliaceous; and the stipules are also large, foliaceous, and deeply notched. These characters are all well represented in the figure, and they are the distinguishing characters of that now deservedly popular section of the *Pelargoniums* to which I have alluded. Has any of your readers this old species in cultivation at the present time? Or can any one favour us with the origin of this special section of the genus *Pelargonium*?—JAS. C. NIVEN, *Botanic Garden, Hull*.

Christmas Roses.—Mr. Ellacombe notes (see p. 512) that Christmas Roses in his neighbourhood are quite a month in advance of the usual time. Allow me to state that this is also the case on the Undercliff of the Isle of Wight. At St. Lawrence they are flowering freely and in great perfection this week.—H. W. H.

Hardiness of Omphalodes Luciliae.—I am able to inform your correspondent (see p. 547) that *Omphalodes Luciliae* is perfectly hardy, having grown it for many years fully exposed in a bleak situation on the Cotswold Hills. It is readily increased by cuttings or seeds.—JAS. ATKINS, *Painswick*.

CYANANTHUS INCANUS.

THIS lovely little plant will be found to form a pleasing addition to our list of choice rock plants, being dwarf and neat in habit. It differs considerably from the only other species of the genus in cultivation, viz., *C. lobatus*, which, too, ought to have a place in every select collection. If possible, *C. incanus* is more floriferous than *C. lobatus*, and, like that species, it should be planted in a dry, sunny, well-drained position, as if the situation be too damp, the fleshy root-stock is liable to rot. It is a good plan even to place something over the plant during the resting season. The flowers are not so large as those of the other species, but they are certainly more charming in colour, which is enhanced by the white tuft of sericeous hairs in the throat of the corolla. The plant from which the accompanying figure was taken, was raised from seed sent to Mr. Gower, at Messrs.

Cyananthus incanus.

Rolissons', of Tooting, from the higher hills of Sikkim. There are other still more beautiful species yet to be introduced from the Himalayas.

J. T. RICHES.

Barnard's Slow-combustion Stoves.—Messrs. Barnard, Bishop, & Barnard, well known for their manufactures of garden implements, trellises, &c., have lately been producing, at their Norwich works, a stove possessing very good qualities. It is claimed for it (1) That it is very slow in combustion, from the fact of its being constructed with a solid fire-brick bottom, which, with the back and sides (also of fire-brick), gives out considerable heat. (2) As the fire does not come in contact with the iron (with the exception of the front bars), no gaseous smells are emitted. (3) When used with a blower, they are a certain cure for a smoky chimney. (4) The prices are low, and the designs new and elegant. [We have tried these stoves, and find they deserve all that is claimed for them. From a horticultural point of view, they are not without importance, as the combustion is such that much less smoke is carried up the chimney than by the ordinary grate. The heat is thrown into the room effectively, and the look of the fire more cheerful than that of the ordinary grate.]

A Free Blooming Pomponé Chrysanthemum.—I have just cut down some plants of a Pomponé, called *Précocité*, that have been in bloom since July last. It has a very full, good flower, and although I have grown it some time, under the above name, it differs in many respects from another kind that is in cultivation under the same name. The flowers of my plant are almost as large as those of *Madie*, *Marthe*, and the same in shape. I have cut constantly from it during the past five months, and when I cut it down for the purpose of getting stock, it was still blooming merrily, and gave every promise of continuing its floriferous character much longer. I consider it a perfect gem, and decidedly distinct from the *Précocité* of some growers. While on this subject, I may allude to the bad condition of the nomenclature of the summer blooming Pomponés, which is mixed up in indescribable confusion, the *Golden Button* of some being the *Précocité* of others and *Hendersoni* of some one else, while we have *Dr. Bois Duval*, *Scarlet Gem*, and lastly *Little Bob* (sent out two or three years since) synonymous. Although I have many of the summer blooming sorts, I cannot recommend them all, some of them being

veritable rubbish, and totally unnecessary, considering the time of year at which they bloom, while others, such as the above-named *Précocité*, *Hanum*, *Madame Picoul*, and *Madame Eugénie Damage*, are perfect gems.—F. T. DAVIS, *Plumstead Common*.

FROM KEW.

LAST week we inadvertently stated that *Calliphurra Hartwegi* was the only known species of the genus. There is, however, another one, also from New Grenada. Last year Mr. Baker found that the plant, which had in many gardens passed as *Eucharis candida*, was not an *Eucharis* at all, but a *Calliphurra*, which he named *C. subdentata*. In the Palm-house, there is at present to be seen in flower a very beautiful new Bromeliad, from Brazil, *Bilbergia macrantha*. The broad, concave, glaucous, spinescent leaves are transversely marked with whitish bars, and overlap each other the greater part of their length, so as to form a sort of cylinder, from out of the top of which springs the gracefully-drooping inflorescence. The flowers are large, the outer perianth segments being bright pink, the inner ones glossy purple, and the anthers golden yellow; the large pink bracts in themselves are exceedingly showy. As a species, its nearest ally is *B. vittata*, but it is perfectly distinct from, and much superior to, that species.

A Cape Irid, *Moraea edulis*, has pretty blue flowers, the three sepals bearing a yellow blotch at their bases. This plant was introduced to this country towards the close of the last century, and is figured in one of the early numbers of the "Botanical Magazine"; it, however, seems to have been, until very recently, completely lost sight of. This may be seen in the cool end of the new range. *Thunbergia Harrisii* is a very splendid, free-flowering climber, from the jungles of Rangoon and Moulmein; it has large blue flowers, and is one of the most handsome of stove climbing plants. *Illicium anisatum* is in bloom in the cool compartment of the Economic-house. In many parts of the south and south-west of England this plant will succeed in the open air, if care be taken to choose sufficiently-sheltered spots. The pretty white flowers are exceedingly fragrant. In China and Japan this species is a small tree, attaining a height of about 20 ft.; it is cultivated in China, where its aromatic fruits are much used for seasoning, &c. In Japan, the tree is always planted near the temples, and garlands made of it are placed before their idols. A good deal of Star Anise is imported to Europe, and is much used for flavouring spirits in France, Germany, and Italy.

In the Orchid-house are some strong specimens, which will very soon be in bloom, of the largest-flowered of all Orchids, *Angraecum sesquipedale*. Thirty-five years after the existence of this "Prince of Orchids" was known, it was introduced to this country by the Madagascar missionary, traveller, and historian, the Rev. W. Ellis. He says that it appeared to grow most frequently where there was plenty of light and air, the roots often running down the side of the tree on which they grow 12 ft. or 18 ft. or more. It does not grow in the moist and thickly-wooded parts of the island, but generally on the straggling trees along the edges of the forest, or in parts where the trees are only thinly spread over the country. The very long-spurred, ivory-white flowers have an odour somewhat like that of the white garden Lily. *Laelia superbiens* has three long flowering stems. In 1839 Skinner discovered this in a Guatemalan village, planted by the Indians in front of their doors. In November of the following year he made an expedition in search of its true habitat, and found immense quantities of it in the gullies near the town of Comalapa, the finest specimens growing out of crevices in the rocks, and sheltered from the north winds. Some of them had pseudo-bulbs 22 in. long, and flowering stems 12 ft. long, bearing upwards of twenty flowers. The sepals and petals are lilac-purple; the waved and crisped lip is yellow, margined with deep purple, the lower half streaked with purple. A very handsome Mexican *Laelia* (*L. anceps*) will be in flower in a few days. Dr. Lindley says that this species is equal in beauty to any of the Cattleyas—that it has a far more graceful growth, in consequence of the length of its slender scaly stem, from the point of which the flowers swing—and that it diffuses an agreeable perfume. It has blooms of a bright rosy-purple colour.

A fine plant of *Luculia gratissima* may be seen in the greenhouse (No. 4); there can scarcely be a more beautiful object than a good specimen of this Nepalese tree covered with its large corymbs of rather fleshy, rose-coloured, and exceedingly fragrant flowers. The earliest-flowering, and one of the prettiest of the Australian Acacias, is *A. platyptera*, with its numberless globular heads of orange-yellow blossoms. There are about 450 species in the genus *Acacia*, of which nearly 300 are peculiar to the Australian Continent, and of these by far the greater number are phyllodineous species, that is, species in which the true leaves are suppressed and their places taken and functions performed by the highly-developed petioles or leaf-stalks. In *A. platyptera* the phyllode is not so highly developed, being some-

times reduced to a mere tooth of the winged expansions of the stem and branches. The rich scarlet flowers of *Brachysema lanceolata* (of which there is a good example in the Winter Garden) contrast admirably with the leaves, which are bright green on the upper and beautifully silky on the lower surface. This plant furnishes the cool conservatory with a colour rather difficult to find during the dull winter months. The ternately-compound leaves and the terminal panicles of white flowers of *Nandina domestica* are very pretty. Travellers state that it is to be found in nearly every Japanese garden. It will do outside in the south of England in tolerably sheltered nooks.

NOTES OF THE WEEK.

New and Rare Shrubs in Ireland.—*Hamamelis arborea* and *Azara Gillesi*, two very interesting shrubs, are now being sent out by Messrs. Rodger, McClelland, & Co., of the Warrenpoint Nursery, Newry, where a very rich collection of flowering shrubs is grown. They have also a stock of *Lambertia formosa*, a rare and beautiful rose-coloured flowering shrub, and *Podalyria* (two species) are likewise offered by the same firm. It is with great pleasure we notice so much intelligent energy in a provincial nursery. The supplemental list of hardy shrubs recently issued by Messrs. McClelland is well worth the attention of all interested in that direction.

Finely-flowered Lapagerias.—We have a note from Mr. Booth, gardener to Mr. Titus Salt, at Milner Field, concerning his *Lapagerias*. It may be remembered that they were so fine in 1875 that a woodcut representation, showing the profuse way in which they flowered, was given in *THE GARDEN* (see Vol. VIII., p. 294). The crop of flowers has been equally great this year. "I have cut," says Mr. Booth, "thirteen sprays this season, containing from twenty to thirty-five blooms on each spray, two and four at a joint, and on one spray there were fifty-seven good blooms, all open at one time, in a length of 31 in., nine blooms being at one joint." This was our variety which we have grown for years under the name of *rubra*, and which is by some called *rosea superba*.—FISHER, HOLMES, & Co., *Handsworth Nurseries, Sheffield*.

Poinsettia pulcherrima.—I have nearly 300 of this now in full bloom in 5-in. pots, the whorls of coloured leaves averaging from 12 in. to 16 in. in diameter, on stems from 6 in. to 14 in. in height, and well furnished with foliage. These plants are the produce of cuttings struck in July and August last.—R. NISBET, *Aswarby*.

Orchids and Palms in Winter.—By the arrangement of well-flowered plants of *Dendrobium nobile*, *Lady's-slippers*, *Calanthes*, *Odontoglossums*, and the beautiful *Saccolabium giganteum* amongst Palms, Ferns, and Grasses, a fine effect has been produced in one of the houses in the Holloway Nurseries. All the plants mentioned are of easy culture, and at this time of the year, when outdoor gardens are comparatively flowerless, such effects might with advantage be more commonly met with than they are. A specimen of *Cymbidium Masteri* in the same house is also finely in flower.

Aphelandra fascinator.—This new *Aphelandra* promises to be one of the most effective and useful stove plants which can be grown for flowering in winter. It has velvety green leaves, with broad, whitish veins, and its flowers, which are brilliant scarlet, are borne in large pyramidal trusses. Its wood is of a softer character than that of others of the genus, and on that account more bushy specimens are likely to be made of it. We saw it in flower the other day in Messrs. Rollissons' nursery at Tooting.

Griffinia hyacinthina.—Wherever *Amaryllids* are grown, this *Griffinia* should find a place. It flowers all through the duller months of the year, and has a colour possessed by few winter-blooming plants. Though an old plant, it is not nearly so often met with as it ought to be. Intermixed with *Crotons*, Ferns, and other fine-leaved plants, its large heads of waxy blue and white flowers have a striking effect. In a cut state, too, the flowers last for a considerable time in good condition. It is now finely in bloom in Mr. B. S. Williams' nursery at Holloway.

The Arnold Arboretum.—A tract of land at Jamaica Plain, Mass., of about 130 acres, is assigned by Harvard University to the Arnold Arboretum, of which Prof. Chas. S. Sargent is the able director. It being desirable to have the land laid out to the best possible advantage, and the income from Mr. Arnold's bequest not being equal to any extraordinary expenditure, Mr. Fred. Law Olmsted, so favourably known as a landscape architect, volunteered his services for the work, and a few of the wealthy gentlemen of Boston and vicinity have volunteered the few thousands needed to pay the surveyors and draughtsmen. Thus this important preliminary work will be accom-

plished without drawing upon the proper income of the fund, and in a manner so thorough that it cannot fail to be of the greatest value to the Arboretum—an Institution, to the development of which arboriculturists and lovers of trees, not only in America, but abroad, look with the liveliest interest.—"American Agriculturist."

We are pleased to announce that M. Alphonse Lavallée has been nominated Chevallier of the Legion of Honour by the President of the Republic. Few men have done so much for horticulture, and particularly towards enriching our collections of trees and shrubs.

Tree Planting at Woolwich.—Some thousands of young trees have been received at the Royal Arsenal, Woolwich, from the Botanic Gardens at Kew, and are being planted in rows by the sides of the avenues and workshops, and grouped in plantations wherever there are plots of ground available. In a few years the appearance of the Royal Arsenal will be much improved by these trees.

An Opportunity.—At a meeting of the Public Parks Committee of the Town Council of Edinburgh the other day, a remit from the Lord Provost's Committee as to a legacy bequeathed by the late Mrs. Ross, for the purpose of forming a rockwork in West Princes Street Gardens, was considered, the Committee recommending acceptance of the sum, and meantime instructing Mr. McLeod, superintendent of the gardens, to consider as to a suitable site and the cost, and report.

Geonoma princeps.—This is a handsome and distinct South American Palm of upright and compact habit of growth, having sturdy fronds and broad lance-shaped leaflets. When better known it will, no doubt, be largely used for general decorative purposes. It was awarded a first-class certificate, the other day, at South Kensington, where it was shown by Mr. Bull.

Impatiens Jerdoniæ.—This, though an old plant, is seldom met with. It might, however, be grown with advantage in pans or terracotta baskets for winter flowering. Its dwarf habit and bright scarlet and orange blossoms, when seen in masses, are very effective, especially when associated with light-coloured flowers. It was shown in good condition the other day at South Kensington.

Hæmanthus albo-maculatus.—This is a white-flowered species with yellow anthers, which, in addition to the beauty of its blossoms, has bright green leaves prettily spotted with white. It is now finely in flower in the Pine-apple Nursery, Edgware Road, where numbers of the better kinds of *Bouvardia* may also be seen in bloom.—J. F.

Indian Strawberry Naturalised in Cornwall.—We have received specimens of the Indian Strawberry (*Fragaria indica*), from the Hon. and Rev. J. T. Boscaawen, with a statement that this plant is abundantly naturalised near Penzance. Further particulars would be of interest; the plant is a native of Nepal, and has been cultivated in English gardens. It is a creeping plant, with wide-spreading, rooting runners, usually three-lobed hairy leaves, and axillary yellow flowers, which are surrounded by a large leafy calyx; these are succeeded by small, red, succulent, tasteless fruits. This Strawberry may be usefully employed on rockwork or in hanging baskets, and is also a good balcony creeper.

The Ghent Show for 1878.—We have received the schedule of the tenth quinquennial International Exhibition which is to be held in Ghent during the first week in April of the coming year. The programme of this Exhibition is very comprehensive. It is divided into three sections—namely, plants, for which 274 classes are provided; arboriculture and the culture of market plants and fruit; also arts and industries, making a total of 321 classes. The prizes consist of objects of art, gold, silver-gilt, and silver medals. The gold medals alone number 117. We can only notice a few of the chief prizes. A gold medal is given by the King for fifty *Azalea indica*, the Queen being the donor of a similar prize for twelve *Tree Ferns*. A gold medal, value five hundred francs, is provided by the federation of the Belgian horticultural societies for forty Palms, and an object of art of the same value is offered by the President of the Society, the Comte de Kerchove, for seventy-five plants in and out of flower, the contribution of the Comtesse de Kerchove being an object of art value three hundred francs for 150 *Hyacinths*. Gold medals of the value of 250 francs are offered by the members of the Council of Administration to nurserymen and amateurs for twenty *Orchids*, also for thirty *Draenas* and fifty *Rhododendrons*. We note also that the English Van Houtte Memorial Committee provide two prizes for Belgian exhibitors of six stove and greenhouse plants of distinct genera, in the form of objects of art of the respective value of 250 and 125 francs. Other medals are offered for horticultural buildings, trellises, and three are to be given for plans for laying out a garden of from three to five hectares (the hectare is about 2½ acres). This Exhibition promises to be without doubt the largest and best show ever yet held there.

TREES AND SHRUBS.

AVENUES.

It is desirable that every park and every town should possess some feature which may distinguish it from others, which, be an object for a walk or drive, and upon which the memory may dwell with affection in absence. There is no more certain way of effecting this than by a well-judged method of planting trees; and it will be found desirable, in order to concentrate the effect and to obtain character, that at certain places in the landscape and certain streets in the town, one particular tree should predominate. How

pleasantly our imagination is stirred by the mention of the Horse Chestnuts at Bushy Park, the Linden trees of Berlin, the Elms of Windsor, and the Oaks of Stoneleigh! Great beauty is obtained by the disposition of trees in an avenue, the essential character of which is that it should be composed of single species. In no way are trees displayed to better advantage; they gain character by their fellowship, and the attention is at once arrested by the uniformity, which, if it were not confined to certain limited parts of the ground, would become intolerable. The well-ordered ranks of stately Poplars, composing the avenue depicted in the woodcut, give a striking and unique effect to a flat and otherwise featureless piece of ground. Their grandeur and formality impose upon the imagination in a way which would be quite absent if the road were bordered by ordinary masses of mixed planting, or by isolated groups; but the effect to be produced by an avenue, such as this, should be strictly localised. The contrast should be sharply defined

between the formal lines of stately trees and the open park or gloomy, tangled wood. Another principle not to be lost sight of is that there should be an object—not necessarily visible—at either end of the avenue. Let it not be purposeless, or half the sentiment is lost. The serried lines should usher the visitor from the entrance gate to the mansion, or from the mansion to the garden; or, in a town, let the avenue lead

to the river, the cathedral, or the central square. Then the object of the formality will be obvious. SALMONICEPS.

CHINESE CYPRESS (GLYPTOSTROBUS SINENSIS).

In searching after materials for his work, the landscape gardener naturally and especially seeks peculiar and varied forms and colours. He thus acquires the ability to compose groupings and effects more and more artistic and attractive. One of the most peculiar forms and exquisite colourings within reach of his employment is that of the *Glyptostrobis sinensis*, sometimes called *pendulus*, a near relative of, and yet strangely unlike, our Southern Cypress (*Taxodium distichum*) the generic name of which it should properly bear. Unroll the curious thread-like leaves of the Chinese species, and you have the American form, and may even at times discover this unrolled form naturally produced on the *Glyptostrobis* itself, a clear case of reversion to a parent type. The Chinese Cypress has long, naked, deeply-penetrating, rather than wide-spreading, roots, and, as far as we know, none of the tendency of its American relative to develop knobs or knees from its larger roots. Whether it would not produce the same curious monstrosities, if grown to a great age in swampy bottoms, may be fairly questioned; as yet it has apparently never been so tried. The wood is extremely light, and the straight, shaft-like stem is enveloped with a delicate flaky bark of the softest brown, according finely with the dainty, aristocratic nature of the tree. Far up on the fine points of its naturally lofty stature, commence the smallest branches compatible with such a habit. These branches, surrounding the tree in graceful and symmetrical curves, cause the pyramidal form to manifest itself at once and remarkably. Indeed, its tendencies seem altogether aspiring. The branches erect themselves at an acute angle with the tree, and the very leaves extend upward along the branches until their slender sprays droop a little just at the tips, thereby es-

An Avenue of old Lombardy Poplars.

tablishing a certain claim to the term *pendulous* usually added to its other names. But the most remarkable portion of its appearance is the colour and construction of the foliage; presenting a light, soft green, like unto no other colour seen among trees, it pleases and rests the eye all the more because of the strongly-defined outline ever present. No feathery, shifting cloud of leaves, or fringed and tasseled shrub; it is simply a calm, beautiful tree, scarcely waving before the passing breeze, and yet elegant and graceful as the trembling Birch.

The construction of the leaves is curious, being rolled in on themselves until they seem like delicate cords, rather than feathers, which the leaves of the American Cypress suggest. It is difficult to explain why so beautiful a tree as that we have just described, does not meet with more general acceptance. Two reasons, however, may be offered, viz., difficulty of propagation, and difficulty of transplantation. The soft, peculiar wood does not readily unite with scion or bud under ordinary methods of propagation; layers cannot be made easily or in quantity, and seedlings will continue to sport and lose more or less the typical form, and assume that of the American Cypress. Transplanting is often rendered unsuccessful by the long, naked tap-root and light wood. Nurserymen would do much towards its wider employment by frequent root-pruning and transplanting to develop more abundantly the small fibres that the roots are somewhat chary of producing under careless treatment. Ill-founded notions respecting its hardness in particular regions may have also proved a bar to its wider distribution, and the late appearance of its foliage in spring, when people would naturally notice it in the nurseries, has not extended the circle of its acquaintance. The peculiar value which *Glyptostrobus* possesses for the landscape gardener lies, after all, in its very narrow, spire-like form. As a single specimen on the lawn, its effect is unique and striking; but in a group of different trees, where the artist desires to combine round and pointed forms for the most varied and picturesque effects, it becomes invaluable. The graceful variety of groups of deciduous trees is especially enhanced by its presence, because such trees are not often pyramidal or pointed. Let us hope that the growing appreciation throughout the country for choicer and more exquisite trees will bring this variety of Cypress into more general notice and employment.—SAMUEL PARSONS, in "Country Gentleman."

Tree Altitudes.—A comparison has lately been made by M. Goppert of the woody growths on the highest points of the earth's surface in various parts, reaching to 17,000 ft. above the sea. The results are these:—(1) Over the whole earth the *Coniferae* appear as the last trees, or those highest in position, represented by *Abietinae* in the northern hemisphere, and *Cupressinae* and *Taxinea* in the southern, e.g., in Chili. (2) As bushes, this great Natural Order plays the same role, *Abietinae* in the northern and *Cupressinae* in the southern hemisphere. (3) Along with them only the *Ericaceae* are to be placed, and they, indeed, far exceed them in space occupied, owing to the large associated growth of the individual species, such as *Rhododendrea* and *Baccinae* in the northern hemisphere, and *Thibaudia* and *Befaria* in the southern. (4) As a quite foreign element to the rest of the high Alpine flora, there occur in the South American Andes *Compositae* as trees and shrubs.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Moving Trees.—A very interesting operation in moving trees is being carried out at Gunnersbury—an old avenue of Oaks being removed, owing to alterations in the estate.

A Weeping Wellingtonia is offered by Messrs. Carter & Co., distinct from the normal form, graceful in appearance, and likely to prove of value for single specimens on lawns. In districts where the ordinary form thrives freely, this is worth a trial.

Robinia dubia.—This is said to be a hybrid between the common *Pseud-Acacia* and *P. viscosa*. It forms a good sized tree, having very short spines, and pale rose coloured flowers, this kind is frequently named *hybrida* *ambigua* and *echinata* in nursery catalogues.—G.

Black Alder.—What is usually known as the "Black Alder" is not related to the Alder family, but is a Holly with deciduous leaves—the *Ilex verticillata* of botanists, and was in former times classed with the genus *Prinos*. Beautiful as this shrub is, when in full bloom, during May and June, it is yet more attractive in autumn and early winter, covered with bright-red coral-like fruit. The flowers are arranged in dense clusters along the stems, and are pure white in colour.

The Eucalyptus Fire-proof.—The merits of this tree would seem, from some statements made at a meeting of the California Academy of Sciences, not to be confined to its absorptive properties, and its value in combating malaria. Eucalyptus shingles are said to be fire-proof. A tree of this species was exposed to the fire in San Francisco which occurred in 1876, and it is still in a flourishing condition. All varieties of the Eucalyptus are stated to be possessed of this valuable quality.—*Lancet*.

THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

(Continued from page 540).

China-Japan Region.

GENERAL DESCRIPTION.—This region, as has already been observed, is extremely rich in gay-flowered shrubs, and evergreen shrubs and trees of the *Euonymus*, *Camellia*, and *Arbor-vitæ* families. It is only the vegetation of the northern half, from about 30° N. lat. northward, and the higher mountains of the other part, that is hardy, even in the southern and western parts of the kingdom. In consequence of the dense population, and the necessity arising therefrom of cultivating all the available land, the really indigenous and wild plants are almost restricted to the mountains and remote parts. But both the Japanese and Chinese are skilful gardeners, and cultivate many of the numerous, useful, and beautiful vegetable productions of their respective countries. They have also raised numerous garden varieties of various plants, many of which have been imported into this country. It is chiefly during the last fifty years that the greater number of the species enumerated in the following lists have been introduced, though some few, and those chiefly quite familiar plants, were introduced much longer ago. Thus, *Kerria japonica* was, it is recorded, introduced in 1700; *Camellia japonica* in 1739; *Hydrangea Hortensia* in 1740; *Salisburia*

A Japanese Sedum (*S. spectabile*).

adiantifolia in 1754; *Chrysanthemum* in 1764; *Aucuba japonica* in 1783; and *Euonymus japonicus* in 1804. The mottled, laurel-like leaves of the variety of *Aucuba* originally imported must be known to everybody. This is a female variety, and until within the last few years no males were in this country; but now the seedling varieties are becoming as numerous as those of *Euonymus*. The latter is one of those plants that rarely fruit in England.

Garden Plants from the China-Japan Region.

Deciduous Shrubs or Trees with Showy Flowers.

Siberian Region.

The number of familiar species in cultivation from this region is not large, but the following list might easily be doubled. They are valuable on account of their extreme hardness.

<i>Clematis graveolens</i> (yellow-flowered)	<i>Caragana</i> (various species)	<i>Rhododendron chrysanthum</i>
<i>Pæonia tenuifolia</i>	<i>Pyrus prunifolia</i> , Siberian Crah	<i>Scutellaria macrantha</i>
<i>Lychnis fulgens</i>	<i>Pyrus haccata</i> "	<i>Statice elata</i>
<i>Halimodendron argenteum</i>		<i>Pinus Cembra</i>

LUXURIANCE OF HERBACEOUS VEGETATION IN EASTERN SIBERIA AND KAMTSCHATKA.—One of the most remarkable features of the vegetation of eastern temperate Asia, in latitudes where the winter is very severe, is the extraordinary size which many herbaceous plants attain. Some Umbellifers, such as species of *Heracleum* and *Angelica*, are especially conspicuous, growing to a height of 10 ft. to 15 ft., and sometimes even higher, forming annual forests of herbage perhaps unequalled in any other temperate region. Associated with these Umbellifers are Nettles, Reeds, Polygonums, and various species of the Aster and Campanula families, &c., all of unusual dimensions for herbaceous plants. Hemp is cultivated in Kamtschatka, where it is said to grow to an astonishing size.

W. B. HEMSLEY.

Cold Houses and their Uses.—I had erected here, two years ago, a long range of these useful structures. The first division is 65 ft. long, with Cherries planted on the back wall, and with a shelf about 2 ft. from the glass in front, which is full at all seasons. Just now—October 29—we have grand pots full of Mignonette and winter-flowering Carnations, pans of Watercress, with *Laurustinus*, all in full beauty, making at this dull season a walk in the Cherry-house quite spring-like and refreshing. These will be duly shifted to the conservatory, and their places filled with boxes, 4 ft. by 3½ ft., for early Peas, followed by Strawberries, Radishes, Mustard and Cress, &c. The next department is occupied by Figs on the back wall, and in this I have no stage just now. It is filled with standard Rosos in pots, which are particularly useful in May for bouquets for the London season. The third and last division has Peaches and Nectarines planted in front, and no place suits Camellias so well as the back wall, which I find furnished with plenty of blossom-buds; and, besides this, I winter therein Carnations, Forget-me-nots, Stocks, and a whole host of other things. My idea is simply this, that if success in hardy fruit culture be a desideratum, this plan should be adopted. In conclusion, I may add that for ladies, no more agreeable promenade could be desired whilst gentlemen are out shooting, than the cool, refreshing atmosphere of such a house, where they would be surrounded by the works of art and nature combined, and with a glass sky to protect them from the unruly elements.—R. GILBERT, *Burghley*, in "Florist."

THE FRUIT GARDEN.

APRICOT CULTURE.

Of all hardy trees I, in common with many others, look upon the Apricot as one of the most uncertain with which we have to deal; but, having been tolerably successful in its culture, a few jottings of my *modus operandi* may not be unacceptable to the readers of THE GARDEN. Many are the hours I have puzzled my brain to try and work out the solution of the mysterious dying off of the limbs, a disaster, unfortunately, too well known to all practitioners; and, though I have at various times had varying theories as to its cause, I feel obliged to admit that I am still somewhat in deep water on the subject; nevertheless, I half fancy the right theory has dawned on my mind. I have never been fortunate enough to have the privilege of growing Apricots under the shelter of glass, but I have for some years now been in the habit of visiting a garden where they are grown extensively in this way, and under such conditions at this particular place the sudden dying off of the branches is unknown, and yet the soil in which they are growing is, in every particular, like that in which ours are growing. Hence the following theory has been forced upon me—shelter does it all, ripens the wood, no frosts to injure unripe wood; constitution it cannot be, as many trees never lose a branch; soil it cannot be, as I have seen them do well in all kinds of soil. I therefore am inclined to believe that if thorough maturity of wood could always be insured the dying off of branches would soon become obsolete; at least, such is my present impression. Well, then, accepting this theory, all our aim should be, in commencing Apricot culture, so to arrange every detail as that perfect maturity of wood shall be guaranteed. We will therefore first refer to

ASPECT OR POSITION.—This ought to be south, south-west, or west; I prefer the first. Of course it is not usual, as Peaches always come in for that position; still, I have proved that Peaches do best on a west aspect and Apricots on a south one; there can, therefore, be no harm in the exchange. I have never yet seen Apricots worth the name grown without the shelter of a wall, and should therefore not recommend the attempt. The next requisites are

DRAINAGE AND SOIL.—Stagnancy is injurious to all fruits, but Apricots are peculiarly liable to injury from this cause; for, though in the growing season a free allowance of water is an indispensable requisite, if at any time the drains get choked, the trees are not long in showing it; and, on examination, it will be found that many of the roots are wholly decayed. In respect to soil, the Apricot is not an epicure, as it will do tolerably well in any soil, from sandy loam to stiff clay, *i.e.*, having regard to drainage; but the best Apricots I ever saw—largest, cleanest, and finest-flavoured—were grown in what is termed a calcareous loam, that is, a soil in which a goodly percentage of lime is present; and this, therefore, should be obtained, if possible; lacking this, lime, in some form or other, should be added to non-calcareous soils—say in the form of lime-scraper, old mortar, or chalk. Light or sandy soils should have a free allowance of chalk, and be made extra firm, to neutralise the effects of the rapid evaporation of moisture, which always takes place from such soils. Manure is not required, except on the poorest of poor soils, and preference should be given to applying it in the form of surface mulchings rather than as an ingredient to be mixed with the soil; whatever tends—as manure in the soil would—to increase a watery, robust growth, which will be difficult to ripen, should be avoided. The depth of soil need not exceed 2 ft., and should be kept sacred to the roots—no overcropping.

PLANTING.—First, as to season, be it remembered that Apricots are the first of our hardy fruits to be in flower; hence it follows that proportionate early root-action takes place; this would, therefore, naturally lead us to plant early in the autumn. October is not too early, as the trees have then time to get a start ere severe frosts set in. I have seen Apricots transplanted in February when in blossom, and yet they have done well; but, to say the least, it is unnatural, and ought never to be practised. The manner of planting is of no small moment in the after success of the trees, and cannot be too

GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS: HERBACEOUS VEGETATION IN SIBERIA.

carefully attended to, for if planted too deep—especially if the stems be buried deep in the soil—the tree will refuse to grow; and if, on the other hand, shallow planting be adopted, results will be equally unfavourable through injury from drought, &c. Wet weather for the operation should be avoided, as the soil is then clammy and cannot be worked in amongst the smaller rootlets.

TRAINING AND PRUNING.—Fan-shaped is the only system of training worthy of adoption with the Apricot, for the simple reason that a blank, through the sudden dying off of a branch, is soon filled up by regulating the tree or working in a new shoot. And here I would say, that I have not the slightest sympathy with that plumb and rule training that is occasionally practised. So long as the branches are all fully exposed to air and light, and do not intercept each other, what matters it if they are a quarter of an inch out of the exact angle? I speak feelingly, having had my fingers and toes all but frozen by trying to please a good old man, who in many respects, was an exemplary gardener; but in this particular apparently preferring a tree for its "pleasant look to the eye," rather than for its fruit. Disbudding is not nearly so much practised with Apricots as it should be. All foreright, outgrowing, and badly-placed shoots should be rubbed off at as early a stage of growth as possible, and others that remain, and which are not intended for new main-shoots, or for training in as lateral fruit-bearing shoots along the main stems, should be pinched at the second or third leaf, which will induce the formation of fruit spurs; this done, very little winter pruning will be requisite, other than the occasional removal of long spurs, or the cutting out of bare branches to be replaced by new shoots. In this manner the renewal of the wood of the trees should always be gradually going on, as the best fruit is produced on wood of from one to three years' growth. Should the trees grow excessively strong, and a check be necessary to make them fruitful, root pruning may be done by digging out a trench 4 ft. or 5 ft. from the wall, according to the strength and size of the trees, cutting clean off all long woody roots, and leaving all the smaller fibrous rootlets as intact as the operation will permit. September and October are the best months for root pruning. As with Peaches, Apricot buds frequently drop off just as they seem ready to open, the cause of which is just about as mysterious as the sudden collapse of the branches; but I am inclined to think that one great predisposing cause may be want of water during the growing season. They should, therefore, be abundantly supplied with water during the whole season of growth, and even after the fruit is gathered. Surface mulchings with stable litter, twice or thrice renewed during the summer, is a most excellent plan, and saves a large amount of watering, and acts as a manure at the same time.

INSECTS AND MILDEW.—Apricots are not difficult to manage in this respect; occasionally, however, green and black fly make their appearance, but a washing with Tobacco water soon settles them. A more formidable enemy is the small, greenish-yellow caterpillar, which curls together the leaves, and if not sought for and destroyed as soon as perceived, causes very great injury. Mildew is sometimes troublesome, and the best remedy for this is a good drenching of water, root and branch.

VARIETIES.—The best are Moorpark, Early Moorpark, Musch Musch, Kaisha, Large Red, Peach, and Hemskerk.
W. W. H.

PRUNING FRUIT TREES.

AUTUMN or early winter is the best and most convenient time for pruning most hardy fruit trees. There is usually at the fall of the leaves more leisure to give the necessary thought and time to the work. Every season brings its work, and when the pruning is put off or delayed it is often hurried over and ill done. When pruning is performed in autumn, there is time for the wounds to at least partially dry and heal, before severe frost sets in. I need hardly say that pruning should not be done during severe frost. It is now pretty well understood that at no season are the roots altogether inactive; although

in autumn and winter the demand made upon them may be less, because the circulation is more languid, yet the movement of sap to all parts of the tree must even then be going on; and this brings me to another argument in favour of autumn pruning. If we assume that a constant circulation of sap is going on from the roots to the branches and buds, and we reduce their number, we must add to the strength and vigour of those that remain. The knife must be sharp so that the cuts may be clean and short. Unskilful or thoughtless pruners often make long ragged wounds which not only look unworkmanlike, but expose a large lacerated surface to the drying influence of the air. If in cutting off or thinning out branches a saw has to be used, it should be a thin narrow-bladed one. All branches should be cut off close to the limbs from which they spring, and the surface of the wound should be cut smooth with the knife. A little tar or pitch rubbed over the wound will keep the air and rain from it, and encourage the formation of new bark. Overcrowding branches in fruit trees is just as great an evil as overcrowding plants in the garden or field, and it has just the same debilitating, pernicious effects. At the same time it is obvious that the definition of the term overcrowding must be left in a great measure to be dealt with by the common sense of individual cultivators. The whole economy of the tree depends greatly upon the regular healthy action of its leaves or lungs; and if they be densely crowded—hid away, as it were, from the sun and air—their action must be damaged and restricted, and the whole system of the tree put out of order. Of course, this does not happen all at once; it goes on for years, the leaves and fruit gradually decreasing in size in proportion as the head of the tree becomes thick, until, at last, neither is produced, except at the extremities of the branches, where they are fully exposed to light. Anybody who has had to do with neglected orchards, must know that such trees are common enough, and must have at times experienced a difficulty as to the best mode of treating them in order to restore them to health and fruitfulness. There is a great dissimilarity in the growth of fruit trees of any given kind; some require but little pruning, but all are benefited by having the branches properly regulated and thinned to admit air and sunshine, so that the trees may have their crop or load of fruit hung regularly all over their branches, and not merely swinging in clusters at the ends, where half, or sometimes more, are blown down, or so bruised by the wind as to be useless for keeping.

In pruning neglected trees, there is always a danger of doing too much at once. If we thin out a neglected wood or plantation of timber trees too severely, we let in the wind, and the cold air chills and stunts the growth, and the thinning may do harm; but if we thin gradually, removing at first a few of the useless trees, gradually letting in more light and air, the trees gather strength, and are soon able to appreciate the freedom of breathing, and the bracing currents to which they had long been strangers stimulate and invigorate both roots and branches. In like manner, in dealing with neglected fruit trees, we must proceed cautiously. All shoots that cross or rub against each other should be cut out, and all young, sucker-like shoots, that often spring from the main branches of old trees, should be cut off or wrenched off close to the stem, to prevent others growing from their base. There are many weighty reasons why fruit trees of all kinds should be regularly pruned. If this were done, the little regulation that would be required would give the trees no check. Whenever an ill-formed branch is crossing, or in the way of a better one, it should be removed at once before it becomes large. In a cold spring, a thick, overcrowded tree, where the blossoms are mostly at the ends of the branches, has not the same chance of furnishing even a partial crop as when the flowers are more equally distributed. A thickly-branched tree, from the absence of light and air, and the confined atmosphere which such crowding generates, encourages the formation of Moss and Lichens, which not only form a hiding-place for insects, but militate against the bark performing its natural functions.

Wall and other trained trees are often too much crowded with growth; not only are the main branches trained too closely, but the spurs are too numerous; the leaves, from being too crowded, lose substance, and, as a matter of course,

the buds which they nourish at their base partake of the like weakly character. When a tree from any cause becomes starved or stunted, the sap vessels in the inner bark lose their elasticity and become shrunk, if I may so term it, and if something be not done to afford relief, the tree will gradually perish of inanition. Hundreds of trees die in this manner long before old age is reached. In such cases heading down, or a severe thinning and shortening, will infuse new vigour into them, and with the new growth will come new life and new powers of production. But at the same time the cause of unthriftiness should be sought for and removed. It may be unsuitable soil, overcropping, or the exhausting effects of insect attacks, and the latter often follow in the wake of the former, and are generally found in combination with them.

E. HOBDAV.

THE VICTORIA AND OTHER GOOD NECTARINES.

We doubt if there be any variety of the Nectarine that approaches the Victoria as regards its cropping qualities, or if it be surpassed for flavour and general excellence; but for a vigorous habit and fertility it is a perfect wonder, and this is not only our own opinion, but the opinion of everyone that we are acquainted with who has grown it. The Peach and Nectarine have never been cultivated extensively in this country for the market, probably because crops are rather uncertain, whether produced under glass or out-of-doors; but we have little doubt that, with Nectarines like the Victoria, the market gardener might calculate with certainty on heavy crops; and everyone knows that good Peaches and Nectarines fetch very high prices, and fair crops realise great profits. The Victoria Nectarine is worth a house or wall to itself. We planted a maiden tree eleven years ago, and it has never missed a crop from the first; and then they are such crops! and the fruit is large and fine—like ordinary sized Peaches, in fact, in the general run. Our tree has been cropped at the rate of about one fruit to every 6 in. of space every year, and it finishes all splendidly, and makes a strong growth the while. We could get about 1s. a fruit in a provincial town, or perhaps more, from the fruiterer's, and anyone can calculate what that would come to in a 30 ft. long house containing some 500 square ft. of training surface, which is the size of a division here, one-half of which is filled with the Victoria. It is doubtful if we have any three or four trees of other sorts that together equal it for a crop year after year; and if we had a range of Peach houses to plant now, we should plant four of the Victoria to one of any other varieties. The flavour is first-rate, and the fruit remarkably juicy and delicious, even when forced early, as our tree has been all its life—and that, as every cultivator well knows, does not promote either health or fruitfulness in a Peach or Nectarine tree. It is true, as had been stated regarding it, that the fruit ripens green on the shady side, and the side next the sun is always dark red; but if the fruit be laid on a tray in the Peach house for a couple of days or so after it is gathered, it will turn a bright yellow colour; and then not a handsomer Nectarine can be placed on the dessert table. It will keep longer, too, than most Nectarines in the fruit room. It is worth a house to itself in any garden, and we propose devoting one to it at the earliest opportunity. We hardly think it is particular as regards soil, for we have nowhere heard of it failing to give satisfaction; and we have no hesitation in recommending Peach growers to plant it exclusively, feeling sure it will give them every satisfaction. One thing we would advise, and that is to give the shoots room in training—4 in. or 5 in. apart at least. When you come to tie in the shoots this will appear rather thin; but this is of no consequence, considering that one can have as many fruit on a shoot as he pleases. We noticed five and six fruit on some of last year's shoots on our tree this summer, and all were good fruit. As has been said before, the tree is a strong grower, and the foliage is large and needs room in order to secure the maturation of the wood; and, this effected, a crop is safe if the trees are ordinarily well managed otherwise. As regards other sorts, one of the least common is the Balgowan, which is an old but excellent sort, and worthy of a place in any collection. Like the Victoria, it is a very vigorous grower, and produces very large fruit, but it is not so prolific. Putting aside some of the newer kinds, which we cannot say much about at present, the next best are Elruge, Violet Hative, Downton, Newington, Pitmaston Orange, and Hunt's Tawny. In buying Nectarine or Peach trees, it may not be unnecessary to say that those with good clean unions should be selected, and great care should be taken to see that they are quite free from gumming, and it is equally necessary to see that they are true to name. Mostly all respectable nurserymen are very particular on this point, and all profess to be, but gross mistakes are frequently made. Of a quantity of trees which we once bought from a respectable firm, several were wrongly named; and the mistake had not been made

through any resemblance of the kinds to each other, for late varieties were substituted for early ones, and *vice versa*.—"Field."

GRAPE-GROWING ON BACK WALLS.

THE following particulars respecting the growth of Grapes on the back wall of a Vinery may not be without interest. I have used the word Vinery, but the house was built for forcing Strawberries; it was therefore necessary to so arrange the Vines that they did not in any way interfere with that crop. The rafters are 14 ft. long, and the back wall 10 ft. high inside. As originally arranged, there was a front stage 4 ft. in width, and another occupying the back portion of the house, some 2½ ft. in height. Vines were planted along the back, and were allowed to bear from the stage upwards. The front Vines were stopped about halfway up the house; there were consequently about 7 ft. of roof and the same amount of back wall covered with bearing wood, which would be about equal to the whole amount of roof-space. The advantages gained were these—the back Vines could not in any way affect the Strawberry plants, and the front ones, not being brought in until April, did not also materially affect them. Those on the back wall were naturally somewhat earlier than those on the roof, and they ripened both fruit and wood perfectly down to the lowest portion of the wall covered by them. It will thus be seen that a crop of Grapes was secured without damaging the crop to which the house was especially devoted, and which, as may be easily understood, could not have been effected by the ordinary way of planting. Plenty of light was admitted to allow of the growth of plants in the summer-time, in proof of which, some Tomatoes and Chilies, grown in pots, ripened off perfectly. I am, therefore, inclined to believe that this method of Vine-growing would prove satisfactory to many. This arrangement was carried out for several seasons with good results; but, owing to its being found necessary to remodel the interior arrangements of the house, Vine culture therein was ultimately abandoned. One or two little incidents connected therewith may be worth mentioning. A stage was erected which covered the greater portion of the wall; it was therefore naturally concluded that the Vines would not succeed in the partial obscurity to which they were now subjected. Nevertheless, it so happened that only a portion of them were taken up; the remainder were merely cut down to the ground. These latter made during the summer such strong growth that they were allowed to remain, and, to my surprise, the following spring they grew vigorously and produced a fair crop of fruit. The shelves of the stage were 1 ft. apart, and were filled with plants until the Grapes were set and swelling. The laterals, too, were stopped at one leaf beyond the bunch, thus leaving it fully exposed to the hot sun during the ripening period; but scarcely a berry was injured. The best bunches, indeed, were those which were nearest the glass, and were not in any way shaded by foliage. I may add that I did not perceive any difference of quality in those grown upon the wall and those upon the roof; the former, however, required a considerable amount of water in hot weather; there would therefore be a little extra amount of labour to take into account, which would, however, be more than compensated for by the working space gained in the house during the summer months. Let it be understood that I am not giving an instance of extra good Grape culture, as the Vines were made to play a subordinate part in the house, and were not allowed to thoroughly establish themselves. Had they remained and received fair play, I have every reason to believe that very good Grapes would have been produced.

J. CORNHILL.

Dyflcet.

Spots on Pears.—M. Prilleux has communicated to the French Academy some observations on the black spots sometimes found on Pears, and which are known to Paris cultivators as *tavelures*. He has noticed that cracks in the fruit usually originate in these spots. All varieties are not equally subject to them; Doyenné d'Hiver suffers most frequently and most severely. Wet seasons favour the appearance of these spots, and standards generally suffer more than wall trees, and those with a south-west or western more than others with an eastern aspect. Some trees are affected year after year, while others similarly circumstanced escape altogether. The spots he finds to be produced by a small fungus, named *Cladosporium dendriticum*, which was first noticed on Apple trees. The filamentary spores take root in and penetrate the superficial tissues, swell at the extremities, and divide into small cells, which again divide, forming a mass of minute blackish cells (as may be seen by lifting the epidermis of a leaf thus affected), spreading their epiphyseous filaments in all directions. The effects are different on different parts of the plants. On a leaf the part affected blackens and dies, but the rest of the leaf

remains. On the bark crevices and nodes are formed, which, however, are not generally conspicuous. On the fruit it is different. The superficial growth is partially checked by the presence of the parasite, whilst that of the minor parts continues; consequently, unless relieved by early excision, the fruit becomes deformed, the dead parts distend, and the exterior cracks, exposing the sound portions within. The existence, sometimes unnoticed, of the fungus on the bark of particular individuals explains its re-appearance year after year on their fruit, although it may not be found on their neighbours. The peculiarity may be communicated by grafting.

EXPERIMENTS IN MAKING VINE BORDERS.

IN April last (see p. 251) I gave, in *THE GARDEN*, an account of some experiments which I was then making regarding the formation of Vine borders. The result is now before me in the shape of a photograph of a bunch of Black Hamburgh Grapes that weighed 5½ lbs. I have also had several other bunches of the same kind heavier, but not so well shaped. These were grown on a border consisting wholly of leaves and manure. It was predicted that Grapes, produced under such conditions, would not be either well-coloured, or of good flavour; but on taking berries from Vines in another house, and mixing them with those just alluded to, I can detect no difference. The Vines in the manure border bore a heavy crop, and finished it satisfactorily, and they were allowed to break of their own accord, which they did regularly and well. The wood is clean and well ripened, and the foliage perfectly healthy, though showing here and there a few warts, which usually occur in the case of Vines grown in ordinary soil. The percentage of large berries was greater on this border than on an ordinary soil one, most of the Vines producing one or two extra large berries, one of which contained seven seeds, and weighed 2 oz. It resembled a Tomato in shape, and was by far the largest berry that ever came under my notice. I hope that none of the readers of *THE GARDEN* will think that I prefer a manure border to one of the ordinary type, but the experiment in question goes a long way to prove that manure should play an important part in the formation of Vine borders, and that the produce is easily and readily influenced by the hand of the cultivator. Were I to attempt such an experiment at any other time, which is not at all unlikely (keeping away from natural soil) there are several ingredients, such as soot, ashes, and lime, that might be used with advantage, as I find worms in the cow-manure and leaf-border to be a great nuisance.

J. HUNTER.

Lambton.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Czar Plum.—I planted this variety in 1876 against a wall having an east aspect, and trained it single cordon fashion. It carried a full crop the first season, and it was the only one out of forty-five varieties that bore a full crop this season. This most excellent Plum was raised by the late Mr. Rivers, of Sawbridgeworth, from Prince Engelbert fertilized by Early Rivers, and it first fruited in 1874.—*RICHARD NISBET, Aswarby Park.*

Spring Ribston Pippin, dessert	May
Rymer, kitchen	December

Melon Wine.—A French millionaire has invented a new dessert. He takes a Water Melon, red to the rind, pours it into a bottle of champagne, and then has it chilled over night. [So we see by an extract from a paper, but the practise is a very common one in Italy, where red wine is used, and the Melon suspended by a cord into a well to make it as cold as possible.]

Cherry Apples.—A very curious vegetable freak is recorded in the "Independence Belge," of an Apple tree in a garden at Bilancourt. It is as follows:—The stock of the tree is Cherry, on which has been grafted the Apple, a species of Golden Pippin. The fruit precisely resembles Cherries—the same stem, the same form, and nearly the same colour; but its taste is that of an Apple, and it contains pips instead of stones. [We give the above for what it is worth.]

PLATE CIV.

TWO NEW ANNUALS

ESCHSCHOLTZIA MANDARIN (E. CALIFORNICA VAR.)
AND SWEET PEA VIOLET QUEEN.

Drawn by Mas. DUFFIELD.

THESE two beautiful annuals, which are drawn on the same plate by Mrs. Duffield, were shown during the past season by Messrs. Carter & Co., of Holborn. The *Eschscholtzia* was selected from the older strains of the well known old *E. californica* (which has long held a prominent place among the glories of our annual borders) by Mr. Robert Gardiner, foreman in the St. Osyth Seed Grounds. Its splendid orange-crimson colour makes it quite distinct from the old species or any of its varieties, which are often distinguished by European botanists and horticulturists by specific names but which the American botanists—best acquainted with them in a wild state—consider forms of *E. californica*. It is on the outside of the petals that the colour is most remarkable, though their inner sides are also richer in tone than the old form. The buds in particular are very deeply coloured; but, in all stages, the colour is wonderfully brilliant and lustrous. It is said to come true from seed. It is, of course, a plant of easy culture.

The Sweet Pea, Violet Queen, is a distinct and pretty addition to the varieties of the Sweet Pea. Of course it may be depended on to come true from seed, which, in its case, has the peculiarity of being quite distinct from that of the other kinds. While on this subject, we may add that the various beautiful varieties of the Sweet Pea are undeservedly neglected in gardens. Even as generally badly-grown from spring-sown plants, the Sweet Pea is the Queen of annual flowers; but when one thinks of the many charming ways in which the varieties, singly or mixed, may be used to adorn the garden, one cannot but wish that good cultivators would pay more attention than they do to Sweet Peas, their graceful arrangement and improved culture.

The Cape Gooseberry.—Permit me to supplement the remarks on this subject with a few cultural details. It is now something more than 20 years since I first grew the Cape Gooseberry, trained on the back wall of a late Vinery; and, although it fruited fairly well in such a position, yet it well repays for more warmth and light. It may be raised from seeds sown in heat, early in the year (but plants from cuttings are best), something after the way in which Tomatoes are raised. The young plants should be grown on and planted out in a warm sunny spot, about the end of May, and the crop will be in proportion to the strength of the plant when put out and the attention which they receive afterwards. In the open air, in our climate, the plants are annuals, and must be raised every year, like Tomatoes, or Capsicums, but under glass they will live and bear freely for years. Although young plants bear the finest fruit, very good crops may be grown in pots trained up to stakes, or, better still, place the pots on the front or back shelves, in any warm house, and train the shoots to wires near the glass. They will do well planted out in a border under glass, and trained to a trellis like Cucumbers; in such positions they make rapid growth and bear abundance of fruit pretty well all the year round. Mr. Speed, at Chatsworth, grows them in a span-roof house trained in this way. They require more ventilation and less atmospheric moisture than Cucumbers, and may be grown successfully in a much lower temperature. In this respect, they are, indeed, very accommodating; so long as frost does not reach them, they may be wintered successfully in a low temperature, if kept fairly dry at the root. Turfy loam, enriched with leaf-mould or old manure, and a sprinkling of charcoal, to ensure porosity, will grow them satisfactorily. When well grown, the fruits are as large as good sized Cherries, and are greenish yellow with an agreeable acid flavour.—*E. HOBDAY.*

Insect Borers (*Tomias callographus*).—Among bark borers that assist in the destruction of the Pine, should be noted this species, which we passed over in the notice of that class of insects which we gave in our earlier volumes. It may be distinguished by its shiny, pitchy black thorax and head, and reddish elytra furnished with three short teeth at the retuse termination of its posterior extremity. Its main burrows are generally distributed in fours or fives, and radiating from a centre—as if four or five females had commenced their operations all from nearly the same spot—as shown in the annexed woodcut. It extends over the North of Europe to Scandinavia and the Ural Mountains, and occurs in Britain near London as well as elsewhere.—*A. M.*

ESCHSCHOLTZIA "MANDARIN" (E. CALIFORNICA, VAR. "SWEET PEA VIOLET QUEEN").

THE FLOWER GARDEN.

WINTER PROTECTIONS.

