Late Vineries.—There has seldom been a season, especially in the north of the kingdom, when Vines that were not assisted in the spring with any fire-heat have been so backward as they are this year; this not alone applies to the ripening of the fruit, but what for another year is of much greater importance—the ripening of the wood, which in many places with late Vines is far from being in a satisfactory state. In houses furnished with heating apparatus, the maturing process can yet be effected, but no time should be lost, as anything to be done in this way must be accomplished whilst the leaves are green and in a condition to perform their functions. Whether the medium for heating be flues or hot-water pipes, I should recommend fires at once being lit, and kept going moderately night and day until the wood is thoroughly brown and hard, with air on during the day more or less proportionate to the state of the weather, and a little on continuously through the night. In houses not provided with heating medium, even in the southern parts of the country, the unripened state of the wood is such as not to give assurance of a crop next year, as in many places I have noticed that where the fruit is colouring, the wood and buds at the base of the leaves have not attained that hard brown colour so desirable in the Vine, even before the fruit is ripe. In houses of this description nothing can be done except to use every available ray of sun-heat, admitting a little air in the mornings as soon as the sun comes upon the glass, increasing it more or less according to the sun-heat during the day, but closing the house still earlier in the afternoons than has previously been recommended, in order to keep the house as long as possible up to 80° or 90°; should the thermometer indicate even more than this for some time after closing, it will be all the better. Keep the atmosphere as dry as possible, using no more water than is necessary for such few plants as cannot be conveniently moved from the house. A little air during the night whilst the Grapes are ripening is an important element in giving colour, but in this exceptional season in houses of the description under consideration, where the maturation of the wood is so far from completion, I should recommend that no air be given after the house is shut up in the afternoon, as it will be much better to sacrifice something in the colour of the fruit than to run the chance of a small crop next year, for by thus keeping the house closed through the night, the temperature will necessarily be considerably higher, warmth being now the principal element in ripening the wood. I frequently meet amateurs, even such as have attained some experience in gardening matters, who entertain very mistaken ideas as to the ripening of Vines, supposing that abundance of air without warmth will effect the process; yet this is a great mistake, as the latter is the most potent and indispensable agent.

Peaches.—Continue to give plenty of air to Peaches that have been forced, and also to such as are grown under glass without artificial heat. Now that the fruit is gathered the leaves may have a good washing with the garden engine to free the foliage from any insects, as even with these late Peaches it is essential to keep the leaves in a healthy condition as long as possible. Where there are inside borders these will necessarily have got dry through withholding water from the time the crop began to ripen; a good soaking should now be given, as, although no leaf growth is going on, should the roots be too dry, the buds for next year's crop will not attain the requisite plump condition before the leaves fall.

Shrubberies.—Where any evergreen shrubs have to be moved, either through becoming overcrowded, or where additions have to be

made, not a day should be lost in carrying out the work. The nature of the soil will considerably influence the mode of procedure with any plants that have attained a large size; in strong, adhesive soils that will hold together, so that they can be moved with good balls, these should be kept intact as big as the means for moving them will allow, and the roots beyond such balls ought to have the soil from around them carefully removed so as to secure as great a length as possible, for upon the amount of the smaller fibres that can be retained will in a great measure depend the progress the shrubs will make for a season or two after removal. In all cases where large plants of this description have to be moved the holes in which they are placed must be made wide enough not only to admit the ball, but also to allow the roots that extend beyond it to be laid out straight, and not twisted round in the unnatural position often done by careless planters. As the soil is being filled in, the roots must be well drenched with water; if this be given now in sufficient quantities no more will be required, as they will at once commence to grow. In light ground it generally happens that very little soil will adhere to the roots, in which case it is still more imperative that as great a length of root as possible be secured. Shrubs that have attained any size and have to be removed in such soil as this will require more support to them from the winds after re-planting than those that can be moved with a good ball. In the case of smaller plants that are to be shifted, proceed as recommended for the larger ones; with these, as with the others, the more roots that are retained with the least mutilation, the less check they will receive.

Cabbages sown about the end of July for the ensuing spring crop will be now quite large enough to plant. The ground for these should be well dug, selecting if possible a piece that has been liberally enriched for the preceding crop, in which case no manure will be required; in planting give more or less room according to the variety, the smaller-growing kinds will do if the rows be 18 in. apart, and the plants be placed about half this distance asunder in the rows; this arrangement will allow for cutting every other out in the spring as soon as they are fit for use. This should be done before they have attained nearly the size of the remaining portion of the crop. Stronger-growing varieties should be allowed 2 ft. betwixt the rows; but the distance from plant to plant in the rows recommended for the smaller growers will be sufficient for these.

Onions.—There is no spring-sown vegetable that I have noticed which has been so much affected by the late season as Onions; these, even in the south of the kingdom, are so fresh and green, and increasing so fast in size, that they appear as if they would keep on growing almost to the end of the month. To ensure their keeping, it is necessary to allow them to remain until they are fully matured; but they must not be permitted to stand too long, or they will commence rooting afresh, which seriously injures them.

Salading.—A little American Cress and Corn Salad should now be sown. These seeds thrive the best when put thinly in rows 10 in. or 12 in. apart; they will come in for use in the spring, and are very handy in case of a failure in Lettuce. Where salad is continuously in demand, a little more Black-seeded Cos Lettuce and Green-courled Endive for wintering in frames should be sown; these also will come in for use in the spring.

Thinning Parsley.—It is a good plan to leave Parsley to prove itself before finally thinning it out; then all the infirm and less curled varieties should be thinned out, and only the best retained. Some prefer to sow Parsley broadcast in a seed-bed, and transplant it into rows afterwards; they contend that not only will the strain be truer to character, but that it will come better owing to being transplanted. There may be something in this, but so also is there in the assertion of those who disapprove of transplanting, viz., that it causes the Parsley to run sooner to seed; for this reason those who wish to save seeds of rather good strains of Parsley should transplant the stock intended for seed. The soil best suited for Parsley is a light sandy loam on a rather dry bottom, enriched with a liberal dressing of farmyard manure, charred refuse, burnt earth, and soot. All might be applied if available, and if not, one or more of the stimulants named. Charred refuse, rough wood-ashes, and soot suit Parsley admirably. The leaves and stems run up with extraordinary vigour, and curl with a prodigality of verdure and size in such a mixture as to render Parsley as unlike as anything well could be to the common Parsley seen in ordinary kitchen gardens. A loose surface is also favourable to its free growth.—F.

Radishes for Autumn and Winter Use.—The Black Spanish, the Chinese Rose, and the large White Californian, may be sown now, in addition to the French Breakfast, in rich, light soil.

Before frost comes they should either be taken up and stored in sand, or the bed should be covered with dry leaves or evergreen branches. If left in the beds snails will spoil a good many of them unless sharply looked after; frequently dusting them with dry wood ashes will stop their depredations and be useful in other ways. The large Californian Radish, when better known, will make a very useful addition to winter and early spring salads sliced up with Bestroot, &c.—E. HOBDAV.

A GIGANTIC PUFFBALL.

THE annexed example of a gigantic Puffball was found in a garden on the top of the sand cliffs of the ballast quarries at Erith. It appeared amongst some Currant bushes, where manure had been dug in freely for Vegetable Marrows. The speed with which it grew is as remarkable as its size, attaining as it did in five days a circumference of 3 ft. 1 in. It measured 1½ ft. high, and weighed 8 lb., and it was still on the increase when pulled up, having grown 1 in. in girth during the previous night. Its skin was bright and smooth,

like that of a white Mushroom, but drier. It was attacked by slugs, which were, however, kept off it by means of a circle of lime placed round it as soon as the depredations were perceived. In the same garden there was also another specimen of this fungus, but it did not grow to any great size, its growth being probably stopped through depredations committed by slugs.

A. DAWSON.

The Rain Tree.—The Consul of the United States of Columbia in the Department of Loreto (Peru) has written from Yurimaguas to President Prado, informing him that in the woods adjacent to the city of Moyobamba exists a tree called by the natives *Tamia-caspi* (Rain tree), which possesses some remarkable qualities. It is a tree about 50 ft. high when at maturity, and of about 3 ft. in diameter at the base, and has the property of absorbing an immense quantity of humidity from the atmosphere, which it concentrates and subsequently pours forth from its leaves and branches in a shower, and in such abundance that in many cases the ground in its neighbourhood is converted into a perfect bog. It possesses this curious property in its greatest degree in the summer, precisely when the rivers are at their lowest, and water most scarce; and the writer proposes that it should be planted in the more arid regions of Peru, for the benefit of agriculturists.

THE LIBRARY.

THE FORMS OF FLOWERS*

WE have before us the latest addition which Mr. Darwin has made to his already voluminous publications. From the year 1831, when, at the age of twenty-two, he started with Capt. Fitzroy as naturalist to the voyage of the *Beagle* for the survey of South America and the circumnavigation of the globe—a voyage which is commemorated in the popular *Berberis Darwini*, a plant which was first introduced to our gardens as a result of this expedition, and which was named by Sir William Hooker in honour of its discoverer—up to the present time Mr. Darwin has been ceaselessly employed, not only in evolving and strengthening the theory with which his name is popularly associated, but in collecting and observing facts, and in publishing the result of his investigations. It is not only the evolutionist who can derive both pleasure and profit from the perusal of Mr. Darwin's works; they appeal to naturalists of every class and kind, and those who differ most from his theories are the first to admire the patience and perseverance which have been displayed in the accumulation of the facts upon which these theories are based. It is difficult to estimate the amount of routine work which our great naturalist has patiently gone through in pursuit of knowledge; in the volume now before us, he casually remarks that to ascertain one fact alone, he was "compelled to count under the microscope above 20,000 seeds of *Lythrum Salicaria* (the Purple Loosestrife), and from this we can form some idea of his energy and perseverance. The various points connected with cross-fertilisation in the vegetable kingdom were fully reviewed and considered in one of Mr. Darwin's recent volumes, which was duly noticed in these pages. On the present occasion he treats of the differently formed flowers normally produced by certain species of plants, either upon the same individuals or upon different individuals of the same species; and these differences have, as we shall endeavour to show, practical bearings which concern horticulturists quite as much as botanists.

"Florists who cultivate the *Polyanthus* and *Auricula* have long been aware," says Mr. Darwin, "of the two kinds of flowers [i.e., those with long stamens and a short style, and those with short stamens and a long style], and they call the plants which display the globular stigma at the mouth of the corolla 'pin-headed' or 'pin-eyed,' and those which display the anthers 'thrum-eyed.'" These two forms he calls respectively the long-styled and the short-styled; and he proceeds to demonstrate that instead of affording a mere instance of variability, as had been supposed, the welfare of the species depends in a great measure upon the existence of these two forms, which usually occur together in about equal quantity. By numerous and careful experiments in the fertilisation of Primroses and Cowslips which had been protected from the visits of insects, the natural agents by means of which cross-fertilisation is insured, Mr. Darwin shows most distinctly "that the long-styled flowers fertilised with pollen from the short-styled yield more capsules, especially good ones [i.e., containing more than one or two seeds], and that these capsules contain a greater proportional weight of seeds than do the flowers of the long-styled when fertilised with pollen from a distinct plant of the same form;" and that the same is the case with the short-styled flowers if fertilised with pollen from the long-styled form, and so clearly is this established, that the term 'legitimate union' is applied to the former method of fertilisation, while the union of two long-styled or two short-styled forms is styled "illegitimate." It needs no demonstration to show that these facts, which rest on unquestionable evidence, have a very important aspect for growers, not only of Primroses and Polyanthuses, but of all flowers in which this difference of form is observable, for the principle is one which holds good in all such cases, so far as our present knowledge goes. Mr. Darwin goes into the question of the specific identity of the Cowslip, Primrose, and Oxlip, which are considered by some authors to be merely forms of one and the same species; he concludes that although these are probably descended from "a common primordial form," they are now as fixed in character

as many others which are universally ranked as true species, and that "they have as good a right to receive distinct specific names as have, for instance, the ass, quagga, and zebra." In speaking of the Oxlip it must be understood that the true Oxlip (*Primula elatior* of Jacquin, the "Bardfield Oxlip" of English writers) is intended. This plant, which is found in England only in Cambridgeshire, the north of Essex, and the west of Suffolk, is, as all who have grown it know, a most distinct plant; as Mr. Darwin says, it differs so much in general appearance from the common Oxlip that no one accustomed to see both forms in the living state could afterwards confound them, and yet it is difficult to define exactly any one point in which the two plants differ, except that in the true Oxlip the linear-oblong capsules are as long as the calyx. We have often wondered that this Bardfield Oxlip has not become more popular as a spring garden plant: we have been the means of introducing it to two gardens, in both of which it grew well and gave great satisfaction. In cultivation it is a much larger plant than any form of Primrose or Cowslip, and flowers very freely somewhat later than its congeners. The blossoms, which are usually described as inodorous, have in reality a very peculiar and rather unpleasant smell, resembling that of the Starch or Grape Hyacinth (*Muscari racemosum*), while those of the common Oxlip have a Primrose-like scent. The common Oxlip, which has often been regarded

Flowers of Primrose showing long-styled and short-styled forms.

as a development of the Primrose, Mr. Darwin thinks "there can be no doubt is a hybrid between the Cowslip (*P. veris*) and the Primrose (*P. vulgaris*), as has been surmised by several botanists. It is probable that the Oxlips may be produced either from the Cowslip or the Primrose as the seed-bearer, but oftener from the latter, as I judge from the nature of the stations in which Oxlips are generally found, and from the Primrose when crossed by the Oxlip being more fertile than conversely the Cowslip by the Primrose. The hybrids themselves are also rather more fertile when crossed with the Primrose than with the Cowslip." It would take too much space to go into Mr. Darwin's proofs of the specific distinctions of the Cowslip and the Primrose, but their comparative infertility when intercrossed, and the absence of any trustworthy evidence that either species when uncrossed has ever given birth to the other species or to any intermediate form, are strong evidences in favour of their specific rank. The Polyanthus is shown to be a variety of the Cowslip, as had been supposed by some authors, though others, such as Martyn, in his edition of Miller's "Gardeners' Dictionary," assigned it to the Primrose.

The practical outcome of Mr. Darwin's observations on Primroses and their allies, so far as cultivators wishing to raise seedlings are concerned, is the fact that by the interbreeding of a "pin-eyed" and a "thrum-eyed" variety the largest proportion of fertile seeds is to be obtained. Many other species of Primula present the same difference of form, and among them the Chinese Primrose (*P. sinensis*), as well as the Auricula and the favourite *P. cortusoides*, and to them the same rule applies. The pin-eyed form of the Auricula is, however, not common among the varieties distributed by florists, as its

*"The Different Forms of Flowers or Plants of the Same Species." By Charles Darwin, M.A., F.R.S. London: Murray, 1877.

flowers are less handsome than those of the thrum-eyed variety. According to Kerner, our garden Auriculas are descended from *Primula pubescens*, which is itself a hybrid between the true *P. Auricula* and *P. hirsuta*. This hybrid has now been propagated for about 300 years, and produces, when "legitimately" fertilised, a large number of seeds, the short-styled form being especially fertile.

The chapters devoted to the common Purple Loosestrife (*Lythrum Salicaria*) are full of remarkable facts established by patient and tedious experiments. In this plant—one of the handsomest of British wild flowers—there are three forms of blossom, each containing a pistil different from that in either of the other forms, and "two sets of stamens different in appearance and function: but one set of stamens in each form corresponds with a set in one of the other two forms. Altogether this one species includes three females or female organs and three sets of male organs—all are distinct from one another, as if they belonged to different species." These forms are described at length, as well as the experiments tried upon them, all of which go to show the great proportionate fertility of legitimate over illegitimate unions, and the remarkable manner in which insect agency is adapted so as to ensure the greatest number of the former class of union, and hence to enhance the well-being of the plant. But one passage we must quote—a passage which Mr. Darwin gives as offering "a remarkable instance [of] how profoundly ignorant we are of the life-conditions of a species." This truth—for it is undoubtedly such—does not speak creditably for the advance which we have made in the knowledge of the life-history of the plants and animals which we describe so glibly: and it suggests that in spite of the improvement in this direction which Mr. Darwin has done so much to initiate and foster, our natural history is still too much a thing of the museum and of the herbarium. The Purple Loosestrife grows naturally "in wet ditches, watery places, and especially on the banks of streams, and though it produces so many minute seeds it never spreads on the adjoining land, yet when planted in my garden, on clayey soil lying over chalk, and which is so dry that a rush cannot be found, it thrives luxuriantly, grows to above 6 ft. in height, produces self-sown seedlings, and (which is a severer test) is as fertile as in a state of Nature. Nevertheless it would be almost a miracle to find this plant growing spontaneously on such land as that in my garden." Here is surely a hint worth taking by those who invest in *Lythrum roseum* superbum, the grand name by which some of our nurserymen have rechristened this common and beautiful plant. We heard just lately of a somewhat similar instance of the prosperity of a species under altered and abnormal conditions; this was the case of a large patch of White Water Lilies, which were growing in a pond from which the water had almost entirely drained away; far from being injured by such a state of things, the *Nymphæa* produced flowers and leaves in abundant luxuriance, both standing erect on their stalks and forming quite a jungle. The large size attained by certain plants when introduced to entirely fresh regions under altered circumstances—as, for example, the Watercress in the rivers of New Zealand—is another aspect of the same subject, or perhaps more strictly speaking, another branch of it.

Such are one or two of the salient points of Mr. Darwin's volume, but it is unnecessary to add that no adequate idea of its value and importance, or of the interest and variety of its contents, can be gained from so brief a notice as we are able to give in the limited space at our disposal. Mr. Darwin's books are too solid to be fairly dealt with in the cursory manner which alone is possible to a horticultural journal such as *THE GARDEN*; but we trust that enough has been said to urge upon our readers to take the earliest opportunity of consulting it for themselves. They will find in it another illustration of the truth that science need not be dry or uninteresting, and they will thank Mr. Darwin, as we do, for this latest addition to his already numerous claims upon our gratitude.

JAMES BRITTEN.

and culture of the plants employed, arrangement of colours, &c. The sections of his work devoted to the arrangement of colours in flower-beds, the mode of planting carpet and other beds, are better than the chapters devoted to the description of the several public gardens round London. It is, in fact, a record of the bedding-out in Hyde Park, with which Mr. Cole is well acquainted. We could wish him a better fate than to be pottering over this, as his intelligence and knowledge are worthy of a better cause. From the point of view of the makers of extremely bad and primeval patchwork by the aid of unfortunate flowers the book is all that could be desired, but the wood engravings are, for the most part, such as one only sees in the ballads that adorn the windows in obscure parts of London. It is to be regretted that there are not a few coloured illustrations added, showing the effect of the bedding-out in its simplest expression. They might serve to show future ages the graces and refinements of which it is capable.

The Plants of Eastern Europe.—As an appendix to the Hungarian "Journal of Botany" there will be printed a catalogue of the "Flowering Plants and Ferns of Servia, Bosnia, Herzegovina, Montenegro, and Albania," compiled by P. Ascherson and A. Kanitz. The first part, containing the Ferns and Grasses, accompanies the August number; the distribution of each species through the provinces is given. A general list of the flora of this part of Europe has long been wanted.

A Study of the Cucumber Family.—In the "Mémoires Couronnés et Autres Mémoires" of the Royal Academy of Brussels, M. A. Cogniaux has published the second fascicle of his "Diagnoses de Cucurbitacées Nouvelles." The account of the genus *Anguria* is completed by a critical review of the species; and the genera *Ceratanthus*, *Apodanthera*, *Elaterium*, *Cyclanthera*, *Elateriopsis*, and *Echinocystis* are successively treated of in an historical *resumé*, an enumeration of the known species and detailed descriptions of the numerous novelties. A plate illustrates the genus *Gurania* by figures of the anthers in the different species.

PUMPKIN SEEDS AND THEIR ACTIVE PRINCIPLE.

THE nature and location of the active principle of the Pumpkin seeds appear to have been determined by Heckel, of Nancy, who has published an interesting memoir on this subject. In the French drug trade Pumpkin seeds are derived from *Cucurbita maxima*, *C. Pepo*, and *C. moschata*, which are equally serviceable against tape-worm, while the black seeds of *C. melanocarpa*, or the seeds of the closely-related genus *Cucumis*, are entirely devoid of medicinal value, since the two latter lack the very membrane in which the active principle resides. The seeds of the three first-mentioned species differ chiefly in dimensions and colour. Those of *C. Pepo* (Pumpkin) are the smallest, having an average length of 6–7 millimetres, rarely as much as 20–25 mm.; they are oblong-ovate, have a groove along both edges, where they are thickened, and have a dirty white colour. The seeds of *C. maxima* are 18–25 mm. long, by 10–15 mm. broad, are regularly oval, and vary in colour from white to orange. *C. moschata* has slightly smaller seeds, 16–22 mm. long, and 9–12 mm. broad, pure white, grooved, and the surrounding thickened edge of darker colour. These three varieties of seeds consist of a perisperm made up of four coats, and an embryo with two thick oily cotyledons. The most external coat of the perisperm is an exceedingly fine membrane, constructed from a single layer of oblong cells, which imparts to certain varieties a characteristic silver-gray appearance. Below this lies the tougher testa, made up from singularly polyedric, finely incrustated cells filled with starch. Both of these coats are removed by washing the dried seeds, while the washing of fresh seeds removes also the next two coats. The first of these—the third coat, counting from outside—is dirty white, of a loose and spongy texture, and consists of spherical reticulated cells. The fourth and innermost coat, finally, which has a dark green colour when fresh, changing gradually to greenish yellow, has a chartaceous appearance and consists of two layers: the outer one made up of hexagonal or pentagonal cells with moderately thick walls, including chlorophyll and a resinous mass; the inner one formed by elongated cells, including starch. The resinous mass in the outer layer of the fourth or innermost coat of the seeds is, according to Heckel, the active tannicidal principle, and not, as has been supposed, the fatty oil residing in the cotyledons. Owing to the absence of this papyraceous membrane, which alone contains the resin in other Cucurbitaceous seeds, these latter are inert. At the same time it is shown that even active seeds become inert, when they are blanched in a fresh state, as all the coats are thereby removed.—"Pharm. Zeit."

The Royal Parks and Gardens of London, &c. (By Nathan Cole. With numerous wood engravings and geometrical designs).—This book is devoted to the history of and manner of embellishing the London parks, and contains hints on the propagation

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 4.

THE principal exhibits at this meeting consisted of a collection of Tomatoes from the Society's Gardens at Chiswick, and a collection of fruit from Messrs. Rivers & Sons, Sawbridgeworth. Cut blooms of Dahlias and Asters were also well represented, as were likewise hardy seedling Begonias, baskets of which were furnished by Messrs. Veitch & Sons.

First-class Certificates were awarded as follows:—

Pelargonium New Life (Cannell).—A scarlet-flowered kind, conspicuously striped with white and salmon, and well suited for pot culture.

Dahlia Louisa Neate (Keynes).—A bold, well-formed, delicate mauve-pink flower, with a creamy-white centre.

Dahlia Charles Wyatt (Keynes).—A stiff-petalled kind having rosy blooms striped and spotted with crimson.

Dahlia Bessie Ford (Keynes).—A bright rose-petalled flower of medium size and good substance.

Dahlia Henry Bond (Keynes).—A brilliant purple-flowered sort, beautifully formed, and very distinct.

Dahlia The Countess (Keynes).—A large, rather flat flower, with whitish purple-edged petals.

Miscellaneous Subjects.—The collection of Begonias from Messrs. Veitch & Sons comprised kinds of dwarf habit furnished with flowers of a variety of colours, from a blush to a deep crimson and scarlet. In addition to the Dahlias from Mr. Keynes, to which certificates were awarded, he also showed other seedlings of a promising character. Messrs. Rawlings, Romford, and Mr. G. Harris likewise sent blooms of Dahlias of a meritorious description, as did also Mr. Turner, Royal Nurseries, Slough; the last-named exhibitor also sent cut blooms of *Petunia Mount Beauty*, a single-flowered kind, of large size, having bright purple flowers with white centres. Cut blooms of *Hydrangea paniculata grandiflora*, *Tropaeolum speciosum*, and *Magnolia Lenné* were sent in good condition by Mr. R. Kinghorn, Sheen Nursery, Richmond. Cut flowers of seedling *Lapagerias* came from Mr. G. Stokes, gardener to Mrs. Charles Crosland, Huddersfield, one variety being evidently a cross between the white and crimson-coloured kinds. Mr. G. F. Wilson exhibited a fasciated stem of *Agapanthus umbellatus*, bearing a very large head of flowers. A vote of thanks was awarded to Mr. Ollerhead, gardener to Sir H. Peek, for a finely-flowered plant of *Onocidium lanceanum*, one spike of which bore forty sweet-scented blossoms of a large and beautiful description. Mr. Cannell sent a box of cut blooms of Double *Pelargoniums* of several colours, varying from pure white to dark magenta; also a box of single blooms of a superior kind. From Mr. Laing came a specimen of *Nephrolepis exaltata compacta*, a Fern of upright habit, and having narrow fronds of a bright green colour; well fitted for pot culture. Mr. Parker sent examples of *Lobelia syphilitica* and *Hydrangea paniculata grandiflora*. A *Coleus*, named *Miss Scholfield*, resembling *Duchess of Edinburgh*, was shown by Mr. H. Craik, Sand Hall, Yorkshire. Messrs. Carter & Co. contributed cut blooms of African *Marigolds* in good condition. Stands of Asters came from the Society's Gardens at Chiswick; amongst them were Dwarf *Chrysanthemum*-flowered, *Pæony*-flowered, and Quilled varieties, all in excellent condition. Examples of a tree *Carnation*, named *Lady of Avenel*, were contributed by Mr. Turner, of Slough: it is a pure white-flowered kind, of good habit, and well worth attention.

Fruit and Vegetables.—Mr. Gilbert, Burghley, sent five kinds of Persian Melons; and several varieties of Peaches, Nectarines, and Pears came from Messrs. Rivers. The collection of Tomatoes from Chiswick, already alluded to, consisted of thirty varieties, of which an account was given in last week's GARDEN (see p. 219). Mr. Turner, Slough, sent tubers of the Potato called *Schoolmaster*, evidently an excellent variety.

OBITUARY.

HUGH ALGERNON WEDDELL died at Poitiers last month from heart disease, from which he had suffered for several years. Though English by birth, he was completely French by adoption. His valuable monographs of the *Urticeæ* and the *Podostemaceæ*, and his monograph of *Cinchona* gave him a high rank as a botanist, but he is perhaps best known in connection with the flora of South America. His travels with the expedition of M. de Castelnau commenced in 1845, in which year the "*Voyage dans le Nord de Bolivie*" was published. The two volumes of the magnificent "*Chloris Andina*" appeared in 1855-57. M. Weddell was at one time *aide-naturaliste* at the Muséum; in early life he paid much attention to the plants near Paris, and gave active help in the preparation of Cosson and Germain's "*Flore des Environs de Paris*," first published in 1842; he was also a good lichenologist. His loss is great, and is felt widely, especially in England, where he had many intimate friends.

Stains on Pavement.—Can any correspondent of THE GARDEN tell me what are the best means of removing stains on flags in the greenhouse caused by fallen flowers being trodden upon?—J. C. R.

HARDY FLOWERS.

AURICULAS.—A well-known grower of these wrote to me a few days ago as follows:—"My plants are getting very active, and I am dreading an autumn bloom." The moist weather has certainly accelerated, to some extent, the development of plants grown under glass, and they are apt to throw up blooming stems, which give imperfect pips, and if allowed to expand, the plants will be weakened for their spring blooming. The best thing to do is to pinch off the head of each bud, and then the stem will gradually decay. If it be pinched out close to the leaf-axil from which it springs, it will sometimes decay rapidly, and communicate it to the plants, thus occasioning incalculable injury. At this time of year the plants are best in a raised frame, under a north wall, with the pots standing on an ash-bed. In such a position the Rev. F. D. Horner has his plants at the present moment, and they have not yet begun, or only just begun to make their autumn growth. The lights are pushed off in dry weather, but drawn over the plants when rain falls, and propped up in front to admit air. All the fine growth made after the summer potting will soon decay, and the autumn growth, which is made during the month of September, will furnish the plants for the winter. My own plants in the neighbourhood of London, which were repotted a month after those of the Rev. Mr. Horner's, are now more advanced, owing to the weather in the south having, in spite of all its drawbacks, been warm and more sunny than that in the north. The plants may now be kept fairly dry, but not dry enough to cause the leaves to flag. The soil should be occasionally stirred, in order to keep the surface open and sweet. No quarter must be given to slugs, which need to be carefully looked after. There is also a small green caterpillar that eats its way into the heart of the plants and destroys them before it is noticed; and it invariably passes over an indifferent kind, and attacks a good variety. Now that rain necessitates keeping the lights rather close over the plants, aphides are apt to gather about their centres. They can be dispersed by means of a camel's-hair brush. The Rev. F. D. Horner has just made a trial of a tablespoonful of paraffin oil mixed with a gallon of water, but as it requires to be applied with great care it should be administered only by some one who thoroughly knows the nature of the plants to be operated on. Any offsets that have put forth a root should be carefully detached from the parent plant and put in round the sides of the pots in which the parent is growing; they soon begin to grow, when they should be potted off singly, or they can be put in store pots in good soil thoroughly well drained, but planted 1 in. below the rim so that a piece of glass can be laid over the pot. Offsets that have not made roots, but which have a piece of tap root attached, will soon make root when treated in this way. No time should be lost in sowing seed. Take an 8-in. pot, place in it 1 in. or more of crocks for drainage, and over these put a thin layer of Moss, then a few small pieces of fibry turf, and fill up with fine fibry turf and leaf-mould, pressing all down gently so as to form a level surface. On this sow the seed thinly, and cover it with a piece of glass, keeping it moist and cool. Some of the seeds will germinate at once, others not till the spring. In the Rev. Mr. Horner's seedling-house may be seen plants of the same sowing, but differing greatly in size. The largest are from the seeds that grew in autumn, the smallest from those which germinated in spring. As soon as the earliest plants are large enough to prick off in 5-in. pots (fifteen or eighteen in a pot) this should be done, as it leaves space for the remaining seeds to break into growth, and they will continue to do this through the winter and on into the early summer. If Moss grow over the surface a little lime water will destroy it without injuring the tender seedlings.

LARGE-FLOWERING CHRYSANTHEMUMS IN POTS.—Plants in the open air will now require attention. If fine flowers be desired, each leading shoot should carry but one bud; and those that break out at the side should be pinched out. Earwigs are getting troublesome, for they insinuate themselves into the neighbourhood of the bud, and prey upon it. They lie so close around it, that it requires watchful care to keep them from doing injury. Each branch should be tied out to a stake thrust into the soil round the rim of the pot; this not only keeps the plant in good shape, but allows air to circulate freely among the branches. As the usual rule is to plunge the pots at this time of the year, it should not be done so deep as to bring their rims close to the plunging material, or the roots will find their way over the sides into it, and by-and-by, when the plants are taken out of the bed, a check will be given to them which may seriously affect the quality of some of the flowers. Mildew must be looked after; it is very liable to make its appearance just now, when the weather is wet and cold. It generally commences its attacks at the tips of the leaves, gradually spreading over them both above and below. Immediately it is discovered, sulphur should be at once applied, and thoroughly dusted on the parts affected, repeating the dose as required. Give the plants plenty of room, so that air may circulate freely among them; this greatly checks mildew. D.

SPRING CABBAGES.

FROM the middle to the end of this month is the best time to plant the main crop of Cabbages for spring use. Cabbages are gross feeders; therefore, to plant them on poor land without manure is the prelude to tough, leathery produce. Practical men doubtless soon discover the best way of cropping and managing land; but the knowledge comes more quickly when one knows something of its geological formation. For years I have grown Cabbages after Onions without manuring or any cultivation beyond a deep hoeing, and the produce is earlier and better, and there are fewer failures in severe winters than when the land has been manured and dug for their especial benefit. This would not, however, be the best plan to adopt unless the land was in good heart. I do not think it is well to plant double the number of plants that are intended to remain, as is sometimes recommended with the view of using half of them in the shape of Greens. In that case trampling and poaching in all weathers to gather them does more harm to the main crop than the Greens are worth. It is better to plant Coleworts thickly on any vacant piece of land, so that when they are cleared off, the ground can be prepared for some other crop. From 18 in. to 20 in. apart each way will be space enough to allow for the Enfield Market and other large kinds; Atkins' Matchless, or the Early York section will do with much less space. It is always a good plan to plant out a small patch—in proportion to the demand—on an early border; they will come in at least a fortnight or three weeks before the main crop on the open quarters. They may be planted much thicker than the former, and the stalks should be pulled up, to make room for something else, as soon as the hearts are cut. A thickly planted crop like this growing on a dry, warm site will be much benefited and forwarded by a couple of good soakings of house sewage, or some other form of liquid manure after Christmas.

E. HOBDAY.

COST OF SOME OF OUR PUBLIC GARDENS.

***Eriothera grandiflora* = *Godetia Whitneyi*.**—This *Eriothera* is reckoned the largest-flowered and prettiest species in cultivation. The plants are 18 in. high, much branched, and the flowers, from 2 in. to 3 in. in diameter, are crowded at the summit of the stems and branches. The ground-colour of the petals is a pale, purplish-tinged pink; some blooms are almost self-coloured, others faintly pencilled with bright purple-crimson, and others again have large, intense blotches of the same hue. Many years ago the pale, unspotted kind was figured and described in the "Botanical Register" as *Godetia grandiflora*, a bush 2 ft. high, and native of the north-west coast of North America. In 1870 the most brilliantly spotted flower was figured and described by Dr. Hooker in the "Botanical Magazine" as *Eriothera Whitneyi*, "first collected by Dr. Bolander in Humboldt Co., California, in 1867." Subsequent observations, however, have,

says Mr. W. Falconer writing in the "Rural New Yorker," proved that both are figures and illustrations of the same species. Pale and highly-coloured flowers are not both found on one plant, and I cannot say whether or not seeds of the pale-flowering variety will produce a progeny having intensely blotched blooms; but next year I mean to satisfy myself on this point.

***Browallia Roezli*.**—This is an introduction of the indefatigable Swiss collector, Benedict Roezli, who deserves to be named as a remarkable instance of what may be accomplished by an indomitable will, and whose adventures, if written, would probably afford another proof, if any be needed, that truth is stranger than fiction. This new species of *Browallia* is described as forming a dense compact bush, 16 in. to 20 in. in height, clothed with shining green leaves. The flowers are either of a delicate azure blue, or white with yellow tube, and are unusually large for the genus. They are produced in uninterrupted succession from spring until autumn. It is said to be a native of the Rocky Mountains, but more probably of the Sierra Madre.—W. THOMPSON.

QUESTIONS AND ANSWERS.

Potato Disease and Salus.—Mr. Fish truly describes the Potato crop (see p. 199) as a wreck. What has been the effect of "Salus" on the disease?—J. GROOM, *Henham*. [We fear, says the "Gardener's Chronicle," it will not do to put too much trust in Salus. The worst patch of Potatoes we have seen this year was one dressed with this material, and by its side was a similar patch of equal size, and planted with the same variety of Potato, which had not been treated with the Salus. It was quite evident that the Salus had acted as a fertiliser, the haulms being more vigorous and taller where the Salus was applied; but the whole patch was equally, and very severely attacked with the disease.]

***Edwardsia grandiflora*.**—We have a plant of this in a large pot in our museum garden here, which from some reason or other has never bloomed though it is quite an old plant. It is planted in a compost of rotten Chestnut wood and leaf-mould. Can Mr. Fraser (see p. 160) tell me why it does not produce flowers, and how it can be made to do so?—PASSERON POWERS. [The cause of the plant in question not flowering is doubtless the peculiar kind of soil in which it is growing; try it in good substantial loam, rather stiff than otherwise, so as to induce it to form short-jointed shoots, which if well ripened will be almost sure to flower the following season. It would probably also do better planted out than kept in a pot.—HUGH FRASER.]

Water Weeds.—Enclosed are three kinds of water weeds which have appeared for the first time since a small lake was cleared out more than two years ago, and which have become a perfect pest. No. 1 grows with frightful rapidity. The waters of the lake, which is in S. Wales, are chiefly from springs rising from the bottom or running into it, with also water from a brook, into which water from a canal at a considerable height, also fed by springs, runs occasionally. What are the names of these water plants, some of which have now begun to appear in two fountains at some distance from the lake, but fed by it?—L. L. [The names of the plants sent are (1) *Anacharis Alsinastrum* or American Water Weed; (2) apparently a *Myriophyllum*; and (3) *Conferva arenosa*. Perhaps some one will kindly advise our correspondent as to the best means of getting rid of these weeds.]

Plants for Wardian Cases.—I have a glass case (4 ft. long, 2 ft. 8 in. wide, and 3 ft. high) with zinc drawer beneath 3 in. deep, capable of being filled with hot water, and heated by one or more oil lamps. There is also in each corner a pipe, $\frac{1}{2}$ in. in diameter connected with the drawer, so as to admit, if needed, vapour into the case. The case stands in a room looking south, but slightly shaded by a tree from the sun. The room is over a warm one, and Pelargoniums have stood all through two winters without the least harm. 1. Will this be likely to accommodate Ferns and Club Mosses such as *Adiantum*, *Selaginellas*, a *Todea*, variegated *Begonias*, North American *Cypripediums*, *Darlingtonia californica*, *Cephalotus follicularis*, and *Sarracenia purpurea*. 2. What is the best Palm for the case? 3. Would a small plant of the *Dicksonia antarctica* succeed? 4. What is the best trailing plant for a case? 5. Would *Odontoglossum Alexandræ*, *Oclogyne cristata*, or any one of the *Cattleyas* do in cork baskets fastened to the top corners? 6. Would a glass for water plants be better in the centre; if so, what plant would do best (glass 14 in. wide, 12 in. deep)? 7. Do the small fountains advertised as self-acting require to be connected with a water pipe, or do they act if placed in an aquarium? 8. Would any of the *Nepenthes* grow in the case? I have the *Begonias* growing in a sitting room window, and this year they have put out from three to five leaves, but I am afraid they will find the room too dry in winter. 9. What temperature in the case would suit them best?—ALFRED BURTON, *Manchester*.

Cucumber Blue Gown.—This is an old but truly fine variety, and excels almost all other kinds in the depth of its colour and the quantity of rich bloom by which it is covered. It is a real black-spine kind, and, as is usual, excels smooth fruit by the richness of its flavour and the crispness of its flesh. It is robust, does well either in heat or in a cool frame, and is a most abundant bearer.—A. D.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

SHELTER FOR ORCHARDS.

Two successive seasons of comparative failure as regards the production of hardy tree fruits ought to induce fruit growers to consider how such failures may be avoided in future. Last year the fruit crop was but moderate, and with many a total failure. This year it is worse; in fact, of Plums, Apples, and Pears—the chief standard orchard crops for market—there is not a twentieth part of an average. Attempts are being made to ascertain, amid the almost general sterility, what particular varieties have borne best this season; but such knowledge must, as a matter of course, prove delusive, as the very sort that produces a crop one year will not invariably do so the next. The lack of fruit this season is attributed to the wood not being well ripened last autumn rather than to the fierce frosts and bitter north-easterly winds that were experienced during the flowering period. The bloom last spring was generally admitted to be abundant, and wherever a few fruits have set, they have invariably been on the most sheltered parts of the tree, clearly showing that protection produced fruitfulness. There is one fact connected with the question of the ripening of the wood that requires special attention, and that is its relation to the production of a second crop, such as often follows any mishap as regards the setting of the first blossom. The wood that produces such blossom and fruit is, in every case, that of a first or early summer growth, both green and pithy; yet, as a rule, such blossoms always set and produce fruits which come to as great a degree of perfection as the lateness of the season will permit. Does not this indicate that there is much less reason to look for the cause of a failure of a hardy fruit crop in the comparative immaturity of the previous season's growth than some would have us believe? If so much is to be said against last summer and autumn with reference to wood-ripening, what of the present, which has been both moist and sunless? Yet this season's wood is ripening well, and this, too, in spite of the fact that the trees are making a very robust growth consequent upon their comparatively fruitless condition. If we get a good fruit crop next year we shall hear nothing about the preceding season's lack of ripening properties; but whether the cause of the present scarcity of fruit be a moist autumn or an ungenial spring, the fact remains that shelter is the one great thing wanted for our fruit trees. Shelter will afford more warmth in autumn, and, what is more important, it will give protection to the blossoms in spring. I find, on inspection, that in nooks or hollows where there is good shelter afforded by tall trees or the formation of the land, there are fairly good crops—in some instances quite heavy crops; but that where the trees are exposed or swept by the winds, there are few or no fruits. Protection to hardy fruit trees of a strictly artificial kind can only be given on a very limited scale and in such a way as to render it, in a national point of view, of but little value; but natural and really efficacious shelter for very large extents of fruit trees might be obtained by planting numerous belts of Spruce or Scotch Fir in such a way as to effectively break all harsh winds coming from the points of the compass included between north-west on the one hand and south-east on the other. Thus, in forming an orchard of great extent, it would be desirable to plant on the extreme verge of the aspects mentioned a double line of Firs; perhaps Spruce and Scotch intermixed would be best, and then similar single lines to correspond at intervals of 100 yds. apart until the entire orchard was fully protected. The Firs in the course of time would tower up and form dense hedges of foliage that would both temper and weaken the force of the wind, and give the trees at the critical period of blooming the best shelter that could be afforded them, whilst they would prove useful in sheltering the trees from fierce westerly winds in the autumn when laden

with fruit. In planting it would be well to put the earliest kinds on the sunny side of the plantation, as these would have their blossoms in the greatest danger, whilst the most robust kinds should be planted on the north side, as these would need less shelter and would also retain their fruit much longer, and thus allow a more lengthy season for ripening. Something of this kind deserves a trial if profitable results are to be expected from fruit culture.

A. D.

FLINTERIES AND CLINKERIES.

IN many respects, where it exists at all, the Fernery is the truest rescript of Nature, and consequently the most tasteful part of an English garden. The Fernery, however, is by no means perfectly understood. Too often it merits rather the name of a flintery or a clinkery; an imitation of natural rocks is undoubtedly meant, but the result, like the "tufa" in an aquarium, is like anything rather than Nature. Ferns are rare on the chalk, rarer still on flint, and unknown in a wild state on clinkers. On the other hand they abound on the carboniferous or mountain limestone, and on many sandstone formations; many also frequent the stumps of trees or the deep vegetable mould of the wood or stream side. Ferns undoubtedly often occur alone in a wild state, apart from all flowering plants, and this justifies their being placed apart in the garden. Let our Ferneries then be made of grey limestone for the Ceterach, Wall-rue, and Polypodium Robertianum, or of the readily-obtainable beautiful iron-shot masses of sandstone. Shade may be said to be a *sine qua non* with nearly all Ferns except the Brake. I have seen the little English Maiden-hair (*Asplenium Trichomanes*) equally flourishing on limestone and on sandstone. Hart's-tongues will grow almost anywhere, deep in a well or down an area, in a thick hedgerow or in a dark corner; but for them, and still more for the Blechnum and the Osmunda among our common English Ferns, the stony sides of a stream or dripping well with a cascade and mirror-like basin are most desirable. Over this can hang a stump or pollard with Polypodiums (Welsh and English), and so varied may be the treatment of these elements that they would not weary one if in every garden. Where the rocks appear as such and not as pebbles, they should be in large masses protruding naturally from their surroundings, not built into a wall or stuck in rows of chips like the "ten-penny nails" in a wall. Of course limestone and sandstone must not (they often are) be mixed helter-skelter. A little Bracken, with its natural allies the Heaths, has a charming effect in the peaty soil of Rhododendron beds. May we see the last of flinteries and clinkeries!

G. S. BOULGER.

ALPINE PLANTS AT HOME.

ALTHOUGH the village of Zermatt lies at a height of some 5000 ft. above the sea-level, the flora of the meadows in its immediate vicinity on either side of the glacier-stream, the river Visp, which flows through it, differs as widely from that which I have described as characterizing the mountain sides above it, as that of our ordinary English fields from what would be furnished by Snowdon or Ben Lawers. The woods which intervene between the two zones—woods where the noble Pinus Cembra asserts its supremacy more and more as we ascend till it reigns alone—are a sort of medium of communication, where they exist, between the two floras. Their own resources of floral interest are by no means contemptible, although the masses of broken rock, which for the most part furnish materials for their undergrowth, are favourable to but a limited section of vegetable life. One very striking Alpine flower is conspicuous amongst the rest, and deserves the palm for general dignity, *Aquilegia alpina*, which grows in considerable quantities amongst the decaying leaves and fibre and Moss in the more open spaces, and of dimensions, I may add, far exceeding the drawing of it in a past number of THE GARDEN. Of many specimens which I examined I found none with white petals, though on one plant they were whiter than the spurs, of a pale, chalky blue. Its cultivation in England is considered difficult, and I have myself found it so, yet I cannot help hoping that where it can have shade, moisture, light soil, with

abundance of leaf-mould and thorough drainage, it will not only establish itself, but flower freely. The next most precious inmate of the woods, judged by considerations of general attractiveness rather than of beauty, is *Linnaea borealis*, which is to be found sparsely, cowering under boles of larger trees, half-buried in Moss. I suspect, to naturalize it successfully, all sunlight but the merest glances must be excluded. The soil must be made up of half-rotten Moss and fibre, and while impatient of stagnant moisture, it must never be allowed to get dry. I have been struck, I may observe, while looking closely into the growth of these Alpine plants in their natural haunts, by perceiving how much more seems to depend on *mechanical* than *chemical* conditions. The constituents of the soil, for instance, may vary ever so much, without affecting the health and vigour of the plant, yet without fail the texture will be found the same, offering just the same facility for the course of the roots, for the retention of moisture, and so forth. *Polygala Chamæbuxus* I found in abundance, the common form of it, and the more striking variety with the crimson instead of orange wings. While speaking of *Polygalas* I wish to record a very showy species which I was not able to identify to my satisfaction, the flowers of a bright rose colour and larger than those of *P. calcarea* are represented, growing on the warm open slopes. Possibly it was a variety of *P. calcarea*, though of the normal form I found no trace. It would be a most valuable acquisition for a rockery, if once established. The May Lily (*Maianthemum bifolium*) ran riot in stony openings beyond the reach of drip, and the ground generally was draped with *Vaccinium Vitis-idaea*. I have said nothing of the Ferns of the district, for indeed I saw little worth recording. *Asplenium septentrionale* was abundant, and *Botrychium Lunaria* of dimensions scarcely credible to those who only see it on chalky downs in England. But nothing rarer than these came in my way, though I heard rumours, which careful search did not enable me to confirm, of *Cystopteris montana*. Let any one who desires to enjoy the flowers of Alpine meadows see them before the ruthless scythe sweeps over them, at the end of June or early in July. The hay of a Zermatt peasant is largely compounded of *Campanulas* (barbata and rhomboidalis), *Gentians*, *Phyteumas*, *Hieraciums*, *Martagon Lilies*, *Cistuses*, and other flowers too many to enumerate. Where a few loose stones give protection, the Alpine Rose (*Rosa alpina*) flourishes in profusion, varying in colour a good deal, dependently on shade and moisture, and the formal, regular foliage is singularly handsome. But perhaps if one of the commoner plants of the valley had to be singled out for pre-eminence in the amount of decorative beauty it supplies, I should fix upon the Cobweb Houseleek (*Sempervivum arachnoideum*). To say that every rock fully exposed to the sunshine was more or less covered by it might be an exaggeration, but yet scarcely so; and then one single surface may have a thousand of its little bud-like nodules, of every shade, from the rich brown of an old Hazel nut to the palest green, and every single one with its quota of cobweb, as though a spider had located itself in each. Where we fail to cultivate it successfully at home, the reason can only be that we will not believe in its hardihood and independence of all the conditions of vegetable life, except sunshine. Give it this and just space enough on the surface of the rock to hang on by, and the less soil and watering—to judge by its native haunt—the happier will it be. By-and-by we shall be wiser in our cultivation of these rich mountain treasures—we amateurs, I mean, who have to look after this department of our gardening, for the most part, ourselves, and often learn our lessons best by means of failures. Probably in very many cases we leave out some one single factor from our calculation which makes our result altogether wrong, for the best manner of cultivation is sometimes not so much an exact following of natural conditions as a compromise; something is wanting which we cannot supply, as, for example, the scorching sun of the short Alpine summer, or the snow covering of the long winter; and the whole problem must be re-adjusted accordingly. What I think we often want is more detailed information of successful methods which have been adopted, entering into very exact *minutiae*; for as far as my experience reaches, the sort of information supplied by horticultural books goes a very little way. It may answer in some particular case, or it may not. When plants are bought of nurserymen, it is always

unwise to buy the half-established (because cheaper) specimens; and so when they are collected and brought home, they must be treated with every care in cold frames or otherwise until thoroughly rooted and in vigorous health, before being placed in their final destinations. It is a great thing to ascertain by careful study how they live at home, but it is also a further and as necessary a step to know what substitute for those home conditions they like best. I have related some of my Zermatt experiences of this summer more with a view of getting information—ultimately, at least—than of imparting it; and nothing will please me better than that any one should be induced by what I have written to follow up some of the tracks I have indicated, and by the superior knowledge they acquire set me right where, as is very probable, I have proved an untrustworthy guide. CANONICUS.

NEW HEATING APPARATUS FOR THE PALM-HOUSE AT KEW.

THE boilers first used for heating this noble structure were completed in 1818, of the pattern known as Sylvester's "fluted conical." As these gave way, tank boilers, which we should now look upon as very antiquated, took their places. Subsequently the old-fashioned tank boilers were replaced by the "chambered saddle" pattern. In the Directors' report for 1875, we read that "five of the existing boilers are from sixteen to seventeen years old, the remaining six are 'improved saddles,' and have been put in during the last three years. This state of affairs was not considered very satisfactory, particularly as each boiler heated a separate section of the house, and a number of fires necessitated continual stoking and a large consumption of fuel; we therefore find the Directors advocating a total re-arrangement of the heating apparatus. This, at last, is being carried out; the number of boilers is reduced to six, and the separate sections of piping are being connected on the "universal flow-and-return" principle, which, as a matter of course, will secure a much more uniform distribution of heat. For many weeks a whole army of men have been employed in re-laying the stoke-hole floors. We believe a considerable thickness of concrete has been laid on 1 ft. of clay, and it is to be hoped that these means will prove effectual in preventing the recurrence of such troubles as were caused last winter by the floods and heavy rains. It seems the water came up through the floor of the stoke-holes, and every visitor to Kew could judge of the nuisance on seeing two powerful steam fire-engines at work on the Palm House Terrace. For some time, so great was the quantity of water that the fires could not have been kept in if the engines had not worked day and night. The puddling of the floors is already done, and the work of fixing the boilers and connecting the pipes is proceeding towards completion. The boiler selected is one recently invented by Mr. E. G. Rivers, of which we had not before heard. On inquiry, we find that its quick action and great heating powers have been fully tested in the new herbarium at Kew. One important feature in its construction is that its various parts can be readily repaired or renewed without removing any portion of the setting. The flues from the eleven original furnaces and boilers were connected with one, which was carried by a tunnel about 160 yards long to the tall shaft by the side of the Richmond Road. In the bottom of this shaft a fire was kept continually burning, in order to create a draught. The only important modification since then has been the disconnection of the twelve flues (the twelfth boiler heated the old Lily-house) in the tunnel, and their being made to discharge into two upright shafts, one in the centre of each wing. This alteration, it is needless to say, improved the draught, economised the heat, and effected a great saving of both labour and fuel. The great size of the Palm-house will be seen by the following comparison of its area with that of two nearly equally well-known plant-palaces, viz., Palm-house at Kew, 24,000 sq. ft.; great conservatory at Chatsworth, 15,276 sq. ft.; great conservatory at Syon House, 7785 sq. ft.

Gentians.—IN THE GARDEN of Sept. 8, I see that Mr. Farrer mentions *Gentiana septemfida* as doing well both in light loam and heavy clay. It seems to be one of the most accommodating of plants, as I have succeeded in growing and flowering it perfectly both in an ordinary border of very light soil, and also in peat among bits of sandstone. In this latter bed I planted last autumn several plants of *G. verna*, and also of *G. pneumonanthe*. The latter has done well, but I lost every plant of *G. verna*. Some that I had in pans, which were removed to the greenhouse during the winter, have done pretty well in a mixture of pot-mould and peat with bits of sandstone intermixed. I should be very glad to know how to succeed with it in the open border.—W. S.

NOTES OF THE WEEK.

CLEMATISES IN AUTUMN.—We have noticed lately some new and charming effects from the happy association of the new large Clematises and the old dense-flowering and sweet Clematis Flammula on trellises, &c. The effect of the large, purplish flowers through the cloud of white blossoms of the old Flammula is very striking.

NO SOONER OUT THAN IN.—Already, and even a week ago, there are numerous holes in the turf of our park gardens, showing where the large pots containing tropical plants have been removed indoors. Is it worth while taking so much trouble for so short a season? These tropical plants cannot be placed in the open air till the London season is nearly over, and must be taken indoors again before people return to town. This is a very artificial phase of gardening, the extension, or even the support, of which is open to very serious objections.

THE WHITE JAPAN ANEMONE IN SHADY PLACES.—There probably exists no more beautiful plant than this, with its swan-white flowers, delicate brush of golden stamens, and tall, stately habit. It seems to thrive everywhere, but I have noted it to be most lovely in the shade, where the flowers are not so much browned by the sun or broken by the wind. It is, I need hardly add, one of the best of all plants for the wild garden, being so hardy and so well able to carry on the struggle for existence with other wildlings.—V.

ROSES AND TRITOMAS.—I have lately seen some large flower beds that were extremely effective, especially at a distance. They were planted alternately with Tritomas and Souvenir de Malmaison Roses, a combination strikingly beautiful, as seen against the surrounding foliage of large trees. The Roses were on their own roots, and the strong suckers which they sent up were each crowned with innumerable lovely buds and blossoms, altogether finer in form and colour than those of which the midsummer bloom consisted. When large beds and ample room are not available, these two plants should always find a place in mixed borders.—J. GROOM, *Henham*.

AUTUMN-FLOWERING IRISES.—*Iris ruthenica* is again in flower in its present situation, which evidently suits it. The bed in which it is growing is between two lines of Poplars and moderately moist. The habit of the plant is very interesting; the foliage forms, as it were, a basin, and from the base of each leaf come two, and sometimes three flowers. This *Iris* has been in blossom now for some time. Botanical authorities state that it blossoms in May, but in this country its time for flowering is evidently September. *Iris pumila* has also been flowering tolerably freely with me for some time past, and seems likely to do so for some time to come.—P. BARR.

NEW GLADIOLUS.—A flower-spike of a very handsome Gladiolus has been sent to us by Mr. Tillery, of Welbeck. "Some two or three years ago," writes Mr. Tillery, "I raised a hybrid Gladiolus between a seedling of *gandavensis* and *carminata*, and this year I have two plants of it in flower. It strikes me that it will make one of the very best varieties for decorative purposes, having with its rich crimson colour the bluish hue of a Cactus in the flaming of the lower petals." In the spike sent the flowers are large and unusually brilliant, their crimson-scarlet colour being set off to advantage by the bluish-white tint on the under petals.