SINCE the memorable winter of 1860-61, there has been no autumn up to the present time in which outdoor plants generally have been in a condition so ill calculated to withstand a severe frost as they are now. Everything is as soft as a continued moist, mild atmosphere, and a saturated condition of the soil, can make it. We have abundant evidence that, under such conditions, not only do all plants that are in any way liable to sustain injury from an exceptionally low temperature suffer, but also that many that are generally looked upon as able to stand our winters unscathed, sometimes succumb. The exceptionally low temperature that occurred seventeen years ago not only killed or greatly injured immense numbers of some Coniferous trees that had been introduced during the first half of the century, but also such things as Hollies, Bays, and Roses, with a host of other trees and shrubs, at the same time when many plants much more tender, that had received a little protection, passed safely through the ordeal. Evergreen shrubs that had been moved early—during the latter part of August, in September, and up to the middle of October—escaped completely, whilst others that had not been touched suffered severely, showing that the check which they received by removal had induced a hardier condition in both wood and foliage. Alterations which I was making necessitated the removal of some standard Roses at the above time, with all their leaves fresh and green upon them; these received no injury, whilst those that were not interfered with were nearly all killed—scarcely a plant escaping. Such portion of

Insect Borers (*Tomiscus challographus*).

evergreen shrubs as we could not move before the latter part of November were much injured, the reduction of temperature in both soil and atmosphere, with insufficient time intervening between the removal and the frost occurring, did not admit of any root development to sustain them; at the same time the ground was covered with a thick coat of snow that prevented the frost penetrating to a depth that affected the roots. Such plants as *Tritomas* and *Lobelia cardinalis*, that were well mulched, the tops of the former being tied up and surrounded by straw and Fern, and the crowns of the latter covered with 6 in. of old tan, were quite safe; they were grown in light sandy soil in a dry situation, circumstances which no doubt still further tended to assist them. The Pampas Grass was also safe with the leaves tied up close, like a truss of straw, to a height of 4 ft., the ends above this being doubled back and tied in with the lower portion. Round this was placed about 3 in. of clean Wheat straw, putting it on quite straight, like a well thatched roof, and securing it with tar twine passed round the whole in several places, and fastened to three tall Dahlia stakes stuck firmly into the ground; the lower part of the thatch covering was left so as to extend well over the roots for a foot or so all round from the collar of the plants, and under this were placed 3 in. or 4 in. of old tan. Even where there is a number of plants to protect, the work is soon done. This protection I

subsequently always used. It requires some years, under the most favourable conditions, to grow large and effective plants of this most beautiful Grass. When destroyed, it takes an equal time to replace it; and as it is not sufficiently hardy to be safe, even in places where it may go unscathed for years it is the height of folly to risk it for the comparatively little trouble involved in protecting it. It would be well at present to protect, as far as possible, everything of a doubtful character, so far as such protection can be carried; and, for this purpose, wherever Fern and Furze (Gorse) are obtainable, there is nothing better or less objectionable in appearance. Especial provision should be made for Tea Roses; a few pieces of Gorse or Fern tied round the heads of standards or bushes on the commencement of frost, first drawing the shoots of the bushes together, and fastening them loosely with a thin Willow or piece of twine, may be the means of securing an acceptable harvest of flowers from these tender Roses; and what holds good of the above is equally applicable to others. T. B.

MODERN FLOWER GARDENING.

UPON no subject are opinions so conflicting as upon that of flower garden embellishment. Truly there is a variety of tastes to satisfy, and it is well that there should be, for we are too much the slaves of fashion. Imitation has of late years prevailed to such an extent that our gardens are mere repetitions one of the other. The bedding system, though attractive, has been sadly overdone—so much so that acres of verdant lawn have been frittered away to give place to geometric patterns for the display of formal plants that exist but for a comparatively

brief season, leaving their places unoccupied for the greater part of the year. It should be remembered that mere quantity and sameness cannot produce pleasing effects unrelieved by a judicious grouping of hardy evergreens of the best types. In short, the amount of bedding plants now generally employed should be greatly reduced, and thus not only would the whole aspect of our flower gardens be improved, but the labour and expense attending their decoration would be considerably mitigated. We must not, however, run into an opposite extreme in this direction; some say away with all architectural embellishments, down with steps, balustrades, vases, and fountains; they are not in accordance with nature; we must have, in place of these, a garden more in accordance with nature. In my opinion, every residence of any importance requires architectural embellishment combined with terraces, balustrades, fountains, and vases. These, with appropriate surroundings, harmonise well with bedding plants, and form a pleasing link between nature and art. True we have terraces so constructed as to baffle all attempts to plant them successfully, and there is also often an inclination to destroy individuality by crowding all kinds of plants into a given design, when a far more satisfactory effect might have been produced by introducing distinct features. We have plenty of material at our disposal for skilful embellishment; indeed, never were our resources so rich.

By the introduction of sub-tropical plants into our arrangements, we have not only produced more pleasing effects, but a way has been opened up for a freer use of good hardy permanent plants.

Carpet bedding has been unmercifully censured for its frivolity, and for the ill-judged contrasts of colours and lavish consumption of plants which it requires. Notwithstanding this, however, it has become established, and will doubtless, in time, be improved. Better combinations of colours are being made, and numbers of hardy plants are being substituted for tender ones, thus giving greater permanency to the system. Plants of stately port have also been introduced into it, so as to break up its monotony and over-formality. This style of planting is successfully carried out in our public parks, and it certainly has its admirers. The chief objection to carpet gardening is its cost, which, it must be admitted, is great where tender plants only are used, such as *Alternantheras*, *Mesembryanthemums*, &c.; but, where hardy plants are employed, it need not necessarily be expensive, and very pleasing combinations may be made with them, and simplicity of design, too, will be found to give most satisfaction.

It is said that by our present system of massing and blending colours in highly-dressed parterres, old-fashioned English flowers have been banished from our gardens; and that, to some extent, is true; but, as a re-awakening interest is being taken in their culture, suitable spots in which to grow them will doubtless be found. Whilst isolation and singleness of effect characterised the old style of arrangement, variety and harmony of the whole, judiciously blended, is what we now aim at; and in this comprehensive system certain types of herbaceous plants become useful, as, for instance, the white variety of *Anemone japonica*, which has the advantage of an ample leafage added to showy blossoms; and there are many others amongst hardy perennials equally suitable; but they require judicious selection, as it is necessary they should have lasting properties as well as fine bloom. Besides, this class of plants give most satisfaction when permanently grouped and established; therefore, the best plan is to plant them in the more picturesque portions of the garden, where they will yield far more pleasure and gratification at all seasons than they possibly could do in more formal arrangements. I willingly take Nature as my guide in garden decoration; but it is quite possible to follow Nature too closely in some of our arrangements. It is not wise to mix different styles of gardening too much together. The most suitable place for herbaceous plants is the wild garden, where they can be arranged in a natural manner, and where their individual beauty can be fully brought out.

It may be said that old-fashioned gardens in the natural style were more enjoyable than our modern ones; and that in a certain sense may be true, but it should be remembered that there was not the abundance of plants suitable for flower gardening that we have now. Neither was much attention paid to grouping or blending of plants. Mixed shrubberies, and the more formal herbaceous arrangements, constituted the main features of embellishment. Young cultivators in those days were not taxed in reference to the blending and grouping of classes of plants as now, and in working out artistic patterns in which to arrange them. It was a special point in the tuition of young men, and mark of merit, that they were well versed in the names of herbaceous plants, which were all arranged in a formal manner, with their names attached, and planted in order of height, as precisely as the soldier upon parade. I remember when I could have run over a whole collection botanically as glibly as possible; and there is a fund of interest attached to the cultivation of hardy perennial plants which I hope to see again come into fashion. And now that bedding out is more fully understood, and the various aspects of the more fashionable styles brought into due proportions, there will be found more time to study the more permanent features of interest. GEO. WESTLAND.

Witley Court.

Anemone Robinsoniana.—I can endorse all that the Rev. Harpur Crewe has said (see p. 545) about this *Anemone*. Five or six years ago I found acres of it in Kent, in an undulating meadow sloping to the south-east. I have carefully kept the knowledge of

its locality to myself, or the London plant collectors would most certainly have dug up every root, although they might be counted by hundreds of thousands. So thickly do they grow in some places, indeed, that the earth is carpeted with their elegant foliage, and plentifully studded with their heaven-hued flowers; close by runs a babbling brook fringed with *Chrysosplenium alternifolium*, and here and there in this charming meadow are large patches of the finest *Orchis mascula* I ever saw.—W. ELLIOTT, *Stapleford, Notts.*

Eulalia japonica variegata.—I notice that this fine plant has been recently alluded to in *THE GARDEN*. I imagine that its full beauty is not yet known in Europe. We obtained some of the original plants of it from Japan, and planted about 120 of them in a row in the spring of 1876. It was very fine last year, but this year it is magnificent, having thousands of flower-stems, which have been the admiration of all visitors since the end of September. The plant itself is very ornamental during the summer months, being of intermediate growth between the old ribbon Grass and *Arundo Donax variegata*; but the flower-stems, which average from 6 ft. to 7 ft. in height, complete its beauty. When the dry north-west winds of winter commence to blow, the plumes to some extent show their character, taking the form of ostrich feathers; but this, in the damp climate of England, would not be seen. If, however, the stems be cut and placed in a warm, dry room, they assume this character in a very short time, and form one of the most beautiful room decorations I have ever seen. This plant is perfectly hardy. Here it has been exposed to a temperature 10° below zero; and it is not particular as to soil. It increases freely by division, and large plants may be made of it in a short time. One of your correspondents thought that it would not reproduce itself from seed; this I consider probable, but every shoot will make a plant, so that seed is not required. The more recently-introduced kind, called *Zabrina*, appears to be only a variety of the above, the flower-stems being identical with *E. j. variegata*; but the plant is very distinct, and quite a novelty as regards variegation. It is, I think, the first variegated plant, having the white across the leaf. I have noticed a Rush with the same peculiarity, but this is also a Japanese plant introduced about the same time, and it will also prove a good addition to hardy aquatic plants, for it appears to grow as freely as any hardy bog weed.—JAMES TAPLIN, *South Amboy, New Jersey.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Aster grandiflorus.—Mr. Elliott sends us, from Stapleford Hall, specimens of this *Aster*, which he describes as the best Michaelmas Daisy in the gardens there. It is often pretty even in December in southern gardens, but we did not think it would flower so well in Nottinghamshire. This plant, being so late a bloomer, would probably repay for growth in pots and slight protection.

Hardy Plants Unseasonably in Bloom.—I have to-day (Dec. 8) gathered here (North Hants) the following flowers, viz., Violets—Czar, Victoria Regina, the double Neapolitan; a handful of the common Primrose, growing in the woods; good blooms of the white-flowered *Menziesia*, *Lithospermum prostratum*, and many kinds of *Violas* and *Pansies* are in bloom, especially the varieties Blue Bell, Perfection, Mulberry, and Princess Teck. Snowdrops are ready to burst from the foliage, and Daffodils are 2 in. above the ground. Altogether, the present promises to be the most unseasonable season I have ever known. The rainfall for November was 60.13 in.—quite unprecedented in this part of the country.—W. W. H.

—Primroses and Violets are flowering abundantly here. The Virginian Stock, after dying down this autumn, has grown up again, and is now in flower for the second time, and Roses (of several good sorts, including Tea-scented ones) are blooming freely in the open garden. I have cut a constant succession of Rose blooms nearly every day until now, and more are budding.—H. W. H., *Wolverton, St. Lawrence, Isle of Wight.*

Lobelia illicifolia as a Hanging Plant.—This *Lobelia* makes one of the prettiest hanging plants with which I am acquainted. During the summer it is covered with lively white starry flowers, and in winter it is smothered with purple berries. It is easily propagated, and is half hardy, but a cool greenhouse seems to suit it best. I am surprised that this plant is not more generally grown than it is.—W. ELLIOTT.

Geranium molle aureum.—I had this plant years ago, but lost it; I have, however, re-discovered it in its old locality, Old Charlton, Kent. It will make a good groundwork for purple *Crocus*, or it may be put to many other uses in the spring flower garden. In spring it is a clear canary yellow, and altogether the brightest golden hardy plant with which I am acquainted.—W. E.

Single China Rose.—The single form of the common China Rose is a most beautiful plant—far more so I think than the double form—and ought to be in every garden. It has claims before even such fine kinds as *Rosa rugosa* and *Rosa pyrenaica*. It may be easily propagated by means of cuttings, and it will flower when but a few inches high. It is, I believe, as yet rare, even in collections in which such plants might be expected to be found.—W. ELLIOTT, *Stapleford Hall, Notts.*

ORCHIDS.

ORCHIDS FOR GENERAL CULTURE.

EVERYONE has not facilities for growing Orchids as a collection, and some are deterred from attempting their culture by the idea that they are very difficult to grow. To a certain extent this is true. Most species require special treatment, and a good deal more attention than can be afforded in gardens where the labour is limited; but there are a few Orchids, nevertheless, about the culture of which there is nothing very difficult, and which might be advantageously included in any ordinary collection of stove plants. Some of these are old, and some new; but we will only mention a few that are good growers, free flowerers, and worth cultivating. The first on the list is the old *Phajus grandifolius*, otherwise known as *Bletia Tankervillei*, and which is a free-growing and vigorous subject, and very ornamental when it throws its magnificent spikes of flower up in the spring. It succeeds well in the ordinary stove, and needs but little attention. When the plants need re-potting, it should be done after they have done flowering, and just when they begin to grow. It delights in good strong turfy loam and peat, or leaf mould, together with sand and plenty of lumpy charcoal and good drainage; in other respects it may be treated like any ordinary stove plant—neither kept too wet nor too dry, either in summer or winter, and during the growing season it should have occasional waterings of liquid manure.

CALANTHE VESTITA.—This, though belonging to a different class, is not unlike the first named in miniature, and requires similar treatment. It is a very pretty Orchid, and popular even among Orchid growers. Healthy bulbs, potted two or three together in 6 in. and 7 in. pots, make nice little specimens. Light turfy loam and peat, with charcoal, form a good compost for it. The bulbs should not be buried in potting, but placed pretty firmly in the soil, and room left for watering. The finest lot of plants of this kind that we have seen were firmly potted in what appeared to be almost pure loam, pressed as firmly about the roots as we would a Strawberry plant. In summer the plants require moderate shade from strong sunshine, and in winter water should be sparingly given, but not entirely withheld.

CELOGYNE CRISTATA.—This is one of the best Orchids for general culture; in fact, it should be grown in batches like the Chinese Primrose or the Cyclamen, and no doubt would be if it was as easily procured. It grows freely in the stove or intermediate house, and produces its lovely white flowers in great profusion. It may be grown in a basket or pot, or on a block; but the pot is most convenient. Good drainage, fibry peat, Sphagnum, and lump charcoal are essentials, and these should be raised in a firm mound above the rim of the pot, and the plant pegged down upon it. Small plants will make good specimens in a short time, being easily divided, and small plants may soon be propagated when it is desirable to increase the stock.

DENDROBIUM NOBILE AND ITS VARIETIES.—These still rank amongst our finest Orchids, whether regarded for the beauty of the flowers or the profusion in which they are produced. Very easy to cultivate, and succeeds best in fibry peat and loam, Sphagnum, and charcoal, packed pretty firmly together about the roots, and raised in a mound above the rim of the pot in the usual way. Plenty of drainage is necessary. Spring is the time to repot, after the plants are out of flower. As a rule, the strongest shoots spring from the base of the old stems; but sometimes they break away from the tops also, and elsewhere. The best plan in any case is to peg all growths down to the soil, and encourage them to root into it. An ordinary stove treatment, and plenty of water during the summer, will easily produce a fine growth by October, when water should be almost withheld; and, unless the plants are wanted in flower early, they may be transferred to a cooler house during the season of rest, but not starved or exposed to cold and damp. A friend of ours, who grows large specimens for the room vases, transfers them to his cool Vineries in autumn. In potting, as we should have mentioned, care must be taken to avoid burying the base of the stems; leave all but the roots clear and above the surface of the soil.

DENDROBIUM FARMERI AND *DENSIFLORUM* are two fine species, that succeed in the stove or intermediate house, and which, according to our experience, continue to grow and flower under very adverse circumstances. We have known plants that had remained in the same pots for years, and been long subjected to a low temperature during the winter and spring, that hardly ever failed to flower annually. They, however, repay genuine culture, and require the same treatment as *D. nobile*, except that they are better left in their summer quarters during the winter. None of the three are troubled much with insects or disease.

ODONTOGLOSSUM CIRRHOSUM.—This comparatively new species is described as one of the most lovely Orchids we possess, and we think it deserves the compliment; but what gives it most value is that it is a free grower, and prefers an intermediate house, or even a warm greenhouse, to the stove. It would perhaps be better wintered at least in the last-named structure, after its bulbs are perfected, otherwise they seem inclined to make a second growth if left in heat. Its free growth is remarkable. A number of very small imported pieces, which we received last autumn, made rapid growth as soon as potted in the spring, and have made fine glossy bulbs, some of which are throwing up flower spikes. Living Sphagnum chiefly, and bits of peat mixed, seem to be all that it requires in the way of compost. The plant delights in plenty of moisture at the root during summer, and should not be dried off altogether in winter, but the soil should be kept sufficiently moist to keep the Sphagnum alive. The leaves are not nearly so sensitive to damp as the *O. vexillarium*. It is, in short, an uncommonly hardy intermediate-house plant, of easy culture, and should be in every collection of flowering plants.

CYPRIPEDIUM INSIGNE, *INSIGNE MAULEI*, *BARBATUM*, *VENUSTUM*, AND *NIVEUM*.—All these, except the last, are robust-growing kinds, easily kept in health; and their flowers, which are abundantly produced, are very ornamental and useful for cutting. The old *insigne* is an exceedingly free grower and flowerer, and *Maulei* is a very superior variety of it. They all grow freely in fibry loam, peat, sand, and charcoal, and should be potted tolerably firm, and well watered while they are growing. To attempt growing them in the usual Orchid compost, consisting of Sphagnum and poor peat, is simply to half-starve them. The pretty little *C. niveum* is a slow rather than a weak grower, and requires the same treatment as the others. Those named are perhaps as cheap and as easily procurable as any; but there are a number of excellent varieties, both new and old, which are equally good growers. Among some of the fine kinds may be named—*Dayanum*, *Argus*, *Domini*, *Sedeni*, *Fairieanum*, *lævigatum*, *Roezli*, *Pearcei*, *Lowi*, and *villosum*.

GOODYERA DISCOLOR.—This is an ornamental foliage and free-flowering plant, allied to the *Anætochilus* class, but far less difficult to grow. When grown for its foliage alone, it should not be allowed to flower; but the flowers contrast effectively with the dark velvety foliage when they are produced. It should have the warm end of the stove, and be near to the glass, but shaded during the summer. As the shoots soon spread out over the surface, it is best grown in a flat, shallow pan, well drained, and filled with Sphagnum, peat, sand, charcoal, and broken potsherds. Young plants may be assisted by a bell-glass at first, and, as they grow, the shoots should be pegged down over the surface of the pot.

AERIDES ODORATUM.—Though the *Vandæ* section are usually supposed to need special treatment, particularly as regards temperature, the plant above named is frequently seen in perfect health in a warm corner of the stove. It will live in cooler quarters for years without suffering much injury, but will not grow much, and rarely flower. We once kept a plant about 1 ft. high in a stove where the temperature was only moderately high during summer, and rather low in winter, for six years, during which time it hardly lost a leaf, but made scarcely any growth. The leaves shrivelled a little, but when the plant was transferred to a moist warm place near the boiler end of a house, the leaves got plump and the plant grew rapidly. There are three or four varieties of *odoratum*, any of which are well worth growing. Plants should be grown in pots half filled with drainage, and potted in fibry peat, charcoal, and Sphagnum, and raised well above the surface of the pot. To save the long air roots, which are thrown out from the stem, from injury, the plant should be placed out of danger from contact with any object. It delights in an almost steaming atmosphere during the summer, but should be kept pretty dry in the winter time. In a mixed collection of stove plants the *Vandas* should occupy a shelf above the hot-water pipes if possible; and if the shelf can be covered with Sphagnum, kept moist, it will insure a sufficiently moist atmosphere about the plants during their growing season.

ZYGOPETALUM MACKAYI AND *CRINITUM*.—Both of these are free-growing plants and sure bloomers, and succeed in fibry loam, peat, Sphagnum, and charcoal. The pots should be well drained, and in potting the plants must be set pretty well up above the rim of the pot, and the compost packed neatly and firmly up to the base of the bulbs to keep them erect. Stove heat and plenty of water at the root during the growing season will suit them, but moisture must be nearly withheld during the winter.

MILTONIA SPECTABILIS AND ITS VARIETIES.—*M. spectabilis* is a beautiful and popular plant, of easy culture. It succeeds in the same compost as the above, but without the loam, and is best grown in a shallow pan. It does not require a very high temperature, and should be shaded from strong sunshine, which turns the foliage

yellow. We have seen a good specimen growing in a Vinery under the Vines, where it stood for some time after the fire heat was withdrawn, and was green as Grass, and healthy, and flowered well.

LYCASTE SKINNERI.—This is another of those popular Orchids which is recommended for general culture. There are numerous varieties of it, all of which are more or less attractive. It requires ordinary stove treatment, and a compost of Sphagnum, peat, and charcoal to grow in, and good drainage. Should be grown extensively.

LELIA PURPURATA.—A magnificent Orchid, and one not very difficult to grow; it thrives in the same kind of compost as the *Lycaste*, and requires much the same treatment in other respects.

Here ends our list. No doubt it might be added to; but we have chosen to enumerate only a few of the easiest cultivated and really useful species, and such as might be added to any mixed collection of stove or intermediate-house plants. When anything like a collection is attempted, and a house cannot be set apart for them, the best plan is to devote a shelf of the stove to them alone, in order that their wants may be more conveniently attended to, putting such as require most heat at the warmest end, and *vice versa*. As regards moisture and shading, &c., what will suit the generality of stove plants will suit the Orchids as well; but, as far as practicable, the latter should have the special treatment they require as regards watering and potting.

S. J.

Phalænopsis amabilis.—I have a plant of this that has been in bloom over three months, and which has now on it thirty-eight expanded blossoms. We have a row of this Orchid in baskets hanging in front of a moist stove, and, although all the plants are by no means in full beauty, I counted the other day on them 140 fully expanded flowers. The long and graceful sprays of blossom, drooping over Ferns and fine-foliaged plants, mingled with spikes of *Calanthe* and that beautifully-scented old favourite, *Zygopetalum Mackayi*, have a lovely effect. Seen under such conditions, Orchids show to greater advantage even than in houses exclusively devoted to their growth, as their great want is foliage, which, in a wild state, they borrow from the trees on which they grow. I may mention that nearly all our plants of this beautiful Orchid vary in size and markings, some having flowers nearly as large again as those of others, while the clear white top petals are in some quite pointed, and in others nearly circular. A general impression exists that these plants flower themselves to death; but, up to the present time, our plants have annually increased in size of foliage and strength of flower-spikes, although they are nearly always in bloom. No one need doubt their ability to grow them successfully if they have a moist stove temperature at command. We make our own baskets, which consist of rough-barked wood, filled with fresh Sphagnum, crocks, and charcoal, with a few lumps of fibry peat; and plenty of tepid water is given at the root at all seasons. They may be grown in pots, but I find that those in baskets are invariably the most vigorous.—J. GROOM, *Henham*.

Greenhouse Stages.—A mode of constructing these which I saw the other day in the Aigburth Nurseries, Liverpool, may be worth notice. The house in which they are erected is span-roofed, some 16 ft. or 18 ft. wide, and is used for Pelargoniums and *Cinerarias*. A pathway runs all round it about 2 ft. 6 in. or 3 ft. from the sides, which leaves a stage of that width all round the house, and a stage some 6 ft. or 7 ft. wide in the middle. The framework of these stages is made of angle iron bolted together, and supported on low, cast-iron standards let into brickwork. On this framework are laid 1½ in. battens, reaching from side to side, fitting up flush at the ends against the iron, but not touching each other by about an inch or so. So far as I could see, no nails or screws were required. The whole had a neat, strong, light appearance, and I should think such stages would be almost indestructible if kept painted. Another departure from the old form of such stages is the arranging of the paths at the end in an easy curve, thus doing away with all friction at the corners, and saving much valuable time, where a great deal of traffic is going on, without loss of space.—E. HOBDAY.

Pilumna fragrans.—One of the best varieties of this lovely Orchid which we have seen is now in flower in Mr. Bull's Nursery, at Chelsea. Its blossoms, which are beautifully fringed, are of the purest white, set off to advantage by a bright golden eye. The perfume of this Orchid is peculiarly refreshing, somewhat resembling a delicately scented Clove-Pink.

Cypripedium macranthum.—A large consignment of this Lady's-slipper, a coloured plate of which was given in *THE GARDEN*, p. 30, Vol. XI., has lately been received by Mr. Williams, of Holloway. Though hitherto scarce, this, the most beautiful of the genus, is therefore now likely to become popular in our gardens.—S.

THE INDOOR GARDEN.

A FEW GOOD ECHINOCACTI.

Echinocactus Cummingi.—This is one of the hardiest of the genus, and its flowers, which are orange-yellow, rank amongst the brightest of that colour, and they are produced in abundance. The plant is small in stature, flowering at the height of 2 in., and rarely exceeding 8 in. The spines are pale brown, and

Echinocactus Cummingi.

when young the plant may be easily mistaken for a *Mammillaria*. I regard it as one of the best of *Echinocacti*.

E. multiflorus.—This is at times confounded by cultivators with *E. oursellianus*; but it is distinct. It has white, reflexed spines. The flowers are pure white, and very beautiful in shape. It is a dwarf plant, seldom attaining more than from 4 in. to 5 in. in height. It is also nearly hardy, and therefore not fond of a close place.

E. myriostigma.—This, without doubt, is one of the most singular plants in cultivation, having more the appearance of the work of a

Echinocactus multiflorus.

sculptor than a natural production. It is covered with white scales of a stellate form, and is almost as hard as a stone. It produces silky yellow flowers freely in summer. It generally has five ribs, but not always, some having only four; while, on the other hand, others have as many as seven. It is a free grower, but slow, attaining 1 ft. in about twenty years. It does very well in a cool greenhouse; those who have seen this plant once will never forget it. It is sometimes called *Astrophytum*.

E. hexædrophorus.—This might be mistaken when young for a *Mammillaria*, but its flowers prove it to be an *Echinocactus*; the whole

plant has a pulverulent aspect. It is a slow grower, which, after the lapse of five or six years, may have attained some 4 in. in height, and, after that, it scarcely shows any change. I have known plants of it in twelve years to only grow 2 in., though doing well and flowering freely. Its flowers are pale rose, spines grey and depressed. Seedling varieties from this kind have been called *Laboureti* and *Saltitella*. When grafted, it grows faster than on its own roots.

12 in. to 20 in. *E. sinnatus* greatly resembles it; it has weaker spines, but is doubtless a variety.

E. obvallatus.—This belongs to a section which has undulated ribs, some more so than others, but all sufficiently marked to be recognised. Its spines are flat, dark, from 1 in. to 2 in. long, and in sets of from six to eight. The flowers of this section are small, and often unable to open on account of the spines being in such a dense

Echinocactus hexædrophorus.

Echinocactus longihamatus.

Echinocactus myriostigma.

Echinocactus obvallatus.

E. longihamatus.—This is a plant quite capable of taking care of itself in the struggle for life. It is one of the most distinct and important of the family to which it belongs. It has a central, hooked, dark brown spine, from 6 in. to 10 in. long. The flowers are straw-yellow. Small plants of it have the mammoose appearance of *Mammillarias*; but when old, the ribs become more pronounced. It is a slow-growing kind, attaining a height of from

mass in the centre. Plants belonging to this section, when raised from seed, vary greatly. I am therefore of opinion that the several varieties found here and there in cultivation are only seedlings. They have a curious habit of splitting if overfed, by which they are often spoilt. They should therefore be watered with care. *Echinocacti* are easily grown. The chief care required is in watering them.

Sudbury House, Hammersmith.

J. CROUCHER.

CHRYSANTHEMUMS AT LIVERPOOL.

CULTIVATORS about Liverpool have long been celebrated for their Chrysanthemums, and it would certainly be difficult to find finer blooms than those which I saw when visiting in that neighbourhood at the end of November. Mr. Tunnington, gardener to Charles MacIvor, Esq., Calderstone, obtained a first prize for cut blooms at the late Liverpool meeting, as well as for standard plants in pots. His collection consisted of plants mostly in 9-in. and 11-in. pots; those in the former size were trained to a single stem, the others had several branches. Both growth and foliage were very robust, the latter almost as broad as one's hand, and of a remarkably deep green colour. Disbudding had been carried out, so that only one bloom remained on each shoot. In growing first-class specimens, it is important to disbud at the right time, and also to select the right bud, for there is usually one that will make a more perfect bloom than the others, and it is not always the terminal one. To secure a first prize, where the competition is keen, it is not only necessary to have good flowers from which to choose, but much judgment and skill are required in selecting and making up a stand. Mr. Tunnington's plants all through the summer stand in a very snug corner, exposed to full sunshine and air, and yet sheltered from the fierce winds that sometimes prevail in this neighbourhood. They were potted in very rough turfy loam and manure, the last shift, especially, had been rich and turfy. In the later stages of growth, liquid manure is also freely given, not always, indeed, of one kind, as Mr. Tunnington believes in giving plants a change of food occasionally, and so varies their liquid diet, sometimes giving guano, at others, liquid manure made with soot or sheep droppings. It is only by the attention given to this and other small matters that excellence is reached. The four standard plants, shown by Mr. Tunnington, were remarkable examples of patient skill in cultivation and training; the kinds were Mrs. G. Rundle and George Glenny. I saw another remarkable collection of Chrysanthemums at Elmswood; and Mr. Hinds, gardener to Sir Thomas E. Moss, at Otterspool, had also a choice collection, tastefully and effectively arranged in the conservatory adjoining the mansion. In the majority of country gardens fairly good flowers, tastefully disposed, are more in request than extra superior culture. The following is a list of the very best varieties of the large exhibition varieties; Pom-pone and Anemone-flowered kinds are not so much grown in the north, although, for home decoration, they are very beautiful, and some of the Japanese varieties are absolutely indispensable, especially for cut flowers. The best kinds were Hercules, Mr. Gladstone, Prince Alfred, Princess of Wales, Prince of Wales, Beethoven, Mrs. Henle, Queen of England, Lady Sinclair, Alfred Salter, Cherub, Isabella Bott, Eve, Beauty of Stoke, General Slade, General Bainbrigge, Oeslan, Blonde Beauty, White and Pink Venus, Nil Desperandum, Empress Eugenie, Jardin des Plantes, Lady Hardinge, Guernsey Nugget, Hero of Stoke Newington, Princess Beatrice.—E. HOBDAV.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Croton falcatus.—This is one of the best Crotons that has lately been sent out. It has lance-shaped leaves from 18 in. to 2 ft. long, elegantly marked with bright crimson, purple, orange, and many shades of green. For table decoration it must eventually become one of the most valuable of plants. It was raised in the Victoria Nurseries, Holloway.—S.

Pteris Dixonii.—This is a pretty, dwarf, crested form of the well-known *Pteris serrulata*. For growing in pans or small pots it is a very desirable kind, and its broad crested pinnae render its fronds useful as edgings for vases of flowers.

Tropaeolum Ball of Fire.—This is one of the best plants that can be grown in a warm greenhouse at this season of the year for furnishing a bright display of colour, and for supplying flowers of a striking character for small bouquets. It is best planted at the base of rafters or pillars in good sandy loam. If exposed to plenty of light and air and well treated, established plants of it will bloom for months in succession. It is also an excellent pot plant.—S.

Improved Hyacinth Glasses.—The new Hyacinth Glasses, recently introduced to public notice by Messrs. Stevens and Williams, Brierly Hill, Staffordshire, are now manufactured in a variety of colours. The design and the mode of supporting the stem are improvements. The uncoloured ones are useful for placing flowers in when not in use for Hyacinths.

The Display of Chrysanthemums in the nurseries of Messrs. Jackson & Son, at Kingston-on-Thames, has this year been very attractive. The whole of the plants have been grown in a natural manner, and are arranged to form a bank extending the whole length of the show-house of the nursery. The Japanese kinds have been particularly fine.

An Old Fern.—M. de Saporta has recently called attention to a fossil found in Middle Silurian rocks at Angers, which represents the oldest known land plant. It indicates a large Fern, allied to *Cyclopteris*, which is preserved in iron sulphate.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

DURING such an autumn as the present, with continuous moist, mild weather, it becomes a necessity to adapt the treatment of plants in greenhouses to the season; the protracted genial temperature that we had through October kept many plants in a growing state later than usual, and, as is well understood by experienced cultivators, plants that make growth thus late are more difficult to deal with through the winter than in seasons when the weather has been such as to induce a gradual hardening up and ripening of the wood before winter sets in. Everything that is at all susceptible of attacks from mildew is more than usually liable to be affected by it during the present autumn; Heaths especially, both hard and soft wooded, and all the softer-leaved Cape and New Holland plants, will require frequent looking over, with the view of detecting any appearance of the fungus as soon as it exists. It is most fatal in its effects upon the leaves, as, where once it gets established, it quickly destroys their vitality, be they old or young, causing them to fall off prematurely, which no after treatment can rectify; not only are plants, when so affected, very much impaired in appearance, but serious injury is done by the roots suffering through the loss of foliage. The presence of mildew is frequently not observed by those who have had comparatively little experience in plant culture until it has done considerable harm; on close examination, plants that are affected by it will exhibit a slight discolouration of the leaves, not over the whole plant, or even any particular branch, but sometimes at the points, or often lower down, and more particularly on the smaller internal shoots towards the centre, that through the growing season have been less fully exposed to the solidifying influence of light and air, but where, if not at once checked, it quickly extends to the strongest and more important shoots. As soon as it is discovered, the plants should be at once laid down on their sides and syringed freely with clean water, so as to wet the entire surface of all the leaves, and whilst the foliage is in this damp condition, the whole should be dusted over with flowers of sulphur. Many contrivances for applying it have been brought under notice, but I have found nothing so handy and effectual as the old-fashioned sulphur-puff; as a substitute a small gauze-bag may be employed, using the material of which it is made double if it be found that the sulphur passes too quickly through it singly. The sulphur should reach every leaf of the affected plants, as the mildew will often have extended much further than can be traced with the naked eye; keep the plants still laid down whilst the sulphur is being applied, turning them over as required to get at every part. In this position less of the powder will get to the soil on the surface of the pots than it otherwise would do, and where, if allowed to remain, it might do considerable injury by being washed down to the roots in the operation of watering; its presence there would have an effect similar to that of lime, a substance which is so injurious to the generality of evergreen plants. To prevent any chance of the sulphur thus reaching the roots, it is well, before raising the plants to their proper position, to wash the surface of the ball with a spouted can or the syringe. Replace the plants on the stages as soon as they have got quite dry, allowing the sulphur to remain on for a week or so, during which time, should the weather be windy, do not give much side air, or it will blow the sulphur on to the surface of the balls; after leaving it on for the length of time just named, the destruction of the fungus will be complete, and the plants should be again laid down on their sides and syringed freely with clean water, so as to wash the whole of the sulphur off. Another remedy for the destruction of mildew is to mix flowers of sulphur with water at the rate of from four to six ounces to the gallon, allowing it to stand for a few days, during which it should be stirred up several times, then pour the water gently off. This can easily be accomplished, as the sulphur, being heavy, will settle to the bottom; with the water thus impregnated, syringe all affected plants, wetting both upper and under surfaces of the whole of the leaves, laying the plants down over a tub, or trough, in a way that will catch the water, and allowing them to remain in this position until quite dry, as the water in which the active properties of the sulphur are held in solution must not be allowed to reach the roots. Amateurs will find either of these certain remedies for mildew on all plants that are affected, pot-Roses included.

Pelargoniums.—Both the large-flowered and Fancy varieties should now be kept in a temperature of not lower than 40° in the night, nor above 5° higher than this; and, where there is a small house or pit that can be devoted to these and other things that do the best where a little more warmth is kept up than in an ordinary greenhouse, where nothing more is attempted than merely to exclude frost, when there is an appearance of cold nights, a little fire-heat should be turned on.

Primulas, so useful at this season, are much less liable to damp when kept as warm, or even a little warmer, than *Pelargoniums*; the reason these plants are so subject to lose their lower leaves, which rot off near the base of the stalk, a complaint that often extends to the main stem, causing the destruction of the plants altogether, is that the usual cool greenhouse treatment through the winter, when their vital energies, consequent upon this being their flowering season, should be actively at work, is not sufficient to keep them in a healthy condition. In all cases they should be kept as near the light as it is possible to place them, with the atmosphere as dry as it can be maintained. Where there is sufficient warmth, as above indicated, to keep them growing, as is their wont, light is essential to prevent the flower-stems being drawn up weak; and where, by necessity, they are kept cooler than they like, an abundance of light will reduce the disposition to damp.

Cinerarias, sown first in the spring, as advised for coming into flower early, will be much benefited by a temperature such as above, but no higher, as any attempt at forcing with them is detrimental to their well being; in their case they will be better for standing on some moisture-holding material, which will keep their leaves in a healthier condition than if stood on dry shelves; when necessitated to place them in the latter position, I have found it an advantage to lay *Sphagnum* about 1 in. thick on the surface of the shelves, damping it slightly from time to time. There are few greenhouse plants that bloom naturally, or can be induced to do so without anything approaching to absolute forcing, but are much better kept at a temperature such as the above, a little higher than that of an ordinary greenhouse; but where a single house has to do duty for all, including plants it is desirable to keep quite at rest, there is no alternative but to make a compromise betwixt the requirements of both, although a little may be effected by placing the whole of the plants that are in the most active condition at the warmest end, keeping the others at the opposite end, at which point the greater portion of the air required can be given, which will still further tend to make a difference.

Camellias.—See that those of which the flower-buds are in an advanced state have the soil kept moderately moist, as, although not requiring to be so wet as when the summer's growth was progressing, still they will never bear being as dry as some things. When *Camellias* are stood in a conservatory attached to a dwelling, where there is usually a little fire-heat kept on, with the atmosphere proportionately drier, care must be taken to apply some water to the floor, especially in the immediate neighbourhood of the pipes, to correct the drying influence of the latter. Where there is the convenience of a small house or pit, where a temperature of 55° can be kept up in the night, this will be found most useful for bringing many things on into flower, such as *Genistas*, *Acacias armata* and *Drummondii*, *Azaleas*, both the ordinary garden hybrids and the hardy purple-flowered *amcena*; *Richardias* and winter-blooming *Epaerises* will also bear, for a few weeks, such a temperature; and scarlet *Pelargoniums* that have been prepared through the summer by exposure to the full sun out-of-doors, and confining their roots in small pots, so as to bring about that somewhat stunted condition which, with this class of plants, is essential to the production of flowers, rather than leaf-growth, when subjected to heat. If the soil in which the roots of such *Pelargoniums* are placed has become poor and exhausted, a little weak liquid manure will be an advantage. Here again, with all such plants, endeavour to get them as near the roof glass as circumstances will permit of; at no time in the year is this so necessary as in the winter, with plants that are under the influence of a temperature that accelerates their flowering. *Hyacinths*, *Tulips*, *Crocuses*, *Narcissus*, and *Lily of the Valley* will do well in such a house, although the progress they make in flowering will not be near so rapid as where under the influence of a higher temperature; consequently where these plants, especially the *Lily of the Valley*, are wanted in flower by a given time, they must be started considerably sooner than if more heat can be given them.

Bulbs of all kinds that were potted early and plunged in ashes, with a covering of the same material overhead, will by this time have made considerable growth; they must not be allowed to remain in such a position so long as to cause the foliage to become drawn out too much. Some of the ashes may be drawn away where enough top growth has already been made, plunged in the open air under a wall as is frequently done, when the crowns have advanced far enough and the bulbs are not wanted for immediate forcing, they may be removed to a cold frame or pit, where protection from frost can be given; or to a greenhouse or Vinery; but, in all cases, the exposure of the young leaves now in course of development must be gradual, for if they be subjected to full light whilst in the blanched state, caused by the covering they have been under, the leaves will be so far crippled as to prevent their making further healthy progress.

Shrubs for Forcing.—Any shrubs, such as *Rhododendrons*, *Ghost Azaleas*, *Andromedas*, *Kalmias*, *Dentzias*, *Prunus*, *Gnelder Roses*, or others of similar description, should at once be taken up and potted, for, should severe weather set in, there may be some difficulty in getting the work done. Do not use larger pots than is necessary to admit the roots with a little soil; on the other hand, there ought not to be any unnecessary mutilation by reducing the size of the balls, so as to compress them into pots not sufficiently large to hold them, as all reduction of root-power that takes place is not only calculated to lessen their flowering capabilities, but renders them less able to recover their strength when again planted out after forcing. The soil they are put in may consist of old potting material, or, this failing, such as has been used in frames for Cucumbers or Melons; but, in any case, it should be moderately dry, for if taken from out-of-doors in its present saturated state, it is not fit to place the roots of even the commonest plant in.

Potatoes.—Late varieties, in common with the earlier kinds, are much more affected with the disease than in ordinary seasons, and even where care was taken at the time of lifting to pick out all that were perceptibly diseased, I find that some still keep decaying, and probably will do so up to the end of the year. I have found a little newly-slacked lime dusted over them, scattering it in handfuls as the stock is being again looked over, to be one of the best preventives against the disease spreading, for where any that are diseased lay in contact with others in the store, it very quickly spreads unless something be done to destroy the vitality of the fungus. In such a season as the present, when there is every prospect of Potatoes being very dear, it is worth while to take more than usual precautions to secure the keeping of those that were sound when lifted; the drier and more airy the place in which they are stored the better, with the additional essentials of being cool and dark. Many who have not room to grow a sufficient supply of Potatoes buy in about this time all they will require. I would, however, recommend this to be delayed for some weeks yet, until the disease has ceased to spread amongst the late dug kinds.

Carrots and Beet, taken up and stored a few weeks back, should be looked over to see that they are keeping properly, as sometimes these roots, when stored with layers of ashes in the usual way, take to fermenting, in which case they become a putrefied mass in a very short time. It is not well to pile them up too deeply, as, under such conditions, they are more likely to be affected in the way just mentioned.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

December 17.—Examining Cucumbers, stopping them where required, and picking off all useless blossoms. Making a new border for *Roses* 18 in. deep, and filling it with good loam and manure. Looking over Cauliflower plants, picking off all decayed leaves, and stirring the soil amongst them.

Dec. 18.—Getting into spare frames a quantity of large *Endive* for protection. Turning over Mushroom manure to sweeten. Covering up part of another *Seakale* bed. Getting manure wheeled on to the land whilst the weather is favourable, and mending Box edgings in the kitchen garden.

Dec. 19.—Getting up another lot of *Snow's Winter White Broccoli* and putting them in spare cold pits. Getting more *Asparagus* into frames and renovating the linings. Staking and tying some newly-planted trees and shrubs. Cleaning the walks and Grass in pleasure grounds. Looking over the Grape room, removing bad berries, and filling up the bottles with water where required.

Dec. 20.—Sowing Mustard and Cress and getting in another batch of French Beans. Covering up *Endive* and Lettuces to blanch. Lifting and root-pruning some dwarf-trained Plum trees that were growing too grossly. Rolling down all gravel walks firmly, also all the Grass as fast as weather will permit.

Dec. 21.—Getting into the forcing pit some more *Lily of the Valley* and *Deutzia gracilis*. Proceeding with the pruning of large deciduous trees. Clearing off all decayed vegetables and prunings and burning them. Getting into the Mushroom-house a little more *Chicory* and *Dandelion* to force.

Dec. 22.—Looking over *Pelargoniums*, stopping them, and picking off dead leaves; examining *Pines* and watering any that require it. Looking over the fruit-room, and removing any fruits that are rotting. Fruits in use for dessert:—*Pines*, *Grapes*, *Pears*, *Apples*, and *Nuts*.

Something like 90,000 lb. of snails are sent up daily to the Paris markets from the gardens of Poitou, Burgundy, Champagne, and Provence, where they are specially reared for this purpose.

THE LIBRARY.

THOMPSON'S GARDENERS' ASSISTANT.*

(NEW EDITION.)

ISSUED nearly twenty years ago, and just at a time when such a work was much wanted, this book was accepted as a standard authority on everything relating to vegetable and fruit culture, the name, position, and acknowledged ability of the author being a guarantee, it was felt, of its practical character and trustworthiness. With the flower garden Mr. Thompson did not attempt to deal so fully as with the other departments, and this omission, it has always been acknowledged, was the fault, or rather want, of the work, otherwise so complete. This want it has been the chief aim of the promoters of the new edition before us to supply. We are informed, in the preface, that it is in the section devoted to the flower garden that the greatest change has been made, and that the subject is now treated with that fullness which its importance requires—the new matter added under this head amounting to “well

nigh one-third of the original work.” In order to judge how far this promise has been fulfilled, it will be necessary to allude separately, but briefly, to the different subjects embraced in this section, and treated by the different writers who have assisted in its compilation.

The first chapter is devoted to the flower garden and pleasure grounds, and deals chiefly with the laying-out of the grounds and planting arrangements, &c., &c. The subject is treated at considerable length, and as fully, perhaps, as the circumstances and plan of the work will permit; but it will be observed that, while in the original edition the author seldom or never obtrudes his own opinion dogmatically, but contents himself rather with laying down general principles and pointing out errors and defects to be avoided, the writer on the flower garden in the new edition, with questionable taste, steps considerably out of his province to give the reader a good deal of his own private opinion, rather positively asserted, on some points. Mr. Thompson, in discussing the subject, leaves the position of the flower garden an open question, realising, perhaps, that it is well to “consult the genius of the place” in such matters, but this wise and wholesome rule is disregarded by his successors. In noting “a few of the mistakes as to position, construction, and the use of plants, that have done much to bring discredit on this style of gardening,” the writer tells us it is a mistake to place the flower garden in a “prominent position adjacent to the windows of the mansion, and occupying the foreground of an extended view.” “The introduction of colour,” he adds, “in ever so slight a degree, in front of the mansion, where the windows command a broad open landscape or park scene of moderate extent, is a glaring mistake.” Perhaps the best

reply that could be offered to such an unqualified statement is, that in many of the very best examples of the choice of a position for the flower garden this rule has been completely set aside—the flower garden occupying the most “prominent position” in front of the mansion, and merging gradually into the pleasure grounds beyond, and these again becoming finally lost in the distant landscape—the whole forming an easy blending of nature and art, and exhibiting a gradual transition from the one to the other. Abrupt divisions or terminations between the flower garden and the park or woods, are always objectionable: but it is difficult to see where the former could be placed, in many instances, without occupying the foreground of an extended view, when it is remembered that both fronts of a mansion are almost invariably placed so as to secure the best and widest view possible. On this point, indeed, the author appears to be as much puzzled as any one, for he abruptly leaves the subject without telling us where the flower-garden should be placed, merely hinting that a suitable site, more or less confined, may be found for it, without interfering with anything else, from which it may, or

may not, be inferred he would place the flower garden, like a “sticking plaster,” anywhere out of sight. This is a question, we are afraid, which the writer on flower gardening has not grasped in all its aspects, and he has disregarded the opinions of other and competent authorities. The position of the flower garden is a question, in fact, on which no arbitrary rule can be laid down. Everything depends upon the configuration of the ground and the character of the landscape. Where the position is flat and occupies the foreground of an extended view of level Grass fields or cultivated land,

Orangerie in the Petit Trianon, wreathed with Wistaria in flower.

the above objections apply to some extent, although some of our best landscape gardeners could furnish examples of such situations treated successfully without shutting out the landscape; but, when the mansion occupies a commanding position, and the ground in front is sloping, or precipitous and irregular, with a far-stretching landscape of hill and dale, and woods beyond, the case is quite different, and an artist would think twice, probably, before he neglected such a position and facilities, and such opportunities of displaying his skill. Many of the Scottish Castles afford good illustrations of this style. When the eye is lifted up, it can take in a prospect miles and miles in extent, and it can drop back again to the pleasant picture in the foreground without any effort or without discerning any incogruity in the scene. In such a case the flower garden does not really come between the eye and the distant prospect, nor does the one detract from the other in any sensible degree. “A Plan of a Flower Garden in Kent,” by Mr. Marnock, published in THE GARDEN a few weeks ago, it may here be stated, is a sufficient commentary on the style recommended in the new “Gardeners’ Assistant.”

Before leaving this part of this subject, in which “glaring

* “Thompson’s Gardeners’ Assistant.” New Edition, Revised and Extended. By Thomas Moore, F.L.S. Blackie & Son, Edinburgh and London: 1878.

mistakes" are so forcibly pointed out, it is interesting to note that the only phase of flower gardening the conductors of the work have thought fit to illustrate is one which must be regarded as exhibiting the feeblest conception of their task in this direction—that is "carpet bedding," so called, a style of garden decoration which is not perhaps carried out extensively in a dozen gardens in the kingdom, and which in hundreds of cases would not be tolerated. That no better or higher phase of garden embellishment could be suggested, since it was considered desirable to illustrate the subject, is a lamentable blot on a work of such pretensions.

The succeeding chapters in this section treat upon Hardy Arboreal and Shrubby Plants, Hardy Conifers, the American Garden, Herbaceous Plants, Florists' Flowers, Bedding and Sub-tropical Plants, Conservatory and Greenhouse Plants, the Stove and Forcing House, and Floral Decorations. Cultural directions are given in each chapter, and those subjects suitable for furnishing the flower garden and pleasure grounds are fully catalogued and described. The chapters on Hardy Trees and Shrubs and Herbaceous and Alpine Plants, &c., are worthy of particular mention, as the species are here brought together in a more handy and accessible form than they have ever been before, we believe, and in this respect alone the "Gardener's Assistant" will, in future, have a greatly increased value for the gardener.

We now turn to those sections of the book devoted to the kitchen garden, pruning and training, and fruit culture. The additions to the first do not call for particular mention, and this applies also to the chapter on pruning and training. Considering the interest the last subject has excited of late, and the change of opinion and practice that has taken place within the last twenty years, particularly as regards the Apple and Pear and stone fruits, it might have been expected that, in a new edition of such a work, experience would have been brought down to the present time, but this has not been done. There is reason to fear that a narrow spirit has operated disadvantageously in some portions of the work by preventing the introduction of useful matter from other sources. Coming to the subject of Vine-culture, which has an interest for so many, we find that little or no use whatever has been made of recent experience. Mr. Thompson brought the subject well down to his own time, but that part of his work would certainly bear revising a little now. It is perfectly well known that no gardener cares a farthing, at the present day, for the practice of Oak Hill some thirty or forty years since; nevertheless, this has all been served up over again, with some comments added (under the head of Garden Structures) on the different conditions under which Black Hamburgh and Muscat Grapes ripen most successfully in England and Scotland, which will probably amuse our friends in the north, who, we believe, have not yet resorted to the practice of tying their Muscat Grapes up by the points of the bunches to ripen them as well as those grown in the south. The same authority also makes quite a misleading statement on the subject of Vineries, when he states that "the requisite heat is more easily and economically maintained in small houses than in large ones," as he might have satisfied himself by arithmetical demonstration. It has been demonstrated often enough, surely, that the maintenance of the requisite temperature, easily and economically, in hothouses, does not depend so much upon the relative size of the structure as upon the number of cubic feet of air it contains in proportion to the radiating surface exposed in the roof, ends, and sides—in other words, a large and lofty house is sooner heated, proportionally, than a small house, and keeps its heat longer. The engravings of glass structures are rather too much after one pattern and one maker. The descriptive notes, with plates, on "Insects Injurious to Plants," by Mr. Andrew Murray, form a useful feature of the book. The plate of carpet bedding will serve to show future generations what the art of flower gardening was in the nineteenth century. Sections of a number of ordinary structures are printed on one side only of thick fine plate paper! These common cuts might have been printed in the usual way without loss, and much space and paper saved thereby. A number of coloured plates—clean, but not very artistic in design—help to make the book more expensive, without being more useful.

J. S. W.

KITCHEN AND MARKET GARDEN.*

MESSRS. MACMILLAN have just published the "Kitchen and Market Garden," by contributors to THE GARDEN. In this place we can say no more of the book than that it is handy in form, and published at a price (4s. 6d.) that will not interfere with its utility. It differs from previous books in the same way, at least, in including the market as well as the kitchen garden. All good gardeners well know that the practice most worthy of their attention, and, as far as possible, their imitation, is that of the best market gardeners near London and other large cities. Notwithstanding this, very little notice has been taken of market gardening in any books hitherto published on the kitchen garden. This was brought about by the fact that market gardeners are a class apart. Information concerning their work was not obtainable without some trouble, and the market gardener is usually too busy a man to write himself. Both on the staff of THE GARDEN newspaper, Mr. W. Falconer and Mr. C. W. Shaw made what we believe to be the first attempt at long and systematic observation of the best culture as it is in London market gardens. The result is embodied in this book, which also contains the practice of the best private gardeners in England—among them being Mr. Thomas Baines, the late James Barnes of Bicton, A. Dean, Richard Gilbert of Burghley, J. Groom, D. T. Fish, E. Hobday, J. Simpson, W. Tillery, and W. Wildsmith. The question of market and kitchen gardening is of some national importance. It is not only desirable that our private gardens should be in the highest degree productive; the supply of our markets with good vegetables and salads is being now, to a large extent, undertaken by foreigners. There is no good reason why it should be so; if we take advantage of all our opportunities, we ought at least to supply our own markets with vegetables and salads without foreign aid. The publication in a concise form of the information necessary for the carrying out of every kind of market and kitchen garden cultivation, in the best manner known up to the present time, will, it is hoped, be useful to this end and otherwise in all that concerns the cultivation of vegetable crops.