CAMPANULA VIDALI AND ITS INTRODUCTION.—In Notes from Kew (see p. 128) occurs the following passage:—"So far as is known this species is absolutely confined to a single rocky island off the east coast of Flores. It has never been gathered but once, and that was some twenty years ago by Captain Vidal during his survey of the island." A reference to the "Natural History of the Azores," by F. Du Cane Godman, published by Van Voorst in 1870, states that this plant occurs very locally on the coast of Santa Maria and San Miguel. The author goes on to say that its introduction into English gardens was not from the original discovered habitat of Flores, but from one or both of the other islands named, and that a plant of this species from his garden was carried to Kew.—HENRY BUCKLEY, *Wheeleys Road, Edgbaston*.

Kew Gardens.—The select vestry of Richmond have unanimously passed a resolution pledging themselves to do all in their power to assist the Kew Gardens Rights Defence Committee in their efforts to obtain the opening of Kew Gardens at an earlier hour than at present, and to the substitution of an iron railing for the unsightly brick wall bounding the gardens in the Richmond Road. Dr. Selle, in proposing the resolution, observed that no fewer than 58,000 persons visited the garden last Bank Holiday, and a great number, being ignorant of the hour of opening, were kept waiting about outside until one o'clock. The committee only wished to have the pleasure grounds open at an early hour, and did not desire to interfere with the arrangement of the botanical department in any way. The Kew Garden Defence Committee have received about £100 towards the preliminary

expenses of the movement, and the Members for the division (Mid-Surrey), besides sending a subscription, have promised their support in the House of Commons if necessary. The movement deserves the support of all interested in horticulture. It is nothing less than absurd that a garden which costs the nation so much should not be open as early in the day as any other public garden. Frequently it happens that people in town and with little time to spare would gladly pay a visit to Kew if it were not that the arbitrary and unreasonable habit of opening it only in the afternoon interferes with their plans.

SHOW OF LILIUM AURATUM AT CHELSEA.—Several hundred plants of this Lily may now be seen in flower at Messrs. Veitch's. They are in 6-in. and 8-in. pots, single stems bearing from eight to twelve blossoms. They are arranged in banks on each side of one of the houses. Though extremely useful when mixed with ornamental-leaved or flowering plants of other kinds, yet these Lilies when grouped in the way just named are strikingly effective.

ROMNEYA COULTERI.—This may be termed the queen of all the Poppy-worts—a swan-white flower nearly 6 in. in diameter, and with a veritable mound of beautiful golden stamens in the centre. We are indebted to Dr. Moore for specimens from Glasnevin, where it has flowered, an account of which was given in last number of THE GARDEN (see p. 228).

A NOBLE INDIAN LILY (Lilium neilgherrense).—I find that this Lily will grow and flower well without any special culture, the blooms under such conditions measuring 9 in. in length—under better cultivation they would doubtless attain in every way larger proportions. Their fragrance is delightful, and the blooms are of great substance: as a conservatory Lily it is perhaps one of the finest.—P. BARR.

GASTRONEMA FLAMMEUM.—Numbers of this handsome Amaryllid may now be seen in bloom in the Pine-apple nursery. It is a plant seldom met with, but it well deserves attention, its rich flame-coloured flowers being scarcely less beautiful than those of a Vallota. It has the habit of flowering before the leaves appear, but this may be remedied by planting it amongst Ferns or Mosses.—S. C.

DWARF EARLY-FLOWERING CHRYSANTHEMUMS.—Neat little plants of these may now be seen in quantity in Covent Garden market. They consist of yellow, white, and red flowered kinds, all very dwarf in habit, and useful at this season. For furnishing cut blooms alone such plants are valuable, and are highly appreciated in the market.—S.

ONCIDIUMS AT HOLLOWAY.—Several varieties of Oncidiiums are now very effective in Mr. Williams' nursery at Holloway; they consist of such kinds as *O. Rogersi*, *Marshallianum*, and *varicosum*, all distinct and fine kinds. Small plants in 4-in. pots are producing branching flower-spikes, from 2 ft. to 3 ft. long, gracefully beset with large and brightly-coloured blossoms.—C. S.

THE GOLDEN-LEAVED ELDER IN AUTUMN.—As an effective plant in shrubberies, or as an isolated specimen on Grass, this Elder is one of the most valuable of yellow-leaved plants. It grows as freely as the type, and even during the summer months its leaves are strikingly bright in colour, contrasting well with those of a more sombre hue. It is used in Hyde and Battersea Parks, where it is planted in beds and associated with Prince's Feather, but isolated specimens are obviously the most effective.—S.

MINIATURE APPLE TREES.—At the Alexandra Park fruit show on Thursday last, Messrs. George Paul & Sons showed a collection of miniature Apple trees of a most interesting character. They were about 4 ft. high, had been lifted from the ground and placed in baskets of Cocoa-nut fibre, and were literally loaded with good fruit. In seasons like the present, when in large orchards of established trees scarcely a fruit can be found, it is gratifying to find that small trees such as these, which can be planted 3 ft. apart, will yield heavy crops.

TRITOMA (KNIPHOFIA) MACOWANI.—This has been flowering freely with me for some time in 4½-in. and 3-in. pots, in which the plants vary in height from 1 ft. to 2 ft. Its graceful foliage and dwarf growth make it interesting to those who like plants of a distinct and striking character in their conservatories. As an outdoor plant with established stools throwing up from twenty to fifty spikes of bloom each, its value may be readily imagined. Herr Max Leichtlin considers it to be even hardier than *Tritoma glaucescens*, which has never sustained any injury during winter in my grounds.—P. BARR.

FUNGUS FEASTS.—The third annual conference of the Cryptogamic Society of Scotland will be held at Dunkeld during October 10, 11, and 12. The president is Col. Drummond Hay, and the secretary Dr. Buchanan White, of Perth. The business of the conference will consist mainly in excursions, conversazioni, and an exhibition of specimens. The Society is now prepared to issue a First Century of "Fungi Scotici Exsiccati," which will contain many of the new species and rarities recently discovered.

THE KITCHEN GARDEN.

YOUNG ASPARAGUS BEST FOR FORCING.

THERE can, I think, be no doubt that young three or four-year old plants that have been specially prepared for the purpose, and that have never been cut from are the best for forcing. In their preparation there is much that may be done to encourage vigorous development both as regards stem and foliage during summer, that will be followed by correspondingly finer produce when forced. One good strong root, with well-developed crowns, will produce more in bulk and weight than several weak ones; and what is of more importance, the heads will be much finer than they otherwise would be. There is really no loss of space by giving the plants plenty of room, and by thinning out all weakly shoots in summer in order to throw strength into the main stems, and all seeds that are produced on the latter should be picked off before they get large. No one, no matter how good his appliances for forcing may be, can obtain fine heads from weakly roots; and I might almost say, scarcely any one can fail if the plants have been well prepared for forcing. When a plant or tree that is expected to produce its crop out of season has been well prepared, the work is half done. If the stock of plants be limited, unless there is a special reason for wishing to have Asparagus early, it will be better to delay forcing till the end of October or beginning of November; but with a good stock of such plants as I have endeavoured to describe, forcing may begin at any time after October 1, and in that case the first batch of plants should be headed down at once; this will give a little stimulus to the dormant buds, and will cause them to break more quickly with less artificial heat than would be necessary if the removal of the growth had been delayed till the time of lifting. It will be, so to speak, a continuation of the growing season; no doubt some little sacrifice of quality has to be submitted to, but that is inevitable with most things forced early, and there is less waste or loss in this respect in the case of Asparagus than with other matters, as the main object is to take the most of the growing power out of the plants and then throw them away. No doubt if any one chose to incur the expense Asparagus might be had all the year round, either forced or from beds in the open air, but few plants force so easily when fairly treated. There are various ways of forcing Asparagus, but the one most commonly practised is to make up hotbeds, of stable manure and leaves in such proportions as shall produce a steady temperature near the surface of about 65° or 70°. This will generally be secured by building up the beds about 3 ft. high at back and 2 ft. at front, beating the material down tolerably firm so as to have a steady heat for a month or so. When the bed has reached the right temperature, and there is no danger of any serious fluctuation (which can easily be ascertained by keeping a stick thrust into the beds and watching it daily), 2 in. or so of light rich soil should be placed all over the surface, and on that the roots should be laid close together. The roots of the Asparagus should be lifted with great care, so as to avoid all unnecessary mutilation, and when carefully arranged, they should be covered with light soil thinly or heavily, according as the produce is required to be green or blanched. In the latter case 8 in. will not be too much, whilst in the former 3 in. will be ample. Whenever the weather is favourable, free ventilation will improve the flavour in the later stages of growth. Asparagus may also be successfully forced in pots or boxes; or temporary arrangements may be formed on the shelves or stages of forcing-houses, by which a good supply may be obtained without incurring the expense of hotbeds, always supposing, of course, that the space in the houses can be given up for a time for such a purpose. Where Vineries are started early, this mode of forcing might be used more than it is to supplement the hotbed system, as by improvising some temporary troughs over or close to the hot-water pipes, there would be no difficulty in getting sufficient heat to bring it on quickly enough to ensure succulency. Later in the season the permanent beds may be—and, in fact, often are—forced gently by covering them with movable frames and lights, and filling in around them with hot manure and leaves.

E. HOBDAV.

CARPET BEDDING.

OF all systems of flower-gardening, this is the most artificial, inasmuch as its effectiveness wholly depends upon the amount of labour bestowed on it in the way of shearing, pinching, and pegging. I admit that the best examples of carpet beds in public parks, where labour is abundant, and where there is little else to look after, is at first sight so striking that owners of private gardens resolve at once to adopt the system pure and simple, totally ignoring the fact that in the altered circumstances under which private gardens are carried on, the effect produced will be altogether different. The question as to how carpet beds are to be kept in the necessarily highly-dressed condition which they require is one of the most perplexing with which modern gardeners have to deal, for even under the ordinary system of filling beds with flowering and fine-foliaged plants, it is more the rule than the exception for the kitchen and fruit gardens to be deprived of the labour which they often urgently need. It should also be borne in mind that the forms of flower beds in public parks have been modified to suit the carpet-bedding system. Beds of simple outline are the rule, but in general the flower gardens attached to country mansions are laid out geometrically, either on the Grass, or, more frequently, as in the Italian style, in gravel and Box, with accompanying vases, scroll-work, and edgings, the latter forming the divisional lines, and the beds themselves, if filled with distinct colours in leaf and flower, making up one harmonious whole. But if we begin to subdivide each bed into separate compartments of rainbow-like colours, the general effect will be lost—nothing will be left but inextricable confusion. There may be many and glaring faults connected with the oft-derided system of the scarlet and gold of ordinary bedding-plants for furnishing geometrical gardens, but as a rule they are associated with such a wealth of foliage that it is almost impossible to over-colour a country garden. With reference to single isolated beds, I like those in Battersea Park in which handsome or stately-foliaged plants are inserted at sufficient distances apart to allow of a full view of the carpet below them. The latter should not be clipped or pegged, but left to grow as it will, thus forming a more agreeable combination than the flat, unbroken surface of the orthodox carpet bed.

Henham.

JAMES GROOM.

Gladioli within the Reach of All.—I send you cut spikes of a few inexpensive Gladioli in order to show what is now within the reach of every body—varieties which a few years ago were prohibitive as regards price; now any one wishing to cultivate this plant need not be deterred from doing so on account of its price, and as to cultivation nothing can be easier. When the Gladioli season is over with us, generally about the 10th or 15th of May, we trench a piece of ground deeply, manure heavily, and plant the bulbs thickly: if the weather sets in very dry, we occasionally give them a soaking with water. This season has been particularly favourable to Gladioli; they have not required any water, and for the last fortnight we have been cutting flowers two or three times a week from the same beds, and we shall go on cutting for the next four or five weeks. The importance of hardy bulbs in a decorative point of view is even now but little understood by many. Those who grow them as they ought to be grown can have Daffodils in February, and they will last till May—then Lilies afford a succession of blooms till the Gladioli come in, and these last continue flowering till the frost destroys them. Just now we have beds of Tiger Lilies in excellent condition, and our plants of *Lilium auratum* have been flowering since July, and they will continue as long as the weather is favourable. *Lilium speciosum* has also been very fine, a condition in which it will continue for some time. Autumn Crocuses have just commenced flowering, also autumn Scillas. The Colchicums are in bloom, and will continue till cut down by cold weather.—P. BARR.

The Lawson Cypress in Devonshire.—As a description of this Cypress was given in last week's GARDEN, it may be interesting to know its rate of growth under favourable conditions. Our largest plant is now 36 ft. in height. It was planted sixteen or seventeen years ago when it was about 3 ft. high. Two others of which I sowed the seed in 1859, are now 30 ft. in height. We have others, between 20 ft. and 30 ft., but some produce seed so freely that their growth is much checked thereby: the soil in which they are growing is a rich light loam, resting on rock, and the situation is well sheltered on the southern side of a hill, where the drainage is naturally perfect.—J. GARLAND, Killerton.

GARDEN DESIGN.

THE GARDEN] STREAMLET.

It used to be supposed and stated too frequently in books that a garden being a "work of art," there was in consequence some occult reason why Nature should be kept within very strict bounds therein. Not agreeing with this, we find pleasure in illustrating subjects that show how natural a garden may be without losing any other charm. Such scenes we only find by accident in days when a trace of any intelligible design is not evident in many of the most famous gardens. The present example is a little stream that rushes down a grassy valley. Beyond, it may be seen emerging from a wood of Pine and other trees, under the shade of which it ripples among Ferns and Sedges. There is, of course, no reason why garden streams should not be free from false lines and curves, with which they are too often associated. What a charming home such a place forms for naturalising in the Grass numerous hardy flowers, including water-side ones!

RATING GARDENS.

THE law enacts that the rate shall be founded upon "the net annual value" of the ratable land or hereditaments. The Parochial Assessment Act, 6 and 7 William IV., cap. 96, defines "the net annual value" to be "the rent at which the same (land or buildings) might reasonably be expected to let from year to year, free of all usual tenants' rates and taxes, and tithe commutation rent-charge, if any, and deducting therefrom the probable average cost of the repairs, insurance, and other expenses, if any, necessary to maintain them in a state to command such rent." In order to discover what the rent is, at which the property "might reasonably be expected to let from year to year," the place itself, and not the acts or desires of landlord and tenant, must be chiefly considered. The test is, not what rent is actually paid, but what in the opinion of persons in general is the market value per annum of the property in question. A landlord, out of feeling of relationship or friendship, might be willing to accept an almost nominal rent from one particular tenant; or, another tenant might for some special reason be glad to pay a fancy price for the same premises. In neither of these cases would the rent be of that reasonable kind contemplated by the framers of the statute. In the former instance the sum paid per annum would only be a portion of the reasonable rent, while in the latter only a portion of the sum paid would be rent at all, the rest being a kind of premium voluntarily paid by the tenant by reason of the premises being of exceptional value to him. In neither case could the rate be calculated from the rent actually paid. It will be observed that the statute requires the rent to be such as could be reasonably expected from year to year, and not for a term of years. In the case of *Staley v. Castleton, Overseers*, the facts were that a silk mill was closed in consequence of the depression of trade. The owners of the mill appealed against the rate. Mr. Justice (now Lord) Blackburn decided that the rate was to be made upon the estimate of rent to be expected reasonably. A tenant would give nothing for it as a silk mill just then. Things might improve, and a tenant might be found who would take it for a term at a larger rent, but that was not the calculation intended by the Act. Again, in the case of the Attorney-

General *v. Lord Sefton*, it was held that duty did not attach to land that was unproductive at the time the defendant succeeded to it, though it might become very valuable in the future. Again, it was held in the *Tyne Coal Company v. Wallsend Overseers* that the colliery, which was drowned out, and had been so for six years, must be rated at its value from year to year as it was then, and not as if it were a going concern. In each of the cases cited above, the property had depreciated in value through no fault of the respective owners. In other words, the rate was to be calculated according to the present, and not the prior, nor future, nor speculative worth. In the case of *Harter v. Overseers of Salford*, Mr. Justice Crompton said—"If the premises are unlettable, they are not ratable; but if they are unlet merely because the owner stands out for a higher price (*i.e.*, one above their reasonable value) they are liable to be rated at a fair rent." In the same case, Mr. Justice Blackburn laid down that where premises are to be let, and are not *de facto* let, in practice they are empty, and not considered ratable. But when the landlord retains possession, and has actually some beneficial occupation, he is ratable, at least, to the extent of that benefit. No exact case is recorded of appeal upon rating of an unproductive nursery greenhouses, forcing frame, or Vinery; but the cases above cited seem to point that the same principles should apply to this sort of property as are laid down in *Staley's* case, and in that of the *Tyne Coal Company*.—"Gardener's Chronicle."

A Garden Streamlet.

Islets of Forget-me-Not.—The islet of Forget-me-Not in the canal in Rollisson's nursery at Tooting is a pretty and a very suggestive object. It is made up of a few large flakes of the common Forget-me-Not thrown on a rough piece of board, which forms a raft for it. In outline this is so irregular that no one suspects it to be anything else than a charming little island of Forget-me-Not. This plan would in some places be found useful in preventing the plant being overrun by coarser vegetation, and in allowing it to be seen in greater mass and floating on the water instead of growing on the bank. In forming such rafts, other plants might easily be mixed with it, such, for example, as the North American Pitcher Plant, which is perfectly hardy. The little white Bog Arum would be pretty in such a position. Treating aquatic and bog plants in this way is one of the best methods of adding to the interest of a garden. Justice has never yet been done to aquatic and

bog plants in any garden which we have seen. The various pieces of water in Rollisson's nurseries offer the best opportunities for cultivating aquatic plants, which we hope may be taken advantage of to the fullest extent, as we fancy hardy aquatics will one day be more used in garden decoration than at present.

An Indian Versailles.—Having spent a quarter of a million in the erection of the palace of which the Prince of Wales was the first occupant, Sindia, the Maharajah of Gwalior, is surrounding it by a garden which promises to be "a wonder of the world." The architect of both, Major Michael Felose, C.E., is happier in the control of countless lakhs of rupees than most of his Western brethren. In the paradise or pleasure-park around the palace he is accordingly raising ten garden houses, each of a separate variety of Hindoo architecture, yet all harmonious, and a winter glass palace imported from Vienna. Artificial lakes he is connecting by fine bridges, so arranging the water as to cause it to rush with a sound that will cool the ear as well as the eye. The houses are built of and roofed with enormous blocks of white sandstone. The path is to be paved with the marble of Jeypore. The water for the lakes is brought in 3-ft. sandstone pipes a distance of sixteen miles.

A "MODEL DOCKYARD."

JUDGING from the heaps of Docks one everywhere sees so carefully stored up in some nook or another, one would be inclined to think that cultivators considered this a model mode of dealing with what the very action itself shows is deemed to be a great nuisance. Now, as we have this very morning been occupied in analysing some of these "model Dockyards," we make no excuse for a few words in explanation of the results of our deliberations. We would first notice that the district in which our observations are made is one composed of stone-brash of the inferior oolite and inferior oolite sands, all more or less light soils. Docks, however, are common to both heavy and light lands, and the same species are everywhere; the other plants would vary according to soil and situation.

MODEL DOCKYARD WEEDS, AUG., 1877.

Botanical Names.	Common Names.	No. 1.	No. 2.	No. 3.	Remarks.
<i>Rumex crispus</i>	Curled Dock.....	—	—	—	The most abundant.
" <i>acutus</i>	Pointed-leaved Dock	—	—	—	Not so common.
" <i>obtusifolius</i>	Blunt-leaved Dock...	—	—	—	Common.
<i>Chenopodium album</i>	Fat Hen, Goosefoot	—	—	—	Common to rich soils.
<i>Papaver Rhæas</i>	Common Red Poppy	—	—	—	Everywhere on light lands.
" <i>dubium</i>	Long-headed Poppy	—	—	—	Occasionally on heavier soils.
<i>Senecio vulgaris</i>	Groundsel.....	—	—	—	Common.
<i>Chrysanthemum segetum</i>	Yellow corn Marigold.....	—	—	—	On the sandy soils very common.
<i>Lavatera arborea</i>	Tree Mallow.....	—	—	—	Escaped from cultivation.
<i>Datura Stramonium</i>	White Thorn-apple	—	—	—	
" <i>Tatula</i>	Purple Thorn-apple	—	—	—	Common to the district.
<i>Avena fatua</i>	Wild Oat	—	—	—	
<i>Aloupecurus agrestis</i>	Black Bent	—	—	—	The "Black Couch" of the district.
<i>Agrostis alba</i>	Squitch	—	—	—	The common Squitch Couch.
<i>Corn</i>	Wheat, Barley, Oats	—	—	—	From the farmyard.

Now, here we have noted the weeds observed on three separate heaps, probably some half a mile apart.

No. 1 is the true model Dockyard; it was made as follows:—Dock roots were picked up from the field some two years ago, and put up neatly by the side of the road, with the avowed object of letting them rot. Well, the result has been that, while some of the young plants in the bottom of the heap have really gone to mould, those at the top have grown and rooted in the mould below, with the result that different plants of Docks on this very heap have singly produced 28,000 seeds this year. Many seeded the first year, and even then the model Dockyard was fully established! But what a store of seeds is now concentrated on that same heap! Now, if we ask what is to become of such a heap, we shall find that the practice is to pull up the Docks after they have seeded, and cart away the rotted materials, of course with the scattered seeds, to the land, in which case we need not be surprised to find a thick crop of young Docks, to follow perhaps upon the very piece of land from which we had so carefully abstracted their parents. Still, sometimes it will be the case that such heaps are not removed for years; then the seeds are gradually scattered abroad from this centre by wind, birds, or sheep straying along the roads, by all of which means a pest of this kind is, though sometimes slowly, yet surely spread from a common centre.

No. 2 is an ordinary roadside manure-heap, and contains, in addition to Docks, other weeds of the district. This was carted from the cattle-sheds, and the weeds upon it are just those from the hay, especially seed hay, or brought in the litter. This is the second year in which we have observed this heap. It was the other day covered with Docks hastening to seed. These, however, have been all pulled up since, or enough Docks would have been spread with this manure to crop the land over thickly.

No. 3 is a heap made up of the sweepings of the farmyard. This is particularly interesting, as showing how strange plants may be distributed, so as in time to add to our native weed-list. The source of these weeds is as follows:—The *Datura* being cultivated for medicinal purposes, its seeds have been scattered about the yard to which it has been brought for the purpose of being packed. The Tree Mallow is growing in the garden which opens to the yard, into which the ripened seeds are continually falling. Now, as these have been swept to the heap from the yard with the commoner weeds in the list, it will easily be seen how such weeds may be taken to the farm; and, indeed, it is by no means uncommon to trace these three foreigners into most of our arable fields. Now, when any of our common weeds may be suddenly found to spring up in a field to a more than ordinary extent, it is said to be "natural to the land;" but such cannot be said of these foreigners, and hence they may serve to show the means whereby weeds extend. The fact is they are really cultivated. Even our model Dockyard is seen to be a

means for spreading the Dock, and somehow or other it will be found that, when weeds of any kind appear in greater quantity than usual, it will be because we have sown their seed.—"Field."

Carnations from Cuttings.—It does not seem to be generally known that Carnations, Picotees, and Pinks may be struck like Pelargoniums and quite as easily. Some writers I see still advocate the old system of layering, an operation which entails a large amount of labour, patience and time, requisites that every one does not possess, especially amateurs. First of all, let us get rid of the idea that dead or decayed leaves, &c., must be removed, except for neatness sake. To be told, too, to remove the old surface-soil, and replace it with equal parts of turfy loam, leaf-mould and clean sand, which must be well mixed and passed through a fine sieve, and to cut fern leaves for pegs, is certainly going a long way to make flower-growing tedious and distasteful, especially to those who have everything to buy. My method is very simple, and although Carnations are subject to great ravages by wireworms (of which my ground is full), I seldom lose one out of every dozen cuttings put in. I take a piece of ground to make a bed 4 ft. wide, dig and manure it, also rake the surface fine to give a neat appearance. In October I take pipings either cut or drawn from the parent plant; and with a small stick dibble them in, and water to settle the soil, after the manner of putting in Pelargonium cuttings; there I leave them until bedding out time next May, when I take them up and replant them where I wish to make a show. Now some may say it is too late to replant in order to have a good show of flowers, but by planting them in rather rich soil, I find them to flower quite as well as those layered and planted in October. For a front row, to cover the bare stems of standard Roses, or for the centre of a large bed, nothing can be better. In the same manner I strike Viola Blue Perfection and Yellow Violas (only put in in September), and find them to strike freely.—W. V., Northwich.

SCENT-YIELDING PLANTS.

By G. W. SEPTIMUS PIESSE, Ph.D., F.C.S.

Mints.

THE plants included in the genus *Mentha* are nearly all highly aromatic, containing in their leaves a very pungent volatile oil or otto. The kinds best known are the Peppermint, Pennyroyal, and Spearmint. Of these the Peppermint is that which now most concerns us. Some of the fairest fields in Surrey—those in the neighbourhood of Mitcham, Carshalton, Beddington, Sutton, and Wallington—are devoted to the growth of Peppermint. Nearly all this district occupies a plateau surrounded in the distance by hills, and Waddon Marshes being in its centre, well indicate the general run of the soil, which, with plenty of sand, just suits the growth of Peppermint. The plants are readily propagated by dividing the roots, which are planted 1 ft. apart each way. This is done in April, and great care is taken to prevent weeds from growing amongst them, so as to ensure a pure sample of oil. The fields are ploughed up and the crop changed about every five years; little else is used in the way of manure besides the spent herb from the stillhouse, which is put on the land in spring, after having had about half a year to ferment and decay. Peppermint is also largely grown in North America in New York County, Ohio, and in St. Joseph's County, Michigan, as well as in Strathroy, in Canada. The oil imported from these countries finds a ready sale in London, and thence it is sent to Northern Europe. In dealing with a subject of which Parliamentary Blue Books take no cognizance, it is difficult to fix statistically the quantity of oils obtained annually, but I should say that not less than 33,000 lb. of it are produced in Surrey alone. The best English oil has an average value of, say 30s. per lb., but the American and Canadian oils only realize about half that sum, a circumstance to be attributed not so much to climate or the quality of the plant itself as to weedy cultivation. Weeds get carried into the still with the Peppermint, and as many of them yield an oil, the true Peppermint oil thus becomes deteriorated. In Surrey two varieties of Peppermint are grown—technically known as White Mint and Black Mint. The Mint harvest, as a rule, begins about the third week in August, and all is not garnered until the end of September. During this interval the stills are worked night and

day without cessation, Sunday excepted. The Mint is cut with a sickle or scythe, and is left to dry on the land; it is then tied up into "mats" of, say 56 lb. each, and taken to the stillhouse. About sixty mats, or over 3000 lb. weight of crop

Black Mint.

are produced by each acre of land. In Surrey there are about 1200 acres under Mint alone, namely, 500 acres of White, and 700 acres of Black Mint. The White kind yields, on an average, 24 lb. of oil to the acre, say, $24 \times 500 = 12,000$ lb.,

White Mint.

which, at the very low price of 30s. per lb., shows a value of £18,000. The Black Mint, which yields more oil than the White, averages some 30 lb. to the acre, but it has a lower market value, say 25s. per lb.— $30 \times 700 = 21,000$ lb.; this

gives a value of £26,250, or a total of £18,000 + £26,250 = £44,250. These figures surely ought to induce young emigrants to some of the British Colonies to commence without delay the culture of scent-yielding plants. The White Mint is more susceptible of injury from spring frosts and summer droughts than the Black kind, hence both are grown in order to make sure of a crop of some kind. The operation of distilling is simple enough; it consists of hoiling the herb in water, and passing the steam generated through a hollow wormed pipe placed in a vat of cold water; the oil rises with the steam, and is condensed in the worm, falling out at the end into a receiver; the oil floats upon the water, and is ladled off from time to time. "A charge," as it is termed, for the still consists of twenty mats of 56 lb. each, or half a ton of Mint, and about 70 gallons of water. It is then boiled slowly with a steady fire for seven hours, at which time all the oil is out of the Mint; the still is then emptied by means of a tap of any water remaining, and the spent Mint is forked out of the alembic, an hour being allowed for this work and to effect another charge. Three charges are thus worked during the twenty-four hours, or what is equivalent to the product of an acre of land. Persons interested in scent-yielding plants are welcome to inspect the stillery of Piesse & Lubin, Mitcham Road, Croydon. At this time of the year—August and September—the stills are mostly employed in working Camomile (of which a good deal is cultivated at Beddington), Pennyroyal, Lavender, and Mints; at other times they are used for distilling Caraway seed, Cedar and Santal wood, Cloves, Patchouly, Thyme, &c.

Hughenden House, Chiswick.

[In order to determine correctly the names of the Mints mentioned above we sent specimens of them to Dr. Boswell, of Balmuto, Kirkcaldy, author of the last edition of English Botany, and the following is his reply:—"The two Mints you sent me from Messrs. Piesse & Lubin are both forms of the Peppermint (*Mentha Piperita*), judging from the flower-spikes. The White Mint is nearest to the form known as *Mentha Piperita officinalis*, and the Black Mint to *M. P. vulgaris*."]

Top-dressing Seed-bearing Cucumbers.—For several years I have had much difficulty in getting Cucumber plants to hold on sufficiently long to fully ripen a crop of seed fruit, the strain upon the plant being much greater where numbers of large fruit are left to ripen than is the case where the fruit is cut as fast as it becomes large enough for table. The difficulty to be surmounted has been a strong tendency on the part of the plants to shank off just on the surface of the soil, and altogether collapse in a few days. Last year I adopted the plan of surfacing the soil with a good dressing of short stable manure with good results, as much fewer numbers collapsed. This summer after the plants were well established, I procured a quantity of road manure with which there was a considerable amount of grit; into this I found the plants rooted freely at the joints, which kept them fresh and vigorous, and they matured a good crop of seed fruit. In pulling up the plants I found that in several cases the main stems were quite decayed, but that the joint roots had kept the plants alive. Nevertheless these have produced a crop averaging ten seed fruits each, all large and plump, and as good as could be desired.—A. D.

"Grass Nuts."—In a list of plants eaten by the Californian Indians, we observe this name applied to the Brodiaeas and other plants now well known in English gardens. "There is the Beaver-tail Grass Nut (*Cyclobothra*), the Turkey Pea (*Sanicula tuberosa*), the purple-flowered Grass Nut (*Brodiaea congesta*), the tulle Grass Nut, a small bulb growing in wet places; the climbing Grass Nut (*Brodiaea volubilis*), sometimes planted for ornament; the little Soap-root (*Chlorogalum divaricum*), the wild Garlic (*Allium*), the eight-leaved Garlic, and several others; the Yellow-blossomed Grass Nut (*Calliphoa lutea*), and several other Grasses of this kind. There is one other Grass Nut worthy of mention, with a black bulb (*Anticlea*), which the Indians consider poison, although it probably contains no more poison than other members of the Liliaceous kinds."

Canned Indian Corn.—More than 5,000,000 cans of "corn" are now packed in Maine annually, and sold in various parts of the world, giving employment to from 8000 to 10,000 persons during the packing season. The corn in this case means Indian Corn of a peculiar variety, gathered young, and preserved in tins. It is now often seen in London shops. We ought to grow the plant for use in the green state.

THE FRUIT GARDEN.

FRUIT GROWING IN KENT.

From the "Royal Agricultural Society's Journal."

KENT has been celebrated for the production of famous fruit for several centuries. Drayton, in the first decade of the seventeenth century, thus apostrophised the county, in his quaint "Polyolbion":—

"O, famous Kent!

What country hath this isle that can compare with thee,
Which hast within thyself as much as thou can'st wish?
Thy conyes, ven'son, fruit, thy sorts of fowls and fish:

Whose golden gardens seem th' Hesperides to mock:
Nor there the Damson wants, nor dainty Apricock,
Nor Pippin, which we hold of kernel fruits the king,
The Apple Orange; then the savoury Russeting,
The sweeting for whose sake the plowboys oft make war."

And sundry other fruits, of good yet several taste,
That have their sundry names in sundry countries placed."

Fruit lands—orchards—are frequently mentioned in charters or deeds granting or conveying lands in the reign of Charles the First and James the First, in various Kentish parishes where fruit is now grown. Lambarde, in his "Perambulation of Kent," says that King Henry the Eighth's fruiterer planted at Tenham in 1583, "by his great coste and industrie, the sweet Cherry, the temperate Pipyn, and the golden Renate," having obtained the "plantas from beyond the seas." Since the time of Lambarde's work the area of the fruit plantations in the county has varied considerably, to a certain extent according to the profit made from the cultivation of Hops, which were brought from Flanders in the sixteenth century. When Hops paid well, fruit trees were grubbed up and Hops were planted in their stead. When Hops did not pay, fruit trees were substituted for these more speculative plants; and this alternating process has been continued up to recent times. Hasted, in his "History of Kent," published one hundred years ago, remarks of certain parishes in East Kent, that "there were large plantations of fruit till they were dis planted to make room for Hops, which are found to thrive well in old orchard ground." He adds, "Orchards are beginning to be planted again in consequence of the low price of Hops." The climate of Kent is temperate, and in most seasons the common fruits ripen well; the mean temperature of the three summer months is about 61°, and that of the three winter months about 38°. The average annual rainfall is about 26 in. There is strong evidence that the climate was more genial in earlier times, as Grapes were largely grown, and ripened out-of-doors, and wine was regularly made from them. Mention is made of Vineyards—vineæ—in the records of the survey of Domesday, taken in the early part of the eleventh century. In the reign of Edward the Second, when that king was at Bockinfold in Kent, presents of wine and Grapes were sent him from the Vineyards near Rochester. Hasted states that he "knew two exceedingly fine Vineyards in the county, one at Tunbridge Castle, the other at Barming, from which quantities of well-flavoured wine had been produced." In the parish of Hunton, at Buston, the former seat of the Fane family, there are remains of an old vineyard, and three distinct terraces rising above each other may be traced. These are faced with brick walls, and are protected from the north by a hill. This is called the "old vineyard" to this time, and fine fruits of many kinds are grown in great abundance on the rich soil of its sheltered slopes. It very seldom happens that Grapes ripen thoroughly in these days, even in the hottest summers in the most sheltered spots in the county, or that Grapes are grown out-of-doors at all fit for making wine. Grapes cannot be produced fit for wine-making purposes unless the summer temperature exceeds 64°. Humboldt, the authority for this statement, wrote:—"Taking an example, for instance, from the cultivation of the Vine, we find that in order to procure *potable* wine, it is requisite that the mean annual heat should exceed 49°, that the winter temperature should be upwards of 33°, and the mean summer temperature upwards of 64°." From the fact that Grapes do not ripen now in Kent as they did four or five centuries ago,

it must be inferred that the climate has undergone a change, that the mean summer temperature has gradually been lowered. This may be the reason why the old sorts of Apple, the Ribston and Golden Pippin, and other more delicate sorts, do not thrive as well as those of later origin, and more to the manner born. It is suggested that this slight and gradual change in the climate of Kent is due in some degree to the clearing of the forests, with which parts of Kent were formerly covered; such as the great Forest of Anderida, which extended from Lympe through the Weald of Kent into Hampshire, and Saenling Forest in the extreme east of the county; with other forests, described by Mr. Furley in his 'History of the Weald,' that have been grubbed since the Saxon period. Mr. Furley mentions that the Isle of Thanet, now an open tract of fine arable land running out to the North Foreland, was formerly covered with timber. The removal of these great forests and woods, which has gone on steadily since the date of Magna Charta, has let the cold wind and sea breezes from the north-east and the south-east, sweep directly over the unsheltered land, chilling the air and lowering the temperature. Although Humboldt held that extensive forests are among the causes tending to lower the temperature of a district, it by no means follows that their clearance would ensure an increase of temperature. Dr. J. C. Brown, in his recent work entitled 'Forests and Moisture,' has shown that disforestation makes a country more dry, and that planting gives a country humidity; but he has not shown that a climate has been altered in respect of heat or cold, in its mean summer temperature, either by disforestation or by the planting of trees. Fruit-plantations and orchards in Kent have been planted and replanted, grubbed and re-grubbed, most promiscuously during the 300 years preceding this generation, to make way for Hops when that very uncertain crop was profitable, as well as after successive large growths of fruit, which from the then comparatively limited demand, and the heavy costs of conveyance, barely paid expenses. Foreign competition, it is true, was insignificant, with regard to soft fruits, as Cherries, Gooseberries, Currants, until within the last forty years; yet there was no trade with the thickly populated towns in the north of England and in Scotland, until railways had made the carriage of goods cheap and expeditious. Since the development of the railway system, there have not been such capricious alterations in the fruit-growing acreage, which has been steadily increasing.

In the parts of the county suitable for fruit-growing, almost all the farms have a certain proportion of fruit-land, as a hedge against the contingencies of Hop growing. The profits of fruit-growing are not so large as those of Hop-culture in good seasons; on the other hand, the chances of possible losses are not nearly so great. Men may make or lose fortunes by Hop-cultivation; but fruit land of fair quality will show a steady remunerative return upon an average of many years. During the last ten years much land has been planted with fruit in the north-western part of this county, between Orpington and Crayford. Large woods of poor quality, which grew Birch, Beech, and other trees of low value, have been grubbed there, and planted with Plum, Damson, and Apple trees, Gooseberry and Currant bushes, Raspberry canes, and Strawberry plants, which pay well, especially the last named, as the distance from London is short, and the fruit can therefore be sent in fresh and early to the markets. In the Weald of Kent, also, where Apples alone were grown until quite recently, Black Currants, Gooseberries, and Plums have been, and are now being, planted to some extent. Fruit of various kinds is also cultivated throughout the country by persons who have a few acres planted with fruit trees, and who are, as a rule, a most industrious and prosperous class; as well as by cottagers in their gardens. In good seasons a few Apple or Plum trees, or some rows of Gooseberry or Currant bushes, help materially to pay their rent. A garden of this kind, well stocked with fruit trees, has often been the means of giving an industrious labourer a rise in position. Fruit is grown mainly in three particular districts of the county, situated in East, Mid, and West Kent, whose respective areas are determined in a degree by geological conditions. In the first-named district fruit is cultivated in the parishes lying between Boughton-under-Blean, to the west of the city of Canterbury, and Rainham, a few miles east of the city of Rochester.

Lambrade has it that there were thirty fruit-growing parishes here, but there are hardly so many in these days. Cherries are grown here in large quantities; in fact, this is the Cherry garden of England *par excellence*, though other fruits are grown and the acreage of mixed plantations is constantly being increased. The soils upon which the greater part of the fruit is grown in this part of East Kent are clays and loamy clays of the Thanet beds; the "plastic clays" of the Woolwich and Reading beds, and of the Oldhaven beds, as at Selling. These all crop up variously in this locality, and overhang the chalk, whose hills form the range known as the "back-bone of Kent," stretching through the whole upper part of East Kent, through North and West Kent. There is an almost continuous stratum of the Thanet beds above the chalk from Rainham to Sittingbourne, upon which the fruit is principally grown. Between Sittingbourne and Boughton Bleau, the limit of the fruit-growing line, the Woolwich beds—the middle division of the lower London Tertiaries—appear in alternation with the lower series of Thanet beds. To these formations the upper parts of East Kent owe their fertility. Upon these most of the orchards, plantations, and Hop grounds are situated. A small proportion only is placed directly on the mere surface-marls of the chalk. In Mid Kent the fruit plantations are upon the Hythe beds of the Lower Greensand. The best and most productive soil is the clay loam on the beds of "Kentish Rag," in the neighbourhood of Maidstone, upon which all fruit trees do well. Mr. Topley comments as follows upon this:—"The most fertile district of the Hythe beds is that near Maidstone. Enormous quantities of Hops are grown here, and also Filberts and fruit."

Fruit is grown also upon the lighter and "stone shattery" soil of the Hythe beds, but the greater bulk of it is produced upon the ragstone soil which is undoubtedly, as Mr. Topley suggests, more fertile in the neighbourhood of Maidstone than elsewhere. The Thanet, and the Woolwich and Reading beds are found in the third fruit-growing division of the county; by their super-position over the chalk, making the district eminently suitable for the production of fruit. It is curious to note how sharply the fruit-growing line is defined here, and how perfectly concurrent it is with the outcrop of these beds, running from Halstead, near Sevenoaks, to Chelsfield, then, after a break, to Orpington, and on through the Crays. Until quite recently, Apples were the only fruit grown

in the Weald, though in the last ten years other fruits have been cultivated. In the term "Weald," as locally used, the whole of the district in Kent "under the hill," or southward of the Lower Greensand formation, is included. Geologically, it comprises the Weald Clay and the various sands and clays of the Hastings Sand. Fruit does well on the former, as at Marden, Staplehurst, and Cranbrook, and upon the Grinstead Clay of the latter formation, as, for instance, at Brenchley and Horsmonden. An improvement has taken place in the management of fruit-land in Kent during the past twenty-five years; and at the same time greater facilities of transit and a steadily increasing demand have led growers to add largely to

their plantations. This is proved by the Agricultural Returns for 1875, which show an increase of 846 acres in 1875 over the returns of 1874; the acreage of arable or Grass lands used for fruit in Kent being 12,032 acres against 11,186 in 1874. Foreign competition has assumed enormous proportions, and is becoming more formidable each year. This has stimulated Kentish producers to pay greater attention to the cultivation and management of fruit-land, as well as to the selection of better and more attractive sorts. In those parts of the county where the soil and climate are suitable, the production of fruit is very great and the quality is for the most part good. The area, however, of land that is specially adapted to the successful growth of fruit is limited and confined, as has been shown, to a few districts sharply defined by peculiar geological features. Situation, or the "lay of the land" as it is called by the natives, has also its influence in deciding whether land is fruit-land proper, just as in Hop-growing certain aspects and position

Wall of Peach trees in the Potagerie at Versailles, engraved from a photograph taken in April, 1877, by Jules Lemercier. Showing the trees when in flower and before the young shoots begin to cover the surface between the erect branches. The trees are protected from frost during the flowering season by a straw mat temporarily fixed on the top of the wall. These trees, having vertical shoots, are quickly and easily formed. The wall is perfectly covered with the trees as shown in the engraving, in which no alteration from the photograph whatever has been made.

are essential, *ceteris paribus*, to constitute really first-rate, "lucky" Hop-land.

Though a certain amount of improvement has taken place in the methods of fruit-culture, there is much still to be done as regards the methods of planting, the actual cultivation, and the pruning of the trees. The delicate and important operation of pruning, which makes all the difference between high and low production, is, it must be confessed, but imperfectly understood by Kentish fruit growers, and their tree-cutters or pruners. Instead of the careful selection of the wood most likely to bear fruit—in place of a *raison d'être* applied to every stroke of the knife—the typical tree-cutter hacks and slashes away ruthlessly, aiming principally at obtaining a symmetrical

cup-shaped form rather than at retaining the wood most likely to bear fruit. He is paid by the tree, and cannot afford pauses for reflection as to individual shoots or buds, like the careful interested pruners in France and Belgium, or like some of the best English gardeners. He and his employers have certain rough-and-ready formulas which guide the knife, as for example, "Black Currants bear on this year's wood, therefore all old wood should be cut away;" and the general idea pervading the mind of the pruner is that he cannot cut Black Currant bushes too hard. In the case of other bushes—Red Currants, for instance—the fruit is for the most part developed on the old wood, therefore all young shoots are religiously excised. There is this to be said, that where a grower has 40 or 50 acres of fruit, it would be practically impossible to give each tree, each shoot, each bud the individual attention that is given to the cordon-trained trees of Mid-central France. With regard to Apple trees, their pruning is performed in the most desultory manner. In many cases they have not been pruned for generations, and are overgrown with unproductive branches. Now and then it happens in some orchards—to use the graphic words of a correspondent—"that an ordinary workman is sent in with a saw to cut the Apple trees, and is expected to earn more than his money in faggots." It was formerly the prevalent notion, still holding to some extent, that fruit trees require but little manure. Apple and Cherry orchard-lands were mown or fed off with lean sheep year after year, with the result that the trees only bore a crop once in two years, and the fruit grew small by degrees and beautifully less. The owners of the celebrated Cherry orchards in East Kent have found out the folly of starving the trees. For the last few years they have manured the land liberally with manure brought from the London stables and cow-sheds, which has largely increased the quantity and improved the quality of the fruit. Sheep fed with corn and cake feed off the Grass, and it is now quite the exception to mow orchard-land. The cultivation of fruit affords constant work of a comparatively pleasant and easy nature to very many hands throughout the summer. Picking all fruit but Apples is usually done by women, who are paid by the day, or by the sieve or bushel and who earn from 1s. 6d. to 2s. 3d. Packing is performed by careful men, who arrange the fruit in sieves so that it may appear to the best advantage, covering it with paper, dried Grasses, or Fern leaves, and fastening it down with transverse sticks laid across. The East Kent growers send their fruit by rail and steam-boat to London. Nearly all the fruit grown in Mid Kent is forwarded by rail. In a good year the railway stations in the chief fruit-producing localities are thronged with vans laden with fruit, from the early green Gooseberry season, in May, until the Apples have all been gathered, at the end of October. Many of the West Kent growers, being near London, send up their fruit by road. As a rule, the best fruit is sent to Covent Garden—"The Garden," as it is styled—to the Borough, and Spitalfields Markets. Very choice fruit, however, generally finds its way to Covent Garden. A large proportion of the fruit is consigned to salesmen, who first satisfy the requirements of fruiterers, greengrocers, and "costers," for retail purposes. Afterwards the agents of large jam and preserve manufacturers at Liverpool, Manchester, Birmingham, Glasgow, and other towns, buy enormous quantities; the inferior and damaged qualities go to smaller houses for smashing up into a heterogeneous mass, named in accordance with the demand. In some cases Strawberries, Raspberries, and Currants are sold by the growers to contractors by the ton. To give an idea of the extent of jam-making, the "Liverpool Courier" stated lately that at a manufactory at Bootle about 15 tons of preserves are made in one day in a good fruit season. The large towns in Scotland chiefly take Damsons, Black Currants, and Warrington Gooseberries. It might be supposed that Kentish fruit-growers, only forty miles distant from London, would not be affected in any great degree by the competition of foreigners in the matter of soft fruit, *i.e.*, fruit of a perishable nature, as Gooseberries, Raspberries, Currants, and Strawberries; yet, as a fact, the cost of carriage of a ton of fruit from France to the London Docks is no more than from Maidstone to the London markets. Rents and labour are cheaper in France and Belgium, while the climate of the former country is far more suited for the

production of fine well-flavoured fruits than our own. M. Bréhaut remarked upon the point that "in making any comparison between the state of fruit cultivation on the Continent, as compared with that in England, it must always be borne in mind that much of the land devoted to the purpose is, as regards climate and soil, the best in the world." Continental growers are able to send fruit to London earlier than the home producers. They send Strawberries, Cherries, and other fruits in quantities, and "take the edge off the appetite of the people," to use the forcible remark of a worthy salesman, "before Kent Cherries are fit to eat." There is, however, the solatium that if Kent growers do not get the first "pull," they have the field pretty well to themselves for a time, after the foreign soft fruit season is over, before the Gages, Plums, Apples, and Pears are ripe. Still, in spite of all the advantages possessed by the "foreigners," their fruit is not so good, taking it generally, as that grown in Kent, which is acknowledged to be, on the whole, better than any other that comes to London. Fruiterers and salesmen say that the foreign fruit has much improved in flavour and size, and is steadily improving, while the imports are increasing year by year, as may be seen by the returns of the Board of Trade, which show that the total amount of "raw" fruit imported into England in 1875 had reached the enormous amount of 2,220,412 bushels, as against 1,128,568 bushels in 1871. France sends Strawberries, Cherries, Red Currants, Gages, Plums, Pears, and Apples; and sent to this country 581,170 bushels of "raw" fruit in 1875, against 354,606 bushels in 1871. Plums and Currants arrive from Belgium and Holland. Apples and Pears are imported from Spain. Immense quantities of Apples come from America, of fine quality and flavour, almost equal to Ribston or Cox's Pippins in good seasons. These arrive generally in excellent condition, being packed in barrels like oil-cake; and they interfere much with the price of Kentish Apples. For example, last year, Newtown Pippins of splendid appearance and excellent quality were selling at rates which materially depreciated the value of the best Kent Apples, of which the crop was very small. There can be no doubt that so long as sugar continues to be cheap the demand for fruit will be, as now, enormous, and will probably absorb even a largely increased supply. At the same time, such large additions are being steadily made to the home and foreign plantations, that Kent growers, though they plant on, do it with a degree of anxiety which makes them, and ought to make them, most careful in their selection of proper kinds of fruit for their new plantations, as well as in the renovation and cultivation of those that have been long established.

Having glanced at the history and conditions of fruit-growing in Kent, it will be well to describe the methods of cultivation usually adopted. Two principal systems or methods of planting fruit prevail in Kent: one according to which it is intended that the land under the standard trees shall be eventually laid down with Grass; the other, where the land will always be cultivated and kept constantly filled up with fruit trees, and bushes under the standards or half-standards. East Kent growers for the most part adopt the former method, because it is not good for Cherry trees that their roots should be disturbed after a certain time. The standard trees are planted first on well prepared arable land, with Hops or fruit bushes, which give a return until the standards come in. When these have arrived at a good size the Hops and bushes are taken away and Grass seeds are sown. Apple orchards are occasionally formed in this way; but Apples are generally grown on the other system—in permanent plantations set out and planted with Plums, Damsons, Gooseberries, and Currants (and Filberts in some parts of the Mid Kent district), which are renewed from time to time as occasion requires. In an orchard which is eventually to be laid down with Grass, the standard trees, if Cherry trees, are set from 24 ft. to 33 ft. apart each way, giving from forty to seventy-five trees to the acre. If Apples be planted they are set about the same distance apart. Plums or Damsons are very often put between the Apples or Cherries, and are taken out when they get in their way. In a plantation that is to be permanently cultivated, the Apple trees are set about 30 ft. apart. Plums or Damsons would be set in between

each Apple tree, and Gooseberries or Currants between the rows, $6\frac{1}{2}$ ft. apart, so that there would be forty-four Apple trees, forty-four Plum or Damson trees, and 1031 bushes on each acre. Where Filberts are grown under Apples, they are usually planted about 13 ft. apart, which would give about 257 trees to the acre, and Plums or Damsons are not generally planted in this case. The cost of preparing the land and of planting it as a mixed plantation, with all incidental expenses, varies from £16 to £20 per acre, according to the sorts and number of trees planted. Apple trees cost 1s. 6d. each as an average. Plums and Damsons 1s. each. Filbert and Cob trees 4d. each. Gooseberry and Currant bushes from 10s. to 14s. per 100. The annual average cost of cultivation, including rent, interest on outlay, tithes ordinary and extraordinary, rates, maintenance, and other expenses, exclusive of all charges connected with picking and selling the crop, which would, of course, depend upon its amount, ranges from £13 to £16 per acre.

(To be continued).

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Fruit of the Parsley-leaved Bramble (*Rubus laciniatus*).—Just now, when hardy fruits are scarce, this merits attention. At Castle Ashby Mr. Beech has a remarkably fine example of it laden with clusters of ripe fruit, which is three times as large as that of the common Bramble. It is jet black in colour when fully ripe, and has an agreeable flavour. At Castle Ashby it is planted against a pillar, and the branches have been trained along stout wires right and left till it has reached a distance of 30 ft. It grows freely and fruits abundantly, and, apart from its fruit, it is a good ornamental plant. It is attractive in leaf, still more so when in flower, and additionally so in fruit.—D.

Strawberries in Pots.—These should stand thinly in some open situation where they can receive as much sunshine as possible, removing all runners and weeds. If by any chance worms have found their way into the pots, a good watering with lime-water will dislodge them without injuring the plants; this is an evil which ought, however, to have been guarded against, by either setting the pots on beds of ashes, or on some other impervious substance. Two or three good waterings with liquid manure will, now that the pots are filling with roots, be beneficial at intervals of a week or so, but it must not be continued too late, especially if the plants be intended for early forcing, or it may excite their crowns too much, and so delay that maturation which is so essential to the production of a good crop of fruit.—E. H.

Gathering Pears.—Pears, as might have been expected, are later than usual this year, and being only a light crop the most will have to be made of them. The Bon Chrétien and the Bergamote must not be allowed to hang on the trees too long, or they lose that juicy richness which a good Pear ought to possess. Gansel's Bergamot is a delicious autumn Pear if gathered in time, that is, as soon as the stalk can be got to part from the tree, whereas if allowed to hang a few days too long it would be no better than a Turnip. To make the most of these Pears this year they should be gone over several times so as to catch them the moment they are fit for gathering. That favourite autumn Pear, Marie Louise, may hang on the tree as long as it will without losing any of its richness of flavour, and in this way the season can be prolonged, but it should be netted up from birds and wasps.—E. H.

The Pomegranate in America.—General Stoneman is cultivating the Pomegranate to the extent of 5000 trees at San Gabriel, Los Angeles County, and thinks that he can make it succeed in the eastern markets by sending it there in large quantities in proper cars for the purpose. This may be classed among promising experiments.

Unfermented Wine.—At a late meeting of the Potomac Fruit Growers' Society, Dr. Goss, in a paper on the Preservation and Utilization of Fruit, gave his plan for making wine from Grapes and other fruits without fermentation as follows:—Press out the juice from the crushed fruit; then add one-fourth as much water to the pomace as there is juice, which is pressed also into the same vessel. This addition of the water causes the juice to settle or filter more readily. When settled, boil to one-third the quantity of the pure juice first pressed out, in a glass, stone, or porcelain-lined kettle set in another vessel containing water. To each quart of this syrup add a tablespoonful of salt. In this way wines may be successfully made from various fruits. All should be well corked and kept in a cool place, and they will keep for years.

THE FLOWER GARDEN.

THE PARIS DAISY

(*CHRYSANTHEMUM FRUTESCENS*).

This is a vigorous half-hardy plant in one season forming, when planted out, bushes 3 ft. in height, and as much in diameter. It is much branched, and very symmetrical in habit; the foliage is pinnate and fleshy, of a glaucous blue colour; the flowers are large, pure white, with a yellow centre, and produced in the greatest profusion from June, until cut down by frost. This plant is extensively grown on the Continent for summer bedding as well as for pots. It is of far greater value for winter flowering than for any other purpose. Plants now in $4\frac{1}{2}$ -in. pots, if preserved from frost, will produce abundance of flowers until January. It is readily propa-

gated from cuttings, grows in any ordinary loamy soil, and must be considered a desirable plant for all who appreciate white flowers during the winter months. P.

LIMNOCHARIS HUMBOLDTI.

THIS interesting aquatic plant covers the surface of the water in which it is planted with broad, heart-shaped leaves of a beautiful glistening green, and soft yellow flowers, which last in beauty for several months. It commences, as a rule, to flower in August, and continues in blossom till quite late in the season; it will thrive either in running or still water, planted from 6 in. to 9 in. below the sur-

face, and I have even seen it successfully grown in tubs sunk in the ground. The tubs, which should be about $1\frac{1}{2}$ ft. in depth, should be half-filled with loamy soil, and then filled up with water. The overflow from these tubs converts the ground in their neighbourhood into a kind of artificial bog, in which may be grown *Sarracenia purpurea*, *Pinguiculas*, *Primulas*, *Ranunculuses*, *Grass of Parnassus*, and many other interesting plants of kindred character. A. P.

SPRING BULBS.

Crocuses.—Now and onwards to the end of November is a good time to make plantations of Crocuses. They should be obtained not later than the end of September, and when got they should be spread out in a dry, cool place till wanted for planting. Bulbs obtained at the end of November or beginning of December frequently fail—they are kept in a heated place, and consequently dry up—they have to be kept turned over for the purpose of picking out any that

may have decayed, when the shoots and skins are frequently rubbed off, and there is this positive advantage about early planting that, the sooner the bulbs are in the ground the sooner will they begin to make root and establish themselves. In planting dig out a trench 9 in. in depth and 4 in. in width at least; break up the soil at the bottom, and then put in 3 in. in depth of a mixture of decayed cow manure, leaf-mould, loam, and some finely sifted mortar rubbish; on this put a single line of bulbs, with a little rough white sand about them, and then cover it with some good loam. Deep planting is absolutely necessary, as the young bulbs are formed above the old one, which decays, and thus the roots are brought nearer the surface every year. Another advantage in planting deeply is that the bulbs are safe from harm when the surface soil is gently forked over in autumn. When the shoots are coming through the soil, if it be stirred and some good manure added as a top-dressing, the plants will derive much benefit from the application.

Hyacinths, Narcissi, and Tulips.—The forcing season, as regards these bulbs, has commenced in nurseries around London where plants are grown for market. Certain varieties of Hyacinths, a few of the early single and double Tulips, and the double Roman and Paper-white Narcissi are used for the purpose. They are grown both for their flowers in a cut state and for marketing in the shape of plants, and they are planted in large or small pots accordingly. The bulbs reach the growers by the middle or August; they are then potted, and placed on an ash bottom in the open air, and then they are covered with 6 in. of manure and spent Hops. Watering is left to what rain may happen to fall. The bulbs soon make growth, and as soon as they get near the time for throwing up their trusses and spikes of bloom, they are taken indoors. The early Roman Hyacinth and the double Roman Narcissus reach England in August, and they are prepared for forcing at once. This explains how blooms of the Roman Hyacinths can be seen in Covent Garden market in October.—D.

Clematises at Kew.—Like the Tricolor Pelargoniums and many other popular flowers, there is rather too much sameness amongst Clematises, especially the hybrids from Jackmanni. The subjoined half-dozen I selected the other day at Kew are good and distinct. They are planted round the edge of one of the large beds of shrubs, and trained to stakes. Except for purposes of comparison this is not the best way of training them, but no matter in what manner they are treated, when in flower they are very effective, especially when looked at from a distance. The following are the kinds just alluded to, viz., Otto Froebel, white very large; Sensation, greyish mauve; Madame Van Houtte, white shaded with blue; Lady Bovill, very distinct shade of mauve; Thomas Moore, puce-violet; Flammula maritima, white, sweet-scented. The last is a very desirable acquisition, evidently a free vigorous grower, with larger flowers than Primulas.—E. H.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Christmas Roses.—These have grown well this season, and whether in single clumps in borders or in beds, a surface-dressing of some good rotten manure and leaves will be found to be of great benefit, as it will induce the production of blossoms. If in beds, they should be cleaned before adding the dressing, and it may also be desirable to previously break up the surface-soil.—D.

Climbing Rose, Reve D'Or.—As a climbing Rose, Reve d'Or has been strongly recommended (for the south of England) for covering the walls of houses. Planted seven years ago at Westwell Vicarage, it now covers a space of 24 ft. high by 12 ft. broad on the east aspect, and has gone round to the north side, covering a space there nearly as large; the stem is 12 in. round, and from within 1 ft. of the ground to its very outmost branches it is covered with bunches of blooms, thousands upon thousands, in all stages of development. It is in colour very like Madame Falcot; the description of Madame Falcot would also apply to this. There has been no peculiarity of treatment, it has been allowed to run away as it liked, but its most vigorous habit has led every year to the thinning out of an immense quantity of shoots.—"Florist."

PLATE XCI.

BURSER'S SAXIFRAGE.

(SAXIFRAGA BURSERIANA).

Drawn by H. HYDE.

ALL Saxifrages are beautiful, either as regards leafage or bloom, but none even of the conspicuous flowering kinds surpass this in vernal beauty. The plant is of dwarf, indeed, almost Moss-like habit, forming broad patches and spreading rapidly over the earthy interstices of warm, moist sandstone rockwork, if planted where it does not suffer from stagnant moisture. The blossoms are borne singly on slender red stalks, which rise 2 in. or 3 in. above the general surface of the plant, and are, as will be seen, pure white, the margins of the overlapping petals being elegantly frilled or crisped. Interspersed among the fully-expanded flowers the unopened buds (which are of a dullish crimson-brown colour) show themselves to excellent advantage, and enhance the pearly whiteness of the petals. Of all Alpine Saxifrages this merits the most attention. It belongs to a group which is the most interesting of the genus, comprising, as it does, such kinds as *S. Vandelli*, *squarrosa*, *Tombeana*, *calyciflora*, *cæsia*, *diapensioides*, and a few others. *S. Burseriana* flowers in January and February before the Snowdrops, and even before the flowers are expanded, the brownish-scarlet buds, just emerging from compact silvery tufts of foliage, have a cheerful effect. It flowers very freely and soon forms good-sized tufts in the open border or on rockwork, preferring a dry sunny situation and calcareous soil. The annexed figure was prepared from a plant lifted from an open border in the Hale Farm Nurseries, Tottenham, where it had been growing for several years. It is a native of the Austrian Alps, and a plant that all lovers of hardy spring flowers should possess.

Burser's Saxifrage (*Saxifraga Burseriana*).

Double Rockets.—Now is the time to obtain cuttings of these and also to plant out the side shoots in some fine soil, into

which they soon root. There are two distinct forms of the Double White as well as of the Double Purple Rocket in cultivation. The former is a tall-growing white, which turns to a pale flesh-colour with age; the other is the old white variety, of dwarfer growth, and with smaller and more compact flowers. The latter is very scarce indeed. It can be met with in the neighbourhood of Manchester and elsewhere in the north, but it is little known in the south, where it does not flourish so well as the common variety. There is the old Purple Double Rocket and a free-growing dwarf form known as Compactness, which has also larger and darker flowers. This can be easily propagated. During the autumn and winter months snails are very fond of the plants. They attack the white much more than they do the purple forms.—D.

A Wistaria-covered Cottage.—The Wistaria may often be seen on the walls of cottages, but seldom covering the whole roof. I noticed, however, the other day a cottage near Gravesend entirely covered with it. It was planted on the south side near the doorway, and numbers of large spreading limbs stretched themselves all round the sides and over the roof; indeed, the house was almost hidden amongst green leafage and a second crop of flowers. By training this plant on all sides of the house a great advantage is gained, inasmuch as the flowers are produced on the different aspects in succession, and by the time the latest blooms are over on the worst exposure a second crop is produced on the sunny side.—S.

Art Studies.—I would advise all the *chefs* and *cordon bleus* of the great clubs to take a walk down the line of ornamental flower beds skirting Park Lane. They will there see specimens of chromatic floriculture that would be invaluable patterns for *mayonnaise* and other salads.—"The World."

THE GARDEN IN THE HOUSE.

ASPIDISTRAS.

THESE were formerly placed in the Arum family; they are, however, undoubtedly Liliaceous plants. From the elasticity of their constitution, they have long been favourites, especially in France, for the decoration of apartments. Keep them fairly watered, sponge the leaves now and then, and there is scarcely a limit to their endurance, even under such conditions as would totally fail to keep life in very many of our common hardy flowers. The two plants mentioned in these notes furnish excellent examples of species that will thrive well in drawing-room, stove, greenhouse, and in warm spots in the open border. As at present restricted by Mr. Baker, the genus *Aspidistra* contains but one species, *A. lurida*, a native of China, the Eastern Himalayas, and Khasia. *A. punctata* of Lindley is synonymous with this. The plant known so long under the name of *Aspidistra elatior* is now removed into the genus *Plectogyne*, and bears the specific name "*variegata*." It is indigenous to Japan. Not to mention its intrinsic merits,

Fig. 1.—*Aspidistra lurida variegata*.

very much interest attaches to it in consequence of the extreme peculiarity in the structure of the flower. The beautiful, smooth, glossy, striated, stalked leaves spring from thick, creeping rhizomes, and the flowers are borne singly on very short peduncles. So short are the flower-stalks that the flowers are often more than half buried in the soil. The bell-shaped perianth is of a dull purple colour, eight-cleft. The style is thick, and expands into a large discoid eight-rayed stigma that closes up the top of the tube as completely as the lid of a box. How

Fig. 2.—Immature fruit of *Aspidistra*.

fertilization is effected, many observers have been much puzzled to know. The eight stamens are inside the box, whose walls are dusted all over with pollen: but how this pollen finds its way to the stigma is the question. If the stigmatic plate be held upside down, four little holes are visible, and

according to Delpino's conjecture, minute insects crawl through these into the pollen-dusted box beneath, and emerge with pollen adhering to their bodies. They then fly to another flower, over and about the stigmatic rays of which they wander some time before finding another entrance. Be that as it may, fertilization very rarely takes place. Indeed, in Mr. Baker's revision of the genus in the "Journal of the Linnean Society" it is stated:—"Although the plant is not uncommon in our greenhouses, I am not aware that it ever produces fruit." Our figures represent two fruits from the respective establishments of M. Truffaut, of Versailles, and M. Touzet, of Paris. At first the fruit is deep green and extremely hard;

Fig. 3.—Fruit, section of fruit, and seed of *Aspidistra* (natural size).

when it arrives at full maturity it colours slightly and emits a Pine-apple odour. Figure 1 shows a plant with fruit *in situ*; fig. 2, an immature fruit; fig. 3, fruit natural size, and section of ditto; also seed natural size. G.

NOTES ON MR. ELLACOMBE'S PLANT-LORE OF SHAKESPEARE.

SHAKESPEARIAN readers are much indebted to any one, who, like Mr. Ellacombe, brings his special knowledge of a particular department of science to bear on the illustration of their author. I have not the presumption to question any of his botanical statements: but from the broader stand-point of Shakespearian criticism, there are some which seem to me open to exception; and in the expectation that the papers on "The Plant-lore of Shakespeare" will be reproduced in a more accessible form, I have thought it desirable to submit certain corrections for his consideration; at all events, the statements questioned are fair subjects for discussion in the pages of the journal in which the papers have appeared. I trust I shall be believed in saying that I offer my remarks in no carping spirit, and with unfeigned respect for the author of the papers criticised. The supplying of a few omissions will perhaps not be considered an impertinence.

Apple.

Mr. Ellacombe is entitled to his own opinion on the heretofore vexed question whether, in his quotation No. 12 "Caraways" is meant for a kind of Apple, or for Caraway seeds. He has, no doubt, duly considered all that has been written on the subject: but by the generality of readers the following quotation from Cogan's "Haven of Health," 4to, London, 1595, which, from consideration for your space, I select from a number of passages, cited from Shakespeare's contemporaries in the Variorum Shakespeare, will be deemed conclusive against him:—"Howbeit we are wont to eate Carawaies, or Biskets, or some other kind of comfits, or seedes, together with Apples," adding medical reasons not necessary to be here reproduced. And as late as the middle of the seventeenth century Ralph Austen, in his "Treatise of Fruit Trees" (p. 79, 2nd ed., 4to, Oxford, 1657) says:—"If Apples offend any through winde, eat with them ginger or other hot spices, or Carroway seeds, Fennell seeds, or the like." The practice of eating ground ginger with Melon (no doubt for the same reason) is within the recollection of the present generation. Has the Caraway Apple any resemblance to the Kerry Pippin? If so, the one name

may be a corruption of the other; if not, I should suppose the former to derive its name from being a sort suitable for eating with Caraway seeds, or, in other words, from its being specially regarded as table rather than culinary fruit.

Having deprived your correspondent of his Caraway Apple, I will make the best amends in my power, by supplying him with another, which is omitted from his list, viz. :—

Mercutio. Thy wit is a very bitter-sweeting : it is a most sharp sauce.
Romeo. And is it not well served in to a sweet goose ?

Romeo and Juliet, act ii., sc. 4.

Bachelor's Button.

This flower, though not exactly named by Shakespeare, is believed to be alluded to in the following passage :—

Hostess. He will carry't, he will carry't; 'tis in his buttons; he will carry't.

Merry Wives of Windsor, act iii., sc. 2.

The supposed allusion is to a rustic divination, by means of the flower, carried in the pocket by men and under the apron by women; as it was supposed to retain or lose its freshness according to the good or bad success of the bearer's amatory prospects. With the botany of this or any other plant I may have to mention, I do not meddle.

Balm.

In the statement that in Nos. 10 and 11 the reference is to the *Melissa officinalis*, there is no doubt a misprint or erroneous reference for Nos. 13 and 14. In Nos. 10 and 11, as in all the Nos. from 1 to 12, the allusion is to the medicinal confection.

Broom (see Furze).

Caraways.

If what is above written under Apple be the explanation of the passage from "2nd Henry IV." Caraways, as a spice, will be as much entitled to a note of its own as Cloves or Mace, Nutmegs or Coloquintida.

Cowslip.

Has Mr. Ellacombe nothing to tell us about "the crimson drops i' the bottom of a Cowslip"? It is beyond my province to do more than point out that the commentators have taken exception to the phrase.

Cypress.

In the quotation No. 2, Cypress is not the name of a plant, but of the textile fabric now called Crape. It is a mere variation in the spelling of "Cypres," or "Cyprus."—the "sable stole of Cipres lawn," of Milton's "Penseroso." In the quotation I copy the spelling from the editio princeps of Milton's Poems (1645). We have the same word in the "Winter's Tale," act iv., sc. 3—"Cypresse blacke as ere was crow," as the first folio prints it: but Mr. Ellacombe rightly omits the passage, because modern editors (correctly enough if the spelling must be modernized) print it "Cyprus." In quotation No. 4 (in which there is a misprint of act ii., sc. 4 for act ii., sc. 1) it may admit of question whether we are to understand chests made of Cypress wood, or chests used for keeping Cyprus garments. I incline to the former, though there is perhaps a parallelism to justify the latter, in the mention of a "satin coffer" in "Pericles," act ii., sc. 1.

Fennel.

The virtues of Fennel, as enumerated in the quotations from Longfellow, do not comprise either of those attributes of the plant which illustrate the two passages from Shakespeare. The first alludes to it as an emblem of flattery, for which ample authority has been found by the commentators. Florio is quoted for the phrase "Dare finocchio," to give Fennel, as meaning to flatter. Why, I know not, as no explanation is given: but in attempting to ascertain, I observe, for what it may be worth, that in Spanish the same word "hinojo" means both Fennel and the knee. In the second quotation the allusion is to the reputation of Fennel as an inflammatory herb, with much the same virtues as are attributed to Eringoes.

Fig.

In some, if not all, of the quotations 5 to 11, the reference is not to the fruit so named, but to an insulting gesture, called

"making the fig," the explanation of which is too unwholesome a subject to be here discussed: but see "Douce's Illustrations of Shakespeare and Ancient Manners," l. 492. This is certainly the case whenever the word *fig*, *figo*, or *fico* is used as a term of contempt; but in a few cases it is questionable whether it be not an allusion to the practice of murdering by means of a poisoned Fig.

Furze.

In the second quotation, "long Heath, brown Furze," is certainly the usual reading; but the passage has been the subject of an emendation by Sir Thomas Hanmer, which seems to me to be entitled to more general acceptance than it has met with, and at least deserves notice in a paper with the objects of that under discussion. Gonzalo, in imminent danger of shipwreck, says—"Now would I give a thousand furlongs of sea for an acre of barren ground—Ling—Heath—Broom—Furze—anything"—anything that is land, however worthless for purposes of cultivation. Gonzalo, in his extremity, did not apply a distinctive epithet to Furze, to enable future botanists to discriminate between *Ulex europæus* and any other plant. Mr. Ellacombe seems to have been aware of the emendation, from his allusion to the first half of it under Heath and Ling. In his paper "furlongs" is misprinted "acres." See my note on Shakespeare's use of "furlong" as a measure of space, in "Notes and Queries" of the 23rd June last, and subsequent correspondence on the subject.

Gilliflower.

Mr. Ellacombe is no doubt right in connecting the Gilliflower with the Carnation; but the question is, what Shakespeare meant by it; and in the passage cited under the latter heading, from the "Winter's Tale," he shows, by naming both, that he was speaking of different flowers. At all events, under one or other heading should have been quoted :—

Polixenes. Then make your garden rich in Gillyvors,
And do not call them Bastards.

Winter's Tale, act iv., sc. 3.*

In both the passages the word is printed "Gilly-vors," or "Gillyvors," in all the folios; and the most recent editions, Cambridge, Globe, &c., recur to the old spelling, for which the commentators give an additional reason, not perhaps necessary to be here discussed.

Holy Thistle.

For "those," line 11 from bottom of page, read "thou."

Hyssop.

The passage from "Othello" wants elucidation; for the aptness of the selection of the plants named in it is by no means evident, and the commentators, so far as I am aware, have not discussed it. The following passage from Lillie's "Euphues, the Anatomy of Wit," sign. A, 7, ed. 1617, may help to throw light upon it, or at least be suggestive to others :—"They might also have taken example of the wise husbandman, who, in the fattest and most fertile ground, soweth Hempe before Wheat, and graine that drieth up the superfluous moisture, and maketh the soyle more apt for corne; or of good gardeners, who, in their curious knots, mixe Isope with Time, as aiders the one with the others; the one being drye, the other moist." Mr. Ellacombe's remarks, s. v. Strawberry, on the antipathies, &c., of plants have a bearing on this subject.

Ivy.

Having no objection to make, or correction to offer, I am perhaps going beyond my declared object in suggesting a botanical point. In quotation No. 4 it will be observed that it is by the seaside where the shepherd expects to find his sheep browsing on Ivy. In this passage Shakespeare has closely followed the prose novel, on which, as is well known, the "Winter's Tale" is founded, namely, Robert Greene's "Pandosto; or, the History of Dorastus and Fawnia." In the novel the shepherd "waundered down toward the sea cliffs, to see if perchance the sheep was browsing on the 'Sea Ivy,'"

* I adopt Mr. Ellacombe's numbering of the scenes, but in the Globe Edition, which follows the authority of all the folios, the scene is numbered 4, the chorus forming the first scene.

whereon they do greatly feed." Would it not be worth while to inform us whether this is or is not any other plant than the *Hedera Helix*, or whether it is only to be found on the sea-coast of Bohemia, or elsewhere in the land of Faerie?

Mustard.

Comparing this with other headings, I fail to discover where the line is drawn between Shakespeare's mention of the growing plant and that of its produce, or for what other reason the subject is dismissed without even the quotation of the Shakespearean passages in which the word occurs, which are six in number, besides three in which Mustard-seed occurs as the name of a fairy in the "Midsummer Night's Dream." The condiment, in the form in which we now expect the grocer to provide it, does not date from an earlier period than 1720, when Mrs. Clements, of Durham, having conceived and put in practice the happy thought of grinding the Mustard seed fine in a mill, and bolting and dressing it in the same manner as wheat flour, obtained the patronage of George I., and made her fortune by vending her celebrated Durham Mustard. But even in Shakespeare's time there was probably some mode in which it was prepared for sale, as appears from "2nd Henry IV.," act ii., sc. 4:—

His wit is as thick as Tewkesbury Mustard.

Ray, in relation to a Gloucestershire proverb in which Tewkesbury Mustard is mentioned, says it refers to the "*Mustard balls* made there and sent into other parts;" but the earliest edition of Ray's "Proverbs" I have at hand to refer to was published long after the date of Mrs. Clements' preparation. Usually the seed was roughly ground in the quern, or hand mill, in which condition it may have been used dry, as we now use pepper. That the grinding of it was part of the ordinary domestic economy is shown by a passage in Scot's "Discovery of Witchcraft," 4to, London, 1584, in which he mentions that the maids were wont to set a bowl of milk for Robin Goodfellow 'for his pains in grinding malt and mustard and sweeping the house at midnight.' In the Christmas Husbandry fare described in chapter xxix. of Tusser's "Five Hundred Points of Good Husbandry," 4to, London, 1610, "good Mustard" is one of the articles enumerated, in precedence even of more substantial viands:—

"Good bread and good drinke, a good fire in the hall,
Brawne, pudding and souse, and good mustard withall;
Beefe, mutton, and porke."

And in the "Taming of the Shrew," act iv., sc. 3, it is spoken of rather as a special relish than an ordinary seasoning like salt or pepper.

Palm Tree.

In the passage No. 5, the propriety of the comparison of Timon in his adversity with the Palm arises from the belief in its power, not only to bear up against, but even to benefit by, repression. Lillie's "Euphues, the Anatomy of Wit," sign. A. 8. v., ed. 1617, has:—"It is proper for the Palme tree to mount: the heavier you load it the higher it sprouteth." And Buttes, in his "Dyets Dry Dinner," 1599, quoted by Malone in relation to another passage, says:—"This tree is of a most aspiring nature: it will bear no coals [not submit to injuries]: it resisteth all burden, bearing it upward with his armes and bonghes." Bartholomew Glanville, "De Proprietatibus Rerum," fo., London, 1535, B. xvii., ch. 116, speaking of the Phoenix dactylifera, says:—"In the south countrey is a maner Palme, that is alone in that kynde, and none other springeth ne cometh thereof. But whan this Palme is so olde that hit faylethe all for aeye, then ofte it quyknith and springeth ayen of it selfe. Therefore men trowe that Fenix, that is a byrde of Arabia, hath the name of this Palme in Arabia. For he dyeth and quicneth and liveth ofte, as the forsayde Palme doothe, as Plinius saith there."

There is another passage in Shakespeare which, as the above quotation from Bartholomew Glanville in "De Proprietatibus Rerum" shows, ought to have been inserted either under this heading or that of "Date," namely—

Sebastian.

That in Arabia
There is one tree, the Phoenix Throne; one Phoenix
At this hour reigning there.

Tempest, act iii., sc. 3.

Mr. Ellacombe is perhaps right in omitting another passage:—

Horatio. In the most high and palmy state of Rome.

Hamlet, act i., sc. 1.

It is doubtful whether in this word, which Shakespeare has made familiar to modern ears, the allusion is to the Palm as an emblem of victory and the scriptural type of vigorous growth, or as the hunting term for the flat part of a stag's horn when at its full maturity (see Nares' "Glossary," s.vv. "Palm," "Palmy," and "Palmed Deer."). Of course, the word Palm in this sense is derived from the spreading frond of the Palm tree, or from their common original, the Greek *παλαμη* and Latin *palma*, the primary meaning of which is the palm of the hand.

Pear.

In an interesting paper by Mr. Hudson Turner "On the State of Horticulture in England in Early Times, chiefly previous to the Fifteenth Century," printed in the "Archæological Journal," vol. v., p. 301, it is stated that the Warden Pear had its origin and its name from the horticultural skill of the Cistercian monks of Warden Abbey, in Bedfordshire, founded in the twelfth century. Three Warden Pears appeared in the armorial bearings of the Abbey. The Warden pie retained its name long after it ceased to be served up in pastry, and became what we should now call a dish of stewed Pears, the only difference being that instead of Saffron we use a pink colouring matter, if any.

Pomegranate.

It would be ungracious to supplement Mr. Ellacombe's papers with remarks, however appropriate, not necessary either to illustrate the subject or to correct errors; but, as in the case of the Palm quotation from "Timon of Athens," so in No. 2 from "Romeo and Juliet," it is due to Shakespeare to notice a peculiarity in the plant which makes his mention of it specially appropriate. Mr. Knight, in a note which I cite secondhand from the New Variorum Shakespeare, has pointed out the attachment of the nightingale to the Pomegranate tree, no doubt noted by Shakespeare from some of the old books of travel; and quotes a similar remark from Russell's "History of Aleppo," adding that "a friend, whose observations as a traveller are as acute as his descriptions are graphic and forcible, informs us that throughout his journeys in the East he never heard such a choir of Nightingales as in a row of Pomegranate trees that skirt the road from Smyrna to Boudjia."

For "Batte's 'Dry Dinner,'" tenth line from the bottom of column, read "Buttes' 'Dyets Dry Dinner.'" The work is quoted above under Palm tree.

Primrose.

In first quotation for act v., sc. 2, read act i., sc. 6.

Quince.

The connection of the Quince with the preparations for Juliet's wedding deserves a little further illustration, as it seems to have had a symbolism connected rather with conjugal happiness than with its dedication to Venus, even assuming, on Mr. Ellacombe's authority, that the fruit sacred to her was the Quince. In Lillie's "Euphues and his England," sign. A. 6, ed. 1617, Euphues writes:—"I will be bold to counsell thee, knowing it never to be more necessary to use advice then in marriage. Solon gave counsell, that before one assured himselfe, he should be so wary that, in tying himselfe fast, he did not undone himselfe, wishing them first to eate a Quince Peare, that is, to have a sweet conference without brawles; then salt, to be wise without boasting." I have not succeeded in tracing the reference to Solon, unless it be found in a passage in Plutarch, giving an account of a law of Solon in relation to unfruitful marriage with an heiress, in which case he sanctioned a connection between the wife and one of the husband's nearest kinsmen of her own selection; and it was enacted that "such a new married wife should be shut up with her husband and eat a Quince with him." M. Dacier, or his English translator, has a note on this passage, that "the same ordonnance was observed in all marriages, the legislator

thereby giving to understand not only that the married couple were to abstain from giving each other hard words (for it is the quality of the Quince to sweeten the breath), but also that they should be watchful and intent upon their mutual safety and preservation, it being likewise the property of the Quince to deaden the malignity of poison and render it ineffectual." There is nothing in all this to connect the Quince with the Golden Apple of Venus, which she acquired by competitive examination for the inauspicious prize of the Goddess of Discord. Perhaps the tree she planted in Cyprus was a seedling from it; but writers on the subject, and more especially Prof. Martyn, in his edition of Virgil's "Eclogues," maintain that it was a Pomegranate.

Rue.

There is another Shakespearian passage which should have been quoted, viz. :—

Antony. Grace grow where these drops fall.
Antony and Cleopatra, act iv., sc. 2.

A comparison with quotation No. 2 shows clearly that Grace here means Herb of Grace, or Rue.

I do not understand Mr. Ellacombe to allege an etymological connection between Rue and Ruth, but only to trace a popular name from the original suggestion, prompted by similarity of sound, through the stages of Herb of Ruth, Herb of Repentance, Herb of Grace. In Shakespeare's hands the connection between Rue and Ruth is one of those verbal quibbles, the excessive use of which is, at least to modern taste, a blemish to his works. Another instance, applicable to the present subject, of this play upon words is perhaps contained in the following passage :—

Friar Laurence. In man, as well as herbs, grace and rude will.
Romeo and Juliet, act ii., sc. 3.

The passage from "Hamlet" is one which yet awaits explanation. Even in the utterances of insanity we expect a meaning, understood between the poet and his audience, though the language may be intentionally incoherent. Possibly the offer of Rue to the Queen contained a covert allusion to a supposed property of the plant, referred to in Barnabe Googe's "Four Bookes of Husbandrie." He says (p. 55 a., ed. 1586) that this herb "can not abide the presence of an unclean woman." With this clue I think I see a glimmer of meaning in the language and acts of Ophelia. "For me," she says in effect, "it is, as its popular name implies, the symbol of that grace which forms the topic of Sunday discourses; for you, it is a reproach to an incestuous life." The distinction, by a not very correct application of heraldic language, according to a favourite practice of the poet, is called wearing the Rue with a difference.

The respectable authority last quoted repeats the belief as to the prosperity, in this instance, of stolen goods. He says, "it delighteth in the shadowe of the Figge tree, and being stolne, as they say, it prospereth the better: it is sowed with cursing, as Cummin and divers others;" of which, he says, at p. 57 a., "it is sowed best, as they thinke, with cursing and execration, that it may prosper the better." I presume Mr. Ellacombe will disapprove of these cultural directions, but as they are of a peculiarly practical character, the readers of THE GARDEN may like to be acquainted with them.

Speargrass.

The reference to authorities in favour of the suggestion that Yarrow or Milfoil is meant is in such general terms that I know not whether this note will add anything to the materials for a decision on what is confessedly a doubtful question. Professor Lindley, in an article on *Achillea millefolium*, in Morton's "Cyclopædia of Agriculture," says "it is sometimes called Nose-bleed, because the leaf, loosely rolled together and put into the nostrils, causes, by an external blow of the finger, a bleeding of the nose, which proves more or less copious according to the state of the vessels within." Something of the same sort, but less to the purpose, is mentioned in the Appendix to Forby's "Vocabulary of East Anglia" (ii. 425), describing the use of it by way of amatory divination. Nose-bleed is found in the Botanical Glossary in Skinner's "Etymologicon Linguae Anglicanae," with the synonym of

Millefolium, and a similar notice of the property from which it derives its popular name. We have then distinct evidence of this plant being notoriously used for the purpose described by Bardolph: but whether it is what Shakespeare calls Speargrass is a question on which I do not venture an opinion. The objection that it is not in fact a Grass is, I suppose, equally applicable to the *Equisetum*, while in the one case its use for the purpose in question is a fact, and in the other it is, at best, an inference. As to a soldier pricking his nostril with a Reed, he might just as well have pricked it with his dagger. Similarity of sound, that *ignus fatuus* which has led so many critics into a bog, would point to *Asparagus*: for a compromise between the two corrupted forms "Spearge" and "Sparrowgrass" would bring us exactly to Shakespeare's word; but the plant does not seem applicable to the purpose alluded to.

JOHN FITCHETT MARSH.

Hardwick House, Chesham.

GARDENING IN EGYPTIAN DESERTS.

Of all lands which gardening might render beautiful none is so destitute of natural attractions or variety of surface as the great expanse of sandy desert (alternating, as it does, here and there with low mud flats or glaring snow-like deposits of salt), which extends right across Egypt, from the Mediterranean on one side to the Gulf of Suez on the other—a region in which salt sands and arid winds seem to have excluded even the most remote prospect of spontaneous vegetation, and where all the charm of plant life (doubly, nay immeasurably, more interesting amid such ultra-desolate surroundings) is, and must ever be, dependent on gardening art and industry. The completion of the Suez Canal, apart from facilitating European and Eastern commerce, has also been the means of introducing vegetation, more or less beautiful, into a locality where it was previously unknown; also, if report speak truly, of having rendered the climate, bad as it now is, more favourable for cultural purposes, since a current of cool air now flows along the Canal, and attracts the precious burden of the rain-clouds to a tract of hot sands previously destitute of showers. Of all Eastern nations the Arabs would appear to be the very worst cultivators of the soil, and wherever an artificial oasis is found one may generally trace its origin to an European owner. At Suez, for example, the houses of the French, English, and other European residents are draped with fresh green creepers, and the little gardens are gay with annuals and other flowers. Glancing down one of the little narrow streets leading to the shingly beach, I saw some picturesque old buildings, almost entirely covered with bright green leafage and large lilac-purple flowers, which at a distance of 100 yards or more I concluded to be a *Clematis*, although a little reflection told me that was impossible. A nearer view proved it to be *Batatas paniculata*, a most elegant-habited plant, having trailing stems 40 ft. to 50 ft. in length, clothed with digitate leaves like those of the blue Passion-flower, but of a brighter green tint; among the leafage is produced a succession of Ipomœa-like flowers, 2 in. or 3 in. in diameter. This plant is deservedly a favourite here, and is popularly known as the "Fochow Creeper," being as highly valued in China as it is here; further inland it is used to cover the light fences of yellow Reeds, around which it twines in a graceful way, reminding one of the pretty pink-flowered *Convolvulus* of our own cornfields and hedges. Happening quite by accident to meet with the hospital physician, Dr. Flood, a Norwegian, I had a good opportunity afforded me of seeing his garden, which is one of the most interesting in the whole place, and like most others here is protected from dust and winds by a close fence of *Arundo*. In the centre of one division is a specimen of *Pandanus utilis*, 20 ft. to 30 ft. in height, and much branched above; the common Bamboo reaches a height of 50 ft., forming large, feathery tufts, and the Date Palm (*Phoenix dactylifera*) grows fairly well. *Hibiscus Rosa-sinensis* was in great beauty, bushes 12 ft. high and with heads 12 ft. in diameter, covered with great crimson blossoms, each nearly 6 in. across; a tall growing *Erythrina*, which had been cut back a month or two ago, was sending up a great sheaf-like mass of wand-like, leafy shoots from the old trunk, each terminated by a spike of bright coral-tinted flowers. Passion-flowers luxuriate and

clamber from tree to tree at their own sweet will, with *Aristolochia ornithocephala* and the glossy-leaved *Tecoma jasminoides* for associates. I was agreeably surprised to find the Virginian Creeper growing moderately well in moist, shady positions, but with none of that wild luxuriance seen in the back gardens of London. That it is not a success here is not so much to be regretted, seeing that the "Fochow Creeper" is quite as beautiful in leafage, equally graceful in habit, far more luxuriant under a hot sun, and having moreover a floral beauty peculiarly its own. *Vinca rosea* and its white variety are perfectly at home here, forming compact bushes 2 ft. to 3 ft. high, and the same in diameter, and bearing flowers in abundance. Castor-oil plants attain a height of 12 ft. to 14 ft., becoming much branched, and they fruit much more freely than in the London parks. Some of the specimens I saw here are old and have thick, woody stems, but they possess none of that luxuriant leafage and freshness so commonly obtainable in English gardens during the summer months. Shade being so essential to comfort in a hot climate like that of Egypt, most of the walks which are not overshadowed by *Acacias*, *Mastic*, *Tamarisk*, or

Batatas paniculata on a house at Port Said.

Bamboo, are trellised over and covered by creepers. *Lantanas* of various kinds submit to this kind of culture, and with excellent results; indeed, I saw nothing whatever finer in its way than a covered or trellised path over which these plants had been trained. The hot, dry air and sun seem to suit their growth admirably, for here they covered the trellises with great fleecy masses of dark green foliage; this last, however, could scarcely be seen from above on account of the innumerable heads of flowers with which every bit of growth is studded. Succulent plants, such as green and variegated American *Agaves*, *Yuccas*, columnar species of *Cereus* and *Euphorbias*, grow luxuriantly, and one little summer-house was entirely covered, and that by no means sparsely, with an enormous specimen of *Cereus Macdonaldiae*, a scandent species, having jointed, triangular phyllodia, and large, white flowers, similar to those of the night-flowering *C. grandiflorus*, and equally fragrant. *Mesembryanthemums* are used here and there as edgings to the flower beds, and of course are perfectly at home, growing and flowering freely, and, being mixed, their crimson, pink, buff, yellow, and white star-like flowers have a

pretty effect. *Daturas* or *Brugmansias* form compact bushes, and flower freely, and the *Marvel of Peru*, which is, as a rule, so unsatisfactory in English gardens, is here a marvel of floriferous vigour and variety in the way of colour. Scarlet *Pelargoniums*, both single and double varieties, are evidently much admired, being found in conspicuous positions in nearly every garden, forming old bushes 2 ft. to 3 ft. in height notwithstanding the hot sun, however, they do not flower nearly so freely as younger specimens do in many Continental and English gardens. Large clumps of *Crinums*, *Malvas*, and single-flowered *Hollyhocks*, *Zinnias*, *Sunflowers*, *Larkspurs*, and other common annuals are interspersed among the shrubs and trees; indeed, there is in the gardens here a total want of the meaningless formality so prevalent in the gardens of Europe; the first essentials here are shade and fresh greenery, with the addition of flowers sufficient for variety and contrast, and the good results of such a mode of arrangement is variety of the most satisfying description, the visitor being irresistibly attracted from one point to another by some plant or flower distinct from those previously seen; there is scarcely any portion of these gardens which does not contain ample materials for the most agreeable pictures of vegetation, and that this should be so is a matter of some surprise, seeing that both earth and water have to be brought from *Ismailia*, a distance of nearly fifty miles, and that nothing can be done in the way of culture except by careful irrigation. To favour this operation the flower beds and little plots where a few *Radish*, *Lettuce*, or other salad vegetables are cultivated, have to be constructed a few inches below the general level, so as to prevent any waste of water. Fruit trees are not much cultivated; *Figs* and *Grapes* are, however, found in most gardens, and the *Prickly Pear* (*Opuntia vulgaris*) also grows well and fruits abundantly. A pyramidal *Apple* tree in good health, bearing half-a-dozen fruit, was evidently considered a great curiosity by the old, white-turbaned Arab gardener in charge. I had nearly forgotten to mention that the *Australian Blue Gum* tree (*Eucalyptus globulus*) succeeds here fairly well, its leaves being used in the hospital as an antiseptic dressing for flesh wounds with good results, and infusions of the bark for dysentery were under trial. The fruit and vegetable market and shops of *Port Said* are fairly well supplied with produce, the islands of the Mediterranean, *Malta* and *Sicily* contributing most largely. *Oranges* and *Lemons* were obtainable, as were also small *Apples* and *Plums* in quantity, but of inferior quality, and only fitted for culinary uses. *Melons* were, together with *Oranges*, by far the best dessert fruits obtainable. Large *Water Melons* were abundant, at prices varying from 6d. to 1s. The true *Water Melon* is an immense green fruit 12 in. to 15 in. in diameter, and of an oblong shape, having a dark glossy-green skin; its crystalline flesh is firm, but deliciously cool and melting, and in hot weather a most welcome assuager of thirst. The numerous seeds are almost as large as those of the *Vegetable Marrow*, and of a black colour; these are imbedded in the rosy, salmon-coloured flesh, and not confined to the central cavity within the fruit, as is the case with the kinds grown in English gardens. *Dried Dates*, *Figs*, and *Nuts* were abundant, as a matter of course. *Vegetables* were represented by long *French Turnips*, *Aubergines*, *Garlic* of excellent quality, *Onions*, the large *Red Soup Gourd* of the *Paris* markets, *Capsicums*, *French Beans*, *Peas*, *Cabbage*, *Maltese Potatoes*, and large quantities of *Okra*, a vegetable but very seldom used in European cookery, although common throughout the East, and also in the warm American States. These impressions of Egyptian gardening are derived from observations made in a peculiarly dry, hot, and sandy district, in which, as previously mentioned, even the first two elements of gardening, namely, soil and water, are naturally absent. Perhaps the most fruitful and verdant part of Egypt is that watered by the overflow of the Nile, or by artificial irrigation on a large scale carried on in the vicinity of that river, and where the vegetation is both abundant and luxuriant, more so, in fact, than that of most other inter-tropical countries. The tract here described is naturally barren as a granite rock, and the difficulties to be overcome by the cultivator are so great that the results, comparatively speaking, are but little less successful than those obtained in many far more highly-favoured regions.

F. W. B.

THE INDOOR GARDEN.

THE SCARLET MITRE-FLOWER.

(MITRARIA COCCINEA).

THIS is a free-growing, and equally free-flowering, dwarf Gesneriad from San Carl de Chiloe, that requires a cool greenhouse temperature. The time of blooming, as in the case of most other plants, is somewhat regulated by the temperature in which it is kept, but it will generally be from the beginning of July to the end of October. Its flowers, produced much in the manner of a Fuchsia in succession for a considerable length up the shoots, are of a bright scarlet colour; the bracts are mitre-shaped—hence the derivation of the name. It is easily

Mitraria coccinea.

grown, and strikes freely in sand covered with a propagating glass in a temperature similar to that required for propagating Fuchsias, and will thrive in peat with a moderate addition of sand. The shoots should be occasionally pinched, to induce a bushy habit of growth, and the plant requires a few sticks for support. It needs a fair amount of water during the growing season, but should be kept drier in the winter; the shoots ought to be cut back after flowering. It makes a welcome addition to the greenhouse during the early autumn months when flowers are scarce, and will be found very suitable for a small house.

T. BAINES.

Potting Soil.—Within the next few weeks is the best time to get in loam and peat for potting purposes. Amateurs often labour under two impressions about potting soils that are quite opposite, and both are erroneous; one is to suppose that pot plants generally can be made to grow in any sort of material; the other is an idea that unless the best loam is available, it is useless attempting the cultivation of many subjects; and frequently expend considerable sums in getting it from long distances, when they have plenty near at hand that would answer all ordinary purposes. If the soil be free from mineral impregnations (iron in particular), wherever the turf is composed of close, moderately fine Grass that has lain for some years, it may be reasonably expected to answer; it should not be dug more than 3 in. in thickness, so that it may be thoroughly permeated by the roots of the Grass, as the mechanical influence of these root fibres, in keeping the soil in a porous open condition congenial to the plants which are to be grown in it, is of equal importance to the chemical elements contained in the soil. The reason why the present is the best time of the year for getting it is that the roots of the Grasses are at this season the most abundant, and have attained a

tough, matured state which enables them to last, or in gardening parlance, to wear well. It should be stacked up in the open air in a heap ridge-fashion, so as to throw off the rains, laying the Grass side downwards. Where, as with most amateurs, it has to be used for many species of plants, some needing a little manure, others a good deal, it is better not to mix any with it at the time of stacking it, as when it is prepared for use, manure more or less, according to the requirements of the subjects to be grown, can be added. In respect to peat it is somewhat different; for plants that absolutely require soil of this nature it is necessary to procure it of a sufficiently open description, such as obtainable from high-lying ground where Grass and Ferns grow freely; and not either the soft boggy stuff with almost the consistency of putty, or that of a hard impetuous nature generally met with where the strong varieties of British Heath grow. Both of these latter are to be avoided; the former is totally unfit for anything but Rhododendrons, or other hardy shrubs, and the latter is usually poor, and even when well mixed with sand not well calculated for the roots of tender plants. Peat may generally be dug somewhat thicker than loam, but, like it, should be stacked up out-of-doors, where it is much better than under cover, except for so long as is requisite to dry it sufficiently for use. I should never recommend more soil, either peat or loam, being got in at once than is necessary to last for a year, as after that time deterioration takes place by the decomposition of the fibres. Leaf-mould should also be procured to mix with the loam for Primulas, Cinerarias, and similar subjects; with the above, some well-rotted manure, silver sand, and Sphagnum Moss, amateurs will find that they have got all that is needful in the way of soil for whatever plants they may choose to cultivate.—T. B.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

September 17.—Sowing Red and White Turnip Radishes in pits. Potting outdoor-struck Pelargoniums. Pricking out Cauliflowers and Red Cabbage plants. Clearing off a piece of Turnips, and heavily manuring and digging the ground for Coleworts. Clearing out Melon pit, adding a little more soil and manure, and planting it with dwarf Beans for winter bearing. Tying up Lettuce and covering up Endive to blanch. Cutting back all young growth on Tomatoes, and exposing the unripe fruit to the sun. Turning a large heap of manure, and adding a little salt and soot to it for general use. Clearing off the surface of early Vine border, and giving it a top-dressing of loam, horse-droppings, and coal ashes.

Sept. 18.—Potting Dutch bulbs in a mixture of loam, manure, charcoal, and sand. Filling up all spare frames with Lettuce and Endive. Dressing early Black Hamburgh Vines with composition to kill insects. Erecting a temporary frame over pot Strawberries on which to place spare lights to keep off heavy rains. Rolling newly made gravel walks. Looking over all young fruit trees, and applying new ties and stakes where necessary. Gathering Hawthornden, Cellini, and Golden Pippin Apples; also a few Golden Drop Plums.

Sept. 19.—Potting off variegated Pelargoniums. Putting in another batch of Osborn's forcing French Beans and Ashleaf Kidney Potatoes that have been previously started in pots for forcing. Roping Onions. Washing woodwork in houses, and, when wet, cutting shreds and making labels and flower-sticks.

Sept. 20.—Putting in cuttings of Cerastium under hand-lights. Potting off Centaurea candidissima as soon as rooted; also putting a few Primulas and Cinerarias into their flowering pots for early blooming. Weeding and thinning out all overgrown Parsley. Hoeing amongst all late-planted Endive and Lettuce. Putting hay-bands round Cardoons and earthing them up.

Sept. 21.—Putting in Tomato cuttings to furnish plants for early fruiting. Shaking out and re-potting old plants of Tricolor Pelargoniums. Thinning out Endive and Lettuce. Manuring and roughly digging the ground previously occupied by Cauliflowers. Weeding and cutting the runners off pot Strawberries. Preparing frames for Cauliflower plants by putting a thick layer of green turf Grass side downwards, then 1 in. of good mould in which to prick out the plants, which are placed 6 in. apart each way. Gathering Berberis, Reine Claude de Bavay, and Coe's Golden Drop Plums.

Sept. 22.—Putting in Tom Thumb and Indian-yellow Pelargoniums in large store boxes and pots. Earthing up Celery when the soil is dry. Thinning autumn-sown Carrots and Turnips. Weeding Box edgings, &c. Gathering Gansel's Bergamot, Citron de Carmes, and Dunmore Seedling Pears, and Ribston Pippin Apples. Fruit in use for dessert—Pines, Grapes, Melons, Peaches, Nectarines, Figs, Plums, Pears, and Apples.

TREES AND SHRUBS.

THE SWISS PINE (PINUS CEMBRA).

THIS Conifer was introduced into Britain in 1746 from the Alps of Switzerland, where it is abundant; it also grows naturally and forms large forests on other mountains of Europe and in northern Asia; it is generally found in the highest regions, close upon the verge of perpetual snow. It is of slow growth and does not attain large dimensions, averaging about 50 ft., and rarely exceeding 80 ft. high; its timber is said to be of good quality, and is much used by the Swiss peasants for making carved figures and fancy goods; it is also used for cheap turnery work, the wood being fine-grained, soft, and very durable when not exposed to alternate changes of wet and drought: being a very resinous wood, it emits an agreeable fragrance. The seeds, it is said, are eaten by the natives, and are much relished as an article of food, chiefly as dessert. Although this Pine has been grown for many years in this country, it has not been cultivated extensively; one reason for this is possibly because it has not been cheap enough to plant in large quantities with a view to a profitable return. Another reason probably is the slowness of its growth, for it rarely makes a greater progress than about 12 in. in a year when fairly established in permanent quarters, and even not so much as that in poor soils and on exposed sites; in the nursery, through being constantly shifted, it only grows on an average about 6 in. during a season. It has been mostly planted throughout the country

Cone of Pinus Cembra.

in Pinetums, or as a specimen tree in ornamental grounds with full liberty to develop its lateral branches, and without the benefit of nurse trees and close shelter to help to draw it up to a clean stem. Probably, if it were tried in a plantation amongst other trees, and subjected to the same treatment, it is quite possible it would be found to grow more rapidly. Its habit, so far as we have been able to judge from specimens grown in open situations, is stiff and formal, of an elongated conical shape, and branched in regular whorls from the ground to its top—a form that can hardly be called beautiful or ornamental, but no doubt desirable by way of contrast amongst trees of more graceful habit of growth. I am told that the form of this tree, when growing naturally on the Alps, is very similar to that of the Stone Pine (*Pinus Pinaster*). In that case its form would be just the reverse of what it is in this country, the Stone Pine having an irregular flat-headed habit and picturesque outline. The foliage of the *Pinus Cembra* is pretty, being of a pleasing light green on the upper side, while underneath it is partly silvery, thus adding a dash of glaucous colouring amongst the green. The leaves are in five, and from 2 in. to 3 in. long. The cones are erect, bluntly ovate, nearly as broad as long, and of a violet colour when young. There are specimens of it in England from 50 ft. to 80 ft. high—a proof that, notwithstanding its slow growth, it will in this country attain a height equal to that of its native habitat.

G. B.

Japan Judas Tree (*Cercis japonica*).—The Japan Judas is one of the most beautiful and attractive of the early flowering shrubs, and deserves a much more general appreciation and use than it has received. It is a bush of slow growth, attaining a height of from 8 ft. to 10 ft. in as many years, very symmetrical and compact in habit, which makes it valuable as a decorative plant for small gardens, and does not lessen its value as an ornament for large lawns or parks. It differs greatly from the old and well-known American Judas Tree, and is vastly superior to it in being dwarf and compact in habit of growth. The flowers are larger, more thickly set on the stem, and of a much brighter and prettier colour. The foliage is larger, darker green, and much more abundant. The flowers open about the 1st of May, and are in perfection before the 15th. They are small, with stems so short as to be scarcely visible, and borne in clusters or knots all along the branches, looking as though they had burst forth from the hard, apparently lifeless wood. Every limb and twig on the whole plant, from the ground to the top of the tallest branches, is then clothed with a dense mass of bloom of the brightest shade of rosy-pink, before the leaves appear. When planted amidst evergreens or early starting shrubbery to supply a green background, and in full bloom, it is certainly one of the most attractive and gorgeous sights to be found among flowering shrubs. The leaves, which appear soon after the flowers are faded, are particularly pretty, being nearly round in shape, 4 in. to 6 in. in diameter, thick and leathery, of a rich, dark green colour, and produced in such abundance that the bush appears to be a solid mass of verdure, making it an especially attractive shrub during the summer, when not in bloom. It appears to be generally hardy in the latitude of Philadelphia, though the flower-buds are occasionally injured by very severe winters. To guard against this, a situation protected from cutting winds, and where water will not lie around the tree, is desirable. It has been in this country at least twenty years, but the difficulty of propagating it is such that the market has never yet been supplied.—“Gardener’s Monthly.”

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Finely-grown Catalpa.—Allow me to bring under your notice what seems to me to be a very fine *Catalpa*, which was beautifully in flower in the last week in August. The specimen in question is 30 ft. in height, and 45 ft. in spread of branches. It stands in the courtyard at Claydon, and is pretty well sheltered by means of surrounding buildings. *Aesculus macrostachya* was also in full flower at the same time. *Ceanothus americanus*, covered with pretty white blossoms, was likewise a striking object amongst shrubs; and there was another *Ceanothus* with pale blue flowers, with the name of which I am unacquainted. The old *Rubus odoratus* is another good shrub for autumn. All the above are well worth the attention of planters.—J. M.

Infant Hawthorns in Flower.—In THE GARDEN (see p. 206) is a representation of a seedling Hawthorn in flower, furnished by Mr. William Stewart, Jun., of Dundee, who adds that he “had never seen anything of the sort before.” Such an occurrence may not be common, but we may state that fully half-a-dozen plants flowered in our seedling beds this year.—R. & A. MORRISON, *The Nurseries, Elgin*.

The Golden Catalpa.—This makes a good companion for the Silver Maple (*Acer Negundo variegatum*), either planted in groups in shrubberies, on the lawn, or as centres to flower-beds. The golden tints of its foliage are especially effective just now.—H.

A Handsome Eucalyptus.—Some of the *Eucalypti* have beauty as well as fragrance. The annual report of the Director of the Melbourne Botanic Garden, in referring to improvements in portions of the grounds, says that several specimens of the gorgeous scarlet-flowering *Eucalyptus filicifolia* are planted there, and then adds:—“This magnificent plant, from Broken Inlet, Western Australia, produces its flowers at a much earlier stage of growth than any other species of the genus with which I am acquainted. Its bloom resembles a ball of fire more than anything else with which I could compare it. I have seen the Flame Tree of Illawarra and the brilliant scarlet masses of *Erythrina laurifolia* on the banks of Rewa in Fiji, but neither surpasses the effect produced by the floral display of this *Eucalyptus*.”

A Weeping Hemlock Spruce.—A weeping form of this is described in the “Rural New Yorker.” The habit is so decidedly weeping and the leaves and branches so thick that it was at once suggested to graft it upon high stocks, about the same, for instance, as the Kilmarnock Weeping Willow is worked upon the stock of which it is a variety, viz., *Salix caprea*. But the great expectations of securing an evergreen tree-form of unique and incomparable grace, thus reasonably entertained, have not been fulfilled. Mr. Samuel Parsons, of Flushing, writes as follows:—“We graft it readily upon high stocks in the nursery, but it does not thrive as well—the naked stem cracks and suffers, and the massive foliage, like most evergreens parched on high stems, is too heavy for grace and proportion, and is beaten and tossed by the winds.”

LANDSCAPES OF THE GREAT PAINTERS.

CALAME—BORN 1810, DIED 1864.

No landscape painter ever seized upon the true characters of picturesqueness more happily than the Swiss painter Calame. He commenced his artistic career by colouring little prints of Swiss scenery at very low wages; but as he took the utmost pains with all he did, he gradually acquired a thorough knowledge of effects, both as regards form and colour, and at length felt sufficient confidence to attempt original subjects, instead of colouring or imitating the productions of others. Eventually he became, after many disappointments and some failures, one of the greatest landscape painters of his time, and his pictures, lithographs, sepias, and sketches in chalk are very

residence in Geneva and his beautiful villa in its charming suburbs, became a rendezvous of distinguished men, and of the sovereigns and princes of Europe; and to pass through Switzerland without having enjoyed the privilege of a visit to the *atelier* of Calame, deprived such a tour of one of its cheerful and most coveted gratifications. The annexed example is from one of his works in black and white, the spirited and expressive pencilling of which, as in his various other works of the same class, exhibits a thorough mastery over the principles of effective treatment to which few have attained. It represents a group of Oaks growing on the margin of one of the smaller Swiss lakes. The treatment of the ramifications of the gnarled branches is admirable in its characteristic boldness, as is the effect of the flat-topped rocks, worn smooth

PARQUIER, DEL.

CALAME inv.

SARGENT, SC.

Landscapes of the Great Painters: Lake Scene in Switzerland.

numerous, though he did not achieve excellence till a comparatively late period of his career. His finest works are those belonging to his "specialty," the scenery of the high Alps, which he treated with a poetical feeling peculiarly his own. Among these works his "Monte Rosa after Sunset," the highest peaks of dazzling snow still receiving the rosy glow of sunrises, after all else in the landscape had sunk into the blue depth of twilight, is perhaps the most interesting, if not the finest, and forms one of the chief ornaments of the museum of Neuchâtel. Equally well known are "The Haendeck," "A Region of the High Alps after a Storm," "The Lake of the Four Cantons," his "Four Seasons," his "Mont Blanc," "An Avalanche of Rocks" (purchased by Louis Philippe), "A Tempest in a Forest of Oaks," and many others. Calame, though comparatively young when he died, lived to reap the just rewards of his talent and persevering industry. His

by the action of the water, which stretches out to some distance in the shallows of the lake. This effect might be made to afford a hint to landscape gardeners under the following circumstances:—Let it be supposed that it is desirable to form a small lake in a stretch of park scenery where immediate effect is desirable, in which case full-grown trees are necessary; and as such trees cannot be transported to the edge of the artificial water, let the artificial water be made to approach the trees, if any exist in the neighbourhood of the situation where it is sought to introduce a more or less extensive expanse of water. Supposing a single tree or group of trees of picturesque character to be available as adjuncts to the outline of the water, an effect precisely similar to Calame's striking sketch might be easily produced; indeed, by the addition of natural masses of stone grouped together on nearly a level, and carried out to some little distance in the shallow water near the bank, almost

a perfect fac-simile of Calame's picturesque drawing may be produced in living trees and real water within the short time necessary for excavating the bed of the pond or lake. Or if such a feature as a small lake already exist, but is bare or uninteresting as regards the banks, let its margin be extended till some such object, if available, be reached, so as to impart variety to some part of its shore. It is in this way that the more picturesque works of our great landscape painters might be used as hints or texts by a landscape gardener of taste and enterprise.