FERNS OF THE BRITISH ISLES.†

THE popularity of Ferns is, no doubt, great, but we should hardly have thought that publishers would have ventured on the production of so many handbooks on the subject as have appeared during the last few years. The idea, however, of publishing photographs of Ferns from Nature is a good one, though this art must fail in rendering much of their grace and beauty. The little work just brought out by Mr. Van Voorst is a laudable effort in this direction. It is everything that can be desired in binding, paper, and printing, the photographs are remarkably uniform and good in tone, the scientific portion of the work is accurate, and, last though not least, its price renders it accessible to every one who has a drawing-room table to put it on. From its possessing these good points, we shall not be surprised if it speedily reaches a new edition, so we need not apologise for some strictures both on the design and on its execution. Is it educationally advisable to substitute the identification of objects from the superficial characters shown in pictures for that based on minute examination and description? Admitting the desirability of a portfolio of Fern photographs, are there not already enough descriptive works on the subject to render letterpress unnecessary? In the sketch of the structure of Ferns prefixed to the present work, the only phrases to which exception may be taken are "seeds or germs" for the spores, and "branch of the leaf" for the spore-bearing part of the frond in *Osmunda* and *Ophioglossads*. It is a pity that *Hymenophyllum* and *Trichomanes* should be placed among the *Polypodiaceæ* and separated by the alphabetical arrangement, and there is no reason, according to modern views of structure, for the exclusion of our interesting little *Marsilea*, *Pilularia globulifera*, if the *Ophioglossaceæ* are admitted. It is to be regretted that the letterpress has not been arranged so as to be opposite the plates, and that these latter should be in an order of their own, and on no less than eight different scales. The photographs seem, in some cases, to have been taken from dried specimens; at all events, that of the *Osmunda* is flat, and gives no idea of the true grandeur of the species; that of the *Brake* is poor; that of the *Hart's-tongue*, stiff; whilst the *Adiantum* should have been taken in a hanging position. *Ruta muraria*, being taken while growing, is very good, as are also *Asplenium Trichomanes*, *A. marinum*, and *Polypodium Dryopteris*; but *Polypodium calcareum* is too slender, whilst the recurring of *Lastrea æmula*—here called by the ugly name *Fenisecii*—is not well

* "Kitchen and Market Garden." By contributors to THE GARDEN. London Macmillan: 1877.

† "Ferns of the British Isles." Described and Photographed by Sy. C. London: Van Voorst.

shown, and, as might be expected, the portrait of the Killarney Fern has little of its true grace. The plate of *Ophioglossa* is ill-arranged; but the woodcuts throughout the work are excellent, as is also the glossary. The table of the distinctive features of critical species on pp. 53-55 is an excellent idea. Something might have been said as to the variability of the Hart's-tongue, Lady Fern, and other species, and room might have been found for reference to Mr. Francis Darwin's interesting account of the glands of the common Brake (*Journ. Linn. Soc.*, vol. xv.). As extreme dimensions are generally given in manuals, it may be of interest to mention that a specimen of this species has been measured 10 ft. 6 in. from the ground, in Bedfordshire. In spite of the blemishes mentioned, we can recommend this work to the notice of amateurs. G. S. BOULGER.

KEEPING WALKS CLEAN.

No garden can be considered in proper condition unless its walks are, at all seasons of the year, free from weeds and littery matter of all kinds, and, at the same time, smooth, solid, and as dry as possible, walks with a loose or shifting surface being exceedingly uncomfortable to walk upon. A correspondent of *THE GARDEN* (see p. 556) states that his walks are infested with weeds, and wants to know how he can best eradicate them. At the present season, or so long as the weather keeps open, the best way, perhaps, would be to have them pulled up by the roots, and in March next to turn the gravel, adding a coating of fresh material, then rake smooth and level, but keep the central part slightly elevated, and roll well down with a heavy iron roller. By careful hand-picking walks may be kept free from weeds at all seasons. But during such wet and damp autumnal months as we have lately experienced it is quite impossible to prevent the surface becoming more or less discoloured by the development of minute species of Moss. With some kinds of gravel this is more likely to happen than with others; but it nevertheless often occurs in the case of the very best kinds, viz., that which contains a portion of loam or chalk, and which has a consequent tendency to bind or become solid. Where such walks are more or less near shrubs and trees, especially where they pass under branches of the latter, this tendency to become green during damp weather will be increased. It is, however, seldom desirable to break up, or turn the gravel of such walks more than once during the season, and the most suitable time to do this is in spring. When that has been done, select the earliest occurrence of dry settled weather during the month of April, or of May, to give a thorough dressing of dry salt; the longer this lies upon the surface, before it becomes melted by rainfall, and the more intense the sunshine during the time it so lies, the more effectual will be the application. Walks treated in this manner will not only be free from weeds and worm-casts during the remainder of the season, but their surface will retain a bright, clear, and cheerful appearance, and their solidity or firmness will be materially increased. Salt is sometimes applied to gravel walks and roads in a liquid state, or in the form of strong brine used quite hot, or as near the boiling point as possible. This is said to be very effectual in preventing the growth of weeds. Sundry other solutions are also recommended for the purpose. But I know of nothing more effectual than a liberal dressing of dry salt, sufficient to whiten the entire surface of the gravel. A slight sprinkling is of little use, and may even increase rather than diminish the evil which it is intended to cure. In applying such a dressing as has just been recommended, it is, of course, necessary to exercise caution, in order to prevent the salt coming in contact with the Grass, Box, or other plants, which may form an edging to the road or walk operated on. In the garden here, some walks which were salted early in the season, have been free from weeds ever since, and at the present time contrast very favourably with others, formed of the same materials, but which had not been salted. The surface of the former is clean and bright, while that of the latter is discoloured and dark. Culford. P. GRIEVE.

— "G." (see p. 556) would most effectually get rid of the weeds on his walks by using a solution of carbolic acid—say about $\frac{1}{4}$ lb. to 4 gallons of water. Apply it with a fine-rosed watering-pot, and carefully avoid touching the edgings of Box

or Grass, as the case may be, for the liquid is sudden death to all vegetation. The walks may then be surfaced with fresh gravel, and weeds will not trouble him again for a long time to come.—W. W. H.

— I would not recommend "G." to put any kind of salt on his walks, and then coat them over with gravel, when they are so much over-run with weeds as he says they are. It is very questionable if the salt would thoroughly destroy them; and if it did, there would be a layer of dirt left, with which it would not be wise to mix with the new gravel. When walks get in a bad state with weeds, the best thing to do with them is to take a draw-hoe and scrape every particle of the surface off, clearing it altogether away, then coat them over with fresh gravel. I have found this to be a better way of cleaning walks than any other which I have seen tried. CAMBRIAN.

ROSES.

A FEW GOOD GREENHOUSE VARIETIES.

In a house here that is planted with Camellias, Roses—principally Teas—are planted out amongst them; some of them are against the pillars that support the roof, and are trained along the rafters, partly for shade to the Camellias; others are trained to upright poles until they get above the Camellias, when they are allowed to spread just as they like. The blooms which they furnish for cutting are extremely useful, coming in, as they do, when the Camellias are failing. The first to bloom is the White Banksian, which flowers early in March, and continues to do so until the end of April. It is generally in full bloom at Easter, a season when white flowers are in great request; few white greenhouse climbers can equal it at that period. It covers a large roof space. All the pruning which it gets is done when the bloom is over; then nearly all the shoots are cut back to the main stem, an operation which causes it to push strong shoots, from 6 ft. to 10 ft. long; these are allowed to hang down as they like, and the following spring they are covered with bloom during their entire length. *Maréchal Niel* is trained to the rafters, and does well, coming in after the Banksian. *Cheshunt Hybrid* is a good dark-coloured, highly-scented Rose, and one which makes a good climber, but it is late in blooming, not coming in until the *Maréchal* is nearly over. *Gloire de Dijon* does well, but its colour is not so fine indoors as out; *Catherine Mermet* is one of the best; *Adam Bell*, *Lyonaise*, *Madame Sertor*, *Madame Willermoz*, and *Rubens* all do well with me. I have tried several others, but, for some reason or other, they do not answer for greenhouse culture. Green fly does not trouble them much, perhaps because I use plenty of water at the roots and overhead, applying it in the latter case with the syringe. I have nearly always some buds fit for cutting. N.

Hereford.

Umbrella-shaped Rose Trees.—We grow most of our dwarf Roses on the long-rod system, viz., cutting out the old wood at the winter pruning, and retaining the strongest annual growths, which are pegged down, at certain distances apart, with long stout pegs, cut from the refuse Pea sticks. On the summits of the Rose-banks, standards of free-growing kinds, such as *Charles Lawson*, are planted and pruned in a similar manner as the dwarfs, the points of the shoots being tied to pegs driven in a circle round the tree. By this means they form regular-shaped and beautiful heads, for the shoots break regularly into growth from every eye, and when in bloom form beautiful objects.—JAMES GROOM, *Henham*.

Baroness Rothschild Rose, the Best Autumn Bloomer.—Amongst all the leading sorts of Roses, this one has bloomed most freely this autumn. There were some very fine flowers on it in October, and the last of them were not cut until the middle of November.—CAMBRIAN.

Testimonial to Mr. Drummond.—Mr. James Drummond, who has been forty-nine years gardener at Blair-Drummond, being about to retire from active duty, a number of his friends, who esteem him highly for his professional ability and upright personal character, intend presenting him with a testimonial. Mr. Drummond is one of the veterans of the fraternity of practical gardeners, and well deserves some notice on retiring. Subscriptions will be received at the Union Banks of Stirling and Doune.—"Gardener."

It has come to this. In Holborn, opposite the Inns of Court Hotel, an ironmonger advertises, "The Gladstone Tree Feller." It seems to be a very ordinary kind of axe.—"Truth."

THE KITCHEN GARDEN.

KITCHEN GARDENING MADE EASY.

Let me now take up the subject of Onion culture, and I may remark at the outset that Walker's Thame Oxford is the best of its class, the bulbs being large and well shaped. I never trench for Onions; merely dig the land deeply, and manure heavily. The seed is sown in rows, 1 ft. apart, in the last week in March; thinning and hoeing receive attention as usual, and when the bulbs are ripe they are lifted and carted off the land, to be harvested. We then cultivate the land to the depth of from 4 in. to 6 in., and plant Cabbage in rows, 13 in. apart all ways. By the middle of June the greater part is used, and, when all are cut, we lift the stumps, rake the ground, and plant that most useful Broccoli, Veitch's New Protecting, and other varieties, for succession. The planting is done—in that simplest of all plans of planting, and I may add, the most effective—with the crow-bar. I never let a Cabbage crop stop for the sake of the sprouts, which, I admit, are always plentiful; but they form such a harbour for slugs and caterpillars, and all the ills that a garden is heir to, that they are best out of the way. By sowing Coleworts in the middle of July, and planting them out after the Potatoes are off, 9 in. apart, one can cut as often as required really good little heads, which for flavour stand in the first rank amongst Cabbages. This makes three crops with only one digging. The site in question is again manured, and laid up roughly for early Potatoes.

Burghley.

R. GILBERT.

— Kitchen Gardening made Easy! The Gardener's Millennium would seem to be at hand, kitchen gardening being invariably the hardest work with which gardeners have hitherto had to contend. Therefore, when one of our greatest authorities on kitchen gardening proposes to diminish our labour in that department one-half, it may be as well to have a clear understanding before commencing our next campaign, as Mr. Gilbert calls it. With the directions for the first season's cropping I entirely agree, as Peas like deeply cultivated and well-enriched land, and the whole of the Cabbage tribe do best on solid ground; but, after a crop of Brussels Sprouts, the soil, owing to frequent trappings in all weathers in gathering the produce, will be as hard as an ordinary footpath; therefore, will Mr. Gilbert recommend us an easy method by which the land may be properly prepared for Potatoes, or put in such condition as he would consider the best for ensuring good results? Easy modes of culture all of us would appreciate, but we also want good crops. Surely Mr. Gilbert never plants Potatoes, more especially Early Kidneys, in hard, unbroken ground, and whether digging is performed with a spade, or by means of a cultivator, matters little, as far as saving of labour is concerned, as I feel satisfied that the operator who pulverises land deep enough for Potatoes with a cultivator would not term the operation easy work. For several years past our spades have not been so constantly in use as formerly, as Parkes's Steel Digging Forks do the work much better. I need scarcely remark that Carrots delight in loose friable soil; in fact, their quality is determined to a great extent by the character of the soil, a rather poor, sandy, loose soil, that cannot be compressed into a solid mass, producing better Carrots than heavy clay lands would under the best of culture. Economy of labour in our gardens is a question deserving the highest consideration, and all of us must feel grateful to Mr. Gilbert for any remarks which he may make tending to effect that desideratum. But, from his own description of the routine of cultivation adopted at Burghley, and the well-known success that attends his management there, I am of opinion that the stirring with the cultivator which he describes, is quite equal to ordinary digging, and that any one undertaking the operation on stiff, adhesive soil, after a crop of Brussels Sprouts, would come to the conclusion that Kitchen Gardening Made Easy was a somewhat ambiguous term.—J. Groom, *Henham*.

— I do not consider that Mr. Gilbert is quite correct in stating that Strawberries, Broccoli, Celery, and Potatoes are grown without digging the ground. Admitted, the ground is well trenched for the Strawberry crop; Broccoli follows without further spade-work, and a first-rate plan it is; but I think the working of a Celery crop—first taking out trenches, afterwards earthing up, and finally digging up the crop—is almost equal to a trenching of the ground instead of digging, leaving the land in good order for almost any other crop. It therefore seems to me that the Broccoli crop is the only one produced without digging the ground.—J. M., *Winslow*.

Giant v. Dwarf Celery.—The past season has been an exceptionally favourable one for the growth of Celery. We find Incomparable Dwarf White, if procured true to name, unsurpassed for general purposes; it is not, perhaps, adapted for growers for sale, as, when bundled for market, it is small in comparison with Har-

ison's Leicester Red, Lion's-paw White, and similar varieties; but, when dressed for the table, either as a salad or as a cooked vegetable, it is all that can be desired. The heart is very solid and compact, and the outer leaves short and sturdy, so that when carefully blanched there is little waste in comparison with that which occurs in the case of long, straggling-habited kinds. Where the kitchen garden is of limited extent it is of the first importance to grow varieties of vegetables that will attain perfection in a limited space, and, as Celery forms an important item in kitchen gardens, a variety like this is invaluable. The principal point as regards Celery culture is to avoid all kinds of checks to growth, by sowing for the main crop, in very gentle heat, in March or April, and pricking out the young plants, as soon as they are large enough, in beds protected by spare lights. Thus managed they make fine, sturdy plants by the end of May, when, if not checked through lack of moisture, there will seldom be any loss from running to seed or from any other cause.—J. Groom, *Henham*.

DANDELION SALAD.

POSSESSING, as I do, very decidedly "phytophagous proclivities," I was glad to see an article by Mr. Dennis (p. 529) on this subject. But does he mean that one may cut leaves from plants growing wild "from November to March," and eat them dressed in the manner described? Is it not the case, that they require to be blanched with a slate or tile, like Endive, before they are at all palatable? Again, is it not probable that they would be more tender and agreeable during the summer months? Whether eaten green or blanched, there is, without doubt, one period of the year at which they are at their best, and another at which they are at their worst, and it would be interesting to salad eaters to have information upon these points. Mr. Dennis has done good service to lovers of vegetables in their uncooked condition, by directing attention to the importance of drying the surfaces of salading before adding the dressing. He recommends using a towel; some cooks swing the "green food" in a Cabbage-net, whirling it through the air with great speed, and thus removing all superfluous moisture. I should never be surprised to learn that our ingenious American cousins have invented a centrifugal machine for drying salading as they do clothes. There is one important point which requires notice in your correspondent's account of the manner in which he dresses Dandelion salad. He says, mix pepper, salt, and vinegar, "which pour equally over the salad, then add more vinegar, and lastly the oil." It cannot be too often repeated, that vinegar makes vegetables flabby, while oil keeps them in a fresh, crisp condition. Hence, no salad of any kind is worth eating five minutes after it has been made unless it has been dressed with oil first. The cut-up salad should have a very little Olive oil (not flask oil) poured over it, and then be well tossed and mixed with a wooden spoon and fork; when this has been properly done, every part of the salad will be greased with the oil rather than oiled, and there must be no oil left at the bottom of the salad bowl. Afterwards, any kind of dressing may be poured over the salad, merely bearing in mind that oil and vinegar will never mix, unless the oil has first been incorporated with mustard, hard-boiled egg, or some other thick substance.

W. T. T.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Peas from June to December.—We gathered our first Peas here on 30th June, and our last dish we had yesterday—a good quantity and very good. Some were of the sort called *Ne Plus Ultra*, and some were the produce of seed saved from the first crop. They were sown early in August. The plants when pulled up on Saturday still had binoms upon them. They were entirely free from mildew.—J. P.

Blanching Endive.—After trying various ways of blanching Endive, such as putting a slate over each plant, turning a flower pot upside down on them, and laying a board on the top of each row, I find that none of these plans answers the purpose so well as lifting the plants with good balls attached to them, packing them as closely as they will stand in cutting boxes; and then setting them in a dark Mushroom house. Thus treated, in ten or twelve days, every leaf becomes white, and they do not decay as they do outside. A dark cellar would no doubt blanch them equally well.—CAMBRIAN.

Veitch's New Protecting Broccoli.—I had an opportunity last week of seeing a large breadth of this Broccoli growing at Warnham Court, and a finer plantation of the kind I never saw; the heads were from 8 in. to 10 in. in diameter, very solid and compact, and well protected by the foliage. The seed from which they were raised was sown the second week in April, and when large enough the produce was planted out between rows of early Peas, and when the Peas were cleared off their place was filled with Snow's Winter Broccoli—which promises to form a succession to the above. Veitch's Autumn Giant Cauliflower has also been wonderfully fine this season.—H. HARRIS, *Horsham*.

A COUNTRYMAN ON "KILLED SEED."

A FIELD o' young turnmuts is gay to behold,
When 'tis yaller all over wi' patches o' gold.
But 'taint all gold glitter like sunshin' so bright:
That there's charlick, unlucky in husbuan's sight.

And the grain-crops, so plenty as aims on some ground,
When they comes to be ripped med poor projuice be found.
Barren wuts to bad farmin' be like to be doo;
Likewise charlick unlucky though smilnn' to view.

But when crops, root or grain, comes up scanty and thin,
Or broke out in hear spots like a mangy dog's skin,
'Taint the fault o' sitch tillidge as 'counts fur the weeds;
On the best land no shoots wun't come up from dead seeds.

The sower med goo forth his seed for to sow;
But the live seeds is all o' the kit as 'ool grow.
'Tis from they that red poppies and carn-flowers prevails;
But dead seeds be like dead men—they don't tell no tales.

Now the dalers in seed has dovised a deep thing;
Mixes up with live seed seed killed dead as wun't spring.
For they goes and they bakes it that no weeds med rise,
And bear witness agin 'um to nobody's eyes.

To cotton and cloth we know'd tricks was applied,
And we knows, too, that silk's mixed wi' stuff when 'tis dyed.
Loomaasy, how Progress in craft do proceed!
There 's a species o' shoddy now mingled wi' seed.

Rogues be rogues, to be sure, sitch and all o' one strain;
But the wust rogues for farmers be them rogues in grain.
To chastise sitch offenders no fines wou'd prevail.
For their potion I 'd gi'e 'em hard labour in gaol.

In the good times of old, rogues like they, up and down,
At the cart's tail 'd been properly whipped droo the town,
And then set in the stocks their misdeeds to requite,
Or stood in the pillory, and sarve 'um aright.

For the tricks o' the Seed Trade 'oodst make theeself match?
Thee goo, and thee get thee an old flannel patch
From out of a blanket the Misus med spare,
Or a petticoat as she no longer wed wear.

Soak in water loo-warm, nigh the vire let 'a stand,
Then a hotbed in little thee 'st got to thy hand.
Sow thy seeds in 't, all counted; the live uns 'ool spront,
By the dead, which they wun't, the deceiver's found out.

Whensoever I that there ixperiment tries,
'Tis from few seed I finds as e'er spronts fails to rise.
For I knows honest folks, and I dales whero I knows:
That's the way for a feller to rip as 'a sows.

—"Punch."

Ageratum Countess of Stair in Winter.—Where cut flowers are in demand, this *Ageratum* I find to be very useful at this season of the year. Cuttings of it put in the first week in September, on a slight bottom-heat, will strike root in a few days, when they should be potted off, or better still, transplanted into small boxes 4 in. or 5 in. apart, and afterwards encouraged to grow, pinching out the centres, when each plant will throw out about half-a-dozen shoots from the bottom. When 3 in. or 4 in. high, the boxes should be removed to some sunny situation in the open air, where the shoots will get a little woody before the plants are moved indoors, which should be done before frost sets in. They should be placed on a shelf in the greenhouse, where they will get plenty of light and air, when each shoot will produce an enormous head of bloom of a lovely pale blue, a colour not very plentiful at this season. When done flowering, if placed in a little heat, they will produce abundance of shoots, from which to propagate bedding plants; and I may add that this variety of *Ageratum* is the best blue-flowering bedding plant with which I am acquainted, and one which looks bright even in wet weather.—THOS. SPELMAN, Derry Castle.

Mr. Joseph Wheeler, for fifteen years gardener to the late J. Philpot, Esq., of Stamford Hill, and during that period a successful exhibitor of stove and greenhouse plants, at the Royal Horticultural and Botanic Societies, and occasionally elsewhere, has been appointed gardener to Sir F. H. Goldsmid, Bt., M.P., Bendcomb Park, Cirencester.

Roots at the Smithfield Show.—At this show finely grown Potatoes, Turnips, Carrots, and Mangolds were shown in great quantities, by Messrs. Carter & Co., Sutton & Sons, Webb, Harrison, Gibbs, and others; and good examples of produce grown with the aid of Amies' chemical manures were also exhibited.

QUESTIONS AND ANSWERS.

Covering for Cold Pits.—What is the best covering, at a moderate cost, for cold pits in winter? Something warm and waterproof is required. Archangel mats, covered with waterproof cloth, answer the purpose very well; but, if the waterproof cloth be new, it is very costly, and if it be bought second-hand, cut from old rick-cloths, I find that all its goodness is nearly worn out. The Malabar Thatch Mat looks to me as if it might be useful, but is it found to answer? The thought occurs to me that in use it might be too brittle.—W. B. L.

Eradicating the Brake (see p. 533).—Many years ago I was informed, by the late Mr. Edward Newman, that the Brakemay be eradicated by repeatedly mowing off the young fronds when only 3 in. or 4 in. high; and that, by doing this as often as the fronds appear, the rhizomes will be "bled to death" in one season, and the plant killed. I cannot imagine that anyone, who understands the mode of growth of this Fern, would expect to eradicate it by mowing it in the autumn.—W. T. T.

Epiphyllums after Flowering.—Can you inform me whether the ends of Epiphyllums that have bloomed this season should naturally fall off; and, if they do not, whether it is necessary to break them off to the first joint? I have noticed that they remain on till the following autumn and then fall off; but if they do not come off they prevent, I think, fresh growth being made. Any information would greatly oblige.—Y. X. [If you mean the stalks of the flowers, it is immaterial whether they fall off or are cut away; for, if the plants are strong, they will break into fresh growth at every joint, whether cut back or not.—T. B.]

Wintering Pelargoniums.—I have often seen Pelargoniums hung up in a cellar as "W. W." mentions (see p. 556), but I never saw them do any good afterwards. The best way of wintering old Pelargoniums is to lift them, cut all the long roots off, and all the shoots into the first or second bud or leaf from the main stems, and then pack them into any old cutting boxes, covering the roots with a little soil. Give them one good watering, and then they may be wintered either in a loft, dry shed, or greenhouse. They keep capitally in this way without taking up much room, and being so hard cut in they make fine dwarf bushy plants in spring.—CAMBRIAN.

Sowing the Corsican Pine.—I have just received some seeds of *Pinus laricio*, from the forest of Valdionella, in Corsica. Had I better sow them at once in boxes, or keep them until the usual seed sowing season? I also have some seed of the *Alnus cordata*, about which allow me to make the same enquiry.—J. M.

Early Melons.—Will any practical reader of THE GARDEN kindly inform me which is the best moderate-sized green-fleshed variety for very early work?—WM. R.

Begonia Frœbeli.—Will Mr. Clews (see p. 513) kindly state the *modus operandi* by which he has succeeded in raising a stock of this from seed?—WM. M.

Mildewed Grapes.—What is the best plan of preventing ripe Grapes from becoming covered with and spoiled by mildew? On Saturday last I had a house full of magnificent bunches of Black Hamburgh, perfectly ripe, and also of one or two other kinds, equally ripe; but on Monday morning, when my gardener came to gather a quantity, he found that nearly all the Black Hamburghs were covered with mildew and spoilt, but that none of the others had then become affected—nor have they since. So sudden a collapse has quite taken me by surprise, and I cannot account for it, excepting that Sunday was a very wet day, and the rain at times was almost like a water-spout. We keep the house slightly warm and dry, with a little sulphur on the hot-water pipes; but the roots (which are outside the house) had no protection, and I fancy the wet had penetrated down to them and has caused all this mischief. I shall feel much obliged if you can tell me how to save the remainder, and prevent a recurrence another year.—A REGULAR SUBSCRIBER. [This case shows the necessity of always being on the watch for the appearance of mildew, for, no doubt, it had been on the Vines some time before it was noticed, but the dull, wet Sunday would, of course, accelerate its progress. Nothing can now be done to save the Black Hamburghs; but, to prevent the disease spreading to the others, sulphur should be applied at once, and the best way is by the syringe. Choose a dry day, and fire up well, so as to heat the pipes, and ventilate freely. Then mix sufficient sulphur in a little milk till it is thoroughly disintegrated, and pour it into a pitcher of clean water; keep it stirred up, and syringe the Vines and bunches till they are thoroughly drenched in every part. If the day be dry, the pipes hot, and the ventilators open, the Vines and fruit will dry in about a couple of hours without being anything the worse, except that the berries will be covered with sulphur dust, which, however, will brush off easily with a camel's-hair pencil before the fruit is used for dessert, and, in the case of late Grapes, without injuring the bloom. This is a desperate remedy, but it is the only one likely to succeed. Afterwards keep the house cool, and perfectly dry, and ventilate a little—always keeping a little heat in the pipes as well. If, as is stated, the crop of Grapes is "magnificent," it is hardly likely the roots are in a bad state; but, if the foliage be still green, and the wood not well ripened, it may be desirable to drain the border more thoroughly. It may be stated that the above plan has been tried upon ripe Grapes with the most complete success, but the disease had not made such serious progress. In winter, after the fruit is cut, clean and wash the Vinery; paint the Vines with sulphur, and watch for mildew next summer, and apply sulphur freely on its first appearance. It almost invariably appears on the upper sides of the leaves first, and then attacks the fruit.—J. S.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

A CHRISTMAS DINNER-TABLE.

Most people at Christmas time surround themselves with their relations and friends, and make Christmas week quite a little festival; but the principal day, I need hardly remark, is Christmas Day itself. I shall therefore give a description of the floral arrangements of a dinner-table suitable for that day, leaving my readers to use their own discretion as regards table-decorations during the remainder of the week. At this season, as a rule, scarlet and crimson are the favourite colours; therefore, I shall select crimson and white as the prevailing tints in my arrangement. Let us suppose the table to be of a moderate size to hold say about twenty people; I select a table of this dimension, as if required larger, the same decorations, if placed a little wider apart, and with the addition of a few specimen glasses or small vases, will do equally well. In the centre I should place a large-sized plant of *Cocos Weddelliana*, with flowers round its base; at each end I should place a similar plant, or any other light-growing Palm in the same style, also with floral arrangements round its base. Between the centre piece and each end plant, I would place a vase, in form consisting of a trumpet rising out of a flat tazza; then round the centre piece I should group four glass baskets, and opposite to each person I would put a specimen glass containing a coat flower and a lady's dress bouquet alternately. I will presume that the decorator does not care to place the plants through the table, so I shall not enter into details as to how that should be managed. Select plants of graceful growth; what I mean by this, as applied to *Cocos*, is plants well balanced and not one-sided. This Palm, I need hardly remark, is one of our most graceful table plants, but its form is often spoiled by being cut where it looks a little faded; discoloured leaves, however, which show to disadvantage by daylight, are often unobservable when subjected to artificial light. Each of the plants should be placed in circular zinc trays, made for the purpose, about the size of the lower dish of a large March vase, that of the centre piece being larger than those at each end. The space round the pots should be packed with Moss, well damped, so as to represent a green mound from the edge of the tray to the top of the pot. Having got the three trays, with the pots packed in each, in their respective places on the dinner-table, the next thing to set about is the floral dressing round their bases, beginning first with a fringe of mixed varieties of Ferns placed so as to fall, or rather lay, out lightly on the table-cloth. I should intersperse fronds of golden varieties through those round the centre piece, and arrange them so that the golden or undersides of the fronds showed up; a few silver kinds would look well amongst those round the end plants. Next, as regards the flowers; well, round the centre plant I should be tempted to arrange the following blooms, viz., Arums, Poinsettias, Roman Hyacinths, Azaleas, scarlet Begonias, and Maiden-hair Fern, and twined up the stem of the *Cocos* a few sprays of *Lycopodium scandens*; the two end arrangements I should make match, and in their adornment use white Camellias, Poinsettias, scarlet Pelargoniums, white Heaths, Primulas, Hyacinths, Maiden-hair Fern, and up the stem *Lycopodium scandens*; the two vases should have very light-growing Ferns round the edges of the tazzas, and in the tazzas themselves nothing would look better than Eucharises, white Primulas, scarlet Pelargoniums, Roman Hyacinths, and Maiden-hair Fern; while in the trumpets I would place plume-like arrangements of scarlet Begonias, Lily of the Valley, and Maiden-hair Fern only. The four small glass baskets I should fill with sprays of well-berried Holly, and round the handles twine sprays of small-leaved variegated Ivies. Any flowers generally employed for button-hole bouquets will be suitable for the coat flowers and dress bouquets. In the way of fruits I should have a Melon, Pine,

black and white Grapes, Pears, Apples, Walnuts, and Filberts, with the addition of crystallised and preserved fruits, ice, &c. In the finger-glasses, three small leaves of Mrs. Pollock or Lady Plymouth Pelargonium, with a single pip of scarlet Pelargonium pierced through the centre of each, have a pretty effect floating on the water.

ANNIE HASSARD.

Vases and Gardening.—A friend, who has good opportunities of judging, tells us of the mistaken use of vases now made in country seats by certain "fashionable" landscape gardeners. Vases of terra cotta and artificial stone, often of poor design, are dotted about so thickly in situations unfitted for them as to destroy all repose and all good effect. Vases well placed, and well filled, of good design, may, and sometimes do, form a beautiful feature in a garden; but there are many beautiful gardens in which not one vase is seen, and many extensive ones in which half-a-dozen would suffice. Where the nature of the ground necessitates a terrace or a wall, the lines of these are better for being broken by the graceful forms of vases. It is even then well to be sparing as regards their use; but, where the nature of the ground does not furnish opportunities for their use, to scatter a leprosy of vases about is one of the worst of blunders in landscape gardening. The effect reminds one of the Euston Road displays of statuary ware; only in making the comparison, it is fair to remember that the owners of these displays have a reason for showing them which the country gentleman cannot plead. In the variety of advice that is offered, it is difficult often for a country gentleman to decide what is best, but one thing we think he may be assured of, and that is an extensive display of terra cotta and like rubbish has nothing to do with either good gardening or good art.

NOTES OF THE WEEK.

Kew.—Several Aloes in the collection at Kew are now in bloom. These large-growing Liliaceous plants are very striking, and, apart from the importance of several of them from an economic point of view, are worthy of notice on account of their peculiar style of growth and handsome spikes of reddish flowers. Humboldt says that the Liliaceæ is one of the vegetable forms by which the aspect of Nature is chiefly determined. In many places in the Tropics, where some of the Aloes occur in great abundance, they impart a peculiar and unique character to the landscape. *A. arborescens*, *A. pluridens*, and *A. platylepis* (all from the Cape of Good Hope) have flowers resembling each other, but the leaves vary considerably in form and size. *A. ciliaris* makes a pretty pillar or rafter plant; its small ciliated leaves and short spikes of orange-red flowers are very beautiful. *Rhipsalis salicornioides* affords an excellent example of mimicry in members belonging to two widely-separated Natural Orders. This Brazilian Cactaceous plant has succulent, jointed, leafless branches, much resembling the Marsh Samphire of the sea coasts and salt marshes of England. The little yellow flowers are terminal, and, when the sun is shining (for they remain closed during dull weather), are very pretty.

In the centre of the No. 1 or Aroid-house is a good-sized specimen of *Brownea coccinea*, a very handsome Leguminous tree from Venezuela; it has pinnate leaves, and pendent, Rhododendron-like heads of scarlet flowers. It is well worth a place in any stove where room can be spared for it. All the *Brownias* are splendid plants, and the colouration of the young leaves, when first developed, is most pleasing and effective.

The following three plants in the Palm-house claim our attention:—First is an East Indian Jessamine (*Jasminum hirsutum*). The thick-set, deep green, simple, hirsute leaves, and the large bunches of very fragrant, snow-white flowers contrast admirably, and render the species a most desirable and attractive one. Considerably more than a century has elapsed since its introduction to English gardens; but, at the present time, it seems far from common. *Hoplophytum calyculatum*, a pretty Bromeliad from the interior of the province of Santa Catharina, in Brazil, has a dense capitulum of citron-yellow flowers borne on a scape nearly as long as the leaves. Like most of the Bromeliads, this is of the easiest cultivation. *Pittosporum zeylanicum* is an evergreen shrub, with greenish-white flowers, the great number and sweet scent of which make up for deficiency in brightness.

Vaccinium erythrinum—introduced by Messrs. Rollison, from Java, in 1852, is now in flower in the Winter-garden. It is a compact, handsome, evergreen shrub, the young branches, as well as the petioles and mid-ribs of the leaves being red, and the terminal clustered racemes bearing drooping reddish-purple flowers. *Phylla ericoides* is a Rhamnaceous bush, from the Cape of Good Hope, which

was cultivated by Philip Miller, in 1731; it is of neat habit, and the little white flowers are slightly odoriferous. We are told that about Liebon this plant has naturalised itself and covers considerable tracts in the same manner that Heath does in this country.

Leucopogon Cunninghamii and *L. lanceolatus* are two graceful greenhouse shrubs from Australia; they have neat foliage and drooping spikes of small white flowers. Both may be seen in No. 4, and are well worth a place in every collection of cool-house plants.

Aphelandra nitens is in flower in the stove. The beautiful metallic polish of the upper surface of the leaves and the dark reddish-purple of the under combine with the bright scarlet of the corollas to make this species one of the most handsome of all the *Aphelandras*; it is a native of Guayaquil in New Grenada, whence it was sent to England by Mr. Pearce, when collecting for Messrs. Veitch.

Several distinct shades of colour may be observed in different plants of that splendid little epiphyte, *Sophranitis grandiflora*. The vivid orange-red flowers of *Masdevallia Veitchiana*, being flushed with purple, are very striking. *M. ignea* and *M. amabilis* have similarly shaped flowers, and, though not so fiery as *M. Veitchiana*, are equally vivid in colour. Nearly all the *Masdevallias* come from considerable elevations on the Andes of Peru and New Granada, and, consequently, require a cool and constantly humid atmosphere. Not many years ago, but very few species were known; now, not far from a hundred are to be found in cultivation. Almost, without exception, they are strikingly beautiful little plants, and a good collection might be grown in less room than that occupied by three specimens of some of the larger growing Orchids. *Dendrobium formosum* is a magnificent species with very large flowers—white, with the exception of a yellow blotch at the base of the lip. *D. heterocarpum* has cream-coloured petals and sepals, the lip being deep, almost golden, yellow, streaked and veined with reddish lines. This is a handsome and fragrant species, and was received at Kew from Assam in 1852.—†

Enormous Shaddocks.—Messrs. Garcia have in their windows, in Central-row, Covent Garden, Shaddocks that remind one of the King of the Pumpkins. We had no conception that any of the Orange tribe could bear such large fruit. They weigh 8 lbs. each, and come from the West Indies.

New Potatoes.—On the 7th inst., at Biarritz, a friend provided me with a good sample of new Potatoes for dinner, taken from the open ground. The seed was planted in August last.—W. N.

Narcissus Clusii.—This pretty Hoop-petticoat *Narcissus* is now finely in flower in the Hale Farm Nurseries, Tottenham. Bulbs of it were planted in August last year in a temporary frame and light sandy soil; and the abundance of bloom which they are now producing shows the advantage of planting in time for the bulbs to make good growth and become established during the summer. Imported bulbs, though planted immediately they arrive, cannot be expected to flower well the same year.

Dendrobium Wardianum.—A plant of this magnificent *Dendrobium*, now in bloom here, has upwards of sixteen flowers on one growth. The plant is one of recent importation, and the flowers are individually much larger than those of the ordinary type, being 4 in. across.—WILLIAM COTTRELL, JUN., *Eccles Old Road, Pendleton*.

Iris alata.—This lovely *Iris* is now flowering beautifully at Tottenham. The greatest drawback to its culture is the flowers being spoilt by soil-splashes during heavy rains. If, however, the bulbs were planted among *Stoncrop*, or in Grass, on warm sheltered banks, their pale blue blossoms would remain uninjured, and would prove a source of attraction when our gardens are comparatively flowerless.

Migration of Plants.—In a part of Holm Fen, near the Great Northern Railway, are springing up, apparently spontaneously, hardy Heaths of several species. Years ago the land was under water, but is now well-drained, and will, no doubt, in the course of time, be brought into cultivation. I mention this as an instance of the way in which Nature clothes bare surfaces with what is perhaps the fittest covering for the time being. But the question that rises uppermost in the mind is, how did the seeds or plants get there? For there are no such plants within miles of them. Have they been transported thither by water, or wind, or how?—E. HOBDAY.

A White Odontoglossum Alexandræ.—A plant of this is now in flower in Mr. Day's garden at Tottenham. Its petals are broad and full, and beautifully imbricated, and as white as driven snow, not a shade of any other colour being visible except the rich golden eye. For the spotted variety this makes a charming companion.

WITH the next number of THE GARDEN, the last of the year, the Index, &c., and an engraved portrait of Mr. James McNab, of the Royal Botanic Gardens, Edinburgh, will be published in the form of a supplement of 16 pages.

Foreign Edition of "The Garden."—An Edition of THE GARDEN is now printed every week on thin paper for transmission to foreign countries. In this manner the weight is kept within that allowed to be sent to all countries within the "postal union" for one penny. This will facilitate the distribution of the paper in America, the Colonies, and on the Continent.

Eucharis candida.—Specimens of this beautiful plant are now flowering freely in Mr. Bull's nursery, at Chelsea. With the value of *E. amazonica* for bouquet-making, every one is acquainted, but for some purposes this small flowered kind is even more suitable. Associated with it are well-flowered specimens of *E. amazonica* and *Pan-cratiun speciosum*, three of the best and most sweetly-scented tender flowering plants in cultivation.

Angræcum sesquipedale.—Several large, healthy plants of this Orchid are now rapidly opening their blossoms in Mr. Williams' nursery at Holloway. A singular circumstance connected with this *Angræcum* is that from the time the tails of its flowers commence to develop themselves until they have done growing, they are in perpetual motion, doubtless the result of rapid growth and a strong flow of sap.

A New Belgian Grape.—We have a portrait showing a large, handsome Black Grape, called *Muscat Charles Alberdienst*, now being sent out by Mr. C. Alberdienst (30, Rue des Douze Chambers), Ghent, Belgium. We know nothing of the fruit; its introducer describes it as one of the best varieties known. The plate shows a large, handsome, tapering bunch, resembling a Dutch Hamburg.

Odontoglossum Roezli.—One importation of about 2,000 plants of this beautiful Orchid has just arrived at Messrs. Veitch's nursery, at Chelsea. Each of the plants were fastened with wire to pieces of wood, and stood upright in deep boxes, with small strips of wood between each row to keep them from moving, and although they have been on the journey over six weeks their foliage is as fresh and healthy as if just gathered; a white variety has pushed into flower on the way.

Garrya elliptica in Pots.—This pretty winter-flowering, hardy shrub makes a good pot plant for the cool conservatory. We lately saw a quantity of plants of it in pots in Messrs. Osborn's nursery at Fulham, which were literally laden with pendent racemes of blossoms. In vases, or on pedestals, such plants are very ornamental, and last uninjured for a long time, provided they are not subjected to a very warm temperature.—S.

Odontoglossum crispum.—One of the best varieties of this lovely Orchid which I have seen this year is now in flower in Mr. Bull's nursery, at Chelsea. On one spike, which is gracefully arched, are nearly twenty large, crisp, waxy, beautifully-coloured blossoms. The plant in question is only a small one; what, therefore, may we not expect from well-established examples of it grown beyond the reach of London smoke?—P. W.

Luculia gratissima in Small Pots.—Young plants of this beautiful greenhouse shrub, in Messrs. Osborn's nursery at Fulham, are now especially attractive. They were struck from cuttings just before the flower-buds showed themselves, and the result is neat plants, from 6 in. to 8 in. in height in 5-in. pots, surmounted by a large head of deliciously fragrant blossoms. The *Luculia*, being somewhat difficult to convert into a bushy specimen, a good effect might be made by placing eight or ten plants, similar to those just alluded to, in a deep pan or pot just as they showed flower.

Odontoglossum Uro-Skinneri.—Few Orchids last in flower for so long a period as this. Its flower-spikes, which often reach 5 ft. in length, continue to grow and bloom for several months in succession; the blossoms themselves, too, keep in good condition for a long time in a cut state. It is a cool-house Orchid, easy to grow, and should be found in every collection.

Lælia carminata.—This, though seldom seen, is one of the most attractive of winter-flowering Orchids. Its blossoms remind one of those of a *Bougainvillea*, as far as colour is concerned, but they are much more delicate in texture. Good examples of it are now in flower in Mr. Day's collection at Tottenham.

Gentiana acaulis in Pots.—Flowering plants of this *Gentian* have lately made their appearance in Covent Garden Market. Considering the easy culture of this plant, and the length of time during which its blooms last, it is surprising that it is not more extensively grown in pots than it is for the decoration of the cool greenhouse or conservatory at this season of the year. If good plants of it be divided in spring and each piece be planted out in good sandy soil and leaf mould in a sunny situation, they will make good-sized plants by autumn, when they may be lifted and potted in 5-in. pots, well watered, and placed in a shady situation until again established, when they may be placed in a cold frame to which plenty of sun and air

are admitted. When in flower they may be removed indoors, and if a little weak guano-water be given them once a week they will continue to grow and flower all through the winter. In spring they should be again planted out and treated as before.—S.

Angræcum bilobum.—This, one of the prettiest of small-growing Orchids, may now be seen in flower in Messrs. Veitch's nursery at Chelsea. It bears pure white, waxy, star-shaped blossoms which last for a long time in good condition.

Bolbophyllum odoratissimum.—This pretty little Orchid, now rarely seen, is at present in flower in Messrs. Veitch's nursery at Chelsea. Its blossoms are perhaps more singular than handsome; but they are very sweetly scented, and on this account are largely used by the Burmese ladies in the decoration of their hair.

The Exhibition of the Pelargonium Society for 1878 will be held in the gardens of the Royal Horticultural Society at South Kensington, on Tuesday, June 18, in conjunction with the Rose show to be held on that date. The schedule is now ready, and includes thirty-four classes, in which the prizes amount in the aggregate to £111. It may be well to remind cultivators that members only can compete.

Agave yuccæfolia.—This is a narrow and curved-leaved spineless plant, lax in growth, attaining a height of about 2 ft. The leaves are about 2 ft. long, and dark green, with brownish spots on their

Agave yuccæfolia.

under sides. When well grown, it makes a good and useful bracket plant; the flower-spike is slender and graceful, and the plant generally has more the habit of a Yucca than that of an Aloe.—J. CROUCHER.

Poinsettia pulcherrima.—This may now be seen in such quantities, at Old Sneyd Park, near Bristol, as to produce quite a dazzling effect. Large quantities of it were struck in July and August, and grown on for flowering in small pots, which are useful when the plants are wanted for house decoration, and the restriction of the roots keeps the plants dwarf. Those in question vary from 6 in. to 18 in. high, and their scarlet whorls of floral leaves measure from 17 in. to 18 in. in diameter. Many larger specimens may also be seen at the same place, with whorls of bracts that measure fully

23 in. across, and there are as many as forty-eight in a whorl, and thirty-six whorls on a plant. Is not this an unusually good result?—E. M.

New Kind of Christmas Trees.—A new sensation might be made in many households this Christmas if the stereotyped Spruce Fir were ignored for the children's party, and well-shaped pyramid Holly, all aglow with rich scarlet berries, substituted in its place. Many thousands of these in nurseries are this year literally covered with berries, and as, in all well-ordered establishments, these are annually transplanted, they have a compact bunch of roots instead of the few long, woody roots usually found on the Fir. Instead of being placed in the heavy, clumsy flower-pot, they should be planted up in neat, round wicker baskets, lined inside with Moss to prevent the soil from passing through, and be also dressed over the surface with Moss. The basket and its dressing of Moss would afford many vantage points for the fixing of the tiny ornaments, whilst in dressing the tree care should be taken rather to make its berried beauties prominent than to overburden it with tawdry decoration. There is room for the development of taste even in this small matter.—A. D.

Two Rapid-Growing Trees.—Three-year old trees of *Alnus Oregona*, range up to 10 ft. high. In general appearance this tree does not materially differ from *A. glutinosa*, but in rapidity of growth it far surpasses it. Three-year old trees of *Fraxinus Oregona* range up to 6 ft. high. The foliage of this is somewhat larger and brighter than that of the Common Ash, and the bark of the young shoots is black and shining. These trees would, probably, not be quite hardy in the colder parts of England, or perhaps in some few central spots in Ireland, but here, within six miles or so of the sea, they grow freely. A rather curious circumstance connected with them is that, this last summer, though very wet and cold, the Ash has grown much more than in the previous summer, which was much warmer, whereas, quite the contrary is the case with the Alder, which has not grown this season much more than half what it did in the previous one.—T. SMITH, *Newry*.

NOTES AND QUESTIONS ON TREES AND SHRUBS

Garrya elliptica.—Several fine specimens of this, the most beautiful of all evergreen winter-flowering shrubs, growing against a wall in the Wood Lane Nurseries, at Isleworth, will shortly present a striking appearance, they being now heavily laden with long pendent catkins full of flower buds.—S.

Birds and Holly Berries.—Hollies as a rule are this season loaded with berries, but the birds have already begun to take them; a good sized bush of the *latifolia* that ripened its fruit very early, and was particularly bright and beautiful, has now not one berry upon it. I never remember to have seen birds attack the Holly before, until driven to do so by hard frost and snow.—T. SMITH, *Newry*.

Standard Euonymus.—All the variegated leaved varieties of *Euonymus* make interesting and useful plants when grown in the form of standards on clean stems, from 2 ft. to 3 ft. high. Numbers of them are grown in this way in Messrs. Lee's Nursery, at Isleworth. All the kinds, including the silver leaved *E. radicans*, are grafted on stocks of *E. europæus* at the desired height; they make bushy heads quickly, and when planted in beds or on lawns are handsome objects.—S.

The Holly and Mistletoe Season in Sherwood Forest.—It is just now worth any one's while to pay a visit to the Holly and Mistletoe growing parts of Old Sherwood Forest. So rich and grand is the display of red berries on the one hand, and pearl berries on the other, that old foresters say they never saw the luxuriance excelled. The past year has been most favourable for the growth of both Holly and Mistletoe, but especially for the latter. Some of the Hawthorn bushes fairly bend with the weight of their excessive growth of the parasite.

Menziesia polifolia alba.—Where there is a demand for flowers during autumn and winter, this should be grown extensively. Plants in large beds of it in Messrs. Rollisson's nursery, which were in full bloom all summer and autumn, have just made new growth, and will produce abundance of white blossoms, which are admirably adapted for making into small bouquets all through the winter.—S.

Trees in Washington.—The trees most largely planted are named in the order in which they are valued by the Commission. First is the Silver or White Maple (*Acer dasycarpum*), then American Linden (*Tilia americana*), American Elm (*Ulmus americana*), Scarlet Maple (*Acer rubrum*), Box Elder (*Negundo aceroides*), Sugar Maple (*Acer saccharinum*), American White Ash (*Fraxinus americana*), English Sycamore (*Acer Pseudo-Platanus*), Button Ball (*Platanus occidentalis*), Tulip Tree (*Liriodendron Tulipifera*), Honey Locust (*Gleditsia triacanthos*), and Norway Maple (*Acer platanoides*). These, and some twenty other kinds in smaller numbers, are set from 20 ft. to 25 ft. apart, and there are miles and miles of streets in which not a dead tree, or one diseased, can be seen, showing that the planting must have been done in the best possible manner.—P. HENDERSON.

WINTER PROTECTION.

This important and oft-explained precaution, that demands attention yearly, may seem to the more experienced too trite to afford much interest even at this season of the year. But it should be remembered that all are not experts, and that, with all due respect to superior knowledge, even experts may catch a slight suggestion of value from the recorded experience and methods of others. We apprehend, however, that the principles on which secure protection is based remain much the same everywhere—the only variation consisting in certain changes of methods that adapt them to any peculiar circumstances. The following remarks will suffice to indicate the processes that have with us proved most successful:

THE PROPER SEASON FOR APPLYING WINTER PROTECTION.—A strong temptation to cover up plants for winter presents itself to the inexperienced during the first cold snaps of November. The ground is firmly frozen, and now it seems natural to suppose the time for winter covering has arrived. But there never was a greater mistake. Such early spells of cold usually last but a short time, and may be succeeded by much warm weather, thus exciting the sap of the plant under cover, and thereby exposing it to injury from a succeeding heavy frost. The hardening off process is as necessary to the plant in the open ground, as under a proper system of greenhouse culture. Several really cold periods in early winter, brought to bear on the uncovered plant, serve to prepare and adapt it for the endurance of subsequent hardships. Little injury, moreover, occurs from cold in December to any tolerably hardy plant. It is the proper season of rest, and the diminished power of the sun works the less damage, because dawn and midday present no such violent contrasts of temperature as are wont to appear in early spring. A large majority of all plants that die from the effects of cold, die, therefore, in March and April, and hence the danger of removing covering too early in spring. Give, then, such plants as you wish to remain out all winter, a good freezing, and protect with judgment any time from the first to the middle of December.

INJURIOUS METHODS OF PROTECTION.—It is not uncommon to hear people claiming credit for extra care given to their plants in winter because they have covered them with a barrel, or some other close protection. Nothing is really more injurious. The air, being confined, becomes colder, and concentrates its effects on the plant until one might term it a case of smothering with cold, if such an expression were admissible. All hardy, or even half-hardy vegetation requires, during winter, some of the influences that come with the free action of the outer air, which also serve to temper, at the same time, the otherwise concentrated cold. Not only is such close protection unsafe, but we should seek the thinnest, lightest covering that will shelter from sun and sleet. All heaping of hay, earth, &c., too high about the plant is to be avoided, and especially should care be taken to leave untouched with the knife any growth of plants, like Roses, which require sharp pruning to develop flower-bearing wood. Such excision only makes an entrance for cold and rain, to the consequent rotting or freezing of the heart of the plant. The pruning can be safely performed in spring.

THE SAFEST METHOD OF PROTECTION.—Heap a moderate amount of earth about the plant from one to six inches deep, according to its size and nature. Cover this with a light mulching of leaves or hay, and then apply a sort of hood over the top by means of evergreen boughs stuck in round about, and left sufficiently open to allow a free play of air without too much exposure to sleet and sun. Should evergreen boughs be scarce, a convenient hood may be constructed by tying the ends of a bunch of straw together, and then hanging it over a stick somewhat taller than the plant and inserted in the ground alongside it. This may be so adjusted as to protect sufficiently the foliage of the plant, which is all we need desire. Such simple methods of protection are available for every one, and were their employment more general, we should hear less of winter-killed Rhododendrons and other evergreens, planted perchance where we could hardly expect a Norway Spruce to pass unscathed. Fate seems to ordain that a beautiful and choice plant, slightly delicate in winter, must be the very one to take the most exposed and unsuitable position. Wherever this is necessary, however, a judicious system of winter protection at least should be followed.—S. PARSONS, in "Moore's Rural."

Tritoma grandis in Ireland.—This charming winter flowering plant is now in great beauty here and promises to continue so for some two months yet to come. It will of course require some protection during frosty nights, which is easily effected by means of Spruce branches and mats. In most gardens they will, I imagine, have done blooming, and I attribute the flowering so late of this plant here to its being transplanted in April; for I find that transplanting has a wonderful effect in retarding the blooming period of this and of

T. Uvaria. I had to move some of these last April, but one clump of T. Uvaria remained undisturbed; this flowered at the usual time, but the transplanted ones did not show a single spike until the plants in the clumps in question had done flowering, thus prolonging the blooming period to twice its usual length. After T. Uvaria was over, T. grandis began to push up its spikes, which were not altogether over before the transplanted ones followed in succession, thus giving us Tritomas six or seven months instead of as many weeks.—THOS. SPELMAN, Derry Castle.