NOEL HUMPHREYS.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Epiphyllums that were recommended some time ago to be stood out in a sunny position should at once be taken indoors; the stronger growers may occupy a shelf, or any other place for the winter where they can receive a moderate amount of light, with just sufficient water to keep them from shrivelling. The varieties of *E. truncatum* may be similarly treated for some time yet, but if required to flower early through the winter they must be placed in heat.

Berry-bearing Solanums that were in the spring planted out in the open ground should at once be taken up and potted; it is necessary to do this with as little breakage of the roots as possible, as their leaves, though not at all of a delicate nature, will be injured if the roots be mutilated to any considerable extent; to avoid this, if the ground be dry give it a good soaking the day previous to taking up the plants; 6-in. pots are quite large enough for winter-struck plants, or such as were raised from seed at the beginning of the year, but in the case of those that are older and were out back before planting out, the pots should be a size larger. These Solanums require a good supply of water, consequently it is necessary to drain the pots well; any soil of fair quality and moderately porous will answer for them. On taking up pot at once, after which (different to the treatment advisable for most newly-shifted plants) give as much water as will thoroughly permeate the soil; and should they appear to require support put a small stick to the stem of each. If a frame or pit be at liberty it will be the best receptacle for the plants, shutting the lights down so as keep them somewhat close, shading the glass whilst the sun is upon it to obviate the necessity of giving much air. They should be damped overhead with the syringe once a day, and on no account allowed to suffer for want of water at the roots. If a pit or frame be not at disposal, stand them close under a north wall, where they will be completely out of the reach of the sun, and protect them with mats from the wind until they have got established; they must also be kept quite moist at the roots and syringed overhead. As soon as the roots have fairly commenced to grow in the pots they may be gradually exposed to the sun.

Veronicas, that were planted out in the spring with a view to their being taken up and repotted similarly, will need pots a size larger than for the Solanums, but in no case should they have more space allotted to them than the roots require without being too much cramped. If a portion of the plants have been prepared for successional flowering by stopping once during the summer, they will afford a continuance of blooms up to the end of the year. Treat them as recommended for the Solanums.

Campanula pyramidalis.—The white and blue varieties of these that have been out-of-doors through the summer should also now be taken up and potted: it is not advisable to give them all the room they will require, but put them for the present into pots of sufficient size to contain their roots and a moderate amount of soil, moving them early in the spring into others from 9 in. to 12 in. in diameter according to the size and vigour of the plants; see that their roots also are efficiently moist before taking up, give them a moderate watering as soon as potted, and immediately transfer them to a frame where they can be kept tolerably close and shaded until they have commenced growth. They are nearly hardy in the south of the kingdom, and will merely require through the winter keeping in a house or pit from which frost and damp can be excluded.

Greenhouse Hard-wooded Plants.—In the north of the kingdom it will not be safe to allow Heaths or any other hard-wooded pot plants to remain longer out-of-doors, for even should no frost occur, they will be liable to suffer from too much rain; previous to taking such plants indoors, the pots should be well scrubbed, so as to give them a clean appearance through the winter. Where there is no house or pit for Heaths, they should be placed at the coldest end of the greenhouse, as near to the roof as possible, as they will bear more air directly in contact with them than New Holland plants, such as *Pimeleas*, *Adenandras*, *Aphelexis*, *Chorozemas*, *Boronias*, *Correas*,

and *Epacris*, which require more warmth, and should be placed at the opposite end of the house. In the southern parts of England such subjects as the above may be allowed to remain until the end of the month, unless there should be an indication of frosty nights. There is no better time in the year for potting spring and summer flowering Heaths than the present; but where any of these plants have to be shifted, it should be done immediately, for although they continue to make roots almost to the end of the year, still it is better to pot them at once, thereby affording them an opportunity of getting established in the new soil. The advantages gained in moving them now are that their flowering is not interfered with, and there is not nearly so much danger to the health of the plants as if they had been potted during the hot summer weather.

Kalosanthes should not be allowed to remain out any longer. These plants are especially adapted for amateurs, as they flower freely and do not suffer from slight inattention; but they are light-loving subjects, and through the winter should be accommodated with a position close up the glass.

Lilies.—Any plants of *Lilium auratum*, *L. eximium*, or other species that flowered early, and the tops of which are now dead, should be potted, as there is nothing like completing this work as soon as the plants go to rest, when their roots are in the most dormant condition; the size of the pots required should be regulated by the number of bulbs in each. An 8-in. or 9-in. pot is sufficient for a large bulb of *L. auratum*, giving more room where several are grown together; a 9-in. pot is quite large enough for three or four bulbs of *L. eximium*, or others of similar strength. Avoid the shallow potting too common with these plants, all of which emit a large number of roots from the young stem formed annually above the bulb, the top of which at the time of potting should at the least be $3\frac{1}{2}$ in. or 4 in. under the soil. After potting keep the soil moderately moist and no more. A cold frame will suit them for some time to come.

Double Primulas struck in the spring and now occupying small pots should at once be moved into those in which they are intended to bloom. Moderate-sized plants grown in 6-in. pots are generally much more satisfactory than larger specimens requiring more room, and amateurs who have not had much experience with these most useful winter-flowering plants will find them far more manageable in pots of the above size than if larger; for they are somewhat liable to damp off unless they can be accommodated with a temperature of 50°, and are much more apt to do so when grown in a large body of soil than if more confined at the roots.

Wasp Nests and Cyanide of Potassium.—About this time of year wasps are great pests in gardens. All kinds of fruit on open walls and Grapes under glass are destroyed in great quantities by them. Traps placed about the fruit may catch a few, and cloth or net protectors may keep some of them off the fruit, but still, where they are plentiful, many of them will make their way to it. Under such circumstances no remedy is so good as killing them, and for this purpose nothing answers so well as cyanide of potassium. It is a poison, but may be procured from any chemist: use in the proportion of 1 oz. to half-pint of water; in this solution saturate a handful of cotton and insert it immediately in the mouth of the wasp-hole. The fumes soon reach the nest and destroy its occupants in less than an hour. When those outside come nearer the cotton than 1 ft., they fly round about it for a short time, and then fall to the ground. In two hours after inserting the cotton I have lifted them up in handfuls. I destroyed a nest to-day in this way without any trouble: a long narrow hole over 2 ft. in length led to the nest, and after the cotton was put in, this passage was so completely filled with dead wasps that the fumes could not penetrate to the nest, the entrance to which had to be cleared in order to let the cotton further in; 4000 dead wasps were counted from this nest alone, and there would probably be as many more uncounted. To be able to kill this number of wasps without more trouble than that just described is a great advantage.—A. B. Y.

Potato Hampshire Hero.—A really first early Kidney, positively earlier and larger than the Ashleaf; flesh and skin perfectly white, and boils as mealy as a Regent; top short and well adapted for pot, frame, or early border growth. This Potato will in time prove to be a veritable garden acquisition, and its tubers are good six months after lifting. It promises to become specially valuable as an early ripener and a long keeper.—A. D.

Vines from Gethsemane.—There is at this time growing, in more than one of the greenhouses in the vicinity of Hawick, young Vines which have been propagated from one growing in the garden of Gethsemane. They were struck in the early spring of this year from eyes which were brought to Hawick by one of our most liberal-minded and much-respected ministers.—"Scotch Papers."

SOCIETIES AND EXHIBITIONS.

CARLISLE INTERNATIONAL EXHIBITION.

SEPTEMBER 6, 7, AND 8.

THIS show collectively was a very large one, and, taking the adverse summer and the lateness of the season into account, the great bulk of the productions was of a meritorious character. Fine-leaved plants, including Palms, Tree Ferns, &c., as might be supposed, formed the most imposing part of the show, but there was also a number of flowering subjects, both hard and soft-wooded, interspersed amongst them. The names of those who competed for prizes, as well as of those who exhibited large groups not for competition—such as the leading London and provincial nurserymen, who came out in such force as seldom occurs—will convey an idea of the extent and importance of the show, which needed nothing but fine weather to have made it one of the most successful ever held in the provinces. The gathering of gardeners from both England and Scotland, with some from the Sister Isle, was the greatest we ever remember to have seen. The extent of the display may be imagined when we mention the size and number of the tents, which, in all but one or two cases, were fully filled. A large circular marquee 100 ft. in diameter was occupied by large plants; another tent leading from the entrance, 250 ft. by 50 ft., was similarly filled; the fruit and cut flower tent was 400 ft. by 30 ft.; the vegetable tent, 100 ft. by 30 ft.; that devoted to dinner-table decorations, 100 ft. by 40 ft.; one filled with different subjects was 100 ft. by 40 ft. The tent—300 ft. long by 40 ft. in width—wherein was most of the tender plants, was well warmed with hot-water pipes by Mr. Corbett, of Carlisle; the boiler employed was one of Hartley & Sugden's, of Halifax, wrought iron-welded. The heating of this tent was not a mere make-believe, as often occurs when tender plants are exhibited, but was quite warm enough to be agreeable, like, in fact, the temperature of an intermediate-house. There was a telegraph office erected on the ground. The whole of the tents were most effectually lit with gas from pipes running well above the plants, so as not to be in danger of injuring them.

Stove and Greenhouse Plants.—In the principal class for amateurs, twelve stove and greenhouse (six in flower and six fine-foliaged), from Mr. Thornber, gardener to T. M. Shuttleworth, Esq., Preston, had an easy victory, showing in grand perfection for so late in the season. His blooming specimens consisted of a beautifully-flowered *Dipladenia insignis*, *Statice profusa*, and *S. imbricata*, from 4 ft. to 5 ft. through, in excellent condition; *Allamanda nobilis*, covered with canary-coloured flowers; *Ixora coccinea*, and the finest pot specimen of the White *Lapageria* we have seen. The fine-foliaged plants were *Gleichenia dichotoma* and *G. dicarpa*, each not less than 8 ft. through, equally large and well-grown examples of *Cycas circinalis*, *Phormium Colensoi* variegatum, *Croton majesticum*, and *Cordylina indivisa*. Mr. Todd, gardener to A. B. Stewart, Esq., Glasgow, who was second, also had a good group; the best of these were *Erica Aitoniana* superba, *E. Marnockiana*, *Ixora javanica*, *Gleichenia Spelunce*; the fine Palm *Astrocaryum mexicanum*, and the pendulous-fronded Tree Fern *Alsophila australis* Williamsi. In the class of six stove and greenhouse plants, Mr. Hammond, gardener to Sir W. Lawson, Brayton Hall, was first; amongst others he had a very finely-flowered *Vallota purpurea*, the good old *Rondeletia speciosa*, and a well-grown example of that most elegant of Palms, *Cocos Weddelliana*. Mr. Shand, gardener to the Earl of Lonsdale, Lowther, was second; he staged a well-flowered *Erica Marnockiana*, and a very large plant of *Lilium speciosum*, associated with well-grown, fine-leaved subjects. Mr. Scott, gardener to Gavin Steele, Esq., Bothwell, was first in the class of *Crotons*, amongst which was a fine example of *C. irregularis*; Mr. Hammond was second. In the class of six stove and greenhouse plants in flower, Mr. Thornber was first; noticeable in his collection was a well-flowered *Ixora coccinea*; also *Anthurium Scherzerianum*, bearing about three dozen blooms, and an equally fine *Eucharis amazonica*; Mr. Hammond was second, and Mr. Shand third. In the class of three Palms Mr. Thornber was again first, and Mr. Todd second, both showing clean, evenly-grown plants. Heaths came from Mr. Scott and Mr. Todd. Of six exotic Ferns Mr. Todd, who was first, showed in his lot the scarce *Gleichenia Mendelli*, *G. semivestita*, and *Todea superba*, large and in good condition. In the class for eight dinner-table plants there was a spirited and very close competition between the first and second prize collections, Mr. Thornber getting first with a fine group, light and airy in appearance, as these always should be; Mr. Todd was second. Nine stove or greenhouse plants in 12-in. pots were shown in excellent condition, though not very large; Mr. McIntyre, gardener to A. A. Richardson, Esq., Lisburn, Ireland, was first; his most meritorious plants were *Encephalartos villosus*, *Latania borbonica*, and *Dracena Baptisti*, still one of the best. In the class of four *Dracenas* the first prize was awarded to Mr. Hammond, who exhibited beautiful examples of *D. amabilis*, *D. Mooreana*, *D. Baptisti*, and *D. Regine*; Mr. Blackwood, Eden Hall, made a close second, and Mr. Todd was third. For twenty stove and greenhouse plants (nurserymen) Mr. Troughton, manager to the Preston Nursery Co., was deservedly awarded the first prize; his collection consisted of lofty Tree Ferns, Palms, a beautiful example of *Croton Weismanni* and *C. majesticum*, *Cycas circinalis* in fine condition, and a large and finely-flowered *Lapageria rosea*, *Erica Austriana*, *E. amula*, and *E. Marnockiana*, fresh and evenly bloomed; *Eucharis amazonica* and *Phenocoma prolifera*. Messrs. J. & R. Thynne, Glasgow, were second with a fine collection, containing the beautiful *Croton Johannis*, the weeping *Cyathea Burkei*, a stately *Areca*

Baueri, and *Dasyllirion glaucescens*; this group was not so well furnished with flowering plants as the first prize lot. In the class of six Orchids (nurserymen) Mr. B. S. Williams, Victoria Nursery, Upper Holloway, was first with a finely-flowered example of *Oncidium Marshalli*, and a very fine variety of *Odontoglossum Alexandræ* named *O. A. fimbriata*. Mr. Pat-tinson, Carlisle, was second.

New Plants (fine-foliaged) in 12-in. pots.—Mr. Todd, who took the lead, showed a very effective group, in which *Macrozamia Mackenziei* and *Adiantum gracillimum* were conspicuous; Mr. Hammond was second. In the competition for Mr. Bull's cups, given for twelve new plants sent out since the commencement of 1874, Mr. Thornber was again first; his group contained *Plectocomia Andersoni*, *Encephalartos villosus* ampliat, the very distinct Tree Fern *Sadleria cyatheoides*, *Todea intermedia*, *Croton Disraeli*, *Arabis elegantissima*, and a nicely-flowered *Dipladenia Brearleyana*; Mr. Hammond, who was second, staged a good collection of smaller plants; Mr. McIntyre was third. In the class of twelve new plants not yet in commerce, Mr. Bull, King's Road, Chelsea, was first, and Mr. B. S. Williams second. Messrs. Veitch, of Chelsea, and Mr. B. S. Williams, each staged groups of new and rare plants, amongst which the *Nepenthes*, *Sarracenias*, and Orchids were in beautiful condition; these two exhibits formed such an assemblage as is not often seen. Messrs. Ireland & Thomson, Edinburgh; Little & Ballantyne, Carlisle; R. P. Kerr & Sons, Liverpool; J. Dickson & Sons, Chester; R. Thynne, Glasgow; R. Pattinson, Carlisle; Clarke & Co., Carlisle; T. Armstrong, Carlisle; Barron & Sons, Borrowash; and the Preston Nursery Company also staged some extensive collections. Amongst these we noticed *Cattleya Sedeni*, a cross between *C. devoniensis* and *C. superba*; its sepals and petals are rosy-purple, while the whole of the labellum is of the deepest crimson with a shade of maroon; it beats *Lælia Turneri* completely out of the field. *Sarracenia Chelsoni*, *Nepenthes hybrida maculata* major, *N. Rafflesiana pallida*, and *Athyrium Goringianum farinosum* all received first-class certificates. A number of plants of a very distinct race of hybrid *Begonias* were shown by Messrs. McClelland & Co., Newry; they were quite equal to any we have seen, one especially, named *International*, bore flowers of great substance, and of the most brilliant crimson; the foliage may be described as that of a miniature *B. manicata*, but not at all coarse; another, named *Cleopatra*, was magenta-crimson, dwarf and compact, the leaves being nearly hidden by a profusion of flowers; Firefly, a striking sort, had flowers almost circular in outline. A new *Croton*, called *Etna*, was a brilliant kind, with medium-sized leaves, somewhat smaller than those of *C. pictum*; the young leaves are green and yellow, assuming, as they get older, the brightest crimson. Unfortunately these plants did not arrive until the second day of the show, or no doubt they would have been awarded first-class certificates.

Dinner-table Decorations.—A large tent was wholly filled with these. The first prize (a 25-guinea cup given by Lady Musgrave, Eden Hall) was won by Mr. Cypher; the second was awarded to Mr. Shand, whose table was the heaviest in the competition; third, Mr. Lewen, gardener to Colonel Buchanan, Drumpellier.

Cut Flowers.—Amongst these Roses stood in the front rank. For twenty-four, the executors of the late John Harrison, Darlington, were first, with flowers that would have been considered highly creditable much earlier in the season; second, Mr. H. Dickson, Belfast; and third, Mr. Smith, Stranraer. For twelve Roses, Mr. Burrell, Darlington, was first with a good dozen; second, Mr. Summers, gardener to C. W. Scott, Esq., Dumfries; Mr. A. Kirk, gardener to Mrs. Mackie, Castle Douglas, was third. Messrs. Cranston & Mayo, Hereford, exhibited some beautiful Roses not for competition. For twenty-four Dahlias (nurserymen)—Messrs. Dickson & Sons, Belfast, were first with a beautiful exhibition; Mr. Thompson, Fenham, was second; and Messrs. Little & Ballantyne, Knowfield Nurseries, Carlisle, third. Twelve Dahlias (nurserymen)—Messrs. Dickson were first, and Mr. Thompson second. Dahlias were also forthcoming from amateurs in considerable quantities. For twelve blooms, Mr. J. Paterson, Carlisle, was first with a well-matched dozen; Mr. W. Veitch, Carlisle, was second. Phloxes were in beautiful order, showing how well they stand a wet season. For twelve, Mr. Summers took the lead with a very good stand; Mr. Postlethwaite was second. Eighteen *Gladioli* came from Mr. R. Gray, Kilkerran Castle, Ayrshire, who staged a beautiful lot which received the first prize (amongst these were some of the very finest examples of this showy autumn flower which we have ever seen); second, Mr. McDougall, Grasmere. A large number of bouquets were shown, varying much in merit. Brides' bouquets were shown by Mr. Perkins of Leamington, Mr. Crummond of Sunderland, and Mr. Cypher of Cheltenham, to whom prizes were awarded in the order in which their names stand. Mr. Perkins was also first in the class for three hand bouquets with equally handsome productions, Messrs. Turner of Liverpool being second, and Mr. Cypher third.

British Ferns came from Mr. Craig, gardener to the Hon. Mrs. Howard, Levens Hall, who showed distinct and well-grown kinds, to which a first prize was awarded; second, Mr. Graham, gardener to J. Allan, Esq., Moffatt. Messrs. Barron & Sons, Elvaston, obtained the first prize for Coniferous plants; second, Messrs. Dickson & Turnbull, Perth.

Fruit was shown in large quantities. In the principal class of sixteen dishes, Mr. Coleman, gardener to Earl Somers, Eastnor Castle, was deservedly first. This collection comprised beautifully-finished Black Hamburgh, Muscat of Alexandria, Black Morocco, and Madresfield Court Grapes; good black Jamaica and smooth Cayenne Pines; Bellegarde and Galande Peaches; Pitunston and Elruge Nectarines;

Eastnor Castle and Golden Gem Melons; Diamond Plums; Morello Cherries; Brown Turkey Figs, and Jargonelle Pears—all good, and even in quality. Mr. Johnson, gardener to the Earl of Strathmore, Glamis Castle, was second. In Grapes he had rather the advantage over his opponent; his Muscats, Black Alicante, and Gros Guillaume were very fine, but in other fruits there was somewhat of a falling off, nevertheless it was a very meritorious exhibition. Mr. Ingram, gardener to the Duke of Northumberland, Alwick Castle, was third. His best examples were Queen and Charlotte Rothschild Pines—very fine fruit; Muscat of Alexandria Grapes; Royal George and Violette Hative Peaches. In the class of twelve dishes Mr. H. Wallis, gardener to Sir H. Thompson, York, was first with amongst others good Muscat of Alexandria and Black Hamburgh Grapes, Royal George Peaches, and Brown Turkey Figs. Mr. McKelvie, gardener to the Duke of Roxburgh, Broxmouth Park, was second; he had fine Muscat of Alexandria Grapes, Walburton Peaches, and Violette Hative Nectarines. Mr. Upjohn, gardener to the Earl of Ellesmere, was third; and Mr. Dixon, gardener to J. Whyte Melville, Esq., St. Andrews, was fourth. In the class of ten dishes (Pines and Grapes excluded), Mr. Shand was first; and Mr. H. Graham, second.

Pines.—First, for Queen, Mr. Ingram, who showed a couple of fine fruit; second, Mr. Sandford, gardener to the Earl of Bective, with a pair little inferior. Two Pines (any other variety)—First, Mr. Coleman. Heaviest Pine—First, Mr. Sandford.

Grapes.—Eight varieties (one bunch each)—Mr. G. Reid, gardener to A. H. Moncur, Esq., Dundee, who was first, staged a really fine lot including Muscat Hamburgh, Muscat of Alexandria, Lady Downes, Black Alicante, Black Hamburgh, Mrs. Pince, and Gros Colman with very large berries; the bunches stood upon the stands as firm as possible, not a berry moving from its place, the only fault being the predominance of Black kinds; Messrs. Lane, Berkhamsted, who were second, also had a good collection, the best were Bowood and Alexandria Muscats, Alicante, and Gros Colman. In the class of four varieties (one bunch each) Mr. Hammond was first and Mr. Coleman second, both exhibiting good examples; third, Mr. R. Kirke, who had large bunches. In the class of Black Hamburghs (two bunches) the first prize (a silver cup, value £5 5s., presented by Messrs. Boyd & Sons, Paisley) was awarded to Mr. Coleman for well-finished clusters; second, Mr. Upjohn, who had larger bunches but not so well coloured. Muscat Hamburgh (two bunches)—first, Messrs. Lane; second, Mr. Smith, gardener to the Countess of Stair. Madresfield Court (two bunches)—first, Mr. Fraser, Stobo Castle; second, Mr. Harrison. Black Alicante (two bunches)—first, Mr. Hammond, who showed that variety with larger berries than usual; second, Mr. J. Curror. Lady Downes (two bunches)—first, Mr. Hammond, the berries in this case being unusually long; second, Mr. Fraser. Mrs. Pince (two bunches)—first (a silver tea-service value £6 6s., presented by Messrs. Mackenzie & Moncur, Edinburgh and Glasgow), Mr. Reid, who showed bunches in every way good; second, Mr. Hammond. Any other Black Grape (two bunches)—first, Mr. Hammond; second, Mr. Ferguson, gardener to B. Shaw, Esq., Selby. Muscat of Alexandria (two bunches)—first, Mr. McKelvie, with clusters fine in every way; second, Mr. Ferguson; it is worthy of remark that Muscats were relatively much better coloured than the Black kinds. Duke of Buccleuch (two bunches)—first, Messrs. Thomson & Sons; second, Mr. Fraser. Any other White kind (two bunches)—first, Mr. Curror, with Buckland Sweetwater; second, Mr. Anderson, gardener to the Earl of Stair. Black Alicante (one bunch)—first, Mr. Mason, Dumfries; second, Mr. Paterson. Lady Downes (one bunch)—first, Mr. Reid. Barbarossa (one bunch)—first, Mr. Ferguson. Muscat Hamburgh (one bunch)—first, Mr. Reid, a fine bunch and a good example of successful Grape-growing. Any White kind (one bunch)—first, Mr. Kirk, with Buckland Sweetwater. Heaviest Bunch of Black Grapes—Alicante, 13 lb., first, Mr. Dickson, gardener to J. Jardine, Esq.; second, Mr. Hammond. Heaviest Bunch White Grapes—first, Mr. Dickson, with Syrian, 9 lb. One bunch of Black Grapes, finest bloom (not less than 1 lb.)—first, Mr. Lees, gardener to the Marquis of Downshire, Hillsborough Castle, Ireland, with Cooper's Late Black, which appears to be a distinct variety, the bunch of which is smallish, with moderate-sized berries, like a rather long form of Hamburgh, black as a Sloe, and profusely covered with bloom.

Peaches.—First, Mr. McFarlane; second, Mr. Fox.

Nectarines.—First, Mr. Hanagan, gardener to R. C. Naylor, Esq., Cheshire; second, Mr. J. Dickson.

Apples, Pears, and Plums, as might be supposed, were scarce, and only moderate in quality.

Vegetables were shown in great quantities and in good condition. For twenty dishes Mr. Sandford was first, and Mr. Nicholl second. Potatoes, notwithstanding the disease which is making such havoc in the north, were produced in fine condition, in fact, too much cannot be said in praise of the vegetables collectively.

There was an extensive display of hothouses, boilers, and garden appliances of all descriptions, covering a considerable extent of ground.

ALEXANDRA PALACE FRUIT SHOW.

SEPTEMBER 13, 14, AND 15.

At this exhibition fruit was well represented, notwithstanding the bad season which we have experienced. Of collections, the best came from Mr. Coleman, gardener to Earl Somers, Eastnor Castle, who had remarkably well-finished bunches of Muscat of Alexandria, Black Hamburgh, and Lady Downes Grapes, the berries and bloom in all cases being perfect; a smooth Cayenne Pine-apple, well ripened, and weighing from 5 lb. to 6 lb., together with two good, finely-coloured Melons, Early Crawford Peaches, Pittmaston Duchess Pears (ripe and good but rather small), Figs, Plums, and Cherries. Next in point of merit was a collection from Mr. Bannerman, gardener to Lord Bagot, in which were good examples of Duke of Buccleuch, Black Alicante, Gros Colman, and Black Hamburgh Grapes; very fine Barrington Peaches, Queen and Black Prince Pine-apples, and Morello Cherries. In smaller collections, Mr. J. Neighbour sent good examples of White Magnum Bonum Plums, and Violette Hative Peaches; and in the same class we remarked good fruit of Kirke's Plum and Bellegarde Peaches. In the class of eight varieties of Grapes, the best came from Messrs. Lane & Son, Berkhamsted. They consisted of large and well-finished bunches of Muscat of Alexandria, Gros Colman, Bowood Muscat, and Golden Queen, the latter being, however, too unripe to be able to judge fairly of its character, but both berries and bunch were all that could be desired. The next best exhibition of Grapes came from Mr. Wildsmith, gardener to Lord Eversley at Heckfield, who had larger bunches than Messrs. Lane, but not quite so good in berry or finish: among them were large clusters of Barbarossa, White Tokay, Trebbiano, and Black Hamburgh. The best three bunches of Black Alicante came from Mr. Josiah Freeman, Beechwood Park, Dunstable; these were in all respects remarkably fine, the bunches being symmetrical in shape, large as regards berry, and beautifully coloured. From other growers also came good examples of the same variety. Madresfield Court Grape was shown, but here as elsewhere it was wanting in colour—the best came from Mr. J. Chard, Clarendon Park. The best examples of Buckland Sweetwater came from Mr. J. Bain, Downton Hall; Mr. Miles also had fairly good examples of this variety. The best three bunches of Black Hamburghs came from Mr. Coleman, the berries in which were the best coloured of any we have seen this season. Very fine bunches, though not so well coloured, came from Mr. Coomber, Hendre Park, Monmouth. In the class of three bunches of Muscat of Alexandria, Mr. Coleman was again first with well-ripened and excellent examples, and Messrs. Lane & Sons sent bunches but very little inferior; several other exhibitors, too, had remarkably good fruit of this Grape. Lady Downes Seedling was well shown by Mr. Wright, Thurlston Lodge, Ipswich, Mr. Chas. Tyler, Bishop Stortford, and others. The best-flavoured bunch of Black Grapes came from Mr. Bannerman, who showed a small but well-ripened cluster of Black Hamburgh, and the best-flavoured White Grape was Foster's Seedling, from Mr. Taylor, Hampstead Heath. The best bunch of Black Alicante came from Mr. J. Peed, Norwood Road, and Mr. Wildsmith, Heckfield, had the best bunch of Black Hamburgh. The heaviest bunch of Black Grapes (Barbarossa) was shown by Mr. J. Peed, the next by Mr. Wildsmith, whose bunch weighed 5 lb. 9 oz.; Mr. Wildsmith also had the heaviest bunch of White Grapes (White Nice). For ornamental baskets of Grapes Mr. Coleman was first with finely-coloured clusters covered with bloom; a fine basketful was also shown by Messrs. P. & S. Kay, Finchley. Mr. Coleman was likewise first for the best bunch of White Grapes, which consisted of a remarkably fine cluster of Muscat of Alexandria; Mr. Thomas, Oakleigh Park, had also well-ripened bunches, but not so large in the berry as those from Eastnor Castle. Altogether White Grapes were of unusually good quality. The best pair of smooth Cayenne Pines came from C. Ross, gardener to C. Eyre, Esq.; they weighed respectively 7 lb. 6 oz., but they were not ripe. The best Queens came from Mr. Churchfield, Westwood House, Sydenham. Single dishes of Plums—black, red, and yellow—were shown in quantity, as were also Figs and Peaches. The best Plums (any sort) came from Mr. Haycock, who showed very large, ripe examples of transparent Gages, Belgian Purple being the next best kind. In collections of fruit from which Pines were excluded were also good Peaches, Plums, and Figs, the best of which came from Mr. Cox, gardener to Lord Beauchamp. A dish of Greengage Plums came from Mr. Fry, Eastcott, Pinner, who obtained the first prize. The best dish of Kirke's Plum was shown by Mr. Murrell, and a good dish of Jefferson came from Mr. Pragnell. Mr. Chisholm, Maidstone, sent the best Figs; other exhibitors also showed fruit of first-rate quality. Mr. Coleman furnished the best dish of Peaches (Royal George); they were of unusually large size and well-coloured. Mr. Miles had a good dish of Crawford, and a kind named Exquisite, of an apricot colour, was well shown. The best Nectarines were Pittmaston Orange, the finest fruit of which came from Mr. Coomber, Hendre Park, Monmouth. Of Melons there were thirty specimens, the first prize for the best Green-flesh was won by Mr. Holder, Maidstone, with a small fruit of Bromham Hall; to a small fruit of Read's Scarlet-flesh, sent by Mr. Bain, was awarded the first prize for a Scarlet-fleshed Melon. Among Kitchen Apples the best appeared to be Lord Suffield, Hawthornden, Cox's Pomona, and Alexandra. The best collection of Apples came from Mr. Goldsmith, Sandhills, Surrey, who had large, clear-skinned fruit of some of the best kinds. The best dessert Apples fit for table came from Mr. C. Haycock, Barham Court, Maidstone; they consisted of Summer Golden Pippin, Kerry Pippin, and Red Quarrenden.

Clearing Runners from Strawberries.—Runners should be cleared away at once; for not only do they exhaust the soil uselessly, but they do harm in other ways, especially by overcrowding the main foliage on the permanent plants, and so in a measure weakening the crowns for next year's supply.—E. H.

Vegetables were well represented, collections of sixteen varieties, as well as smaller collections, being shown in great numbers. The best came from Mr. Pragnell, Sherborne Castle, who had remarkably fine examples of Model Potato, Sherborne Improved Onions, large heads of Cauliflower, Tender and True Cucumber, Canadian Wonder Beans (fresh and young), good Celery, Cardoons, Leeks, and Tomatoes. The next collection in point of merit came from Mr. Arkell; it comprised good Capsicums, Mushrooms, Tomatoes, Peas, &c. An equally good collection was furnished by Mr. Miles, Wycombe Abbey, who had very large Tomatoes and Onions, good Beans, and Brussels Sprouts. Good collections of salad vegetables were shown, consisting of Endive, Lettuces, Cucumbers, and others used for that purpose.

Miscellaneous Subjects.—Roses were for the season well represented in a cut state. A good collection of them came from Messrs. Cranston & Co., Hereford, in which were all the best autumn-blooming kinds. Messrs. Paul & Son had also an excellent collection, as had likewise Mr. Cross, Oxford. Messrs. Wm. Paul & Son also sent several stands in good condition, and from Mr. Ramsey, Waltham Cross, came a small collection of Roses. Mr. Chas. Turner, Slough, sent a group of Lilies in flower in pots. Messrs. Paul & Son sent small pyramid Apple trees in baskets loaded with fruit, in order to show the advantage of small trees in seasons like the present. Cut blooms of Asters were shown in good condition by Mr. John Morgan, Wray Park, Messrs. Saltmarsh & Son, Chelmsford, and others. A good stand of cut blooms of Verbenas came from Mr. Dobree, Somerset. Dahlias, which occupied a large table, were in every respect good. They came from Mr. Keynes, Salisbury, and Mr. Dobree. Good kinds were also contributed by other well-known growers.

In the dinner-table decoration department only three exhibitors presented themselves. The first prize was awarded to Mr. W. Soder, gardener to O. Hanbury, Esq., who had light and tastefully-arranged stands, consisting of Vallotas, Water Lilies, Encharis, and other flowers, Ferns, and Grasses, and six dishes of fruit effectively laid in Fern. The second prize was awarded to Mr. Chard, Salisbury, who had a good showy table, but the flowers were too heavy; the centre piece consisted of a Cocos Weddelliana, draped with Lapageria rosea, the base being covered by a group of Vallotas, Lilies, &c.; the side stands, which were of glass, were filled with Ferns and flowers of a light description. Wedding bouquets were sparingly represented, but a very neat one, composed of Eucharis amazonica, Odontoglossum crispum, Stephanotis, Roses, and Maiden-hair Fern, was shown by Miss E. Stuart, Holloway.

The New Early Peaches.—It was stated in THE GARDEN last month that the Early Beatrice Peach and Early Rivers have seen their best days as far as American cultivators of early Peaches are concerned. Their Early Alexander Peach ripens ten days before the Early Beatrice, and is said to be of far better quality and size, fetching 15 cents per lb. while the Beatrice would not sell for 1 cent. Their Early Amesen is likewise found to ripen as early or earlier than the Beatrice, and to be of better quality. The Maryland Early Peach is another variety, measuring from 8 in. to 8½ in. in circumference, and is stated to be excellent in flavour. I know that Hales' Early Peach is a good variety here, and it would be a great boon to growers if the early sorts just named were imported for trial. The Early Beatrice is at best but second-rate in flavour, of small size, travelling badly, and only fit for growing in pots to furnish dishes of Peaches very early. The Early Rivers I shall discard, for after fruiting it three or four years, I find it to crack at the stone and to be poor in flavour. The Early Louise is an excellent early Peach, and worthy of being extensively grown. Hales' Early is of better quality than Early York, and ripens a week or two earlier. Perhaps one of the very best early Peaches is the Groesse Mignonne, when true. It is succeeded by the Malta, an old variety of the Noblesse section, but the most deliciously flavoured of all Peaches.—WM. TILLEY, Helbeck.

Ascent of Water in Plants.—This was the subject of a paper read by Prof. M'Nab at the recent meeting of the British Association. Experiments made by him, and the results of which were published some time since, showed that the rapidity of the ascent of water in the xylem of the stem of a plant was nearly 40 in. an hour. Since the publication of the result Prof. Pfitzer, of Heidelberg, has made many experiments on the movement of water in plants. By him three methods were adopted. He first experimented by observing how soon leaves which had become flaccid from want of water regained their normal position when fed with the liquid. His second experiment was simply a repetition of that initiated by Prof. M'Nab, viz., he used lithium, which could be detected with the spectroscope, instead of water. His third series of experiments combined both the other methods, and as a result of them it was found that in the Sunflower the velocity of the ascent of water in the xylem was nearly 22 metres per hour—that is, one-third of a metre, or 13 in. per minute. Later on, however, Prof. Pfitzer adopted a new method, suggested by Prof. Koehne. He substituted a solution

of indigo and carmine, such as is extensively used by microscopists for water and lithium, and the results obtained by means of it corresponded precisely with those recorded by Prof. M'Nab, whose method of experimenting was adhered to. An important source of possible error in conducting these experiments has, however, been pointed out by Prof. Koehne, who has shown that the air or gases in the vessels of the wood of transpiring shoots are in a state of diminished tension. Shoots cut under mercury in a few minutes exhibit a rise of mercury in the stem of from 20 to 38 centimetres. In the Sunflower the tension of the air in the vessels equals 46 centimetres of mercury. This rise of mercury or other fluids in the vessels, due to diminished tension, Prof. M'Nab styles the abnormal current through the xylem. If the abnormal current were more rapid than the normal, experimenters might be led into grave errors, but Prof. M'Nab showed that there was demonstrative evidence that this condition does not exist.

NOTES AND QUESTIONS—VARIOUS.

Zinnias—In order to have good flowers of these, the plants must have rich soil and some liquid manure should also be given them occasionally. I have recently seen some cut blooms of Zinnias rivalling the Ranunculus in size, fullness, symmetry, and richness of colour. If compilers of schedules of prizes at flower shows would strike out Verbenas, which are generally poor things as cut flowers, and substitute Zinnias, the exhibition would thereby be the gainer.—D.

Dahlias unfitted.—Dahlias are certainly not benefited by being annually lifted and dried. Last winter, as we all know, was exceptionally wet, and although we left all our Dahlia roots in the open ground, merely covering the crowns with coal ashes, not a single failure has occurred, and I never remember seeing them so luxuriant or floriferous as they now are. In shrubby borders we have had them left out for several winters without any protection in the way of external coverings.—J. Groom, Henham.

Plants in the Paddington Canal.—Within the last few days I have gathered, within a mile of Westbourne Park Station, the following notable plants in the Paddington Canal:—Flowering Rush (*Butomus umbellatus*) and the Arrow-head (*Sagittaria sagittifolia*). Both were in flower. None of the floras of London give so near a station for the *Butomus*. The first mile of the canal, after passing the Kensal Green, is certainly better than the next two, which are, in fact, absolutely barren.—RUSSELL, in "Baywater Chronicle."

Plants for Wardian Cases.—Mr. Alfred Barton (see p. 244) will find some of his questions answered in my article on "Heated Plant Cases" which appeared in THE GARDEN for July 21. *Adiantums* and *Todeas* might be grown in such a case as he describes, but they could not be successfully associated, as the climatic conditions requisite for their cultivation are very different. *Selaginellae* are most accommodating, and would do well with either of the above species of Ferns. *Cephalotus follicularis* grows well in a plant-case, and so, no doubt, would *Darlingtonia californica*, *Sarracenia purpurea*, and *Nepenthes*, though I have no experience of these, and should think that they would be found too large for a case of the dimensions given. One of the very best Palms for a case is *Areca lutescens*. Variegated *Begonias* will grow almost anywhere. *Tradescantia zebrina* and *Ficus repens* are excellent trailing plants for the purpose. I should imagine that a *Dicksonia antarctica* small enough for the case would not be a very characteristic or desirable specimen; *Cypripediums*, *Odontoglossums*, and *Oncidiums* may all, with due care, be cultivated in a warm plant-case, the first-named planted in the bed of soil, and the others in baskets. I have no experience of *Coelogyne cristata*, and cannot recommend *Cattleyas* for the purpose. A small circular aquarium might be placed in the centre of the case, but it would, in my opinion, be as great an eyesore as the diminutive washhand-basin ponds which disfigure some gardens; however, it is a matter of taste, and no doubt many small water plants could be well grown in this way. The best way of making an aquarium fountain is to bring a small pipe from a cistern.—BOVEATON RADWON.

Fertilization of Alpine Flowers by Insects.—In my last article on Alpine Gentians, I supposed that the chief, if not the only fertilizer of *G. bavarica* and *verna* might be *Macroglossa stellatarum* with its proboscis of 25-28 mm. length. Yesterday, near the Albula pass, I was fortunate enough to confirm this supposition by direct observation. Altogether I saw five specimens of *Macroglossa stellatarum* at work, one on *Gentiana bavarica* and *verna*, three on *Primula integrifolia*, and one on *Viola calcarata*, each of them in a few minutes fertilizing some hundreds of flowers. For instance, the last of my five *Macroglossa* specimens, which I observed with the watch in my hand, in less than 4 min. visited 103, and in other 6½ min. 194 flowers of *V. calcarata*. As an illustration to what I have said in a former article on Alpine Orchids generally being adapted to cross-fertilisation by Lepidoptera, I may mention that near my present domicile there grow nine species of Orchids, eight of which (*Nigritella angustifolia*, *Platanthera bifolia*, *Grymnadenia conopsea*, odoratissima, *albida*, *Habenaria*, *viridis*, *Orchis globosa*, and *nustulata*) are adapted to cross-fertilization by Lepidoptera, whilst only a single one (*Orchis latifolia*) is adapted to cross-fertilization by other insects.—HERMANN MÜLLER, *Wiesenstien, Albula Valley, Switzerland*, in "Nature."

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

GARDENING IN THE LONDON PARKS.

FLOWER GARDENING in our public parks has this year been as efficiently carried out as usual, although the season has not been one of the best for the proper development of the plants. In Victoria Park, however—the worst situated as regards smoke—the trees, especially the Hollies and Willows, for which this park is noted, are in unusually good condition. Hawthorns are heavily loaded with berries, and well-established table-shaped trees, isolated beside the lake, are well worth the attention of visitors. In the herbaceous borders the double yellow flowers of *Helianthus multiflorus* fl.-pl., associated with masses of the stalwart, brilliant scarlet *Tritoma Uvaria*, have a striking effect from many points of view. These borders are also gay with Lilies, Gladioli, *Antirrhinums*, and many other flowering plants, judiciously intermixed with fine-leaved subjects, such as Tobacco and Castor-oil plants, and *Solanums*; the Golden-leaved *Catalpa*, too, is used here with good results along with *Acacias*, *Cannas*, and similar plants. Giant Hemps may also be seen interspersed here and there amongst the shrubs, and with excellent effect. What is termed carpet gardening is this year well carried out here, though the designs are less complicated than usual, and the colours more subdued. One of the most effective beds has for groundwork *Mentha Pulegium gibraltarica*, edged with two rows of *Echeveria secunda glauca* placed 1 ft. apart, the intervening space being filled with dwarf green Sedums, evenly-sized plants of *Sempervivum tabulæforme* being inserted at intervals amongst them. The central portion consists of *Alternantheras*, Golden Feather, *Mesembryanthemum cordifolium variegatum*, and small *Sempervivums*, set out in neat designs. Amongst beds of flowering plants, a few are well worth attention, though the recent rains have somewhat marred their beauty, especially in the case of *Pelargoniums* and *Verbenas*. Sub-tropical and other fine-leaved plants have not grown here quite so freely as they did last year, but there are, nevertheless, several very effective combinations of them. A large clump of *Aralias*, *Acacia lophantha*, *Ficus elastica*, *Wigandias*, Golden-leaved *Abutilons*, *Eucalyptus globulus*, and others, is very effective, as are also round beds of Tobacco plants edged with Beet-root and *Echeverias*. A mass of *Acacia lophantha* planted thinly amongst *Stellaria aurea* has a fine appearance, and beds of *Amarantus salicifolius* are likewise very brilliant, although the plants have not this season attained their usual height. Groups of *Erythrina Crista-galli* will shortly be in full bloom, and green-leaved *Cannas*, edged with white-leaved *Solanums*, have a fine effect. Castor-oil plants have done fairly well, and so have *Wigandias*, which are planted in masses by themselves in sheltered positions.

In Hyde Park perhaps the most striking features are the carpet beds along the side of Park Lane, which look fresh and gay compared with the dusty-leaved *Pelargoniums* and *Calceolarias* under the trees next the road. When grown under trees *Pelargoniums* and similar plants are never satisfactory: fresh green turf would be preferable. Even a few carpet beds would be more appropriate, inasmuch as the plants used in them are better able to withstand rain than flowers, and moreover should they get dusty, it can be readily washed off with a watering pot. One of the most striking beds is planted with Golden Feather *Pyrethrum*, on which are embroidered triangular and diamond-shaped designs composed of *Coleus Verschaffelti splendens* and *Perilla*, the whole being edged with *Alternantheras* and *Echeveria secunda glauca*. Between the beds, in the form of isolated specimens, are Palms and other fine-leaved plants, and large Sweet Bays, in tubs. Another pretty bed consists of *Pelargonium Manglesi* and *Viola Bluebell*, the colours of which contrast effectually with an edging of *Alternantheras* and *Blue Lobelia*. A mixture of *Gazania splendens* and *Iresine Lindeni* makes a showy mass edged with *Blue Lobelia*, *Alternanthera*, and *Mesembryanthemum cordifolium*. Sub-tropical

plants have not done well here this season, and many of them have been removed indoors some time ago. *Musas*, Castor-oil plants, *Wigandias* and in the "dell" at the head of the Serpentine are sadly disfigured by wind, clearly showing that the position is not a good one for them, at least in cold seasons. Large Palms, too, look very brown and unhappy, and would be better exchanged for something of a hardier character.

In Battersea Park the sub-tropical plants are this year in excellent condition, scarcely a brown leaf being observable on any of them; even *Musas* of large size have escaped the cutting winds. In shady nooks under trees may be found *Dracænas*, *Cycads*, *Arecas*, and other Palms, together with large Tree Ferns and Screw Pines, all in luxuriant health. Plants of the Crimson-flowered *Hibiscus* placed in recesses and backed up by shrubs look at a distance not unlike groups of single-flowered *Camellias*; mixed with other plants such as *Yucca aloifolia* and Golden-leaved *Abutilons* these *Hibiscuses* are very effective. A large bank planted with groups of the fine-leaved *Jacaranda mimosæfolia* and *Acacia lophantha*, surrounded by *Abutilon Darwini tessellatum*, *Eurya latifolia variegata*, India-rubber plants, and scarlet-flowered *Begonias*, constitute an effective feature, as do also round clumps of *Acacia lophantha*, Japanese Maize, and variously coloured *Lantanas*. The Golden-leaved Elder and *Catalpa* are used with good effect in raised positions. One of the prettiest beds consists of a groundwork of *Vitis heterophylla variegata*, edged with Japanese Honeysuckles, *Alternantheras*, and Silver Sedums with neat plants of *Grevillea robusta* placed at intervals, also *Ficus rubiginosa*. Large beds of *Fuchsias* of various kinds are unusually effective, the plants being from 2 ft. to 3 ft. high and heavily laden with bloom, the undergrowth being variegated *Veronicas* edged with *Euonymus japonicus aureus variegatus*. *Cannas* are in full bloom, and contrast well where grown on banks with glossy dark-leaved Hollies and overhanging Maples. A recess, filled with Silver-leaved Maples (*Acer Negundo variegatum*) alternately with *Rhus glabra laciniata*, and Tree Carnations with an undergrowth of *Coleus*, is strikingly effective, the edging consisting of yellow-leaved *Pelargoniums* (Creed's Seedling), and the Silver Sage (*Salvia argentea*). Carpet bedding is carried out here in its usual excellence, the best beds being those planted with *Alternantheras* and other coloured plants with specimens of *Dasyliirions* and similar subjects planted amongst them. A good arrangement is that made against the lodge near the river. Here a semicircular bank is planted with *Pelargoniums*, *Ageratums*, and similar plants, the background being White Dahlias; on the turf in front of this are well-arranged carpet beds, and isolated specimens of Palms, Agaves, and other ornamental-leaved plants, the whole being very effective. S.

Ornamental-leaved Maples.—The following notes, respecting some of the handsomest of the *Acer* family, have been sent to us by Mr. Berry, of Longleat:—*Acer platanoides Lorbergi*.—This beautiful new variety of Maple well deserves special notice on account of its richly-coloured foliage and free habit of growth. Its leaves, when newly unfolded, are a bright reddish-purple, not much inferior as regards brilliant colouring to *A. polymorphum rubrum*. It will, I think, make a highly ornamental tree, and form a beautiful contrast to *Acer pseudo-platanus corstorphinense*, the foliage of which is yellow when fully opened in spring. *A. Wagneri laciniatum*.—This is a fine, free-growing Maple, with beautiful, large, glossy, bright green foliage, which becomes richly coloured in autumn. *A. platanoides laciniatum*.—This peculiarly cut-leaved variety is not quite so vigorous a grower as the last-named. Its leaves are deeply cut and turned in at the points, giving them an appearance like that of an eagle's foot. *A. platanoides dissectum*.—This is another fine, cut-leaved Maple, which is well worth knowing. *A. platanoides Schwedleri*.—This somewhat resembles the kind last mentioned, but its leaves are a little larger, and it appears to be a more vigorous grower. *A. pseudo-platanus purpureum*.—This forms a stately tree; its foliage is large, handsome, and deep purple on the under side. A fine, ornamental tree, suitable for park planting.

Arundinaria falcata.—This nearly everywhere bloomed and died last year, mine doing the same: numbers of self-sown seedlings are, however, coming up where the plant stood; the seed therefore evidently ripened, though it appeared to me to be bad. Has this happened elsewhere?—A. RAWSON, Bromley Common.

HARDY ROCK PLANTS.

ONE of the chief aims of THE GARDEN, from its commencement, has been that of rendering hardy plants popular, especially Alpine or rock plants, and had I only a few yards of ground at my disposal and wished to make the most of them, I should certainly convert them into a rockery, on which I could grow a choice collection of Alpine plants. There are many beautiful subjects that could be grown better on rockwork than on the level ground, as, for example, the Primulas, including the Alpine Auriculas, and Primula curtusoides; also Saxifrages (both the large-leaved and the mossy sections), and the many varieties of Sedums, Sempervivums, and hundreds of other plants quite as interesting. It is difficult to lay down definite rules for the construction of a rock garden, as so much depends on the space and position at command. This much I may say, however, that it is not necessary that it should be in a shady position, for many Alpine plants will bear a fair amount of sunshine; at the same time while most rock and Alpine plants enjoy a certain amount of moisture, anything like stagnation would be fatal to them. If, for instance, a heap of clay be thrown together that has been dug out of the foundation of a new building and covered with rough stones, although a little soil is put between them to give the plants a start, those on the top of the mound may flourish for a time, but those lower down would either perish or drag out a miserable existence. In this case the water would not be able to percolate the mass of clay, and being thrown off the top would so deluge the plants on the sides in winter that they would perish. Therefore, however a rock garden may be formed, the first consideration must be perfect drainage, and another equally important point is suitable soil. Sometimes in forming rockwork hollow spaces are left about the stones and crevices, and the roots of the plants getting into these become too dry and frequently die off. To have a rock garden properly made, the lower parts of it should be well drained as the work proceeds and the crevices filled up, in order that superfluous water can pass freely away without leaving any cavity under or near the plants. Anything like straight lines should be avoided; on the contrary, aim at an irregular surface. If the rock garden be on a limited scale, even then there might be a miniature dell and a gentle rise, with occasional recesses and projections as fancy may dictate. As to materials, I would confine them as far as possible to good stones. One of the best pieces of artificial rockwork which I have seen is at Belvoir Castle; there the rock builder has imitated, as far as possible, the natural cliffs which abound on every hand. The large stones employed are laid on their natural beds, and now that they have become weatherbeaten casual observers might easily mistake them for natural rocks. Here every plant looks as if it were at home, and despite the unfavourable weather with which they had to contend last spring, all bloomed most satisfactorily. Amongst them are broad patches of Arabis Aubrietia, and Linaria; healthy clumps of the spring Gentian and Dorianicum austriacum; also Oxlips, Primroses, and Saxifrages in abundance, for all of which is afforded plenty of space for full development. It is a mistake to arrange the stonework in such a way that there is not room enough for the roots; a common error is attempting to crowd too many stones into the space at command, thus leaving few and small niches for the roots of the plants. Assuming, however, that the piece of rockwork consists of an irregular pile of stonework and earth, with interstices sufficiently roomy for Alpine plants, the next point is the most suitable kinds with which to clothe it. Instead of having those that bloom at the same time, I prefer a collection that would flower in succession from early in February right away into the dead of winter. If the rock garden be only limited, I would avoid all coarse-growing plants, and only use such as are close in habit, and which will at all times bear close inspection. A bed of Scarlet Pelargoniums or Yellow Calceolarias is seen at a glance, and is only admired for the striking effect produced by gaudy colours; but a piece of rockwork properly constructed and planted, be it only about 4 square yards in extent, will create much interest. Many fine plants occur in our Alpine and herbaceous collections, and if only a little care be taken as regards the choice of positions suitable for particular kinds, the cultivator will be amply rewarded by the way in which they will succeed. Some

Sedums and Sempervivums will even flourish on bare walls, and should therefore have a sunny aspect in the rock garden, for they require but little moisture; but Primulas, Gentians, and some of the Saxifrages enjoy a little shade in summer and a good deal of moisture. As regards shrubs I would not introduce many, in fact, if the object be to make it an Alpine garden I would not introduce any, nor plants of very tall growth. The following is a selection of the very best Alpine and rock flowers, and they are such as will grow on any soil with or without the aid of rocks or stones:

<i>Acæna microphylla</i>	<i>Erysimum ochroleucum</i>	<i>Ranunculus</i>
<i>Acantholimon</i>	<i>Erythronium</i>	<i>amplexicaulis</i>
<i>glumaceum</i>	<i>Deus-canis</i>	<i>montanus</i>
<i>Achillea Clavennæ</i>	<i>Euonymus</i>	<i>rutæfolius</i>
<i>tomentosa</i>	<i>radicans variegatus</i>	<i>Sagina glabra, var.,</i>
<i>umbellata</i>	<i>Fragaria indica</i>	<i>corsica</i>
<i>Adonis vernalis</i>	<i>Galanthus nivalis</i>	<i>Salix reticulata</i>
<i>Æthionema saxatile</i>	<i>plicatus</i>	<i>serpyllifolia</i>
<i>Ajuga genevensis</i>	<i>Gaultheria procumbens</i>	<i>Sanguinaria</i>
<i>Alyssum alpestre</i>	<i>Genista prostrata</i>	<i>canadensis</i>
<i>saxatile</i>	<i>sagittalis</i>	<i>Santolina incana</i>
<i>Andromeda tetragona</i>	<i>Gentiana acaulis</i>	<i>Saponaria ocymoides</i>
<i>Anemone angulosa</i>	<i>Geranium argenteum</i>	<i>Saxifraga aizoon</i>
<i>apennina</i>	<i>cinereum</i>	<i>Andreswii</i>
<i>blanda</i>	<i>lancastræense</i>	<i>cæspitosa</i>
<i>coronaria</i>	<i>Geum montanum</i>	<i>Cotyledon</i>
<i>fulgens</i>	<i>Gypsophila prostrata,</i>	<i>granulata plena</i>
<i>Hepatica</i>	<i>and others</i>	<i>hypnoides</i>
<i>palmata</i>	<i>Helianthemum in var.</i>	<i>juniperina</i>
<i>pavonina</i>	<i>Helichrysum</i>	<i>ligulata</i>
<i>Pulsatilla</i>	<i>arenarium</i>	<i>longifolia</i>
<i>ranunculoides</i>	<i>Hutchinsia alpina</i>	<i>oppositifolia</i>
<i>stellata</i>	<i>Hyacinthus</i>	<i>pectinata</i>
<i>Antennaria dioica</i>	<i>amethystinus</i>	<i>Scilla bifolia</i>
<i>tomentosa</i>	<i>Iberis corifolia</i>	<i>sibirica</i>
<i>Anthyllis montana</i>	<i>correæfolia</i>	<i>Scutellaria alpina</i>
<i>Antirrhinum rupestre</i>	<i>Garreuxiana</i>	<i>Sedum album</i>
<i>Arabis albidia</i>	<i>gibraltarica</i>	<i>Ewersii</i>
<i>petræa</i>	<i>Sempervivens</i>	<i>glaucom</i>
<i>Arenaria montana</i>	<i>Tenoreana</i>	<i>kamtschaticum</i>
<i>purpurascens</i>	<i>Iris cristata</i>	<i>pulehellum</i>
<i>Armeria vulgaris rosea</i>	<i>nudicaulis</i>	<i>rupestre</i>
<i>Astragalus</i>	<i>pumila</i>	<i>Sieboldi</i>
<i>monspessulanus</i>	<i>reticulata</i>	<i>spectabile</i>
<i>Aubrietia, in var.</i>	<i>Isopyrum thalictroides</i>	<i>spurius</i>
<i>Bellis</i>	<i>Leucojum vernum</i>	<i>Sempervivum</i>
<i>hortensis aucu-</i>	<i>Linaria alpina</i>	<i>arenarium</i>
<i>bæfolia</i>	<i>Linum alpinum</i>	<i>calcareum</i>
<i>double vars.</i>	<i>arborescens</i>	<i>glaucom</i>
<i>Bulbocodium vernum</i>	<i>Lithospermum</i>	<i>globiferum</i>
<i>Calandrinia umbellata</i>	<i>prostratum</i>	<i>hirtum</i>
<i>Calceolaria Kellyana</i>	<i>Muscari botryoides</i>	<i>montanum</i>
<i>Callirhoe involucrata</i>	<i>Heldreichi</i>	<i>soboliferum</i>
<i>pedata</i>	<i>Myosotis alpestris</i>	<i>tectorum</i>
<i>Campanula alpina</i>	<i>disitiflora</i>	<i>Senecio argenteus</i>
<i>cæspitosa</i>	<i>palustris</i>	<i>Silene acaulis</i>
<i>carpatia</i>	<i>Narcissus Bulbocodium</i>	<i>alpestris</i>
<i>Cenisia</i>	<i>juncifolius</i>	<i>Elisabethæ</i>
<i>fragilis</i>	<i>minor</i>	<i>maritima</i>
<i>garganica</i>	<i>Nierembergia rivularis</i>	<i>Pumilio</i>
<i>marialis</i>	<i>Oenothera marginata</i>	<i>Schaftæ</i>
<i>pulla</i>	<i>missouriensis</i>	<i>Smilacina bifolia</i>
<i>Raineri</i>	<i>taraxacifolia</i>	<i>Sternbergia lutea</i>
<i>turhinata</i>	<i>Omphalodes verna</i>	<i>Symphandra pendula</i>
<i>Cerastium, in var.</i>	<i>Orobis cyaneus</i>	<i>Thalictrum</i>
<i>Colchicum, in var.</i>	<i>vernus</i>	<i>anemonoides</i>
<i>Convulvulus lineatus</i>	<i>Oxalis Bowiei</i>	<i>minus</i>
<i>Soldanella</i>	<i>floribunda</i>	<i>Thlaspi latifolium</i>
<i>Cornus canadensis</i>	<i>Pentstemon procerus</i>	<i>Thymus lanuginosus</i>
<i>Coronilla iberica</i>	<i>Phlox divaricata</i>	<i>Triteleia uniflora</i>
<i>minima</i>	<i>reptans</i>	<i>Tunica Saxifraga</i>
<i>varia</i>	<i>subulata</i>	<i>Vaccinium Vitis-idea</i>
<i>Crocus, many species</i>	<i>Plumbago Larpentæ</i>	<i>Veronica candida</i>
<i>and varieties</i>	<i>Polygala Chamæbuxus</i>	<i>fruticulosa</i>
<i>Cyclamen europæum</i>	<i>Polygonum</i>	<i>prostrata</i>
<i>hederæfolium</i>	<i>vacciniifolium</i>	<i>saxatilis</i>
<i>repandum</i>	<i>Potentilla alpestris</i>	<i>taurica</i>
<i>Daphne Cneorum</i>	<i>pyrenaica</i>	<i>Vicia argentea</i>
<i>Giantia deltoidea</i>	<i>Primula amoena</i>	<i>Vicia minor</i>
<i>dentosus</i>	<i>Auricula</i>	<i>Viola calcarata</i>
<i>neglectus</i>	<i>integrifolia</i>	<i>cornuta</i>
<i>petræus</i>	<i>marginata</i>	<i>lutea</i>
<i>annulatus</i>	<i>officinalis in var.</i>	<i>odorata</i>
<i>Dielytra eximia</i>	<i>Veitchii</i>	<i>pedata</i>
<i>Diotis maritima</i>	<i>viscosa</i>	<i>Waldsteinia geoides</i>
<i>Dryas Drummondii</i>	<i>vulgaris, in var.</i>	<i>trifolia</i>
<i>octopetala</i>	<i>Prunella grandiflora</i>	<i>Zapania nodiflora</i>
<i>Eranthis hyemalis</i>	<i>Pulmonaria officinalis</i>	<i>Zauschneria californica</i>
<i>Erica carnea</i>	<i>Puschkinia scilloides</i>	<i>Zietenia lavandulæfolia</i>
<i>Erodium Manescavi</i>	<i>Ranunculus alpestris</i>	R. K.