Plants in Bloom in Anglesey.—I have sent you a few specimens of flowers now in bloom here* in the open air; I could have added a Gloire de Dijon Rose, but that I want to save them for Christmas. I have seen several inquiries in THE GARDEN as to getting the Anemone to bloom early. This year and last year mine were in bloom from the end of September until the middle of May; they are a mass of bud now. I simply put them in the ground and never lifted them, and never protected them in any way. The Gazania stood out in the open ground unprotected last winter, and the blooms sent are from these plants; the Mignonette the same; the Lobelia gracilis is as full of leaf and blossom as if it were midsummer; the Globe Artichokes are in full foliage in the kitchen garden, and have plenty of young heads on them. About a week or ten days ago we had a slight frost in the afternoon, which changed during the night to rather high wind and rain. The next day, to my surprise, every Holly, of which I have a great number, shed most of its leaves, though not in the least discoloured. No other evergreen was affected, and I never noticed a similar instance before; the berries also fell.—W. L. BANKS.

Peristrophe angustifolia aurea variegata.—This is a graceful fine-foliaged plant with a dense-spreading habit. Its leaves, which are ovate-lanceolate in shape, are golden-yellow in the centre, margined with dark green. It succeeds either in a stove or greenhouse, but it is much improved both in colour and habit by keeping it in a stove. It is readily propagated by means of cuttings placed in a slight bottom heat. As regards soil, it likes a light loam, mixed with a little leaf-mould and sand. When the pots get well filled with roots it enjoys copious supplies of weak liquid manure. It flowers freely if allowed to do so, producing blooms of a lilac-purple colour, very much resembling those of the old Justicia speciosa. What is worth knowing is that it is never attacked by insects of any kind. From its habit of growth I should think it ought to make a pretty basket plant, where such is desired, as its branches hang down most gracefully over the side of the pots, almost concealing them from view. In order to have a good pot specimen of it, it requires a little training, and only a little. I place a neat stake for the centre shoot, and six or seven at equal distances apart round the edge of the pot, inclining their tops outwards; to each of these I tie a shoot and pinch them back to 8 in. When side shoots are produced from the axil of every leaf, these I allow to grow at their own free will. A plant of it in the stove here in a 7-in. pot is 2½ ft. through, and nearly as much in height. It is associated with Ferns, amongst which it has a delightful effect.—T. SPELMAN, Derry Castle.

Old Hardy Plants.—Can any one tell me where to procure Ranunculus pyrenaicus fl.-pl., R. gramineus fl.-pl., Parnassia palustris fl.-pl., or the double white Primula pyrenaica mentioned by Parkinson?—W. E.

Eryngium Serra.—This highly ornamental Sea Holly is perfectly hardy, and if planted out in spring in rich sandy soil, will, by the following autumn, attain large dimensions. Its spreading Agave-like leaves, which are produced close to the ground, render it one of the best of green-leaved subjects for planting on raised positions in any part of the garden or pleasure grounds.—S.

Helleborus angustifolius.—This is one of the best of Christmas Roses. Its flowers, which are produced several weeks earlier than those of H. niger, are of the purest white, large, and of good substance. In bouquets they are much more effective than those of the ordinary Christmas Rose, which usually have greenish tinted petals. On a bed of it in Mr. Parker's Nursery, at Tooting, the blossoms are just beginning to expand.—S.

Imported Lilies.—I see that "Dunedin," in his article on Lilies (see p. 557), refers to an importer, who advertises in your paper, and rather leads people to believe that they cannot reckon on imported Lilies flowering the first season. In fairness to the person alluded to, I must say that last year I bought 100 bulbs of him at 1s. each; I planted them here and there in Rhododendron and other beds, and, so far as I know, not one failed to flower, and some produced as many as seven blooms—in my opinion a very satisfactory result.—STEWART HARDY.

* Hydrangea, Fuchsia, Primroses, Virginian Stock, Nasturtiums, Double Fervew, Snapdragon, Saponaria, Omphalodes.

THE INDOOR GARDEN.

ORCHIDS FOR WINTER BLOOMING.

ORCHIDS now opening their blossoms, or showing signs of soon doing so, will require some attention, otherwise there will be a great display at one particular time, and none afterwards. To avoid this, a little skilful management is required; for instance, while we may expect a considerable amount of gaiety to be maintained for some time by the plants which we have enumerated during the past few weeks, we must look ahead, and endeavour to so regulate the supply as to have a succession. The flowers of both *Dendrobium Wardianum* and *D. crassinode* are on the point of expanding, and as they are comparatively short-lived, a few plants of each species should be removed to a cool house, and kept comparatively dry, by which means their progress will be retarded for a long time. I may remark, in passing, that the original form of this plant is a much later bloomer than the more robust growing kind which has, during the last year or two, been introduced in considerable quantities. The same remarks as to retarding will also apply to that old, but universal favourite, *D. nobile*, some of the flowers of which are opening now, but we do not want them all at once. *D. japonicum* does not find much favour with the higher class of Orchid growers but it is really a desirable species where choice and delicate flowers are required for cutting. It is a dwarf, free-growing plant, which bears cutting well, and it is seldom quite without flowers at any time of the year. It varies in colour from pure white to deep rose, and is admirably adapted for bouquet-making. The genus *Bletia* is not a fashionable one, but one species, *B. Shepherdii*, produces, during the winter months, finely-branched panicles of rich purple flowers, which last a long time. It therefore deserves a place in every collection. There are several other fine varieties of *Bletia*, but as they bloom later in the season I shall not now further allude to any of them.

A Study of Foliage.

Having said something about retarding Orchids, I must next week add a few words on forcing them. This is a somewhat vexed question; nevertheless, I have seen Orchids forced in many instances, and with good results.
W. H. G.

CHINESE PRIMULAS AT BIRMINGHAM.

A RECENT visit to Birmingham afforded a favourable opportunity to inspect the Chinese Primroses grown by a well known cultivator — Mr. Tomkins, of Sparkhill, a suburb of that town. Mr. Tomkins raised and sent out, a few years ago, two very fine kinds, named respectively *Princess Louise* and the *Marquis of Lorne*, the first a fine white, and the latter a good deep coloured purple; and it was not improbable that with such seed parents some further fine kinds might have been produced. In one respect, my visit was too early, as the great mass of plants were yearlings, and would not be in full bloom before the middle of March; these, however, were chiefly the stock of the two above named kinds, and as, of all the best sorts in Mr. Tomkins' hands, some few very fine old plants were in flower, it was possible to see each variety in its very best form, as it is an acknowledged fact that *Primula* plants of the second year invariably produce the finest flowers. At Sparkhill, *Primulas* are grown in broad, light, airy, span-roofed houses, but rather too high; and to this defect is to some extent attributable the fact that the plants generally are more drawn than would be the case if kept near the glass. The difference in the seedling plants which I recently saw at Messrs. Suttons' Reading Nursery and those at Sparkhill was most marked, and the same might have been said of the young double sorts as compared with those which I saw a few years since in the span-roofed houses at Messrs. Henderson's nursery at St. John's Wood. Probably the dense smoky atmosphere of Birmingham has something to do with the matter, and it is but fair to Mr. Tomkins' grower to say that in all other respects his young *Primulas* were

worthy of commendation. The cream of the collection just referred to was about a score of very fine plants of single kinds growing in 6-in. pots, all of the second year's growth, and nearly all in fine flower; these were elevated on inverted pots, and thus brought nearer the light, and the benefit was apparent in the robust, yet generally compact, habit of growth, especially in those of the Princess Louise variety, which has, in a marked degree, the sturdy and compact habit so peculiar to any good strain of white-flowered kinds. There were also numbers of fine double sorts, mostly in good bloom, and although not such large plants as those shown by Mr. Gilbert, they were perhaps more compact in growth, and the best kinds produced flowers of fine quality. Of these Mr. Tomkins has raised some good kinds, his *alba magnifica* (white shaded rose) having received a first-class certificate at South Kensington. Some of the best also were from Messrs. Henderson's fine collection; but, except that they were some of the best-grown large plants of the double kinds I have seen, I much doubt whether any of the more recently raised double kinds excel those raised by several growers in the neighbourhood of Southampton some ten or twelve years ago. Unless sent from a distance, it is, however, a remarkable fact that we never see such fine examples of the culture of the double *Primula* shown in London, and it is but fair to conclude that just now the best plants of these are to be found at Sparkhill and at Burgley. Like Mr. Gilbert, Mr. Tomkins gives his large plants generous cultivation; this is the secret of the fine robust foliage and fine flowers which some of them produce. A mixture of sweet fibrous loam and well-rotted cow-manure, with a sprinkling of crushed charcoal, makes a good compost for Chinese *Primulas*, and Mr. Gilbert bears testimony to the value of a good drainage, consisting of pieces of charcoal, as not only keeping the soil free of superfluous moisture, but also as tending to sweeten and purify it. Of large single-flowered plants then in bloom, I found specimens of the two kinds named; also the rich carmine-coloured variety on both the plain and Fern-foliaged sorts, a few having salmon-tinted flowers and Fern foliage, and the purples also on both forms of foliage. The Princess Louise kind has flowers of good substance; they are also very large and massive, and are produced in large heads. The colour is white, shading off to rose as the flowers age. The Marquis of Lorne has the usual dark foliage associated with purple flowers, and it is of the habit generally found in all dark-coloured strains. The flowers are large, of good substance, and of good colour, the shading being deepened towards the edges of the petals, and increasing with age. This kind does not excel the good purple strains, with which we have long been familiar, except in a trifle more substance of petal; but the edges of the flowers are less fimbriated. The carmine kinds are identical with what Mr. Bull has sent out under the name of the Florence, and are also precisely similar to what has long been grown as *splendens grandiflora*, a rich rosy-carmine. With this strain I have long been familiar, as it was common in the south ten years since, and is found plentiful there now. In saying this I do not wish for a moment to detract from the merits of the plants seen at Birmingham, but it would be absurd to assert that these constitute a strain peculiar to that part of the country. If any one doubts this, it is but necessary to refer to some of the drawings made of flowers ten years ago, by which it will be seen that in the way of obtaining varieties of the single *Primula* we have rather retrograded than progressed. The salmon kind is as well known as the carmine, and is one of the most pleasing forms of all; the foliage of this kind, whether Fern or plain, is at all times of a pale green hue, and, without doubt, it sported originally from the white variety. The beautifully flaked forms were not found at Sparkhill, neither were the lavender-tinted kinds, except in a semi-double state. Perhaps the best single kinds ever found in the hands of any firm were those grown a few years ago by Messrs. Windebank & Kingsbury, of Southampton, who had some fourteen to sixteen kinds all distinct. Mr. Tomkins' chief novelty is a single plant of a two-year-old seedling from the Princess Louise, on which there are two trusses bearing already several expanded blooms; these are of the same hue of colour as the parent, but of very large size for a *Primula*, and the petals are so full that the edges, instead of overlapping, seem to force each other up, and the flower is so crumpled that it presents quite a semi-double form. To those who would judge the merits of a flower by its evenness, flatness, and precision of shape, this would of course be a great defect; but, fortunately, stern florists' rules are not enforced in the case of the Chinese *Primrose*, and the peculiar form displayed in Mr. Tomkins' seedling plant will add materially to its popularity. The foliage of this plant is of a very robust but compact Fern kind. Carefully crossed in a high temperature with other colours, no doubt this plant might be induced to yield some beautiful and novel kinds. One of the most striking novelties in the Chinese *Primula* which I have seen is now in the hands of the Messrs. Suttons, at Reading. It is a break from the white variety, the result being a strain having dark foliage and flowers of a deep, rich rosy-purple hue, that deepen with age, yet retain that close, compact

habit, so peculiar to their white variety. This will prove to be a valuable addition to this family of winter-blooming plants. To be successful in seeding the Chinese *Primula* great care is required at this time of the year; it is useless to attempt fertilisation with the brush except at a temperature of from 50° to 60°, as the pollen must be dry to be fertile; damp is also a most destructive enemy to the flowers. A. D.

Dwarf Poinsettias.—We have here a number of old Poinsettias which were liberally treated in order to induce them to push strong shoots, and in the end of August the tops of these were taken off, potted in 3-in. pots, and plunged in bottom heat. By this method we get dwarf plants with heads of bracts double the size of those obtained in the ordinary way. About a fortnight after the tops were taken off, the old plant pushed a somewhat deformed shoot that made slow progress for a few weeks, but afterwards it grew freely, and at the present time it has three heads of bracts on it of medium size. The new Poinsettia *plenissima* is a valuable addition to the above, not only because it was a greater number of bracts of better colour but because it keeps in good condition till February. We had one last year that kept well even till March.—T. COATS, Pains Hill, Cobham.

An Indoor Town Garden.—I called the other day at Messrs. Pounce & Son's establishment, 18, Westbourne Grove, where I was much pleased with some beautiful Fern cases, baskets, and vases, all tastefully arranged in an upstairs room devoted to a special show for the season. The room is, indeed, literally a floral bouquet, but the best thing which I saw was a side window fitted up as a case; at the bottom is a tank, in which water plants seem to be perfectly at home; there is rockwork up the sides clothed with *Ficus repens* and Ferns hung in rustic baskets. What is chiefly conspicuous is the elegance of arrangement, and the proof afforded by it that if townspeople chose they might, without much trouble, enjoy some of the beauties of the floral world at all seasons—not, as is too often the case, badly arranged on ugly wire stands, but placed in natural-looking cases, vases, and baskets, that assist rather than mar Nature.—J. CROUCHER.

Improving Ageratums.—A few years ago it occurred to me that the *Ageratum* possessed many qualities, which, if properly developed, would bring it to the front as a bedding plant; evidently it had not had that attention bestowed on its improvement which its merits deserved; I resolved to try what could be done with it. After procuring a few packages of the best seed I could get, I sowed it, and raised a large number of seedlings, which were very disappointing, scarcely one was worth keeping; very late in the season I discovered one which was a decided improvement, and which was afterwards named Countess of Stair, and was sent out a few years ago by Mr. Williams, of Holloway. The principal step in advance made by this batch of seedlings was variety of colour; seed was saved from the best varieties, taking into account colour, habit, and constitution. For a number of years the same process has been going on, and the result is highly satisfactory; we have now got almost every shade of blue, not a few approaching pure white, others white with red buds, the flowers tipped with pink and other shades of red, some flesh-coloured; a scarlet is within the range of probability. We have now a few varieties possessing all the requisites of first-class bedding plants—abundant flowers, striking colours, strong constitutions, compact and moderately dwarf habit, and as easily kept over the winter as *Pelargoniums*. We test the best varieties by growing them in beds and lines. Those which attracted most attention last session were—Lady Jane (sent out by Mr. Williams last spring), colour blue, 12 in. to 16 in. in height, abundant flowerer and free grower, with fine constitution; Beauty, fine dwarf, nearly white variety, a pretty distinct bedder, from 8 in. to 10 in. in height, comes early into flower, has a strong constitution, and is easily wintered; Cupid, the finest of all the dwarf blues, very fine bedder, compact habit, from 6 in. to 8 in. in height, comes early into flower, strong constitution, and consequently easily wintered.—A. FOWLER, in "Gardener's Chronicle."

THE extent to which floral decoration is carried on among the wealthier classes in America may be inferred from the following extract, descriptive of a recent marriage in the Vanderbilt family. The marriage-bell hung in front of the Fifth-ave window of the parlour. Its rim was within 6 feet of the floor, and it was 4 feet in diameter. The lining was all of white flowers, and the same kind of flowers on the exterior were varied on three sides by clusters of Pansies, masses of Roses, and Victor Hugo Carnations. On the front of the bell, the monogram, composed of the letters T and V, was arranged in block letters, the T being of Violets, and the V of maroon Carnations. The clapper was a closely packed pendant of scarlet *Bouvardia*.

VALLISNERIA SPIRALIS.

THIS interesting aquatic plant grows abundantly in running streams in the south of Europe. It is a perennial, producing from a very short stem numerous pale-green, Grass-like leaves, about $\frac{1}{4}$ in. in breadth, and from $1\frac{1}{2}$ ft. to 2 ft. in length. The flowers of the two sexes, which are borne on different plants, are totally distinct from one another. Those of the female have a cylindrical ovary, bearing at the top three small, spreading calyx lobes, enclosing three stamens and three stigmas, the whole being confined in a tubular spathe. Each flower is borne at the end of a very slender, spirally-twisted stalk, which uncoils in proportion to the depth of the water, so as to let the flower float on the surface. The male flowers are very minute, white, and globular, seated upon a short stalk just emerging from the base of the plant. When matured, they separate from the stalk, and rise with their own buoyancy to the surface, where they float about, allowing their pollen to escape, and fertilising any female flowers with which they come in contact. After fertilisation has taken place, the stem coils up, drawing the flower to the bottom of the water, where it perfects its seeds. The leaves of this plant are very beautiful when seen under the microscope, and so transparent as to allow the observer to watch the movements of the fluids

Vallisneria spiralis.

contained in the cellular tissue. It can be grown in any vessel containing from 9 in. to 12 in. of water, either in the drawing-room or conservatory, taking care to keep the water clean, and as far as possible of a uniform temperature. Sandy loam suits it best, either potted and then plunged in the water, or planting at the bottom of the vessel. If in pots, they may be surrounded and hidden from view by pieces of ornamental stone; and I would recommend this mode of culture in preference to planting in the vessel, as the pots can be easily removed and cleaned when necessary. A. P.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Chamædorea glaucifolia.—This is one of the most graceful of Palms, having long Grass-like leaflets. Well-grown plants of it in 6-in. pots are admirably adapted for room decoration. It grows rather tall, but in other respects it would make an excellent market Palm.—C.

Luculia gratissima.—A number of plants of this in full flower are making a fine display just now in Mr. Williams' nursery at Holloway. This glorious shrub would doubtless be oftener met with than it is were its culture better understood. It is generally thought to require a stove; but an intermediate house suits it best.—S.

Abutilon rosæform.—For market purposes this rosy-flowered Abutilon will, no doubt, ere long be largely grown. Its dwarf, branching habit renders it suitable for culture in small pots, and the profusion of flowers which it produces for months in succession, would make it saleable for a much longer period than that allotted to most plants.—Q.

Lapagerias in a Cold Pit.—A well-established plant of *Lapageria rosea*, trained along the back wall of a brick pit in Mr. Parker's nursery at Tooting, has lately been flowering profusely, and, to all appearance, will continue to do so for some time yet to come. The pit, which is not heated in any way, is used for hardy Ferns. Any one, therefore, having a small unheated house, may grow a plant or two of this valuable climber. At Gunnersbury, trained outside, it flowers freely every year, but its roots are inside.—R.

THE FLOWER GARDEN.

THE WILD PLANTS OF NEW ENGLAND.

I do not know that it will be especially interesting to your readers if I give you some account of a few of the wild plants which grow in limited localities in Massachusetts. But, residing for a short time on the sea-shore in the southern part of our State, near Buzzsaw Bay, I have thought that a brief notice of the plants met with might be useful to all lovers of the wild garden, of which you are so zealous an advocate. To me occasional visits here have been specially attractive and pleasing, as well as instructive, giving me an opportunity to renew my acquaintance with the flowers of my boyhood, when I tramped miles—through wood and field, and pasture and swamp—in search of plants which I find all here in the small space of a few acres. The grounds are situated on a cove opening into the bay, and extend a quarter of a mile or more along the shore, running back about the same distance to the town road. On the front and sides of the house, which stands some 200 ft. from the shore, the land has all been cleared, and is an open lawn to the old walls on either side; but to the rear of the house, a few rods distant, as far as the town road, are about 20 acres of woods and bushes. The avenue to the house, which is about a quarter of a mile long, leads through these bushes and trees, so thick and dense as almost to exclude the sunlight, and it is only wide enough for a single carriage, the branches and foliage forming a dense thicket up to the carriage rails. No knife or saw, or scythe or sickle touches either trees or Grass; only when too close the former are lopped off, to allow a passage through them. As you emerge from this, through the old inner gate, whose posts are thickly studded with Moss, to the open lawn, the view is delightful, with the cove closed in by projecting woodlands on each side, the open bay beyond, the opposite shore six miles off, covered with a dense growth of wood, and the broad sea in the distance. Here no steam engines, with shrieks and puffing, no saw mills or manufactories, with their noisy machinery, disturb the quiet of the place; no tall chimnies discharge volumes of smoke; no rows of brick warehouses mar the beauty of this delightful shore. On the contrary, the village—with its hotel and church spires, three miles distant—is just seen over the hill on the west, and the lighthouse a little farther off on the east. In the distance, fifteen miles away, lie Oak Bluffs, the fashionable resort of those who love show and noise, and headaches and heartaches, instead of the quiet pleasures of the peaceful seashore. My first visit here was towards the end of July. As I left the railroad station, situated almost in the woods, with only a few scattered houses, half a mile from the village, and turned into the old road leading along the shore, a very few rods brought me to the thicker woods which border the road for four miles. Here the first object which attracted my attention was the *Lilium pennsylvanicum*, which grows all along the roadside up to the very carriage-track; but a little distance further I saw the tall stem of *Lilium superbum* towering up above the underwood, loaded with buds, and a fortnight later one blaze of flowers, some of the stems of bulbs which I dug up measuring 7 ft. high. Jogging slowly along, to study the vegetation, the next plant was that most beautiful of all American herbaceous plants, the well-named "Butterfly Weed," *Asclepias tuberosa*, in clumps many years old, for I cut flowers from the same plants six years ago, which were covered with hundreds of umbels of real orange-coloured flowers—a sight never to be forgotten. We now come to a little creek, which runs into the bay, and catch a glimpse of the village and bay, but soon enter the forest road to find it bordered on either side with *Clethra alnifolia*, just beginning to open its buds, but later one mass of erect spikes of blossoms, filling the whole air with their fragrance. For full half a mile we rode through this mass of *Clethra*, relieved by dense clumps of *Prinos glaber*, with its glossy, Myrtle-like, evergreen foliage, actually glistening in the sunlight. The common Milk Weed (*Asclepias syriaca*), with stems 4 ft. high, displayed quantities of its globular heads of bloom. Leisurely toiling up one of the low sandhills, nothing could be prettier than the little Cassia (*C. chamæcrista*), with its tiny stems wreathed with yellow flowers, and its Mimosa-like foliage, bordering the roadway. The scene soon changed again, and we entered a dense wood, composed mostly of White Pine, where nothing but massive Ferns and great Fungi of all colours checked the roadside path. Further on we passed through a low, swampy spot, on one side of which is a Cranberry bog, artificially made, but for some reason neglected, and it was then, and is to-day, one garden of wild flowers, which I need not name here, unless it be the pretty *Arethusa bulbosa*, with its bright "crystalline purple" blossoms. Again slowly winding up another small sandhill, of which there are only two on the road, the *Vacciniums*, with the berries just beginning to colour, clothed the scanty soil, and here and there the *Viburnum*.

nums, some with red, and some with bright blue berries, formed massive shrubs against the old stone walls, the branches bending under their weight. The whole road of three miles is a wild garden of rare beauty. The larger ponds are covered with the snowy flowers of our fragrant Lily (*Nymphaea odorata*), and the shallower ones and ditches are filled with *Pontederia*, covered with spikes of blue flowers. The trees which abound are the white and pitch Pines and *Juniperus virginiana*; the yellow, white, and red Oaks; the scarlet Maple, already beginning to don its autumn livery of blazing colours; Birches, Poplar, *Ilex opaca*, *Sassafras*, and that beautiful tree the Tupelo (*Nyssa biflora*), quite green with its glossy Camellia-like foliage, but now changing to its scarlet-crimson hue like a garnet among emeralds, dazzling in its brightness. But we now turned into the avenue and were soon lost in the thicket, coming upon the lawn to find a plant which had just opened its first bloom, and worthy of prominent notice, not only for its beauty, but for the contrast between the sombre avenue, the sparkling water of the bay, and the deep verdure of the grass as it glistened with the dew. This was a clump of *Hibiscus palustris*—at home—its huge lovely rose-coloured flowers—unlike all else that grow here—and looking like some hot-house, or tame plant, set down there in anticipation of some admiring visitor. I must not omit, too, a notice of another plant truly named by somebody who had an appreciation of the beautiful—this is the Meadow Beauty, *Rhexia virginica*. In every little bit of land it grows in profusion, sometimes in a few scattered roots, but usually in clumps 4 ft. or more in diameter, forming a dense mass of flowers of the brightest pinky-purple, set off by the very prominent golden stamens. Next to *Asclepias tuberosa* there is no plant which is so strikingly attractive. I have had brilliant beds of *Phlox Drummondii*, but when I state that this fully equals, if it does not surpass it, some idea of this beautiful plant may be formed. The coloured plate in *THE GARDEN* did not do justice to it; in fact, its peculiar bright tint is a difficult task for the painter to imitate. I have not, of course, enumerated one tenth of the plants and shrubs on the road, but having got into the house, after a quiet rest, I will again take up the subject.

C. M. HOVEY.

EVENING PRIMROSES.

THESE are amongst the most showy and healthy of late summer blooming plants, and surely about the easiest grown. I admit that from June onwards they are in their glory, but many species and varieties in late summer, from increased growth, of necessity become more glorious. Amongst them we have tall-growing sorts like *Eoothera Lamarckiana* and fragrans, and decumbent carpets, as in *trichocalyx* and *caespitosa*; white flowers as in the last-named two, *coronopifolia* and *speciosa*, often changing with age to pink or rose; and few plants have more brilliant yellow blooms than those of *missouriensis* and *Lamarckiana*, besides they are so big—4 in. to 6 in. across. Nearly all are more or less fragrant, fragrans, *caespitosa*, *marginata*, and *eximia*, being particularly odoriferous. As a truly hardy and neat perennial, *fruticosa* var. *linearis* is one of the best, its little bright yellow flowers being profusely borne all summer, but most lavishly in June and July. All are not equally fond of the night as their name might suggest, for many species are open by day, as, for instance, *E. linearis*, *speciosa*, *taraxacifolia*, and *trichocalyx*. Many of our finest evening Primroses are natives of west of the Mississippi States, as California, Utah, Missouri, and Texas, and, consequently, several are not quite hardy here. It is advisable to winter the more tender sorts—biennials or perennials—in frames, and where practicable, save seeds and raise seedlings annually. So far as I am acquainted they all bloom the first season from early seedlings. Some of the true perennials, and particularly the prostrate-growing ones, are shy seedling in our garden, but the tall growers seed freely. *Missouriensis*, *linearis*, fragrans, *Lamarckiana*, and biennis withstood last winter (40° below zero) unprotected in the open garden, unsheltered; *caespitosa* survived under some leaves on a wooden shutter, but alongside of it *trichocalyx* perished.—WM. FALCONER, in "Gardeners' Monthly."

Outdoor Plants in Bloom.—Although we have slight frosts every morning, the following plants are in bloom here in the open ground:—*Helleborus niger*, *Veronica*, *Pelargoniums*, *Fuchsias*, *Mignonette*, *Tea* and *China* Roses, *Madame Falcot* Rose, *Pyrethrums*, *Canterbury Bells*, *Tritomas*, *Schizostylis*, *Wallflowers*, *Lælia speciosa*, *Polyanthus*, *Narcissus*, *Violets*, *Primroses*, *Alpine Auriculas*, *Polyanthuses*, *Pansies*, and *Chrysanthemums*. I cut the other day several bunches of bloom off *Habrothamnus elegans* on a south wall, where it has bloomed beautifully throughout the summer. It is planted against the wall of a house, where it has stood two winters, coal ashes being put over the roots to protect them from frost.—W. DIVERS, *Worton, Maidstone*.

TREES AND SHRUBS.

RETINOSPORA ERICOIDES A MISNOMER.

At page 558 Mr. Meehan asks—"Is not Mr. Syme mistaken when he charges M. Carrière with saying this is a native of Japan?" If I were to answer *no*, I should not be far wrong, as Mr. Meehan may see by referring to page 141 of the first edition of M. Carrière's book on Conifers. But the truth is, I never to my knowledge, not even in the article criticised, charged M. Carrière with saying any such thing. I never even mentioned *R. ericoides*. What I then wrote about was *R. juniperoides* (*R. deoussata*, &c.), and even with the beautiful engraving of a twig of the same before him, Mr. Meehan has, unbidden by me, jumped to the conclusion that it was the same as the mongrel-looking plant that was raised some years ago in the Messrs. Ellwanger and Barry's Nursery, and now very well known as *Thuja ericoides*, *Thuja Ellwangeriana*, and *Retinospora Ellwangeriana*, &c. In branches which Mr. Meehan has of the American seedling, the "upper portion is the normal *Thuja occidentalis*; the lower, *Retinospora juniperoides*." I, on the contrary, submit that the upper portion is the normal *T. occidentalis*; the lower, *T. occidentalis* in its juvenile state. Am I to believe that Mr. Meehan is unacquainted with the fact that in the earliest stage of their existence all the individuals of *T. occidentalis*, and, indeed, all the *Cupressinae*, present the juvenile feature of leafage of this American seedling, and that they are all more or less alike? This much I infer when he takes my description and the illustration of *R. juniperoides* at page 404 to be intended for what in this paper I have called the American seedling. I begin to think that *R. juniperoides* may not have reached America yet; and I shall have great pleasure in sending to *THE GARDEN* office a small twig to be forwarded to Mr. Meehan. Truly, "it seems strange to us over here that our friends in America should be so mystified over these things, which are old to us in England." I have never described Ellwanger and Barry's famous seedling, but when I do, Mr. Meehan may rest assured that I shall not require to consult the "Proceedings of the Chicago Meeting of the American Association for the Advancement of Science," or any other popular "proceedings" or books on Coniferae, to find a proper name for it. With the plant and other related forms before me, I shall have little difficulty in raising it out of its present popular synonymy to its proper generic position. I do not profess to gauge the exact knowledge of my intelligent countrymen respecting "the biological law which induces the dimorphism" in the plant under consideration, and other *Cupressinae*; but, as a humble tyro in this branch of botany, I have to confess that I am only now endeavouring to master the rudiments, if I may so speak, of this profound yet wayward law; and should be so grateful to any "intelligent" American for a comprehensive exposition of its workings in the case of the dimorphism of the American seedling and kindred Conifers, believing, as I do, that the intelligent handling of such a law may be made to at once account for the dimorphism in the individual under consideration, the polymorphism presented by the individuals of a species, and the polymorphism perhaps of all vegetable organisms.

GEORGE SYME.

IVY-CLAD TREES.

IN verdure trails the Ivy shoot,

O'er bole and branch, with leaves that shine
All glossy bright, tenacious twine,
And the else naked woodland scene
Clothes with a raiment fresh and green.
Fair is that Ivy twine to see!

The common Ivy of our woods has been a general favourite for ages past; and, although so many new and beautiful varieties have been raised, it still has its admirers, and there are few who cannot associate the Ivy with some pleasing remembrance in days gone by. It is, perhaps, never more beautiful than when seen clinging and climbing over some old ruin, whether it be the remnant of an abbey, castle, church, cottage, or pollard tree; and, if it can be said to lend a greater charm to one more than another, I give the preference to the latter. The furrowed bark on the decayed trunk of some old, picturesque tree, covered with the delicately and beautifully-veined, angular-lobed leaves, gives life and richness to the scenery, even in the depth of winter; but it may be mentioned that Ivy, when not creeping or adhering to an object, loses the veins and lobes of its leaves, and becomes entire margined, and deep green. The annexed woodcut represents the stem of a tree densely clothed with Ivy, and its verdant festoons, hanging

carelessly, but gracefully, in mid air, or linked from bough to bough, are pleasing features in woodland scenery. Ivy is scarcely so attractive in spring and summer as in autumn and winter; when the foliage of trees has assumed its brown and varied rich autumnal tints, the deep green leaves of this ever-green creeper present a pleasing effect; or, when the ground is covered with snow in winter, an Ivy-clad tree, amid its polished, lively green furniture, forms perhaps one of the most cheerful pictures to be found in woodlands. On almost every estate, however small, there are some few trees—old trees that are of no value save for ornament, and that have matured their growth—that may be given up to Ivy by those who appreciate and admire its picturesque charms. It may also be allowed unlimited freedom on any inferior undergrowing trees that have been overtopped by better ones, of which there are generally too many on nearly every property, particularly where judicious thinning has been neglected until too late to be of any benefit. In natural copses, when not grown for profit, Ivy forms

Ivy-clad tree trunk.

an ornamental feature, especially on the Birch, the bright green of the former contrasting charmingly with the white bark and brown airy twigs of the latter. Ornamental Fir clumps, too, with the stems of two or three of the most inferior trees clad in Ivy, become thereby much improved in appearance; but the Ivy rarely creeps amongst the branches of the Fir; when it has reached the foliage, the dense shade repels its further advance, and it then seems to retrace its steps, so to speak, and forms pendent festoons, as it develops lateral growths, down the stem to the base. I need scarcely add that Ivy will grow in almost any soil or aspect; it, however, prefers a dry, well-drained subsoil. There is no reason why every park, pleasure ground, wilderness, or ornamental island should not have, at least, a few Ivy-clad trees. The wild garden and rockery, too, can hardly be said to be complete without a few Ivy-covered objects. Lovers of creeper-clad trees should, however, take care not to allow young-growing trees, or any fine, healthy, ornamental timber to be taken possession of by Ivy, for, as Shakespeare (a little altered) asserts—

The Ivy that hides the princely trunk,
Sucks the verdure out on 't.

Whether Ivy draws nourishment from the juices or sap of a tree, as Shakespeare infers, I am not prepared to say; but I am rather inclined to believe that it receives sustenance from its own roots, which no doubt impoverish the ground in which the tree is growing. It is, however, an indisputable fact that when Ivy is allowed to take possession of growing young trees, and particularly those with smooth bark and soft-wood, it tends to check the flow of sap, and prevents the proper development and expansion of the stem; its tightly-laced and interwoven mass of dense plaits also excludes light, air, and moisture, which are so beneficial to tree life. The production of foliage, too, gradually diminishes; and when Ivy has established itself on young trees, covering them from stem to branch, and from branch to twig, the result is often slow but premature death.

GEORGE BERRY.

Longleaf.

The Weeping Deciduous Cypress.—The attractions and many valuable qualities of the ordinary American Cypress have been long known; it is employed in ordinary plantations, and to those who have seen it in southern swamps, memories of knobbed and gnarled roots protruding above the earth or water, and grand, great trunks, will readily appear. Its place in the landscape gardener's work is either singly or in masses, along the shores of lakes or streams, and in valleys or low spots. High, dry situations do not so well accord with its nature, and the meagre growth caused by the employment of such positions often give rise to a dislike that its many excellent qualities render quite unjust. The foliage is feathery and graceful, but appears late in spring, a fact which prevents purchasers from recognizing attractions that do not exist during the time usually selected for their visits to nurseries. This defect, however is amply compensated for by a beauty which lingers on far into autumn. The masses of foliage vary much in appearance, now drooping and thick, and again sparse and irregular. A straight, tall stem, with a fine brown bark lends it a certain air of elegance, and the outline of foliage is usually somewhat pyramidal and symmetrical. Most trees have produced, at one time or another, weeping forms, which have been perpetuated by grafting or layering, and to this rule the Cypress offers no exception. Indeed, the more or less weeping tufts of foliage exhibited on almost every tree, would suggest at once the possibility of a truly weeping form presenting itself. Such a form does really exist, but is scarce and little known, and has been offered to the trade in limited quantities under the name of *Taxodium distichum pendulum*, or, in plain English, weeping deciduous Cypress. This tree does its weeping on a somewhat original plan, which is, however, on that account, none the less graceful. We find, indeed, the systems quite various by which different trees perform this operation of weeping. The Beech, for instance, throws out erratic branches, which sometimes seem to have hardly decided whether to go up or down, until they have extended some little distance from the parent stem. Evergreens, on the other hand, are apt to hug the trunk, and the umbrella-like forms of some Willows and Elms describe curves regular almost to primness. The Weeping Cypress, however, possesses the double attraction of assuming the most perfect curves, and at the same time an irregular grace that resembles somewhat that of the Weeping Beech. It gives us pleasure to call attention to this fine weeping tree, not only because it is little known and very beautiful, but also because we may thereby obtain increased means of producing varied effects by means of weeping trees. It is deserving of consideration that as yet little attempt is made to group weeping trees in designs by themselves. They are almost entirely employed as single specimens, or grouped with other trees, to their own decided loss of effect and beauty.—SAMUEL PARSONS, in the "Country Gentleman."

The Danger of Yew Trees.—An important case has been tried in the Chesam (Bucks) County Court by Mr. J. Whigham. Mr. E. G. Crowhurst, the other day, summoned the Amersham Burial Board for £30, the value of a horse, which was alleged to have died owing to the defendants' negligence. It appeared that the animal was turned out to graze in a meadow adjoining a cemetery, and died on the 20th September from having eaten Yew growing in the burial ground. Mr. Whigham held that the defendants were bound to make the fence sufficiently high to prevent animals in the adjoining meadow eating the Yew, and he gave the plaintiff a verdict for 20 guineas.

Cattle Poisoned by Eating Yew Branches.—Another well-authenticated instance of the poisonous effects of the Yew upon cattle feeding on it has been recorded by Professor Wilhelm, of Graz, in a German paper. A bull and a heifer died suddenly at a cattle show in the South Tyrol, where they were on view. An investigation was held, which resulted in tracing the mishap to the presence of branches of Yew interwoven in the floral decoration of their stalls upon which they had fed heartily.

THE EDUCATING POWER OF HORTICULTURE.

HORTICULTURAL pursuits claim an educating power measured only by the will of the worker. Using the term horticulture in its popular sense, as embracing all that belongs to the garden, lawn, and orchard, we see that it must reach, in some way, every home. This influence is circumscribed neither by sex, social position, occupation, nor age. Other occupations mould classes of men, serving to make them clannish or exclusive. But in the pursuits of horticulture, we find a tendency to elevate and broaden all our conceptions of true manhood, and to mould the taste and aspirations of the race. We may differ in politics, religious faith, and daily occupation, but we meet here on a common ground to recognise a common bond of sympathy and a common manhood. We shall see the educating power of horticulture when we consider the fact that it tends to give stability to a rural population. Nothing else can bind families to their homes like trees, fruit, and flowers. They are living things. We watch their growth from day to day. They are linked in memory often with the bright and sweet things of the past. We learn to love them and to love their history. The ordinary products of the farm soon ripen and are gone, but here nature slowly unfolds her purposes, requiring patient waiting and constant care for many years. Hence, men learn to love these trees. They give a peculiar charm, in the eyes of the owner, to the picture of the home. The farm crops, as a rule, hold the family only from spring to fall, and the owners of stock may roam, like their herds, from hill to hill, or from country to country; but he who plants trees, finds himself by the strongest possible ties—both of interest and affection—bound to the soil. The social, political, intellectual, and moral advantages secured by permanent population, cannot be measured. It is enough to know that the highest order of civilization can be reached alone by such a people. Horticultural pursuits serve also in an eminent degree to quicken observation and thought. New fields of inquiry are constantly opening to view. Each day will press home new questions. The answers we shall seek for either in our own experience or that of others; the result, with the better class of minds, will be a quickened observation, more careful study, and a more profitable social intercourse. The range of observation extends over a very wide field, and the enquiries demanding solution will lead to every department of natural science—not to science as taught in the class-room alone, but to nature herself, and to the practical application of science to the wants of man. For example, it is well to be able to determine the family, species, and variety of the plant; but it is more important to know how that plant can be used in the interest of man. Or again, it is not enough to understand the theory of hybridisation; but it is the work of the horticulturist to make a practical application of the doctrine, and reach desirable results. The laws, also, of bud growth, beautiful as they may be in theory, derive all their importance from a practical application. The mysteries that hang around the microscopic fungus growth, that seems to fill all that measureless world below the natural vision, take a strong hold on the mind of the scientist; but when they come to the farmer or horticulturist, in the shape of rust, scab—or it may be blight, sweeping away in an hour the hope of the year—they assume a practical importance out of all proportion to their size. These are not simply subjects of scientific inquiry, but practical questions involving the interests of man. Questions of like character, ranging through every department of natural science, will meet the horticulturist at every step. There will hence be secured, by the pressure of the surroundings, a practical mental culture, its extent and value measured, in a large degree, by the will of the man. Horticultural pursuits also favour a denser population than ordinary farming. Smaller farms are occupied, and residences are located nearer together. And hence larger privileges are conferred upon families and neighbourhoods. The very nature of the occupation brings men much in contact with their fellows, and more abundant opportunities are offered for social improvement, as compared with other occupations. The work of the horticulturist, both with respect to its influence upon himself and upon others, is a matter of grave moment. In the production of fruits and vegetables, he labours in the most efficient manner to supply the physical wants of man; but there is an almost infinitely wider range of work in supplying the higher wants of man's nature. That great truth that "man does not live by bread alone" has been accepted in a comprehensive sense. The flowers—those fragile emblems of a higher and purer life, that brighten for an hour the festive hall, or bend with dewy fragrance over our coffined dead—so speak that even the rudest mind must learn. The man of culture would add to the delights of home the means of gratifying his love for the beautiful in Nature. Trees, shrubs, and flowers are gathered from every clime, and each adds its own peculiar attraction to the home. Finished by the hand of experience and correct taste, that home, with its perfected framework, becomes a thing of beauty; and, while ministering to the wants of the owner, it stands as a teacher

whose power for good no man can measure. Man cannot move through scenes of beauty without feeling their power. That beauty, in a certain sense, becomes a part of his being. While the horticulturist may gather many lessons of rich experience from his own work, that work will abide as an earnest and successful teacher many years after he has gone. Let him plant a beautiful tree; slowly, year by year, it raises its head heavenward. The planter and those who knew and loved him, pass away; but a hundred years hence, there stands the monument of his work in all its glory! For a long century it has taught the passing crowd, giving grateful shade to the weary, and engraving upon the mind of each passer-by its lines of perfected beauty. We say then to the boy, to the young man, and to the man of grey hairs—plant trees, plant orchards, plant forests, plant long-lived trees by the roadside and about your homes. Lay out your grounds with an eye upon the years of the far future, knowing that your work is to stand as one of the teachers of the ages to come.

ELRIDGE GALE.

SENDING PLANTS TO BE NAMED.

In common with other journals treating of natural history, we frequently receive specimens of plants, with a request that we will name them. This we are willing to do, whenever possible, but our task would be rendered much more easy than it is at present if our readers would be a little more careful in their selection of the specimens which they send. The following hints are offered upon the subject, and their adoption, while it will materially lessen our own difficulties, will render our answers much more definite and satisfactory to our readers than has sometimes been the case. The knowledge of what to send, and how to send it, may therefore be acceptable to such of our readers as are in the habit of consulting us with regard to plants. Of ordinary flowering plants, a specimen should show at least flowers and leaves—two or more of each, when possible, to allow for withering or other damage in transit. The more perfect any specimen is, the more certain is the accuracy of its determination; so that, when possible, fruits and root leaves (which are often different from the stem leaves in form) should be added. With regard to Ferns, a fruiting frond should be sent whenever possible; it is often impossible to determine even the genus to which a barren frond should be referred. Of Orchids a single bloom is often as much as can be spared, and in these plants it is nearly always sufficient. With regard to British plants, especially in the many instances where from the nature of the case (as in the contents of a bird's crop) the material is but scanty, the locality whence the specimens came should always be specified: this of course also applies to foreign plants, apart from such as are cultivated. Ordinary plants may be sent after having been dried, as a botanist can recognise them in a dried state almost as well as when living. Orchid blossoms, however, are best sent fresh: they should be inclosed in a small tin box, or, if placed in one of slighter material, the address and stamp should be placed on an ordinary luggage label, which may be attached to the box with string; in this way the danger of smashing the box by the post-office stamp is greatly reduced, if not altogether avoided. When more than one plant is sent, each specimen should be placed in a separate paper, with number attached. With regard to the preserving of plants for a herbarium, regarding which we are frequently consulted, few things are more simple, and few receive less attention. It should always be borne in mind that, to the scientific botanist at least, the elegance or prettiness of a specimen is quite subordinate to its completeness. The great point to be kept steadily in view is the presentment of each plant as far as possible in its entirety; thus, roots and root-leaves, buds and fruits, seeds and seed-vessels, are at least as important as the stem-leaves and flowers which frequently form the sole representatives of a species in the collections of amateur botanists. With a view to future examination, it is a good plan to collect a few more flowers than are absolutely required, and place them in a little pocket or capsule upon the same sheet with the selected specimen; by this plan material for dissection is at hand without the risk of damaging the selected specimen. Plants may be dried very well in old newspapers, although both Newman and Benthall issue specially prepared drying-paper, which may be preferred when expense is no object; and the plants, while in process of drying, should be subjected to regular even pressure, sufficient weight being applied to keep the plants quite flat, yet not so much as to crush the tender parts. Ironing is adopted by some persons, and in some instances has the effect of preserving the colour, but it is not to be recommended. Plants having blossoms which tumble off very easily, such as the Speedwells, should be dried in the field when possible, and may well be placed in a small pocket-book taken out for that purpose. Some botanists recommend the drying of plants as soon as collected, and for that purpose take out with them a drying apparatus; but this incumbrance is neither necessary nor desirable. The larger

fruits should, as a rule, be kept in small boxes, as if placed in the herbarium they make the pressure unequal, and, moreover, are difficult to fasten to the paper. The mounting of plants is a matter upon which different opinions are held, some preferring the Continental plan of placing the specimen loose in a folded sheet of paper, others gumming them firmly down, others attaching them to the sheet by means of strips of gummed paper placed across them. This, although the most troublesome, is on the whole the best plan.—“Field.”

Chinese Vase Modelled after a Gourd.—It is noticeable that many of the finest forms of vases are modelled after fruits,

though in few cases is the original so clearly seen as in the quaint vase of which we give an illustration.

THE ENVIRONS OF LONDON.

LORD BEACONSFIELD in one of his novels speaks in tones of enthusiasm about the environs of London. There are few capital cities so dingy at the centre, but none so lovely in its centre. The suburbs of Paris are hardly to be compared with the suburbs of London. This loveliness is most apparent in the opening days of spring. The railway with its multiplied conveniences allures the tourist to far-off lakes and mountains and seaboard in our own and in other lands. This is well. But it is also well that the Londoner should know all about the neighbourhood of London. South and west the environs are especially beautiful. People who have not much time to travel, and like to travel near home, can hardly do better than make a circuit of the environs of London in a phaeton if they will, or, almost better still, by pedestrianising. Many pleasant expeditions of this kind do we gratefully recall. The course of the silvery Thames has always been especially pleasing to us, chiefly so when set free from the trammels of time and the subserviency to return tickets. We have followed the course of the imperial river from its *embouchure* to where its seven fountains spring beneath a cluster of leafy trees in an obscure Gloucestershire hamlet. It must be owned that the nearer Thames has very much changed its character within recent years. That fine Mall at Chiswick immediately develops into a congeries of miserable houses, in striking contrast to the famous villa where the Prince and Princess once gave their garden parties. Brentford is one long, dark, dirty street. The Middlesex bank of the river is for miles almost one continuous town; but the left bank, with the old towing-path, is free for miles. The broad reaches of the river seem clearer within recent years. The genuine Londoner knows no more thorough enjoyment than to wander forth on a holiday by rail or boat to Kew. Leaving the gardens on the left, he lounges by the river-side past Isleworth, on the opposite bank to that on

which Richmond stands. Then he ascends the famous hill for that famous view, and devises further wanderings. He takes the route through Richmond Park, past Lord Russell's house to Ham gate, and then across the gorse common to the long avenues of Ham House. The deserted appearance of the old magnificent mansion is positively a blot on suburban London. We think of the days when gay companies ascended the steps and walked through the avenues to the water-gate. Almost opposite is the Duc d'Aumale's place, which is now converted into the Orleans Club. From Twickenham ferry we row up to Teddington Lock, having refreshed ourselves at the ait on the river. At Teddington you are close to Bushey Park and the gardens and galleries of Hampton Court. We venture to say that this expedition is the pleasantest and most easily manageable of any in the vicinity of London. We prefer taking as the starting-point some spot on the Thames where it has ceased to be tidal, and wandering at will through the country-side. How many such a sweet spot there is!—the lazy fishing-village of Shepperton, and Arnold's Laleham close by; Blackpots, with the Windsor scenery at hand; Bisham Woods, Medmenham Abbey, Cliveden's fair domain, Pangbourne, and Streety. Summer picture-like days come forth in memory—pure enjoyment, chance companionship, pleasant adventures; and all through the vision the silvery Thames comes gliding on with its melody and freshness. If you want to get to the really pretty places outside London, as a rule you must get out of the postal districts, and come nearer to the 20-mile limit. You will find lovely bits of landscape at times, so to speak, islanded amid bricks and mortar; but you have, as a rule, to get further and further away from town before you come to them. Many of us remember the time when Norwood Hill was the chosen resort of gipsies, and a shady country lane ran through the pretty village of Anerley. It is not so far to Chislehurst and the Crays, and there is many a lovely Kentish village as sequestered as in the days so long since gone by. We like the old driving-road from London to Brighton. It is a noble road, often with immense margins of broad turf, and the country lanes branching out on either side will lead you into noble scenery of wood and downs. Then we affect greatly the northern heights of London and the great North road, and own to a weakness for the Welsh Harp, liking the fishing, the *al fresco* life, but not bargaining for a torpedo. If you want a patch of perfect loveliness, whither a thousand painters have come in their day, commend us to Burnham Beeches, a tract free, open, richly wooded, as in the days of the Conquest.

Overdoing.—An evening contemporary writes to the following effect:—“Friends, kindly send no flowers.” Of late this request has begun to appear at the end of announcements of deaths in American papers, and, though at first sight quaint, is not less sensible. The custom of sending flowers to friends on any occasion of festivity or sadness is a German one, which, like many other Teutonic fashions, reached the United States of late years. It has, however been carried to extremes, until, from being a friendly token of sympathy, it has become something akin to an intolerable nuisance. When a child was born the house was never at rest for one hour from people calling with flowers; when the baby came of age, was married, or died, the floral compliments of sympathy were equally paid, often from people who could ill afford the expensive wreaths and bouquets which rich *parvenues* had made the rage. The tax was becoming a heavy one, and was often paid at a time when the mourners wished to be left alone to their sorrow. Not only this, but, as with the marriage cards in England and the betrothal cards in Germany and Scandinavia, the omission to send flowers on certain occasions was deemed a slight, and often ended in friends becoming estranged. There are a good number of other customs which might fitly follow the flower one. For instance, who has lived or travelled in Germany and not witnessed the burdens of costly bouquets which are piled on departing guests, often flurried with many things, and which floral gifts can only be conveyed at great personal inconvenience? Then there are the presents which must be given at Confirmation time, and at birthdays, and at marriages, and in France at Easter. These habits originated in the kindest of feelings, but in the rush and hurry of modern life have become a burden. The poor bachelor in Paris is frequently forced to flee the city about Easter time to escape the Easter-egg tax, the observance of which often puts him under obligations to his tailor and his bootmaker; while many a family in Germany and Denmark is reluctantly compelled to look askance at cultivating intimate relations with a house whose many daughters will by-and-by bleed their purses for the presents which ‘society’ ordains the gift of on certain stated occasions. The cost of living is increasing out of all proportion to the increase of wealth; and if we are to be kept from bankruptcy and live in comfort, we must abate some of the little multiplied extravagance of social intercourse, even at the expense of a temporary wound to our generous souls.”

POLYGONUM SACHALINENSE.

AMONG the plants which might well have illustrated Mr. Hemsley's recent notes on garden plants from the Japan region, there is one, which we have since had engraved, which is a notable addition to the free and vigorous type of herbaceous plants that of late years only have begun to be appreciated and properly placed in our gardens. This has come into cultivation subsequent to the handsome and vigorous *Polygonum cuspidatum* now popular where hardy plants are grown. It is even more vigorous than *P. cuspidatum*, and the leaves are very large, so much so as almost to merit the name of a fine foliaged plant. Our engraving is from a portrait of an isolated specimen taken last summer, and the engraving shows only a portion of the plant sufficient to illustrate its fine habit. The specimen in question grew as a gigantic isolated tuft on the Grass, in which way it has room to grow, and which also permits of its fine form being seen. It is well adapted for the wild garden, and also for association with the vigorous herbaceous plants on the turf in the pleasure ground. For those

METANDE DE BAR

Portion of a tuft of Giant Knotweed isolated on turf.

whose gardens will not admit of such special places for this and similar plants, a tuft, well placed on the edge of a shrubbery, will well repay the planter. It would, however, be best, not in the shrubbery, but just a few feet free of it.

Coronilla glauca Out-of-doors near London.—A few days ago I noticed, in the garden of Mr. W. H. Hardy, Torrington Park, Finchley, a fine plant of *Coronilla glauca* growing out-of-doors, and full of flower. It is a bush 4 ft. high and 5 ft. through. Mrs. Hardy planted it there four years ago. It faces the west, and is protected by the house, which stands high and in an open position. The flowers are large, and the plant is in a very healthy condition, and certainly does not lead one to suppose that it should be grown in a greenhouse, which, I believe, it usually is. There is also a smaller plant on a southern aspect. Is the hardness of these plants exceptional?—ROBERT OSBORN, Fulham.

Holly and other Berry-bearing Trees.—Judging by appearances, there will be no lack of berries for church and house decoration this year, as was the case last season, although even then, in this neighbourhood, we had plenty and to spare. This year Holly trees are loaded to excess with berries, which are so plentiful on some trees as to give them, at a distance, quite a scarlet appearance, and both variegated and plain-leaved kinds are equally well furnished. Yew trees have also been so loaded that their branches were literally bent down with the weight of fruit, but now the birds have thinned them considerably. The same remark also applies to the *Pyraecantha* and *Arbutus*.—W. D., Winton, Maidstone.

PLATE CV.

RHODODENDRON NOVELTY.

Drawn by H. HYDE.