NOTES OF THE WEEK.

HYDE PARK.—The mounds placed between the Serpentine and the "Row" have recently been completely removed. They would have obscured the view, and were a mistake from the commencement. The Row itself is being re-made with great care, although thoroughly overhauled last year. It is to be hoped it will prove satisfactory this time. The road has been raised in the centre, which will probably be detrimental to the line of trees there—already in a poor state. These would, however, probably be better removed altogether: if a line of trees be wanted in the centre, it would be better to begin anew with one species carefully chosen to suit the position.

MANGOES IN COVENT GARDEN.—These well-known Indian fruits are now exposed for sale in Covent Garden Market; they are about as large as a good-sized Lemon, and similar in shape but darker in colour. They may be sometimes met with in this country in hot-houses, where they are grown for ornament, their fruit being seldom eaten. In India and Brazil, however, ripe Mangoes are much esteemed, and the nripe fruits are used in tarts, pickles, and other conserves.

THE NEW EMBANKMENT GARDENS.—The new garden between Charing Cross Station and the Houses of Parliament is one of the prettiest in London, the flowers being bright, turf fresh, and plantations healthy and varied. The only drawback is the villanously ugly mud edgings to the beds. Assuredly the most unjustifiable puerility ever introduced to the flower garden were these low, cracked sections of mud walls to flower beds. We observe that these edgings have been done away with to a great extent in Hyde Park, and with great advantage.

A BRILLIANT CURRANT BUSH.—The Golden-flowered Currant (*Ribes aureum*), apart from its beautiful yellow, sweet-scented flowers, and glossy, smooth, pale green, summer foliage hanging on straw-coloured twigs—is with me just now (September 18) the most brilliantly-tinted shrub I think I ever beheld. Instead of the colouring being partial or patchy, as is sometimes the case, the whole plant is ablaze, so to speak, with the brightest of fiery tints, which, when viewed from a distance, look almost like a bush on fire. On closer examination, it is found that the finely cut and highly polished leaves are richly suffused with a lovely colour, varying between bright purple and brilliant vermillion. This shrub, though by no means new, is but seldom met with, although so valuable in autumn on account of its effectively-coloured foliage.—G. B.

THE GARDEN OF THE HOTEL DIEU AT PARIS.—The "Lancet" Commission speak highly of the garden in the new hospital at Paris:—"The garden itself, with its bright green turf and gay flower-beds, sets off to the best advantage the simple but elegant buildings which surround it. The general effect is magnificent, and one could imagine oneself in the courtyard of a palace not unworthy of the Grand Monarque. Besides the central garden, there are four others in the courts, enclosed by the six main pavilions, so that the patients of every ward have the advantage of a most cheerful outlook.

LAPAGERIAS AT CHELSEA.—The corridor in Messrs. Veitch's nursery is just now gay with white and rose-coloured flowers of *L. alba* and *L. rosea*. Instead of the shoots being formally trained to the trellis-work under the roof—a method too frequently practised—they are allowed to droop loosely, by which means, when thickly laden with bell-shaped, waxy flowers, as we find them here, a much better effect is produced. In sunless places in cool houses even in London these plants succeed perfectly, and can therefore scarcely be too highly valued. In Covent Garden Market blooms of these Lapagerias are fixed by means of wire to long shoots of *Ficus repens* in order to form festoons, wreaths, &c.; this obviates the necessity of mutilating the plants, and associated with the round, green and bronze leaves of the *Ficus*, the waxy, bell-shaped flowers of the Lapagerias are equally effective, and shoots of the *Ficus* can always be had in abundance.—C. S.

A PLEASANT-TASTING EMETIC (*Ungnadia speciosa*).—The above-named, highly-ornamental, hardy flowering shrub or small tree is a native of Texas and is known in America under the name of Spanish Buckeye. Its foliage resembles that of the Hickory, and its blossoms those of the well-known *Cercis Siliquastrum* or Judas tree. The Chestnut-like fruits (which are produced in pods of three, somewhat resembling those of the *Enonymus* or Spindle tree in shape, but about five times the size) have an agreeable sweet taste when eaten, but according to Dr. George Vasey (the learned compiler of the catalogue of the forest trees of the United States, prepared for the Philadelphia Exhibition) are strongly emetic. This tree was first introduced into European gardens in the year 1843 by means of seeds

sent to the University Botanic Gardens at Vienna by Dr. Lindheimer. It is still scarce and but little known or seldom seen in our gardens, where the beauty of its delicate, pale rose-coloured flowers, with their pendent and deep red-tipped anthers, as well as the above-named medicinal quality possessed by its fruit, should render it well worthy of more extended cultivation. It is well figured in a coloured plate in the tenth volume of Van Houtte's "Flore des Serres," tab. 1059.—W. E. G.

ACIS AUTUMNALIS.—This charming little autumn-flowering bulb is now in bloom about London. It thrives best in fine sandy soils, and is an interesting subject for the choice rock garden.

AUTUMN-FLOWERING CROCUSES.—The following Crocuses are now in bloom in my grounds, viz., *C. speciosus*, dark and light blue; *C. byzantinus*, rich purple, a remarkably fine species, and one of the most distinct and beautiful of Crocuses, the inner petals being about one-third the size of the outer; *C. pulchellus*, silvery-lavender, stigma orange, anthers white—a delicate little species.—P. BARR.

THE EARLY CRAWFORD PEACH.—This Peach, which is of American origin, was the handsomest kind shown the other day at the Fruit Show at Alexandra Park. Several dishes of it were furnished by good growers, and in each case the fruits were of good size and of the richest orange colour tinged with crimson; it is a good cropper and excellent in flavour; it is reported to reproduce itself true from seed.—C. S.

PITCHER-PLANTS AT CHELSEA.—The large house devoted to the culture of Nepenthes in Messrs. Veitch's nursery is now well worth a visit. Here are hundreds of plants growing vigorously, and forming numberless well-formed pitchers of all sizes. Large plants of *N. Rafflesiana* bear from twenty-five to thirty pitchers, each capable of holding at least a pint, and on the more rare *N. Veitchii* is an equal number of round, conspicuously-coloured pitchers. Suspended from the roof or placed on pedestals as they are here, such plants admit of Ferns and other shade-loving subjects being grown underneath them.

THE FLAME NASTURTIUM (*Tropæolum speciosum*).—This beautiful creeper, so much admired in the north of Scotland, where it thrives luxuriantly, but so seldom seen in good bloom in the south, is now sparkling with bright blossoms in Mr. Kinghorn's Nursery at Sheen, Richmond. A few roots received from the north and planted in a mixture of sand, loam, and peat, on the north side of a low wooden fence last March, have run up and overtopped the twiggy sticks, 9 ft. high, that support them. This plant, which is a profuse bloomer, is deserving of more general cultivation than it receives, its bright scarlet flowers being exceedingly handsome and showy; the only attention which it has had has been frequent waterings overhead.—J. F.

TABLE DECORATION.—Messrs. Wyman & Sons are about to publish "Floral Designs for the Table: Being Plain Directions for its Ornamentation with Flowers and Fruit," consisting of twenty-four original coloured designs, easy of execution, and illustrating the most perfect mode of decorating the breakfast, luncheon, dinner, or supper table. We hope the "gorgeous" and the "splendid" will not be the only effects illustrated in this volume. Even the prize designs at our flower shows are over-elaborate and gaudy.

A CIVIC CUSTOM.—On Tuesday at noon the master (Mr. Samnel Williams), the wardens (Mr. Henry Bollen and Mr. Alderman Knight), and the Court of the Fruiterers' Company—a civic guild founded in the third year of the reign of James I.—waited, by appointment, upon the Lord Mayor in the saloon of the Mansion House, and presented him with a splendid assortment of the choicest fruits of the season, including Grapes, Peaches, Apples, Pears, Melons, and Green Gages. Formerly the gift consisted of twelve bushels of Apples, which, neatly packed in baskets and covered with linen napkins, were brought from Farringdon Market by porters and escorted by the beadle of the company to the Mansion House. On its arrival in former days the Lady Mayoress used to direct her housekeeper to take charge of the fruit and put a bottle of wine in each basket for the use of the carriers, who were "regaled" with a dinner. At the ceremony on Tuesday the Lord Mayor was accompanied by Lord Elcho, M.P., Mr. Scott-Russell, the Rev. R. J. Simpson, Sir John Bennett, and other gentlemen who had been with him on public business. The master of the Company in appropriate terms offered the fruit for the Lord Mayor's acceptance, and his lordship suitably acknowledged the gift, and, following the custom, invited the company to dine with him at the Mansion House later in the year.

A NEW WORM DESTROYER.—We have received from Messrs. Rutley & Silverlock, of the Strand, a cake of "Soap," which is made from the seed of the Tea plant, and which is said to be efficacious in destroying worms in lawns. It is said to be much used in China for this purpose. We propose having it tried. It somewhat resembles a cake of rough Mushroom spawn.

GARDEN FLOWER SCREENS.

TEMPORARY hedges composed of quick-growing plants, principally annuals, are often found to be very useful for separating certain portions of the grounds from others, and concealing objectionable objects, &c. Among the subjects most useful for this purpose may be mentioned *Tropæolum aduncum* (Hooked Indian Cress, or Canary Creeper). The plant, however, is perhaps best known as the Canary-flower, so called on account of the fancied resemblance its blooms bear to that well-known bird. It is a native of Peru, but is sufficiently hardy to flourish in the open air of this country during the summer months. The various kinds of Sweet Peas are sometimes used as garden screens, but their period of flowering being somewhat contracted, they are not so suitable as the Canary-flower; the climbing varieties of the *Convolvulus* or Bindweed, although well suited to the purpose, have the drawback of their blooms being only expanded during a portion of the day, and remaining quite closed during unfavourable weather. The well-known and much-esteemed Scarlet Runner Bean (*Phaseolus vulgaris*), with its bright scarlet flowers, forms a most effective herbaceous hedge or screen, and is of course profitable as well as ornamental; and in addition to this, there is also a variety bearing pure white flowers, which, if intermingled with the scarlet-flowered kind, forms a very pleasing effect. I have quite recently seen a rustic arbour or summer-house in a cottage garden rendered exceedingly beautiful by being covered and festooned by these plants. During the summer months here an herbaceous screen is generally used with the view of concealing from a much frequented walk beds of Asparagus and similar rough-growing culinary vegetables. The screen is about 450 ft. long and is between 7 ft. and 8 ft. high; it is much admired when in full leaf, and is formed of the following annual climbers, viz., the Canary-flower, varieties of the *Convolvulus* major, and the various kinds of Sweet Peas. The seeds are mixed together in the proportion of two parts of the Canary-flower to one each of the *Convolvulus* and Sweet Peas, and are sown in a drill about $1\frac{1}{2}$ -in. deep, not earlier than the second week of April, as the seed of the Canary-flower will not germinate freely until the soil becomes somewhat warm, and during its early stages it is liable to be injured by frost; so that as soon as the plants are fairly above the ground, it is sometimes considered necessary to place a few Spruce Fir twigs among them as a protection, if the season be favourable. This protection is generally afforded by the Sweet Pea plants, which usually take the lead, and are closely followed by those of the Canary-flower, with a profusion of its neat and curious-looking yellow blooms, while are long the splendid flowers of the striped and beautifully blue-flowering *Convolvulus* begin to unfold themselves, in company with the various coloured varieties of Sweet Peas, the admixture producing an exceedingly gay appearance. The supports for the plants are stakes similar to those used for the tallest varieties of the culinary Pea, about 7 ft. or 8 ft. long, and these are fixed as firmly as possible in the ground, and to them the plants cling with the greatest tenacity, and soon form a dense hedge, which acts as an effectual screen. The Canary-flower and *Convolvulus* will also cling to upright poles, and will grow to a height of 15 ft., or even higher, should this be desired; and where poles are used, they should be placed at a distance of 15 in. or 18 in. from each other. When Sweet Peas cease to flower no blank is apparent, as they are by that time completely covered and concealed by the other plants forming the screen, which usually continue in full beauty until destroyed by the autumnal frosts. Before this takes place it is advisable to gather the necessary quantity of the Canary-flower seed, as it is easily destroyed by frost.

Outford.

P. GRIEVE.

Yellow-flowered Plants.—These are not, as a rule, in great favour, and few are met with in cultivation. This is doubtless partly due to the fact that the predominant colour of our wild flowers, especially in autumn, is yellow. Indeed, after passing the middle of this month, when the Heaths are over, there are few other than yellow-flowered wild plants in bloom; and some of them, such as the Ragwort, for example, continue in flower long after the leaves of most plants have lost the blue element of their green, and the yellow of approaching winter is only too conspicuous. It may also be partly

due to the rarity of plants suitable for cultivation having yellow flowers of clear, soft, and agreeable tints. When the *Calceolaria* fails it is difficult to find a good substitute for it. Yellow Pansies, when of vigorous growth, are very effective, because the foliage is of a deep dark green: therefore in using yellow it should always be borne in mind that it is one of the constituents of green, and should be associated with a green, in which the other element, blue, prevails.—H.

Sheltered and Moist Situations Best for Fruit-bearing

—In a sheltered nook of the park here stands a very old Crab tree commonly called by the villagers Molly White's Marling Crab. I grow in quite a hole, which even in dry seasons is always moist, and is sheltered on the east, south, and west by a small belt of Beech and Elm trees at a distance of about 40 ft. each way. It is a well-proportioned tree, about 40 ft. high, and the circumference of the branches is about 110 ft. On Sept. 15 I gathered six bushels of good sized fruit off it, that is, exclusive of windfalls and stolen fruit. Last year it bore none. Its leading shoots have made rather over 2 ft. of growth this season. Another case showing the value of protection is as follows:—In the most sheltered part of the orchard I have three trees carrying heavy crops of Apples, while in more exposed parts some trees are producing only a small quantity, and I may add that two of the trees carrying fruit stand close to the edge of a pond. This, and the case of the Crab tree, seem to prove that fruit trees standing in moist situations and sheltered have the best chance of bearing a crop.—J. SIMMONS, *Calverton Hall, Notts.*

Orchids now in Flower.—Large numbers of plants of the comparatively rare *Lælia Dayana* may now be seen in flower in Messrs. Low's nursery at Clapton. They are growing in small wooden baskets placed thickly on stairlike stages. The blooms, which are of the richest carmine and purple, resemble in form those of *L. pumila*, but they are almost as large as those of *L. purpurata*. Associated with these are hundreds of plants of *Oncidium varicosum* in flower, small plants bearing several strong flower-spikes, on which are some very large, rich golden blossoms. At this season of the year, when good indoor flowering plants are scarce, these are doubly valuable. *Dendrobium eburneum*, too, is flowering freely, and the blooms are very fragrant. The beautiful *Saccolabium Blumei* majus may also be found here in good condition, the blossoms being well coloured, and produced on large, well-formed flower-spikes. The more common *S. Blumei* is also in bloom, but it is not nearly so good as the larger variety.—S.

Cape Heaths at Clapton.—In the Clapton Nursery Heaths are grown by thousands, especially the winter-blooming kinds, such as *E. hyemalis*, *gracilis*, *Wilmoreana*, and others. They are placed during summer and autumn on beds of ashes in the open air, where the brightness of their foliage shows how well they appreciate the exposure. These plants are struck from cuttings in autumn and winter, the cuttings being obtained from young plants in 3-in. pots, which are being grown on for next year's flowering. Small points of the young shoots 1 in. long are taken off and placed under a bell-glass, having been previously sprinkled with water to keep them fresh until they can be made and inserted in the pots. The leaves are removed from the lower half of the cuttings by means of scissors or a sharp knife; they are then inserted thickly in 6-in. or 7-in. pots well drained and filled with sandy soil. A margin of about $\frac{1}{2}$ in. is, however, left unoccupied by cuttings all round the pots, to admit of a bell-glass being placed over them. After being put in, the cuttings are watered, and placed on wooden stages in a long, lean-to house, each pot being covered with a bell-glass. Very little heat is given, but careful attention is paid to watering them. When the cuttings are struck, they are potted three in a 3-in. or 4-in. pot, and when again established, they are placed on shelves in houses or in pits, where a still cooler temperature is maintained. In spring they are potted off singly in 4-in. pots, each plant having a small stake affixed to it, to prevent it from becoming loosened at the root. During summer, the plants raised in this way are placed in cold pits, and in the autumn they are topped, to keep them dwarf and to supply more cuttings. In the following spring they are potted into 5-in. or 6-in. pots, and placed out-of-doors for the summer, during which time abundance of water is given them, and they are set far enough apart to allow sunshine and air to have free access to them to ripen the wood, which is the main point to be observed, in order to get them to flower freely. As one now finds them, each plant is furnished with five or six strong shoots thickly beset with bloom-buds from top to bottom. As cold and unfavourable weather approaches, if not otherwise disposed of, they are placed in frames or houses where they can receive plenty of air, and after the flowering season is over, such as are left are cut down and potted in 8-in. or 9-in. pots to make large plants the following season. *Epaorises* are grown in a similar manner, but not being quite so hardy, they are kept in temporary frames, where they can be sheltered if necessary.—C. S.

TREES AND SHRUBS.

THE DWARF ALMOND

(AMYGDALUS NANA).

THIS is a valuable little shrub on account of the early period at which it flowers (March and April), and the gracefulness of the slender twigs on which the blossoms are produced. It forms a low, creeping, deciduous bush, 2 ft. or 3 ft. high, with smallish, oblong-linear leaves tapering to the base, serrated on the edges, and quite glabrous. The flowers are rose-coloured, and, as will be seen, open

Amygdalus nana.

thickly on the shoots before the leaves appear. The fruit is like that of the common Almond, but very much smaller. It is common all through the plains of Russia, and throws up an abundance of suckers. There is a white-flowered variety of it with much larger leaves than those of the kind just noticed. This may be found in cultivation under the names of *A. campestris* and *A. Beeseriana*.

GEORGE GORDON.

Propagating Evergreen Trees and Shrubs.—Cuttings of all kinds of evergreens, planted now in fine sandy soil, will form a callus during the autumn and winter and emit roots early in spring,

and in a couple of years will develop into small plants that would be useful for many decorative purposes, independently of the desirability of improving the character of the shrubberies. The choicer kinds of *Coniferae*, *Aucubas*, &c., will do better if they can be put in pots and plunged in Cocoa-nut fibre or sawdust under glass, where they can be kept close, in a cold frame on the north side of a fence. If taken off with a heel, that is, with a piece of the last year's wood at the base, they, like the majority of plants propagated by cuttings, will root with greater certainty.—H.

The Golden-leaved Elder.—On page 247 "S." correctly notes the Golden Elder as one of the best of coloured plants for enlivening shrubberies; but I must add that it is frequently condemned for its inconstancy in colour, particularly when it attains a considerable size. It is in this respect, like many more self and parti-coloured plants, that it shows itself to the best advantage when in a young and vigorous state. It is, however, easily propagated, and when rooted grows so luxuriantly that, considering the purpose for which it is required, it need never be allowed to arrive at any great age or size. I find, moreover, that large plants of it can be kept up to the colour standard by winter-pruning the shoots to within a few inches of where they started from the preceding spring. I know a large plant that used to be grand in colour, but last winter it was left unpruned, and now, in consequence of such neglect, it is almost green.—GEO. SYME.

Poisoning by Laburnum Seeds.—Four years ago I was called to the Richmond Street School to see twenty children, who after dinner were attacked with sickness. Skin cold and clammy; pulse quick and very feeble; eye-pupils very much dilated. With great difficulty some were roused out of their sleepy condition. Immense anxiety prevailed, as the children had not left the dinner-table more than twenty minutes. I was quite at a loss for the moment, and should not have thought of Laburnum seed but for the fact that on the very morning of the affair I was engaged in investigating the cause of death of some fowls, and was quite satisfied it resulted from swallowing the Laburnum seed. For many years we could not account for the loss. I further noticed some would eat them, whilst others would not; and secondly, I noticed that those that ate Mulberries were not affected. I gave the children bread and water, with mustard emetic. I could not find a trace of the seed in the vomit of those that suffered most, and were supposed to have eaten the least. I feel sure we ought to give great attention to such a dangerous tree, which is becoming a favourite in the garden. Brandy and beef-tea, with ammonia, were administered, which, with mustard baths, did good service. All recovered within twenty-four hours.—JOHN VANCE, *Plaistow*, in "Lancet."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Berberis Wallichii.—It seems that the *Berberis* we have all along been calling *B. Jamesoni* is really the *B. Wallichii*, *B. Jamesoni* being quite distinct and very scarce.—W. E. G.

Pinus Cembra.—The cone of *P. Cembra*, as represented on p. 263 of *THE GARDEN*, is unnaturally small, and therefore calculated to mislead. Healthy, well-grown specimens are from 2½ in. to 3 in. long, and proportionately wide.—S.

A Scented Eucalyptus.—Mr. Bull has introduced a species of Gum tree (*Eucalyptus citriodorus*) the leaves of which have a delicious halm-like odour. If it prove a vigorous grower, the tree may become famous for planting in malarious places, for such a halm odour escaping from a large surface could scarcely fail to have a good effect on the air.

Aquatic Trees.—The top of Grand View Mountain, near Middlebury, Vermont, has a remarkable pond, about three quarters of an acre in extent. Except a small space in the centre, it is covered with a thick Moss, strong enough for people to walk upon. Poles are pushed through the Moss at any point, but none have ever touched the bottom, yet there are large trees growing on it, and people walk in safety, the Moss forming a thick mat or carpet described as exquisitely beautiful.—[We find the above quoted in various papers. The condition is common enough in Canada, and probably elsewhere.]

Trees in Cornwall.—The comparative absence of trees in Cornwall affords a remarkable contrast in this respect to Devonshire. On the high grounds they are few and poor, and even in the hollows they do not attain any great size. Running about for some days, we did not happen to see a single tree worth taking notice of, and half-a-dozen miles from the Land's End they utterly fail. On the whole, Cornwall may be described as a treeless land. The hedges, however—many of them at least—are, like those of Devonshire, magnificent. One in particular above the Linyher was a perfect marvel of vegetation. In the course of a mile or two we noticed growing on it in wild luxuriance nearly all the ordinary trees of the country—Oak, Beech, Elm, Thorn, Hazel, Birch, Ash, Bramble, Ivy, with Foxgloves and dozens of other wild flowers past naming.—"Scotsman."

THE APPLE IN KENT.

(Continued from p. 255).

THIS fruit is grown chiefly in Mid Kent and the Weald of Kent. It is also grown in East and West Kent, though not to any great extent. In the first-named district the acreage of Apple orchards has recently decreased, especially of those under Grass in the neighbourhood of Maidstone. The trees had become, in many cases, cankered from rough pruning, or overburdened with useless wood from the absence of judicious thinning. No pains had been taken to replace trees that had died. The Grass had been systematically mown and kept unmaunured, or had been fed off by lean stock. It is only recently that the occupiers of Grass orchards have discovered that fruit trees require a large and regular supply of manure, and that Grass land has more than enough to do, unassisted, to repair the waste caused by constant mowing, or feeding off with animals getting their whole subsistence from it. Many Apple orchards of this description, which old men can remember as having been abundantly productive of Nonpareils, Ribston Pippins, Margils, Golden Russets, and other Apples of choice quality, rare size, and excellent flavour, have been grubbed up to make room for Hops. As the best land was invariably selected for Apple orchards, in times when Hops were not so highly esteemed, it is found that Hops always thrive remarkably well in the "old orchard" grounds. Most of the Apples now produced on the Greensand are grown on land that is dug and hoed continuously, either upon full-sized standard or half-standard trees. The former, from too much or too little pruning, and neglect of long standing, are in an unsatisfactory state, not yielding a tithe of what might be expected. The half-standards, though not frequently met with, are comparatively young trees, having been trained in the way they should go in more enlightened times, and their fruit is of better size and quality. As has been shown, the land is thickly covered with trees of various kinds, so that in midsummer it is often as difficult to force a way through some fruit plantations as through an ordinary copse, and it is a question whether the under trees, whose roots are nearer the surface, do not absorb the bulb of the manure and thus starve the Apple trees. In the Weald of Kent Apples are grown principally on Grass land, the fruit grown in this way being of a somewhat better colour and quality than that which has been produced on cultivated land; and practical men hold that, independently of this, all Apples grown on the Weald clay and Hastings sand are superior in colour and size and make better cider than the fruit grown in other parts of Kent, though there is not much difference as regards quantity. It is certain that Apples grown on Grass are not so liable to specks and blemishes. In the formation of an Apple orchard intended for Grass, it is found in practice to be best to plant the trees on well trenched land, and to lay it down after a few years, when the trees are well established. I have planted Apple trees of the excellent variety known as Lord Suffield on Grass land and on cultivated land at the same time, both being manured in the same way; those on the cultivated land grew away from those on Grass in a remarkable degree, and bore fruit the second year, while the others did not bear for three or four years. Apples are raised entirely from grafts. The tendency to reversion in this plant, in common with others of a fruit-bearing character, renders it impossible to depend upon plants raised from seed, or upon obtaining like from like. If the pips of the best sorts of Apples be planted, they reproduce heterogeneous varieties. When chance has developed a prodigy, it is well known to fruit growers that this can only be surely perpetuated by scions or grafts. Mr. Knight, in his "*Pomona Herefordiensis*," described a method of raising new sorts, by crossing varieties by artificial impregnation. Mr. Knight certainly produced new sorts, but it is questioned whether they were not the results of chance or of fecundation by insects. Upon this point the leading pomologist of the day lately made the following communication to me:—"I have endeavoured to raise seedling Apples by artificial impregnation: having kept them in pots under glass, I have been able to preserve them from any other fecundations, but the plants have not yet borne fruit." There has been a fallacy prevalent, that trees raised from grafts do not survive

the parent stock—that when an Apple tree dies all those trees that have been propagated from scions taken from it die in mournful accord. Mr. Knight, who was President of the Horticultural Society in the latter part of the last century, firmly believed in this curiously unnatural provision, and attributed the decay of the best sorts to its action. "The Golden Pippin," he wrote, "is in the last stage of decay, and the Styre and the Fox-whelp are hastening rapidly after them. I think I am justified in the conclusion that all Apple plants propagated from the same stock partake in some degree of the same life, and will attend it in the habits of their growth, their maturity and decay, though they will not be affected by any incidental injuries the parent trees may sustain after they are detached from it." The *naïveté* of this illogical statement is amusing. If an Apple tree die peacefully in its bed, having come to a green old age, its offshoots forthwith one and all decay. If, however, a tree be blown or cut down, the offshoots are not expected to commit suicide. Many generations of original trees have died and their descendants flourish yet. The Golden Pippin still exists in Kent, and the Styre and Fox-whelp are still plentiful in Herefordshire, in spite of Mr. Knight's funeral sermon in 1797. Notwithstanding this *reductio ad absurdum*, there can be no doubt that Apple trees produced from cross-fertilized seed would be more vigorous and fruitful than those reared in the usual way from a long series of stocks propagated by scions. This process is certainly unnatural, though it is convenient, in consequence of the tendency to atavism inherent in most plants that have been improved by selection. Artificial fecundation is a delicate operation, requiring careful manipulation and nicety of management, which prevent its general adoption. It is true it is practised in a rough way by the peasant girls of St. Valery, who go forth armed with Apple-blossoms to *faire ses Pommes*, to fecundate a peculiar sort of Apple tree whose flowers are devoid of stamens; but this is done to secure fruitfulness without reference to propagation. Mr. Darwin shows most clearly in his recent interesting work that cross-fertilization of plants improves them in most important points, and that continuous self-fertilization through many generations tends to gradual degeneracy. The conclusions arrived at by Mr. Darwin, after a most elaborate exposition of experiments upon various plants, are "that cross-fertilization is generally beneficial and self-fertilization injurious. This is shown by the difference in weight, height, constitutional vigour, and fertility of the offspring from crossed and self-fertilized flowers, and in the number of seeds produced by the parent plants. . . . After plants have been propagated by self-fertilization for several generations, a single cross with a fresh stock restores their pristine vigour, and we have a strictly analogous result with our domestic animals." Very curious notions have also been extant from very early days as to grafting. Pliny gives a graphic account of a grafted tree which was covered with all kinds of fruits—Nuts, Berries, Grapes, Pears, Figs, Pomegranates; but the tree did not live long is his conclusion. Lord Bacon also gravely speaks in his "*Silva Silvarum*," of Apple scions grafted upon a Colewort, which produced great flabby Apples. Kentish growers now generally discredit the absurdities as to grafted trees, and attribute the decay of some old sorts as the Ribston Pippin and the Nonpareil, in particular places, to the exhaustion of essential elements in the soil, to bad treatment, to constitutional delicacy, and liability to blight and canker. To these causes may be added the change in the temperature, to which allusion has been made. The Crab is the proper stock upon which to graft Apples, but as the supply of these stocks is limited, the best stocks are selected from those that have been raised from pips for that purpose in a nursery, and are grafted with scions of the kind required. The stocks are chosen from those sorts which have clear, hard stems, and are moved into the orchard when they are from four to five years old. The process of grafting requires much care and nicety, but as this has been so elaborately treated in a former number of this journal, it is not necessary to describe it again. Most growers cut the young tree hard the first year it is planted out, as this is supposed to favour root development. A practical and most successful grower, however, objects to this practice, considering "that the tree has enough to do to establish its roots

without being weakened by cutting." For the first few years the young Apple tree should be pruned so as to keep the middle well cleared out and the leading shoots as level as possible. When the tree is well established slight pruning will be necessary once in two or three years. Not nearly enough attention is paid to pruning the trees after they have become fair-sized. Now and then a raid is made upon those that are most bushy, which are hacked and cut about unmercifully, and it is not strange that Apple trees of the best sorts, invariably the most delicate, decay prematurely. Very few growers prune their Apple trees scientifically or manage them thoroughly in other respects. Here and there a plantation may be found where the trees have received systematic and proper treatment from the date of planting, where good fruit is produced in abundance; and it is asserted confidently that the land in Kent really suitable for Apple growing may be made to yield fruit not much inferior in quality to the traditional Nonpareils, Scarlet Nonpareils, Golden and Ribston Pippins, and other sorts, whose sweet memories linger yet in the recollection of Apple-loving octogenarians. To ensure this, however, there must in most cases be a fresh start; the land must be unexhausted, the management more skilful, and the treatment altogether more liberal. The pruning and clearing out of large Apple trees which have never been properly pruned, must not be done *per saltum*—at one fell swoop—but should rather be extended over several years. If large trees that are embarrassed with branches and filled up with spindly shoots, be cleared out at once, canker will certainly be produced in those of a delicate nature, and the most hardy sorts will be seriously weakened. It is better to prune Apple trees in the autumn, as soon as the fruit has been gathered, because it is more likely that fruit buds will be developed from pruning at that season than after winter cutting, which usually tends to create comparatively unproductive wood. The pruner of trees crowded with wood must aim at gradually cutting the oldest superfluous branches, so that each branch left may stand out by itself and get a full share of air, light, and sun. If the fruit grower employ only ordinary labourers to prune his trees, he should examine each tree himself, and mark with chalk those branches which he thinks should be cut away. In the case of young trees that have been properly trained, and of older trees that have been reduced to a proper state by gradual pruning as above described, the amount of pruning required is very trifling. The fruit in most sorts comes upon spurs or short twigs on wood that is at least two years old, generally from buds that are covered till late in the autumn with clusters of dead leaves. The chief objects are to ensure a proper supply of these fruit-bearing spurs, and to keep them from being crowded and starved out by unfruitful shoots or suckers that grow out on all sides in many sorts. There are a few varieties, however, in which the fruit is grown upon slight shoots. These require thinning out and shortening if possible to prevent the fruit from injury from wind.

CULTIVATION.—Cultivated fruit plantations are seldom manured with farm-yard or stable manure, as from its bulk it is difficult and expensive to put on land thickly covered with fruit trees. Shoddy is very largely used, at the rate of from 1 to 2 tons per acre, costing from 48s. to 100s. per ton, according to its percentage of ammonia. This is easily got in, and suits fruit trees well. Rags, both mixed and woollens, form a capital easily-applied manure; the quantity put on and the cost are about the same as in the case of shoddy. Fish manure, Rape dust, and the refuse from furriers' and tanners' shops are all good manures. I have tried superphosphate of lime without much apparent benefit. From kainite of potash put on fruit land at the rate of 7 cwt. per acre, it was thought that good results followed, though the effect of this manure could never be traced when applied for other crops; for Apples, like Hops, absorb an enormous quantity of potash from the soil. All manures are put on in the winter, and the land is dug afterwards with the Kentish spud which is used in Hop gardens, having four flattened tines, as early in the winter as possible, before any bloom-buds are developed, so that the diggers may not injure them and rub them off. The plantations, or "plats" as they are locally termed, are hoed over with plate hoes two or three times during the summer to check the

weeds, which grow luxuriantly in the shade of melancholy boughs. Many large fruit growers in East and Mid Kent sell the fruit on the trees by auction or private contract to middlemen, who, making fruit-buying a regular business, thoroughly understand the picking and packing of fruit, and the best time and place to sell the various kinds. Sometimes they are salesmen, or connected with salesmen in the London markets, who are well versed in the mysteries of the trade. This saves the growers much trouble, as they are generally busy with the all-engrossing Hop harvest when the Apples, Pears, Plums, and Nuts require attention. This is not so much done near London, where Hops are not grown to any extent.

DISEASES.—Besides canker, mainly caused by injudicious pruning, to which Ribston Pippin, Golden Pippin, King Pippin, and other delicate sorts are specially liable, a plague of caterpillars appears occasionally just as the trees are beginning to bloom. Twice within the last twelve years they have stripped the trees in certain situations of every vestige of blossoms and leaves. The caterpillars invariably follow a long spell of cold east wind, appearing on the trees unsheltered from its influence, showing that their juices have been changed by it, and rendered grateful to the tastes of the invading hosts. Washing the bodies of the trees with quicklime-wash in the winter is adopted to destroy the eggs that are deposited in the summer under the bark, as these eggs contain the destructive larvæ or caterpillars. Old trees and young trees on some soils are overspread with varieties of grey Lichens, which cover the trunks, the large branches, and even the small boughs and twigs. These Lichens are epiphytic, deriving their sustenance from the carbonic acid and moisture of the air, and not in any degree from the tree. Two specimens of these Lichens sent to Mr. Carruthers have been identified by him as *Ramalina fastigiata* and *Evernia furfuracea* respectively. Mr. Carruthers is of opinion that lichenous growth is not in any way injurious to the tree, as he believes that it is not found upon the younger branches, whose stomata still absorb carbonic acid. It may, however, be very frequently found even upon the smallest branches and twigs of Apple trees growing on the Kentish rag, and must tend to check, if not entirely to cut off, the supplies they would otherwise take in from the air. Apple growers believe that it is most injurious, and that a tree cannot be perfectly healthy when covered with it. They send men to throw up quantities of quicklime with scoops, like flour scoops, fastened to long poles, into the trees in damp weather. This adheres to the Lichens, quickly burning them up, and the tree is made clear and free. Salt water was recommended to check lichenous growth, in a paper read at the Maidstone Farmers' Club, as it had been noticed that trees near the sea-coast are perfectly free from them.

VARIETIES.—The chief sorts grown in Kent are, commencing with dessert Apples, the Ribston Pippin—*facile princeps* among Apples—now unfortunately a somewhat shy bearer. The King Pippin is much grown in Mid Kent and the Weald; this is a handsome Apple when well grown, but it is inclined to be specky on the rag-stone, though doing better on the Weald Clay. Joanettings and Summer Pippins (early kinds), are also grown and bring good prices. Red Quarrendens, Farleigh Pippins, Pearmain, Nonpareils, Golden Knobs, which ordinarily keep well until Apples come round again, bringing high prices in Covent Garden market, are found in most Kentish plantations and orchards. The Margil, whose flavour is nearly equal to that of the Ribston, and, as Dr. Hogg remarks, is of a better size for dessert, is too shy a bearer, and is not therefore extensively grown. The Blenheim Orange, a large handsome Apple, is much grown near Maidstone and in the Weald. Cox's Orange Pippin has been planted extensively of late. This is a high-class Apple for dessert from November to January, supposed to have been raised from a pip of a Ribston Pippin. The principal cooking Apples grown in Kent are Keswick Codlins, Gooseberry Pippins, Hawthorndens, Northern Greenings, Wellingtons, Winter Greenings (all valuable sorts), the Golden Noble, and Lord Suffield (a very fine-flavoured, early-bearing sort). Tower of Glamis and the Manx Codlin are chiefly planted now. In most old Apple orchards there are several other sorts of little value, such as the Gough—an acid and very low-class Apple, but an abundant bearer. Cider is but little made in Kent now;

its quality is comparatively poor, and the natives wisely prefer beer. The custom of giving drink to labourers is happily not much observed in the county, and there being but little demand for cider, growers send windfalls and low-class Apples in barrels to London, where they find a sale at some price for the "smashers," as low-class jam makers are styled in costermonger parlance; though, as a correspondent remarks, "since the Adulteration Act there has not been such a demand for rubbish." As many as 500 bushels per acre have been grown in plantations where the trees were in their prime. Taking an average of seven years of the average Apple-growing land in the county, the crop per acre per annum would be about 130 bushels. The average price per bushel for Apples home to the grower, for the last ten years, has been about 2s. 2½d.; the expenses for picking, packing, carriage, commission, and return of sieves, amounting to about 1s. 4d., having been deducted. For the preceding ten years, the average price, clear of all these expenses, was about 1s. 10d. per bushel. The annual yield per acre of the orchards under Grass must be regarded as being 20 per cent. larger than that of the plantations in respect of Apples, but the average annual yield of both taken together amounts to about the quantity of bushels stated above. The fruit growers in Kent do not appear to have tried growing, upon a large scale, Apples and Pears on low bush trees, obtained by working upon true Paradise stock, whose influence tends to dwarf the habit of growth, and to produce fruit abundantly. These bushes can be easily pruned and root-pruned if thought desirable. There are several plantations of these near London, one notably at Chiswick, belonging to Mr. Dancer, who grows quantities of the finest fruit upon this system, which it is thought might be adopted successfully by the large fruit growers in Kent.

(To be continued).

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Cobbett's Fall Apple.—The finest tree of Apples I have seen this year was of this kind. It is a large and excellent cooking Apple, and although by no means a new variety, it appears but little known in proportion to its merits.—JAMES GROOM, *Henham*.

American Blackberries.—It has been asked (see p. 163) if any of the American Blackberries are worthy of cultivation in this country. I have grown one variety—the Lawton, a finely flavoured kind—but our climate does not seem to suit it, as it only bears and ripens well in exceptionally warm summers. I can highly recommend the Parsley-leaved Blackberry (*Rubus laciniatus*) as one of the best varieties grown. It is a great bearer, and makes one of the best of preserves when combined with a few Apples.—W. TILLEY, *Welbeck*.

Simple Grape Growing.—That excellent Grapes may be grown without elaborate border preparation many examples prove. A very good one came under our ("Journal of Horticulture") notice the other day near Penge railway station. Mr. Baily simply made a narrow ridge on the surface of the garden (not excavating) of the loamy clay, mixed freely with stable manure, and in this planted his Vines, adding to the ridge as they increased in size. The Vines have for some years produced wonderfully heavy crops and no shanked berries. To borders above ground and rich surface dressings Mr. Baily attributes his success.

The American Cranberry as a Pot Plant.—Having on several occasions attempted to grow Cranberries with singular non-success, I am fully sensible of the importance of having at last, in a way, gratified my ambition. My early endeavours were founded on the idea of an artificial bog; I laid down beds of peat, provided water to swamp the ground, and planted Cranberries, but seldom saw the fruit. The plants were obtained from various parts, and all I could imagine as to their wants I carried out, but to little purpose. Four years ago I received from a friend about 1 pint of selected American Cranberries (*Oxycoccus macrocarpa*). They were nearly as large as Cherries, and of the most beautiful amber and crimson-scarlet tints. I planted these, and soon became possessed thereby of numbers of fine plants. A considerable portion of these were planted out, and, like their predecessors, came to little good. But a few that I reserved for pot culture have fruited freely, and are extremely handsome plants. These have been grown in spongy peat in large pans, which are kept in about 1 in. in depth of water. I believe my failures in Cranberry culture to have resulted from keeping the plants too wet, for although they are natives of bogs we do not find them in watercourses; my pot plants did not thrive when I kept them deeply immersed, as I did at first, cherishing the idea that they must be aquatic in constitution. When I adopted a maximum of 1 in. of water for the pots to stand in, the plants made rapid progress. I can assure those who find time and have the good taste to grow something besides bedding plants, that the American Cranberry is, for its beauty alone, well worthy of their attention.—"Gardeners' Magazine."

PEAR MONSEIGNEUR DES HONS.

THIS variety was obtained from a pip of Rousselet de Rheims, by M. Gibey Lorne, of Troyes. It grows and bears well on the Quince, but where standards are wanted they should be worked on Pear stocks. The fruit is of medium size, round, of a yellow colour suffused with brick red and spotted with grey; the flesh is melting and perfumed, and the fruit is usually ripe about the middle of August.

In Warttemberg this Pear grows strongly as an orchard tree, and there the fruit is used for drying, cooking, and for dessert.

M. BALTET.

Adventitious or Air Roots on the Vine.—These are so called from being produced on the stem, and being suspended in the air like so many threads. They are of the same character as the true roots, and only require to be brought into contact with the soil to become such. These air-roots are sometimes produced in great profusion from every part of the stem, frequently attaining 1 ft. or more in length, and so give the Vine a strange appearance. There is no particular harm in them *per se*, but their presence betokens a want of proper action on the part of the true roots running naturally in the soil. They are a sign of bad health, and are frequently the precursors of shanking; they give evidence that the proper roots are not in a condition to supply the great demands of a large expanse of foliage, &c., and that, aided by a warm, moist atmosphere within the house, Nature is trying to supply this want. Close warmth and moisture will induce the formation of such roots from Vine stems at any time; but if the true roots in a border be in a perfectly congenial condition, no air or adventitious roots will be produced in any ordinary well-managed Vinery; they are, in short, the result mainly of the roots being in a cold, wet border. To prevent their formation, or to recover Vines subject to this evil, the amelioration of the borders must be seen to. Some varieties of Vines, such as those of the Frontignan class, being of a more tender constitution, are more subject to the formation of air-roots than others. When they are produced they need not be cut off, except for appearance sake, for they will wither up and die as the wood ripens.—"Florist."

Vegetation of the Miocene Period.—The accompanying engraving represents a landscape as it may be supposed to have existed at the period of the Miocene or middle Tertiary formation. Judging from the evidence afforded by fossil plants, this was the great epoch for the development of monocotyledonous plants, as many as a hundred and eight-five species of these having been found in the Miocene formation. Among Cryptogams, Lichens have as yet only been observed in Baltic amber and on lignites of the Miocene age; in the same amber are preserved nearly all the fossil Mosses and Liverworts that are known. Coniferous forests entered largely into the flora of this period; and the amber to which reference has already been made, was originally a resinous exudation from some of these Coniferous trees, which were probably near allies of the Thuja and Cypress of recent Canadian and Asiatic forests. Besides the Conifers, large forests of Oak, Ash, Birch, Beech, and Willow existed in Northern and Central Europe towards the close of the Tertiary period. The remains of species of *Salix* and *Liriodendron* (*Tulip*-tree) are found in Italy, the recent analogues of stems occurring in Japan and North America, and *Liriodendrons* being also represented in China by an at present undescribed species which seems to be a native of the Kin-Kiang hills. The flora beneath the trees consisted largely of *Primulaceae*, *Crassulaceae*, *Scrophulariaceae*, *Ericaceae*, &c.: while Honeysuckles climbed up the trees or formed hushes, and *Loranthaceae* of different species were parasitic on the trunks and branches. The researches of Prof. Heer have done very much to elucidate the European flora of the Miocene period, and should be consulted by any one anxious to obtain a thorough knowledge of the subject.

VEGETATION OF THE MIOCENE AGE.

THE GARDEN-CRAFT OF SHAKESPEARE.

ANY account of the "Plant-lore of Shakespeare" would be very incomplete, if it did not include his "Garden-craft." There are a great many passages scattered throughout his works, some of them among the most beautiful that he ever wrote, in which no particular tree, herb, or flower is mentioned by name, but which show his intimate knowledge of plants and gardening, and his great affection for them. It is from these passages, even more than from the passages I have already quoted in which particular flowers are named, that we learn how thoroughly his early country life had permanently marked his character, and how his whole spirit was most naturally coloured by it. Numberless allusions to flowers and their culture prove that his boyhood and early manhood were spent in the country, and that as he passed through the parks, fields, and lanes of his native country, or spent pleasant days in the gardens and orchards of the manor-houses and farm-houses of the neighbourhood, his eyes and ears were open to all the sights and sounds of a healthy country life, and he was, perhaps unconsciously, laying up in his memory a goodly store of pleasant pictures and homely country talk, to be introduced in his own wonderful way in tragedies and comedies, which, while often professedly treating of very different times and countries, have really given us some of the most faithful pictures of the country life of the Englishman of Queen Elizabeth's time, drawn with all the freshness and simplicity that can only come from a real love of the subject. "Flowers I noted," is his own account of himself (Sonnet 99), and with what love he noted them, and with what careful fidelity he wrote of them, is shown in every play he published, and almost in every act and every scene. And what I said of his notices of particular flowers is still more true of his general descriptions—that they are never laboured, or introduced as for a purpose, but that each passage is the simple utterance of his ingrained love of the country, the natural outcome of a keen, observant eye, joined to a great power of faithful description, and an unlimited command of the fittest language. It is this vividness and freshness that give such a reality to all Shakespeare's notices of country life, and which make them such pleasant reading to all lovers of plants and gardening. These notices of the "Garden-craft of Shakespeare," I now proceed to quote; but my quotations in this part will be made under a different plan to that which I adopted in the account of his "Plant-lore." I shall not here think it necessary to quote all the passages in which he mentions different objects of country life, but I shall content myself with such passages as throw light on his knowledge of horticulture, and which, to some extent, illustrate the horticulture of his day, and these passages I must arrange under a few general heads. In this way the second part of my subject will be very much shorter than my first, but I have good reasons for hoping that those who have been interested in the long account of "The Plant-lore of Shakespeare," will be equally interested in the shorter account of his "Garden-craft," and will acknowledge that the one would be incomplete without the other. I commence with those passages which treat generally of—

I.—Flowers, Blossoms, and Buds.

- (1) *Quickly.* Fairies use flowers for their charactery.
Merry Wives of Windsor, act v., sc. 5.
- (2) *Oberon.* She his hairy temples then had rounded
With coronet of fresh and fragrant flowers;
And that same dew, which sometimes in the buds
Was wont to swell, like round and orient pearls,
Stood now within the pretty flow'rets' eyes,
Like tears that did their own disgrace bewail.
Midsummer Night's Dream, act iv., sc. 1.
- (3) *Gaunt.* Suppose the singing birds, musicians;
The Grass whereon thou tread'st, the presence strowed;
The flowers, fair ladies.
Richard II., act i., sc. 3.
- (4) *Katharine.* When I am dead, good wench,
Let me be used with honour; strew me over
With maiden flowers, that all the world may know
I was a chaste wife to my grave.
Henry VIII., act iv., sc. 2.

- (5) *Ophelia (sings).*
White his shroud as the mountain snow
Larded all with sweet flowers,
Which bewept to the grave did go
With true-love showers.
Hamlet, act iv., sc. 5.
- (6) *Queen.* While's yet the dew's on ground, gather those flowers.
Cymbeline, act i., sc. 6.
- (7) *Song.* Hark! hark! the lark at Heaven's gate sings,
And Phoebus 'gins to rise
His steeds to water on those springs
On chaliced flowers that lies.
Ibid., act ii., sc. 4.
- (8) *Arviragus.* With fairest flowers,
While summer lasts, and I live here, Fidele,
I'll sweeten thy sad grave.
Ibid., act. iv., sc. 2.
- (9) *Belarius.*
Here's a few flowers; but about midnight, more;
The herbs that have on them cold dew o' the night
Are strewings fitt'd for graves. Upon their faces.
You were as flowers, now withered: even so
These herblets shall, which we upon you strew.
Ibid.
- (10) *Juliet.* This bud of love, by summer's ripening breath,
May prove a beauteous flower when next we meet.
Romeo and Juliet, act ii., sc. 2.
- (11) *Titania.* An odorous chaplet of sweet summer-buds.
Midsummer Night's Dream, act ii., sc. 2.
- (12) *Friar Laurence.*
I must up-fill this Osier cage of ours
With baleful weeds and precious-juiced flowers.
The earth that's Nature's mother is her tomb;
What is her hurrying grave that is her womb,
And from her womb children of divers kind
We sucking on her natural bosom find,
Many for many virtues excellent,
None but for some and yet all different.
O, mickle is the powerful grace that lies
In herbs, plants, stones, and their true qualities:
For nought so vile that on the earth doth live
But to the earth some special good doth give,
Nor aught so good but strain'd from that fair use
Revolts from true birth, stumbling on abuse:
Virtue itself turns vice, being misapplied;
And vice's sometimes by action dignified.
Within the infant rind of this small flower
Poison hath residence and medicine power:
For this, being smelt, with that part cheers each part;
Being tasted, slays all senses with the heart.
Two such opposed kings encamp them still;
In man as well as herbs, grace and rude will;
And where the worser is predominant,
Full soon the canker death eats up that plant.
Romeo and Juliet, act ii., sc. 3.
- (13) *Iago.* Though other things grow fair against the sun,
Yet fruits that blossom first will first be ripe.
Othello, act ii., sc. 3.
- (14) *Dumain.* Love, whose month is ever May,
Spied a blossom passing fair
Playing in the wanton air;
Through the velvet leaves the wind,
All unseen, can passage find.
Love's Labour's Lost, act iv., sc. 3.
- (15) Fair flowers that are not gathered in their prime
Rot and consume themselves in little time.
Venus and Adonis.
- (16) The flowers are sweet, the colours fresh and trim,
But true sweet beauty lived and died with him.
Ibid.
- (17) Rough winds do shake the darling buds of May.
Sonnet 18.
- (18) With April's first-born flowers, and all things rare,
That Heaven's air in this huge rondure hems.
Sonnet 21.
- (19) The summer's flower is to the summer sweet,
Though to itself it only live and die;
But if that flower with base infection meet,
The basest weed outbraves his dignity:
For sweetest things turn sourest by their deeds—
Lilies that fester smell far worse than weeds.
Sonnet 94.
- (20) Yet nor the lays of birds, nor the sweet smell
Of different flowers in odour and in hue
Could make me any summer's story tell,
Or from their proud lap pluck them where they grew.
Sonnet 98.

"Of all the vain assumptions of these coxcombical times, that which arrogates the pre-eminence in the true science of gardening is the vainest. True, our conservatories are full of the choicest plants from every clime: we ripen the Grape and the Pine-apple with an art unknown before, and even the Mango, the Mangosteen, and the Guava are made to yield their matured fruits; but the real beauty and poetry of a garden are lost in our efforts after rarity, and strangeness, and variety." So, nearly forty years ago, wrote the author of "The Poetry of Gardening," a pleasant though somewhat fantastic essay, first published in the "Carthusian," and afterwards re-published in Murray's "Reading for the Rail," in company with an excellent article from the "Quarterly," by the same author under the title of "The Flower Garden;" and I quote it because this "vain assumption" is probably stronger and more wide-spread now than when that article was written. We often hear and read accounts of modern gardening in which it is coolly assumed, and almost taken for granted, that the science of horticulture, and almost the love of flowers, is a product of the nineteenth century. But the love of flowers is no new taste in Englishmen, and the science of horticulture is in no way a modern accomplishment. We have made large progress in botanical science during the present century, and our easy communications with the whole habitable globe have brought to us thousands of new and beautiful plants in endless varieties; and we have many helps in gardening that were quite unknown to our forefathers. Yet there were brave old gardeners in our forefathers' times, and a very little acquaintance with the literature of the sixteenth century will show that in Shakespeare's time there was a most healthy and manly love of flowers for their own sake, and great industry and much practical skill in gardening. We might, indeed, go much further back than the fifteenth century, and still find the same love and the same skill. We have long lists of plants grown in times before the Conquest, with treatises on gardening in which there is much that is absurd, but which mark a practical experience in the art, and which show also that the gardens of those days were by no means ill-furnished either with fruit or flowers. Coming a little later, Chaucer takes every opportunity to speak with a most loving affection of flowers, both wild and cultivated; and Spenser's poems show a familiar acquaintance with them, and a warm admiration for them. Then in Shakespeare's time we have full records of the gardens and gardening which must have often met his eye, and we find that they were not confined to a few fine places here and there, but that good gardens were the necessary adjunct to every country house, and that they were cultivated with a zeal and a skill that would be a credit to any gardener of our own day. In Harrison's description of "England in Shakespeare's Youth," recently published by the new Shakespeare Society, we find that Harrison himself, though only a poor country parson, "took pains with his garden, in which, though its area covered but 300 ft. of ground, there was 'a simple' for each foot of ground, no one of them being common or usually to be had" ("Edinburgh Review," July, 1877). About the same time Gerard's Catalogues show that he grew in his London garden more than a thousand species of hardy plants, and Lord Bacon's famous "Essay on Gardens" not only shows what a grand idea of gardening he had himself, but also that this idea was no Utopian idea, but one that sprung from personal acquaintance with stately gardens, and from an innate love of gardens and flowers. Almost at the same time, but a little later, we come to the celebrated "John Parkinson, Apothecary of London, the King's Herbarist," whose "Paradisus Terrestris," first published in 1629, is indeed "a choise garden of all sorts of rarest flowers." His collection of plants would even now be considered an excellent collection, if it could be brought together, while his descriptions and cultural advice show him to have been a thorough practical gardener, who spoke of plants and gardens from the experience of long-continued hard work amongst them. And cotemporary with him was Milton, whose numerous descriptions of flowers are nearly all of cultivated plants, as he must have often seen them in English gardens.

And so we are brought to the conclusion that in the passages quoted above in which Shakespeare speaks so lovingly and

tenderly of his favourite flowers, these expressions are not to be put down to the fancy of the poet, but that he was faithfully describing what he daily saw or might have seen, and what no doubt he watched with that carefulness and exactness which could only exist in conjunction with a real affection for the objects on which he gazed, "the fresh and fragrant flowers," "the pretty flow'rets," "the sweet flowers," "the beauteous flowers," "the sweet summer buds," "the blossoms passing fair," "the darling buds of May." H. N. ELLACOMBE.

Food Reform.—I hear something of the projected establishment of a "Dietetic Reform Club," with a view of affording dining accommodation to vegetarians visiting London. The promoters of the movement would do better, I fancy, could they open a few good vegetarian restaurants in the metropolis, open to all and sundry. I am not wedded fanatically to the doctrine of wholly abstaining from animal food; but I cannot help thinking that most English people, taking one month with another, eat a great deal more meat than is good for them. But where are you to get a succulent vegetarian dinner? If you try the system in your own house (not constraining other people to follow your example), the cook, after a few days, gives warning, as "not been used to them outlandish ways;" and your family, while scornfully suffering you to go your own way, secretly opine that you are either out of temper or growing stingy, or going mad.—G. A. S., in "Illustrated London News."—[This is too true, one pities a vegetarian who has to exist away from his garden; and in any town that we know of food reform has little chance till garden food is good, fresh, and varied, and is as easily obtained as bread or beer.]

Poisonous Honey.—An accident which a short time since befell the war correspondent of the "Daily News" in Armenia, recalls the fact, long known but generally forgotten, that honey sometimes possesses virulently poisonous properties. In this case the correspondent having drunk some water sweetened with honey was shortly afterwards seized with headache, vomiting, coldness of the extremities, temporary blindness, followed by a cataleptic state that appeared to bring him to the verge of death. Suspicion of an attempt to poison fell upon an innkeeper and he was arrested, but an examination of his honey, which was from the Batoum valley, where Hemlock and Henbane grow abundantly, revealed the source of the injury. It is interesting to note that this incident occurred within a few miles of the spot where more than 2000 years ago a similar accident, but on a larger scale, happened to the "ten thousand" during their celebrated retreat. Xenophon says that two marches from Trebizonde the Greeks encamped in some villages that had been abandoned, where there were a great number of beehives. All the soldiers who ate of the honey suffered from delirium, vomiting, purging, and inability to stand. Those who ate but little appeared intoxicated, whilst of those who ate more some were raving and others seemed to be dying. The soldiers lay on the ground as after a defeat, and a similar consternation reigned. None died, however, the principal effects passing off next day, though three or four days afterwards the sufferers had the appearance of sick people who had used a violent remedy. Dioscorides, Pliny, and other authors also mention poisonous honey. Pliny attributes the poisonous properties of one honey from this district to the bees frequenting a plant fatal to the beasts of burden and to goats in particular, which he calls Aegolethron, or Goat's-death, a plant that (according to the "Pharmaceutical Journal") has been identified with *Azalea pontica*.

Protecting River-sides.—Willows luxuriate in the immediate vicinity of water: they throw out thick matted roots in abundance, which protect the bank, while the annual cuttings of the wood will in most instances be equal to the heritable value of the land they occupy. There are many instances to be met with where much valuable land is lost through neglect, and landowners and tenants would not only be adding countless and varied charms to the landscape, but improving and enriching the district, were proper attention bestowed to the utilising of river-sides. That river-sides can be utilized to return a fair remunerative rent must be admitted as a fact if we calculate that, according to a writer in the "Journal of Forestry," 6000 tons of Willows are annually imported and sold in the English market at £5 10s. per ton. Surely British economy can compete with foreign industry, and the £33,000 worth of Willows annually brought from Holland and France successfully cultivated at home. Willow is easily propagated, and requires little or no attention either in planting or after treatment. Black Willow or "Sallow" forms an excellent hedge planted along the verge of rivers, and beyond the cost of planting is attended with no expense.

THE FLOWER GARDEN.

HELIANTHUS ARGOPHYLLUS.

Less remarkable for the dimensions of its flower-heads than the common Sunflower and its varieties, the *Helianthus argophyllus* possesses several advantages over these plants, in the greater abundance of its capitules, its more graceful habit of growth, and in the silvery grey colour of its foliage. It usually grows from 4 ft. to 5 ft. high, and branches to the very base, the branches themselves being much ramified—an arrangement which ensures an abundant supply of flower-heads. These are about 3 in. across, the ray-florets being a bright yellow colour, and the disc of a blackish-purple. The whole is densely clothed with a soft grey pubescence, especially the younger branches, which gives it a silvery aspect to which its specific names alludes. There is, however, often considerable

The Silvery Sunflower (*Helianthus argophyllus*).

variation in this feature among the seedlings, and it is found necessary to save seed only from those plants which exhibit the silvery pubescence in a marked degree. In situations where it may not be desirable to allow the plant to attain its full height, it may be kept dwarf by stopping the leading shoots. This species and the equally interesting *H. cucumerifolius* of more recent introduction from the same region (Texas) are well suited for small gardens where the coarser species would be out of place.

W. T.

Brugmansias Planted Out.—These are exceedingly effective when planted out-of-doors in summer, or plunged in pots so that the roots can find egress. The large drooping blossoms are produced in abundance, and make effective objects in sub-tropical gardens. Well-established plants headed in closely will improve every year.—JAMES GROOM, Henham.

PLATE XCII.

THE ST. JOHN'S-WORTS,

WITH A COLOURED FIGURE OF *HYPERICUM PATULUM*.

SEVERAL of the St. John's-worts are very beautiful, especially when set off by the dark foliage of other shrubs. The genus *Hypericum* is a very large one, and it has a very wide area of distribution, occurring in Arctic, temperate, and sub-tropical regions, and on the mountains of most tropical countries. Upwards of 150 species are known, and they are chiefly spread over temperate Europe and Asia, a few extending north of the Arctic circle. Nearly a score of species are found in the mountains of India, being spread over the Himalayan range and the mountains of the peninsula, and two are abundant in Ceylon. Six or eight species have been collected in the mountains of tropical Africa, two or three of which extend to the Cape of Good Hope, and one to the Isle of Bourbon. *H. japonicum* and *gramineum*, both widely dispersed species, are abundant in New Zealand and the eastern side of Australia. In America St. John's-worts abound in certain parts, from Canada southward through the mountains of Mexico and South America to Chili. And in all these distant regions it is not difficult to distinguish them, for although the foliage of different species is very diverse, they possess in common an unmistakable family likeness. With few exceptions the flowers are yellow, but those of *H. virginicum* are tinged with pink, according to Dr. A. Gray's description, or quite red, as figured in Andrews's "Botanists' Repository." There are also some white-flowered species, as I learn from Benthum and Hooker's "Genera Plantarum," which I suspect are South American, but I have no books at hand to clear up this point. There is also one Indian species described as having large white flowers which turn yellow. None of the South American species appear to have been introduced into European gardens. They are chiefly remarkable for the great variety of foliage they display. Some of them resemble Heaths; others are more like Junipers; and *H. connatum* has connate leaves like the Yellow-wort, *Chlora perfoliata*, but they are conspicuously veined and coriaceous. The genus is represented by nine indigenous species in the British Islands, and two or three others are more or less perfectly naturalized; amongst them are some that rank with the most ornamental, and are included in the following selection. Although upwards of fifty species have been introduced and cultivated at different times, there is too much sameness in their general character to admit many of them in an ordinary garden. All the species are herbs, or shrubs of small size, with opposite, undivided leaves, commonly covered with transparent glands or black glandular dots. The stamens in nearly all the species are very numerous and conspicuous, and united in three or five tufts, and the three or five styles afford distinctive characters of the species.

Spreading St. John's-wort (*Hypericum patulum*—Thunberg).—This fine species was discovered by Thunberg, in Japan, nearly a century ago, but it was first introduced into this country about twelve years ago. Seeds of it were sent from Japan by the unfortunate Richard Oldham, one of my most esteemed associates during my early days at Kew, who, after a year or two's successful collecting, fell a victim to dysentery. Being cut off so young, there is little in our gardens to keep his name alive; and it is, therefore, a pleasure to me to be able to put it on record here in connection with one of the comparatively few living plants for which we are indebted to him. This plant, on the authority of Thunberg, was commonly cultivated in Japanese gardens at the time of his visit, and he also observed it growing wild. But it is not confined to Japan, being common in the temperate regions of the Himalayan Mountains at an elevation of between 3000 ft. and 7000 ft., whence a small-flowered variety was introduced at the beginning of the present century by Messrs. Whitley, Brame, & Milne, of the Fulham Nursery. This was figured in the "Botanical Magazine," t. 2375, under the name of *H. uralum*. Thus it will be understood that in its wide range this species presents considerable variation, and some of the varieties are less ornamental than the one portrayed in the accompanying figure. It is a shrub from 1 ft. to 3 ft. high, with spreading branches, the younger ones having a red bark, and the petals are twice as long as the stamens. It is needless to dwell on its other characters, but in the descriptions of other species, this will be taken as the basis of comparisons. Its flowering season is September and October, and its hardiness seems to be undisputed.

Hooker's St. John's-wort (*H. Hookerianum*—Wight and Arnott; *H. oblongifolium*—Hooker, Bot. Mag., t. 4949).—This is closely allied to *H. patulum* in floral characters, but it is of larger dimensions in all its parts. It forms a shrub 6 ft. to 8 ft. high, with reddish-brown branches, and leaves, in luxuriant specimens, 3 in. to 4 in. long, and the flowers are upwards of 2 in. in diameter. A native of the mountains of Northern India, in the Sikkim Himalays,

THE ST. JOHN'S WORT, *HYPERICUM PERFORATUM*

at from 8000 ft. to 12,000 ft., and Khasia at from 4000 ft. to 6000 ft., also in the Nilghiri Mountains. It was introduced in 1823, but it is now very rare, if it still exist in English gardens. It is described as a truly lovely hardy shrub.

Nodding St. John's-wort (*H. cernuum*—Roxburgh; *H. speciosum*—Wallich).—A shrubby species, 3 ft. to 6 ft. high, with lanceolate leaves, 1 in. to 3 in. long, and white eventually yellowish flowers, 2 in. in diameter, in terminal clusters of three to five. It is a native of western temperate Himalaya, from Kumaon to Sirmour, at from 5000 ft. to 7000 ft. Not introduced.

Nepaul St. John's-wort (*H. nepalense*—Choisy).—A trailing plant, with slender, weak stems; leaves less than 1 in. long, and small flowers. Not particularly ornamental, but very hardy, inhabiting the Himalaya Mountains at an altitude of from 10,000 ft. to 12,000 ft. Introduced in 1826.

Kalm's St. John's-wort (*H. Kalmianum*).—A North American dwarf, shrubby species, with oblong-lanceolate leaves about $1\frac{1}{2}$ in. long, and numerous flowers about $\frac{3}{4}$ in. across. The stamens are very numerous, as long as the petals, and scarcely united at the base, and it has five styles; the petals are narrow and do not overlap each other, as in the foregoing species. *H. prolificum* is closely allied, differing mainly in its broader foliage. Both were introduced about the middle of the last century, and do not present any remarkably ornamental features.

Fetid St. John's-wort.—This is the shrubby species commonly met with in English gardens, and deserving of notice for its hardness, capability of flourishing in almost any soil, and for its long flowering season, often remaining in bloom till the end of October. It is a much-branched shrub, 3 ft. to 5 ft. high, having oblong-lanceolate, obtuse leaves, about 2 in. long, and yellow flowers $1\frac{1}{2}$ in. in diameter, borne in clusters at the tips of the branches. The leaves emit a peculiar goat-like odour when crushed, and the flowers of this species are easily recognised by the three very long styles, which project considerably beyond the stamens. A native of the south of Europe, introduced in 1640. It grows well in partial shade.

Tutsan (*H. Androsæmum*).—This native species deserves mention on account of the agreeable odour exhaled by its leaves when dried, which they retain for years if kept in a book. It is very similar, if not identical, with coumarin, the fragrant principle of the Tonquin Bean, Fenugreek, and some other plants. A native of hedgerows and woods in the south and west of England. The leaves are 2 in. to 4 in. or more in length, and the flowers relatively small. In Sussex it bears the popular name of Sweet Amber. The name Tutsan is said to be a corruption of the French *toute saine*, which might be rendered *heal-all*. Formerly the leaves were applied to open wounds.

Rose of Sharon or Aaron's Beard (*H. calycinum*).—In its way, this is the most valuable of the genus, as it is an admirable plant for clothing shaded or partly shaded banks and woods. Moreover, its flowers are larger than those of any other species, being from 3 in. to 4 in. in diameter, and of a beautiful bright yellow, contrasting well with the large, glossy, dark green leaves. It seems almost superfluous to add that it is a prostrate almost evergreen shrub, because it is the species most commonly seen in gardens, a distinction it fully merits. A native of South-eastern Europe, now established in a wild state in many parts of these islands.

Elegant St. John's-wort (*H. pulchrum*).—An herbaceous species, and one of the prettiest of our native plants, growing in dry copses and on heaths and commons. Its slender, flexible stems rise to a height of 1 ft. to 2 ft., and are clothed with small, cordate, obtuse leaves, and terminate in many-flowered panicles. The flowers are from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in diameter, yellow tinged with red, and the petals bordered with black glands; the anthers also are red. Said to be the badge of the McKinnons. It is very widely dispersed in Europe northward into the Arctic regions.

Woolly St. John's-wort (*H. Elodes*).—A pretty native plant for the banks of pools and lakes. It has short stems, clothed with roundish, woolly leaves. The pale yellow flowers are small, but the red glandular dots on the calyx give them an attractive appearance. This and the next differ from all the others in having from nine to fifteen stamens only.

Red-flowered St. John's-wort (*H. virginianum*—Andrews, Bot. Rep., t. 552).—At first sight this plant, as figured by Andrews, reminds one more of a *Boronia* than a *Hypericum*. A hardy, herbaceous plant resembling the last in habit, and interesting on account of the colour of its flowers, but not particularly showy, as "the flowers are of short duration, and only a few are open at the same time." A native of North America from Canada southwards; introduced into England by a Mr. Lyons in 1840. W. B. HEMSLEY.

ANNUAL MESEMBRYANTHEMUMS.

SUCH a long-winded name as *Mesembryanthemum* for an annual almost alarms one, and that, too, belonging to our common Ice-plant (*M. crystallinum*), of which the annexed is a representation, a plant grown in most large gardens for garnishing purposes; it is also sometimes used as a pot plant, but it is most effective when planted out on rockwork, or better still, on some old terrace wall, if such exists, allowing it to fall over its face. It will grow from 3 ft. to 4 ft. in a season, and on warm days has a cool and refreshing look. Its flowers are unimportant compared with the crystal-beespangled stems and foliage, and the richer the ground the greater the crystal development. Seeds of it should be sown in heat in March. There

Ice-plant (*Mesembryanthemum crystallinum*).

are two varieties of it, one with red and the other with white flowers. I may add that this is not the Ice-plant of cottage windows; that is a perennial named *M. cordifolium*. *M. pomeridianum* is a strong-growing species, with broad, spatulate foliage and large, purple and rose coloured flowers. As its specific name indicates, it flowers in the afternoon. It is not so common a kind as the last, but it well deserves a place on a south border. *M. tricolor* is perhaps the most showy of the annual *Mesembryanthemums*; it is a neat plant with cylindrical foliage, and is not a creeper; it grows 6 in. or 8 in. wide and 4 in. or 6 in. in height; of its flowers, which are abundant, some are purple and the others rose, the result being a good contrast; this species should be sown in a sandy soil in the open garden about the end of April, as it dislikes transplantation, and it lasts longer in the ground than in a pot. *M. pinnatifidum* is a pretty little plant which has the habit of *M. crystallinum*, but is not so rampant a grower; the foliage is semi-pinnate, and the flowers small and red in colour. *M. anatomicum* is

another kind, curious rather than showy; it is not generally grown as an annual, but it does best treated in that way; it creeps on the ground, and seems to get rid of its epidermis as quickly as possible, a circumstance which gives it the appearance of a skeleton.—J. CROUCHER, *Hammersmith*.

Rose Hedges.—Without discussing the comparative advantages of budding or grafting Roses, or of growing them on their own roots, it is sufficient to state here that the Rose may be easily propagated both by division and cuttings, and when extensive planting is resorted to for furnishing borders, beds, or shrubberies, either plan may be adopted. The flowers on such plants may not, perhaps, be what are called first-class, but it costs little to have plenty of them, and they are not so very inferior after all. Years ago we divided many hundreds of old Rose trees, planting them in good soil, and all did as well as could be desired. The work was begun in October and finished in November. The plants were split up into fragments with a bit of root to each, and planted and mulched at once for the winter. A large number of plants were reserved to form a Rose hedge; these were shortened back very little at pruning time, and were planted against a wire fence, on to which they were spread out and tied, and they now form a hedge which produces more flowers than all the Roses in the place do together, and they are not few. Our collection embraced a miscellaneous variety, but for hedge planting it is best to select the most vigorous-growing kinds and plant tolerably thick, and it is better if the hedge be not allowed to grow more than 4 ft. or 5 ft. high, unless climbing Roses are used; but I am speaking of a hedge that is allowed to grow pretty much as it likes, without troubling to cut or train much of it. Ours is clipped off in February, and the branches are spread out here and there, or layered to fill up gaps, but that is all. In making Rose plantations, too much stress can hardly be laid upon mulching the roots to exclude frost in winter. Many of the weaker kinds of Roses, and in severe winters even the hardy kinds, often perish, particularly in the north and in cold districts, if not mulched, which throughout the cold or droughty springs seems just to work wonders. Any loose vegetable refuse will do for the purpose, but nothing surpasses well-rotted stable manure laid on thickly.—C., in the "Field."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Golden Moneywort (*Lysimachia Nummularia anrea*).—This golden variety of the old Creeping Jenny will be welcome everywhere both as a basket plant and to plant round the edges of window boxes or on rockwork.—E. H.

Acanthus Candelabrum.—I noticed a plant of this flowering finely in the herbaceous department at Kew the other day. It is a striking background plant; or it would have a good effect as a single specimen in some quiet grassy nook.—E. H.

Helianthus multiflorus fl.-pl.—Looking over a border of herbaceous plants a few days ago, I was struck with the rare beauty of some large clumps of this Sunflower. They had been established for years, and had thrown up striking heads of bloom. These, associated with herbaceous Phloxes, Anemone japonica and its varieties, *Physostegia imbricata*, and some of the *Pompona Dahlias*, would make a rare display till late in autumn. This fine *Helianthus* should be included in every group of showy perennials.—D.

Primroses and Cowslips.—A specimen of an abnormal floral development found by Prof. McNab at Howth, in Ireland, was shown to the British Association. It consisted of a Primrose plant, from the stem of which grew a true Primrose and a Cowslip flower. Accompanying it were specimens of a hybrid plant, the flowers of which partook of the nature of Cowslips and Primroses, and the object of displaying them with the abnormal growth was to suggest how the mutation was probably occasioned.

Bed-straw for Carpeting Ground.—A few years ago I found amongst some odd gatherings from Axe Edge a few tufts of *Galium saxatile*, with which every mountaineer who knows anything of botany is familiar, because of the exquisitely beautiful beads and carpets of snow-white flowers it presents to view on moors and mountains in the later days of summer. These tufts were, with other things of the kind, planted in peat and forgotten. They lived and grew, and one of the results is to prove that this particular *Galium* or Bed-straw is a valuable surfacing plant for beds of *Liliums*, or for any purpose, indeed, for which a close green Moss-like growth of herbage may be required. It needs a peaty or gritty soil, and apparently starvation is good for it as a garden plant, for when thoroughly starved it forms a very close mat-like growth, and does not flower, so that as a green surfacing it is as nearly perfect as can be imagined. In a border here, the chief occupants of which are *Lilium* stems and hardy *Cyclamens*, this *Galium saxatile* has obtained a hold, and forms a continuous carpet of green, and, being somewhat starved, is exceedingly Moss-like and never flowers. Those who understand the use of the Mossy Saxifrages, small-leaved Thymes, and Mints for surfacing, together with shades of green, rich, carpet patterns, are advised to consider the claims of this Bed-straw; but it is peculiar in its requirements, and perhaps for that reason the more valuable, as it may come in well where other equally desirable plants would do no good.—"Gardeners' Magazine."

"SCIENCE" AND FLOWER FERTILIZATION.

WE are inclined to think that those who know most about the fertilization of plants will be least inclined to agree with some of the statements in the following extract, which strike as being most remarkable for loose reasoning and boldness of assertion. The following is culled from the report published in the "Times":—Sir John Lubbock, M.P., recently delivered a lecture in the Royal Pavilion, to the members of the Brighton Literary Association, on the "Relation of Plants to Insects." If flowers were useful to insects, he said, insects were indispensable to flowers. The beautiful and varied colours of many flowers were due to the existence of insects. The hues, lines, and shades found in day flowers were invariably absent in night flowers, and the reason was that, as they bloomed at night, they could not be seen. Those flowers which were not fertilized by insects did not possess either colour, scent, or honey. In the great majority of instances the relations between insects and flowers were mutual, but in some plants it was different. There was a North American plant which actually seized and devoured the insect which alighted on its leaves. By means of a diagram Sir John illustrated this process by which the insect-devouring plant captured its prey. Representations of open and closed leaves were shown. Sir John said that a number of interesting experiments had been tried with those leaves, and it had been found that they very much disliked cheese, which disagreed with them and made them extremely ill. He then entered into a description of the simple structure of flowers, and dwelt at considerable length on the results of the fertilization of flowers by different causes. Those fertilized by insects reached the highest state of excellence. Self-fertilization, he said, tended to dwarf the flowers. In the case of a *Convolvulus*, experiments had been tried by which it was shown that where the flower had been self-fertilized it only grew to a height of 5 ft., while a flower fertilized by the pollen of another plant had grown to a height of 7½ ft. The hon. lecturer then mentioned some experiments to test if bees were or were not able to distinguish colours. He said he had taught a bee to come to a certain place for honey, and he had then placed a quantity of honey on some blue paper. He allowed the bee to come to this honey several times, and he then placed some more honey on a piece of orange-coloured substance. During the absence of the bee on one occasion he took advantage of the opportunity and shifted the positions of the two lots of honey. The bee came as usual to the spot where the blue paper had formerly been placed, and stood as if in doubt near to the orange-coloured substance, and then it dashed over to the blue paper and commenced feeding from it as usual. The lecturer said he had experimented with a variety of colours and found it was always the case; if they used a bee to take honey from a certain colour, he would always select that colour from among others. [It is amusing to notice that the lecturer can give the last passage as a proof of his proposition.] It was fortunate for them that bees enjoyed the same colours and liked the same smells as they did, as there were certain flowers which were fertilized by flies, who preferred livid yellow, dingy red, and very unpleasant-smelling flowers, and they were invariably accompanied by a very disagreeable odour. Therefore, if the majority of flowers were fertilized by flies, they would find that their gardens lost many of their present charms. After referring to the physical action of flowers of the class fertilized by insects, the lecturer went on to refer to the different plants which repelled the visits of insects. Why were some flowers sticky and some slippery, and what was the use of hair upon plants? These conditions were to repel the visits of unwelcome insects who could not make use of the pollen they robbed the flower of for fertilizing purposes. He proceeded to explain the physical adaptation of insects to the flowers with which they were so nearly allied. Referring again to plants, he said that they found that at certain particular hours flowers closed. This habit of going to sleep was very curious, and different flowers kept different hours. The reason for it, however, was obvious, for flowers which were fertilized by moths and other night-flying insects would derive no advantage from being open by day, and on the other hand, those fertilized by bees would gain nothing by being opened at night. The closing of flowers, he believed, had reference to the habits of insects, and it must be confessed that the opening and closing of flowers were gradual, and that the hours varied greatly according to circumstances. Although it would be possible to construct a flower clock, he was sure in these days it would not be of very much use. The arrangement of the colours, form, and scent of flowers—all had reference to the visits of insects, and were disposed in such a manner as to secure the great object for which these visits were destined, so that it came to pass that just as gardeners, by selecting seeds from the most beautiful varieties of flowers, begat others as beautiful, so insects by the fertilization of the largest and most beautiful flowers unconsciously, but not the less effectively, contributed in a large degree to the beauties of our woods and fields.

THE AMATEUR'S GARDEN.

BY THOMAS BAINES.

Richardia æthiopica that were planted out in the spring should now be lifted with care, in order to avoid injury to the roots, placing those plants with a single crown in 6-in. pots, and others in pots proportionate to their size; but where the spring planting-out system has been adopted (which is by far the best for this useful decorative subject), large pots are unnecessary. This again is one of the plants that will bear the soil being kept quite moist immediately after potting, which is necessary to prevent the leaves from flagging. A cold frame, pit, or greenhouse will answer to keep them in for some weeks until they get established in the pots, when later on through the winter they can be forced into flower by putting them in heat, for which purpose they are well adapted.

Roses in Pots in the open air, especially the more tender Chinese varieties, should not have the soil saturated with moisture, as, like most other hardy plants, their roots when in pots, are much more susceptible of injury from this cause than when planted out. If a few loose lights can be temporarily fixed over them, they will thrive much better than if fully exposed.

Tree Carnations in pots for winter forcing and Mignonette should be put in frames if the weather be very showery; if fine, and stood in a sheltered place, they will take no harm uncovered for a few days yet, as the more air they get at this time of the year the better.

Fuchsias that have been in the open air after flowering may remain out so long as there is no sign of frost sufficient to kill their tops, on the appearance of which their heads may be cut in freely, previously allowing the soil to get tolerably dry. They can be stored under a greenhouse stage, or in any similar place where they will receive a little light, keeping the soil through the winter slightly moist. So treated they will grow away much freer in the spring than if the roots be allowed to become dust-dry.

Bedding Pelargoniums.—Where a sufficient quantity of these have not been put in, some cuttings may be taken off now, using good-sized, moderately firm shoots for the purpose, stripping off all leaves except two or three small ones at the points; they may be put closely, say eight or ten in 6-in. pots, in which way they will occupy less room through the winter than the earlier-struck plants, but having rooted more lately, they will not be so strong, or calculated to bloom so soon in the spring as the earlier-struck plants. They can be placed at once in a cold frame or pit, or on a shelf in a greenhouse or vinery close to the glass, giving only as much water as will keep the soil slightly moist; in this way the greater portion will root through the autumn.

Kitchen Garden.—Where Cauliflowers, sown last month for wintering in frames and under hand-lights, have come up too thickly, they should be at once thinned sufficiently to allow space for their making short, sturdy growth, until large enough to plant in the frames, &c. The same applies to late sowings of Cabbages, as when the above are allowed to become overcrowded in the seed-bed, they are so weakened as to be ill-calculated to withstand the winter.

Salad.—Continue to plant out more Lettuce and Endive at short intervals. Complaints are often made of blanks in the supply of these through the winter and spring, the cause of which may invariably be traced to not sowing and planting them in sufficient quantities for successional growth. For the late plantings the driest position in the garden should always be selected; this is especially the case where the land is naturally damp, or of a moisture-holding character. In such places, beds formed so as to give a considerable slope that will throw off the water, will be found much the best.

Spinach.—A little more Winter Spinach may also be sown; this will come in for use during the spring, and should the winter be severe such sowing will be much more likely to withstand it than the earlier ones, and it will not be disposed to run to seed so soon in the spring, and will consequently furnish a later supply. The earlier crops of Winter Spinach should be thinned out so as to leave the plants about 6 in. apart, but it is not necessary to reduce them to this all at once, as if allowed to stay doubly as close for some time longer they can then be thinned out for use as required.

Turnips sown late should receive timely thinning so as to give them plenty of room, or they will make little more than tops; and as the time for their growing is now short this work must not be delayed.

Onions.—Exceptionally late as spring-sown Onions are this year, it will now be quite time to take them up. There is no better way of preserving them than at once tying them up in moderate-sized

bunches and hanging them in an airy, cool place, either in a shed or against the wall of a building with a projecting eave; this is especially necessary where they are required to be kept as late into the spring as possible. Brown Globe and James's Long-keeping are two excellent varieties for this purpose, and if kept quite cool through the winter they will remain plump and hard without showing a disposition to grow in the spring until some weeks later than if they had been kept in warmer places. The frost of any ordinary winter will not injure them when dry, even when exposed to the open air.

Carrots in many cases will now be ready for taking up: if allowed to remain too long in the ground they commence forming new root fibres, which greatly injures their quality. Carrots sown late to stand through the winter must be thinned out to 3 in. or 4 in. apart in the rows.

Globe Artichokes.—All flower-stalks should now be removed from these with the larger leaves attached to them right from the bottom, so as to fully expose the young suckers at their base; where this is not done the latter are so soft and weak through being shaded by the larger leaves as to be in the worst possible condition for wintering satisfactorily. This Artichoke is all but hardy, and where it perishes by frost the cause is generally to be attributed to the neglect of the above precaution.

Celery.—Continue to earth up Celery as it is required for use, so as to allow sufficient time for its blanching, but do not apply more than a few inches of soil to the general crop required for winter and spring supply, as when it is earthed up to any considerable extent thus early it cannot possibly keep. All that is intended for later use should now have the suckers pulled out, and the smallest outside under leaves that will usually be found lying on the ground may also be taken off; but this removal of the leaves should not be carried on to too great an extent, as it checks growth. Each plant ought to be slightly drawn in with a piece of bast tied round it, yet not so as to bring it so close together as to prevent light and air getting to the young central leaves, but only as far as necessary to keep the outer ones from being broken by the wind; as a further support, 2 in. or 3 in. of soil may be drawn to them; this will not interfere with the application of water, which in dry seasons it is requisite to give during the remainder of this and the ensuing month.

Groundwork.—All land that has been occupied by Dwarf or Early Runner Beans, Broad Beans, Peas, Spinach, Lettuce, or other exhausted crops, should at once be cleared and hoed, and all the weeds and vegetable matter sent to the refuse-heap. If a little lime be sprinkled amongst this to destroy slugs and their eggs, the material when rotten will be found very useful for digging into the ground, especially where the soil is of a heavy nature. Where Potato haulm is diseased many argue that it should be removed from the land and burnt, as if applied afterwards to the ground it subsequently disseminates disease. I have frequently tried this so far as to put the diseased tubers and haulm in a heap by themselves to rot, and have used the material the following spring as a dressing for Potatoes, and never could detect the slightest difference betwixt its effects and that of ordinary manure on the crop. Not only is the appearance of a kitchen garden much improved by the removal of all exhausted crops, but slugs and snails are much less troublesome, as they will not remain unless they can obtain shelter. There is no better remedy for the destruction of these pests than sprinkling the ground two or three times a year with newly-slacked lime; this is much more effectual than heavy dressings at longer intervals, as it not only kills them but it also destroys their eggs, and at no time can it be applied with greater advantage than during the autumn directly the ground is cleared.

Storing Apples and Pears.—Few seasons have occurred in which the Apple and Pear crop, especially late-keeping kinds, will require so little room for storing, yet their successful keeping so much depends upon the apartment intended as their store-house that a few words of counsel concerning it may not be out of place. With amateurs they are often stored under the worst possible conditions, namely, in upper rooms, garrets, or similar places, where the atmosphere is so dry as to extract the moisture from them, and this causes them to shrivel and become tough and leathery, and alike indifferent for dessert or cooking. Apples and Pears should always, where practicable, be kept in an apartment as cool as possible, with only just sufficient warmth to exclude frost, admitting but very little air except for the first few weeks after gathering (whilst the fruit is undergoing what is known as the sweating process), during which time Apples, to a greater degree than Pears, emit a quantity of moisture. The place in which they are stored should be on the ground floor, which should be paved with flag-stones, tiles, or other similar material, but not boards. I have found no better method of keeping dessert Apples than placing them in large glazed earthenware vessels covered with a little straw or dry Ferns; in this way they

cannot be so readily examined for the purpose of picking out any that may be decayed, but if carefully handled in gathering so as to avoid the slightest bruising, there is little to fear from premature decay, and even where a few go bad it seldom affects those in contact with them to the same extent as Pears. Late-keeping varieties of Pears, such as Easter Beurré, Beurré Rance, and Ne Plus Menris, will keep well in the same way, looking over them at intervals to remove any that show signs of decomposition. The non-absorbent nature of these earthenware vessels counteracts the disposition to shrivel to a greater extent than anything else I have been able to find, and on wet, sunless summers, such as the present has been in many parts of the kingdom, the inclination in these keeping sorts to shrivel or ripen prematurely is always greater than if the season had been bright and dry.

THE BURGHLEY CULTIVATOR.

I HAD half-a-dozen cultivators of this kind made this spring, and I find them most useful. In the beginning of April, when clearing off Brussels Sprouts, Broccoli, &c., I use them to prepare the land for early Potatoes, instead of digging it. Last August the whole of our winter Greens were mulched with fresh manure from the stables,

and this, becoming thoroughly decayed, got well mixed with the soil by the cultivator from 3 in. to 6 in. deep, leaving the land like a bed of ashes; whereas, if the spade had been used, it would have been lumpy and unfit for early Potatoes, which like the land smooth. Fine shallow drills were drawn, and the Potatoes planted with good stiff sprouts, which were obtained by having been laid thinly on shelves. Thus treated, they were up and growing at once. Again, among growing crops, nothing is so desirable as to keep the ground well open, and this can be done by using the cultivator, of which the annexed is a good representation, except that the teeth are too much pointed; they should be more flattened or chisel-pointed.

Burghley.

R. GILBERT.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

September 24.—Potting *Humea elegans*, *Colens*, and Scented-leaved *Pelargoniums*. Filling up all frames and cold pits as they become empty with Lettices and Endive. Planting early border with August-sown Cabbage plants. Cutting turf to stack away for potting purposes. Hand-weeding Strawberry quarters, and cutting off all runners, afterwards mulching the ground with well-rotted manure.

Sept. 25.—Sowing Mustard and Cress for succession. Taking up *Alternantheras* and potting them; also a few *Coleus* for stock. Removing all cuttings struck in heat to a cold frame to harden. Giving first-spawned Mushroom-bed a little warm water. Pricking out on a large border Carter's Heartwell Early Marrow Cabbages plants to stand the winter. Watering Pine-apples with manure-water; also late Peas, Cauliflowers, and Celery.

Sept. 26.—Potting variegated Ivy and a few Carnations. Rearranging Fernery. Earthing up French Beans in pots. Lifting a portion of the main crop of Carrots and stacking them away in dry sand in an open shed. Moving pot Vines out of pits and placing them against a south wall, to finish the ripening of the wood and fruit-buds. Examining all fresh-planted shrubs and putting a few stakes and ties to those likely to be injured by wind. Turning manure for Mushrooms and salting terrace walks. Gathering Louise

Bonne of Jersey and Marie Louise Pears; also Wormsley Pippin Apples.

Sept. 27.—Taking up plants of *Mesembryanthemum cordifolium* and potting them for stock. Giving a top-dressing of soil to Cucumber beds. Storing away *Caladiums* on dry shelves. Earthing up Celery. Clipping hedges, and cleaning shrubbery borders. Gathering Coe's Golden Drop Plums and Barriington Peaches; also Ribston Pippins and Cornish Gilliflower Apples; and Flemish Beauty and Brown Beurré Pears.

Sept. 28.—Potting double white Primulas, Cinerarias, and *Solanum capsicastrum*. Clearing off a piece of Turnips, and manuring and digging the ground for other crops. Transplanting Early White Naples and Giant White Tripoli Onions. Gathering all unripe Tomatoes, and hanging them up in Vineries in a sunny position to finish ripening; also picking Cucumbers, Button Mushrooms, Cauliflowers, hard White Cabbage, and Capsicums for pickling.

Sept. 29.—Potting Hyacinths and Tulips; also Osborn's early-forcing French Beans. Taking up and potting Mrs. Pollock and Tom Thumb *Pelargoniums*. Gathering Passe Colmar, Duomore, and Doyenné du Comice Pears; also Lucombe's Seedling, Court of Wick, and Coddle Pippin Apples. Fruit in use for dessert—Pine-apples, Grapes, Peaches, Plums, Pears, and Apples.

Hathaway's Excelsior Tomato.—This is one of the best-shaped and handsomest of all Tomatoes. It is, however, said to be inferior in flavour to other kinds, and it is not quite so prolific. For

exhibition purposes it is, nevertheless, considered to be one of the best; and a kind named Stamfordian (supposed to be a selection from it, the fruit of which attains a very large size) is also becoming popular as an exhibition variety.—S.

Lifting Potatoes Early.—The other evening I was talking to a neighbour who remarked: "Last year I saved all my second earlies by lifting them early, and they were also of excellent eating quality, but this year I delayed the work a few days too long, and more than half of them are bad, and the remainder will not keep." I have noticed a wonderful variation, even in the same field or garden, in the same kinds, due entirely to the character of the soil. I have come to the conclusion that on dry sandy soils where the disease never assumes a virulent form Potatoes may bide their time, and the work be done leisurely if it suits the cultivator, and at taking the average of seasons on rich adhesive soil they should be lifted before the disease attacks them if the crop is to be saved. Sperturbation is another evil that would be avoided by early lifting. I find the best way of storing them when lifted early is to lay them in small heaps in some dry dark cellar or shed, and cover them with straw; or else place them in small narrow ridges in the open air, and well cover with straw and a thin layer of earth round the base and about half way up the ridges. In this position they will remain three or four weeks, and can then be sorted over and properly secured for the winter.—H.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Green Tops of Peas for Soups and Flavouring.—Any one who has spare seeds of Peas may turn them to good account by sowing them thickly in boxes under glass, in succession, during the autumn and winter. The young tops should be cut off for use when about 4 in. or 5 in. high.—H.

Hundredfold Pea.—I have grown more than a dozen sorts of Peas this season, and nearly all of them have been kinds which are named in selections of Peas as the best in their sections; but none of them, however, has proved so productive as Hundredfold, the rows of which have been completely covered with dark green pods. It also yields a longer succession than any other, and I have been frequently told that it is the best Pea amongst the whole when cooked. Next year, therefore, the half of our Peas will be Hundredfold.—A. B. G.

GARDENING IN EGYPTIAN DESERTS.

THE land of Egypt is one of the many regions where a fine climate and a glorious sun only make the country a desert without the aid of water. If we could only effect an exchange of some of our watery riches for their bright skies! Surely that must be considered one of the most noble of all the fine arts which can beautify an arid desert with all the charms of vegetation, even though it be at the cost of soil and water procured many miles away. At five miles interval along the Canal from Suez to Port Said, are picturesque little stations for signalling purposes (each being the residence of a Frenchman, who superintends the working of signals and telegraph block system by which the passage of ships is regulated), and most of these have pretty little gardens surrounded by a matted fence of pale yellow Reeds or a stately hedge some 12 ft. or 14 ft. high, of the Greater Reed (*Arundo Donax*). Here this plant is also seen in all its luxuriance, forming great rainbow-like patches 10 ft. or 12 ft. in diameter at the base, the wand-like, leafy stems curving gracefully outwards and forming a most effective screen from dry winds. Its vivid greenness is heightened by contrast with the neat whitewashed houses and other offices, each of which has a low-pitched overhanging roof like that of a Swiss chalet, and is rendered more picturesque and comfortable by the addition of shady, creeper-laden verandahs. As to the flowers, scarlet *Nasturtiums*, *Pelargoniums* of the Zonal section, *Zinnias* of divers colours, and *Sunflowers* seem especial favourites—singularly enough, however, the *Sunflower*, luxuriant as it is in our temperate English gardens, is here sadly deficient in vigour and stateliness; its co-partners, the parti-coloured *Zinnias*, are, however, perfectly at home, growing healthily, the profusion of their large flowers and the brilliancy of their colours being so marked as to raise a doubt as to their identity with our own varieties. Here and there a stunted Date Palm or two may be seen, but they do not thrive by the Canal, although there are fair specimens close to the "Well of Moses," and elsewhere at Suez: the most stately and fruitful, however, affect the better-watered alluvial tracts bordering the Nile, or cluster beside the little fresh-water canals and irrigating channels by which fresh water is carried from the great river, these being fringed, moreover, with other vegetation, and especially by tall-growing Reeds of different kinds and a few coarse Sedges. A free-growing shrub, which at a little distance might readily be mistaken for the graceful *Tamarisk*, is extensively propagated by cuttings inserted in the moist sand which fringes the salt water of the Canal, and is useful in fixing the shelving, sandy banks on either side. Other plants used for the same purpose are tall Reeds and coarse, mat-like tufts of Sedge; but none of the plants employed seem so effective as the Blue Shore Grass of our northern coasts. The prettiest of all the little station gardens to which previous allusion has been made is undoubtedly that at the old town and ferry of Kantara, through which large numbers of pilgrims pass every year on their way to or from Jerusalem. The boat was anchored here for the night, and a row of five Lombardy Poplars, fresh and verdant, served as a reminder of home, the illusion being heightened considerably

by the cool breeze and the cheerful chirping of crickets innumerable all along the sandy banks. The station-houses, a little hotel, and other offices stand at different elevations on a group of sand-hills, and here, as so often happens in Europe,—where the wealth of tree beauty and greenery is so great—most of the picturesque beauty of the landscape is gained by the addition of that little row of tapering Poplars. That there is a depth and richness of moist soil here is shown by the extra luxuriance of the flowers and shrubs; here the Oleander—or "Rose of the Desert," as the Arabs term it—flourishes in all its glory of flower and fragrance. When I saw this shrub in Paris for the first time, I was astonished to find such a "thing of beauty," remembering that it is generally such a dusty, ill-favoured scapegrace as grown in our English gardens; but here again the plants were far superior in floriferous vigour to those of the Continent, forming fresh, leafy bushes 10 ft. or 15 ft. in height, every branch being terminated by an immense cluster—a natural bouquet, in fact—of rose, crimson, white, buff, or yellow flowers, as the case might be, rosy-crimson, salmon, and white kinds being, however, most noticeable, and all exhaling a fragrance almost equal to that from our own Rose gardens during June and July. The flowers, moreover, were nearly equal to those of Roses in size, shape, and colour. A little wood of these Oleanders grew at

Vegetation by the Suez Canal.

the base of the green, statuesque Poplars, *Sunflowers*, *Zinnias*, *Celosias*, an American *Agave*, a few dwarf *Musas*, and a tuft of *Arundo Donax*, all helping to form one of the brightest and prettiest little gardens I ever remember to have seen even in temperate climes. Here, in contrast with the barren sands, extending as far as the eye could reach on every side, it seemed a little paradise, and here, at least, it may be said that the desert has been made "to blossom as the Rose." No sooner had this little garden—this oasis in

the desert been explored than I longed for an hour ashore at Port Said, considering that if such high culture were practicable in the arid desert, what must it not be at Port Said, by the blue Mediterranean? I had excellent opportunities of seeing the gardening and also the fruit and vegetable market at the last-named port; but on the coast, as further in the interior, I found gardening had to be carried out under difficulties, which nothing but the cheap and abundant Arab labour obtainable would have been able to overcome. Port Said is a small town standing on a shingly beach but a few feet above high-water mark, and behind the short street of low, airy, verandahed houses, low mud flats and sands extend far further than the eye can reach, these being tenanted by thousands of long-legged flamingoes and lazy vultures, the latter, aided by hordes of ill-fed, wolfish-looking curs, being, perhaps, the best of all scavengers in an eastern town. The population comprises representatives of all European nations and a large proportion of Arabs. Town gardening is represented by a small public garden—square would be a better name, only that this plot of half an acre or more is circular and laid out like a conventional Rose garden, having a dumb-waiter-shaped fountain in the middle of a central basin of fresh water, surrounded by curved beds, and intersected at right angles by shingle walks. On the rockwork at the base of the fountain *Adiantum Capillus-Veneris*, *Tradescantia zebrina*, *Cyperus alternifolius* and

other common stove plants seemed to enjoy the sun and moisture, the surrounding beds being filled with *Acacias*, that is to say, *Robinias*, *Erythrinæ*, *Poinsettias*, *Hibiscus Rosa-sinensis*, *Lantanas*, *Vincas*, and *Arundo Donax* (one of the freshest and most beautiful of all fine-foliaged plants, and one which in this climate seems to enjoy perennial beauty), intermixed with *Brugmansias*, *Marvel of Peru*, and common annuals of various kinds. One of the best features in the gardens at Port Said is the abundance of fresh green creepers and climbing plants which tastefully drape the balconies and verandahs of the whitewashed houses, and trail in profusion over porticoes, old walls, and fences, in all directions. Among the plants so used *Lantanas* of various colours are conspicuous, together with *Thunbergias*, *Cucurbits* of various kinds, *Passion-flowers*, and *Aristolochias*, *Jasmines*, *Tecoma jasminoides*, *Convolvuli*, and a few straggling but floriferous scarlet *Geraniums*.

F. W. B.

CHINESE SCARE-CROW.

THIS consists of a Bamboo firmly fixed in the ground, to the extremity of which are fastened pieces of cord. These are passed through bottles, the bottoms of which have been knocked out. To the end of each cord is attached some light material which the wind can easily blow about. The Chinese generally use part of a cuttle-fish for this purpose, but anything will do that will wind-wave, even a

piece of slate or board. The bottles are fastened by their necks to the cords, and inside them, attached to the cord, is a nail or a small piece of iron, which, striking against the sides when the wind moves the apparatus, produces a singular kind of noise sufficiently loud to frighten birds. Care must be taken to prevent the bottles from striking against each other. When two or three are put on one stick, the cords should be of different lengths.

The Wild Flowers of New Zealand are neither numerous nor generally very beautiful. In the early spring festoons of *Clematis indivisa* hang on the shrubs in the skirts of the great forests, and warn the native gardener to prepare for the duties of the coming year. Then *Sophora grandiflora*, a shrub-tree, and almost the only one that sheds its leaves in winter, puts forth its clusters of large, papilionaceous blossoms, reminding the colonists by their yellow colour of the wild Daffodil of the early British spring. *Dysoxylum spectabile*, a tree whose leaves resemble those of the Lilac, its timber pencil cedar, and its fruit the Chestnut, now also hangs out its sprays of white bell-flowers from shoots proceeding from the bark of mature limbs, and not from the terminal branches. As the spring advances, *Aristolochia racemosa*, a shrub bearing a strong resemblance to the American blossoming Currant, is in bloom in the forest clearings. Towards Christmas the woods are in their glory; then the grand *Rata* (*Metrosideros robusta*) is suffused with a rosy

blush by reason of its multitudinous crimson Myrtle-like blooms peeping out among its green leaves all over its great crown; the curious flowers of *Astelia* hang delicately out between the stout grassy leaves of *Epiphytes*, perched high up on the branches of the great trees; then both white and crimson Myrtle blooms hang from creepers running like the shrouds of a vessel up the trunks of the giants of the forest; then sweet-scented *Dendrobiums* hang pendent from many a stem, mingling their yellowish blossoms with silky and transparent fronds of *Trichomanes* and *Hymenophyllum*; then the native Screw Pine, bound like Ivy with a network of rootlets to some supporting stem, expands in the midst of its sedge-like leaves its curious spadices and its white, sugary spathaceous bracts, sought after by the natives and schoolboys as a delicacy; then, too, *Weinmannia racemosa* is gay with a profusion of racemes of white Veronica-like blossoms; then on the edges of precipices *Rhabdanthamus Solandri* displays its orange-coloured bells, and *Knightsia excelsa*, a tree whose timber presents a curious interwoven appearance, bears its Honeysuckle blossoms. On the mountains at this season *Ranunculus nivicola*, a robust Buttercup, reminds the mountain shepherd of his native fields; and on the volcanic peaks, just beneath the snow-line, may now be found in full bloom dwarf *Veronicas*, *Senecio elaeagnifolius*, *Claytonia*, *Forstera*, *Gaultheria*, *Ozothamnus*, and other interesting plants. On the sea cliffs to the north, *Metrosideros tomentosa* puts forth its really splendid cymes of crimson Myrtle blooms, and a beautiful crimson Veronica, with a large, dark green, glossy leaf, may be found in the same locality. There is a great dearth of herbaceous-flowering plants here; the Buttercup, a white Linum, *Orisia*, a feeble Violet, and Daisy, with a small, pale *Mesembryanthemum*, being nearly all that we possess. Strangers, however, from almost every clime are stealing in upon and amidst the native plants. The purple Foxglove of Britain, and the white species from the Canaries, now grow by the sides of the forest roads, while Thistles, Hawkweeds, Daisies, and Buttercups are everywhere. In our gardens *Agave americana* is quite at home, variegated and other *Yuccas* send up pillars of Tulip-shaped blossoms, *Camellias*, 6 ft. or 7 ft. high, bear profusion of delicate blossoms, *Rhododendrons* open their cups shedding rich fragrance around, while near to the sea *Geraniums* and *Pelargoniums* blossom all the winter; indeed, a bouquet may be gathered in North New Zealand any day in the year, both in the forests and in the gardens.—“Science Gossip.”

Vegetation in Norway.—The climate of Norway is not so bad as might be supposed. The tepid waters of the Gulf Stream bathe its shores up to the North Cape; at Christiania, with a latitude like that of South Greenland, the mean temperature of the year is still 5° C. The length of the days during summer compensates to some extent the small elevation of the sun. Thus Norway can cultivate numerous fruit and forest trees; can produce Wheat up to the 64th degree of latitude (which is that of Hudson's Straits), Oats up to the 69th parallel, Rye still further, and Barley beyond the Polar circle. Some interesting peculiarities of Norwegian vegetation have lately been pointed out by M. Schubeleg. The precocity of the native graminæ is remarkable, and the short duration of vegetation. The time for indigenous Wheat is about 90 days, 97 for Victorian Wheat, and 105 for Tuscan Wheat. In the most favourable years, crops of native Wheat, sown on May 4, have been reaped in fine condition on August 4, after only 74 days' vegetation, while in France 131 days are required. Seeds brought to a more southern country lose their precocity only after several generations; while seeds imported from the south give at first late harvests, but become acclimatized after three or four generations, reaching maturity at the same time with their congeners. Again, seeds from the south increase in weight and size, while seeds from Christiania, if sown at Breslau, produce much smaller seeds. The further north you go, the larger are the leaves of plants found to grow, as if from absorption of a larger amount of solar rays. And the aromatic principles of plants are remarkably developed in high latitudes. Celery, Horseradish, Garlic, and Parsley have a much stronger taste in the north.

The Double Cocoa-nut (*Lodoicea Seychellarum*) as a Medicine.—The kernel of the Sea Cocoa-nut is in great repute among the Arabs and Indians as a strengthening medicine; it is nearly 1 in. thick and very hard, having much the appearance of vegetable ivory; it has no odour or taste; when soaked in water it softens a little and can be split into thin fibrous bundles. Examined under the microscope, says the “Pharmaceutical Journal,” these are seen to be composed of spindle-shaped cells having a central cavity, from which club-shaped canals extend to the cell wall, where they are opposed to similar canals belonging to a neighbouring cell. The Palm which produces this nut grows in the Seychelles, and the nuts are exported to India and Arabia. From the leaves very beautiful work-baskets, hats, bouquets, and many other fancy articles are made. A description of the Nut is unnecessary, as it is to be seen in most museums and cannot be mistaken for any other object.

AMERICAN NOTES.

Timber Screens for Orchards.—Mr. Barnard, of Pawnee County, Nebraska, said, at a horticultural meeting in that State, that a good timber screen would protect an orchard at a distance of a rod for every foot in height. It should be only on the side of prevailing winds. Mr. Budlong, of Franklin County, said that he formed his screens by planting two rows of White Willows 12 ft. apart; four rows of Cotton-wood, 16 ft. apart; and four rows of Black Walnut at the same distance. The remark was made that the efficiency of a screen depended much on the surface of the land; in one place it would afford ample protection, at another almost none.