THIS very distinct *Rhododendron* was raised from seed in the nurseries of Mr. Anthony Waterer, at Knaphill, from whose richly-stored nursery it was sent to us for illustration. It will be seen that its distinctness consists in having the margins of the petals instead of the centre light in colour, varieties light towards the centre being plentiful. It is something in these days to get a really distinct new variety of *Rhododendron*, and to the best of our belief this is unique. It will probably in time give rise to a race of new varieties of this precious hardy shrub. Mr. Waterer has no account to give of its origin or parents. It came, like many other good plants, "among the rest" of the seedlings. When it first bloomed, five years ago, the plant was not a vigorous one, and Mr. Waterer, charmed with the flower, feared it might be a mere temporary sport; hence he was greatly pleased to see the new feature even more marked in the plants since they have become vigorous. It is a perfectly hardy kind.

Mate or Paraguay Tea.—Allow me to add a few words to the account given in THE GARDEN of the Paraguay Tea (see p. 552). Like Chinese Tea, there are different qualities made and known to the natives. The principal kinds are, first, that which is made from the half-opened leaves; secondly, the leaves from which the midribs and principal veins have been removed; and, thirdly, the later leaves and young twigs, dried or roasted, and reduced to a powder. In this latter form it is packed very tightly into large bags, made of the skins of animals, or into the skins themselves, as may be seen in the Kew Museum, where there is an entire skin of the great ant-eater so packed. The unbroken leaves are put up into square packages of metallic paper, upon which is printed the name of the tea and of the firm selling it, and in this way it is a regular article of trade in most of the towns. These packages are very similar in appearance to the tinned paper packages of Chinese tea, often seen at grocers' shops in this country. With regard to the vessels in which the infusion is made, they are formed either of gourds or of earthenware; if of the former, they are either carved or mounted in silver, and if of the latter, they are more or less painted with various devices and glazed. The stem part of the gourd, as represented in the figure on p. 552, is not used as a spout but a handle, a spout being unnecessary in consequence of the infusion being sucked through the tube, or bombilla; and those bombillas, like the caps themselves, vary much both in the material used, and also in the elaboration of workmanship. The commonest is a simple tin tube enlarged at the base and perforated with holes; another kind is made of wicker-work, and the best of silver. These tubes, as well as the mounting of the cups, are often highly chased.—JOHN R. JACKSON.

Alphonse Karr and his Lilacs.—M. Alphonse Karr, whose "Voyage Around his Garden" may possibly be remembered pleasantly by some readers, is resuming the congenial work; but his final voyage is this time in another garden, quite remote from the first, and presenting, in many points, very different subjects for his agile and learned pen. The first was in Normandy, the present is at St. Raphaels, a fishing village near Nice, where he had spent more than a dozen years. It is a pretty nook, where the Pines come down from the Alps almost to catch the spray of the Mediterranean. Spite of the plentifulness of vegetation in Italy, there were no Lilacs at Nice, and M. Karr introduced into his garden all the varieties familiar to him, and others to which his attention was directed. They form a field, or, rather, a fairy forest. At the end of March they are all in bloom, and, being in great variety, the bloom is on some till the end of about three weeks.—W.

The Greek Oracles as Meteorological Observatories.—Dr. E. Dohlen, in an interesting lecture published in Berlin in 1872, entitled "Die Orakel," endeavours to show that the earliest demand for prophetic knowledge among an agricultural community related to weather, and that the chief oracles were those of Apollo, the sun god, while also the earth and the sea had their shrines. Many of the earliest responses referred directly to weather; and the earliest prophets, Tiresias and others, are said to have understood the language of birds, or, in other words, to have drawn prognostics from their flight. If once the character of an oracle had been established by successful forecasts of weather, it is easy to see that political and social problems would be referred to the same authority, and the experience of those in charge of the shrines would enable them to dictate counsel which would at least bear a safe construction for their own credit.

THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

(Continued from page 561).

Himalayan Region.

GENERAL DESCRIPTION.—The mighty range of mountains in North India is very lofty throughout, and some of its peaks are the highest in the world, Mount Everest and Mount

Himalayan tree—The Bhotan Pine (*Pinus excelsa*).

Deodunga reaching an altitude of 29,000 ft., or more than five miles. Shrubs and small trees ascend to 12,000 ft. or more; and *Myricaria germanica* has been found up to 15,000 ft., and *Caragana pygmaea* up to 16,000 ft. Herbaceous flowering plants, belonging to such families as the Ranunculacæ, Cruciferæ, &c., occur in some parts at an elevation of above 18,000 ft. At this height the pressure of the atmosphere is not much more than two-thirds of what it is at sea-level, and the other climatal conditions are so different to those obtaining in this

country, that the plants which have been introduced from time to time do not seem to have gained a secure footing.

Himalayan Bamboo.

Yet there are many very beautiful herbaceous plants growing between 9000 ft. and 18,000 ft. that would not be killed by the

Himalayan herbaceous plant—*Saxifraga*.

cold of our winters. Shrubs and trees growing above 8000 ft. or 10,000 ft., according to the situation, are hardy; but our

Himalayan shrub—*Jasminum officinale*.

ordinary winters, being too mild—or rather, perhaps, very little heat being necessary to stimulate them into active growth

—they suffer very much from late spring frosts, especially when quite young. Many of the handsome Coniferæ of this region are consequently unavailable for planting in this country. Nevertheless, there are some noteworthy exceptions, and almost all those commonly planted are very distinct and desirable, and hardy in the climate of London. In the temperate parts, such other genera than those mentioned below occur, as *Euonymus*, *Rhamnus*, *Æsculus*, *Acer*, *Morus*, *Celtis*, *Ulmus*, *Quercus*, *Castanea*, *Rhododendron*, *Berberis*, *Magnolia*, &c., &c. The climate generally is a very humid one, and in the eastern and central parts the average rainfall is from 200 in. to 600 in. in different localities. The latter is the largest average rainfall recorded for any part of the world.

Garden Plants from the Himalayan Region.

General List of Herbs, Trees, and Shrubs.

<i>Clematis montana</i>	<i>Aucuba himalaica</i>
" <i>orientalis</i> , &c.	<i>Rhododendron arboreum</i>
<i>Meconopsis Wallichii</i> , and several other species. <i>M. horridula</i> occurs up to a height of 17,000 ft.	" <i>campanulatum</i>
<i>Magnolia Campbellii</i> —a magnificent species, still very rare in this country	" <i>Thomsoni</i> , &c.
<i>Berberis nepalensis</i>	Nearly all the fine <i>Sikkin</i> species are hardy in some parts of the south-west, but not elsewhere.
<i>Æsculus indica</i>	<i>Morina longifolia</i>
<i>Spiræa Lindleyana</i>	<i>Jasminum officinale</i>
<i>Rubus biflorus</i> (syn. <i>R. leucodermis</i>)	" <i>revolutum</i>
<i>Potentilla atrosanguinea</i>	<i>Syringa Emodi</i>
" <i>nepalensis</i>	<i>Polygonum Brunonis</i>
<i>Cratægus Pyracantha</i> var. <i>crenata</i> , much superior to the South European form	<i>Rheum nobile</i> (recently introduced)
<i>Cotoneaster microphylla</i>	<i>Pinus excelsa</i>
" <i>buxifolia</i> , and several other species	<i>Abies Morinda</i> (<i>A. Smithiana</i>)
<i>Saxifraga crassifolia</i>	<i>Cedrus Deodara</i>
<i>Cornus fragifera</i> (<i>Benthamia fragifera</i>)	<i>Juniperus squamata</i> , and other species
	<i>Lilium giganteum</i> , &c.
	<i>Thamnocalamus Falconeri</i> (syn. <i>Arundinaria falcata</i>), one of the best and hardiest of the Bamboo tribe.

The North American Region.

GENERAL REMARKS ON THE CLIMATE.—From what has been said of the course of the lines of equal temperature, corresponding to those for the winter, summer, and annual means in the United Kingdom, across the North American Continent, it is evident that the vegetation of an immense extent of that country must be sufficiently hardy to thrive with us. The extremes of summer and winter temperatures are very great. Thus, at New York, which is about 10° further south than London, the summer is as hot as in the south of Europe, and the mean winter temperature there is about the freezing-point; whilst Quebec, in 46° 50' N. lat., enjoys a mean summer temperature of about 65°, or equal to that of Paris, and a mean winter temperature of about 20°, or as low as that of St. Petersburg. The significance of these facts has already been pointed out, but attention is directed to them again here because many North American trees that are hardy in this country fail to ripen seeds in consequence of the summer heat being insufficient.

CENTRES OF DIVERSE TYPES OF VEGETATION.—The temperate part of North America might be sub-divided into several regions, characterised by different predominating types of vegetation. For example, the eastern and central States of the Union abound in a great variety of deciduous trees, as Maples, Oaks, Poplars, Magnolias, &c.; the plains of Nebraska, Kansas, Oregon, Utah, &c., are sparsely wooded, and present in places a rich flora of herbaceous plants, whilst other parts are very barren; and in the mountain ranges, on the western side of the Continent, most of the gigantic Coniferæ are at home. A very striking feature of the North American deciduous forests in autumn is the brilliant and varied tints the leaves of different trees assume. One valuable and distinct North American type, characteristic mainly of the eastern coast, is the genus *Yucca*.

HISTORY OF INTRODUCTION OF NORTH AMERICAN PLANTS.—*Yucca gloriosa* appears to have been one of the first plants introduced from North America, as Gerard (1596) enumerates this and *Thuja occidentalis* in his catalogue. During the seventeenth century Tradescant and Compton, the first of whom travelled in the country, introduced a considerable

number of species, among them *Robinia Pseudo-Acacia*, *Platanus occidentalis*, *Taxodium distichum*, *Celtis occidentalis*, *Lonicera sempervirens*, *Cratægus coccinea*, *Liquidambar styraciflua*, *Negundo fraxinifolia*, *Aralia spinosa*, *Menispermum canadense*, *Quercus coccinea*, &c. The Tulip tree was introduced by the Earl of Norfolk, in 1663. During the eighteenth century a very large number of deciduous trees and shrubs was introduced from the United States, many of which are still very rare, and have probably been propagated very little, if at all, and not re-introduced. Most of the fine Conifers of the west mountain ranges, and the handsome flowering shrubs and herbaceous plants of the same side of the Continent, were discovered and introduced during the present century.

ENDEMIC GENERA.—Among the genera peculiar to North America, the following are familiar examples:—*Calycanthus*, *Sarracenia*, *Liriodendron*, *Eschscholtzia*, *Ptelea*, *Symphoricarpos*, *Kalmia*, *Halesia*, *Nemophila*, *Pentstemon*, *Dodecatheon*, *Sequoia*, *Calochortus*, and *Yucca*.

REPRESENTATIVE SPECIES IN THE MEDITERRANEAN REGION, &c.—A few genera represented in North America, and in the eastern part chiefly, are also represented in the Mediterranean region by closely allied species or forms. Such are *Platanus* and *Liquidambar*. Of *Lupinus*, otherwise an American genus, extending to the south, there are several annual species in the Mediterranean region. These peculiarities in plant distribution have led to the supposition that in former times America and Europe were united by land. On the other hand, there are more genera which seem to indicate an Asiatic migration. *Rhododendron* is widely dispersed in the temperate regions of Europe, Asia, and America, though absent from large tracts. *Azalea*, if we regard it as a distinct genus, is represented in Asia Minor, China and Japan, and North America. *Cercis* and *Philadelphus* have a similar range.

SIDE-SADDLE FLOWERS.—The curious *Sarraceniaceæ*, or side-saddle flowers, with pitcher-shaped, radical leaves, are confined to North America, with the exception of the monotypic *Heliamphora*, a native of Venezuela. There are about six species of *Sarracenia*, chiefly inhabiting the marshes of the eastern States; and *Darlingtonia californica* is only found on the western side of the Continent.

The lists which follow form together only a small selection of hardy North American plants.

Garden Plants from the North American Region.

Deciduous Trees having more or less Ornamental Flowers.

<i>Magnolia tripetala</i>	<i>Æsculus</i> (<i>Pavia</i>) <i>californica</i>	<i>Cercis canadensis</i>
" <i>acuminata</i> , &c.	" <i>rubra</i> , &c.	<i>Prunus virginiana</i>
<i>Liriodendron tulipifera</i>	<i>Acer rubrum</i>	<i>Cratægus coccinea</i> , &c.
<i>Tilia americana</i>	<i>Robinia Pseudo-acacia</i>	<i>Amelanchier canadensis</i>
<i>Ptelea trifoliata</i>	<i>Cladrastis lutea</i>	<i>Halesia tetrapetala</i> , &c.
		<i>Catalpa bignonioides</i>

Evergreen Trees, Exclusive of Coniferæ.

Magnolia grandiflora, hardy only in the south and west.

Deciduous Trees with Inconspicuous Flowers.

<i>Acer dasycarpum</i>	<i>Morus rubra</i>	<i>Quercus coccinea</i>
" <i>saccharinum</i>	<i>Planera aquatica</i>	" <i>alba</i>
" <i>strictum</i> , &c.	<i>Ulmus americana</i>	" <i>rubra</i>
<i>Negundo fraxinifolia</i>	<i>Celtis occidentalis</i>	" <i>tinctoria</i>
<i>Rhus typhina</i>	<i>Platanus occidentalis</i>	" <i>phellos</i> , &c.
<i>Gleditsia triacanthos</i>	<i>Carya olivæformis</i>	<i>Fagus ferruginea</i>
<i>Liquidambar styraciflua</i>	" <i>alba</i>	<i>Ostrya virginica</i>
<i>Nyssa aquatica</i>	" <i>glabra</i> , &c.	<i>Populus angulata</i>
<i>Laurus Sassafraz</i>	<i>Juglans nigra</i>	" <i>balsamifera</i> , &c.

Trees and Shrubs of the Coniferous Family.

<i>Pinus Banksiana</i>	<i>Abies Meuziesi</i>	<i>Juniperus virginiana</i>
" <i>muricata</i>	" <i>Douglasii</i>	<i>Libocedrus decurrens</i>
" <i>insignis</i>	" <i>canadensis</i>	<i>Thuja gigantea</i>
" <i>mitis</i>	" <i>balsamea</i>	" <i>occidentalis</i>
" <i>Benthamiana</i>	" <i>nobilis</i>	<i>Cupressus Lawsoniana</i>
" <i>macrocarpa</i>	" <i>grandis</i>	" <i>macrocarpa</i>
" <i>Strobus</i>	" <i>amabilis</i> , &c.	" <i>nutkaensis</i>
" <i>monticola</i> , &c.	<i>Larix americana</i>	" <i>thyoides</i>
<i>Abies nigra</i>	<i>Sequoia gigantea</i>	<i>Taxodium distichum</i>
" <i>alba</i>	" <i>sempervirens</i>	<i>Torreya californica</i>

American Flowering Tree (*Catalpa syriaca*).

American Deciduous Flowering Shrub (*Azalea*).

North American Evergreen Shrub (*Kalmia latifolia*).

Western American Conifer (*Sequoia gigantea*).

American Flowering Shrub (*Stuartia virginica*).

*Hardy Plants from the North American Region.***Shrubs chiefly remarkable for the Beauty of their Flowers.**

Those preceded by an asterisk (*) are evergreen.

<i>Calycanthus floridus</i>	<i>Symphoricarpos racemosus</i>
" <i>occidentalis</i>	* <i>Andromeda Mariana</i>
<i>Berberis (Mahonia) Aquifolium</i>	* " <i>floribunda</i>
<i>Ceanothus americanus</i>	* <i>Kalmia latifolia</i>
" <i>azureus, &c.</i>	* " <i>angustifolia, &c.</i>
<i>Stuartia virginica</i>	* <i>Rhododendron maximum</i>
<i>Æsculus (Pavia) macrostachya, and</i>	* " <i>catawbiense</i>
other species	<i>Azalea calendulacea</i>
<i>Cerasus ilicifolius</i>	" <i>nudiflora, &c.</i>
<i>Spiræa Douglasi, &c.</i>	* <i>Gaultheria Shallon</i>
<i>Rubus spectabilis</i>	<i>Elaeagnus argentea</i>
" <i>odoratus</i>	<i>Maclura aurantiaca</i>

<i>Eschscholtzia</i>	<i>Phlox</i>	<i>Dodecatheon</i>	<i>Tradescantia</i>
<i>Lupinus</i>	<i>Gilia</i>	<i>Cypripedium</i>	<i>Adiantum, &c.</i>
<i>Clarkia</i>			W. B. HEMSLEY.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Stoves.—Amateurs who possess a plant stove, wherein subjects that require a high temperature to cultivate them are grown, with the usual centre bed, in which fermenting material is placed, will find this the best time of the year to renew the tan. Where there are means for introducing a sufficient body—say from 2½ ft. to 3 ft. in depth—it will retain its heat for a long time, varying little for the first eight or ten weeks, during which time it will keep up a temperature of from 85° to 90°. There are many disadvantages attendant upon plunging stove plants indiscriminately in bottom-heat, which, with all but a comparatively few things that do not succeed except their roots are kept warmer than their heads, more than counterbalance the benefits obtained from bottom-heat; but nevertheless, were it only on the score of economy in fuel, the use of tan will be found an advantage, inasmuch as the high temperature it so long maintains assists materially in keeping up the requisite heat in the atmosphere, to which may be added the invigorating influences arising from the gases which it gives off whilst in a state of fermentation; but to reap the full benefit from it, it should be used whilst quite fresh, as soon as discharged from the vats, and not after being allowed to lay for a considerable length of time exposed to the open air, fermenting in a body. With those who follow out the practice of plunging their plants in bottom-heat, it is necessary to counsel caution in seeing that the pots are not put in too deep at first, or the roots may be wholly destroyed, or seriously injured by overheating of the material during the first six weeks after the tan is introduced. Where a body of it exists, such as already indicated, bulbs, like *Eocharis amazonica*, or *Amaryllis*, that completed their growth early, and have now had sufficient rest, will have their flowering considerably accelerated by plunging in a bed such as that under consideration, first seeing that the soil (which, during the time of resting, will have been kept comparatively dry) is sufficiently moistened, after which, they, in common with all other plants that are plunged, will require much less water than where no plunging is resorted to, on account of the moisture absorbed from the plunging material through the pots. Where there is any difficulty in procuring tan, and there is at command a good body of the harder description of leaves of deciduous trees, such as Oak or Beech, these may be used; they will not heat nearly so much as the tan, but will produce a good genial warmth, and improve the condition of the atmosphere of the house.

Peach Houses.—I frequently meet with amateurs who express a wish to force Peaches, but are reluctant in making the attempt, under the impression that there is much difficulty in procuring a crop of this fruit grown under the influence of artificial heat; yet such by no means is the case, provided a few essentials in their cultivation are kept in sight. No doubt where very early forcing is attempted it is sometimes a difficult matter to get a sufficient quantity of fruit to set for the production of a full crop, but amateurs will generally be satisfied if their forced Peaches are in early enough to have the fruit consumed previous to such as is produced in a house where mere protection is given to the trees that are allowed to come gradually on by solar influence, without the further use of fire-heat than such as may be necessary to keep the bloom safe during the nights when sharp frosts occur. One source of failure, by the buds falling off previous to the bloom opening, frequently happens through the soil in which the roots exist in inside borders being allowed to get too dry; in wet localities, where there is proportionately little sun, this root-drying process is often carried out through the autumn under the impression that it tends to ripen up and mature the wood; but this must be effected by other means, as it is not in the nature of the Peach, whose vital energies are always more or less in motion, even after the leaves have fallen by the slow but gradual development of the buds, to have its roots in soil devoid of moisture; another prolific source of the bloom-buds falling may be frequently traced to over-strong dressings with the different Insecticides that amateurs are advised to apply to their trees under the assumption that their use will insure a crop, whereas, unless employed with caution, they are often the direct means of destroying it. Trees that are intended to be started so as to produce a crop about the time already indicated, may at once be pruned, retaining sufficient but not too many bearing shoots, the result of which would be an overcrowded condition in both the young wood and foliage, consequent upon which neither could receive enough light and air to get properly matured and solidified, and the current year's crop of fruit would, in like manner, suffer. If any dressing of the trees be attempted, with a view to the destruction of the eggs of insects that may exist, I should recommend nothing further being employed than sulphur, at the rate of 3 oz. to a gallon of water, 2 oz. of soft soap, a little soot, and as much clay as will bring the mixture up to the consistency of moderately-thick paint, applying it over the whole surface with a brush, being particularly careful that in the operation the brush is used very gently upon the young wood where the fruit-buds exist; the trees should then at once be tied in their places and allowed to remain until the time comes for starting them, which may be about the middle of February, at which time of closing the house they may be kept about 45° in the night, rising the temperature slightly as the trees progress. Although, as I have already said, Peaches, started at this time, are more manageable in getting the blooms to set freely than when forced earlier, nevertheless, it is well to use means calculated to insure success, as if many more fruit are formed than the trees can carry, thinning is an easy process; during the time when the bloom is open means should be taken every day, even if only for an hour or two, to get the atmosphere of the house quite dry, this will have an equally drying effect upon the pollen, which is of the greatest importance in fertilizing the flowers; no difficulty will be experienced in this if the weather happens to be bright and sunny, as by giving the necessary air whilst the sun is shining on the glass the desired end will be effected; but should it be cold, wet, and cloudy, it will be requisite to use as much additional fire-heat for a few hours during the middle of each day, as will permit of enough air being given to induce this dry condition of the atmosphere; whilst it is in this state many growers go over the trees with a camel's hair brush, dispersing the pollen on the flowers individually, or use a larger brush made of the softest Turkey feathers; but with Peaches, forced no earlier than those in question, I have always found that, by briskly tapping the branches or trellis to which they were tied with the hand so as to produce vibration, a good set could be insured. As soon as the fruit is fairly set, the trees should be syringed with tepid water every day, and see that the soil is well moistened down to the bottom of the border. Commence thinning the shoots early, so as not to waste the energies of the trees in making a quantity of useless wood, yet do not carry out the operation too far at a time, but do it by degrees; the same holds good with thinning the fruit. The temperature may be increased gradually in the day as the weather advances, and also in the night, but 50° will be enough for the latter, until the crop is further advanced; care must be taken that it is never allowed to rise too high in the day. This is a matter of vital importance until the stoning process is complete, and with small houses close attention is required, as they fluctuate through the influence of the sun much more rapidly than those of considerable size, where a larger body of air is enclosed. Until after the stoning is completed, the temperature should never be allowed, even for a single hour, to rise above 80° without air being freely admitted; by the necessary timely admission

GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS: PINES IN THE HIGHER REGIONS OF THE CALIFORNIAN SIERRAS.

of air in the morning anything near the above heat will not occur. It is in the afternoons, when the houses are closed, as they should be sufficiently soon with a view to economising fuel, and the production of a genial growing atmosphere, that it sometimes happens that the sun will on a sudden break out fiercely, and in the case of small houses will, in a short time, run up the temperature a great deal too high, the effect of which, as previously stated, often being to cause the fruit to drop. After the stoning process is fairly completed, more heat may be applied. Never by any means overcrop, it is always unsatisfactory in one if not two ways; where more fruit is left than the trees can support, it is deficient in both size and quality, and the bearing capabilities of the trees are permanently injured. By the time the crop is half-grown, all leaves that intercept the sun from each fruit must be removed, without which that great essential in the appearance of a well-grown Peach—colour—will be wanting. All through the different stages of growth sufficient air must be given, of course regulated by the earlier or later period and the state of the weather, but nothing like a close atmosphere must be attempted with this fruit, and, as the crop commences to ripen, admit more air, with a drier condition of the atmosphere. In the early stages of growth, as soon as the trees are out of bloom, continual watchfulness must be exercised for aphides, which often, about that time, make their appearance; their presence is easily detected by a slight curling of the leaves; no quarter must be given them, or serious injury will result. There is no better remedy than by syringing with tobacco-water, and, after the first brood are thus exterminated, the daily syringing of the trees with clean tepid water to promote healthy growth, and to keep down thrips and red spider, generally prevents any further trouble with aphides. After the crop is gathered, endeavour to preserve the leaves in a healthy state, free from red spider, by the use of the syringe or garden-engine, until they begin to show signs of falling naturally. During the whole period, from the starting to the completion of the crop, as also afterwards, the soil should be kept in a moister condition than necessary for most other fruits. Nectarines, which are nearly allied, as a matter of course conform to the same treatment, and amateurs who are disposed to try their hands at Peach-forcing may do so with a fair prospect of success by following the treatment thus briefly detailed.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

December 24.—Potting a few Volutas. Painting Fig trees in Fig house with a mixture of soot, sulphur, lime, and Tobacco-water, and getting them tied in. Cleaning dead leaves from Violets in frames, to prevent damp. Pruning Vines in second Muscat-house. Cleaning up the pleasure-grounds and rolling down firmly all newly-laid turf; cutting evergreens for Christmas decoration.

Dec. 26.—Getting into gentle heat a few old Fuchsias, to supply cuttings. Getting a newly-made border planted with Tea Roses. Giving early Asparagus a little warm manure-water. Looking over the Grape room, taking out bad berries, and filling up the bottles where required. Washing the paint and glass in second Peach-house.

Dec. 27.—Sowing Mustard and Cress. Pruning second Peach-house, and getting the shoots tied in. Cutting and tying in Chinese Arbor-vitæ hedges. Cutting down and layering some old Thorn hedges, and putting in young plants where required. Getting the Vines in second Muscat-house cleaned and painted over with composition; also forking up the border, and giving a top-dressing.

Dec. 28.—Potting 100 pots of French Beans, and earthing up a more forward lot. Getting manure on to the land whilst the weather is dry. Planting Yew hedges for protection. Getting on with the digging and trenching as fast as the weather will permit. Making another Mushroom bed, and turning over manure to sweeten.

Dec. 29.—Getting into gentle heat a few more Lily of the Valley, Deutzias, Dielytras, Hyacinths, Cinerarias, and Roses. Looking over fruit-room; also Potatoes and Onions, and removing any that are bad. Tying mats. Making labels. Cutting shreds. Cleaning nails. Fruits in use for dessert:—Pines, Grapes, Pears, Apples, and Nuts.

WHICH IS THE BEST PAVEMENT?

The judges of the group containing exhibits of materials used in paving, at the late Philadelphia Exhibition, have made an interesting and important report on the subject, and, as the latter is one that closely concerns the public, the conclusions of the judges are given at length, as follows:—

Wooden pavements have had a fair and patient trial in the United States, and are now very generally condemned as to streets subjected to heavy traffic. They are slippery in wet weather, and are very

perishable from their inability to resist either the wear of the street traffic or the causes of ordinary decay.

DURABILITY.—Assuming each of the pavements to be excellent of its kind, and the foundation to be solid, so that no ruts and depressions, except those produced by actual wear, can be formed, tough stone blocks will possess the longest life of the three, and wooden blocks the shortest, asphalt lying between the two, and very near the stone.

As to first cost, the order of cheapness is given thus: First, wooden blocks in America; second, asphalt, and third, stone blocks, and as to cost of maintenance and repair the order is thus placed: Economy of yearly maintenance, inclusive of first cost, good stone stands first, asphalt second, and wood third. In facility of cleaning the order is first, asphalt, second stone, and third wood, whether the cleaning be done by sweeping or washing. Stone is, of course, the noisiest pavement, and the difference between the slipperiness of the wooden, asphalt, and stone pavements is not very great, supposing the street to be kept reasonably clean. The deductions of the jury are as follows:

In respect, therefore, to the comfort and convenience of persons using the street as well as those residing upon it, the order of merit would seem to be asphalt, first, wood second, and stone third, for all streets except such as are habitually crowded with heavy and busy traffic, in which case stone must be placed first and asphalt third.

The hygienic objections to a pavement of granite blocks are, first, its constant noise and din, which exert an injurious effect upon persons suffering with nervous diseases, and especially upon infants and all classes of invalids; and, second, its open joints, which collect and retain the surface liquids, and throw off noxious vapours and filthy and unwholesome dust.

Exceptions to wood may be made upon the same grounds, and, in addition to this, the material itself is subject to inevitable and often to early decay and decomposition, in the process of which poisonous gases and noxious miasma are set free.

M. Foussagrives, professor of hygiene in the medical school at Montpellier, France, expresses the deliberate opinion "that a city with a damp climate, paved entirely with wood, would become a city of marsh fevers." He also says, in speaking of asphalt pavements, that "the absence of dust, the abatement of noise, the omission of joints—permitting a complete impermeability, and thus preventing the putrid infection of the sub-soil—are among the precious benefits realized by asphalt streets."

Considered, therefore, with respect to the health of the people, asphalt stands conspicuously first, stone second, and wood third in the order of value and merit.—"Philadelphia Enquirer."

Mr. Gladstone on Timber-felling.—The "Sheffield Telegraph" says that a firm of manufacturers in that town lately forwarded to Mr. Gladstone one of their original American patent axes, which they make a specialty of. The blade was of polished steel, and the handle of Hickory. Acknowledging the gift, Mr. Gladstone writes:—"December 13. Gentlemen,—I am very glad you have added that useful article, the American axe, to the list of our home productions, and I thank you for favouring me with a specimen which seems, as much trial as I have made, to possess all the merits of the original. I find it necessary to study efficiency in proportion to weight, and it is under this issue that I think the American axe comes out well, especially for soft or free-grained woods. The handle is, I think, excellent; but I always wish it were cut straight across at the end, at a right angle to its direction or axis.—I remain, gentlemen, your faithful servant, W. E. GLADSTONE." The same paper publishes the following correspondence which has taken place between Mr. Henry Claydon, grocer, of Clay Cross, and Mr. Gladstone:—"Clay Cross, December 6.—Right Honourable Sir,—A timber feller named Hopkinson, who claims some celebrity in that line of business in Clay Cross, who is fifty-four years of age, and who is really, according to his age, considered one of the best timber fellers in Derbyshire. He is particularly anxious to measure himself with Mr. Gladstone in that line either in Hardwick-park, or Chatsworth-park, or anywhere else, as Mr. Gladstone thinks proper. He also desired me to say that he would stake a sovereign that his (Hopkinson's) tree would be down before Mr. Gladstone's tree, taking them equal in circumference. Hoping you will favour me with an early reply to the above solicitation, in order that I may communicate your decision to Hopkinson on the above subject, I have, &c., HENRY CLAYDON, Clay Cross."—Mr. Gladstone's reply is as follows:—"December 12.—Sir,—I regard the challenge which you have transmitted to me as a great compliment; but I at once give in. I never had pretensions to excellence; and if I had had them, by this time, from age and other causes, they would have been lost. I wish your friend may long enjoy his laurels.—Your faithful servant, W. E. GLADSTONE."

THE FRUIT GARDEN.

A WEST OF ENGLAND FRUIT NURSERY.

THE Merriott Nurseries, Crewkerne, celebrated for their fruit trees, are situated in one of the pleasantest parts of Somersetshire. The climate is warm and genial, and the soil is well adapted for the growth of fruit trees. To these nearly thirty acres are devoted, and a considerable acreage is also planted with forest trees and shrubs. Amongst the latter, those that will withstand the sea-breeze are made a speciality, there being in this district a growing demand for sea-side shrubs. Fruit trees, however, constitute the staple stock. Of Apple trees alone there are said to be over 1200 kinds, Pears being in proportion. Growing so many varieties has its disadvantages as well as advantages, for sometimes trees may be kept for years and never asked for, thus occupying space which might be more profitably used. In addition to young saleable trees, there are also in this nursery hundreds of fine permanent pyramidal trees grown for the sake of their fruit, with which that of doubtfully-named kinds is compared. One tree of each kind of Apple, Pear, Plum, and other fruits is planted along the sides of the walks in alphabetical order, a great advantage as regards nomenclature; for it is not by the fruit alone, says Mr. Scott, that we can form a correct opinion as to the name of any particular kind, but by comparing the wood and venation of the leaves, the latter not being affected by climate or soil, as in the case of the fruit. Pears are for the most part grafted on the Quince stock, but many kinds do not fruit so well under these conditions as they ought to do; therefore, strong-growing sorts, such as *Beurré de Amanlis*, are first grafted on the Quince, and the following season other kinds are grafted on them. *Marie Louise* and *Louise Bonne* of Jersey, if grafted direct on to the Quince, do not fruit for some years; but if double grafted, good fruiting trees are obtained the second year afterwards. Other kinds, however, do best under reverse circumstances, and it is only by years of patient experiment that it can be determined under what conditions different kinds succeed the best. Apples on both the *Paradise* and the *Crab* stock appear to thrive luxuriantly. It is a singular fact that in so large a collection of Apple trees, both young and established, as exists in this nursery, as well as in the immediate neighbourhood, not a trace of American blight can be found; indeed, Mr. Scott informed me that he had proved beyond doubt that it would not live thereabouts; even trees brought to the nursery, though sadly affected by it, have, in a short time after being planted, recovered. It must not, however, be inferred that trees from this locality planted elsewhere will not be liable to be attacked by American blight; on the contrary, if taken where it exists, they would no doubt in time be as liable to it as any others; but the fact, nevertheless, shows how much more the successful culture of fruit depends upon soil and climate than upon any art which man can bring to bear upon it. Of Apples in this neighbourhood there is this year a great scarcity. There was a remarkably fine show of bloom, a great proportion of which set, but the sudden alternations of heat and cold in spring caused nearly every fruit to drop. Cider Apples, however, appear to be plentiful in some parts of Somerset and Dorset. A Cider Apple grown in the Merriott Nurseries, named *Hangdown Horner*, is a very peculiar kind, owing to its tendency to weep; in whatever form the tree is grown, unless kept upright by means of strong stakes, the branches will soon bend to the ground. It is an immense cropper, even in its young state, and would be valuable as an ornamental tree in shrubberies and similar positions. Cherry trees, which are grown in large quantities, thrive luxuriantly, making shoots every season from 3 ft. to 4 ft. in length. They are mostly grafted on the *Mahaleb* stock, but there are a few kinds which will not grow satisfactorily on it; these, therefore, are worked on the common Cherry or double-grafted on strong-growing kinds, as in the case of Pears. Grafting takes place in February, and such trees as are transplanted after the graft has become established are planted deep enough in the ground to just cover the point of union between stock and scion. Peaches and Nectarines occupy large plots of ground, and are very healthy. At the time of my visit—the

middle of October—all superfluous growth had just been cut off them, in order to admit as much sun and air as possible to ripen the wood. Several large Apple and Pear trees here had been completely divested of their outer bark, an operation which had been done for an experiment in order to get rid of canker. This kind of treatment seemed to have the desired effect; as far as could be seen the trees had not suffered in the least, and the bark was gradually growing over the bare stems. Such operations should, however, be conducted with caution.

The approach to this nursery passes through long avenues of healthy Conifers. Narrow borders contain dwarf plants of *Retinospora ericoides*, and other interesting kinds, and I also noticed *Cryptomeria elegans*, *Araucarias*, and golden and green-leaved *Thujas*, intermixed with flowering plants, and here and there a glimpse was caught of the richly-coloured beds of autumn *Colchicums*. Two fine plants of *Pampas Grass* were also growing here, each of which bore over seventy plumes, on stalks from 12 ft. to 15 ft. long. A pair of plants of the graceful *Arundo Donax* were likewise each provided with from fifty to sixty strong stems, 12 ft. high, and as thick as a good walking-stick. In winter a little protection is given to the roots of this *Arundo*, which is all the attention it requires. Large specimens of the *Cockspur Thorn*, laden with scarlet fruit, were remarkably showy, and *Cotoneaster microphylla*, grown as a standard from 6 ft. to 8 ft. high, and the branches allowed to droop to the ground, was very effective, covered, as it was, with coral berries. *Magnolia grandiflora*, grown in the form of pyramids, was also very attractive, as were likewise examples of *Weeping Holly*, and the sweetly-scented, white-flowered, *Camellia-leaved Ligustrum macrophyllum*. *Phoradendron tenax*, *Melanthus major*, and *Aralia Sieboldi* all grow freely here in the open air, and remain undisturbed for years. The houses consist of span-roofed structures for sheltering tender plants and raising Ferns and other decorative plants. In one house were noticeable neat plants of the scarlet-flowered *Russelia juncea* and *Coprosma Baueriana* planted out, and covering a large space of rafters, and, besides being ornamental, furnishes abundance of cuttings for stock. C. S.

Mistakes in Buying Fruit Trees.—Many years ago, when the different sorts of fruits were little known, and the difference between good and poor varieties was not so well appreciated as now, it was common for purchasers of trees at the nursery to select large trees of handsome growth, without much regard to anything else. Since that time, purchasers generally have learned the importance of selecting the best varieties, but they still attach too much importance to a handsome top, and forget the roots. When a symmetrical head is connected with a mutilated root, it often occurs that more anxiety is shown to save the top entire than to transplant the tree in the best manner. Some would choose a handsome pyramidal form, with deficient bottom, before a less attractive tree as regards form, with a full and perfect mass of fibres. The one, if it lives, may recover its vigour in two or three years; the other, properly attended to, will be scarcely checked in growth by removal, and a few years hence will make the finest appearance of the two. As commonly taken up by nurserymen, trees are necessarily deprived of a large portion of their fibres. Before, or at the time of setting out again, these must have their tops lightened by pruning back a portion of the young shoots. The larger the tree, the more important the operation. But the trouble is, the planter dislikes to lose any of the fine top, and leaves it untouched, often to the serious detriment of the tree. It was for this reason that a large planter found that badly-shaped trees always grew better than handsome ones. They were bought at lower prices, and the purchaser was willing to cut them back. Medium or small trees do better than large ones for three reasons: 1. The roots are more easily taken up entire. 2. They are awayed less by winds. 3. They are more apt to get the required pruning back, as the owners are not afraid to use the knife.—“Country Gentleman.”

Preventing Vines from Bleeding.—I know of nothing which stops bleeding so effectually as joiner's knotting. After pruning, take a brush and daub it on the cut parts, when the surface will become covered as it were with glue, and no sap will ever find its way through it.—M.

The Victoria Plum.—This is the surest fruiting Plum in cultivation. It does equally well as a standard or bush as against a wall. This year it produced double the quantity of fruit of any other sort, and in other seasons, when there has hardly been a fruit on any other variety, the *Victoria* has been loaded. Although generally classed amongst culinary Plums, it is quite admissible as a dessert variety.—CAMBRIAN.

PLATE CVI.

PEARSON'S GOLDEN QUEEN GRAPE.

Drawn by MRS. DUFFIELD.

It is no easy matter in the present day—in this age of competition and rivalry—to produce anything which shall hold its ground against the attacks of critics, and stand the test of time without being swept away by the stream which is ever carrying away into oblivion the changing fancies of the public taste. It is, indeed, a great merit to have given something to the world which shall keep alive the fame of its author long after his work is done. Every gardener in the midland counties is familiar with the name of Pearson, the horticulturist. He was a true lover of the gentle art. Gifted with great natural talent, aided by careful training, he devoted his time and attention to fruit culture, particularly to improving the qualities of different kinds of fruit. His extensive nursery grounds at Chilwell, near Nottingham, were specially adapted for his experiments in this direction. Among hardy fruits, we have a seedling Filbert called Pearson's Prolific, an excellent variety, dwarf in habit, and an abundant bearer; trees 2½ ft. high are frequently laden with nuts. In dessert Apples, we have Pearson's Plate, a delicious little Apple of the first quality and resembling the old Nonpareil and Nottingham Pippin, a second rate Apple of strong, vigorous growth, and an excellent bearer. Every orchardist acknowledges the superiority of the old Bess Pool Apple, the uncertainty of its crop being its only fault. In Pearson's Improved Bess Pool, this defect is removed, and the list of our culinary Apples has received a desirable addition. Not content to confine his labours to the orchard, he and his contemporary, the late much-esteemed Thomas Rivers, tried to remove the prejudice which existed against hardy fruit culture under glass. In this variable climate we too often see

The seasons alter : hoary-headed frosts
Fall in the fresh lap of the crimson Rose,

and one night blast all our hopes of a fruit crop. Mr. Pearson devoted much study and attention to finding out the method of constructing orchard-houses, as well as to growing hardy fruits under protection, and we know that in both directions he was eminently successful. He acted upon the principle (which may well be followed) that only the best varieties of each kind of fruit are worth the expense and trouble of this mode of treatment. In the large additions which he made to his glasshouses, he adopted an economical and improved construction, and in 1865 published a valuable treatise upon the building and arrangement of orchard houses. This book, "Pearson on the Orchard-house," contains many practical hints which I have found most useful. Mr. Pearson gave great attention to improving the constitution of the Vine. Mildew and red spider (the great pests of the Vine grower) have tried the patience of many gardeners; the causes of their appearance have furnished themes for every writer on the subject of the Vine, and the fertile imagination of quacks has been employed in devising nostrums for their cure; but careful and attentive cultivation, encouraging a free and healthy growth, is the best antidote which I know of. When a member of the Fruit Committee of the Horticultural Society, he ascertained that the native Grapes of North America enjoy a comparative immunity from the attacks of mildew and red spider, and he resolved to cross one of them (the Strawberry or Fox Grape of the Americans) with one of our best bothouse varieties; obtaining a few eyes from Mr. Barron, he soon fruited this variety, and resolved, in all cases, to use it as the female parent. This experiment excited much interest, especially from the extraordinary character of the foliage produced. The Strawberry Grape has small, woolly leaves, very slightly cut, indeed, nearly heart-shaped: the leaves of the seedlings were all deeply cut, some of them small, but others of immense size; indeed, so much so as to be quite curiosities. The fruit varied as much as the foliage, being of all colours and of every degree of unpleasant flavour, excepting one or two which were golden in colour and very sweet. One only was thought worth keeping—Ferdinand Lesseps. It was exhibited in London in 1870, and received a first class certificate. This Vine is a strong grower, and an abundant

bearer: the fruit is of medium size, of golden colour, with a very rich and peculiar flavour, composed of a mixture of Muscat and Strawberry. Its peculiarity is its chief recommendation, the aromatic flavour being too strong for most tastes. Mr. Pearson then crossed this Grape with other varieties, and from the [hatch of seedlings he raised Dr. Hogg, Mrs. Pearson, Abraham Bass, and others. From a distinct cross with the Black Alicante he produced the seedling called Golden Queen, the subject of this notice, and of the coloured plate. The bunch is about 11 in. long, and 6 in. or 7 in. across, with a stout stalk: the berry stalks are rather long, but stout and warted: the berries are from 1 to 1½ inches long; they are oblong and oval. In bunch and berry this Grape resembles the Madresfield Court, but in colour it is a bright gold. The flavour is that of Muscat of Alexandria, without the aroma peculiar to Muscats, being, in fact, a rich, fleshy, sweet Grape. The prevailing taste of the age for delicacy and softness in clarets and other wines, renders a fruit of a negative and refreshing character, without any distinct or pronounced flavour or smell, particularly acceptable. The foliage of this Vine shows its hybrid origin, being strong and dark-looking, having a leathery feeling to the touch more like that of a Fig than that of a Vine. The wood is of a bright cinnamon colour, and, taking fruit and foliage together, it is, perhaps, one of the most beautiful Vines in cultivation. The robust leaves and vigorous habit attest the goodness of its constitution, and I am informed that when grown in houses with other sorts, it is found to be nearly proof against mildew and red spider: when the

Pearson's Golden Queen; berries natural size.

Vines near it have been attacked, not a leaf of the Golden Queen has been touched. It received a first-class certificate from the Royal Horticultural Society, in 1873. It may particularly be termed an amateur's Grape, being so distinct in foliage and fruit, easy of cultivation, a free setter, with large and even berries. It is a late Grape and keeps fairly well. Possessing these excellent qualities, "Her Golden Majesty" may well be thought worthy of her producer. She adds another tribute to the memory of an eminent horticulturist—a genial neighbour and friend. Many new sorts of Grapes have of late years been brought before the notice of gardeners, but of these the greater part succeed only when treated in an exceptional manner. When they are planted in houses with other varieties failure and disappointment are the only results. It is of great importance that new kinds of fruits, when recommended by the certificate of the Royal Horticultural Society, should not be tested solely by the beautiful appearance of bunch or berry, or by their exquisite flavour; some guarantee should be given to the public that the new comer is likely to flourish under general, instead of exceptional, cultivation. Mr. Pearson's Sons (who have succeeded him in his business) have offered an annual prize for the finest bunches of the Golden Queen exhibited at the London shows. They thus testify their belief in the excellence of the Vine, and I hope that as it is now so generally known among the leading growers, there will be a spirited competition. The Brothers Pearson are men of energy, and fully alive to the requirements of the present day. We can only hope they will carry on the work their father has begun, and prove themselves no unworthy inheritors of his fame. There are lands still unconquered, and harvests yet unreaped awaiting the hand of the horticulturist. When I look back on the last 20 years, I cannot be unmindful of the great progress which has been made in this science; but I believe

the art to be yet in its childhood. Happy are those who shall behold the glories of its prime! The diffusion of education, the improvement in the public taste in this country (in a great measure due to increase intercourse with other nations), the acknowledged necessity for more general culture, and last, but not least, the higher tone which has for some time prevailed in that branch of literature specially devoted to horticultural matters—all these seem to point to a brilliant future.

Hillside, Newark-on-Trent.

W. NEWTON.

Grape Growing at Oak Hill.—In the review of "Thompson's Gardener's Assistant" (see p. 576), the reviewer says, in reference to Grape-growing, that it is perfectly well known that no gardener, at the present day, cares a farthing for the practice at Oak Hill some thirty or forty years ago. Now, I can go back to fifty years ago to the practice at Oak Hill, and maintain that there were as good black Hamburgh and Muscat Grapes grown there in the late Mr. Dowding's time as we see now grown by the best cultivators. I never saw the Grapes grown there by Mr. Davis, who succeeded Mr. Dowding, but I believe they were about the best, and brought the highest prices, when sold, in Covent Garden market. There were no Gros Colman, Barbarossa, nor Trebbiano grown at the time to which I refer. Nor were any of the monster bunches produced as have cropped up during the last few seasons. The black Hamburgh, however, then produced bunches, at Oak Hill, from 6 to 8 lbs. in weight, with berries as large as Rivers' Early Prolific Plum and as black, and Muscats from 4 to 5 lbs., of fine shape, with amber-coloured berries. What do we see now in these monster bunches but unthinned berries badly coloured, to produce which the crop has to be sacrificed? There never was a greater fallacy in Grape-growing than in trying to produce large bunches, even for purposes of exhibition (unless for weight), for compact bunches, of good size, always show best if the berries are of fair size and well coloured. From extra large bunches of Grosse Guillaume, Trebbiano, and others, I generally clip off some of the shoulders, so as to have them compact to show well on the dessert table.—WILLIAM TILLEY, *Welbeck.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Apricot Branches Dying.—I have always attributed the sudden death of Apricot branches to sunstroke, having noticed cases to occur on due south aspects more frequently than on others, and in many instances where the knife has been too freely used during the spring pruning, the mischief in some cases having taken place during the previous autumn.—W. E.

Early Melons.—In answer to W. R. (see p. 530), permit me to say that for early work I find nothing equal to Gilbert's Victory of Bath. It has a good constitution, is a free setter, medium in size, and excellent in flavour. I have gathered three good crops in one season from the same plants grown in pots, plunged in a bark bed amongst Pines, trained over the centre pathway, and kept well supplied the whole time with weak liquid manure.—JAMES SMITH, *Waterdale.*

Effect of Mistletoe on Apple Trees.—Is Mistletoe really as injurious as the article on "Field Culture of Hardy Fruit Trees" states it to be (p. 549)? I have been doing my best to encourage it upon my Apple trees, under the impression that it is harmless. Can any of your readers also inform me whether Mistletoe is ever found upon Fir trees in England? I saw this summer in Switzerland, at the entrance of the Vald' Anniviers, Rhone Valley, probably as many as one hundred Fir trees clothed with it from top to bottom.—E. W. EVERLEY. [There is little reason to doubt that the Mistletoe is injurious to Apple trees, from the fact that the limbs or branches on which it may be seen growing are generally much weakened and diminished in size compared with those on which there is no Mistletoe. When a tree is heavily laden with large, dense bushes of Mistletoe, in addition to having its juices extracted, it is deprived, in a great measure, of light and air. It may, therefore, safely be said that Mistletoe not only impairs the health of Apple trees but diminishes the fruit crop as well. But why encourage its growth on valuable fruit trees when it may be grown on so many different varieties of other trees? The following is a list of those on which it has been found to grow in this country, the first five or six being those on which it is most commonly found, viz.:—The Apple, Hawthorn, Lime, Poplar, Maple, Willow, Mountain Ash, White Beam, Acacia, Horse Chestnut, Birch, Mesquite, Plum, Pear, Almond, and Oak. I have never seen it on Fir trees in this country.—GEORGE BERRY.]

Hertfordshire Dwarf Cauliflower.—We are now cutting good heads of this fine summer and autumn Cauliflower from open quarters. The plants, indeed, are heading so fast that, besides obtaining a full daily supply from them, I have been able to store 300 fine heads in frames for late use.—RICHARD NISBET, *Aswarby Park.*

THE KITCHEN GARDEN.

FORCING POTATOES.

ALL things considered, the old Ashleaf Potato, if true, is still as good as any for forcing. Select good-sized, whole tubers, and place them, crown upwards, in shallow boxes or trays, and then cover with a layer of Moss or Cocoa-nut fibre refuse. The boxes should be placed in some light, airy position, where there is just a little warmth; under a greenhouse stage will do, as there is not much gained by pushing Potatoes hastily and prematurely into growth. If there be a Peach-house at work, a few may be started in pots at once; but as soon as the growth shows above the soil, they must occupy a light position as near the glass as possible. A Vinery will hardly do so well, as too much heat and shade will draw them up weakly, and the size and quality of the produce depend upon the growth being strong and vigorous. Three sets of tubers may be planted in each 12-in. pot, which should be well drained, as stagnant moisture about them spoils their flavour. Place one large crock over the hole at the bottom, and on this place 3 in. of rough pieces of turfy soil; the water will pass through this freely, and the plants later on will derive some advantage from it. On this put 5 in. or 4 in. of light, rich compost, consisting of loam and leaf-mould, with a sprinkling of wood ashes. In preparing the sets, one good strong eye or bud for an early crop is better than more, and all but the strongest one should be rubbed or cut out. Cover with 2 in. or 3 in. of soil, which will leave space for an earthing up when the stems have grown 5 in. or 6 in. high. Potatoes grown in this way will furnish a few early dishes; but the main forced crop will be better grown on beds of leaves and stable manure in pits or frames. The leaves and manure should be well prepared, as it is a regular steady heat that is required. The early beds may be composed of equal parts leaves and manure; later in the season more leaves may be employed, if in a situation where they are plentiful. Of course, where leaves are used to the extent of one-half or more, there will not be much danger from overheating; but even then no time will be lost by throwing them and what manure is available into a heap to ferment. This brings up the heat quickly, and the turning and mixing that follow in making up the bed sweetens the whole, and the bed will be in a fit condition to receive the plants sooner than if no such trouble had been taken.

If pits be used for forcing the first crop, fill up with the fermenting material to within 15 in. of the glass, treading it several times during the operation. Unless treading be resorted to, it should be filled to the top of the walls, as it will subside considerably when the soil is placed on it; such settlement will take place in proportion to the depth of material, which will be sure to go down sufficiently to afford room for the Potato tops by the time they require space. There is only one danger to be apprehended from having Potatoes near the glass, and that is frost on cold nights, and this will have to be guarded against by using warm coverings. About 1 ft. in depth of light, rich, good peat soil will be sufficient, and the Potatoes should be planted in rows about 14 in. apart and 8 in. between the sets in the rows. If planted 6 in. deep they will not require earthing up in the ordinary sense of the term, but a little warm, fresh soil placed round the stems with the hands when about 6 in. high will be beneficial. When Potatoes are grown on a moist bed of fermenting materials they will not require much water beyond what ascends in the form of vapour carried up by the heat of the bed during the early growth. Treatment somewhat similar to this will be required when Potatoes are forced in movable frames and lights, and the early crops should have both deeper and wider beds than will be necessary later in the season. As the days increase in length and warmth, temporary beds may be made up anywhere, and be sheltered with straw covers. I always begin digging from the open air by the middle of May, merely planting on a warm, raised border, and covering every night with straw-covered frames.

E. HOBDAV.

The Price of Turnips.—Not long ago a correspondent, complaining of the price of Turnips in London, recommended growers to send their crops to market instead of feeding them off with sheep.

At that time Turnips were, in this locality, esteemed a glut, and growers complained that barely 1s. per dozen bunches was obtainable. The crop of Turnips this year has been a remarkable one, and they ought to be sold very cheap indeed; but it is a fact that even now, although the present market price to the grower has advanced to about 1s. 6d. per dozen bunches, yet single bunches are retailed at 4d. each or 4s. per dozen. The reason for this almost prohibitable price to the consumer is obvious; there are too many middle men in the vegetable trade, each of whom expects to make 50 per cent. profit, whilst the unfortunate grower, who has borne all the burden of cost and labour in producing the crop, gets but a poor return. If producers and consumers could be brought into immediate contact, both would be greatly benefited.—A. D.

KITCHEN GARDENING MADE EASY.

My starting point, this week, is with that king of vegetables, the Potato, and here I must halt for a moment to say we gardeners, as a rule, grow about ten times too many varieties. Taking Myatt's Prolific, all in all, I pronounce it to be the Prince of Potatoes, and for garden culture, with the exception of an early south border of old Ashtops, as they come a few days earlier, I will grow nothing else for the future. They come off early, and, if taken up in time, are free from disease, and a good crop of Potatoes, without disease, is worth a king's ransom. The land for the first crop in this case is dug and slightly manured, and laid up roughly for the winter frosts to pulverise. The sets are planted out before the first week in April by drawing shallow drills, from 2 in. to 3 in. deep. All my seed is laid thinly in shelves, on an airy room, and by April will be sprouted and bristling with good strong shoots, green and hardy. Putting them into the warm soil, they come up at once and receive no check, as we earth them up twice before the middle of May in order to guard against frosts. When the crop is lifted, we cultivate the land, but not deeply, and plant, in this case with a dibber, Coleworts, Winter Lettuce—that is Lettuce for using all winter; and Endive—which is now, December 15, all protected with Bracken. All being off the ground by February, the land is well dusted with lime and malt dust in equal quantities, and again cultivated, keeping this dressing near the surface. In the first week in April we plant Myatt's Prolific, thus growing two crops of Potatoes and one of Lettuce without the use of the spade or steel digging-fork—and here, I may add, that I have, for days, aye for years, worked these forks, and, for digging, where the land is not manured, or, in the case of stony or flinty land, they are useful garden implements, but for easy work give me the cultivator. *Burghley.* R. GILBERT.