Ripening of Peaches.—We observe a statement in several papers respecting the comparative ripening of the Amsden and Alexander Peaches, given by a western cultivator, in which the Alexander was a week or sooner in maturing than the Amsden. We have no doubt that the statement is correct, and that the difference mentioned really occurred in this instance; but pomologists are well aware that the results of single seasons and single localities cannot decide such questions. Only a few weeks ago we gave the times of the ripening of several Peaches this season in South Carolina, and amongst these examples a Tillotson ripened several days earlier than a Hale, although commonly a week or two later; and in another case Troth's Early Red and Serrate Early York matured with Hale, although the latter is usually greatly in advance. A Tillotson ripened on June 20, much earlier than the average. The Amsden and Alexander commonly ripen exactly together as an average in different places and years.

Co-operative Gardening.—Much may be done in an inexpensive way to promote friendliness and good feeling among neighbours, by the interchange of superfluous garden products. It is one of the disadvantages of the cultivator's isolated position, that each family, to secure a certain supply of vegetables and fruit, must grow a good many more than are absolutely needed. Cultivators are too busy to market the surplus, even if there were enough to make it worth their while. Hence a great deal of good produce goes to waste, while in the neighbourhood may be many families where the surplus would be sure of a welcome, and be repaid by exchange for something else. This year our first Cucumbers were fully two weeks earlier than our neighbours', and we have been able to make several presents of these and some other early vegetables. The same rule holds good with regard to fruit, berries, Grapes, garden seeds, &c. The surplus of most or all these articles is seldom saleable and never sold. What is given does not at all impoverish the giver, and nothing so easily done is more promotive of sociability and friendliness.

The Washington Pear.—We have cultivated this fine late summer Pear for nearly forty years. It possesses several valuable qualities. The tree is a handsome, although rather moderate grower. It succeeds well on heavy and light soils—on strong clay or light gravel. The tree comes early into bearing, and bears heavily. The fruit, although moderate in size, is a handsome clear yellow, finely ornamented with large crimson dots on the sunny side. It is juicy, but not buttery in texture, and with a very sweet and excellent flavour. When the tree is overloaded, and the Pears small, they are not nearly so good as when fully grown and developed in a more moderate crop. Hence, occasionally, the importance of thinning. In this unfavourable year, the dozen trees of this sort on our grounds are bearing largely; and what is worthy of special note, none of them are attacked with the blight, while so many of nearly all other sorts are largely disfigured or destroyed by this disease.

Gas Tar Dangerous to Trees.—In Downing's "Fruit Trees of America" (p. 560 Appendix), is the following, to prevent mice or rabbits from girdling trees:—"The most effectual preventive is the coal tar made at the city gas works, laid on the lower part of the trunk from the ground to the height of 2 ft., with a common painter's brush. Experience has proved that it does no injury whatever to the tree, while it completely prevents, for that season, the attacks of mice, rabbits, and bark devourers of every kind. For young trees, dilute or thin the coal tar with one-half milk." Has any one ever tried the above to know from experience if it be entirely harmless to the tree? I have heard people say they considered tar of any kind injurious to fruit trees.—H. C. E. [We have known trees to be killed by tar, and it would be especially injurious to young and growing trees with tender bark. Common tar, applied to trees in winter with hard bark, becomes dry and hardened before growth commences in spring, and may prove harmless.]—"Country Gentleman."

PINK-APPLES are said to be selling at Key West at 9s. 6d. per hundred.

THE GARDEN OF BRITISH WILD FLOWERS.

THE MARSH-MARIGOLD (CALTHA).—The Order of the Crowfoots having afforded us useful floating plants and a fine margin-plant, if we may use the term, it next gives us an attractive marsh plant for the neighbourhood of our water, the familiar Marsh Marigold or Water-Blobs (*Caltha palustris*), which, like a giant Buttercup, with the glossy leaves of the King-cup, gilds the meadows by our river-sides, as on the Thames at Kew and its tributaries—from the Churn on the

The Marsh Marigold (*Caltha palustris*).

Cotteswolds, and the Kennet at Reading, to the Colne in Hertfordshire, and the Mole and Medway in Kent and Surrey. It generally marks a rich peaty soil, but will grow anywhere. We should consider, however, if our gardeus are to be truly natural and flourishing, the vast difference between the conditions under which a plant will grow and those under which it grows by choice and flourishes. The Marsh Marigold should not, therefore, be grown either actually in the water or in a border, but in such a bog as the Ragged Robin, the Cotton-grass, and the Bog-bean delight in. It is valuable as producing masses of a brilliant golden-yellow from March to May, and is thus specially suited to large grounds. There is a double variety, which has the advantage common to all such, the flowers lasting longer. This is a cultivated form of a rather uncommon wild variety (*C. Guerangerii*), with smaller

Double Marsh Marigold (*Caltha Guerangerii*, fl.-pl.).

flowers than the general form, so that it would be interesting if a double variety of this common, larger flower could be obtained. The species has a wide range in altitude and area, from sea-level to over 3000 ft., and from the Himalayas to North America. A variety known as *Caltha radicans*, now only found in a cultivated state, is worth notice, though of smaller habit. It roots at the stem-joints, and has very gracefully-pointed leaves, of a triangular heart-shaped outline.

THE GLOBE-FLOWER (TROLLIUS EUROPEUS).—An old-fashioned horder favourite is the Globe-flower, well worthy of a place in any garden. It grows about 2 ft. high, with cut leaves and flowers of a clear, pale yellow, nearly 2 in. in diameter, and of that beautiful spherical outline to which the plant owes both

its popular and scientific names. The blossoms are not only pretty, but also fragrant, and generally more or less double. It is not common as a British plant, only occurring northward of Derby, Worcester, and South Wales, and but very rarely in the north of Ireland. It is generally distributed over Northern and Central Europe, and must be reckoned among sub-Alpine plants, reaching as it does the altitude of 3300 ft. It flowers from June to August, and though happy in a border, grows by nature in moist upland pastures or copses. Its uncommonness renders it worthy of naturalization in any garden, but

The Globe-flower (*Trollius europæus*).

especially in the south, where it is not found wild. As colour-associates, Larkspurs and Columbines are among the most suitable for it; the contrast of their irregular outlines with its yellow spheres enhancing the effect. It should not be much massed.

THE WINTER ACONITE (*ERANTHIS HYEMALIS*).—It is hardly necessary to recommend so general a favourite as the Winter Aconite; its small, bright yellow flowers, opening even in January, and keeping up a succession till March, are very valuable as preceding the Crocus and Crowfoot Anemone on lawns, or banks or under trees, or copses. They contrast admirably with the glossy-fingered, leafy rosettes of bracts in

The Winter Aconite (*Erantthis hyemalis*).

which they nestle, and are best suited for spots similar to those dear to the Wood and Apennine Anemone, where they grow scattered like stars, here and there closer grouped as nebulae. The Winter Aconite, though thoroughly naturalised in many parks and plantations (as at Wimbledon, at Oakley Park, Gloucestershire, and Lanyar Plantation, Nottingham), cannot be recognised as truly indigenous. It can be readily obtained from any nurseryman; its distribution is chiefly confined to the west of Europe, from Belgium southwards; it seldom exceeds 4 in. in height, and is propagated by division of the stout, creeping, underground stem or rhizome. It enjoys leaf-mould, and would look well under a spreading Beech or other isolated, deciduous tree.

THE HELLEBORES (*HELLEBORUS*).—Though we have not the beauty of the Christmas Rose (*Helleborus niger*) among our wild flowers, the two British species of the genus are not to be despised for the shrubbery. The dark green of the quaintly-lobed leaves (whence the plants get their popular name of Bear's-foot) contrasting with the pale bracts, stalks, and

flowers, a lurid, poisonous hue is over the whole. There is but little difference in appearance between the two species, the Green Hellebore (*H. viridis*) and the Stinking Hellebore (*H. foetidus*); but, whilst the former is annual the latter is perennial, and the latter has the additional advantages of having more flowers on its stem and a dull purple blotch on its green sepals. It has been suggested that the curious pitcher-shaped nectaries which represent the petals may have an insectivorous function: to investigate this point may interest some owner of a wild shrubbery garden. These two species flower from February to April, and are often naturalised in woods, chiefly on chalk, in the south and east of England. Their Continental distribution is similar to that of the Winter Aconite. Near at hand these plants present a bushy habit, graceful branching, and the contrast of greens above-mentioned; whilst they are yet more valuable for their effect at a distance, which is the

The Stinking Hellebore (*Helleborus foetidus*).

lighting up the lower part of a shrubbery's sombreness with the paler of the two greens.

THE COLUMBINE (*AQUILEGIA VULGARIS*).—Slight though the resemblance of their flowers may be either to pigeons' heads or eagles' claws, no one can dispute the mingled quaintness and grace of form, or the varied beauties of colour in the Columbines. They are all erect-growing, perennial herbs, with flowers at once recognisable from their symmetrical yet unusual form—five petal-like sepals alternating with the five spurred petals. Ranging in size from the little Alpine Columbine (*Aquilegia alpina*), under 1 ft. in height, to the commoner dimensions of from 1 ft. to 2 ft., and distributed throughout the north temperate zone, the five or six species which constitute this genus seem all to agree in liking light soils, sand, rock, or gravel, moist or readily permeable, and generally

The Columbine (*Aquilegia vulgaris*).

shady spots. They may be readily propagated by seed or division. The three best foreign species are the Alpine with blue, the Canadian (*A. canadensis*) with red or orange, and the Sky-blue (*A. cœrulea*), which is also North American, and has sometimes white flowers; but, though perhaps less rank in their growth, these should be supplementary to, rather than in lieu of our old-fashioned favourite, the common species (*A. vulgaris*). This last ranges from the Western Himalaya to Siberia, through Europe and to the Canaries, and occurs

undoubtedly wild in many parts of Britain in shady thickets, though still more frequently as a naturalised escape. When truly wild it is generally single, and of a dull purplish-blue; but in gardens it is commonly white, blue, pink, salmon, flesh-colour, crimson, and maroon or brown, some of the tints being unusual among flowers. It owes much of its beauty, not only to the colour and form of the individual blossoms, which can only be appreciated on a near view or in cut flowers, but to their long drooping stalks over the clump of blue-grey, elegantly-lobed leaves. Personally I think it gains nothing in beauty by being doubled. It flowers freely from May to July, and will stand nearly any treatment, though it looks anything but happy when, as it too often is, scorched in the sun in a stiff clay or loam. I have seen it growing wild by paths in woods, or in the underwood on their outskirts, and even among the Furze in the Warren on Epsom Downs; but to make it thoroughly at home, without losing any of its graces, I should recommend its being placed with Broom bushes and Heather, Foxglove and Fern, shaded perchance by the Queen of the Woods (the Silver Birch), on the sandy or rocky bank of some rivulet or cascade—just such a spot, in fact, as that “Source of a River,” which was one of the most refreshing oases in the weary waste of this year’s Academy. G. S. BOULGER.

Cressingham.

NOTES ON THE PLANT-LORE OF SHAKESPEARE.

MR. MARSH’S kindly criticisms on my papers demand some reply from me. I feel very much obliged to him for them, and thank him not only for the kind way in which he has noticed my work, but also for the many valuable corrections and additions which he has suggested; but on some of these I should like to make a few observations.

His remarks under Balm, Holy Thistle, and Primrose are merely corrections of printers’ errors, which I note for correction. The following call for further notice:—

Apples.—I was aware of the passage in Cogan, and of the fact that Caraways were used as a relieving and corrective accompaniment with Apples. Besides the passages quoted, there is the following from a very interesting bill of fare of a dinner in 1626. It is from the account book of Sir Edward Dering, and may be found at length in “Notes and Queries,” vol. i., p. 99—

“Carawaye and comites, 6d.

A Warden py that the cooke made—we finding y^e Wardens, 2s. 4d.”

In the second course—

“A cold Warden py.”

And in the “complement”—

“Apples and Carrawayes,
Wardens bakt and cold.”

But while I can have no doubt that there were Caraways which were not Apples, I still think it very probable that Shallow’s “dish of Caraways” were the Apples so called. There is certainly no connection between the Caraway Apple and the Kerry Pippin. The Caraway Apple got its name from its supposed resemblance in taste to Caraways, and is a late-keeping Apple, while the Kerry Pippin is an Apple for the present month.

“Bitter Sweeting” is an omission, and I thank Mr. Marsh for pointing it out, as well as “Bachelor’s Button,” the quotation from the “Tempest” under “Palm,” and from “Antony and Cleopatra” under “Rue.”

Caraways.—I agree with Mr. Marsh that I ought to have given a separate clause to these, and have pointed out that they may be either the Apple or the Spice.

Cowslip.—As far as I am acquainted with the comments on “the crimson drops i’ the bottom of a Cowslip,” I can add nothing to them.

Cypress.—I quite agree with Mr. Marsh that my quotation, No. 2, should have been omitted.

Fig.—I am aware that the allusions in Nos. 5 to 11 are to the insulting gesture, “making the Fig,” and that in that connection the reference is not exactly to the fruit named. Yet surely the expression must have originated in some connection with the fruit, and therefore these passages could not have been omitted.

Hyssop.—Mr. Marsh’s quotation from Lillie’s “Euphnes” is a very happy illustration of Iago’s speech, and I thank him for it.

Ivy.—Sheep occasionally feed on Ivy, but I cannot find that there is any plant specially called the “Sea Ivy.” Ivy (*Hedera Helix*) grows luxuriantly on sea-cliffs, and I should suppose that both Shakespeare and Greene only refer to this.

Mustard.—I was in much doubt whether to admit this or not—and I decided against it. But further consideration convinces me that Mr. Marsh is right, and that an account which professes to deal with all Shakespeare’s plants, must admit all vegetable products named by him. I must add therefore not only Mustard, but Mace, Sugar, Pepper, and Ginger—and this, with the editor’s permission, I will do in a short paper by way of Appendix. I am inclined to think, from the passage in the “Taming of the Shrew,” that Mustard was used in Shakespeare’s time very much in the present fashion.

Palm Tree.—I omitted the passage in “Hamlet,” as Mr. Marsh supposes, on Nares’ authority; but I am not sure that I was right, and Nares speaks doubtfully. Perhaps it would be better to admit it with a note of explanation.

Quince.—My authority for connecting the Quince with Venus’s Golden Apple was Rosenmüller’s “Mineralogy and Botany of the Bible,” and his authority is Philostratus’ “Icones,” i., 738, a work to which I have not at present access. I find the same in Phillips’ “Pomarium Britannicum,” though he does not give his authorities:—“It is a fruit that the ancients held in high estimation; they considered it as the emblem of happiness, of love, and of fruitfulness. It was dedicated to Venus, and the Temples of Cypris and Paphos were decorated with it.”

Rue.—Most certainly I did not mean to suggest an etymological alliance between Rue and Ruth; they come from quite distinct roots, but the words Rue (sorrow) and Ruta (the herb) being both in existence together, our ancestors joined them so far as to make the plant an emblem of the feeling. It was a verbal quibble not confined to Shakespeare. The passage from “Hamlet” will probably never be quite satisfactorily explained. I have little doubt that Ophelia uses the words “to wear with a difference” in the only sense in which, as far as I know, the words would then be used, i.e., in an heraldic sense, and I have sometimes fancied that there may have been in the words a covert allusion to the Queen’s husband not being the eldest brother, and so having to wear his “bearings” “with a difference.”

Speargrass.—There is no doubt that the Achillea Ptarmica was called Nose-bleed by Lyte, Hollybush, Gerarde, Phillips, Cole, and others, both from Mr. Beisley’s quotations and from Mr. Marsh’s quotations from Professor Lindley and Skinner; but my contention is that this plant was never called Speargrass, and that some plant more resembling Grass must be sought for, and in such a doubtful question I proposed the Equisetum, which I still think has a good claim for the reasons I assigned. I need not say that Grass was a very generic term.

I feel sure that many readers of THE GARDEN will, like myself, gladly welcome any further criticism from Mr. Marsh.

H. N. ELLACOMBE.

Deodars not Coning in Cornwall.—A Cedrus Deodara planted here in 1841, now thirty-six years old, probably forty from the seed-bed, standing in a sheltered situation about a mile from the shore of Mount’s Bay, is well covered with male catkins, of which it has produced from two to three hundred annually for seven years consecutively, the only one of many here that has flowered at all. No appearance of the cones has, however, been observed. Is this due to the want of a drier climate, or is the Cedrus Deodara a dioecious tree? The Cedrus Libani is classed as a monoecious tree by London, and I should suppose the Deodara must be the same. Cones of the Deodar have ripened and produced seedlings at Killerton, in Devonshire. My catkins have always appeared in August, and fall off in December.—J. J. ROGERS, *Penrose, Helston*. [In the majority of cases the male catkins and the female flowers, according to Gordon, are produced on separate trees; but a considerable number of trees also produce both male and female flowers on the same tree.]

Branched Lilium auratum.—Dr. Wallace, of Colchester, possesses a form of this Lily which he calls “arborescens.” It is an unusual-growing Lilium auratum which threw up a single stem from the ground for about 1 ft.; this then branched out into five stems, each of which was well furnished with buds: forming a bushy head of blooms with a rounded contour. The general effect was very pleasing.

THE LIBRARY.

A BOOK ABOUT ROSES.

THIS is the sixth edition of "A Book About Roses: How to Grow and Show Them." By S. Reynolds Hole, Canon of Lincoln. All who care for sound and pleasant garden literature, as well as Roses, will be pleased to see so many and repeated evidences of the success of Canon Hole's book. Having more than once since its appearance noticed the book, we have now only to add that additions are made from time to time, bringing down Rose-knowledge to the date of issue, and that the present edition contains a coloured plate by the Hon. Mrs. Francklin. The following, among the appendices, will be useful to all interested in new Roses:—

The plan which I have advised the amateur to pursue in the formation of a Rose garden—that is, to buy his Rose trees from the nursery and then to multiply them upon stocks of his own—will be the best for its future continuance also. The best and the cheapest, because, although the foundation will be costly (that is to say, the site, the preparation of the ground, and the material), the superstructure and the maintenance of the fabric will not be expensive items. Once possessed of the most beautiful varieties of the Rose, and planting every November such a quantity of Briers, standard or seedling (or the Manetti, if that should prove the stock most suitable to his soil), as he may deem desirable, the independent Rosarian will grow his favourite flower to perfection, year after year, from his own resources, only requiring in addition those new Roses which promise to be of superior merit, which are regularly advertised by our English nurserymen in the spring, and may be had from them in the month of May. But how am I to know, the amateur will ask, what selection to make from the numerous varieties which are annually announced as "*superbes, ravissantes, magnifiques*"? You do not expect me to purchase some forty Rose trees at 3s. 6d. apiece, in total ignorance of their merits—if any? The gentle amateur, perhaps, in his guileless youth, has risen at some of these gaudy flies, and been painfully pricked by the hook. He flaps his tail in distrust, whenever he sees bright wings on the water, and swims off in search of safer food. It is quite true that a very large proportion of the glittering gems which are sent to us by the French jewellers turn out to be paste, and that some of the diamonds are "Rose" diamonds indeed—that is, not of the first water; but we must remember, at the same time, that there are always some real brilliants among them, and these the Rosarian who wishes for a perfect collection, and the exhibitor who would not be left behind in the race, must obtain at some risk, and at some apparent sacrifice. He cannot afford to wait a season, until a Rose is proved to be of superior excellence, but should have the happiness of knowing, when some novelty is applauded by all, that he purchased it in the preceding May, and that he will have half-a-dozen trees of it next year in his budding ground. These trees, and others of like excellence, will amply compensate for the disappointments around them, and, if he take only a pecuniary view, will repay him with interest for his outlay. I have therefore compiled, from reliable statistics, two tables for the information and direction of amateurs; the one designed to prove to him that Roses of superior merit have been sent out every spring during the last seventeen years, and the other giving the names of those who sent them. The first statement should encourage him to purchase, and the second should be some guide in his selection. He may reasonably expect that those Rosarians who have sent us excellent Roses will continue to do so, and seeing their names attached to the novelties in the spring lists of our nurserymen (these names are given in some catalogues and should be given in all), he will order with a good courage and with happy hopes.

I.

A LIST OF THE BEST ROSES RAISED IN FRANCE AND ELSEWHERE FROM THE YEAR 1859 TO 1877, A.D.

1876.

The following is a selection from the Roses sent out by the French growers in the autumn of 1876, and by the English nurserymen in the spring of 1877:—

HYBRID PERPETUALS.

Duchesse d'Ossuna (H. Jamain), very bright rosy vermilion, large, full, fine form; free perpetual; very vigorous.
John Fraser (Eag. Verdier), very dark crimson, large, very full, very fine form; vigorous.

Madame Berthe du Mesnil de Montchauveau (H. Jamain), beautiful silvery rose, brighter centre, very large, very full and free autumnal; very vigorous.

Madame Devert (Pernet), fine light rose edged with a row of flesh-coloured petals, very large, full, globular form; vigorous.

Madame la Baronne du Medem (E. Verdier), bright cherry-red, very large, very full, globular Aster-shaped flowers; vigorous.

Madame Sophie Fropot (Levet), bright rose, very large, full, fine Centifolia form; vigorous.

Madame William Wood (E. Verdier), deep rose, brighter centre, outer petals paler, medium in size, full, fine form; vigorous.

Madlle. Emma All (Liabaud), rosy-lake, brightened carmine, large, full, globular; vigorous.

Marie Louise Pernet (Pernet), very bright beautiful rose, clearer in centre; a seedling from Baroness Rothschild, very large, fine-cupped form; vigorous.

Marquise Adele de Murinais (Schwartz), pale silvery-rose, tinted with deep rose in opening, large, full, fine form; vigorous.

Marie Louise Margerand (Liabaud), very light rose with lilac reflection in the interior, very elegant globular form, large, very free autumnal; very vigorous.

Monsieur Fillion (Gonod), rose, with very bright centre, flower large, full, with larger outside petals; splendid; very vigorous.

Monsieur Gabriel Tournier (Levet), deep rose; very large, full, fine form; equal. First Prize at Lyons June Show. Vigorous.

Souvenir de Louis Van Houtte (E. Verdier), bright crimson-rose colour, dying off violet; very large, full, cup-shaped, with large petals sweetly scented; vigorous.

HYBRID CHINA.

Souvenir du Pierre Dupuy (Levet), bright red, richly velvety; very large, very full, and of fine form, extra; very vigorous.

TEA-SCENTED.

Comtesse Riza du Parc (Schwartz), colour, china rose with ceppery base; large, full, fine form, good habit, probably fine; vigorous.

Madlle. Lazarine Poizeau (Levet), deep orange-yellow, one of the small free-flowering button-hole Roses; moderate.

Souvenir de George Sands (Ducher), white with deep yellow centre; large, full, fine form; vigorous.

PART II.

AN ALPHABETICAL LIST OF FRENCH AND ENGLISH ROSARIANS, WHO HAVE SENT OUT ROSES OF SUPERIOR MERIT FROM THE YEAR 1859 TO 1875, WITH THE NAMES OF THE ROSES AND THE YEAR OF THEIR INTRODUCTION.

BEAUMAN.

Marie Beauman, 1863

WARD.

John Hopper, 1862

Death of Professor Parlatores.—The death of Filippo Parlatores, Professor of Botany at Florence, is announced. He died full of honours on the 9th of this month at the age of sixty-one. He was well known in connection with his writings on Conifers.

Japanese Wistarias.—Among climbers, the Japanese Wistarias are very beautiful. One variety produces racemes from 2 ft. to 3 ft. long; another has pure white flowers; one has racemes of double flowers resembling small roses, and another has deep green, very glossy foliage freckled or spotted with gold-coloured spots. We saw something of these beautiful Wistarias when in America, but should like to see some evidence of their being made known through our nurserymen. If we mistake not, Mr. Hogg was instrumental in introducing them to America.

WATERCRESSES AT SPRINGHEAD.

WATERCRESSES are said to have grown in a wild state on the banks of the Thames and other places near London for many years before their culture for market was attempted on anything like an extensive scale, and there being then little demand for them the supplies from these quarters were sufficient; but as Watercresses gained popularity in France, Prussia, and elsewhere, so the demand for them in London also increased, and beds for their culture were formed at Springhead and Northfleet, near Gravesend, as far back as the beginning of the present century. What quantity of Watercresses is now consumed in the Metropolis it is impossible to tell, but Mr. Horace Mayhew calculated that 14,958,000 bunches were sold in the course of 1851. Of this amount the street hawkers alone disposed of £13,949 worth. On an average they disposed of 8s. 6d. worth per week each, on which the profit was about 3s. 6d. This estimate of the Cress trade in London does not, of course, take into account the amount brought in directly from the country and disposed of in other ways. As the population of London has so vastly multiplied of late years, the amount now consumed must be much greater, and is daily on the increase, as people are beginning to learn the true value of this wholesome salad; and although this, as just stated, was early in the present century, the Cresses grown at Springhead are still noted for their superior quality. After these beds were started, and the produce obtained from them was found to yield remunerative profits, similar places were soon made where suitable situations existed round the Metropolis, and it is estimated that there are no less than 10,000 bunches of Watercresses disposed of in London daily. Large supplies are now obtained from Waltham, Cheshunt, Uxbridge, and other low-lying places near the Great Eastern Railway, and the annual amount realized by growers for London alone is estimated at over £ 000. The space at Springhead allotted to Watercress culture is about three acres in extent, and consists of a winding ditch varying in width from 6 ft. to 20 ft. The supply of water is furnished by numberless springs of fresh clear water, which bubble out near the banks of the stream in various places and form themselves into a little rivulet. The water contains a good deal of iron, and on the sides of the Cress-beds, where it is somewhat stagnant, the Cress assumes a much more unhealthy colour than that in the middle of the stream. The Cress-beds at Springhead lie in a warm sheltered valley; the sloping banks on either side the stream, and which appear to be exceedingly fertile, are covered with fruit trees, such as Apples, Plums, &c., of which there seems this year to be in this locality a much better crop than we have found elsewhere; and Lettuces thrive exceedingly well near the water. The Watercress is re-planted yearly, generally in August and September, and sometimes in spring. Tufts of the roots are taken up and pulled apart, and planted in rows about 1 ft. apart, after which they are trodden or rolled down, with a view to induce the roots to take quickly. The water is just deep enough to cover the roots, and when fully grown the young shoots in summer represent a miniature meadow of healthy green Watercresses. Cutting is practised three times a week, as many being cut at a time as the markets require. Cutting the Cress is performed by men who, with leather boots to knee, walk in the beds, and with a long knife chop off the most forward of the Cress about 9 in. long, and place it in baskets in such a manner as to allow of a circulation of air through the baskets, in order to prevent the Cress fermenting. Before being placed in the baskets the Cress as cut is dipped overhead in the water, which keeps it fresh until it gets to London, when the purchaser afterwards keeps it well wetted as long as it remains in his possession.

Apart from the interest of the Watercress beds at Springhead, the grounds attached are well worth a visit. One of the largest Weeping Willows in England is here to be seen. Its trunk is about 20 ft. in circumference and from 10 ft. to 12 ft. high, from which issue several sturdy limbs, which have some time been cut back, and are partly severed by their weight from the trunk, and are consequently upheld by iron posts. The head of the tree is of considerable height, and covers a large space of ground with its gracefully drooping glossy-green spray. Amongst other attractive objects are Ivy-covered

bowers, old sheds clad with the double golden-flowered *Kerria japonica* pl. pl., and rare specimens of the large glossy-leaved *Catalpa*, which, as well as the Willow alluded to, appear to derive great benefit from the stream of water which runs close by. Monthly Roses are plentifully planted between annuals of various kinds, Sunflowers and bright-coloured *Pelargoniums* all growing in a natural and therefore pleasing manner. A large sloping bed, facing a residence overhung with Clematis, Roses, and Wistarias, was very attractive. It was occupied by common hardy Fuchsias of various kinds, all of which were bowed down to the ground by their masses of red and purple blossoms. A few scarlet *Gladioli* and other brightly-coloured flowers added to the effect, which was charming. Indeed, all gardening at Springhead appears to be done in a natural half wild manner. This, it must be admitted, is much more enjoyable than formal parterres of flower-beds and borders ever can be. S.

CRYPTOGAMIC SOCIETY OF SCOTLAND.—The days of meeting of the third annual conference will be Oct. 17th, 18th, and 19th, instead of the 10th, 11th, and 12th of that month, as formerly intimated.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—This Society has decided to hold its next spring exhibition in the new Vegetable Market, Edinburgh, and it is proposed to make the show a two days' one. An extra effect will be made to render the removal of the show on this occasion from the always too crowded music hall a decided success.

EIGHTH GENERAL MEETING OF GERMAN POMOLOGISTS.—This will be held at Potsdam in the first week of October, on the occasion of the great fruit show which is to take place there, commencing on the third of the month. The large Orangery at Sanssouci has been lent by the Emperor for the purpose of this display, which is expected to be of unusual extent and splendour. Visits to the Royal Gardens, to Babelsberg, Glienecke, Werder, and other places of interest are in course of arrangement for the amusement of intending visitors.

NOTES AND QUESTIONS—VARIOUS.

Beech Tree Caterpillars.—I have sent some caterpillars which I caught upon a Beech tree, where there are hundreds now stripping the leaves rapidly off the bunches. Would you kindly name them, as I have never seen such caterpillars before?—W. M'A. [*Pygma bucephala*—also known under the English name of the Buff-tip moth.—A. M.]

Milla biflora (see p. 199).—I had several bulbs of this in bloom last year, and I think it a mistake to say that it has been "long lost." It is a beautiful plant, quite in advance of its congener, *Triteleia uniflora*, but much more difficult to manage, and much scarcer. I find that the bulbs often lie dormant like some of the small *Narcissi*, but once get them to grow and they will bloom.—A. Rawson, *Bromley Common*.

Koelerutaria japonica has been long introduced into our gardens, but is not nearly as well known as it should be. It grows from 20 ft. to 30 ft. high, has yellowish-green foliage, and produces spikes of yellow flowers in July. This tree is particularly desirable on account of its unique appearance, and its producing flowers when other trees and shrubs have passed out of bloom. I find the above in "Harper's Bazaar." May I ask if the tree is in cultivation with us?—H. P.

Propagating Wallflowers.—I am now putting in cuttings of some selected dark and yellow Wallflowers. If put into some good light sandy soil, as one would those of Pansies and such like, they strike quickly and make good plants for blooming in spring. Amongst Wallflowers it will always be found that some are finer than others—of a dwarf bushy growth, and with large, well-formed flowers of good quality. The best strain of seed may not ensure kinds so good as these, therefore the expediency of using cuttings. The pretty dwarf *Belvoir Castle Yellow* is best kept propagated in this way in order to preserve the correct type.—D.

Diseased Violet Leaves.—The specimens of diseased Violet leaves enclosed are from plants grown on a border specially prepared for them. Last year we lost all our Violets in a similar manner. How can we avoid such a mishap in future?—W. C. B., *Clapham Park*. [The leaves in question are attacked by a fungus which is most troublesome in the case of the *V. alba odorata* section, especially the white wood and hedge-row Violet, and the old double white, and, indeed, most of the varieties that have leaves of that character—*Belle de Châtensy* not excepted; but it is rarely seen on any of the strong-growing varieties, such as the *Czar*, *Giant*, and *Victoria Regina*—just a spot or so might be seen occasionally, communicated no doubt from the others, but the disease if neglected spreads most rapidly on the first-named varieties. There are two methods of keeping it in check, viz., dipping the finger and thumb in flowers of sulphur and pressing the spots between them, and picking the affected leaves off. Possibly, if very bad, the whole of the leaves might be cut off and a good dressing of fresh soot applied.—GEORGE LEE, *Clivedon*.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

WOMEN AS GARDENERS.

MISS FRANCES POWER COBBE has something to say on this subject not without interest. The subject of gardening, writes Miss Cobbe in the "Women's Gazette," as a remunerative employment for women, to which I ventured recently to call the attention of your readers, has been in the interval treated as follows in a weekly newspaper:—

"Women love flowers, and it is very good for them to love them; and flowers thrive under their care in a way so mysterious as to suggest that, like dogs or birds, they have a certain sensitive-plant sort of satisfaction in being touched by gentle hands, and visited by somebody who will

Out of the cups of the heavy flowers
Empty the rain of the thunder showers,

These things being so, why or how does it happen that women so very rarely undertake gardening as a remunerative employment? and while we find a 'Poor Gentleman' writing condescendingly to the 'Times' that he would not 'object' to take a head-gardener's place, we never hear of a lady-help seeking any such post, though hundreds are already qualified by their skill and experience to undertake it? We will not waste time by lamenting that sheep will follow in beaten tracks, and that the sheep-dogs too often bark at them when they attempt to nibble alongside new ones, but proceed at once to explain how we think the charmed circle of the employments of women may be broken in this direction without too much violence, and ladies encouraged to turn their thimbles into trowels and their needles into pruning-hooks. First, for that very considerable class of ladies who possess a small fixed income, and who have been brought up in the country in the enjoyment and care of a garden—say, the daughters of clergymen, or country doctors, or squires, with estates not big enough to make their head-gardener an authority much too awful to be meddled with by the ladies of the family. When such a lady—say at the age of thirty-five or forty-five—finds herself, as widow or old maid, deprived of her home by the death of her parents or husband, and without any immediate objects in life, she commonly either takes to wandering about incessantly abroad, or settles down in an English watering-place, eking out her small pittance by contrivances, like those of the good ladies of 'Cranford,' and doing such kind turns as her slender means will admit; attending innumerable tea-parties, till she gradually withers in a harmless old age. Why should not such a lady invest her little competence in the lease of a cottage with a good large garden, in whatever locality her connexions may reside, and set about at once rendering this garden profitable by the sale of flowers in the first place, and then, perhaps, of fruit and choice vegetables? We are assuming that she already has thoroughly learned at home the art and knack of cultivating flowers, and that she is physically strong enough to do the lighter part of garden work every day, and to find it healthful and delightful. What she will need, then, will be, once in a way, the work of a labourer for a day or two to dig and manure her ground, and afterwards the help of a boy whom she will train and employ generally as her servant. With one or two such boys working under her eye and along with her, and with a frame or two in which to keep her choice plants in winter, our 'gardeness,' if she know her business, would be able to produce a constant succession of fine nosegays during the greater part of the year. It would scarcely ever be necessary for our lady gardener to advertise her willingness to supply flowers, to obtain among her friends and connections abundant contracts; but if she still had an overplus, a notice in the newspapers would bring her, if we mistake not, more orders than she could meet. In the sales so effected there would be nothing in the slightest degree derogatory to any lady in the land, any more than there is to the greatest nobleman who sells his corn and farm produce."

To these remarks I would add the suggestion, that when her little establishment is in full working order, our lady market-gardener might invite one or more other ladies to board and share her work, who will thus study practical gardening as a profession, and fit themselves to undertake the posts of head gardeners in country seats where a few under gardeners are employed. Some prejudices would need to be overcome in this case, but such situations if procured would be quite as pleasant and profitable, I imagine, to any lady qualified to hold them, as that of elementary village school-mistress, for which so many are now wisely preparing themselves in that admirable institution, Bishop Otter's College. Very soon I feel sure the owners of handsome gardens in search of head gardeners would learn to seek eagerly for a woman, who would lay out their walks and beds, and group their flowers, with the taste and originality of a lady, instead of in the *banale* professional style of a regular head gardener, and who might not think it necessary to oppress the ladies of the family when they venture to gather their own flowers and fruit after the manner usual among such dignitaries. Flower-beds, laid out by one of these officials by rote and rule, bear to a true garden (such as Lady Corisande's in "Lothair") the relation which a gaudy drawing-room, all mirrors and ormolu, furnished to order by a common upholsterer, bears to a room wherein a true woman has dwelt for years, surrounding herself with beautiful and harmonious things, till the very aspect of her chamber reveals something of her soul.

[No doubt we shall have what Miss Cobbe desires when the simplest useful work is honoured and the most ornamental idleness thought meanly of; as yet, that is a long way off. She does not know how much has to be learnt to make a good gardener now-a-days. But there is one thing that women might do at once without apprenticeship—cease to patronise the kind of gardening to which she so very properly objects. In the majority of cases this was forced on gardeners at first by ladies who could see no better way of illustrating in their gardens the beauty and variety of the vegetable world. Nothing is more certain than that the system was at first adopted with regret by many good gardeners. Now, unhappily, we have a school brought up under the influence only of "bedding stuff," as they very properly call it, and who can see little or nothing beyond it. Gardening is certainly charming work for women if the piano and the starched slavery of dress will ever allow them enough liberty to pursue it well.—*Ed.*]

HYPERICUM PATULUM AT COMELY BANK.

By chance, the day after I had read the article in THE GARDEN on the genus *Hypericum*, and studied the excellent plate of *H. patulum* (given at p. 280), I happened to take a stroll through the old-fashioned and out-of-the-way nurseries of Messrs. Cunninghame & Fraser, which lie near the new Fettes College, Edinburgh. I found there one large bush with glossy evergreen leaves, and bearing attractive yellow flowers which, upon nearer inspection, turned out to be a *Hypericum*, which Mr. Fraser told me, upon my taking it to him, was *H. patulum*. There was just one bush of it, and he did not know how long he had had it. The flowers resemble the plate in THE GARDEN very closely, the only differences being that the ovaries in the plant which I saw were not so green as those in the illustration, partaking more of the yellow hue of the flower, and the flowers were not expanded in clusters, but singly or in twos; it certainly is a very beautiful plant, if not the most beautiful of the St. John's-worts. The leaves and flowers are of great substance and of a beautiful glossy texture. Its hardness is undoubted, as here it has stood in the climate of Edinburgh for an unknown number of winters. These gardens are a real paradise to the collector of hardy plants and shrubs. There is no signboard bearing the name of the firm, they do not advertise, nor is there any printed catalogue, and nearly the whole extensive grounds are a wilderness of old-fashioned flowers and shrubs. Here I found a bed of the rare *Narcissus triandrus*, another of *N. montanus*, and one of *N. bicolor*, besides many other rare sorts. Large *Magnolias* thrust sturdy arms out from the old grey walls

mixed with Jasmines, Siliquastrum, and rare Spiræas. There is also a large collection of Alpine plants. An air of repose and old-worldliness rests over the whole nurseries, which amply repay a visit, were it only to find a contrast with the vigorous, pushing manner in which trade is usually carried on.

SALMONICEPS.

A GARDEN OF HARDY EXOTIC FERNS.

CLOSE to Musselburgh, beautifully situated amid fine pleasure grounds and stately trees, stands Pinkie House, the residence of Sir Archibald Hope, of Craighall. It consists of two sides of a quadrangle, with central tower, which dates as far back as James III.'s time; the rest of the mansion is of James VI.'s time, and is considered to be one of the finest specimens of the Scottish manor of that age. The Battle of Pinkie was fought in 1547 within the pleasure grounds; and here also Prince Charles Edward slept the night previous to the Battle of Prestonpans. It is not, however, the history of Pinkie that I am about to write—though that would doubtless be interesting—but to record the fact that within the grounds is to be seen the best private collection of British and hardy exotic Ferns in Scotland. It consists of upwards of 400 species and varieties, all planted out on what may be termed a rockery, which is situated on the south of the flower garden, and within view of the mansion, under the shade of tall trees. Prominent specimens of overgreen shrubs afford shelter from cutting winds to the stately and delicate Ferns, which are placed as it were under their protection. The rockery, taken as a whole, is of an undulating character, nowhere rising over 6 ft. or 7 ft. above the gravel walks on either side, but frequently pierced with narrow paths, which terminate in rounded nooks and corners, and hidden caves suitable to the requirements of Hymenophyllum, Asplenium marinum, &c. Not unfrequently one has to ascend by winding, narrow, stone steps to the ridge, and then descend to another cave or rounded hollow, the steps being in that case entirely hidden with the delicate, recurving fronds of Athyriums, such as *A. Filix-femina cristatum*, plumosum, and all the other forms into which *A. Filix-femina* has differentiated. Advantage has been taken to vary the aspect by means of such plants as *Dracæna indivisa*, *Aralia Sieboldi*, *Phormium tenax*, *Aspidistra lurida variegata*, and *Arnudo Donax*, all of which are to be found quite hardy. *Arundinaria falcata*, which flowered last year, is dead; but self-sown seedlings are springing up everywhere, which, together with *Bocconia cordata* 9 ft. high, and *Cow Parsnips* 15 ft. high, form prominent objects here and there, the whole forming a beautiful background to the flower garden.

The collecting and arranging of this extensive collection has been the work of a number of years, and is wholly due to the persevering industry of Mr. H. Kingscote, Lady Hope's father, and to the care which her ladyship takes of all the plants. Mr. Kingscote is in Scotland only one or two months in the year, but he is, nevertheless, constantly adding to the collection, and he takes much pleasure in relating to any one interested the circumstances under which each plant was collected or got. He is particularly fond of Polypodiums, of which he has upwards of thirty specimens and varieties, and these are not in single patches, but by the dozen; amongst them are *P. vulgare cambricum*, 3 ft. across; *P. v. omnilacerum*, nearly as large; and *P. v. cristatum* in large patches round all the rockery. Prominent amongst the Polypodiums are the following varieties:—*P. auratum*, with golden yellow fronds, with the apex bifid or multifid; *P. Cornubiense elegantissimum*, with finely emb-divided lobes, giving the plant the appearance of the Parsley Fern; *P. multifidum cristatum*, finely crested; *P. pulcherrimum*, with imbricate fine broad pinnae; *P. omnilacerum angustifolium*, with pretty narrow fertile fronds; *P. dissimile*, with fine large fronds; *P. Whytei*, one of the finest and most distinct, highly subdivided; while *P. alpestre* and its variety *P. flexile* were here larger than we usually find them, being at least 3 ft. through. Of Aspleniums, there are here upwards of forty; *A. septentrionale* and *A. germanicum*, rarely to be seen in good condition, are quite at home; of *A. fontanum* the only variety is *lanceolatum*. *Adiantum nigrum* is represented by four or five varieties, the most distinct being *acutum* and *subconfluens*; of *A. Trichomanes* the most distinct are *Moulii* and *cristatum*, with the apex of the fronds highly subdivided and crested; *A. viride*, one variety got on Ben Lawers, was pretty and distinct. Of Athyrium, there are nearly 100 varieties, more or less distinct; but all who know (and who do not?) the Lady Fern, "supreme in her beauty," will not be surprised when I say that some of the varieties are anything but beautiful, speaking comparatively. *Cystopteris montana* is doing well; of others, *C. Dickiana* is the neatest; numerous varieties collected in various places are here in quantity. Of *Lastrea Filix-mas* there

are nearly endless varieties, the most distinct being *cristata*, *angustata*, and *Barnesi*; and of *L. dilatata* the finest is *lepidota* and *Hopei*—a very distinct and beautiful variety found by Mr. Kingscote near the Pass of Killiecrankie, and named in honour of Lady Hope. *Polystichum* is represented by no fewer than seventy-two species and varieties, and they are altogether a splendid lot. From *P. angulare* are got the greatest numbers of varieties, and between some of these, such as *P. grandidens minus* and the tall and stately forms of *P. aculeatum* and its varieties there is every conceivable shape. A seedling found in the woods of Kingscote, in Gloucester, and named *Kingscotti*, is a fine variety, 3 ft. to 4 ft. high, the dark green fronds being of a rigid, upright habit; it will make a useful pot plant; it is farther remarkable in being viviparous in the axils of the higher pinnae. There are also some distinct species; *P. Louchitii*, one of them, from self-sown spores on the rockery, is very remarkable for the length of its fronds, which are quite 18 in. high. *Scolopendrium* are numerous, there being fifty named varieties of *S. vulgare*, besides endless sub-varieties, raised from spores; plants of *S. crispum*, 4 ft. across; one like *Endiviaefolium* was in fine condition; ramose and crested forms are endless. *Woodsia ilvensis* and *W. hyperborea* were growing satisfactorily. In the list of hardy exotics the chief interest will be the number of species which are found to be hardy, and which have hitherto been only met with in the stove or warm greenhouse.

<i>Adiantum Capillus-Veneris</i>	<i>Onoclea sensibilis</i>
" " <i>subrotundatum</i>	" sp. from Bermuda
" <i>pedatum</i>	<i>Osmunda cinnamomea</i>
" <i>venustum</i> , very large	" <i>interrupta</i>
<i>Asplenium Thelypteroides</i>	" <i>spectabilis</i>
" <i>Michauxii</i>	<i>Platyloma rotundifolia</i>
" <i>strigosum</i>	<i>Polypodium hexagonopterum</i>
<i>Athyrium Goringianum pictum</i> , five years out	<i>Onychium japonicum</i> , doing finely
<i>Cystopteris bulbifera</i>	<i>Dictyogramma japonica</i>
<i>Lastrea opaca</i> , strong	<i>Polystichum pteridifolium</i>
" <i>Goldiana</i> , very fine	" <i>vestitum venustum</i> ,
" <i>Standishi</i>	" fine
" <i>erosa</i>	" sp. small, from New Zealand
" <i>atroviridis</i>	" <i>acrostichoides</i>
" <i>erythrosora</i>	" <i>proliferum</i> , New Zealand
" <i>atrata</i> , strong	<i>Pteris scaberula</i>
<i>Lomaria chilensis</i> , fine, healthy	" <i>hastata</i>
" <i>alpina</i>	<i>Polypodium coriaceum</i> , fine plant
" <i>fluviatilis</i> , strong	<i>Struthiopteris germanica</i>
" <i>Boryana</i> , fine large plant	" <i>pennsylvanica</i>
" <i>crenulata</i> , growing everywhere	<i>Woodwardia radicans</i>
" <i>unda</i>	" <i>areolata</i>
" <i>antarctica</i>	<i>Sitobolium punctilobum</i>

And perhaps some others which may have been missed; the above were on the whole doing well. A number of others not mentioned were planted out this year.

R. M.

Black and White Mints.—Dr. Piesse, in one of his very interesting papers now appearing in THE GARDEN, carefully and accurately describes the two kinds of Mint so largely cultivated and distilled by Piesse and Lubin at Mitcham. Though the figures engraved in THE GARDEN of the Black and White Mints give a good idea of their distinctness, I may perhaps be allowed to add my testimony to their totally different appearance as a field crop. By the kindness of, and in company with Dr. Piesse, I visited his fields and still-house a few years since, and secured specimens of both these Mints. Upon submitting them to Mr. J. G. Baker, he gave me his opinion upon them, with which that of Dr. Boswell entirely agrees. These specimens are now in the Kew Museum, and in their dried state even the difference in appearance is very marked, the leaves of the Black Mint being of a much darker green, and the stalks of a deeper purple than the White. The two kinds are very well described in the first part of Bentley and Trimen's "Medicinal Plants," the plant there figured being of an intermediate character.—JOHN R. JACKSON, *Museum, Kew.*

Housing Hard-wooded Plants.—Azaleas, Camellias, and similar plants which have been placed out-of-doors during the summer will require ere long to be removed to their winter quarters. Those performing this work may therefore be reminded that if each plant be placed in a tub of water for an hour or more before being taken indoors, so as to allow the balls of soil, which are generally hard and often dry in the middle, to get well soaked, much inconvenience in the way of watering during the winter will be saved, and the plants will also be more likely to keep in good health.—S.

TREES AND SHRUBS.

THE REDWOOD (*SEQUOIA SEMPERVIRENS*).

THIS forms the second largest timber tree in California. It was discovered by Menzies in 1796, and was introduced into Europe in 1843. It is found here and there throughout the undulations of the coast range in California, on the mountain

Cones and fruit of the Redwood.

slopes, and in sheltered valleys; but it is only in the latter where forests of any extent are found, and also where the largest trees grow. I have pleasant remembrances of my first journey, accompanied by a friend, to one of the largest—probably the largest—of these forests. The Redwoods were distant twenty backward miles, and were reached by one of the sandiest roads I ever traversed. Numerous thickets of young plants of the Douglas Spruce, and occasionally an old specimen 200 ft. or more in height, branched to the ground, grew on either hand, in the lightest of sandy soils resting on a substratum of chalk. Fifteen miles had been traversed, when we entered Pocket Canon—a very expressive name for a

ravine that had by degrees been traced in the hills by a stream flowing to the Russian River—here barely sufficient for a waggon to pass through, and again widening into a glade or “pocket” of considerable extent, a kind of formation repeated down to the river. The sides of this defile were well wooded with Spruce, different kinds of Oaks, Stinking Yew (*Torreya californica*), Laurel (*Oreodaphne californica*), and an undergrowth of *Ceanothuses*, *Arbutus*, *Photinia arbutifolia*, &c. On the islands, where the stream forked, a few large Redwoods grew, but they were few and far between until within a quarter of a mile from the river, where they were massed into a dense dark forest, through which our road, now damp and spongy—the first damp ground we had seen for five months—wound snakelike towards the river, on the brink of which, at about 13 miles from the ocean, we stopped. The river-bed—for it was all but dry—was from about 40 yards wide, and spanned by a rudely constructed bridge of Redwood boles laced together. Following the river in its course the view was disappointingly cut off, at 300 yards or 400 yards from our stand-point by a low hill, through a narrow fissure of which the river forced its way and was lost to view. The view up the river was very different. We stood at the base of a living dark green wall at least 250 ft. in height, and a little over a mile in length. On the opposite bank was another wall of like dimensions, with the river-bed between reminding one of a broad gravelled walk in a long straight avenue, with a peep of a hazy blue mountain in the distant background. Just opposite on the edge of the forest is Big Bottom “City,” in reality a hamlet of a dozen and a half small wooden huts, and a saw mill. Night was fast approaching and fortunately for us we were promised lodgings in the solitary hut on this side of the river. Our host who had “squatted” in the Redwoods, and who now got a livelihood out of the timber, kindly showed us round his estate, pointing out to us and expatiating on the giants of his domain. Until then we had failed to fully appreciate the magnitude of these trees. One lay prostrate on the ground as he had felled it the day before, and was, by actual measurement 303 ft. long and 15 ft. in diameter, cut off at 4 ft. from the ground. The largest tree I measured was 17 ft. in diameter at 6 ft. from the ground, and its height, as stated by our host, was 330 ft. Of this I had no means of testing the truth, but it certainly appeared taller than any of the others around. The trunk near the base was very irregular, owing to the presence of large buttresses (from the principal roots), which at about 12 ft. from the ground disappeared, leaving a pretty regular or rounded hole, destitute of branches for nearly 100 ft., above which they were almost regularly disposed, but of no great dimensions, and seemingly disproportionate to the size of the tree. Beneath it and all around were millions of tiny seedlings from 1 in. to 3 in. in height, forming a striking contrast to the giant parents. Many large trees were broken off at various distances from the ground; and others that had been felled some years previously had again thrown up adventitious leaders, and were forming beautiful trees. I had also an opportunity of counting the annual rings of growth made by one of these trees, and they amounted to 1250, but several of them were rather indistinct. Trees of it have been found at a depth of 30 ft. below the surface of one of the valleys in California; and Mr. Murray, in his “Notes on Californian Trees,” states that “M. Lesquereux conceives that he has identified this tree among the fossil remains of the tertiary deposits of Vancouver’s Island.” On the table before me is a fragment of stonefied Redwood chipped from a petrified tree, which I exhumed from the middle tertiary deposits of California. But petrified Redwood is plentiful in some parts of California, and indeed the nature of the wood is such as to facilitate the process of petrification. It is a dull red colour, close-grained, but brittle and very light, and seems to be little affected by long-continued submersion in water. It is extensively and perhaps principally used for rail and picket fencing; but in addition to this, nearly all the houses and barns in the rural districts are built with it and covered with it in the form of shingles. As yet it has not done very well in this country except in a few favoured localities in which shelter from cutting winds is afforded. Plants of it may frequently be seen all but bare of branches, and these in a very dilapidated condition. All such ought to be cut down to within 12 in. or 24 in. of the ground, when

they will soon push fresh leaders, which will, with the protection afforded by surrounding objects, very soon develop into beautiful heads. If it be cultivated at all, instead of singling the plants out to be starved, let us imitate Nature by planting them in clumps in naturally or artificially sheltered positions. Endlicher called the Redwood *Sequoia sempervirens*. Lambert named it *Taxodium sempervirens*, and there are the following garden varieties of it.

Sequoia sempervirens alba spica (syn. *glauca*).—The peculiarity of this is in the leaves and bark of the vegetating shoots being white or pale yellow, afterwards changing to a bluish green. It is a pretty kind, and quite as hardy as the common form.

S. s. Lawsoniana.—This I have not seen, but it has been described as having short, thick leaves, and a more rigid habit of growth than the type.

GEO. SYME.

NOTES OF THE WEEK.

RHODODENDRON PRINCESS ROYAL.—This, the result of a cross between *R. javanicum* and *R. jasminiflorum*, still ranks among the best of greenhouse Rhododendrons. A large specimen of it in the Chelsea nursery has been in bloom for at least two months, and will to all appearances continue in flower for some time to come. It now bears no fewer than thirty large clusters of rosy-pink or rather flesh-coloured blossoms, which are very effective on the plant as well as in a cut state.—C. S.

THE GIANT AUTUMN CROCUS.—Mr. P. Barr sends us flowers of the noble *Colobium speciosum*—one of the most precious gains for our open-air gardens. The flowers now sent are of a deeper red colour than those which we illustrated in THE GARDEN last June (see p. 548). Other autumn Crocuses now in bloom, in addition to those named last week, are *C. nudiflorum* (rich purple) and *C. Vallicola* (creamy-white).

DWARF ANTIRRHINUMS.—One of the most attractive sights now to be seen in the Tottenham nurseries is several large beds planted with a dwarf strain of Antirrhinums. The flowers, which are abundant, embrace nearly every shade of colour, and the plants themselves are not more than 15 in. high, a great advantage where narrow borders have to be planted. These, in common with some other biennials, are better in masses than in any other way, and if in mixed colours so much the better.—C. S.

SMALL-FLOWERED DAHLIAS.—However highly large-flowered or show kinds of Dahlias may be valued by florists, none are so beautiful or useful as the small-flowered or Pomponé varieties. For supplying cut blooms at this season they are invaluable, and where plants exist on which there are any quantity of buds yet to open, if these on the appearance of frost be lifted, put into large pots, and placed in a cool house, they will furnish an abundance of bloom until late in the year. We noted amongst other kinds at Messrs. Henderson's the other day Little Dear (a pretty little round flower with white, rosy-tipped petals), a pure white kind called Little Beauty, Alliance (rich velvety crimson), and a bright scarlet sort named Seraph, the best yellow being Golden Nugget.—S.

MILLA BIFLORA.—Of course, the statement "long lost" (see p. 199) cannot be meant in an absolute sense, but I think that except in Mr. Rawson's garden, the plant is not to be met with in any other English collection. I have, therefore, to congratulate Mr. Rawson on his possession of it, as well as on the skilful manner in which he has preserved it. It was re-introduced in 1873 or 1874 by Mr. Roetz, and went into the hands of the New Plant and Bulb Company at Colchester, and although many hundreds of it were introduced in the spring of 1875, I offered any reasonable price for it, but in vain. None of the great nurserymen in England, Belgium, or Holland could supply me; it had gone everywhere, and I failed to procure it. It is a plant well worth a little extra care; the whiteness of its flowers rival that of snow, and they are sweet-scented.—MAX LEICHTLIN, Baden Baden.