— I am highly pleased that men like Mr. Groom should not only read, but also criticise, my "Kitchen Garden" notes, and I feel sure that the difference between Mr. Groom and myself only wants explaining, and then we shall go hand in hand. Mr. Groom says (see p. 579):—"Surely I do not plant early Potatoes after Brussels Sprouts without digging?" but I do, and with the best results. Surely Mr. Groom does not allow his man to walk over the whole bed for a dish of Sprouts? My man begins at one end of the bed and clears off every button before him, so that we have no pathways. I mulch the land, as before mentioned, and consequently have no weeds; the mulching keeps the soil moist and forms the best of roads, being clean and tidy. We then, as mentioned in my former notes, use the cultivator, mixing the manure with the top soil, from 5 in. to 6 in. deep. With respect to this being easy work, my men shall speak for themselves. Four years ago they presented me with a timepiece, and my foreman was deputed to make the presentation. After thanking them for this token of respect, I asked them what I had done to merit such a present, when one old man, of forty-eight years' experience, answered:—"You have made kitchen gardening easy compared with what it used to be, by using them cultivators." I can use the spade a little, but I much prefer the cultivator, and so do the whole of my men; in fact, in all soils twice the ground may be got over with it that could be got over with the spade.—R. GILBERT, *Burghley.*

Results of Deep Cultivation.—Mr. Gilbert's method of cultivation must be good, or he could not produce the excellent vegetables which he does. But, in order to prove that deep cultivation, although expensive, is not "hurtful," allow me to make the following statement:—As a rule, we trench our ground every year two spades deep, and turn over the third spade in the bottom of the trench, which gives us a good working soil rather more than 2 ft. deep. On a piece of ground trenched in this manner last winter we have Parsnips (The Student), one root of which measures 17½ in. in circumference at the top, and at 12 in. from the top it girths 6½ in., the length of the whole root being 27 in.; others are more in circumference, but not so long. I may add that one root was 36 in. in length, but being

forked, it was not so handsome as the others. Onions (James' Keeping) on the same square of ground, produced bulbs 13 in. in circumference, the weight of one of which was 15 ozs.; the average size of bulbs, taking the whole crop into account, is 10 in. Leeks (Ayton Castle) measure 6 in. and 6½ in. in circumference. These measurements have doubtless been exceeded elsewhere, but in such a year as this has been, they will, I trust, be considered creditable. It will be seen that I am an advocate for deep annual cultivation.—J. W. BAYNE, *Kingston, Derby.*

Dandelion Salad.—Allow me to inform "W. T. T." that I really do mean that the Dandelion may be gathered from November to March in the open fields, and that when it is dressed in the manner described (see p. 529) it forms a very palatable salad. Although it is occasionally blanched, its flavour is not improved thereby, but the contrary. I may further add that it is during the period mentioned that the Dandelion is found in its most tender condition; it is seldom used during the time when it is in flower, and is, in fact, hard and unpalatable when it grows most vigorously; moreover, in summer it contains such an amount of milky juice that it is far too bitter for the palate. Respecting the mixing, I may inform your correspondent that a salad to be really good should be mixed and eaten immediately; under no consideration should it be allowed to stand. The reason why I prefer mixing the pepper and salt with vinegar is because I have always found that the best plan to distribute them equally throughout the salad, which the viscous character of the oil otherwise sometimes prevents, especially if very great care be not exercised in the mixing.—CHARLES DENNIS, *Southwark Park.*

— If we may take the season when Dandelions are most sought after as indicating the best period at which to gather them for salad, it is from March to June, when they are making active growth. Although when grown and blanched artificially they may doubtless be had in good condition at all seasons, yet, like Lettuces and other salads, I have no doubt that, under ordinary conditions, they are best while making their first growth previous to becoming exhausted by flowering, or through the heat and drought of summer. On fine spring days foreigners hereabouts, with table knife and basket in hand, go out and root up vast numbers of this well-known plant from Grass plots and Grassy banks, somewhat to the astonishment of the rural population, who are certainly strongly imbued with the national prejudice against the use of Dandelion as food in any shape.—JAMES GROOM, *Henham.*

Christmas Vegetables.—Garden vegetables should be plentiful this year, Potatoes not excepted, but these can only be had at an enhanced price. Turnips are very abundant, and so far the weather has kept the late crops growing, and the earlier ones comparatively uninjured. Early Broccoli is not abundant, but when the new winter protecting kind becomes better known, market growers will find it valuable at this season of the year. The Walcheren plantings are mostly cleared off, but in some favoured localities good heads are yet obtainable. One of the most favourite Christmas vegetables is the Brussels Sprouts, and these are still being produced in abundance. Savoy Cabbages want frost to make them tender, but early ones are good and inviting, whilst the tender and marrow-like Collards are just now at their best, and they are unusually abundant. More autumn-grown Onions are seen this year than at any previous time, and full large for pulling. Spinach is largely sown and affords through the open weather many good pickings. Carrots and Parsnips are not so popular for common consumption, and are therefore not largely grown in some gardens, but are chiefly produced in favoured localities. Carrots, especially, are found in some parts of Surrey. Of choicer kinds the high class producer and the importer will do their part in securing a good supply, and only in the improbable event of very severe weather at Christmas can vegetables be scarce.—A. D.

Adulterated Seeds.—At a recent meeting of the Royal Agricultural Society, a Report from its Consulting Botanist (Mr. Carruthers) was read. It stated that during the past year some sixty samples of seeds had been submitted for examination, most of which were satisfactory, no case having occurred this year in which either killed or spurious seeds had been foisted upon the purchaser. The samples that he had condemned were defective either through the presence of worthless or injurious weeds, or through bad or careless harvesting, so that too large a proportion of unripe grains were collected, or the grains were injured in thrashing or in other subsequent treatment. It was recommended that the Society should have power to take the same course as the Chemical Committee had taken for some years, with a very beneficial deterrent effect upon people who were disposed to act dishonestly, i.e., to present quarterly reports on the cases of adulterated, killed, coloured, and inferior seeds brought under the notice of the consulting botanist, for publication, together with the names of the vendors (subject to the approval of the Council) in the newspapers.

EFFECTS OF RECENT SUNLESS SUMMERS.*

BEFORE the close of the year I think it desirable that a few remarks should be made regarding the deficiency of certain fruits, flowers, and vegetables, for comparison with those of future seasons. A considerable portion of the summer of 1876 was comparatively sunless and moist, so much so, that the bearing branches of many fruit trees and flowering shrubs were not sufficiently ripened to mature healthy flowers or fruit, and, therefore, a deficiency in the crop of 1877 has been the result, although the winter of 1876-77 was rather mild. This season, like the previous one, has also been sunless and moist, and therefore many vegetable productions have never been properly matured. At the present time, as far as can be ascertained, the flowering shoots of many shrubs and fruit trees do not appear sufficiently strong to warrant us to expect a full crop another year, two good consecutive seasons being generally necessary for this purpose. The mild weather which we have lately experienced is causing many fruit trees, particularly Pears, to produce late blossoms, which also militates against next year's expectations. In cases where fruit-bearing wood has been ripened by a previous fine summer, it sometimes happens that the fruit blossoms are ruined by late spring frosts. A slight touch of frost occasionally during the spring months is sometimes, however, desirable, for if all the blossoms produced were to come to maturity, the trees would often run a risk of being injured by an excess of small-sized fruit. In a season like that of 1876 the wood formed during the year was not thoroughly ripened, and when the flower-buds of many fruit trees opened in 1877 they were, in general, weak, and frequently colourless, particularly pink kinds, and, in numerous instances, fell off without fruit being formed. In cases in which fruit was produced, a deficiency in flavour was generally remarked; this deficiency in flavour was particularly noticeable in many of the finer wall and standard open-air fruits, such as Peaches, Nectarines, Apricots, Plums, and Cherries, as well as in Apples and Pears, and also in many of the smaller fruits, such as Gooseberries, Strawberries, and Raspberries. Although some kinds of Apples fruited freely, and some were tolerably well perfected, the majority were miserably small and unripe, and many are still seen hanging on the leafless trees. Deficiency in the way of fruit was also observed in the case of such trees as the Crab Apple, common Gean, standard Plum, Black Sloe, Medlar, Strawberry tree (*Arbutus Unedo*), common Black Elder, Bramble, Barberry, Mahonia (particularly *M. aquifolia*), Gaultheria Shallon, *Ribes sanguineum*, Portugal Laurel, and Laurustinus. Amongst hardy ornamental trees and shrubs noticed as being freely covered with fruit, were the varieties of the Service or White Beam trees (*Sorbus domestica*), also the Mountain Ash, Cotoneaster, Thorn, Yew, Snowberry, and almost all the varieties of Holly. Although the Holly was rarely to be seen in fruit last year, this dearth was evidently caused by frost, 167° having been registered during the months of March and April, 1876, at a time when the blossoms of the Holly were approaching perfection. This spring the Holly was later in blooming, and thus escaped certain spring frosts, and a profuse crop of fruit is the result.

Of the smaller description of hard fruits, Filberts and common Hazel Nuts were also scarce. The Hazels were abundantly covered with catkins during the month of January, but the severe frosts which occurred towards the end of that month, and beginning of February, completely destroyed them while in perfection, turning them from a rich yellow to brown. Fruit was likewise scarce amongst ornamental fruit bearing and forest trees. In this part of the country Walnuts have been excessively small, and none ripened. The Horse Chestnut Trees have been fruitless this year, and the leaves were much infested with insects during the spring; the flowers, too, got injured, and few opened. Eatable sweet, or Spanish Chestnuts have also been scarce. A great scarcity has likewise been noticeable in the seeding of the Norway Maple, Elm, Oak, Birch, Lime, and Beech. The Norway Maple and Elm were freely covered with flowers during the early part of April. Throughout that month we experienced collectively 50° of

frost, which injured the flowers of these trees, and probably those of many others which flowered about the same time. In many districts the Beech has been covered with masts but almost all have been found empty. This scarcity, as well as other instances recorded, arises, in a great measure, from the unnatural state of the young shoots, which, although sufficiently strong to produce flowers, were not strong enough to resist frosts, which they are capable of doing when thoroughly ripened by a previous fine summer. On some of the varieties of Fraxinus, ash keys have been produced in abundance, but the great majority of the trees have been fruitless, while with the Plain or Mock Sycamore trees, the samara has, in some cases been plentiful, though generally wanting, even on trees, which usually fruit in abundance. In many situations the young growths of the Sycamore and other trees have been observed to be excessively short and twiggy, when compared with the growths of previous years, while conifers have made luxuriant growth. Laburnum flowered well during the spring months, and are now covered with seeds. Although cones of *Abies Douglasi* are in many places plentiful, few of them contain perfect seeds. Seeds have also been scarce in the case of many annual and perennial herbaceous plants, a circumstance, however, greatly owing to the excessive moisture at the time when they were in bloom. We annually collect seeds from our own Sweet Peas and Mignonette, but this year, not one pod ripened, on the former, nor a seed on the latter. Many perennial habaceous plants have also been late in coming into bloom, and, as a rule, far from strong. Dahlias, Holyhocks, and Gladioli have been sparingly exhibited this year, and the same may be said of Roses and other florist flowers. Almost all plants bedded out have been more or less failures, such as Scarlet Pelargoniums, Verbenas, Calceolarias, &c. Tritomas, particularly *T. Uvaria*, were hardly seen in flower this year before the middle of October, and the Pampas Grass (*Gynerium argenteum*) not till the middle of November, and then only in favoured situations.

Many vegetables have also been deficient. Potatoes in many districts are scarce and inferior in quality; as well as Jerusalem Artichokes. Beetroot, Carrots, and Parsnips are generally small, although good in quality. Many varieties of Peas, French Beans, and Scarlet Runners have been quite a failure this year, as well as Cauliflowers, Cucumbers, and Vegetable Marrows. The stems of the latter in many cases became diseased, and little or no fruit was produced. Many other examples might be quoted; the foregoing, however, are sufficient as a record of the year 1877 in the neighbourhood of Edinburgh. In many parts of England the scarcity of several of the above articles is also complained of, although exceptions are to be found in some places both in England and Scotland. Judging from present appearance, we are likely to experience the same difficulty as last year in forcing many of the hardy shrubs, &c., into flower, in consequence of the unnatural state of the wood and flower buds, the result of the recent sunless summer.

This autumn has likewise been remarkable for the want of the usual autumnal tints on the leaves of the various forest and ornamental trees. During those seasons when the wood and leaf shoots have been thoroughly ripened, the autumnal tints are then very beautiful, in reds, rich yellows, and browns, while this year, with the exception of the Medlar and *Sorbus vestita*, which are now yellow, also certain Azaleas and *Ampelopsis tricuspidata* (the latter on a wall), most other kinds have died a dingy, olive-green colour, and in many instances the leaves were blown off in consequence of the severe gales to which they have been exposed. The Liquidamber (*Liquidamber styraciflua*) is generally one of the latest trees to part with its leaves, and then always of a dark red colour. They are still hanging flaccid on the trees (13th December), of a greenish colour, showing the unripe state of the wood.

Greenhouse Stands.—Will any reader of THE GARDEN kindly assist me with their advice as to the fitting up of a conservatory with shelves and stands? It is 24 ft. square, opening from a sitting-room, and has a low span-roof. As it is built over a room, all the plants must be in pots. The floor is made of cement. I am recommended to have either two or three stands down the centre, and sloping shelves round; but before fitting it up I am anxious for further advice.—A. J.

* Read by Mr. James M'Nab before the Botanical Society of Edinburgh, Dec. 13, 1877.

FLORAL DESIGNS FOR THE TABLE.*

UNDER this title a new work on table decoration has made its appearance. It is from the pen of Mr. Perkins, gardener to Lord Henniker, who, if he has himself arranged tables similar to those illustrated in his book, must indeed be a skilled decorator. Mr. Perkins's work contains twenty-four coloured illustrations, amongst which may be enumerated those of a dinner-table, breakfast-table, luncheon-table, wedding breakfast-table, cricket luncheon-table, harvest home dinner or supper-table, hunt breakfast-table, and the Christmas dinner-table. Mr. Perkins advocates the arranging of flowers simply on the table-cloth in place of in glass or zinc troughs, which are mostly employed for that purpose; indeed, most of the illustrations are examples of this style of decoration. There are designs for small tables as well as large ones, as the following extract from the introduction to the work will testify:—"In this book-making age," says Mr. Perkins, "writers generally give some reasons for their publications. I have two: one is, I think every man should contribute his mite for the benefit of his fellows; the other is, that I think a work on this subject, showing at a glance how a dinner-table for from eight up to one hundred persons should be decorated, will be welcomed not only by those who are called upon to embellish the tables of the upper classes of society, but also by that important and numerous class who are in the habit of giving entertainments which aim to be distinguished by their simplicity and elegance rather than mere costliness." That Mr. Perkins also gives some hints on the cleansing and preserving of foliage for a second day's use, will be seen from the following extract:—"I may mention that in large establishments about five designs will be required for each week, and it will of course be advisable to have them as different in character as possible each night. The materials for the one decided upon may often be gathered two or three hours before wanted, and well damped with clean water (flowers excepted). Fern fronds, Lycopodiums, and such things, are best immersed in water for a few minutes to cleanse them from all grit, &c., and Vine leaves will often require sponging; when all are ready, they should be placed carefully in a flat basket or box, and be put in a cool place until wanted." "As each design will speak for itself, and a brief description is given of the materials employed, it will only be necessary to state that after the company has left the dining-room the groom of the chambers or the under butler should place any Fern fronds, leaves, or anything else worth preserving, into water, whereby many useful pieces may be saved, and be made available for other purposes the following day." Mr. Perkins's book will be found to contain many novel designs well worth inspection, but it may be as well to add that the designs are mostly formal, and may be termed a kind of dinner-table bedding out.

A. H.

Select Bedding Plants.—The following are desirable plants in their respective classes:—*Coleus*: Chameleon, Pine Apple Beauty, M. Crousse, J. M'Indoe, Multicolor, M. Denis Gusrin. *Fuchsias*: Lord Falmouth, T. T. Lawden, White Souvenir de Chiswick, Fireworks, Dr. Kitto Giddings, Mrs. Mein. *Lantanas*: Favorita, Victoire, Distinction, Marquis De St. Laporta, Grandiflora, Princess Louise. *Chrysanthemums* (Pompones): Maroon Model, Model of Perfection, Adonis, President, Madame Marthe, Saint Michael, James Forsyth, Golden Trevenna, Souvenir de Jersey, St. Thais, Rose Travenna, Mrs. Dix. *Pelargoniums* (Zonal): Kloon, scarlet; Astarte, crimson. Lady Eva Campbell, Mrs. Wright, pink; Lizzie Brooks, salmon scarlet; Fairest of the Fair, white, pink centre. *Pelargoniums* (Nosegay): Dr. Rawson, crimson; Louis, magenta; Mrs. Lancaster, red pink; Apple Blossom, white; Mrs. Vickers, deep salmon; John Gibbons, scarlet. *Pelargoniums* (Tricolor): Golden Maria Stuart, John Downie, Miss Goring, H. Reynard, Peter Grieve, Prince of Wales Silver, Mrs. Laing, Dolly Varden, Lady D. Neville, Mrs. M. Masters; Miss Farring, Eva Fish. *Bronze Pelargoniums*: Emperor of Russia, J. Kirkham, Prince Arthur, Mrs. H. Ware, Princess of Wales, Princess of Prussia. *Gold and Silver Edged Pelargoniums*: Princess of Alexandra, Miss Kingsbury, Rosamond Wright, Rhodanthe, Golden Brilliantissimum, Golden Chain.—H. C.

Winter Flowering Pelargoniums.—Pelargoniums are evidently destined to become as universally grown for the decoration of our conservatories and other glass houses during the dullest months of the year, as for the embellishment of our gardens in summer. Of few plants, too, could it be more appropriately said, that it is everybody's flower, for it is found in the palace and in the cottage, and even deigns to brighten, with its brilliant blossoms, windows where sun and air and other life-giving elements are at the best but fitful visitors. The readiness with which it may be propagated from cut-

tings is familiar to us all, and poor, indeed, must be its after culture if it disappoints its owner. At the present time we have a brilliant display of Pelargoniums of all shades, from pure white to the most brilliant scarlet, the soft pinks and whites being exceptionally attractive. But what I particularly wish to call attention to is this; that although the latest additions to this popular flower are vast improvements as regards size of truss, form of flower, and strength and dwarfness of habit and foot-stalk, no one need be deterred from having a similar display because their varieties are old, as our old Vauxvins, Rose Rendatler, Madame Vaucher, Amelia Grisan, &c., are not excelled for quantity of bloom by any new varieties which I have yet tried. The principal points as regards treatment, consist in keeping all blooms pinched off during the summer time, and in having the pots well filled with roots. For winter quarters, a light well-ventilated structure, where sufficient fire-heat to ensure a dry, buoyant atmosphere can be readily applied, will favour the retention of the blossoms in good condition for a considerable length of time. Sufficient root moisture must be supplied to support a healthy development, and all decaying leaves and flowers should be regularly removed.—JAMES GROOM, *Henham*.

Coverings for Cold Pits.—In answer to "W. B. L." (see p. 580), I should recommend him to get some common straw mats, made with wheat straw and tar twine. When well made, such mats keep out the rain, form a good protection from frost, and will last eight or nine years. They are made as follows:—First, be provided with a wooden frame of 1½-in. material, of any size to fit the frame or pit, say 8 ft. long and 6 ft. wide, a size which would fit an ordinary double light pit; then get some strong tar cord and stretch pieces of it, about 1 ft. apart, tightly from end to end of the frame. Next, take the straw in straight rolls, rather thicker than a man's wrist, and lay it crosswise the full width of the frame; then bind it together with smaller tar twine all the way through until the mat is completed; trim the ends with a pair of shears, and the mat is fit for use. Mats made in this way are easily rolled up or spread on the glass.—C. H. KITCHING, *Cokethorpe Park, near Witney*.

QUESTIONS AND ANSWERS.

Exposing Roots of Lily of the Valley to Frost.—Will some of your readers tell me if it is necessary to dig up the roots of Lily of the Valley, and expose them to the action of frost before putting them into force? This practice is followed here with them, and also with other plants, such as Roses, Lilacs, &c.—PARNON POWARS, *Florence*.

Goodyera Rollissoni.—Allow me to apologize to Messrs. Rollisson for my note on Goodyera. I have certainly been labouring under a great mistake. I have to day seen a plant of G. Veitchii from the Continent, also one sent to me as G. Veitchii, and the distinction is certainly great. G. Rollissoni is much the better of the two.—J. SPREAD.

Plaster of Paris and the Phylloxera.—Has any one tried old lumps of plaster of Paris, ground to powder, dug in among the roots of Vines as a cure for Phylloxera? We have none of this pest here to try it on, or I should make the attempt.—PARNON POWARS, *Florence*.

Sowing the Corsican Pine and Alder (see p. 580).—Keep the Pine seeds in a dry airy room until spring. Pinus seeds are generally sown in the beginning of May. Alder should be sown in March. It is not necessary to sow them in pans or boxes, but if the quantity be very small, this may be done, afterwards placing them in a cold frame. When sown in the open ground, the soil should be well dug and worked very fine. The seeds should be lightly covered with sifted soil, and care should be taken not to sow them too thickly.—B.

Hardy Flowers.—I want to get a good book on flowers, with lists of plants and bulbs, and descriptions of the same, saying particularly if they are hardy or half-hardy, and whether, if the former, they will do in a very cold country like ours in the north. I see in some lists that Pentstemons are said to be hardy, but they will not stand the winter here. I should like the book more particularly adapted to outdoor gardening, as I have no greenhouses. I should also desire to have hints given as to the cultivation of plants—their colour, height, and time of flowering.—EUSTACE H. RAYEN, *Sedburgh, Yorkshire*. ["Hardy Flowers" (published by Macmillan), of which a new edition will very shortly be issued, will answer your purpose.]

Begonia Frœheli.—In answer to "W. M." (see p. 580) respecting raising this from seed, allow me to say that the seed was sown on the 14th of March, plunged in a hotbed, the temperature of which was about 45°. The soil used consisted of two-thirds leaf soil, loam and sand. The young plants were potted in thumb pots on the 31st of May, still using the same soil, until they were shifted into 6 in. pots, when a heavier soil (half leaf-mould and half loam with sand) was used. March is, however, I think, too early to sow the seed—that is to produce plants for winter blooming. I intend, next year, to make three sowings, the last as late as June. I may add that whilst the plants were growing I continued the same temperature until August, when they were put into a cold house.—JOHN CLAWS, *Headfort, Kells, Ireland*.

* "Floral Designs for the Table." By J. Perkins. London: Wyman & Sons, Great Queen Street. 1877.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE,"—*Shakespeare.*

DESTRUCTION OF TREES IN SOUTHWARK PARK BY THE GOAT MOTH.

In the various notes which have appeared in *THE GARDEN* respecting the ravages of the caterpillar of the goat-moth, mention of a few trees only is made upon which it feeds. I do not know whether our low-lying position here has anything to do with the matter, but the damage done by the caterpillars of this moth is something astonishing. The following are the names of trees and shrubs, in this park, which I find to be most infested by them, and they are placed in the order in which they are the greatest sufferers, viz., Elms, Thorns, Willows, Bean Trees, Birch, Sycamore, Horse Chestnuts, Lilac, Cornus, flowering Currants, and Guelder Roses. Indeed, I believe its ravages extend even farther. The whole of the trees just mentioned, with one exception (the Horse Chestnut), are completely riddled by these caterpillars, and, although planted within the last ten years, I think it will be difficult to find a single living specimen in another two or three years, so rapid has been the destruction. I have not yet found it on the Plane, Poplar, or Lime—the first two being the best trees with which I am acquainted for this neighbourhood. The only method yet tried for destroying the caterpillar is the one recommended in Vol. III of *THE GARDEN* (see p. 203) by inserting a pointed wire or stick, wherever we find perforations in the bark indicating its presence. The great difficulty appears to be that of finding it when it commences its work of destruction—a matter easy enough when it has eaten out the centre of a young tree, and left behind its perforations, with the sawdust-like deposit usually found at the base of the tree or clinging to it. The caterpillars which we find principally during the summer months are apparently full-grown, when they measure $2\frac{1}{2}$ in. or 3 in., and even more in length. I have placed them in a watering pot with short lengths of various kinds of wood, and in the course of twelve hours I have found their whole length buried in the very centre of the wood. I mention this simply to show what they can do. With regard to spirits of turpentine, or in fact any other spirit, their efficacy must be very limited indeed, as in many instances I find but one perforation and that some distance below the insect, in which case it could not be applied except from below with very little chance of its reaching the caterpillar, or by cutting the tree above, a method which I should not recommend. Where several perforations exist in the case of young trees, the damage done has gone too far for any remedy to be available, except cutting down and burning. It must be borne in mind that my remarks refer exclusively to London, where gardening in every shape is carried on under difficulties not to be met with in the country. I shall, however, give the matter close attention, and I trust that others in London will do the same, with the view of finding out the best means of ridding us of the pest at an early stage of its existence, as, in my opinion, that is the best time to deal with it.

CHARLES DENNIS.

SOME CHRISTMAS FRUITS.

Raisins.

In considering the matter of Christmas fruits, the first that comes to our mind, as yielding essentially a Christmas product, is the Grape Vine, and this not solely on account of its producing Grapes properly so-called, but by reason of its being the source of the tons upon tons of dried fruits commercially known as Raisins and Currants, which form so important an item in the composition of that indispensable adjunct to a Christmas dinner—a plum-pudding. Of the numerous varieties of the Grape Vine at present cultivated in our own hothouses, we have not now to speak; nor are we concerned with the juicy produce of the French and German provinces, Spain, or Portugal. So widely cultivated is the Vine, and so varied are its products, that we must necessarily keep within the limits of our first intention, and speak only of Raisins pure and simple. No plant was better known to the ancients than the Vine, its reputation being founded on the fermented juice of the fruit. But few plants, likewise, are known to attain to a greater age. Though the stems are for the most part slender, the wood, as the plants increase in age, becomes re-

markably compact and hard. Some very old Vines are recorded whose trunks are of sufficient diameter from which to cut fairly-sized planks. In the districts, however, whence we draw our supplies of dried fruit in the form of Raisins, Currants, Muscatels, Sultanas, &c., the plants do not attain to any very great size. The different qualities of Raisins known in trade are the produce either of distinct varieties of the plant, of different soils, or of different modes of drying; this last, indeed, is all-important in producing a fine-flavoured, fleshy, and good-looking fruit. In his account of Spain, Laborde thus describes the mode of drying these fruits:—"In the kingdom of Valencia they make a kind of ley with the ashes of Rosemary and Vine branches, to which they add a quart of slaked lime. This ley is heated, and a vessel full of holes containing the Grapes is put into it. When the bunches are in the state desired, they are generally carried to naked rocks, where they are spread on beds of the field *Artemisia*, and are turned every two or three days till they are dry. In the kingdom of Granada, particularly towards Malaga, they are simply dried in the sun without any preparation. The former have a more pleasing rind, but a less mellow substance; the skins of the latter are not so sugary, but their substance has a much greater relish; therefore the Raisins of Malaga are preferred by foreigners, and are sold at a higher price. To this their quality may likewise contribute, as they are naturally larger and more delicate than those of the kingdom of Valencia." The finest kinds at the present time are, we believe, those that are carefully dried in the sun as they still hang in bunches on the Vines, the stalks being partially cut through so as to interrupt the natural flow of the juices, and the leaves being also removed around the bunches. The Spanish Grape harvest for the preparation of Raisins, commences in August, and during the drying, more particularly of the better kinds of fruit, the bunches are very carefully overhauled, and the small or injured fruits removed. Great care is needed that rain or moisture should not get to them, by which the fruits are often spoiled; and the stalks, instead of being the bright, reddish-brown colour so familiar to us, and always indicative of good fruit, become black or blotchy. When thoroughly dried they are carefully and tightly packed in boxes, varying in size, and are in this way brought into this country. In the neighbourhood of Smyrna large quantities of Grapes are grown entirely for the purpose of drying, the well-known Sultana, a small seedless variety, with a light-coloured fruit, is solely the produce of this neighbourhood. The Vines, which are planted in rows, usually about 6 ft. or 7 ft. apart, commence bearing in the third year, and are considered in perfection at from four to six years old. The gathering of the fruit commences in July, and lasts till about the middle of August, the principal bunches being gathered first, and those from the lateral shoots, which are for the most part smaller, being taken at the close of the harvest. The drying and packing are similar in principle to those already described. Sultanas always realise a higher price in the market than the other kinds of Raisins, and the produce also fluctuates very much. It is estimated that, in the neighbourhood of Smyrna, about 10,000 tons are annually produced. Very large quantities of Raisins have been received from Malaga this season. From August, 1876, to June 30 of the present year, as many as 1,343,000 boxes arrived, against 977,520 up to the same date of the previous year. In the early part of the season, in some districts near Valencia, the Vineyards suffered severely from storms, but the crops, on the whole, appear to have been good. Somewhat similar to the Sultana, in point of its being without seeds, is the Currant, the produce of a distinct variety of *Vitis vinifera*, known as *Corinthiaca*, derived, it is said, from Corinth, the place of its original cultivation. At the present time, it is very largely grown in the Greek islands, especially in Patras and Zante, the best quality being produced in Patras, Vostizza, and Corinth. In a well ordered Currant plantation the Vines are usually found in rows, about 6 ft. apart, and sufficiently distant from each other to allow the branches to form a spreading head which is supported by props. What we have said with regard to the gathering and drying of Raisins is generally applicable to the Currant, therefore it is needless to dwell further on that part of the subject. The Currant crop of the Morea, in 1876, was an exceptionally large one reaching

70,000 tons, of which England took 53,556 tons, the United States of America, 6,431, Canada, 906, Trieste, 2,999, north of Europe, 441, Russia, 659, Marseilles, 32, while 4,926 tons were held for shipment to England and America. It seems from the report from whence the above figures are gathered that the consumption of Currants is steadily increasing all over the world.

Oranges and Lemons.

Next in importance to Raisins and Currants, whether considered commercially, or on account of their productiveness, is the Orange and Lemon. Of the varieties of these fruits we have so recently spoken in the number of THE GARDEN for November 3 (see p. 421), that a few words on their prolific character as fruit bearers will now suffice. We read of single Orange trees producing in one season as many as 20,000 fruits, the annual exportation from St. Michaels amounting, it is said, to 200 shiploads, or nearly 200,000 boxes. It needs some such large quantity to be brought, and that not from one port only, to supply the great demand there is for this favourite fruit, for the Orange is universally relished; it finds its way amongst more costly dessert fruits to the tables of the aristocracy, and from the costermonger's barrow to the gallery of the cheap theatre; nor can the popularity of the Orange be wondered at when the fruits—we say nothing as to quality—can be purchased at the marvellously cheap rate of thirty-two for 1s., a price we saw them marked at not many days since. In trade returns Oranges and Lemons are always classed together, and the quantities imported are recorded in bushels, 2,995,323 bushels having been imported in the year 1876.

Dates.

We shall not attempt to exhaust the list of Christmas fruits, so numerous and varied are they; of their extent, however, a good notion may be had by a visit to Covent Garden Market at this season of the year. But we cannot dismiss this subject without a few words on two all-important fruits, which, though more plentifully seen in our shops just now, are to be obtained at all seasons of the year. We allude to Dates and Figs. Of the former, the produce of the well-known Palm, *Phoenix dactylifera*, immense quantities are regularly consumed as an article of food over the wide range of country in which the Palm is cultivated. It grows to a height of from 60 ft. to 80 ft., and is very generally found through Northern Africa, Western Asia, and some parts of Europe. The trees live to a great age, and produce their fruits abundantly up to 200 years or more. Like our own cultivated fruits, the Date is known in an infinite number of varieties, valuable according to its quality, size, or appearance. Of late years, some remarkably fine and fleshy Dates have appeared in the English markets, the best quality being known as Tafilat Dates. They are very wholesome, and have become much more in favour in this country during the past few years than formerly. In some parts of Africa the natives make a solid black cake by pounding and kneading the Dates, and finally pressing the mass into the form of blocks. When thoroughly dry, they are so hard that they can scarcely be cut with a knife. Small pieces of these cakes, steeped in water, produce a cooling and nutritious beverage. The Date Palm is dioecious, and so to ensure the perfect fertilization of the female flowers, it is customary for the natives to gather the male flowers from the wild Date, and shake the pollen over the cultivated or female plants. The number of spadices borne by each female tree varies from six to eighteen, or even twenty. For exportation, the fruits are gathered before they are quite ripe, the whole bunch or spadix being cut off and dried in the sun, or by gentle artificial heat.

The Fig.

The Fig, though popularly called a fruit, is, in a botanical sense, a fleshy receptacle, or more of the nature of a compound fruit, the actual fruits being the small seed-like bodies mixed up with the pulp of the Fig. The flowers of the Fig are never apparent to the eye, being contained inside the pear-shaped fruit-like fleshy bodies which are produced in the axils of the leaves. The so-called fruit is a succulent receptacle which has assumed a hollow form bearing the true fruits around its internal walls. The Fig tree (*Ficus Carica*) is supposed to have been originally a native of Asia Minor, Northern Africa, and Southern Europe. At the present time, its cultivation extends

throughout the islands of the Mediterranean and along both shores. With us it is well known as a wall-fruit tree, and sometimes as a standard, more particularly, perhaps, in the southern counties and upon the chalk. It is, however, liable to be cut down by severe frosts, sending up fresh shoots in the spring. Its introduction into this country is said to date back to the time of the Romans, and many fine trees of great size are still in existence in various parts of the country. It is in more sunny climes than ours that the Fig becomes a most important fruit tree. In the east a thorough system of cultivation is carried on, and the yield of Figs, at one time, largely increased by a system known as caprification, which consisted of hanging branches of the wild Fig on the cultivated plants. In the fruits of the former is always found a number of eggs of a species of *Cynips*, which, upon being hatched, find their way to the cultivated tree, and passing over the flowers in the interior of the receptacle, leave the pollen which they have conveyed, and so fertilise the flowers. This system of fertilisation seemed to have been known in very early times. It is now being generally abandoned, as it is considered not only unnecessary, but is said, moreover, to spoil the flavour of the fruit. Our supplies of Figs come chiefly from Turkey, Smyrna being the head quarters of the trade. The best quality is here produced. From Italy, and some of the Spanish provinces, as well as from the Greek islands, quantities are also imported. For exportation, Figs, like Dates, are carefully dried in the sun, or by gentle heat in stoves.

The fruits to which we have just adverted, are, perhaps, the principal in demand at this season of the year, notwithstanding the multitudes of others of varied form and character which meet our eyes at every turn. JOHN R. JACKSON.

MITCHELL'S CONVERTIBLE GARDEN LADDER.

THIS is a kind of *multum in parvo*, being a combination of a set of steps with garden wall ladders of various lengths. As a set of steps

it is useful in the conservatory and greenhouse, and also in the pruning of standard and pyramidal fruit trees, and for gathering fruit, &c. It is so constructed that it cannot slip at the foot, and is consequently perfectly safe. As a wall ladder it can readily be increased to double its length, which can be still further increased by adding section to section, or stave to stave. It is provided with a receptacle for the purpose of holding nails and shreds, thereby obviating the use of the nail bag. It has also the advantage of being light and portable, as well as strong, and can be easily unconnected when not required for use, and stowed away in a small space. P. GRIEVE.

Oulford.

NOTES OF THE WEEK.

Kew.—In the mild and equable climate of the West of England and of Ireland, many of the *Grevilleas* will succeed perfectly well in the open air. *Grevillea* is the most extensive, as well as the most handsome, of the *Proteaceae* genera, and contains species from about 1 ft. high—such as *G. ericifolia*—to lofty timber trees 100 ft. in height—such as the Australian Silk Oak—*G. robusta*. In the Winter Garden, the following species are to be seen in flower at the present time:—*G. Helemaniana*, known in some gardens as *G. Preissii*, has a light, airy style of growth; the pale green leaves are pinnate, the lower pinnae being again pinnate, and the segments almost thread-like; the flowers are of a fine red colour, and, in combination with the delicately-cut foliage, make this species one of the prettiest of West Australian plants. *G. macrostylis*, also from West Australia, has a totally different habit from the last-named; it is of neat, compact growth, and its branches are closely set with stiff, ovate, trifid leaves, about 1 in. long, the umbels or fascicles of flowers being borne at the end of nearly every twig. The flowers are nearly 1 in. long, the outer surface being red, the inner yellowish, and the long, curved style exerted for nearly 1 in. *G. rosmarinifolia* has short, dense, terminal racemes of blood-red, green-tipped flowers, and very narrow, linear leaves, deep green above, white and silky beneath. This species will succeed as a wall plant in sheltered spots in all the southern counties.

Other two *Proteads*, belonging to the large genus *Hakea*, are also in flower, the two being widely dissimilar in foliage and habit. *H. semiplana* is a slender-branched shrub, with crowded, terete, slender leaves about 1 in. long, and innumerable crowded fascicles of small, yellowish-green flowers. *H. suaveolens* has axillary racemes of pure white flowers, and rigid pinnate or pectinate leaves. *Templetonia retusa* is a fine bushy Australian Leguminous plant, its large red flowers are borne singly in the axils of its wedge-shaped, maroonate leaves.

A very pretty *Amaryllid* from Natal, *Cyrtanthus McKennai*, may be seen in the Palm-house. From the centre of its tufts of grass-like leaves spring the rather long scapes, each bearing an umbel of several curved, narrowed, funnel-shaped, pure white, deliciously-fragrant flowers.

In the Greenhouse (No. 4) we noticed a good specimen of *Tecoma australis* on one of the rafters. The flowers of this species are neither so large nor so showy as those of many of its congeners, but yet it is worth a place in a cool house; it is a tall, woody, glabrous climber, with more or less twining branches; the ovate leaflets are usually from five to nine in number, and the small trumpet-shaped flowers—in colour yellowish-white, tinged inside with purplish red—are borne in loose terminal panicles. This was introduced by Governor Patterson, from Norfolk Island, in 1793, and was considered to be a *Bignonia*. He stated that a very destructive blight generally makes its first appearance on the young shoots of this shrub, and spreads from thence over the whole vegetation of the island; on account of this the species was named *Bignonia Pandora*. A remarkable *Campanulacean* plant, *Canarina Campanula*, is bearing its large, drooping yellowish flowers from the axils of short axillary branches. (This colour is extremely rare in the Natural Order *Campanulaceæ*, the prevailing one being blue of all shades). This, as its name implies, comes from the Canary Islands; it was cultivated in the Royal Garden at Hampton Court as long ago as 1696. It dies down after flowering through the winter, and remains dormant during the summer.

Among the *Orchids*, the following are the most noteworthy:—The *Javan Vanda* *suavis* has large, extremely odoriferous flowers. In colour they are porcelain-white, spotted and marbled with rich violet, the lip being deep violet. *Catasetum tridentatum*, from Trinidad, has thin, yellowish-green sepals; the upper petal forms a thick, fleshy, yellow hood, and the lower ones are, in texture, like the sepals, but thickly spotted with small, bright, reddish-brown dots. The *Tropical American Epidendrum ciliare* belongs to a section in which the labellum is broken into long and beautiful fringes; its flowers are greenish, with the exception of the pure white lip. Strong plants will bear racemes with more than a score flowers, and are very handsome objects. *Dendrobium tetragonum* is a very peculiar species from Queensland. It is remarkable for its very prominently 4-angled, pendulous stems, slender in the lower portion. The oblong leaves are from 2 to 4 inches long, and are produced from the summit of the stems; the loose racemes consist of a few comparatively large, yellowish-green flowers, bordered with brownish red. This species does not possess much merit from a horticultural point of view. A very delicate and charming *Dendrobe* is *D. Farmeri*; it has short, angular, club-shaped, channelled stems, the young ones bearing from 2 to 4 ovate leathery leaves at the top. From near the summit of the old stems are thrown out the pendulous racemes, which exceed the stems in length. The broad, ovate, obtuse, spreading sepals are of a pale

straw colour, delicately tinged with rose; the petals are of the same colour and form as the sepals, the labellum being orange-yellow, bordered with pale straw colour.

Iris (Xiphion) Histrio blossomed with me in the open border on Christmas Day. It would be impossible to have a more beautiful little flower in mid-winter—but at this rate it is one of the latest rather than one of the earliest flowers of the year.—H. EWBANK, *St. John's, Ryde*.

Azalea Narcissiflora.—For supplying white flowers about Christmas time, this is one of the best *Azaleas* that can be grown. It forces readily, and its blossoms, which are semi-double, are of snowy whiteness, and last in good condition, both on the plant and in a cut state, much longer than those of single-flowered varieties. It is now in flower in several of the principal nurseries about London.

A Violet-Scented Dendrobe.—One of the most sweetly scented of *Orobids* is *Dendrobium heterocarpum*. Its flowers are of a rich creamy-yellow colour, and when fully expended their perfume is equal to that of the most delicately scented Violet. Though not so attractive in appearance as many of the other *Dendrobes*, it well deserves a place in every collection for the sake of its scented blossoms, which last long in good condition. It is now in flower in several nurseries about London.

Schizostylis coccinea and Winter Heaths.—Numbers of well-flowered plants of the beautiful *Schizostylis coccinea*, intermixed with winter-flowering Heaths, *Correas*, and similar plants, in Mr. Fraser's nursery at Lea Bridge, are now making a fine display. As a pot plant the *Schizostylis* deserves more extensive culture than it receives, for its bright flowers are very useful at this season, either when used in the decoration of the conservatory, or for supplying cut bloom. It succeeds best when grown in pots plunged in ashes during the summer, and if rich sandy soil be used for it, and it is kept liberally supplied with water, and moved to a cool frame when unfavourable weather sets in, handsome flowering plants during winter will be the result.—C. S.

National Rose Society.—We understand that the dates of the exhibitions for 1878 are now fixed. The Metropolitan one will be held at the Crystal Palace on Saturday, June 29, and the Provincial one at Manchester on Saturday, July 6, in common with the Manchester Botanical Society. In both instances the terms are stated to be most advantageous to the interests of the Society. The Executive Committee will shortly meet to arrange the schedules, in order that they may be submitted to a meeting of the General Committee.

Japanese Plants at the Paris Exhibition of 1878.—Japan will not only be represented industrially at the International Exhibition of 1878, but also from a horticultural point of view. A large stock of Japanese plants has just arrived in Paris, having been brought over in charge of two native gardeners. They were welcomed by those in charge of the horticultural department of the city of Paris, who at once placed their grounds, hothouses, and even their staff, at the service of their foreign *confères*. The better part of the offer was, however, not accepted, in consequence of the Japanese not being able to speak any language but their own. Besides this, they evidently considered themselves quite capable of managing the plants under their charge without extra help. The plants consist of deciduous and evergreen shrubs of various kinds, and a few Conifers, all of which are dwarfs, the tallest being barely 3 ft. high. The collection includes a few fruit trees, several *Magnolias*, *Daphne japonica*, *Gardenias*, *Spiræas*, *Osmanthus*, &c., also a number of Japanese Maples, among which will no doubt be found several of the well-known species with which we have long ornamented our gardens. Unfortunately, a large proportion of these plants have suffered much from the effects of their two months' voyage, a number having died. A large quantity of Orange trees perished, which is particularly unfortunate, because some of them may have belonged to the so-called hardy sorts of which we have heard so much frequently. On the other hand, it must be remembered, that without in any way wishing to call in question the gardening ability of our foreign colleagues, we must warn them that they are not yet at the end of their disappointments, and it is much to be feared that their want of experience of the climate of Paris will bring about much trouble and many vexations. We may add that these gardeners are strong, robust, and intelligent, and handle their tools, which are few in number, with great dexterity. These tools are of the most primitive character, and would be of but little value to a French gardener. M. Chantin, the well-known horticulturist of the Avenue de Chatillon, in Paris, will supply the plants (some hundreds of thousands) for the ornamentation of the gardens of the Exhibition.—"Revue Horticole."

THE FRUIT GARDEN.

THE VICTORIA NECTARINE.

FROM the favourable remarks in *THE GARDEN* (p. 567) relative to the Victoria Nectarine, it is quite likely that many about planting may be induced to get that variety instead of some others of a more hardy nature, and if so they will, unless living in very favoured localities for the growth of these fruits, be grievously disappointed. For flavour, size, and free-bearing qualities it may, and is, I believe, deserving of all that is said of it; but what do these avail if the tree is too tender to grow except in warm districts? Here, and in many other places with which I am acquainted, it is a failure out of doors. The writer of the article speaks of his tree as having been forced all its life, and I should doubt if he has had any experience of it on open walls, or he would have reason to alter his opinion. That it is a valuable high-flavoured variety to grow under glass in a well drained border I readily admit; but those requiring trees on which they can depend to grow and flourish out doors, must not have the Victoria Nectarine among them. Its parent, the Stanwick, was anything but satisfactory, although greatly lauded at the time of its introduction, through happening to succeed well in one or two places where the conditions were favourable, but I do not suppose that it is now anywhere to be found. There is, however, no fear of the Victoria sharing the same fate; and those who have room in a good light house where they do not require very early fruit, will do well in giving it a trial, or to plant it to come in to succeed others. For forcing, there are none equal to Lord Napier, as it is at least a fortnight before any other, and always colours well, is large and handsome, of most exquisite flavour, and altogether one of the finest Nectarines that that prince of pomologists, Mr. Rivers, ever sent out. It is altogether so good as to be well deserving of having his name associated with it. Besides being so valuable under glass, it appears equally so out doors on walls, as a young tree with us is growing most vigorously, and will soon fill its allotted space. This and the new early Peaches will help to afford a prolonged supply. S. D.

PROPAGATING VINES IN GARDENS.

CONSIDERING the immense quantity of Grapes that are grown in this country, it is surprising that the propagation of the Vine in gardens is not more generally practised than it is. Like the propagation of many other plants, every attempt might not be crowned with success, but a fair percentage might easily be secured; and I can answer for the propagation of young Vines being quite as interesting as that of any other plant. We annually put in a few eyes here which produce a number of canes for forcing, and sometimes we have a few to give away. At one time I always selected the very strongest wood I could get of which to make the eyes, but now I take them from the small wood, because I find that they start much freer into growth, and make equally fine canes as those made from thick wood. For canes to force, Black Hamburgh and Foster's Seedling are the two of which the greatest numbers are propagated; other sorts are generally raised for planting. When pruning, select the wood as it is cut off for the eyes. We have done this with ours, and the pieces which are about 18 in. in length are at present stored with their lower ends in the ground. This prevents the wood from becoming dried up. The first week in January they will be taken in hand, when each bud will be cut away with 2 in. of wood at its lower end. Immediately above the bud the wood should be cut square across, and a slice 1 in. in length should be taken from the lower end, making it taper to a point. This is all that is needed. Fill a 3-in. pot full of loam, leaf-soil, and sand for each eye, then take it and press it into the centre of the pot, fixing the soil firmly round about it with the hand. Let the soil be moderately moist to begin with, and do not give any water after finishing, but set the pots closely together on a shelf or floor in a cool house. Here they may remain until the first week in February; then take them and plunge them in any kind of material where they will have a steady bottom-heat of 70°. About a week after they have been plunged, give them a thorough watering with water at the same heat as that in which they are placed. After this they will soon begin to grow and make leaves. As soon as the young shoots are 6 in. in length, a good many roots will have been formed, and the pots must be taken out of bottom-heat and exposed in any house or

frame where there is a temperature of 65° or 70°. As the bottom-heat in which they were plunged was not above this, they will receive no check, but continue growing, and when the shoots are from 15 in. to 18 in. in length, they must be shifted out of small pots into 8 in. ones, if the canes be intended for planting, and into 12 in. ones, if fruiting rods are required. As, when putting in the eyes, let the soil, which must consist of good fibrous loam, with a little manure and wood ashes added, be moderately moist, when potting, and do not give any water at the root for a week or ten days after this. By that time the roots will be near the outer edge of the fresh soil, and from this time forward water abundantly. To give them justice, they should be grown in a warm, close, house until the latter part of May, when they may be subjected to the same treatment as Grapes that are beginning to colour. When the canes attain a length of 6 ft., pinch the top off, and do not let them grow to a greater length. From this time until they are half-ripened, give liberal supplies of liquid manure. They must at all times be kept perfectly free from insects. They should be fully grown by the middle of August at the latest, and, after that, attention must be principally directed to getting them thoroughly ripened, for in that lies the whole secret of successful culture. Let them be fully exposed to the sun. Do not give them so much water as when they were growing freely, and air must be allowed to circulate freely about them, but they dislike cold draughts. There are other ways of propagating Vines besides that just recorded, but they are more complicated, and therefore less worthy of attention.

CAMBRIAN.

Winter Covering Fig Trees.—Although the wood of Fig trees will withstand any ordinary frost without injury, it is best to be prepared against exceptionally severe weather, as I find trees of several years standing to be much more fruitful than young, fresh-planted ones, which even in poor soil will produce shoots of too luxuriant growth to either withstand frost or produce much fruit; and, as the labour involved in protecting is trivial compared with the crops which a few good trees may be relied on to yield, I find it best in our uncertain climate to cover the trees about the first week in December. Our trees, which are fan-trained, are nfastened from the wall, and the wood is laid in a bundle at its base, where it is easily covered with any available material. We use Reeds for the purpose, from their being plentiful on the marsh lands here, and therefore of little value; they are cut and stored in autumn, and they will last good for several seasons. We cover the bundles of shoots sufficiently thick to exclude light, as that, acting on the frozen wood, is probably more injurious than frost. As soon as all danger from severe frost is over, the covering is removed, when any pruning required is done, and the wood is again fastened in its former position. Short-jointed, well-ripened shoots will almost invariably produce a crop, even when other fruit crops fail. The longevity of Fig trees is proverbial; the finest and most certain-cropping tree we have is probably over 100 years old, and is annually laden with hundreds of fine fruit.—J. GROOM, *Henham*.

Inside Vine Borders.—How am I to make an inside border for Vines in a house in which there are already six Vines planted outside on a grouted border? I can have 5½ ft. wide of a border inside, but I can go much deeper than the outside one, which is only about 2 ft. deep; my front wall is 2½ ft. high from the surface, but there is about 2 ft. of a foundation. Kindly name the number of Vines which it will take, and the best sorts for it. I should add that the house will be without heat, except in very cold or wet weather.—POMPONE. [The border being 5½ ft. wide, the best way would be to fill 3 ft. of that space by first stacking up turves (Grass downwards) to form a front wall, and filling the intervening space between this and the front of the house with turves broken roughly to pieces with a spade, to which has been added a bushel of ½ in. bones to the cart-load, also a few barrowloads of horse droppings. This will give ample space in which to plant the Vines, and the rest of the border can be made next year, or when the Vine roots have become so numerous as to require more room; 2½ ft. will be deep enough. The Vines, when established, will be benefited by a mulching of rotten manure in summer, and, when the bulk of this is removed in winter, a coat of good soil may be put on with advantage. The Vines should be planted 2 ft. apart, every other one being allowed to bear fruit as soon as it will do so. The remainder must not, however, be fruited until well established, when they should be allowed the whole house, those which have borne fruit being cut down. The best kinds are Black Hamburgh, Gros Colman, Black Alicante, and, for white kinds, Buckland Sweetwater or Golden Queen.—S.]

THE FLOWER GARDEN.

GROWING THE FLAME NASTURTIUM.

THE reason why your correspondents fail to get this established most probably is, that they plant it at the wrong season of the year, as by bedding it out early in spring, after first starting the tubers in pots in a greenhouse, I have never experienced any difficulty with it. If planted in the summer, unless it has made some considerable growth before, there is not time for it to ripen, and if overtaken by frost, while in an immature state, the roots are almost sure to perish before winter is over. Those who are desirous of growing this beautiful hardy plant to perfection, should get tubers at once, and pot them in fibry loam, giving them, while doing so, a sprinkling of sharp sand around them, which will prevent moisture lodging in sufficient quantity to cause them to rot. To obviate this, no water should be given till the young shoots appear above ground, and only then in very small quantities, as that is the critical stage with them; but once they get into leaf and start away freely, they, like most other rapid-growing plants, take it up quickly, and are fond of a cool, damp soil to grow in. Nowhere, perhaps, is *Tropæolum speciosum* seen in the healthy luxuriant condition it is in Scotland, as there the atmosphere appears more congenial to it than it is in more southern latitudes, where, in many cases the foliage becomes a prey to red spider, an insect pest to which it is very liable, and is one of the reasons why the plants fail to flourish with many. The situation where it succeeds best is behind a north wall or fence, where it gets plenty of shade, and cooler air than it would enjoy anywhere else. In a place of this kind, red spider rarely attacks them, and, if it does, it is not to anything like the same degree as occurs when it has solar heat to favour its increase, as then it spreads with great rapidity, and it is no easy matter to keep it in check. The neatest way to train the shoots, when the plant is growing near a wall, is to strain pieces of fine string or wire vertically at about 6 in. apart, up which the young shoots will twine, and support themselves against wind and weather. All that is necessary is to start them on their way by leading them to the several strings, so as to regulate the growth, and help to clothe the space desired. In planting, it is always advisable to put some silver sand or sharp grit over the tubers, as it enables them to winter better than they would if they came in immediate contact with the soil. The flowers of *Tropæolum speciosum* are so exceedingly brilliant and attractive that it is a pity it is not more generally known and cultivated. *T. pentaphyllum* is likewise hardy and a very desirable plant to grow; but, unlike its congener above-named, it revels in sunshine, and does splendidly on the south end of a greenhouse or other warm aspect. The habit of this is altogether more robust, and very effective when covered with bloom, which it produces most freely. Both kinds admit of ready increase by dividing the tubers, or from seed or cuttings, but the latter must be put in early to afford time for forming roots of sufficient size to live over the winter.

S. D.

Long-buried Seeds.—I have ever been sceptical as to mummy Wheat and the Oats that are said to have grown when the soil in a Roman station has been disturbed, but I cannot entertain a doubt that the seeds of Henbane will germinate after being buried for many years. I have made the strictest inquiry, and I cannot find that any Henbane has been permitted to flower or seed in the garden here or on the adjoining land within human memory. Yet on almost every occasion when we have disturbed the soil to a greater depth than ordinary a few plants have sprung up. About ten years ago, when I made a sunk fence to cut off the western part of the garden from the adjoining Grass field, quite a crop of these plants appeared. The land had certainly been pasture for many generations, but it was probably in pre-Reformation times a part of the garden of the preceptory of the Knights of St. John of Jerusalem, which stood very near. There seems also good reason to believe that the seed of Flax will retain its vitality for a long period. An ancestor of mine, about the year 1745, laid down to Grass a field which had been under cultivation by the plough. As was not uncommon in those days, the last crop he took was Flax, and Grass seeds were sown amongst it. Somewhere between sixty and seventy years after this my grandfather found it necessary to drain the field, and, as every one who

has had to do with work of this kind knows, in draining work there is always some soil to spare, i.e., more than will fill the trench without a hillock being raised over it. My grandfather disliked seeing these long, unsightly hillocks and ordered the waste soil to be strewn about over the turf. The work was done in the winter, and when spring came a quantity of Flax sprang up among this soil. I was told the above fact by my father, who saw the Flax growing, and who was a careful observer. He did not think it possible that the Flax seed could have been scattered there after the soil was disturbed, but held the opinion most confidently that it had lain in the ground ever since

In a City Garden.

it was "laid down to Grass," upwards of sixty years before.—EDWARD PEACOCK, in "Notes and Queries."

A City Garden.—This glimpse into a quiet city garden, with trees, and Grass, and Ivy, and flowers, may serve to remind us that a city garden may have many charms not usually associated with the town. There are even peculiar advantages for gardening in some cities, where the air is comparatively pure, in the perfect shelter and increased warmth which city gardens often enjoy as compared with the surrounding country. As regards good private gardens in London, they are not nearly so numerous or so well stored as one would expect from the numbers of rich people who have houses in it. Some gardens, such as those of Montague House and of Oak Lodge, may be named as creditable examples of what a town garden may be made; but such are too rare. In Continental cities one is frequently surprised to find a charming oasis of trees, and flowers, and Grass, hidden by high buildings from the noisy street. Through the courtyard and the house, and out into a shady group of trees, with fresh Grass, and Ivy, and Yuccas, and a few evergreens, and the grateful coolness and quiet, is a common experience abroad, where finer trees are often found in small private gardens, hidden from public view by high houses, than in the avenues or public squares.

Such a garden is the one we figure, with its little fresh lawn, ample for the position; old Ivy-clad trees; beds of Pansies in May, when we saw it; hardy Yuccas, and Acanthuses in groups; and Aucubas, Ivy, and Periwinkle on the ground beneath the trees.

CULTIVATION OF PANSIES FOR EXHIBITION.

For spring planting, select a sheltered piece of ground that has been well manured, throw it up in ridges for the winter, and let it remain so until favourable weather has set in in March, when it should be forked over and well broken. In planting Show Pansies, lay out the beds 4 ft. 4 in. in width, and of a length to suit the collection. Plant four in the breadth, leaving 1 ft. between the plants, and 8 in. from the edge of the bed to the outside plants. A bed of mixed Pansies has a fine effect; but, if seed be wanted, it is best to keep the plants in classes. Previous to planting, have some fresh turfy loam at hand, and, having made the hole for the plant, put in some of the new loam in the form of a cone, spread the roots over this, and fill round the neck of the plant with the same loam. This causes the stem of the plant to emit roots, and gives it a fresh hold. When the plants have been growing about two months or so, give them frequent waterings of liquid made of sheep or cow manure, taking care not to touch the foliage or go too near the neck of the plant with it, and when the surface of the bed gets caked, run a Dutch hoe between the rows. Stake the plants as they require it, so that they may not be broken by the wind, and remove all superfluous shoots as they appear, leaving from three to four leading stems for flowering. The plants will be much benefited by a top-dressing of new loam and old cow manure about the middle of June. As soon as they get into a flowering state, pick off the blooms as they expand (in order that the plants may not be weakened more than is necessary) until about ten or twelve days before the blooms are required for exhibition, when all may be allowed to remain.

For shading material, I would recommend cardboard caps tacked on to a piece of wood, the mouth of the cap being 4 in. in diameter. Self flowers should be shaded as soon as the bud has reached its full length prior to opening; but white and yellow grounds may be allowed to half expand, so that it may be seen whether or not the lacing, &c., is complete, and the bloom otherwise in true character. There is a diversity of opinion as to how Pansies should be exhibited. The Scottish Pansy Society makes it imperative that blooms be shown on stands painted green without paper cards, while in the west of Scotland they are universally shown on white cards, about $\frac{1}{2}$ in. larger than the blooms, on stands painted green. I prefer show Pansies to be exhibited on white cards, as they can be set off to the best advantage in that way. The flowers may be cut in the afternoon preceding the exhibition, carding and placing them in their position at once. Young flowers which will not lay had better be kept out of water for an hour or two, when they will be more easily handled. Lead off with the flowers of the largest size—say dark selfs, white grounds, yellow grounds, and so on, varying the colours, so that two of the same class may not be either directly at the side, above, or below each other.

About the beginning of August, pinch a few of the leading stems, which will induce shoots to break out that will make fine, short, stout cuttings which may be taken off by the end of September. Prepare a cold frame, dig deep, and break the soil well, removing any earthworms, as they are apt to draw out the cuttings and cause confusion. As to soil, make up a compost of two parts fresh loam and one river or pit sand; of this put on 3 in.; draw lines 3 in. apart, and insert the cuttings 2 in. from each other, fixing them firmly in their position with the forefinger. Water gently, and keep the frames close for about ten days, shading, if necessary. After this, air may be given, night and day, during favourable weather, and when they are rooted, the more air they get while the weather is fine the better. Remove all decayed leaves as they make their appearance, an operation which is best done with a pair of sharp-pointed scissors. In the west of Scotland it is not practicable to plant in the open ground in autumn; but, where the climate will allow it, and if early blooms be wanted, it is necessary to

do so. Cuttings may be put in in the latter end of July, and planted out in September or October.

The culture of fancy Pansies differs but little from that of the show kinds. They should be planted 15 in. apart, being robust growers, and the situation should be more exposed to the sun than for show kinds, so that their bright colours may be brought out in all their brilliancy. The great improvement that has taken place in this class within these last few years is very marked, many of them having as fine form, eye, and texture as the best of the showy varieties; one, therefore, would require to grow them, or see them in bloom, to form any idea of their real worth and beauty.

The Pansy's chief enemies are wireworm, slugs, and fly. In planting, care must be taken that no wireworms are introduced in the new loam; should they occur, they are easily trapped by small pieces of Carrot or Potato laid about 1 in. under the soil near the plants, and which must be inspected every three or four days. Slugs are best kept down by hand-picking early in the morning and on showery evenings; should fly attack the plants, as it frequently does in June or July, take a common tub or pail, put into it 1 lb. soft soap, pour on it sufficient warm water to dissolve it, and add 1 gill Tobacco juice as received from the tobacconist; mix well, and strain through a piece of coarse pack sheet, and put 1 pint of this to 2 gallons of soft water. With this mixture syringe the plants, selecting a showery evening for the purpose, and apply it every other night until the fly is fairly got rid of. Should the weather be dry when they are infested with this pest, syringe the plants with clean water before using the solution, and syringe again with water in an hour or two.

The following is a list of the best Pansies for exhibition:—

Abbreviations—D. & L., Downie & Laird; D. & Co., Dicksons & Co.; W., White; F., Fulton; T., Taylor; R., Robertson; H., Hooper; D., O., & Co., Dickson, Orr, & Co.; P., Paul; C., J. Cocker & Sons.

DARK SELFS.—Alexander Watt (P.), Beacon (D. & L.), Captain Knowles (F.), Count Bismarck (P.), Dux (D. & Co.), James Dalziel (W.), Juber (D. & L.), J. P. Barbour (P.), John Rowatt (P.), Lizzie (W.), Luna (D. & L.), Mauve Queen (P.), Michael Saunders (P.), Oceola (P.), Rev. J. Morrison (T.), Rev. D. Taylor (D. & L.), Robert Black (D. & Co.), William Forbes (P.).

BLUE SELFS.—Chieftain (D. & Co.), Royal Blue (P.), Sunny Park Rival (C.).

WHITE SELFS.—Bessie Peacock (D., O., & Co.), Jenny Anderson (D. & Co.), Mrs. Todd (P.), Mrs. W. Old (D. & Co.), May Queen (D., O., & Co.), Miss Ramsay (D. & L.).

YELLOW SELFS.—Citron (P.), Dr. Masters (D. & L.), John Scott (P.), Mrs. Horsburgh (D. & L.), Maranta (D. & L.), Yellow King (D. & Co.).

YELLOW GROUNDS.—Alexander McLennan (P.), Captain Cluthie (D. & L.), Clonard (P.), Defoe (D. & Co.), Dr. Livingstone (Small), Ebor (D. & Co.), George Steedman, James Orr (P.), J. B. Pyramidal Sweet Bays.—Where the climate is sufficiently mild for these to be successfully cultivated, there are few evergreens that form prettier objects, or that give the lawn and pleasure grounds so warm and furnished an aspect during winter as Sweet Bays in the form of pyramids. We have several single specimens of them on Grass, which sets them off to the greatest advantage, and in the foreground of shrubberies they are equally effective. The pyramidal form is that which the Bay naturally assumes without any training; but, if left entirely unpruned, the branches become weak, and a heavy fall of snow will sometimes destroy the symmetrical shape of the tree, whereas, if the leading and strongest side shoots be shortened to about half their length in autumn, the tree becomes densely furnished with side spray, and the principal branches are thus rendered sturdy enough to withstand all weathers. In addition

The Flora of Greenland.—On the strips of the land near the coast the Greenland flora, though scanty, is very pleasant to the eye. Vegetation covers the ground in thick masses, forming turf in the level places, while it fills the chinks and crannies of the rocks, and creeps over the surface of the stone, giving a bright appearance to the land in summer. The prettiest thing of all is the Club Moss, with its grateful little white bell flowers like miniature Lilies of the Valley. With it are generally the Dwarf Willow and Birch and the Whortleberry, with its red berry and glossy little leaves. As far as Disco, not further north, there are beds of Lady's Mantle and Angelica, and masses of Holly Fern, the erect red blossom of the Pedicularis, bright little red and white Saxifrages, Dandelion, Potentillas, and Ranunculus, the Arctic Poppy, the sweet-smelling *Ledum palustre*, and the showy purple blossoms of the *Epilobium alpinum*. The study of Greenland botany, interesting in itself, derives special importance from the hypothesis to which its remarkable character has given rise. It has been suggested that the Scandinavian flora, which is one of the oldest in the globe, extended during the warm period preceding the glacial over the whole Polar regions, including Greenland and Arctic America.—CLEMENTS MARKHAM.

A Wrought-iron Park Gateway.

to the pleasant perfume given off by the leaves, the Sweet Bay is a profuse-blooming plant, and with us usually perfects a good crop of black berries. The leaves are in frequent request for culinary purposes, and for drying with those of other scented-leaved plants. Although some of our winters have been severe in this locality, I have never seen a leaf discoloured, while a little further inland it is by no means a rare occurrence for this and similar evergreens to suffer considerably.—J. GROOM, *Henham*.

Propagating Mistletoe.—At this season of the year, when so many possess Mistletoe berries, it may interest some to know how to obtain plants from these berries. Select two or three of the finest of them, and when the wood of any Apple tree, on which it may be desired Mistletoe should grow, is quite dry, take one of the berries between the finger and thumb, and rub it gently on the part of the tree where the Mistletoe is wanted to grow. When the berry breaks, the gummy juice inside causes the seeds to adhere to the bark. In a short time two small prongs will be emitted from the centre of the berry; and these will turn round and root and grow on the branch to which the berry is attached. This is a simple way of propagating the Mistletoe which any one may try with success.—CAMBERIAN.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Yucca recurva.—This, with us, is the most graceful and effective of hardy fine foliated plants. Some single specimens of it planted here about five years ago are now perfect models, both as regards shape and healthy development. Older specimens that have flowered, branch into many crowned heads, and lose the symmetrical proportions of younger plants. A row of established plants of this *Yucca* in terra-cotta vases, flower profusely, a circumstance which I attribute to the restriction put on the roots.—J. GROOM, *Henham*.

Planting Hardy Bulbs.—November is generally recommended as the best month in which to plant out-of-door bulbs; but if any one takes the trouble to lift a few bulbs at that period that have been left in the ground, they will find a good quantity of roots and the top growth considerably advanced, clearly showing that November is too late, as a rule, for planting.—J. G.

Hardiness of *Omphalodes Lucilia*.—I can fully endorse all that Mr. Atkins says (see p. 553) respecting the hardiness of this beautiful plant, having grown it myself for some years, and also from having seen Mr. Atkins' plants which, as he states, are in a bleak situation on the Cotswolds. I have sometimes found that seedlings of it differ in not having that deep glaucous hue that the parent possesses. I have always found cuttings to make the best plants.—E. JENKINS.

THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

South American Region.

As already explained, the extent of country in South America from which we obtain hardy plants is comparatively small, and many of the plants we have in cultivation from that part of the world are only suitable for the milder parts of the kingdom. There are, however, some, such as *Berberis Darwini*, for example, which are perfectly hardy; and nearly every one of those contained in the following list has its special merits. Doubtless further exploration would lead to the discovery and introduction of many other equally ornamental species. The vegetation of temperate South America forms two distinct floras. The plains of the eastern side and centre are almost treeless, except on the banks of the rivers, and covered with coarse Grasses and thorny shrubs. These Pampas, as they are termed, extend northwards, and include part of Uruguay, gradually passing into the forest region of Brazil. *Gynerium argenteum*, or Pampas Grass, is one of the characteristic plants of this region, and the recently-introduced *Eryngium*, as *E. pandanifolium*, *E. bromeliæfolium*, &c., are from the northern part. At the present time thousands and thousands of acres, one might also say square miles, are covered by two or three European plants. The commoner ones are—a Thistle (*Onopordon Acanthium*), Fennel (*Foeniculum vulgare*), and the Cardoon (*Cynara cardunculus*). The western side of Patagonia, as well as the southern extremity, is more or less mountainous, and the coast is skirted with numerous islands. Nearly the whole of it is well wooded, even down to Tierra del Fuego. The most prominent trees in the extreme south are two species of Beech, an evergreen one (*Fagus betuloides*), which is ornamental and quite hardy on our south-western coast, and a deciduous species, *F. antarctica*. According to Dr. Hooker, *F. betuloides* is the most prevalent species in Hermite Island, and becomes a large tree about the Straits of Magelhaens. It forms the prevailing feature in the scenery of Tierra del Fuego, especially in winter time, from its upper limit being sharply defined, and contrasting with the dazzling snow that covers the all but naked branches of the deciduous-leaved species *F. antarctica*. Its upper limit at Cape Horn in lat. 56° is 800 ft.; in the northern part of Tierra del Fuego it ascends to 1400 ft. At Port Famine, on the testimony of Dr. King, trees of the evergreen Beech 3 ft. in diameter were abundant, and one measured 7 ft. in diameter at 17 ft. above the roots. At the northern extremity of the temperate forest region, in the mountains of the province of Araucan, South Chili, is the home of *Araucaria imbricata*. It forms dense forests, and grows to a large size. Our concluding remark on the vegetation of this region shall be in praise of the incomparably beautiful hardy *Fuchsia* (*F. macrostemon*), which, in its southern habitat, presents a number of distinct varieties described by travellers as the great charm and ornament of the vegetation.

New Zealand Region.

The flora of New Zealand has already been pretty fully described and contrasted with the vegetation of the United Kingdom; and some remarks on its climate will be found in the same place. Without exception, it may be stated, New Zealand plants require protection, except in the warmer parts of the kingdom, where, however, perhaps all, except those peculiar to the warmest part of New Zealand, will thrive. It does not come within the compass of this essay to enlarge upon points which would probably interest but few, and therefore the list of New Zealand hardy plants is very small. Indeed, if we compiled a list of plants from the Australasian region, hardy in the Scilly Islands, it would include, besides New Zealand species, hundreds of South Australian plants. A few of the more familiar New Zealand plants are—*Clianthus puniceus*, *Edwardsia grandiflora*, *Veronica Andersoni*, *Phormium tenax*, *Cordylina australis*, *Dicksonia antarctica*, *Griselinia littoralis*, and various species of *Panax*.

HARDINESS OF SOUTH AUSTRALIAN PLANTS.—It may be worth while adding an observation or two respecting the hardiness of some of the Australian Acacias having pinnately-divided leaves, because they are so exceedingly elegant that it is desirable to plant them wherever they will succeed. Several of them which are natives of the mountains of Tasmania and South Australia will bear the ordinary winters of the south and west of England and Ireland; and, if cut down by an unusually severe frost, will shoot from the root again in spring. The hardest are *A. dealbata* (the Silver Wattle of the Australians), *A. decurrens* (the Black or Green Wattle), and *A. discolor*. These trees appear to possess a very elastic and accommodating constitution, as does also a species of *Eucalyptus* (*E. polyanthemos*) in the open air at Kew, which was only very slightly injured by the severe frosts of 1860-1.

South African Region.

With this, the warmest of the regions whence we obtain hardy plants, we shall conclude our remarks on the geographical distribution of plants hardy in the United Kingdom. The number of species is not large; they are all herbaceous plants, or will throw up new stems annually from the root, if cut down, and thus, by their habit of growth, are protected from the influences of weather. A few, like *Kniphofia aloides* (syn. *Tritoma Uvaria*), and allied species, inhabit the mountains which range from nearly 4000 ft. (the Table Mountain) to 8000 ft. (Graaf Reinet), and are perfectly hardy. Others, as *Richardia æthiopica*, and *Aponogeton distachyon*, treated as aquatics in tolerably deep water, escape frost, and are thus so far hardy. Again, many of the splendid Cape bulbous plants, as *Gladiolus*, *Ixia*, *Sparaxis*, &c., may be left in the ground all the winter, if the soil is light and the bulbs not too near the surface. *Melanthus major*, *Lobelia Erinus*, *Phygelius capensis*, and *Agapanthus umbellatus*, are also hardy in this qualified sense.

Distribution of Exotic Plants requiring the shelter of a cool Conservatory or Greenhouse during the colder half of the year.

GENERAL REMARKS ON CLIMATE, &c.—The distribution of hardy plants having been treated of at considerable length, and much that is said under that head being of general application, the outline of the distribution of sub-tropical or greenhouse plants and tropical or stove plants from a horticultural point of view, may be traced in a few pages. The countries whence we obtain sub-tropical plants, are almost identical with those lying between the north and south tropics and the boundaries of the temperate regions as defined under the geography of hardy plants. Frost is almost unknown, and in the warmer parts, bordering the tropics, the temperature never descends to the freezing point. The average temperature of the coldest month, January or July, according as the country is situated in the north or south hemisphere, is from 40° or 45° to 55°, and the mean annual temperature ranges from 55° to 75°. Maritime countries in this zone enjoy a cooler summer than most Continental places in the southern part of the north temperate zone; but here also the mean annual amount of heat may be the sum of a comparatively cold winter and a hot summer.

or the sum of a relatively warm winter and cool summer. The distribution of heat within the tropics is also considerably influenced by the disposition of land and water, though to a much less extent than in the extra-tropical northern regions. The highest mean annual temperature, given by Dove, is $81^{\circ}5$ Fahr., and the regions where this temperature prevails nearly all lie north of the equator. There is, however, far greater

Hardy Passion Flower—Cool Region of South America.

inequalities in the distribution of moisture in sub-tropical, or warm, temperate countries, and this is a point of greater importance in practical gardening. It is not so much the actual amount of rainfall, as the number of rainy days and the average degree of humidity of the atmosphere.

DIFFERENT CLASSES OF PLANTS.—Three different classes of plants are an index to as many different degrees of humidity. The Ferns and herbaceous plants of New Zealand; the shrubby and arborescent vegetation of extra-tropical Australia and South Africa; and the succulent Mesembryanthemums, Stapelias, &c., of South Africa, and the Cactaceæ of Mexico. The first live in a very humid climate, the second in an intermediate, and the last in a very dry one. Another condition of climate is alternately dry and wet seasons, answering to the growing and dormant periods of plant life in most warm countries; and then there are the desert or rainless countries.

RAINGLESS REGIONS.—These are nearly all situated, in both hemispheres, in the sub-tropical regions, and in adjoining tropical regions; not a large area being within the tropics, and scarcely any near the Equator. Collectively these deserts form two interrupted belts around the world—a northern and a southern. The northern, and much the larger, rainless belt, does not correspond to latitude exactly, but it nowhere gets beyond the limits between about 16° and 30° of latitude. The vegetation of these rainless regions is extremely scanty, and reduced to a few thorny bushes and succulent plants. In South-Western Africa, beginning just north of the Orange River, there is a large tract called the Kalahari Desert, and it is in this country where the curious Welwitschia, referred to before, occurs. The total area of desert country has been

computed at about 5,000,000 square miles, or nearly one-tenth of the whole surface of the dry land.

FOOD PLANTS.—In sub-tropical countries the food plants, and other staple crops, are mainly different from our own, though Wheat and Barley are largely cultivated; but they are harvested during the colder season of the year. Maize, Millet, Cotton, Indigo, Yams, Tea, the Orange tribe, various leguminous crops, &c., are among the most useful food plants of the sub-tropical region.

RANGE OF SPECIES.—Allusion has already been made to the general wide geographical range of species belonging to the temperate regions of the northern hemisphere, and examples given to illustrate this truth. On the other hand, in New Zealand, for example, we found that a large proportion of the species are endemic, whereas not one is endemic in the United Kingdom; and many of what we may call northern types, including British species, besides having a wide range in temperate Europe, Asia, and America, also occur in the mountains of tropical Asia and Africa, some extending to New Zealand, and a few even down the mountain range of South America. It was not stated there, however, that typically southern types rarely extend to similar climates in the northern hemisphere. Relying upon geological evidence, it would appear that what now are typically southern, temperate, or sub-tropical orders, genera, or species, have gradually receded southwards, or never succeeded in obtaining a permanent footing in the north, though this does not imply that they were ever so fully represented in the northern hemisphere as they are at the present time in the southern, where they possibly always found their

The Cotton Plant.

maximum development. Taking the Proteaceæ for illustration, the existing range and centres of concentration of the members of this Order are eminently southern. Further particulars on this point are given in the remarks on the vegetation of South Africa, Australia, &c. Nearly all the species have a very limited range in the countries in which they occur, and the genera are also for the greater part confined to one country. Helicia, however, is an exception. This genus is represented by four species in Australia, and extends through the Malayan Archipelago to India and Japan. In Africa the genus Protea numbers sixty species, and one is

found in Abyssinia; and Rbopala reaches the northern limit of the family in South America in Guiana. Finally, there are European fossil remains which are referred to this family by palæontologists. Broadly speaking, the species constituting the vegetation of sub-tropical countries, both in the northern and southern hemispheres, are very much circumscribed in their distribution; particularly those of the southern countries.

EXTENT AND NUMBER OF SPECIES.—With an area of nearly 20,000,000 square miles, the temperate and frigid regions combined, support an indigenous vegetation of only about 25,000 species; and, in any given area, the number is small, when compared with the composition of the flora of the fertile parts of Australia and South Africa. The sub-tropical regions cover about 13,000,000 square miles, 4,000,000, at least, of which are barren deserts; and the total number of species is com-

species are in the gardens of this country, although there has lately been a little revival in the cultivation of the beautiful flowering shrubs of the Cape and Australia. For many years past collectors of living plants have been mainly engaged in ransacking the mountain forests of America, and innumerable Orchids, Aroids, Begonias, Bromeliæ, Palms, &c., have formed the bulk of the spoil. The countries from which we have obtained the principal part of our greenhouse plants are Australia, South Africa, and Mexico, with smaller contributions from the mountains of the northern part of South America, and of India, the southern part of China and Chili. The greater part of the Mediterranean region is really sub-tropical in its climate, but so few Mediterranean plants are sheltered in our greenhouses, that it may be left out of consideration under this head, especially as it is one of the regions of our hardy plants.

W. B. HEMSLEY.

Geographical Distribution of Garden Plants: Succulent Plants in Mexico.

puted at from 40,000 to 45,000. Without making some careful and laborious calculations, it would be unsafe to assert that there is a greater concentration of species in some sub-tropical countries than in any tropical regions; but there can be little doubt on this point. For instance, the area of Cape Colony, South Africa, is given as 200,000 square miles, and the flora is estimated at about 9,000 species.

HISTORICAL.—Little more than a century ago, scarcely anything was known of this enormous floral wealth in Europe. A few Cape plants were introduced early in the eighteenth century, among them a few species of *Pelargonium*, *Mesembryanthemum*, and *Erica*; but it was not till about the year 1774 that this mine was really opened. After that date, and up till about 1820, with certain intermissions, the flow of new bulbous-rooted and hard-wooded plants from the southern hemisphere was almost incessant. It then began to decline, and finally almost ceased, and now probably not a third of the

YOUNG PLANTS IN POOR SOIL.

SOME believe that rich soil is the chief requirement of a large number of our garden plants; it is in every case necessary to give wholesome food, but in the early stages of plant growth, very rich soil is not required until sufficient roots have been made to absorb the manure. It is often the case when soil is very poor, that the pots in which the plants are growing are filled with roots, whilst little or no foliage has been produced. Place the roots of that plant where they can have their fill, and it will be seen what advantage plenty of fibres has over large, thong-like roots; sturdy growth and flowering wood is the result. Often does a Vine in a pot make a growth like a straw, and if the pot be inverted, and the roots turned out, the whole ball is a firm mass of fibre! On the other hand, one may have a Vine having fine growth, luxuriant foliage, strong wood, and probably with a large amount of pith. Examine the roots of that plant, and they will generally be found to be long, rank feeders growing thinly through the soil; but the difference between the two forms of roots is the former keep on extending themselves through

the soil, finding little to draw up into the plant to give it bulk, but growing and increasing in numbers, finding little till the whole space is occupied. We have more than once lifted Vines and Peaches, and though the border was matted throughout there was a very small proportion of wood on either, yet they bore exceedingly fine fruit and took plenty of liquid manure. Figs, I have often seen the same, and no amount of liquid manure would induce growth beyond a few inches which were each season covered with fruit of unusually large size. I would suppose that when Mr. Thomson made that good hit at Dalkeith, of using sand in narrow strips at intervals through his Vine borders in a perpendicular direction, it was to arrest the rapid progress of the large roots; when they came in contact with the sand a large amount of fibres was thrown out which would draw up large quantities of food from the rich soil as soon as they passed through the sand. A saving of border space would be effected at the same time. Fibres drawing up rich food to a plant, and gross roots doing the same, is attended by very opposite results, the former having a tendency to give constitution and provide fruit or flowers, while the latter caters for wood, pith, and foliage only. I remember well, when a youth, employed in the establishment of the late Mr. Catleugh, at Chelsea, that his system of growing Pelargoniums for market (his quota sent for sale to Covent Garden was 30,000 a year), consisted in starting his plants in sandy loam without manure, and that when placed in their flowering pots rich soil was given them. The first secured plenty of fibres. He then allowed them to consume as much as they were able. Stronger plants and finer flowered I have never seen of that class. During the present season we were obliged to use very poor soil for everything, because we had no other. Every pot became crammed with fibres, but not much top growth was to be seen. Since then these plants have had good soil, and those of them which are flowering now are doing extra well. Euphorbias flowering are making shoots like quills; Bougainvilleas are flowering on every inch of growth; and Neriums, Cytisus, Habrothamnus, and many others are doing the same.

M. TEMPLE.

Rendle's System of Glazing.—The present system of glazing horticultural buildings is an endless source of expense and annoyance. What is required in either a plant or fruit house is a waterproof roof, and this is rarely obtained under the old system of glazing. Putty is a very perishable material when exposed to the weather, and the smallest crack or flaw lets in a stream of water. When squares of glass are fitted tightly and putted down closely, fractures often take place on account of the inelasticity or non-yielding nature of the three substances brought into immediate contact. Sometimes the putty cracks and gives way under the pressure of wind, or the expansion and contractions caused by changes of temperature, and many squares of glass are cracked, and thus let in drip. The painting and repairs of glass houses also form a very heavy item in garden expenditure, and any system of construction that will reduce it without any sacrifice of efficiency, must, in the long run, succeed. Although there may not be much saving in the first outlay, yet any one will easily understand that where no putty is used, or any other perishable substance exposed to the weather, the cost of maintenance must be very considerably reduced. Then, again, the elastic bed on which the glass rests prevents, in the ordinary course, many fractures. The jar of a door, or a large hailstone falling on a tightly-packed square of glass may crack or fracture it, whilst glass used on Rendle's system, that will yield under a blow, is endowed with greater resisting power. Among other places where I have seen the system carried out, I may notice a large Vinery at Burghley, on which a new roof on this principle has been erected. Mr. Gilbert speaks very highly of it, not only as to its freedom from drip, but as regards the less liability to fracture; and I think no one can thoroughly examine the system without becoming convinced of its comparative cheapness and durability.—E. HOBDAV.

THE CHRISTMAS ROSE.

Brown leaves and batter'd, move them aside, and lo!
A paleness, purer than the circling snow,
A treasure trove of fairest flow'rs below;
White waxen petals, yet their own faint flush
Of conscious life, a warm and beauteous blush.
The wild wind sweepeth o'er with sudden rush.
They crouch so low, he finds them not, and so,
With golden stamens nestling in their snow,
They lie unharm'd, the sheltering leaves below.
O! Roses, thornless Roses! such as ye
Our floral off'ring Christmas morn shall be.

L. WALEN.

PLATE CVII.

TORENIA FOURNIERI.

THIS is a valuable addition to our indoor gardens, bearing numerous pretty blossoms, and being neat and graceful in form. Our hothouses rarely produced more beautiful objects than well-grown plants of the old *Torenia asiatica*, with its shoots flung down in graceful profusion, and its numerous pretty flowers. At first it was scarcely hoped that the new comer would quite equal the old plant as a stove ornament, but Mr. Barron placed the old and new species alternately in baskets this year, and proved *T. Fournieri* to be in all ways equal to *T. asiatica*, and yet distinct from it. It is charming as a basket plant in a warm house. It is a native of Cochin China, where, M. Godefroy Lebœuf informs us, it is a common little plant in the priests' gardens. Our plant is reproduced

Torenia Fournieri.

from a drawing kindly lent us by Messrs. Vilmorin, of Paris, where the plant is sometimes tried out-of-doors. It is, however, much freer and happier in a warm house. It is easily raised from seed or cuttings, and is of facile culture.

STORING SPINACH IN A COLD COUNTRY.

NUMEROUS have been the means adopted by gardeners to save Spinach for winter use. Heeling-in in a dry place, just before hard weather sets in (something after the plan adopted for Celery), and roofing over, secure from hard frost, was long since one of the means used by cultivators. Laying rails or poles between the rows and covering with litter is another. How to save it, the Massachusetts "Ploughman" relates in a late issue, as practised by market gardeners about Boston. To keep Spinach, it is only needful to cut it on a dry day, about November 10 or 15, and pile it about 6 in. deep upon shelves in a cellar provided with ventilators, so as to be able to keep the temperature as near as may be 32°. The cellar is usually built on purpose in the large gardens, where 1000 bushels or more are stored. An excavation, 20 ft. by 30 ft., is made 6 ft. deep, and walled up at the sides and covered in with a roof of boards and shingles, with a door at one end. Two paths or alleys run the length of the cellar 2 ft. wide, and a shelving of 6-in. boards, with air spaces of 1 in. between, are built up on each side of the alleys; the space between the shelves is 14 in. The cellar should be provided with two or three ventilators of Pine boards 6 in. square, extending from near the floor to a height of several feet above the roof; these are kept open in moderate weather, closed in a very severe cold spell, or in a thaw, the object being to keep the temperature as near 32° as may be. The roof and ends of the pit are covered over with litter of any available kind, to exclude frost. Spinach will keep very well in cold dry weather, in a cellar like this with little waste; but if a warm open spell of weather occurs, it is very likely to decay and spoil. By modifying the conditions for preservation, Parsley, Lettuce, Endive, and some other plants of like nature may be easily kept. These modifications will easily suggest themselves to the practical gardener, and in the West, at least, we think the plan may be made to pay.

TORENIA FOURNIERI

THE INDOOR GARDEN.

THE DOUBLE POINSETTIA.

LAST season I directed attention to the more brilliant shade of colour of this splendid novelty, as well as to the marvellous persistency of its bracts, a single bract continuing in flower, in an intermediate house at a temperature of 55°, from November to May. Another feature, very prominently manifested this season, is a later habit. Plants of this and of the common variety, started together and treated alike, have shown a difference of a month in the time of colouring. *P. plenissima* is so much the more later than the common type. This has much enhanced its value. Planted abreast, the common *P. pulcherrima* would be beginning to fade before the supplementary bracts of *P. plenissima* had made much progress. One of the most valuable features of the latter variety is, also, that the first bracts do not show any tendency to fade or droop when the supplementary ones develop, though these continue to come for several weeks—sometimes a month or two in succession—so that the entire bract or series of bracts continue in beauty to the last. This adds immensely to the gorgeous grandeur of the plants. Its mode of development is also peculiar, and seems to prove this fine variety to be only an improved sort of *pulcherrima*. It is quite a misnomer to call this a double variety. Those familiar with the old variety have often noticed a few, or many, of the curiously formed yellow flowers producing a scarlet bract from their upper sides. We have had many flowers sport thus towards *plenissima* this season; for *plenissima*, when it first develops its lower tier of bracts, seems to rest awhile and consider what more beauty it may be able to add. At this stage, it strongly resembles the common type, only it has more colour on its crown. Gradually the uncertain shape and indeterminate colours are developed and fixed, and few or any scarlet bracts proceed out of the centre overlapping the lower ones, and filling up the centre with scarlet or brilliant vermillion crowns of glory. It is impossible to exaggerate the beauty of well-grown examples of this Poinsettia. The result, however, depends greatly on culture; the number and size of the bracts, as well as perhaps the intensity of their colouring, being very much dependent on the vigour and health of the specimens. Under similar conditions, however, the *P. plenissima* is several shades brighter than the old *pulcherrima*. The brightened intensity of colour is so marked here as to be obvious to every one who sees the plants growing together; and it is an additional merit of the highest excellence. The new variety has also a rather more compact habit than the old one. Its greatest merit, however, is the doubled or trebled durability of the bracts, and their constant multiplicity. With Poinsettias continuing in beauty two, three, or more months, our plant stoves need never more know a dead season. It is hardly possible to have a more brilliant antidote to our leaden, frozen, or dripping skies from November to March than an abundant supply of Poinsettia *plenissima* in our plant stoves, warm conservatories, and warmer window gardens or glass cases. It is well nigh

impossible to be melancholy in the presence of such intense brightness and beauty. Depend upon it, there are few better cures for low spirits than a plentiful feast of *P. pulcherrima plenissima*.

D. T. FISH.

Seedling Ferns Indoors.—Where large quantities of plants are required for indoor decoration, few plants are more serviceable than seedling Ferns, especially the Maiden-hairs and *Pteris serrulata* and *longifolia*, all of which are easily raised from seed. We find young plants in 2-in. and 3-in. pots useful for forming a fresh, green groundwork for jardinettes and drawing-room stands, as, should any of them become shabby from the ungenial positions which they are frequently obliged to occupy, they can be readily removed and fresh ones raised; or, if required for growing into larger plants the following season, the whole of the old leaves may be cut off, when a head of fresh, verdant fronds will quickly replace them. Where large

specimens of these Ferns are grown, seedlings are usually found springing up abundantly on all moist surfaces, as the seed spores are so light as to be carried and deposited over the whole house. If sown in pans, or on lumps of peat, the seed must not be covered, but merely shaken on the surface, which must be kept constantly moist. The seedlings also enjoy a humid, brisk atmosphere, but when required for decorative purposes they should be gradually inured to a cool and moderately dry atmosphere, so as to harden the fronds and render them capable of withstanding the fluctuations of temperature to which they are invariably exposed. In table decorations small Ferns constitute an important item; where the small pots containing them are enveloped in fresh green Moss, they may be used in a great many different combinations. Some of the freshest and greenest table decorations which we have had this season have been formed exclusively of Ferns on a centre of green baize, on which the candelabra and appendages showed themselves off with excellent effect, while, in the strongly-reflected light, the whole looked as if set on a Grass plot, a bordering of foliage being employed to conceal the limits of the baize. Of the white table cloth only sufficient was visible to accommodate the plate and similar articles.

Cyclanthera pedata.

In Covent Garden, Maiden-hair Ferns are in great request for these and other purposes. They are grown in small pots for the most part alone; but sometimes mixed with Tulips and other bulbous plants. Their fronds, too, in a cut state, are so much in demand that long, span-roofed houses are wholly devoted to their growth.—JAMES GROOM, Henham.

Cyclanthera pedata.—The genus *Cyclanthera*, belonging to the natural Order Cucurbitaceæ, numbers only seven species, natives of Texas, Mexico, Peru, Ecuador, and other parts of South America. The annexed illustration of *pedata* will give a good idea of the habit of the plants. This species, which is an annual, is a native of Mexico, and though it has been in cultivation ever since 1831, it is still far from being common in gardens. Its climbing habit makes it particularly suitable for covering walls and palisades, as well as for

training over wires or in wreaths, and the unripe fruits can be used as pickles. The leaves, which are pale green, are composed of from eight to nine narrow leaflets. The plant is monoecious, the male flowers being borne in long-stalked panicles, and the females solitary in the axils of the leaves.—J.

TREE OR PERPETUAL FLOWERING CARNATIONS.

How the whole character of these have changed of late years! and this change may be attributed to two causes, the introduction of a new race, and a better mode of cultivation. When the improved varieties of the new race are more widely distributed, and the better system of culture is more widely known, Tree Carnations will be as frequently seen in plant houses in early spring, as Cinerarias and Chinese Primulas. Let it be remembered that it is the peculiarity of the Tree Carnation to flower in winter and spring. Some suppose that all Carnations are summer-bloomers, and that to have Tree Carnations in spring considerable forcing is required. He who sets himself to grow Tree Carnations must dismiss the idea that they are identical with the summer flowering varieties; he has to deal with a distinct race, essentially different in character, and requiring special treatment. Happily for him, it is an easily managed plant, if only the work be set about in a right manner.

Many will remember the old tall, lanky Tree Carnation of twenty years ago, with a long stem, little grass, and a few flowers at the extreme top. It is now becoming extinct. Now we have dwarf, stocky, free-growing plants, producing an abundance of healthy grass, and throwing up many flower stems bearing bright-coloured fragrant blossoms. This gain is attributable to foreign seed, and Mr. Turner, who has of late paid much attention to Tree Carnations, saw where his opportunity laid, and, by careful selection, has succeeded in raising a number of varieties, showing improvements, not only in the flower, but also in the habit of growth. His new varieties include Rose Perfection, very bright rose, flower large and smooth; Scarlet Defiance, vivid scarlet, fine shape and substance; Lillian's Glory, pale red, bright and effective; Coronation, crimson scarlet, very smooth and distinct; Mr. Fowler, bright rose, very pretty and sweet; Jessica, white, large and full; Guelder Rose, white, full-sized, well-formed flowers; Fairy Queen, white, flaked with rose, distinct and very fine; Sir Garnet Wolseley, buff ground, striped, and edged with bright red, very dwarf, free habit; Tricolor, pale yellow ground, striped with purple and magenta crimson; and a fine new Continental variety, named A. Allegatiere, glowing bright red, very fine and striking, dwarf, free habit. Probably the best portion of the foregoing will be put into circulation in the spring.

A selection of varieties that can be obtained should include Avalanche, white; Caliban, flaked with rose; Congress, bright scarlet; Eclair, dark crimson; Empress of Germany, large white, slightly marked with bright rose; Garibaldi, rosy-scarlet; Hermann Stenger, rose, flamed with cerise; Indian Chief, dark crimson; King of the Belgians, dark rose; Miss Jolliffe, pale pink, very fine; Oscar, yellow, large and full; Prince of Orange, a yellow Picotee, edged with crimson; Princess Christian, bright pink fading to peach; Queen of the Belgians, white striped with rose; Rosy Morn, deep rose; and Vulcan, bright red. That a certain dwarfness of habit has been acquired is placed beyond doubt; at the same time, much depends on the proper treatment. I will now proceed to supply a few hints as to the culture of these Carnations.

At this time of the year the plants that are showing for bloom should be in a greenhouse where a little warmth can be given them, and air on all favourable occasions, to keep the atmosphere dry and comfortable. It is a great mistake to suppose that forcing, in the ordinary acceptance of the term, should be applied to these plants; all that is required is a little gentle assistance, nothing more. A dry bottom is necessary, that is to say, the stage on which the plants are standing should not be allowed to become wet, as damp will injure the flowers; in fact, so far affect the unexpanded buds that they decay at that stage and never open. Nor must the soil about the roots be allowed to be get too dry, but kept moderately moist; the foliage must be kept clean and free from green fly, which soon increases during the time the plants are kept close.

By means of these simple precautions flowers can be had for a considerable period.

Unlike the ordinary Carnations, which are propagated by means of layers or pipings in summer, the Tree Carnations are increased in early spring by pipings; the young growths put out at the sides of the main stem supply the material out of which cuttings are made. The best time at which to take them is about the end of February or early in March, and strike them in the same manner as Pinks, on a gentle bottom-heat, using a moderately-light, sandy soil, and putting about eight or ten pipings in a 4-in. pot, giving them a good watering as soon as inserted. When properly treated, the cuttings will strike root in about three weeks or so; they should then be potted singly into middle 60-sized pots, and again placed in a gentle warmth, and when well established, hardened off, and then repotted into 48-sized pots, or a larger size, according to the strength of the plants. By the time this stage of the cultural process is reached, the plants may be placed out-of-doors on a layer of cinder ashes, and be kept well watered during the summer months, and as the main shoots increase in length, they should be properly and securely tied out to stakes, as they are liable to be swayed about and broken off by the wind. Those who are about to begin growing Tree Carnations would do well to obtain the plants now or in September, and then, by following the directions above given, a successful blooming season might be looked for.

D.

FLOWER GARDENS UNDER GLASS.

THE year that is now closing is likely to live in the memories of all who have had anything to do with gardening. From a commencement unseasonably and unusually mild, the year advanced into a cold and blighting spring, to be succeeded by a summer so wet, bleak, and sunless, that, in these respects, it has not been equalled for half a century; but for a month of fine weather—from the second week of September to about the same period in October—the whole year would have been one of unbroken damp and cold gloom, for hitherto the autumn and winter have been no improvement on the summer. Possibly these remarks apply to the weather experienced in the northern half of the kingdom more fully than to the south, where, perhaps, the extreme sunlessness was not fully experienced. It is not easy or pleasant to attempt a forecast of what may be the effect of such a year on the products of the one that is to follow. Our impression is, that in consequence of the fine, dry month referred to above, before the sun lost its ripening power, fruit-bearing trees are much better ripened and prepared for the succeeding crop than was at one time expected—all the more so, owing to the scanty crops borne by them this year; so that it is reasonable to hope for better crops next season, should the spring and early summer be propitious. But there lies the uncertainty that may dispel the best of hopes and the most skilful and indefatigable efforts. In certain districts no one, from past experience, looks for a full crop from most of our hardy fruit trees oftener than once in four or five years. We have, not very long ago, directed attention, if that had been necessary, to the uncertainty and unprofitableness of growing such fruits as Peaches and Nectarines in many districts without the protection of glass. Fortunately, this fact has been recognised and acted upon to a very considerable extent, and results have justified the extensive erection of orchard-houses and glass coverings for walls. It is now also recognised that if flower gardening with tender plants is to be successfully carried out in a great many districts, without as many blanks as prizes in a series of years, some such means must be taken, to make it a matter of certainty, and satisfaction, as have been adopted in the case of fruits. If anything is more apparent in the gardening press, as well as through other mediums, it is that there is a deeply-felt disappointment with tender-flower gardening. A day's rain washes it out, and a night's frost lays it low—a mass of corruption, very often, before it has come to its best.

A few Peach trees and a few Plum trees, &c., under glass, are found to yield three times as many, and better fruit, in the course of a decade, than was ever hoped for on the open wall; and the trees continue to live in good health, without being crippled, and half-killed most springs. Just in like manner a much fewer number of tender-flowering plants under glass yield five times the quantity of fine fresh perfect blooms in a season that they do out-of-doors. This is no mere conjecture; it can be regarded as an absolute certainty. In very many localities, at least 5000 plants under the protection of glass will give far more blooms than four times that number during the vicissitudes of the few weeks they can be risked out-of-doors. In

fact, in too many cases it leads to eight month's nursing of the plants for the uncertainty of three or four months' bloom, even in the most favoured districts. We know of no more fruitless effort in the whole round of gardening than to attempt in many localities tender-flower gardening out-of-doors. Of course it may be hard to give up, in such places, what is so fashionable, and so gay and telling for a month or two, in others. We are convinced, however, that such a course would in the end be less expensive, less laborious, and much more pleasure-giving, and vastly more favourable to the true science of gardening, if open-air borders were filled with selections of hardy perennials and shrubs, and if such plants as our now beautiful *Pelargoniums*, and the tender host associated with them, were grown in much less numbers under the protection of a glass roof. Not only would they then be enjoyed in all their untarnished beauty from early summer until winter, but think of the number of varieties of plants which cannot be planted out-doors that could be arranged along with them!

It may be said, "Oh, we have conservatories already." Certainly we have, such as they are; in most cases places, in the first instance, for spoiling plants, and putting them out of bloom and out of health in the shortest possible time. In too many instances conservatories are conglomerations of plants huddled together, with next to no design, and of huge glaring pots and bare stone surfaces, altogether as artificial and devoid of elegance as it is possible to make them. If ever the idea we are advocating be carried out, as it ought, and can be, it must be in lower, lighter, and less expensive structures, though not on these accounts less elegant. The varieties of plants that could be introduced, and the scenes that could be created under a glass roof from year's end to year's end, would form a striking contrast to our ugly conservatories, and more especially to our degraded and jaded-looking tender plants in the open ground. What is wanted are plants on and in the ground, under the eye, and not so much above—a place of ease and order—with a few creepers and baskets, &c., introduced judiciously, and not to such an extent as to shut out the light from the principal plants and flowers. Scenes of such elegance could be arranged under glass as we have seen nothing of as yet.

But what of the expense and labour it would require to carry out such a revolution as this? We answer, What of the labour and expense of large outdoor parterres, for which tens and hundreds of thousands of tender plants have to be reared and tended and nursed for eight months out of the twelve under glass? And, after all, what of the results in many districts? We argue, that if such parterres were curtailed and planted with hardier, though certainly not less interesting plants, and a more limited number of tender plants were arranged under glass, a few years would soon show that of the two the course we are suggesting would be the cheaper. We are not speaking entirely without experience, for this season we planted 14,000 tender plants in a glass house, which remained in great beauty until far on in November, while hundreds of thousands outdoors were nearly a complete blank. As to the labour these 14,000 plants required, we are speaking within the mark when we say that a man or a lad could do it most weeks in two days a-week. How little really in the average of seasons a tender flower-garden outdoors can be enjoyed in many districts, and how disappointing the finish up of it generally is! What scenes the hand and eye of taste could work out in a greatly less space under glass, varying and changing with the seasons! And when days of rain and cold prevent the enjoyment of the shattered remnants of a garden outdoors planted with tender things, what a charming retreat and pleasure the garden under glass would be to the healthy and the ailing alike! And what a contrast and wholesome change from the hardy border plants outside to the glowing beauty and colours of those in the glass-garden! We are confident that it only requires a few with spirit and taste enough to set a good example, to inaugurate a step in a direction like this, which could not but prove a never-failing source of delight to lovers of flowers.—"The Gardener."

Forcing *Eucharis amazonica*.—At all seasons of the year, this beautiful *Amaryllid* may be had in flower where a sufficient number of plants exist to form a succession. Market gardeners near London grow it in quantity, and its pure white, sweetly-scented flowers are always valuable. They place the bulk of their plants in a cool house, and keep them dry at the roots. A few dozens at a time are then removed to a warmer temperature, plunged in bottom-heat, and well supplied with water. In a few weeks afterwards the flower-stems show themselves, and, when fully developed, the plants are placed in rather cooler quarters, to open their blossoms. After flowering, they are again placed in their former quarters, in order that they may have a season of rest. In this way a good succession of flowers is kept up, and sometimes the same plants are flowered

twice a year. Repotting is not, however, practised oftener than is absolutely necessary, as, unless the plants are kept somewhat pot-bound, they do not flower so satisfactorily. Manure-water, applied during the growing season, is productive of better results than frequent shifting or disturbing the roots. Some growers—Mr. Ladds, of Bexley Heath, for instance—have houses occupied by *Eucharis* planted out in beds. This method is a good one where space can be commanded; but where the most has to be made of the house-room available, pot culture is preferable. Mr. Denning, of Norbiton, also has a house planted with *Eucharis*. Under such circumstances the plants make remarkable growth, and furnish a rich harvest of flowers during the dull months of winter, when mostly wanted. *Pauceratums* are also now largely grown by florists for the sake of their sweetly-scented blossoms, which are much prized for the centres of bouquets. They are treated in a similar manner to the *Eucharis*.—C. W. S.

—We grow the *Eucharis amazonica* largely both for decoration in the form of plants and for cut bloom; and, after trying it both with bottom-heat and without it, I have come to the conclusion that bottom-heat in its case is superfluous. This year we have grown and flowered an entire stock of it thus far without plunging the pots or even standing the plants on bottom-heat, and I never remember having had such a continuous or good supply of flowers before. My reasons for discontinuing the practice of plunging the pots was, that on examining the roots of those that had been plunged I found them frequently in a decayed condition, even when the heat employed was of the mildest character; and plants removed from bottom-heat for decorative purposes invariably flagged, and did not retain their blossoms in perfection near so long as those that had not been subjected to the plunging process. I find, in short, that the roots of most plants are more sensitive of changes of temperature than the stems or foliage; I now observe that our plants have retained their fleshy roots in excellent condition, and that they have thereby been enabled to carry a fine crop of flowers, which under cool treatment have retained their beauty for a long period. I may mention that we grow the majority of our *Eucharis* in 3 in. pots, one good bulb producing with certainty a fine spike of four or five flowers. Large specimen pots full of bulbs are beautiful objects for large vases; but where quantities of bloom are required at given dates, single bulbs in small pots full of roots are the ones on which to rely for certainty of supply.—JAMES GROOM, *Henham*.

Lily of the Valley for Market.—Whether as a pot plant, or in the form of cut blooms, the Lily of the Valley is always a favourite, especially at Christmas, when the demand for it being great, it realises high prices; therefore, during the last few years, florists have forced it in large quantities. The single crowns, which are imported from Holland early in the season, usually supply the earliest flowers. They consist of various crowns, such as that represented by the accompanying woodcut, all of which are nearly certain to

Single Bulb of Lily of the Valley.

flower, and they will bear more rapid forcing than perhaps any other plant. As they are imported without any soil attached to them, numbers of them can be placed in a small space, and house room is thus economised. A bed of Cocoa-nut fibre, or other light material, is made for them, under which there is a strong bottom-heat; they are planted thickly in the fibre a month or so before they are wanted to flower. When the blossoms begin to show themselves, the crowns are potted six or eight together in 5-in. pots, and sometimes a few small Ferns are placed amongst them; they are then well watered, and, as the flowers expand, they are placed in a little cooler temperature. For later supplies, imported clumps of crowns are used. Market gardeners always cram clumps containing as many crowns as possible in 5-in. pots; they are then plunged in a bottom-heat of from 75° to 80°, and kept well watered with tepid water. When they show bloom, they are thinned out to six or eight in a pot, as a

medium-sized potful of plants realises as much money as full potfuls, and the thinnings, when potted, supply out blooms. Some mix Squills (*Scilla sibirica*) with their Lily of the Valley, and the two colours combined are very effective. Many tons of roots of Lily of the Valley are used by florists in the neighbourhood of London every year.—S.

PHYLLOCACTUS ANGULIGER.

This singular plant, nearly allied to the old *Epiphyllums*, as they are often called, is not a very strong grower; but it is interesting even when out of flower, on account of its regular saw-like margins. Its flowers are not produced so profusely as in some others of the genus, but an additional value attaches to them, on account of their being

produced in winter, generally about Christmas. They are white, and owing to the length of their tube, they are useful for bouquet-making. This species likes rather more heat than its fellows; therefore it may be kept, during winter, in a dry corner of a stove; but it will live even in a greenhouse. In its native habitat it is an epiphyte; therefore, it will succeed as a basket plant in peat.

J. CROUCHER.

Forcing Cinerarias.—The Cineraria is the most ticklish subject to force with which I am acquainted. It really should not be forced; but at the dead season of the year the buds make little or no progress in a cool temperature, such as suits the plants otherwise. Of course, it is perfectly useless attempting to force the Cineraria if the buds be not well formed and just about to expand, at which stage they will stand for months if not assisted with a little heat. A temperature of from 50° to 55° is high enough, however, and the plants should be placed on a shelf, away from hot pipes, and with their tops quite close to the glass, where they will get every ray of sunshine. One good sunny day will do more to open the flowers than a week's forcing; and once the flowers are out, the plants should be at once moved into a perfectly cool structure, safe from frost, as, if they be kept long in the forcing house, they usually either fall a prey to green fly or lose their foliage. At all times they should have plenty of water at the root, and if the pots can be set on sand or on a flag or slate bottom, all the better.—C.

ORCHIDS.

SEASONABLE NOTES.

TERRESTRIAL ORCHIDS.—Some of these force well, especially *Cypripedium* spectabile. I would therefore recommend those who have a good stock of it to at once place some few plants of it in gentle heat, and those who do not possess it should at once add it to their collections. Its charming flowers are welcome at all seasons; but especially so in winter. The large purple-flowered *C. macranthum*, although somewhat rarer, and the yellow *C. parviflorum*, also force well.

DENDROBES.—*D. heterocarpum* is a plant which varies much in colour; all the varieties of it, however, deserve attention on account of the exquisite odour of Violets which their flowers possess. They are opening now, and will continue to do so for a long time yet to come. This species will succeed either under pot culture or upon a block, whichever may be most convenient to the cultivator. *D. Linawianum*, better known by the erroneous name of *D. moniliforme*, is now finely in bloom. It is a plant which should be in every collection, however small, for its cheerful rosy-cerise flowers have few equals at this season. It is easily accommodated, and should be grown in a pot. *D. Pierardi*, although one of our oldest acquaintances, is still a welcome winter and spring-blooming Orchid. Its flowers, which are produced in great abundance, are white, tinged with lilac. It should be grown in a basket. *D. chrysanthum*, although rather short-lived, forms a good companion to the last-mentioned species. It has rich golden flowers, heavily blotched on the lip with black. It should also be grown in a basket, as its pseudo-bulbs are pendulous.

ODONTOGLOSSUM CIRRHOSUM.—This promises to become an all-the-year-round bloomer, and the beautiful outline and colour of its flowers will cause it to stand in the first rank amongst *Odontoglossums*, popular though the genus is. Some plants of *O. cirrhosum* are now in full beauty, and others have spikes in various stages of development; therefore, a prolonged display may be expected. It moreover appears to conform to the coolest treatment, which is an additional recommendation.

PHALÆNOPSIS require both heat and care, in order to insure healthy growth and fine flowers, and the extraordinary beauty of their large moth-like blooms well repays any extra attention which may be bestowed upon them. The species now in flower are *P. grandiflora* and *P. amabilis*, both pure white, but the former a little stained with yellow in the lip, the latter being similarly marked with rosy-pink. *P. Schilleriana*, with its grey-banded leaves and large, branching spikes of mauve-coloured flowers, is always amongst the most attractive of winter and spring blooming plants.

LELIA ALBIDA.—This forms a good companion to the more robust *L. autumnalis* mentioned a few weeks back; its sepals and petals are white (in some varieties tinged with mauve), and the lip pink and yellow.

CYMBIDIUM GIGANTEUM.—This, it is true, cannot be recommended to those who have but limited space and small houses, but it should always be grown in large collections. It is a plant generally much neglected, but its bold habit of growth and large purplish flowers (which are produced on erect spikes) render it both attractive and imposing. *C. Hookerianum* very much resembles it, but the flowers are more or less streaked and blotched with greenish-yellow. Both may be grown in a cool house; they require some turfy loam added to the soil.

W. H. G.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Sarracenia Drummondii alba.—A fine specimen of this Huntsman's Cup may now be seen in Mr. Williams' nursery, at Holloway. It bears nearly twenty trumpet-shaped pitchers or cups which are of a transparent white colour, veined with purple, and highly interesting as well as ornamental.—S.

Suspended Pans for Crotons.—Nearly all fine-foliated plants require as much sun and light as can be given them, in order to bring out their true colours, and especially is this the case with Crotons. An excellent plan by which this end can be attained in the case of small plants is to place them in suspended pans over the pathways; in this way neat, bushy, well-coloured plants are obtained, space is economised, and the house itself is rendered more attractive.—S.

Adiantum princeps.—This is one of the most ornamental of Ferns. It has long, graceful, branching fronds and elegant pinnae, almost as large as those of *A. farleyense*. It is best suited for a stove or intermediate house, but during summer plants of it grown in 6-in. pots make admirable subjects for room decoration.—C. S.

THE ORANGE TREE SCALE.

Lecanium hesperidum, Linn.; var *Lauri*, Boied. (*Chermes Lauri*, Bouché.

THIS species is well known in the south of Europe as the Orange tree bug or the Orange tree louse. Nor is it unfrequent in the conservatories of this country, being often imported on various hothouse plants, to which it has strayed from the Orange tree, or on the Orange tree plants themselves. It spreads easily, and, in houses that are at all neglected, speedily establishes itself, its habit of wandering to many plants rendering it more difficult to eradicate. When imported into other climates suited for it, it soon becomes a permanent scourge. In California, for example (into which it has been introduced from Europe), it has multiplied in such enormous quantities as seriously to interfere with the prosperity of the

Orange tree Scale.

Orange tree plantations, of which many have been formed in that country.

In appearance it is flat, elongate, oval, twice as long as broad, varying in size from 2 to 4 millimetres; yellow, of lighter or darker shade, with some brown blotches; dorsal disc smooth, with a very sparse and scattered punctuation; antennæ with the fourth joint longest; legs long and thin; the tibia a quarter longer than the tarsus. In the larval stage it is very long, and the antennæ have only six joints; in the adult stage they have seven, like some other species of this group. It is right to add, by way of reminder to the reader, that the number of joints in the antennæ is not a generic character, for it varies in different species, some having eight joints, others seven, and others six. Boisduval says that when the female has finished laying, a great number of eggs are to be seen under the envelope, reposing softly on a whitish down. This is probably an error, arising from mistaking some species of *Pulvinaria* for it, for it appears to be a viviparous species. Dr. Signoret has stated that:—"If we examine a female

arrived at its most advanced stage, and turn her up, it is not rare to see on the abdomen a point where mortification has commenced, through which the embryonal larvæ have passed, for we have never seen eggs laid by her." When the young appear, they move about here and there on the leaves before fixing themselves; they keep by preference on the under side of the leaves (although some individuals may also be often found on the upper side), placed in a line along the midrib; but it is particularly on the young branches that they are to be met with in the greatest quantity. When they are abundant, they occasion a great loss of sap, which exhausts the trees, especially those which, from any cause, may be already languishing. So much so, that Boisduval mentions having seen tubs containing Orange trees, in which the earth was actually wet from the sap that fell like dew upon its surface. This varnishes the leaves with a honeyed, sticky substance, which attracts ants and other insects. In that state the leaves, which are as yet not fully developed, become sickly and predisposed to the attack of a black mucedo (the fumagine, or morphea of the Italians) a fungoid growth which resembles a coating of soot, and is described by Persoon under the name of *Fumago citri*. Seen under the microscope, it looks like an immense forest of interlacing branches. In the environs of Nice and Cannes this affection very often extends to the fruit itself, of which it arrests the development. It is said that this black mould is never observed on any plants but those that have been injured by some coccid or other, and it is very curious that it equally appears on those that have been injured in other countries, as in California, from which we have received leaves covered with the fumagine.

All kinds of the Orange tribe are subject to the attacks of this insect, and although it is chiefly found upon them, whether in the hot-house or the open air, it is not confined to them, but also extends to many other plants growing in their neighbourhood. M. Boisduval mentions having found it upon all kinds of *Myrtaceæ*, on *Pomegranates*, *Magnolias*, *Hibiscus* and other *Malvaceæ*. The common Laurel (*Laurus nobilis*) is another plant on which it fastens, and on which it undergoes some slight modification, sufficient to have induced M. Boisduval to characterise as a distinct species, under the name of *Lecanium lauri*. It seems to us, however, not to be entitled to rank as a distinct species, but to be merely a variety caused by altered conditions of life, and we therefore treat it as such, not separating it absolutely as distinct, but marking it as a recognised variety. In this connection, our readers do not need to be told that many species of scale insect are confined to one species of plant—others wander from their natural food plant to any that may be found in their neighbourhood, others again only wander to allied plants, some wander but do not settle, and others actually fix themselves on a variety of plants. The consequence, however, of the usual habit of the majority of insects being to fix themselves on one specified plant has been to induce observers, when they find a species on different plants, to too often jump to the conclusion that each plant must bear a distinct species, especially if they can find some slight variegation or modification in its colour or appearance, a modification which, however, in all animals is often the consequence of changed conditions of life, and which, therefore, is not absolutely or invariably entitled to the importance which is occasionally attached to it. Although not sound on all points of the Darwinian gospel, I am sufficiently so on the cardinal doctrine of altered condition of life being one of the most potent causes of modification of structure to quite accept the individuals bearing such modifications as good species, always provided that the alteration is permanent. A single individual, however, shifting its peculiarities back and forward, according to its change of ground, does not become a new species each time it does so, and such, I apprehend, is the case with *Lecanium hesperidum* as it moves backwards and forwards from Orange tree to Laurel. The alterations it undergoes, moreover, are not very material in kind, and not greater in degree, than we are accustomed to meet with in other insects, which we do not assume on that account to be new species.

The best plan of keeping Orange trees from these insects, whether one species or two, as well as from the fumagine which follows its attack, is to take care to keep them in good

health, to see that they are not left in exhausted soil, to give them sufficient nourishment at the proper time, and in the proper way to wash and clean them in spring and autumn with a brush so as to clear away any of the insects that may be about them, and generally to cultivate them according to the rules of good horticulture. When strong and healthy they are less liable to be attacked by the insect, and, if they should be, they are more able to withstand their attacks.

ANDREW MURRAY.

TREES AND SHRUBS.

YEWS, ENGLISH AND JAPANESE.

WHEN on a visit lately, to Darley Dale, near Matlock, I had the pleasure of seeing in the grave yard there a large Yew, said by the natives to be 2,000 years old, more or less. It has a straight regular trunk for about 8 ft. from the ground, at which height it divides into six or seven large limbs, two of which are erect, the others spreading horizontally. The trunk, which is hollow, is 33 ft. in circumference. This wonderful plant is certainly

Taxus tardiva (adpressa).

one of the oldest living representatives, in Britain, of those Taxaceous plants which, early in the world's history, adorned the hills of the Devonian Epoch. With a berry-bearing twig of this venerable Yew, and another, much younger, before me, I fail to find that the English Yew has altered in character during all these years. Time, however, when not associated with altered conditions of life, cannot possibly have any influence in producing structural variation in plants. The forms of the genus *Taxus* do not appear to be very well defined, and we have a suspicion that their geographical distribution, which is somewhat extensive, has had great weight with species-mongers. It takes no very liberal description to cover the characters of all, and even the more distinct forms cross freely with the English Yew. Several of the garden varieties of the English Yew differ much more from the typical form than do any of the other so-called species. There are few men, I venture to say, who could distinguish the so-called species one from the other; they might find in them homely individuals of the handsome English Yew, but, probably, nothing more, and while the latter has accidentally, or otherwise, given to us so many distinct, curious, and beautiful varieties, several of which were enumerated and described in THE GARDEN of December 1 (see p. 520), planters can very well dispense with all the other natives of foreign climes—well, with perhaps one exception, the *T. tardiva* (syn. *adpressa*) of Japan, a berry-bearing twig of which is herein illustrated.

The most distinctive features of this Yew are the shape and size of its leaves, which are naturally represented in the engraving. All plants that I have seen of this were females, and either from cuttings, layers, or grafts. When allowed to grow naturally, it has a short stem, and a dense, depressed, wide-spreading head, with all its short, flattened branchlets recurved. In this way it seldom attains to more than 10 ft. in height, but frequently to 15 ft. in diameter of head. It is very ornamental when in berry and looks at home in an extensive rockery, and also when viewed from above. When trained as a pyramid, as is frequently done by tying the branches to a central stake, it forms a handsome, and not a too formal, evergreen. It crosses freely with the English Yew, and two or more distinct varieties are the result, one of which is called *stricta*. It differs from the mother plant in having numerous erect branches, sparsely covered with spreading branchlets, and in having a little longer leaves. There is also a variegated variety characterised by a few of its branchlets and leaves being straw-coloured. There are others, variegated in the way of the old golden Yew, but not yet in commerce. G. SYME.

CALLICARPA GRACILIS.

THIS ornamental berry-bearing shrub, often called *C. purpurea*, is in autumn, one of our most decorative hardy plants. It belongs to the Verbenaceae family, and is a native of Japan. Its flowers are small, delicate, pale-purple, and arranged in axillary cymes all along the branches and branchlets of the current year's growth. Those cymes nearest the base of the branches open first—usually early in August—and are regularly succeeded by the others towards the apex, till by the middle of October all have bloomed. The flowers are immediately succeeded by a crop of very small berries, the more advanced of which, by the end of September, assume a bright lilac-purple or amethyst colour, which is gradually communicated to all the berries as they advance in growth, and in which is centred the horticultural attraction of the plant. By the first week in November the branches are all aglow and continue so till sharp frosts end their beauty; a slight frost does not injure them perceptibly. In warmer and more favoured locations than Massachusetts, this shrub will come proportionately earlier into perfection. It is not usually considered hardy in this State, hence it has been discarded even by our nurserymen, and I cannot find it advertised in any of the catalogues that I have got. Consequently, to the exclamations of admiration, and to the queries as to where it can be procured, expressed by visitors here, I can only say: "I do not know; no one seems to have got it." The stems are not hardy but the roots are. We have two fine old plants, on low ground with a clay bottom, and where the frost remains long in spring; and the stems which shoot up in masses in the spring-time are killed to the ground the next winter, just like those of the Phlox or Larkspur, and though quite unprotected, year after year, they grow up stronger than before. Now, if all these stems be allowed to grow they will become a weakly mass of Osier-like wythes, worthless in a decorative sense, but I thin four-fifths of them as soon as they are a few inches high, retaining the strongest and erasing the weakest. One thinning will not do, so I have them gone over once or twice again, removing the weaklings. This labour is repaid in semi-spherical bushes, some 3½ ft. high by 7 ft. through, and composed of firm, well-ripened, branchy stems that have ample room but not an inch to spare, and that are covered with tiny flowers in August and September, and in October and November with bright and showy berries.—WM. FALCONER, in "Moore's Rural."

The Lacquer Tree of Japan.—Some interest was recently created in Philadelphia by a letter to the "Public Ledger," by a Japanese gentleman who came to the Centennial, offering to introduce the Lacquer tree and the Lacquer business to Philadelphia. It does not seem well known, says the "Gardeners' Monthly," that our *Rhus venenata* is so nearly alike botanically to the Lacquer tree of Japan, and its resinous product so similar to that, that it would be worth while to experiment with that before spending money in importing extensively the Japan form. Of this Lacquer tree in Japan a contemporary says:—Six species of *Rhus* have been observed in Japan, though two of them, *R. succedanea* and *R. vernicifera*, are only cultivated, and originally introduced from China. The cultivation of *R. vernicifera* and the collection of the Lacquer is one of the principal industries of Japan. Some of the villages are completely surrounded by forests of this small tree.

THE DECIDUOUS OR SWAMP CYPRESS.

(TAXODIUM DISTICHUM.)

THIS ornamental deciduous tree, which is indigenous to North America, occupies vast tracts of land in the southern States, where the soil is deep and rich in vegetable deposits. In such localities, and on the banks of rivers, it often reaches a height of 120 ft., and some of the best specimens grow to 140 ft. high, with proportionately large girths of stem. This so-called Swamp Cypress is considered an important timber tree in North America; the heartwood is of a reddish colour, and, when seasoned, it is light, strong, and durable, although less resinous than any of the *Pinus* tribe. It is uncertain when this Conifer was imported into England; there are, however, records of good specimens growing in this country 100 years ago. It is quite hardy in the south and western counties; and, when planted in suitable sites, it grows to a moderate-sized tree, though not likely to be of value as a timber tree in England. When planted in thin, poor soils, and on dry, hilly ground, it does not succeed well; indeed, it makes very slow progress in such situations; but, when planted on the banks of running streams, on ornamental islands, or in any sheltered situation where its roots can receive abundance of moisture, it will be found to thrive well. Its habit, when young, is pyramidal, with a thin, spiry top; but, when approaching maturity, its top presents a more flattened appear-

Taxodium distichum.

ance, its branches become more widely spreading, and, altogether, it is less formal in outline. When old it is not only graceful on account of its Fern-like foliage, but the ramifications of the branches exhibit a picturesque aspect in winter when destitute of leaves. Another characteristic feature of this tree, too, when growing close to water, is the peculiar growths round the base; these excrescences are mostly hollow, and, on old trees, they are often very large, forming broad, conical knobs; what may be the cause of these malformed protuberances I am unable to say. Apart from the elegant, feathery, Grass-green foliage in summer, the *Taxodium distichum* is one of the most effective trees for contrast in the landscape during autumn when clad in its warm, reddish-brown clothing; it perhaps shows off to the best advantage when associated with Conifers of sombre hues, or other dark-coloured evergreens. There are several varieties of this tree. I think, however, none of them is more beautiful than the common form. *T. d. pendula* is probably the most distinct variety, but this even is not superior to the type. There are two good specimens growing at Longleat; the oldest and largest tree is very ornamental and picturesque; its height is 63 ft., the girth of its butt is 9 ft. 4 in. at the smallest part; at 4 ft. up it divides into two main central limbs, girthing respectively 6 ft. 9 in. and 5 ft. 7 in.; the widest spread of branches is 35 ft. The other, and younger specimen, is about 40 ft. high, and girths 4 ft. 2 in. at 5 ft. up; it is well furnished with branches from near the base to the top, and is of a pyramidal habit of growth. This Cypress is deserving of more

attention amongst planters where ornament and variety of foliage is the object desired. It has been but sparingly planted hitherto, and good specimens of it are by no means plentiful in this country. GEORGE BERRY.

A NEW SHRUB (*LIGUSTRINA AMURENSIS*).

OF all the ornamental trees and shrubs which have been introduced within the last few years one of the handsomest and most valuable is the subject of these remarks, the *Ligustrina amurensis*, or Amour Lilac (figs 3 & 4). It is not only a handsome shrub, but it is very free blooming, and its numerous flowers grow in thick compact bunches (fig 3 & 4), giving the tree a peculiar appearance. Its characteristics are as follows:—A vigorous shrub branched from the base, the scales of the leaf buds of a brownish-red, those of the flower

Fig. 1.—*Ligustrina amurensis*. A young seedling of the natural size.

buds often speckled with greyish white. The leaves are very glabrous, pendent, petiolate and tough, polished on the upper surface, of a broad, oval shape, and pointed at the ends. Those of the young shoots are much longer, and more pointed, reminding one of the leaves of the Japanese Privet. Those of the flower stems are of broader and shorter oval, the leaf-stalks being longer. The inflorescence is much branched, and consists of very thick, compact panicles, often measuring as much as 6

Fig. 2.—Pods and seed (A) of *Ligustrina amurensis* of the natural size.

in. in breadth, often larger, and forming thyrsoid bunches. Sometimes they are narrower, as shown in figs 3 & 4. The flowers are shortly tubulated, and measure from $\frac{1}{4}$ to $\frac{3}{8}$ in. in width. They have four and, very rarely, five divisions, of a rounded, oval form, of a beautifully pure white, with an odour reminding one of that of the Privet, but of a much more delicate character. The seed pods, which grow upright, are dehiscent (fig 2), and have two shells which open a very short time after the seed arrives at maturity. The seed (fig 2A), are

of a long oval shape, entirely surrounded by a thin membrane, which forms a kind of wing. The first information which reached us respecting this shrub was published in the "Gartenflora," by M. Regel, Vol. XII, 1863, a translation of which we extract from the "Revue Horticole" of 1863:—The *Ligustrina amurensis* is a shrub which is indigenous to the banks of the

Fig. 3.—Flowering branch of *Ligustrina amurensis* (reduced) with a flower of the natural size.

Amour and the north of China; it bears the flowers of a *Ligustrina* and the seed pods of a *Syringa*. There are two varieties of this species, one of which belongs to the banks of the Amour and the Ussuri and has oval-pointed leaves; while the other, which is a native of the neighbourhood of Pekin; is remarkable for having its leaves almost heart-shaped. This shrub grows to a height of from 10 ft. to 16 ft. It is to be recommended for the abundance of its foliage and beautiful masses of flowers. As it stands the winter in St. Petersburg, protected by a simple covering of dead leaves, it is more than probable that it will be perfectly hardy in the climate of France. The introduction of this charming plant is due to M. Maack, who sent home some seeds of it from the banks of the Amour and the Ussuri.

It will be seen that the *Ligustrina amurensis*, Ruppr., is truly intermediate between the Lilacs and the Privets, as may be readily proved by a visit to the nurseries of M. Armand Gonthier, of Fontenay-aux-Roses, who has some fine specimens of this plant, from one of which figs. 3 and 4 have been taken. Having sown the seeds, we have been able to study their germination, as shown in fig. 1, which is a representation of the plant several days after making its appearance above ground. The young seedling is delicate, the stem being not more than $\frac{3}{4}$ in. long. The cotyledons are narrow and oval, and slightly pointed. Having sown the seeds of several different species of Lilacs and Privets at the same time, we can bear witness that none of the seedlings of these species are at all like those of the *Ligustrina*, which, in this respect, also seems to be intermediate between the two genera.

The *Ligustrina amurensis*, Ruppr. (*Syringa ligustriflora*), Hort.; *Pseudo-Syringa amurensis*, Carr. MS.) is one of the prettiest spring shrubs that it is possible to see; nevertheless, it has one grand defect, which renders its cultivation in the north of France, and even in many parts of the centre of France, a matter of some difficulty. It starts into growth extremely early, even bursting into leaf before the winter is over. On this point, M. Lemoine, horticulturist at Nancy, who was one of the first to introduce this plant into the market, and M. Oscar Thomas, who has grown it for several years in the nurseries of MM. Simon Louis Frères, at Plan-tières-les-Metz, have never seen it in flower. In a letter on this subject, addressed to us by M. Lemoine, he says:—"I have given up growing this plant, never having had the good fortune to see it in flower. In 1861 I received seeds of this species, and introduced them into the market in 1863 under the name of *Syringa ligustriflora*." This is doubtless a great defect, which, however, need not interfere with the cultivation of this plant in northern climates. It is quite worth while to grow it in pots or tubs, so that it may be taken into the Orangery or greenhouse in the winter. This shelter is indispensable wherever the flowering, which takes place about the end of March, would be interfered with by the cold. There is no question as to its general hardiness; the greatest cold has no effect upon it.

We have seen above that the *Ligustrina* grows in two forms—the one of which we are speaking of—which is indigenous to the banks of the Amour, the other, which is found about

Fig. 4.—Inflorescence of *Ligustrina amurensis* (two-thirds natural size).

Pekin, is closely related to the first variety, from which it is only distinguished by its nearly cordiform leaves. Seeing, therefore, that according to geographers the Amour is in the Chinese Mandchou Empire, we can only suppose that the plant found in the neighbourhood of Pekin is a very slight variety of the species we have been speaking of. We are con-

Ligustrum and *Syringa*, or else constitute it a new sub-genus, for instance, *Pseudo-syringa*, a name which we were the first to bestow on it. In fact, judging by its general appearance, and above all by the young plants, one is reminded at certain periods of their growth of the Japanese Privet (*Ligustrum japonicum*). Its inflorescence, its form, and above all the odour of its flowers, so closely resemble those of the Privet, that several botanists to whom we have shown the flowering branches of this plant have not hesitated to refer it to the last-mentioned genus, although the seed pods and seeds connect it with the Lilacs. As for the propagation of the *Ligustrina amurensis*, although it may be done by seed, cuttings, layers, or grafts, it nevertheless seems to us to present certain difficulties which very probably will disappear when we have found out the proper time for planting in the case of cuttings, or suitable stocks if we are grafting. Some herbaceous slips which had been grown in a hothouse which we planted under a bell glass struck easily. As for grafting, we have succeeded better when we have performed the operation under a bell glass during the course of the summer. The *Ligustrina amurensis* may be obtained from MM. Simon-Louis frères, at Plantières-Les-Metz; or from M. Gonthier, nurseryman at Fontenay-aux-roses, near Paris.—E. A. CARRIÈRE, in the "Revue Horticole."

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Tying Plants.—In plant training, amateur cultivators will do well to avoid the two extremes of tying their plants too formally, and the opposite of allowing them to hang about in a straggling, unsightly state. Every plant, so far as is consistent with the position it occupies, should be trained so as to exhibit as near as possible the form it would assume in a state of nature. No more supports should be used than will keep the plant collectively in shape, as anything beyond this is objectionable; the sticks in all cases should never be used stronger than necessary, and ought to be painted a shade of green the least conspicuous, always tying the branches, as far as possible, in such a manner that they will hide the sticks. In the case of the commonest plant, the least susceptible of injury to the roots, the sticks should never be inserted in the soil deeper than necessary to hold them with the branches attached in the position they are placed. With tender-rooted, hard-wooded subjects, it is still more requisite to be careful in this matter; quantities of trained plants in all stages, from a small state up to full-grown specimens, are annually killed by numbers of sticks being thrust unnecessarily deep in the soil, the effect of which, in mutilating all the fine roots they come in contact with, needs only a slight consideration to fully realize. Care should always be taken not to draw the tying material so tight as not to allow room for the branches thickening, more particularly in the case of such plants as go on from year to year without being headed back. This applies to Heaths, Azaleas, and all other plants of a similar hard-wooded character. In this annual training the largest portion of the stock should be first commenced with, as the old sticks from these, replaced by larger ones, will come in for others a size less, and so on until the smallest are completed.

Bulbs, &c.—More bulbs, such as Hyacinths, Narcissus, Tulips, and Crocuses, should be placed in warmth to bring them on into bloom; it is much better to regulate their introduction thus into heat, so that the supply of these flowers may be equal to, but not in excess of, the demand, which will be effected by placing some in warmth at intervals of three weeks or a month. A portion of hardy shrubs, where they are used for forcing, should also be placed in heat; but these, excepting Lilac, should not be subjected to too much warmth, especially so early as this, as they will not stand so high a temperature; nor as later on, when there is an increase of solar light, and nearer the time when growth would commence naturally. The lighter position all such things can occupy the less disposition there will be in the buds to refuse opening, or in the term that gardeners generally employ, to go blind.

Lily of the Valley is one of the most acceptable forced plants grown, and will bear strong heat, but care should always be taken where this plant is forced to use nothing but those crowns that have acquired sufficient strength to flower, as, if weak growths are employed, such as frequently used by the inexperienced, no possible treatment that they can be subjected to can induce them to bloom; hence the disappointment often resulting from the use of home-cultivated plants that have been grown near and under the shade of trees, the roots of which have monopolised most of the fertile elements in the soil, and

through the growing season have absorbed the moisture so indispensable to the Lilies acquiring strength to flower freely. Where much of this desirable winter plant is required, it is better and cheaper in the end to use imported roots.

Potting Soil of all descriptions is much better kept in the open air than in sheds under cover, where it becomes dry and appears to lose a great deal of the properties essential to the support of vegetable life; but all that is required for use during the next two months should at once be got under cover if possible in an open shed, where it can be spread thinly upon the floor and occasionally turned over, allowing it to remain in a loose open state, so as to expose it so far as possible to the drying influence of the air, which, after so much wet, is more than usually requisite. Too much cannot be urged as to getting potting soils for even the commonest subject, into a suitable condition as to moisture before being used, as, if plants are put in it when too much moisture is present, it at once assumes the consistency of a hard baked mass, in every way unsuited to free root-development, without which no plant can make satisfactory progress. It is well to impress upon beginners that it is much better to err in having the soil a little too dry than in the opposite of being too wet, as in the former case the only evil that follows is the necessity for applying water to the plants at a shorter interval after the potting is completed than is advisable, an operation that should always be deferred as long as possible, except in the case of a comparatively few moisture-loving, vigorous-rooted subjects. This getting under cover applies to loam, peat, leaf-mould, rotten manure, and sand; so far as the latter is concerned, if at the time of being used the loam or peat is a little too moist, this to some extent can be corrected by first expelling all the moisture from the sand by placing it in close proximity to the hot-water pipes, or over a boiler-furnace at work; in such condition it will exert considerable drying influences upon the soil that it is mixed with, and as its agency in plant-culture is of a mechanical nature simply to keep the material in which the roots are placed open and porous, there is nothing essential to plant life in it. It is exhausted during the drying process, as would happen if loam or peat were subjected to similar treatment. Cucumber and Melon soil should also be placed where it will get sufficiently dry for use; if shed-room is not available, wooden, or felt-covered shutters put over it will answer a similar purpose, but not act so quickly as if the material was placed on a dry floor. All empty pots should be well washed alike inside and out, crocks broken in different sizes, and also washed clean, ready for use, wooden labels made, and everything prepared so that when the potting season, which with many things, will commence early in the new year, begins, it can be carried through much more expeditiously than when each thing has to be got ready as the whole proceeds; and all plants of a permanent character, both grown under glass, as well as fruit trees in the open air, should have their labels yearly examined; and such as have got rotten, and the writing become indelible, replaced with new; herbaceous plants also, and any shrubs or trees other than such of the commonest kinds, as nothing tends more to the pleasure of a garden than everything being found correctly named, so that any one not conversant with the things grown can easily make out what they are.

Hedges.—Deciduous hedges may at once be cut, acting in the matter with judgment, always keeping them, from their first stages, proportionately wide at the bottom, and narrow at the top; and, with such as have only partially attained the size they are ultimately to be, do not be in too great a hurry to get them up to the full size. This applies to whatever kinds of plants may be used, Beech, Hornbeam, or Quickthorn, but to the latter especially; if ever let go too far, by allowing too great a length of growth to remain from where cut back to last year, the ill-effects will for ever after be observable; and this can only be rectified by half or wholly cutting down the hedge. Any work in deciduous hedge-planting yet remaining to be done should be forthwith completed, particularly where Quicks are employed, as the Thorn, being one of the earliest leafing plants we have, has the ensuing summer's growth very much interfered with, if not planted until near the time the buds begin to swell.

Frames.—Lettuce and Cauliflower plants in frames for planting out in spring, and also those under cloches or ordinary hand-lights, have, consequent upon the continued open weather, been kept in a more than usual growing condition. Use every means to keep the surface-soil in as dry a state as circumstances will permit of, by which they will be better able to withstand the effects of severe frosts; 1 in. or 2 in. of dry coal ashes in the case of the Cauliflower, and proportionately less to the Lettuce, will be an additional protection to the stems. Give abundance of air by full exposure in dry weather, with the lights tilted back and front, so as to admit of a current when it is wet. In this matter, treat similarly Lettuce and Endive for present use, as also such as required during the winter.

Continue to tie up, cover with boards or inverted flower-pots, Endive for a regular supply; this, the most essential plant for winter salads, needs a little more care to effect the blanching process when in frames, so as to exclude frost. Yet, despite all that is said about the convenience of blanching it in Mushroom houses, or any structure wherein there is a little fermenting stable manure, the frames are greatly preferable, as I have frequently seen Endive, as also Rhubarb and Seekale, grown under the influence of the ammonia-charged atmosphere become so affected by it as to have the most disagreeable flavour.

Kitchen Garden.—Any vacant ground yet remaining undug or trenched, should have these operations carried out, and where manure has to be got on this should be done when the surface is frozen. Parsnips in most places are generally found the best when allowed to remain in the ground until just before being used; but, where this course is followed with them at this season of the year, when possibly a protracted frost might set in at any time, a sufficient supply should always be kept under cover; also Horseradish for use, as well as Rhubarb and Seekale roots for forcing. Some of the latter should be put in warmth, where they will make growth from time to time, to keep up the succession. If more Rhubarb is placed under similar conditions, and also a portion of roots put in any building where frost can be kept out and the light excluded, it will come on without artificial warmth. In localities where the ground is moderately dry, and not naturally late, some Early Peas and Broad Beans should be sown, selecting the warmest and most sunny position. Sow only slightly below the surface, drawing soil to cover them in the form of a slight ridge, with an inch of coal ashes on the top; for this sowing also put in a third more seed than would be required later on.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

December 31.—Covering up Vine borders with long litter, just sufficient to keep frost out. Planting border with Early Mazagan Beans. Pruning Mrs. Pince Vines. Turning over leaves and long manure for making hotbeds. Cutting all the Lady Downes Grapes with about 6 in. or 8 in. of wood attached to the bunch, and putting them in bottles in Grape room.

January 1.—Sowing four rows of Sutton's Ringleader, four rows of William the First, one row of Dr. Hogg, and one row of Unique Peas. Preparing pit for Ash-leaved Kidney Potatoes, and turning out a crop that had been brought forward in pots. Washing the paint in Mrs. Pince Vinery with soft soap and hot water. Glou Marceau, Ne Plus Meuris, and Easter Baurré Pears now plentiful and good.

Jan. 2.—Potting off Tomato cuttings. Getting Strawberries plunged in leaves to start them. Tying pot Vines, which have broken satisfactorily, up to the wires. Spawning a new Mushroom bed and moulding it over 2 in. thick. Getting on with digging and trenching as fast as the weather will permit. Turning over a large heap of manure to rot, adding 20 lb. of salt and 1 bushel of soot to the load.

Jan. 3.—Sowing Cucumber and Melon seeds. Painting over the Vines in Mrs. Pince house with composition, and tying up the Vines, afterwards forking over the surface of the border lightly, and giving it a little top-dressing. Looking over the Grapes in bottles, removing any bad berries, and filling up the bottles where required with water.

Jan. 4.—Getting 100 pots of French Beans in, and earthing up a more forward lot; also a few pots of Potatoes. Covering up Endive and Lettuce to blanch. Getting manure on to the land whenever the weather is dry. Filling another four-light pit with leaves in which to plunge Strawberries.

Jan. 5.—Putting in cuttings of Chrysanthemums. Getting on with the pruning and nailing of Pears and Plums on walls. Manuring and forking the ground amongst Gooseberries and Currants. Emptying a four-light pit, and refilling it with leaves and manure for Early Melons. Examining fruit-room, and removing any fruits that are beginning to rot. Cleaning kitchen garden walks. Fruit in use for dessert:—Pines, Grapes, Pears, Apples, and Nuts.

Holly Sports.—We have here a very remarkable sport, from a small leaved Holly. It appeared near the top of this tree, and is now a branch about 1 ft. or so long. The variety has usually a dual character, being frequently composed of about equal parts of the small leaved type, and of an intermediate kind. The most singular part of the matter is that this kind but rarely produces berries, and in this case only the large leaved sport upon this one plant has any, and they are much more elongated than those produced by the typical form.—F. SMITH, *Newry*.

HARDY FINE-LEAVED PLANTS.

SUB-TROPICAL plants have been written upon, and recommended long and enthusiastically, but they have received a cautious and retrograde experience, simply because the majority of them pushed forward are not suited to our climate generally. But there are some plants of graceful or noble form which should not be lost sight of, though many are found wanting, because those some are so sufficiently hardy that they may be very generally planted as permanent specimens without much fear of their ending in disappointment. Now this quality of hardiness is the spice with which we wish to season the following recommendations; and, in doing so, we acknowledge that we only reiterate what has often been presented to our readers before. But we are so satisfied with the beautiful effects of groups, or single specimens of them, interspersed on lawns, among flower beds and shrubs, that we ask no apology for again calling attention to their several merits. The past season of excessive rains seems to have been much in favour of their healthy development, and consequently bringing them out in full beauty. Foremost among the very hardy and bold tropical-looking plants, is certainly the

NEW ZEALAND FLAX (*Phormium tenax*).—In the latitude of Dublin it seems perfectly hardy, and grows into large, strong tassocks, of several feet diameter at the base. In Hampshire, as might be expected, it succeeds perfectly; and we have seen large plants of the yellow-striped variety in the open-air shrubbery in that county. It seems to thrive equally well with its roots submerged in water, or on the top of a dry rockery—the latter position, and in a well-sheltered situation, is to be recommended as the north is approached. The plant does not seem at all particular as to soil; indeed, it seems to prefer a strong and retentive to a light and hungry soil. In the gardens of the Viceroyal Lodge, Dublin, may be seen a number of grand old specimens, which have been planted out many years—being in height and circumference with Pampas Grass and Arundo conspicua.

ARALIA SIEBOLDII is another equally hardy plant, which grows into a strong, dense bush, by throwing up numerous strong suckers from the root like a Hazel—the leading branches, however, becoming as strong as a brush handle. Its large, shining green, Palmate leaves, like a spread-out fan, have an exceedingly tropical appearance. Shelter from draughts and eddies, and strong winds, is all the management it seems to require. With a good-holding, nutritious soil, a large stool of this plant will supply numerous offsets with roots, by which means it is easily propagated. The leaves of this plant ought to be invaluable for table decoration, for getting up bold dishes of flowers for rooms, and for furnishing grates in summer, besides its evident merits as a lawn-plant.

DRACÆNA AUSTRALIS.—It is curious that this is not more generally planted. At Knockmaroon Lodge, near Dublin, is a plant some 16 ft. high, many years planted, with a stem some 6 in. in diameter, which flowers and bears abundance of seeds annually, from which Mr. Presley, the gardener, raises seedlings thick as Onions in a cold frame. Groups of this plant have a most striking effect in a pleasure-ground—Palm-like and unusual. In the Scilly Islands the plant becomes a great tree, luxuriating in the mildness and moisture from the Gulf Stream; but the fact that it annually flowers on young plants in the climate of Dublin, and ripens its seeds, is sufficient proof of its hardiness, and that it will succeed much farther north on the English coast. As we have indicated, it is readily increased from seed, from pieces of the stem, and offsets. If a plant is cut over close to the ground, a number of young shoots soon spring up, which can be taken off as cuttings, and which strike with freedom. We have cut over an old plant with a stem as thick as one's arm, and set it firmly in the ground, and before many weeks it has struck root and become a plant: all the attention was an occasional syringing of the leaves and old stem.

ACANTHUS LUSITANICUS, when well and strongly grown, is a striking plant as a single specimen on a lawn, or as a marginal line round a bed of Bamboos or the last-named *Dracæna australis*. The shining-green, deeply-cut leaves have a luxuriant, sub-tropical effect; and the bold spikes of strikingly peculiar flowers enhance its value for the later summer months. This is an old-fashioned, hardy herbaceous plant deserving of more attention.

FUNKIA SIEBOLDIANA, when well grown, is also a bold, striking plant: its large, cordate, glaucous leaves contrast well with darker-green plants, and with Grass. It delights in partial shade; should be dry at the root in winter, but liberally supplied with nourishment and water in summer; and if raised on a mound or large hollow block, it has a fine effect: it may also be used as a bold margin to beds of taller plants, as recommended for the *Acanthus*. Care must be taken of this plant in spring, as slugs are fond of the young foliage, which they soon destroy, or eat holes into. This is another of the old-fashioned, hardy-herbaceous plants which will come to the front

ARUNDINARIA FALCATA has proved itself almost perfectly hardy, certainly so in the south of England. Last year it seeded freely, and seedlings have come up under the old plants in the open air. We succeeded in raising some young plants last autumn from seed ripened in the open air in August. The fact proves it to be sufficiently hardy for a considerably more northern climate. In the neighbourhood of Dublin it is 12 feet high; and no plant can be more graceful and desirable for beds on the lawn than this elegant Bamboo. *Bambusa metake*, if not quite so graceful as the last, is equally desirable. It is stronger in habit, stiffer in growth, with much larger leaves, likes a deep moist soil and shelter, though perfectly hardy; it soon grows into a rather straggly, dense bush.

BAMBUSA FORTUNEI VARIEGATA is a very hardy, free-growing plant in shelter, and attains a height of 3 ft. in a favourable situation, and as a handsome margin plant for a clump of Bamboos of the larger size, or to *Aralia Sieboldii*.

ARUNDO DONAX and *A. DONAX VARIEGATA* are plants of the same general aspect of the Bamboos, perhaps not so graceful. The green *Arundo* grows freely enough, and is quite hardy; soon makes a large bush in a favourable situation; loses its leaves, however, in winter. The variegated variety is a really beautiful plant, but not so hardy as the green. It has a handsome effect on a rockwork hanging over water.

ARALIA SPINOSA, *RHUS ELEAGANS*, *R. LACINIATA*, *DIMORPHANTUS MANDSHURICUS*, are shrubby plants of a peculiarly tropical habit, especially the first and last. They deserve to be planted about pleasure-grounds as single specimens. The *Dimorphanthus*, an *Aralia*-looking plant of free, soft growth, with leaves of large size, deeply pinnate like *Aralia spinosa* without the spines; young plants look well in the centre of flower-beds.

YUCCA RECURVA is so well known, that the name only requires to be mentioned; it is perfectly hardy and graceful. As a *Dracaena*, it is a plant which will fit in anywhere—in the centre of beds, on the lawn as single specimens, or in groups.

GUNNERA SCABRA is an interesting and curious plant, with its bold foliage like *Rhubarb*, and its curious fructification—a stiff, rigid, columnar spike, covered over at present with bright-red berries or seeds: it suits well as a group on the lawn.

BOCCONIA CORDATA deserves a bed to itself. It has a peoniar, glaucous, sub-tropical aspect, with long spikes of small white flowers in autumn. It is quite hardy, spreads rapidly under ground, and attains a height of 6 feet.—“The Gardener.”

Destructive fire at Messrs. Weeks’.—Our readers will regret to hear that the extensive premises belonging to Messrs. Weeks and Co., horticultural builders and hot-water apparatus manufacturers, King’s-road, Chelsea, have been destroyed by fire, which broke out on Sunday morning last, and in spite of all exertions, the whole of the premises were soon alight, and in about an hour after the outbreak the roof fell in with a loud crash on to the valuable machinery underneath. For more than three hours the firemen continued their exertions. The amount of damage occasioned by the calamity—the cause of which is unknown—is serious, and will fall on the Liverpool, Imperial, and Globe Insurance offices. The proposition made by the Metropolitan Board of Works as to the establishment of a system of fire hydrants throughout the metropolis, as a means of extinguishing fires in lieu of engines, an official intimation to make the first practical test was received after the fire had been subdued. Around the property destroyed eight stand pipes were arranged, and the experiment was in every respect satisfactory. A stack of chimneys over the boiler-house remained standing, above 50 ft. in height, and the water from the eight jets supplied by the Chelsea Waterworks went considerably over them. The inconvenience that must inevitably result from the destruction of Messrs. Weeks’ workshops is great. But this being only one out of four of their business premises, by converting portions of the foundry, boiler works, and stores into temporary workshops, the general conduct of the business will suffer no interruption. Several hot-houses belonging to Mr. Bull, which adjoined Messrs. Weeks’ premises, suffered severely through the intense heat caused by the great body of flame; and some of their contents, chiefly new plants, were destroyed. The resources of this Nursery are, however, such that little inconvenience will be the result.

Seedling Briers.—A point on which I should especially like to know something of the practice of others is the seedling Brier—not the “working” of it, but the growth and treatment in its various stages from the seed. Is anything published bearing on this subject? Neither Paul nor Rivers in their *Rose* books mention it.—E. C.

THE KITCHEN GARDEN.

KITCHEN GARDENING MADE EASY.

LET me now take mid-season Peas, a crop which requires the best and richest ground in order to grow them well. In fact, if Peas be grown in fat land, the produce is fat, and many mid-season Peas get disregarded just because the land is poor; and so, in consequence, are the Peas. My selection of four mid-season Peas is as follows:—First, *Laxton’s Marvel* (not out), a kind which grows from 4 ft. to 4½ ft. high, and which has pods slightly sickle-shaped, containing from eight to ten Peas in each, the flavour of which is excellent; second, *Dr. McLean*, which is well known to be a good variety; third, *Laxton’s Standard*, also a Pea of great excellence; and, fourth, *G. F. Wilson*, likewise a good and useful variety. These four varieties grow about the same height. When staked, I mulch between the rows with long manure, to keep down weeds and to keep the soil moist. When the Peas are cleared off, which is in August, I cultivate the ground on which they grew, treating it with a pinch of guano, and sow *Tripoli Onions*. I always find that the best *Onions* grow on the seed-bed, if properly thinned and the ground well worked. If for exhibition purposes, a good watering with liquid manure greatly increases the size of the bulbs. This crop comes off in July, if pulled green (and I am no advocate for keeping *Tripoli Onions* long on hand). The land is then in the best trim possible for either *Winter Spinach*, *Coleworts*, *Turnips*, or any green crop which is thought desirable, thus having Peas, *Onions*, and a green crop with one digging only.

R. GILBERT.

Burghley.

FORCING RHUBARB.

THE handiest-sized roots for forcing are those about three years or four years old; they can easily be taken up and moved anywhere, where a little artificial heat can be secured. Large old roots cannot be moved without a good deal of mutilation, which weakens the produce. Apples are generally so scarce this year that there is sure to be an early and a large demand for forced *Rhubarb*. With a temperature any where between 45° and 60° success will be certain; of course the temperature should be regular and steady; the plants should not be over heated one day, and starved the next. I know a baker who always grows beautiful early *Rhubarb* in a shed adjoining his bakehouse; the wall of the oven abuts against the shed, and keeps up a steady heat. Strong roots may be taken up and packed in old deep boxes, baskets, or cement casks; these could be moved anywhere where warmth can be had. I always think early *Rhubarb* that has been grown in twilight or partial darkness is better in colour, and more delicate in flavour, than where fully exposed to light. When grown in an atmosphere charged with ammonia from rank manure the flavour is generally unpleasant. This, however, can always be obviated by throwing the manure into a heap, and when it heats well, turning it over, shaking and mixing it well together. This should be repeated if the manure be fresh from the stable in about a week or ten days. In most places leaves can be obtained, and these should always be raked up in autumn, and placed in a stack for hotbed making, covering them with straw or litter, to keep the wind from blowing them about. With a supply of leaves and a little manure, to hold them together, a station for forcing *Rhubarb* may be made in any out-of-the-way corner. It may be either oval or round, but it should at least have a regular outline. Having decided upon the position and its size, drive in a few stout, rough stakes, 18 in. apart, leaving them, when driven in securely, about 3 ft. 6 in. to 4 ft. out of the ground. Fagg-wood or rough branches of any kind may be entwined between the stakes, so as to form a substantial wattled fence round the station; and outside, against this, the fermenting materials (leaves and manure in about equal portions in the shape of good substantial linings) should be placed. The roots of the *Rhubarb* or *Seakale* should be packed nearly close together inside, and should have all the interstices filled up with fine soil. They should have a good watering with tepid water, to settle them, and the top should be covered with hurdles, deeply thatched with straw, leaving a clear space of 18 in. or so between the roots and the roof. I have forced good-flavoured *Rhubarb* and *Seakale* in this way without much trouble or expense. When a good supply of roots is provided, a very small amount of ingenuity will contrive some mode of

forcing them. Roots that have been forced, if not gathered from too severely, if sheltered somewhere till spring, will divide into a number of eyes; and, if planted out on good land, 2 ft. apart, will make excellent plants again in two or three years.

E. HOBDAV.

The Plumed Hydrangea in Masses.—We have to thank Mr. W. C. Barry, of the Mount Hope Nurseries, Rochester, for a photograph showing a mass of this fine hardy shrub in full bloom. Mr. Barry says:—"The bed attracted great attention during the past summer. On my return from Europe, the plants were in full flower, and, notwithstanding the many remarkable and effective beds of flowering and fine foliated plants which I had seen abroad, I thought nothing equalled this. The mass consists of thirty-five plants, with a broad edging of Coleus, the Shah, around it. The contrast between the green grass, the crimson and yellow foliage of the Coleus, and the immense white and pink panicles of the Hydrangea was novel and beautiful. I have often seen and admired large single specimens of this Hydrangea, but masses like this are uncommon, and I call attention to the manner of planting, as it tends greatly to heighten the effect and increase the attractiveness of this noble shrub. No hardy flowering shrub which we cultivate seems to possess so many good qualities. It may be safely predicted, that when it becomes more generally known, none will rank higher in popular estimation."

Conservatory Staging.—I am glad that "A. J." (see p. 603) has paused before accepting the bad advice of his friends, who urge him to put two stands down the middle of his conservatory. Such staging, with staging round the sides, will cost him a good deal of money, and will spoil his house. In a conservatory where plants are not grown, and need not be near the glass, there should be no staging, or but little. If "A. J." wishes to grow herbaceous plants in his conservatory he must have staging near the glass, and he must make the show of his plants of secondary importance. But if he uses the word conservatory in the common sense of a show-house for his plants, let him arrange it thus:—Supposing the sitting-room to open in the middle of one side of the house, let him draw on the floor a square, equal, say, to one-fourth of the area of the house, in such a position that one of its angles be opposite to the sitting-room door, and its remaining three angles pointing to the middle point of each of the other sides of the conservatory. In the centre of this square let a block be placed, or a very large pot inverted, according to the height required. Upon this must be placed a large plant. For summer, the shade of a Tree Fern, such as a Dicksonia, would be desirable—and this may be replaced in winter and spring by a Palm, a large Camellia, or a large Acacia. Around and under this central tree, upon blocks, or inverted pots, flowering plants must be grouped according to the season, and the whole may be edged by small pots or long troughs of Lycopodium and Isoplepis, or by sowings of Lobelia, Myosotis, and the like. Boxes of Christmas Roses should be prepared for the winter season, and bulbs to succeed these. Later again come Cinerarias, pot Roses, and so forth. In each corner of the house a large box, or, still better, a square brick bed should be placed wherein four such plants as Roses, Lapagerias, Tacsonias, or Heliotropes should be grown, and run upon the roof. Clematises and Fuchsias are better in pots, which can be removed in winter. The boxes or brickwork should be thoroughly drained and their sides covered with virgin cork, to receive small Ferns, and similar greenery. Along the sides of the house a long trellis-table may be placed from box to box to receive Lilies, Pelargoniums, and other decorative plants, but even these are better placed bankwise around the house, the back rows being set up upon inverted pots. If some of the money saved from the staging be spent upon a red-tiled floor, the house will look all the brighter.—T. C. A.

—I would strongly recommend "A. J." (see p. 603), to keep the centre of his greenhouse open—put shelves all round the apartment

say about 4 ft. wide, this will give 16 ft. square in the centre. In this way a much smaller number of plants gives a greater effect, as all may be under the eye at once. The centre will make a pleasant lounge or promenade, and may contain some seats and ornamental flower vases, such as the Leicester vases, or others more ornamental. On the floor may also be placed large flower pots, with large plants, such as Acacias and Rhododendrons or Tree Ferns. I can speak with experience in this matter, as in addition to the shelves all round my house I put a centre shelf also which I afterwards removed with great advantage.

Future of the Royal Horticultural Society.—Next year, during March, April and May, the fortnightly Exhibitions will be held in the Conservatory. In June, a four days' Show, which the Council hope will at least equal any ever seen in London, will be held in the gardens. In July, a four days' Provincial Show on a large scale will be held, under the patronage of the Society, at Preston; the funds for this purpose being raised by guarantee. Any surplus from this show will be vested in trustees, for the promotion of similar shows, which experience has shown powerfully stimulate practical horticulture. The Council hope to resume the publication of the Journal of the Society on a suitable footing, and to make satisfactory arrangements with correspondents in foreign countries for the collection and transmission to England of rare seeds and plants. The Council desire to render the South Kensington Gardens attractive to London Fellows and members, and with this object will provide a band and give promenades every Saturday, while the attendance justifies the outlay. These promenades will commence on Saturday, January 19th, will, during the winter, last from 3 to 5 p.m., and be held in the Conservatory, which will be warmed, and when necessary lighted at dusk; fellows' tickets and small book orders will admit to them; and, to render them select, the minimum charge to the public will be half-a-crown. Although the position of the Society has improved to an extent that could scarcely have been anticipated at the beginning of this year, the Council must remind fellows and members, especially those resident in London, that the aggregate amount of their annual subscriptions is still far short of the £10,000 which must be raised from that source during the next twelve months, to prevent the forfeiture of the South Kensington Gardens. The money must come from the subscriptions of Fellows and other annual subscribers; if not so raised the gardens will be forfeited and perhaps built over; if so raised, they will be secured to the Society for 15 years. The Council believe that if fellows and members exert themselves individually to induce their friends to join the Society, the amount required, which exceeds the average income from subscriptions in the years 1871 to 1874 inclusive, by less than £2,000, can easily be obtained. If the gardens are to be preserved this effort must be made at once. 179 debenture holders have accepted fellows' privileges, (except that of voting) in lieu of interest on their debentures, and the Council believe it will be possible to make a similar arrangement on a more extended scale for 1878. All the expenses of the Society for the year have been paid up to date and out of revenue.

Hardy Plants.—What is the name of the enclosed Chrysanthemum? We find it very useful at this late season of the year. I also send a hybrid Myosotis, which seems to be a perpetual bloomer. It is a strong grower, and has been in bloom since last May. This Forget-me-not cannot be too largely grown, as with very slight protection it may be had in flower during the whole winter. The enclosed small variety of Sedum acre is a charming little plant for rockwork or carpet bedding. I found it a summer or two ago on Mickleham Downs, Surrey, along with the true Sedum acre aureum, which keeps its golden tint throughout the summer.—W. E., *Stapleford Hall, Notts.* [The Chrysanthemum, judging from the flowers alone, resembles the one that used to be grown occasionally in London collections of herbaceous plants as *C. lacustre*.]

Cocos Weddelliana.—Will some reader of THE GARDEN inform me whether or not this is quite a cool greenhouse Palm?—C. B.