FLOWER GARDENING AT THE CRYSTAL PALACE.—The grounds here this year are unusually attractive, and from many points of view the masses of Pelargoniums, Dahlias, and other showy subjects are seen to good advantage. The most effective feature, however, is perhaps the Rosery, the sloping circular bank round which is tastefully planted in simple but appropriate designs composed of Iresine Lindenii, Centaureas, Blue Lobelia, Golden-leaved Pelargoniums, Leucophyton, and Alternantheras of various shades of colour and habit. Veronica inana is also used in these beds with good effect. The isolated round beds on the lawn are also very effective, the more so as they are placed at a greater distance apart than usual. These are planted with dwarf crimson and white-flowered Dahlias. Beds planted with Tritoma Uvaria, Phloxes, and double-flowered Sunflower

(*Helianthus multiflorus* fl-pl.) are likewise worthy of notice. The carpet beds are good of their kind, the colours being well arranged, and the plants not so formal and closely shorn as one generally finds them. Pink and crimson Monthly Roses, which are planted extensively round large clumps of Rhododendrons and in borders, are still gay with blossom, and the grounds throughout are in better keeping than we have before seen them. Inside the Palace the Tree Ferns and Palms are growing vigorously, and the water-tanks are, as usual, full of interesting aquatics.

THE GRASS IN HYDE PARK.—There is a long article in the "World" condemning the state of the Grass in Hyde Park, and a very unjust and ill-considered one, for the turf is as good as it can be under the circumstances.

TASSELLED ASTERS.—Messrs. Saltmarsh & Sons have sent us blooms of tasselèd Asters, which, after having been exhibited at Alexandra Park show on the 13th, 14th, and 15th inst., and again at the Crystal Palace on the 21st and 22nd inst., are now (25th) quite fresh, and would no doubt last for several more days in good condition. The blooms are very large and beautifully coloured, and for mixing in stands amongst cut flowers of other kinds are very valuable. The comparatively short season during which Asters are in bloom is, to some extent, a drawback to their culture; but by making an early sowing in heat, and two or three successional ones afterwards, and by planting these alternately, a long succession of bloom might easily be maintained. If a sowing be also made late, say the end of June, or even later, and the plants grown on liberally, lifted in autumn and placed indoors, there seems to be no good reason why good pot plants could not be obtained late in autumn, when effective flowering plants are scarcer than at any other season of the year.—S.

KEW.—In the Succulent-house there are several good plants in bloom. *Stapelia deflexa* has a brick-red corolla, and the lobes are thickly stipellated; it emits an abominable odour, as a proof of which we may mention that the corona of one of its flowers was quite surrounded by the eggs of some insect that had no doubt been attracted by the carrion-like smell. *S. coronata* has densely-hairy flowers of a reddish-brown colour, a large blotch in each lobe being yellowish, transversely barred with brown: this is a very pretty species. *S. varians* is also a handsome plant, and in general appearance seems to come near *S. patentirostris*, wrongly figured in the "Botanical Magazine" as *S. sororia*. *Cotyledon ramosissimum* is a very pretty dwarf-growing Cape succulent, with large pendent reddish flowers. *Dyckia brevifolia* has a rosette of stiff green leaves, striated beneath, and a short panicle of yellow flowers. It is growing near the beautiful *Dyckia argentea*, which has long, arching, white leaves, and is said to be the only specimen of its species in Europe. *Vitis cirrhosa*, from the Cape of Good Hope, has fleshy leaves, much like those of the Virginian Creeper in general outline. It is now in fruit, and its fine, bright red, coral-like fruits are exceedingly pretty. In the stove, *Aristolochia Duchartrei* claims our attention: it is one of the showiest species in the large genus to which it belongs; the broad, funnel-shaped mouth of the flower is a creamy-white, blotched irregularly with red-brown. *Ipomœa Horsfalliæ* is a beautiful climber, worthy of cultivation in any stove; its very deep, rich glossy rose-coloured flowers contrast well with the green quinate leaves. The herbaceous ground is worth a visit just now. The prettiest *Toad-flax* is *Linaria dalmatica*, a native of Eastern Europe and Western Asia; it is a fine bush about 3 ft. high, literally one mass of bright yellow flowers: the leaves and stems are very glaucous. *Cosmos bipinnatus* is a charming Mexican Composite, about 4 ft. high, with finely-divided feathery leaves and bright red purple flowers, somewhat like those of a single Dahlia: all the species of this genus are extremely ornamental plants; they are New World annuals. *Phygadeuon capensis* has drooping scarlet flowers, and is very effective either as a border or wall plant. *Silphium laciniatum* (the Compass-plant), would make a fine object as a single specimen on a lawn; it has large heads of yellow flowers, and a stout stem about 9 ft. high; the ovate deeply-pinnatifid leaves are very handsome: this species is known in the South-western part of the United States, especially in Texas and Oregon, as the "Pilot-weed," the "Polar-plant," &c., on account of the peculiar property it possesses of turning its leaves towards the north. This "polarity" has long been familiar to hunters and other denizens of the prairies, who, when lost on dark nights, easily get their bearings by feeling the direction of the leaves. Mr. Meehan, of Philadelphia, says that those who affirm the polarity and those who deny it are both right. In a plant in his own garden the young leaves showed an unmistakable northern tendency, which they lost on becoming older. The *Silphiums* are all tall-growing perennials. In the Kew collection, *S. terebinthaceum*, *S. perfoliatum*, *S. ternatum*, and *S. trifoliatum* are in flower; as also an unnamed species remarkable for the very large size of its radical leaves. No other species of the genus exhibits the peculiar tendency of *S. laciniatum*.

THE FLOWER GARDEN.

TREES IN TUBS.

WE are no admirers of trees in tubs on terraces. They are expensive and rarely ornamental objects. It is considered correct taste to use them in geometrically laid-out terrace gardens; but we could point to many terraces in England and elsewhere where their absence is no blemish. A row of trees in tubs is no more necessary to the good effect of the terrace garden than a row of balloons. The culture of Orange, Bay, and other trees in tubs is a Continental custom, and much more desirable in parts of Northern Europe, where few Evergreens can be grown in the open air, than in Britain. It is, as a rule, very much better performed on the Continent than here, and those who adopt it with us should know the conditions essential to success. Although we now often see handsome specimens of hardy Evergreens grown in tubs in this country, tender subjects alone were kept thus when the system originated. It was found that the Oleander and Orange trees could be grown very well by storing them in any sort of half-lighted, frost-proof structure in winter, and placing them in the open air in summer; and hence these plants became very popular for that purpose. But the conditions are now wholly altered in the garden, and growing trees in tubs is foolish work, entirely unworthy of a time when we have scores of beautiful Evergreens to adorn our gardens and that require no tubs.

POLYANTHUSES.

I AM just repotting my gold-laced kinds of these. They were planted out at the end of May last on a cool, shady border, where only the morning sun fell on them, and having been kept clear of weeds during the summer, top-dressed, and well watered in dry, hot weather, they have done well and made fine plants. Those large enough to make good flowering specimens for next spring are being potted into 4½-in. pots, the offsets into small "long toms." I am using a soil consisting of fibry turf, well-decayed, dry cow manure (previously baked in order to kill any insects in it), leaf-mould, a little sand, and some powdered charcoal; and when potted, the plants are placed on a deep bed of ashes, somewhat raised, which occupies a cool, shady corner. Here they will remain till severe weather makes it necessary to house them in a frame for the winter. I am in favour of earlier repotting than some growers practise, because at this season of the year the Polyanthus assumes a vigorous autumnal growth, and roots are put forth immediately below the leaves. In this manner the plants acquire renewed strength to produce their spring flowers. I like to see these roots establishing themselves in the soil in pots by the middle of September. In my case, when the plants were lifted, the soil was shaken from their roots, and any decayed or needlessly lengthened parts of the tap roots were cut away. It is not necessary to have the tap-root below the point from which the rootlets spring. I pot pretty firmly and rather deeply, burying the stalks of the lowermost leaves a little way. The deeper the plants are put into the soil now, the more serviceable in the spring late dressing is likely to be to them. My collection now consists of George IV., Cheshire Favourite, Exile, Cox's Regent, President, Lancer, a very fine sort; and the following comparatively new kinds, raised in the neighbourhood of Newcastle-on-Tyne, viz., William IV., Formosa, and Telegraph, making altogether nine varieties. I am desirous of adding to my collection Hutton's Earl of Lincoln, Maud's Beauty of England, Addis's Kingfisher, and Clegg's Lord John Russell. I have made many inquiries for these, but as yet without success. I am almost afraid that all, or three of them at least, are lost to cultivation. In addition to these I have a few specially pro-

missing seedlings which I shall bloom for the second time next spring. One of them is a flower of great size, finely and evenly laced with deep gold; but it is a pin-eyed kind. I am hopeful it may prove of value as a seed parent. I shall be glad if any reader of THE GARDEN can assist me in obtaining plants of named varieties in cultivation that I do not already possess; but I want only those worthy the attention of the cultivator. D.

WINTER AND SPRING GARDENING.

NOW that summer-blooming plants are getting past their best, cultivators must begin to consider what the empty beds are to be filled with during winter and spring. As a rule carpet bedding this season has been best, as owing to the dull, wet weather which we have experienced, there has been a scarcity of bloom where such plants as Pelargoniums, Calceolarias, &c., have been used: as to filling the beds and borders when vacant, there need be little difficulty. A bed of common Forget-me-nots edged with white Daisies forms, when in flower, a charming combination; Golden Feather Pyrethrum, where it stands the winter well, has a pretty effect as spring advances, forming as it were a bed of gold; Arabis alba edged with a broad band of red Daisies has a fine appearance; then there are Saxifrage in profusion that might be employed with advantage; Auriculas, too, when massed look well when in flower; and Anubria purpurea makes a charming purple bed; while Golden Thyme and Sempervivums, or as many call them Houseleeks, can be used with advantage as edgings to small beds; Pansies such as Cliveden Yellow, Imperial Blue, and Cloth of Gold, are charming subjects in their way; of Daisies there are the Aucuba-leaved, the Double White, Red and Pink, and others innumerable, all of which should be planted in large quantities; the Golden Dead Nettle, too, is a pretty, dwarf, hardy plant, of which enough is not made; then there are the hardy Candytufts, which keep in flower for a length of time; Wallflowers, such as the Yellow Dwarf and Blood-red Dwarf, and the strain used at Belvoir Castle; the double German

The Survival of the most Unfit: Trees in tubs.

Wallflowers are capital plants for the spring decoration of beds and borders. In addition to these there are, likewise, Primroses such as the Double Lilac or Mauve, and even the common Wood Primrose might be used in certain situations with advantage; Polyanthuses, when in flower, are also very pretty. Hardy annuals, too, such as Silenes and Saponaria calabrica, flower well during the spring months. Hepaticas, both blue and red, double and single, are likewise beautiful in spring; and Ajuga reptans purpurea makes a good, dark purple edging. Many other plants could be named, but when we consider what hosts of bulbs, such as Crocuses, Snowdrops, Squills, and Daffodils there are, one feels that enough has been enumerated, and they wholly consist of plants within the reach of all interested in spring flowers. Some handsome-leaved shrubs, such as Aucubas, Golden Euonymus, and even variegated Ives, might also be introduced for the sake of contrast. J. B.

West Lodge, Chapel Town, Leeds.

The White Musk Mallow (*Malva moschata alba*).—This is one of the prettiest plants in flower at the present time. It is a pure white variety of one of our British plants, which is found growing abundantly in some localities by the roadsides in dry, gravelly soil. The white variety is more attractive in every respect, and forms a branching, pyramidal bush composed of numerous branching stems about 2 ft. high, clothed with dark green, deeply divided foliage, and it bears abundance of pure white flowers from 1 in. to 1½ in. in diameter. It is a hardy perennial, and will grow in almost any soil or situation, but a hot, dry place suits it best. The whole plant is slightly musk-scented, a circumstance from which it derives its specific name.—A. P.

THE SPECIES OF PHLOX.

By JAMES BRITTEN, F.L.S.

With eight original illustrations by Isaac Sprague, Grantville, Massachusetts.

The genus *Phlox* is one of the most popular and most extensive of those for which our gardens are indebted to the woods, plains, and mountains of North America; with the single exception of *P. sibirica*, which, as its name implies, is a native of North Asia, all the species are North American.

The genus belongs to the Order Polemoniaceæ, an Order which, though containing comparatively few species, is of no mean importance from a horticultural stand-point; it contains not only the familiar Jacob's Ladder (*Polemonium coerulæm*) of our cottage gardens, and that magnificent climber *Cobæa scandens*, but the pretty and popular annual *Gilias* and *Leptosiphons*, as well as the invaluable *Phloxes*, which we are about to consider somewhat in detail. This is the more readily done, seeing that Professor Asa Gray published in the "Proceedings of the American Academy" for 1870, a revision of the species of *Phlox*, in which the many varieties in cultivation are reduced to their proper rank, and an arrangement based on easily recognised characters is proposed. Some such revision was urgently needed, as many mere varieties had received specific names, and were ranked as truly distinct: thus Don in his "General System," published in 1838, enumerates thirty-eight, while Professor Asa Gray only admits twenty-seven, including several discovered since Don's time. This arrangement is followed in the following enumeration, in which, however, we purpose to give fuller descriptions than the brief technical Latin characters by which each species is defined in Prof. Gray's revision, as my aim is to benefit the practical rather than the scientific botanist. I have added to the list of published figures quoted by Prof. Gray, and have in almost every case verified his references; while the descriptions are in a great measure based on the large series of specimens in the British Museum Herbarium.

The genus *Phlox* may be described as consisting for the most part of perennial plants, a few annual ones being known, of which *P. Drummondii* is the most familiar. They are herbs with opposite, sessile quite entire leaves and cymose showy flowers, which are usually white or of some shade of purplish-red, sometimes pale blue, never yellow, the cymes being composed of open clusters, which either terminate the stem or are crowded together in the upper axils. The calyx is narrow; the corolla is flat (salver-shaped) with a long tube, in which the filaments are unequally inserted; the slender style, as is usual in the Order, is three-cleft. The flowers are succeeded by ovoid few-seeded capsules, which when ripe open with some force and project the seed to some distance; cultivators will therefore do well to gather them just before they are quite ripe, placing them in a small packet where they can discharge the seeds without danger of losing them. Most of the species are readily propagated from seeds, which are freely produced, and germinate readily in heat, being sown shortly after they are ripe; the herbaceous species are, however, more frequently increased by cuttings or division. Full directions for the cultivation of the dwarf rock-garden species of the *P. subulata* type, will be found in *THE GARDEN*, Vol. XI., p. 503. It is scarcely necessary to speak in favour of the cultivation of *Phloxes*; the taller species have held their own family well in spite of the disregard into which herbaceous plants were at one time falling, and the smaller kinds need only to be known to be appreciated. Some of these are at present quite unknown to cultivation, and of those of which we give engravings, some have not, so far as we are aware, been previously figured. Prof. Gray observes that natural hybrids seem to be somewhat freely produced among the species of *Phlox*; and that "many species have been so long cultivated and hybridized that their specific names have given place in many instances to the names by which they are distinguished by horticulturists." It does not, indeed, appear that many artificial hybrids have been raised, although there is undoubtedly a good opening here for work of this kind, especially among dwarf-growing species.

It is much to be hoped that something will soon be done with regard to introducing some of the *Phloxes* here described. With scarcely an exception, they are all most desirable plants, so much so, that it is difficult to specialise any one in parti-

cular. Yet with the exception of the two first species, and *P. Drummondii*, they are hardly known or represented even in large gardens, although it is certain that they would amply repay cultivation.

Section I.

Broad-leaved Perennial *Phloxes*, native of Eastern North America.

SUB-SECTION 1.—THYRSIFLORE.—Tall plants, with strictly upright stems, many-flowered pyramidal or oblong panicles, with very short flower-stalks; lobes of the corolla quite entire. To the two species forming this group are to be referred all the manifold tall, shrubby, perennial *Phloxes* which are so ornamental in the foregrounds of shrubberies or at the back of narrow garden borders. They were formerly known in cultivation by the name of *Lychnidea*, and are sometimes mentioned under this title in the general literature of the end of the last, or beginning of the present, century. Sims, writing in 1792, says:—"They were first introduced under the name of *Lychnidea*, which, though a Latin term, is now familiarised to the English ear." (See *Bot. Mag.*, t. 163). We have so recently entered upon the cultivation of these herbaceous *Phloxes* (see p. 184) that it is unnecessary to do so on the present occasion; a list of the finest named varieties will be found at the page mentioned, to which we refer our readers for cultural details.

1. Panicked *Phlox* (*P. paniculata*, L.).—This is a tall plant, with smooth, stout stems from 2 ft. to 4 ft. high and large, pointed, narrowly egg-shaped leaves, tapering (or the upper somewhat heart-shaped) at the base. It has a large pyramidal panicle of very fragrant pinkish-purple or white flowers, of which the calyx-teeth

Panicked *Phlox* (*P. paniculata*).

are elongated into bristle-like points. It is sometimes called *P. americana* in old-fashioned gardens. In the variety *acuminata* (which was at one time ranked as a species, and is figured as such in *Bot. Mag.*, t. 1880) the leaves (which are broader, with narrower points) are downy beneath; the stem is also downy, or sometimes roughly hairy, and occasionally spotted below. The rough form is figured in Sweet's "Flower Garden" (2nd series, t. 114) as *P. corymbosa*; *P. scabra* (another rough plant) and *P. cordata* of the same work (t. 248 and 2nd series, t. 13) are also referred to this species by Dr. Gray; the latter, however, is depicted with a spotted stem, and may be a hybrid between *P. paniculata* and *P. maculata*. *P. paniculata* was cultivated in England by Sherard in 1732, and is engraved in Dillenius' "Hortus Elthamensis," t. 166. The variety *acuminata* was introduced to cultivation by Lyons in 1812, under the name of *P. decaussata*, and from this the late or autumnal varieties have descended. Another form, called *P. undulata* by Aiton, was grown by Philip Miller in 1759. In its native country, *P. paniculata* is widely distributed in rich, moist meadows and woods. *P. decaussata* is the name by which the numerous varieties of hybrid *Phloxes* are designated in catalogues. These hybrids are mostly produced between the different forms of *P. paniculata*; but it is probable that the next species (*P. maculata*) enters into some of them. It is not our intention to enter into any detailed account of these numerous hybrid forms, which differ from each other in many important features regarded from a cultivator's stand-point. Some are early, flowering in June; while others do not begin blossoming until August or September; some are scentless, others fragrant; some smooth, others hairy; the flowers are self-coloured, variegated, striped, eyed, or shaded; the plants differ in habit and in the size and form of the panicles, while there are also varieties with variegated leaves.

2. Spotted *Phlox* (*P. maculata*, L.).—To this species, as to the last, many of the plants in cultivation under different names have been reduced by Dr. Gray. It is a smooth or rarely roughish plant,

with rather slender purple-spotted stems, from 1 ft. to 2 ft. high. The lower leaves are narrow, the upper somewhat broader below, rounded at the base, and tapering to a narrow point. The panicle is usually narrow and oblong, although in one form (*P. pyramidalis*) the lower branches are elongated, so as to give the panicle the pyramidal appearance which is characteristic of *P. paniculata*. The calyx-teeth differ from those of the species last described in being narrowly triangular, short, and scarcely pointed; the flowers in the normal state are purple. It was cultivated in England by Philip Miller in 1759, and grows throughout the United States (where it is known as Wild Sweet William) in rich woods and river banks. The blossoms are often sweet-scented, a circumstance which has suggested specific names for two of the varieties. One of these, *P. suaveolens* of Aiton, which was introduced by Peter Collinson at Mill Hill about 1766, has white flowers and frequently spotless stems. This is the *P. longiflora* of Sweet's "Flower Garden," 2nd series, t. 31. The other fragrant form is described by Sweet (t. 224) as *P. odorata*; this has red-lilac flowers. The *P. pyramidalis* already alluded to is a very floribund, cultivated state of *P. maoulata*, which is often met with in gardens, having a pyramidal panicle of fragrant red-purple flowers and the characteristic spotted stem of the species; it was known in gardens about 1800, but does not seem to have been met with in a wild state. It is beautifully figured in Smith's "Exotic Flora," t. 87, and in Sweet's "Flower Garden," t. 233. Loddiges also has a plant called *pyramidalis* ("Cabinet," t. 342), but his figure does not justify the name. Another variety is figured by Sweet (2nd series, t. 46) under the name of *P. penduliflora*, characterised by its panicles drooping before the expansion of the flowers; and he also has a handsome hybrid which he calls *P. reflexa* (t. 232).

SUB-SECTION 2.—CORYMBOSE.—Stems ascending or upright, often spreading at the base; flowers in terminal corymbose cymes; corolla-lobes broad, entire, or obcordate.

A.—Plants smooth and glabrous throughout (the stem or corymb rarely roughish); calyx-teeth short, triangular; corolla-lobes rounded, entire.

3. Ovate-leaved Phlox (*P. ovata*, L.).—The stems of this species are ascending, creeping or decumbent at the base, and usually less than 1 ft. high; the leaves are bright green, oblong-lanceolate or ovate, the upper sometimes heart-shaped at the base, the lower narrowed into the leaf-stalk, acute, or pointed; the flowers are crowded on short peduncles, pinkish-purple, about 1 in. across; the calyx-teeth are short, ovate, and acute. Curtis, in his description in Bot. Mag., t. 523 (where the plant is figured), says:—"The leaves of the stalk vary very much in breadth, but the radical leaves, especially those of the young shoots which are pushed out from the root after the plant has done flowering, always preserve their character. The flowers nod on their first coming out." This Phlox is very generally known as *P. Carolina*, and is so called in all our older books; Dr. Gray, however, says that *P. ovata* is the earlier name, and is the more to be preferred, as the original of *P. Carolina* is one of those forms which seem to pass gradually into *P. glaberrima*. It was in cultivation in England before 1728, but was soon lost, and re-introduced about 1811. It is a native of woods from West Pennsylvania to Michigan, Virginia, North Carolina, &c. It is the plant figured by Sweet ("Flower Garden," t. 29) under the name of *P. triflora*. The species varies a good deal in habit, being sometimes much taller and more lax than is usually the case.

4. Smooth Phlox (*P. glaberrima*, L.).—This is a slender, erect plant, 1 ft. to 3 ft. high, with narrow, very smooth leaves (the margins being rather rough) 3 in. or 4 in. in length, tapering gradually to a point. The cymes are few-flowered and loosely corymbed; the flower-tube is long (nearly 1 in.), and the calyx-teeth sharp-pointed; the blossoms are pink, purplish, or whitish. This Phlox is figured in Sweet's "Flower Garden," 2nd series, t. 36, and to it are referred *P. carnea* (Bot. Mag., t. 2155, and Loddiges' "Cabinet," t. 711), a form with lilac or reddish flowers; *P. suffruticosa* (Bot. Reg., t. 68), with dark red-purple flowers and spotted stems; and *P. Carolina*, of Bot. Mag., t. 1344, which has a rough, puberulous stem; other synonyms are given by Dr. Gray. This species was cultivated by Philip Miller in 1731; its strikingly smooth appearance justifies its specific name. According to Mr. John Dominy, the early-blooming race of the tall-growing or herbaceous Phlox has descended from the form known as *P. suffruticosa*.

B.—Plants with upright or spreading flowering stems, which, as well as the oblong or lanceolate leaves, are more or less clammy-pubescent; calyx (which is also clammy) deeply cleft, with very narrow, elongated, or bristle-like teeth.

5. Florida Phlox (*P. floridana*, Bth.).—A slender erect plant, with much the habit of *P. glaberrima*, from which it is readily distinguished by the simple, closely-pubescent stems, as well as "by the

much longer and narrower teeth of the glandular-pubescent calyx." It grows about 2 ft. high, having long, narrow-pointed leaves and crowded cymes of not very numerous pale purple flowers, which are about 1 in. across. Dr. Gray doubtfully refers to this species the *P. Carolina* of Sweet's "Flower Garden," t. 190. As its name denotes, this species is a native of Florida.

6. Pilose Phlox (*P. pilosa*, L.).—Stems slender, often branched, erect or nearly so, 1 ft. to 2 ft. high, varying from pilose to nearly smooth, which is also the case with the narrow spreading leaves which usually taper to a sharp point, the uppermost being rounded at the base: the conspicuous calyx-teeth are very slender, often produced into spreading bristle-like points, and are nearly as long as the tube of the corolla: flowers in loose corymbs, pink or rose-coloured. This species is said to have been introduced to English gardens by John Fraser, who brought it back from North America in one of his seven voyages to that region: dried specimens had previously arrived here from John Bartram, who sent them to Sir Joseph Banks in 1764. There are good figures in Bot. Mag., t. 1307, and Loddiges' "Cabinet," t. 1251; t. 1731 of the latter work is by mistake also referred by Dr. Gray to this species. It seems uncertain whether the description of *P. pilosa* in Martyn's edition of Miller refers to this or to the next species; but it would appear that one of them was cultivated by Philip Miller in 1759; if so, Fraser can only claim to have re-introduced it.

7. Showy Phlox (*P. amoena*, Sims).—This species has been much confused with the preceding, which it nearly approaches in some of its forms. It is a softly pubescent plant, with simple ascending stems from 6 in. to 15 in. high, and oblong, narrow, rather acute or obtuse leaves, the upper of which are situated immediately at the base of the corymb. The calyx-teeth are narrow and acute; the flowers are bright purple, sometimes white, about as large as those of *P. pilosa*. It has been described by American botanists as *P. Walteri* and *P. pilosa*. Like the last-named species, it was discovered by Mr. John Fraser, in 1786, and was introduced by him, after several unsuccessful attempts, in 1810: it is figured in Bot. Mag., t. 1308. A very pretty plant, *P. procumbens*, is figured in Sweet's "Flower Garden," 2nd series, t. 7; it is supposed to be a hybrid between *P. amoena* and *P. subulata*.

8. Divaricate Phlox (*P. divaricata*, L.).—This is an old inhabitant of our gardens, having been cultivated by Philip Miller in 1758. It

Divaricate Phlox (*P. divaricata*).

is a somewhat low-growing plant, having spreading or ascending stems which are decumbent at the base, and give off barren shoots; the flowering stems vary from $\frac{1}{2}$ ft. to $1\frac{1}{2}$ ft. in height, the leaves

of which are slightly ciliated at the base; the peduncles are slender and elongated, mostly though not always one-flowered; the flowers are oblong-ovate; the lobes of the lilac or pale blue corolla are usually notched at the end, but sometimes (in var. *Laphami*) entire; the slender calyx-teeth are much longer than the corolla-tube; the flowers form a loose-spreading, panicle cyme. This *Phlox* is figured by Curtis in *Bot. Mag.* t. 163, and in Loddiges' "Cabinet," t. 1418; it is the *P. canadensis* of Sweet's "Flower Garden," t. 221, which is a strong-growing form of more upright habit.

9. Creeping Phlox (*P. reptans*, Michx.).—This species is one of very distinct habit, having long creeping runners rooting at the joints given off from the base of the stem. The radical leaves and those on the runners are roundish-ovate, rather smooth and thick;

Vernal Phlox (*P. verna*).

those on the stems are few, narrower, longer and rather blunt. The flowering stems are short, from 4 in. to 10 in. high, terminated by a rather close, few-flowered cyme of showy violet-purple blossoms, the lobes of which are entire; the narrow calyx-teeth are shorter than or about as long as the tube. This species was another of those discovered in Georgia by John Fraser in 1786; living plants were brought by him to Europe in 1801. It is the *P. stolonifera* of Sims (*Bot. Mag.* t. 563); a form with larger and richer-coloured (reddish-violet) flowers and broader and darker leaves is figured in Sweet's "Flower Garden," 2nd series, t. 293, and in Loddiges' "Cabinet," t. 1596 as *P. crassifolia*. It is a desirable plant for rockwork. A very handsome form of robust habit, having rose-coloured flowers with a darker centre, is that named *P. verna* in many recent catalogues.

SUBSECTION 3. SPARSIFLORE.—Low-growing, diffuse plants, with linear leaves and pale violet flowers with wedge-shaped lobes, each lobe deeply divided into two narrow segments.

10. Bifid Phlox (*P. bifida*, Beck.).—This species has slender, ascending-branched stems, 6 in. high; linear leaves which are at first pubescent, becoming nearly glabrous; and few pale purple flowers on slender peduncles, the lobes of which are cleft to or even beyond the middle. It is a native of the prairies of Illinois and Missouri.

11. Stitchwort Phlox (*P. Stellaria*, Gray).—This is a quite smooth, tufted plant, with rather rigid narrowly linear leaves, the upper

Stitchwort Phlox (*P. Stellaria*).

are pale blue, sometimes nearly white, the lobes being deeply cleft. This elegant little species, which has not previously been figured,

has at present only once been found, and that as long ago as 1829; it was discovered by the late Dr. Short in the fissures of the most precipitous rocks of the cliffs of Kentucky River, probably above Lexington. The specific name has reference to the resemblance which the plant presents to a *Stitchwort* both in leaves and flowers.

Section II.

Dwarf, perennial, shrubby, evergreen *Phloxes*, with tufted, creeping stems, subulate (awl-shaped), fascicled leaves, and inversely heart-shaped corolla-lobes. The plants falling into this section are regarded by Prof. Gray as forms of one species.

12. Awl-leaved Phlox or Moss Pink (*P. subulata*, L.).—This is a very beautiful little plant as will be seen from the figure of one of its varieties in *THE GARDEN*, Vol. XI., pl. 78. It is a native of dry rocky hills and sandy banks, from New York to Michigan and Florida, forming broad matted tufts, which when in flower have a very handsome appearance. The leaves are very numerous, awl-shaped, lanceolate, or narrowly linear; the calyx-teeth are awl-shaped and erect, with spiny point; the corollas, which are $\frac{1}{2}$ in. to 1 in. across, vary in colour from pinkish-purple or rose with a dark centre

Awl-leaved Phlox (*P. subulata*).

to white, the wedge-shaped lobes being notched or more rarely entire. The flowering stems are erect, the blossoms being disposed in few flowered cymes. This species was introduced to English cultivation in 1786, and is figured in *Bot. Mag.* t. 411. *P. setacea* is given at t. 415 of the same work, where it is stated to have been introduced by Mr. John Fraser in 1788. Although often figured and described as a distinct species, it has no characters by which it can be separated from *P. subulata*: the leaves are rather longer, and less crowded.

Bristly Phlox (*P. setacea*).

P. nivalis is a very pretty form with snow-white flowers, which differs from *P. subulata* in having a short style, and ovules commonly, but not always, in pairs (rarely three) in each cell, whereas in *P. subulata* the style is usually long and the ovules are solitary: this is figured in Loddiges' "Cabinet," t. 780 and in Sweet's "Flower Garden," t. 185. *P. Hentzii* has a white corolla with entire or nearly entire lobes, and a short style. *P. aristata* of Loddiges' "Cabinet," t. 1731, seems to be a weak form of this, with fewer and much less rigid leaves and white flowers with notched lobes. *P. frondosa* is a vigorous garden form, and one of the best known at the present time. *P. Nelsonii*, a pretty little white-flowered plant, is a garden hybrid between two of the above *P. subulata* named forms, which was raised about twenty year since by the then rector of Winterton, Norfolk, after whom it is named; it is the result of a cross between *P. nivalis* and *P. frondosa*, according to Mr. Burbidge, or between *P. nivalis* and true *P. subulata*, according to Mr. Niven in *THE GARDEN*, Vol. XI., p. 502—where will be found full cultural details with reference to this group of *Phloxes*. Even in its wild state *P. subulata* is a very variable plant: a large specimen in the British Museum Herbarium, sent from North America by Bartram in 1754, has quite a lax, diffuse habit.

Section III.

Western species, shrubby or partly so, rarely herbaceous, with one to three ovules in each cell; branches one or few-flowered; leaves mostly small or narrow, with more or less thickened margins. The species of this section nearly approach each other, and are hence difficult of discrimination.

SUB-SECTION I.—**EVERGREEN PERENNIAL PHLOXES**, forming cushion-like tufts; leaves short, sometimes very small, densely clothing the stems up to the solitary sessile or nearly sessile flowers, persistent (not falling away) when old: ovules solitary. The species in this sub-section are arranged in an order commencing with the smallest and most imbricated-leaved, going on to those of laxer habit with spreading leaves.

A.—Dwarf Moss-like plants; leaves very short, imbricate, scale-like: covered especially at the margins with cobweb-like hairs, corolla lobes entire.

13. Richardson's Phlox (*P. Richardsonii*, Hook.).—This beautiful species is a native of the Arctic sea-shore of North America, where it was discovered by Dr. Richardson, who accompanied Sir John Franklin in two of his earlier expeditions, and in honour of whom it is named. It forms lax, cushion-like tufts, with short, narrow, leaves about 3 lines long, slightly woolly at the margins, and bearing a profusion of brilliant lilac flowers, the tubes of which exceed the calyxes by about half their length. It is figured in Hooker's "Flora Boreali-Americani," vol. ii., t. 160.

14. Selaginella-like Phlox (*P. bryoides*, Nutt.).—This small species forms dense, copiously and softly woolly cushions, and resembles *Selaginella impestri* in habit; the cushions are supported (in old plants) upon thick, tough, woody stems. The leaves are scale-like, compactly imbricated in four ranks, about $\frac{1}{2}$ line long; the tube of the corolla slightly exceeds the calyx, and the wedge-shaped lobes are about $\frac{1}{2}$ line in length. This was discovered by Nuttall on the dividing ridge of the Rocky Mountains (about lat. 42°), and so far as we are aware has not since been met with.

15. Mossy Phlox (*P. muscoides*, Nutt.).—This little plant closely resembles the preceding; it is densely tufted, with copiously ciliated, hoary-pointed, very short leaves, compactly imbricated as in the last species; a large, descending root, and large, white sessile flowers with a yellow spot in the centre, the lobes being wedge-shaped and entire. "The whole plant is depressed to the appearance of a hoary *Bryum*, no part of it hardly rising to the height of $\frac{1}{2}$ in. from the ground." It is a native of the Rocky Mountains, at the sources of the Missouri.

B.—Broadly-tufted plants with more rigid subulate hairs, 3 or 4 lines long, less closely adpressed to the stem than in the three preceding; flowers white.

16. Hood's Phlox (*P. Hoodii*, Richards.).—Dr. Richardson, who named this Phlox in memory of his lamented companion, Lient. Hood, says:—"This beautiful species is a striking ornament to the plains in the neighbourhood of Carlton House, forming large patches, which are conspicuous from a distance." It is an almost smooth plant, with many densely-tufted stems, imbricate silvery, shining, rigid, awl-like leaves, which are woolly at the margins, and terminal, sessile, solitary flowers. It occurs throughout the Saskatchewan region, from lat. 54° to the Rocky Mountains, about lat. 44°.

17. Hoary Phlox (*P. canescens*, Torr. & Gray).—This species

Hoary Phlox (*P. canescens*).

forms broad and mostly compact mats, a few inches high, grey or whitened by the soft cobweb-like or woolly down with which the small, slender, needle-like, rigid, ascending leaves are thickly covered. The tube of the corolla exceeds the calyx; the pretty, abundant

white corollas have entire or slightly notched lobes. As will be seen from our engraving, it is an attractive plant, worthy of being introduced to cultivation. It is a native of the Rocky Mountains of Colorado, extending throughout Utah to New Mexico and the Sierra Nevada.

C.—Leaves green, needle-like or subulate, rigid or loose, destitute of cobweb-like hairs.

18. Tufted Phlox (*P. caespitosa*, Nutt.).—This species, as will be seen from our figure, much resembles the last in habit. It forms dense cushion-like tufts 3 in. or 4 in. high, having short, rigid, unusually imbricated leaves, which completely cover the short stems, and are glabrous except at the edges, which are fringed with short bristly

Tufted Phlox (*P. caespitosa*).

hairs. The solitary flowers which terminate the branches are pale violet or white. It is a variable plant: the variety *rigida* has been described as a species; it has needle-like, recurved, spreading leaves, which are thinly sprinkled with glandular hairs. Var. *condensata* is a very compact form with smaller flowers, which has been confounded with *P. Hoodii*. It is a Rocky Mountain plant, extending from Colorado to Montana, Oregon, and Sierra Nevada, rising to the height of 11,000 ft.

19. Douglas's Phlox (*P. Douglasii*, Hook.).—A beautiful plant, forming broad but rather open tufts, glabrous or slightly pubescent; stems ascending, much branched; leaves needle-like, usually spreading $\frac{1}{2}$ in. in length, with tufts of shorter ones crowded in the axils; corolla-tube longer than the calyx; corollas purple or white, with entire obovate lobes about 3 lines long. This is indeed, as Sir William Hooker describes it in the "Flora Boreali-Americani" where the plant is figured t. 158—"a most beautiful species, bearing copious and almost sessile blossoms, and intermediate in habit, as it were connecting the *P. speciosa*, subulate, &c., with the little *P. Hoodii*." It is a variable plant, growing on high plains and mountains, at from 5000 ft. to 10,000 ft., and extending from Colorado and Utah west to the Sierra Nevada and the Cascades. The var. *diffusa* (*P. diffusa*, Benth.) is a form of moister or more shaded situations, with procumbent stems and laxer, less rigid leaves: it occurs chiefly on the Pacific slopes from the Yosemite to lat. 49°. The var. *longifolia* is a form with more slender and rigid leaves, from half to two-thirds of an inch in length: this occurs chiefly east of the Rocky Mountains, and in Utah *P. Douglasii* was introduced into cultivation in England from the Rocky Mountains about thirty years since.

SUB-SECTION 2.—Beautiful plants woody or sometimes herbaceous at the base, with numerous single or loosely tufted stems; leaves usually long and narrow, rarely subovate; flowers solitary or subcymose on long peduncles.

A.—Flowers with long styles—a character, Dr. Gray observes which is "most convenient and useful in the arrangement of these otherwise almost inextricable Western Phloxes."

Frigidæ: leaves and stems loosely tufted somewhat flaccid.

20. Siberian Phlox (*P. sibirica*, L.).—A very beautiful plant, recalling to mind, especially in dried specimens, a dwarf *Dianthus*. The stems are from 2 in. to 4 in. high, pilose-pubescent; leaves narrowly linear, often villous at the margins; flower-stalks without leaves, growing singly from the axils of the upper leaves; flowers purplish, or white with ten purple stripes, often nearly 1 in. across; corolla-tube as long as or a little longer than the calyx; lobes entire or often notched. This is the only species of Phlox which is not American: it is a native of Eastern Siberia and Kotzebue's Sound.

Temperatæ: Stems shrubby at the base and (as well as the leaves) rather rigid, erect, or ascending; flowers white or rose-coloured, the tube exceeding the narrow, subulate calyx-lobes.

21. Narrow-leaved Phlox (*P. linearifolia*, A. Gray).—This species and the next are very similar in habit and general appearance, as is shown by the figures given. *P. linearifolia* is a very smooth plant, occasionally somewhat hairy-pubescent above, from 1 span to 1 ft. high, with corymbs of numerous handsome flowers; leaves very narrowly linear, 1 in. or 2 in. long; calyx, angled, deeply divided, the segments broadly membranous at the base, and produced above into needle-like points, which nearly equal the tube of the corolla in length; corolla-lobes obovate, wedge-shaped, entire; ovules two in each cell. This is the *P. speciosa* of Lindley in the "Botanical Register," t. 1351, but not the plant first described by Pursh under that name. It is a native of the interior plains of Columbia River and its tributaries.

22. Long-leaved Phlox (*P. longifolia*, Nutt.).—This is a somewhat viscid-pubescent or smooth plant, with tufted stems about a span high from a woody base; the leaves are narrowly linear, or sometimes lanceolate, from 1 in. to 2½ in. in length; calyx much as in the last species, but smaller and considerably shorter than the corolla-tube; flowers, white; corolla lobes obovate or oblong-wedge-shape, entire; ovules usually solitary in each cell. A very distinct,

Narrow-leaved Phlox
(*P. linearifolia*).

Long-leaved Phlox
(*P. longifolia*).

and, for gardening purposes, a much more desirable form is the var. *Stansburyi*, which is a more rigid, more pubescent, denser, and dwarfer form, with broader (lanceolate or ovate-lanceolate) leaves about ½ in. long, and with proportionately larger and more conspicuous flowers, the corolla-tube of which is often twice as long as the calyx, and the lobes sometimes notched; there are often two ovules in each cell. From dried specimens this plant appears very distinct, but it is stated that it passes into the genuine form. *P. longifolia* is a native of the eastern part of the Sierra Nevada, extending north and east through the interior regions to and beyond the Rocky Mountains; the var. *Stansburyi* occurs chiefly in the southern districts, extending into New Mexico and Arizona. *P. humilis* of Douglas is a small form of *P. longifolia* with shorter peduncles.

23. Oregon Phlox (*P. adsurgens*, Torr.).—This is a small-flowered species, known only from Oregon, and not likely to be of horticultural importance. It is a smooth plant, with spreading, ascending, slender stems, under 1 ft. high; the leaves are ovate or ovate-lanceolate, acute, ½ in. long, often shorter than the internodes; the peduncles subcymose, and, as well as the calyxes, glandular-pubescent; corolla-tube much exceeding the calyx, nearly 1 in. long, with obovate entire lobes, 5 lines in length; style exserted.

B.—Flowers with short styles—*i.e.*, style not longer than the ovary or stigmas.

24. Handsome Phlox (*P. speciosa*, Pursh).—This well-named species is from 1 ft. to 3 ft. in height, the flowering stems (which are viscid-pubescent above or nearly glabrous) diffusely ascending from a branching woody base; the leaves are lanceolate or linear, 1 in. to 2 in. long, the upper broader at the base; the showy white or rose-coloured blossoms are in many-flowered corymbs, the lobes being deeply

Handsome Phlox (*P. speciosa*).

or sometimes but slightly notched, a third to half-an-inch long, the tube but slightly exceeding the calyx. This beautiful Phlox is a native of the Sierra Nevada, extending northward to the borders of British Columbia. *P. Sabini* of Douglas is a form with entire or nearly entire corolla-lobes: the var. *Woodhousei* is a dwarf form, with linear lobes and smaller flowers, and is found in Arizona. Our figure represents a low diffuse-growing variety.

25. Dwarf Phlox (*P. nana*, Nutt.).—This is a glandular, pubescent or hairy, sometimes almost smooth plant, with spreading, branched stems from a woody base, from a span to 1 ft. in height: the leaves are linear: flowers few, but showy, the rose-coloured or white corollas being usually 1 in. or 1½ in. across: the tube slightly exceeds the calyx

Dwarf Phlox (*P. nana*).

in length, and the large broad lobes are entire or nearly so. There are usually three ovules in each cell. There is a smooth variety *glabella*, in which the branches are more simple, and erect, with narrower leaves. This species is a native of New Mexico and the adjoining borders of Texas and Colorado.

Section IV.

Annual species, natives of Texas, more or less covered with sticky, many-jointed, mostly glandular hairs: leaves rather broad, the upper alternate; calyx-lobes (in fruiting specimens divided almost to the base) slightly recurved or spreading; style shorter than the stigmas; seeds subulate-angulate.

26. Drummond's Phlox (*P. Drummondii*).—This popular garden annual, in some of its many forms, is now as well known as the earlier-introduced shrubby species. Seeds of it were sent over to this country in 1835 from Texas by its discoverer, Mr. Thomas Drummond, whose name it bears, and these soon vegetated, since which time the species has been deservedly popular. It is hardly necessary to describe in detail so well-known a plant; but in addition to the characters of the section, the leaves are often lanceolate or oblong, the upper subcordate or half amplexicaul at the base; the flowers are corymbose, upon very short pedicels; the calyx segments linear-subulate and pointed; the corolla-tube much curved and hairy, three times longer than the calyx, the lobes being wedge-shaped and entire; ovules solitary in each cell. The flowers in the wild plant are of a beautiful purple with a darker eye; but the cultivated forms present almost every variety of colour, from white to scarlet, passing through numberless shades of lilac, pink, and rose, some being beautifully striped and variegated. This species is figured in *Bot. Mag.*, t. 3441; "*Botanical Register*," t. 1949: and *Sweet's "Flower Garden*," 2nd series, t. 316.

Besides the mere florist's varieties, two well-marked forms of this species are described by Dr. Gray. *Var. villosissima* is a very distinct-looking plant, which ought to be brought into cultivation. The stems, leaves, and calyx-lobes are covered with long viscid hairs; the leaves are narrowly lanceolate; and the flowers are fewer in number, but larger, and very handsome. *Var. tenuis*, on the other hand, is almost useless for garden purposes; it is about a span high, with less hairy and mostly linear leaves, and loose-flowered cymes of small flowers; it is a native of Eastern Texas.

27. Roemer's Phlox (*P. Roemeriana*, Scheele).—This elegant Phlox does not appear to have been figured. It is a low-growing species, branched from the base, almost smooth, except for the hairy margins of the leaves and calyx-tube; the leaves are oblong-lanceolate, the upper spatulate, those of the stem mostly alternate; calyx-lobes linear, spreading; flowers few, but very large and rose-coloured; the corolla-tube about equalling the somewhat spreading calyx-lobes; ovules many (four or five) in each cell. This desirable species is a native of Central Texas.

Phlox Hookeri, a plant with bright yellow flowers, figured in Hooker's "*Flora Boreali-Americani*," ii., t. 159, is now considered a species of *Gilia*.

Index to the Species.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Mountain Evening Primrose (*Oenothera montana*).—Few plants just now are more effective than this, its handsome yellow flowers being produced on established plants in great quantities. Though the blossoms individually do not last long they are produced so freely in succession that they may make a good display for many weeks either in the rock garden or shrubbery. In character this *Oenothera* somewhat resembles *O. macrocarpa*, and is well worth culture where a showy autumn-flowering plant is required.—C. S.

Flower Garden on St. Paul's.—It is only twelve years since the Dean and Chapter of St. Paul's actually spent £40 on the improvement of its churchyard. And yet people say it is neglected! Few know that there exists a flower-garden on the roof of St. Paul's, the products of which gained a verger prize at the last City of London Flower Show. He does not, however, go so far as Quasimodo's successor at Notre Dame, but draws the line at Cabbages.

THE FRUIT GARDEN.

THE PEAR AND FILBERT IN KENT.

(Continued from p. 276).

Pears

are not systematically grown on a large scale in Kent, and are not attended to by any means as they should be. They are grown more in East Kent than in any other part of the county. Many of the old trees are of indifferent kinds, whose fruit cannot compete with that grown abroad, and is frequently a drug in the market. The chief sorts grown are the Chalk (a second-rate Pear), Doyenné d'Été, Beurré de Capiaumont, Chaumontel, Catillac (most excellent for cooking), Williams's Bon Chrétien, Marie Louise, Hazel, Beurré Rose, Bergamot, Duchesse d'Angoulême, the Seckle (with a fine aromatic flavour), and two or three common early Pears whose names are not known. There are signs that fruit growers are bestowing more care on the cultivation of Pears, and are planting good sorts that will ripen in due rotation. Good Pears generally command high prices, as those who have to buy them for dessert know well, for it is difficult to get any good-looking Pears under 6d. to 8d. each, and such Pears cost but little more to grow than the small, hard, indifferent sorts that take up space in many Kentish orchards. Pear trees are planted with Apple or Cherry trees, and occasionally by themselves with bushes under them. They require little pruning after they are well established, and bear spud cultivation as well as Apple trees, though they do better on Grass than on land that is cultivated.

Filberts.

The Filbert (*Corylus Avellana*)—a corruption of "full beard," as it was originally styled, to distinguish it from smaller Nuts—so highly appreciated at dessert, is cultivated extensively in the neighbourhood of Maidstone. It is not grown to any extent beyond a circuit of seven or eight miles round that town, though there are a few plantations at Ightham, about thirteen miles north-west of it, and in the West Kent fruit-growing district. It does well upon the best soils of the rag-stone, but thrives exceedingly upon the Atherfield clay, locally called the "coomb," which has been described as follows by a practical farmer:—"There is a very narrow belt of land running along the escarpment of the rag-stone, which, though of a very heavy and adhesive texture, is astonishingly productive in Hops, fruit, and grain." The situation best suited is a southern slope, sheltered from rough winds, which are apt to snap off the delicate shoots in the early spring and bruise the blossoms. Filbert trees are always grown on cultivated land, planted under standard Apple, Pear, and Plum trees. Fruit bushes are generally planted as well. Filbert trees are set about 13 ft. apart, giving 257 trees to the acre: they are invariably propagated by suckers obtained from old trees, and put in nurseries until they are two or three years old, being carefully pruned and trained to the required form. The first operation in an established Filbert plat is to open a small trench round each tree, to get the suckers or "spawn" from off the roots and lower part of the stems. Rags, shoddy, fur-waste, sprats, "sheep-trotters," Hop-bines, are used for manure. Digging the land is done with the spud peculiar to Kent, before Christmas if possible; before the trees are pruned, that the bloom, which appears very early, may not be rubbed off. Pruning or cutting Filbert trees is a most elaborate process. Each branch is examined by the tree cutter, who leaves the finest young wood that he sees, or ought to see, at a glance if he knows his business, to be bloom-bearing, and cuts away all wood of coarser, older growth, comparatively unfruitful. The "bloom," or cluster of pistilline flowers, is remarkably pretty, like a small scarlet star upon the extremities of the shoots. It is fertilized by the "catkins," as the staminate flowers are called, growing on the same branches, some of which are left by the judicious cutter. After the pruning the trees look mere skeletons. A stranger who had seen Filbert trees thus naked and forlorn in the winter, would be surprised to see them in September with a wonderful wealth of leaves, branches, and Nuts upon them. A typical tree has a stem of about 2 ft. in height, from which the branches are trained to spread out laterally, and to form a centre of a saucer-like shape, with a diameter of 7 ft. or 8 ft.,

and a height of about 6 ft. After pruning, nothing is done until July, when most growers have the long suckers taken from the middle of the trees, and the leading shoots are broken off to relieve them from the burden of supporting unproductive wood. Mr. Webb states that he saw some Filbert trees near Maidstone which had grown 40 lbs. of Nuts on each tree. A crop of a ton, or even more, is occasionally grown; but the average yield may be set at about 8 cwts. per acre. Filberts are frequently sold on the trees, as the growers have Hops to attend to, and do not want the trouble of picking and selling them at the busiest time of the year. They are for the most part sent to Covent Garden, in sieves which hold about 28 lb. of green, and 40 lb. of ripe or harvested Nuts. It is customary to send a portion of the crops to London when the bunches are quite green, and the kernel not by any means fully developed. There is a certain demand for these, as they look well on the table, though at this time they have but a mere *soupeon* of the true Filbert flavour. When Filberts sell well at this stage, some growers send their whole crop up, as the weight of green Nuts is nearly double that they would have if duly harvested. Prices of Filberts range from 5d. to 1s. per lb., according to the supply. They are not much influenced by the competition of foreign Nuts, none of which have the flavour or the appearance of the genuine Kentish Filberts, although the quantity of Nuts of all kinds imported is very large. The value of the imports of this duty-free fruit, which chiefly comes from Belgium, France, and Brazil, amounted to £584,325 in 1875, as against £408,291 in 1871. The Kent Cobnut, or "Lambert's Filbert," is superseding the old-fashioned Filbert in a degree, and is generally preferred for new plantations. It is a much larger Nut than the Filbert, with a thicker shell, and is a more hardy and more abundant bearer. As these trees do not thrive so well under standards as Filberts, they are now generally planted by themselves, with bushes under them, or with Plums, Damsons, or half-standard Apple trees. They are treated in the same way, requiring, perhaps, to be cut a little harder than Filbert trees. A casual observer would not notice the difference between Cob and Filbert trees, but their leaves are different; the whole growth of the former is more vigorous, and its "bloom" or pistilline cluster is darker than the Filbert bloom. As a rule Cobnuts make rather higher prices than Filberts.

Knight's Monarch Pear.—Although early kinds of Pears are this season long in becoming fit for table, this kind is dropping from the trees and showing signs of premature ripening. It is certainly neither heat nor drought that is causing the fruit to fall, as the season has been unusually wet and the temperature low.—J. GROOM.

PLATE XCIII.

THE BEST FIGS

(WITH A COLOURED FIGURE OF NEGRO LARGO).

Drawn by H. HYDE.

No first-rate fruit has been so much improved of recent years as the Fig. So little was it grown in this country that a few old kinds formed our collections, while far finer varieties were in cultivation in Spain and Italy. Some of these have recently been obtained for our gardens. Of the best yet introduced we now give a selection, with a figure of a very fine variety.

Negro Largo.—Fruit of the largest size, long pyriform; skin jet black, marked with longitudinal ribs extending the whole length of the fruit; flesh pale red, very tender and juicy, and the juice is highly flavoured, and when fully ripe the flesh and skin become quite melting. A very strong-growing, but free-fruited variety.

Bourjassotte grise.—Fruit medium size, roundish, somewhat oblate, skin chocolate, covered with a thin bloom; flesh, deep dark red, thick syrupy juice, very richly flavoured: very best Fig in cultivation.

Grosse verte or Ne-bian.—Fruit large or above medium size, roundish, obovate, marked with obscure longitudinal ribs, skin a bright pea green, becoming a little yellow at maturity, and not covered with any bloom. Flesh very dark red throughout, with a rich and sugary flavour: very excellent large Fig, requiring heat to ripen.

Lee's Perpetual or Brown Turkey.—Fruit large and pyriform, skin brownish-red covered with blue bloom; flesh, red and very luscious. One of the best for outdoor culture as a standard, being hardy: good for general use.

De la Madeleine.—Fruit below medium size, roundish, turbinate, and flattened like an Onion; skin yellow, dotted with long greenish white specks; flesh white under the skin, with a faint tinge of rose

towards the centre. A very early Fig and hardy: will bear well on open walls.

White Marseilles.—Fruit above medium size, quite round, with well-marked, longitudinal ridges running from the stalk to the apex; skin green, turning to pale green when ripe; flesh opaline, exceedingly rich and sugary: one of the most delicious Figs in cultivation. Forces well. Fruit ripens freely against a wall in the open air. This is the variety so much grown in Sussex.

White Ischia.—Fruit small and turbinate; skin greenish yellow, and so very thin that when ripe the flesh shines through and imparts a brownish tinge to the fruit. This is well adapted for pot culture, and forces well. It is also very productive.

Royal Vineyard.—Fruit medium-sized, long pyriform, and prominently marked with longitudinal lines; skin very thin, hairy, of a fine purple colour, and covered with thick bluish bloom; flesh bright reddish, very juicy and melting. An abundant bearer.

Profit and Ornament on Surfaces usually bare.

Outhouse covered with Plum trees in the Potagerie at Versailles. Photographed by Jules Lemercier in April of the present year, and engraved exactly after the photograph.

Col di Signora Bianca.—Fruit medium-sized, pyriform, and marked with very distinct, longitudinal ribs; skin thick green, changing to yellowish white, and covered with a fine grey bloom; flesh of the darkest blood-red: very thick, syrupy, and most delicious. Fine large Fig, but requiring heat.

Brunswick.—Fruit very large, long pyriform, oblique at the apex, which is very much depressed; skin greenish yellow in the shade, tinged with pale brown on the other side; flesh opaline, tinged with very pale flesh colour towards the centre. Fine large Fig for general culture. There is a wonderful difference between the appearance of the first and second crops of fruit of this Fig, the fruit of the former being very long, that of the latter short and turbinate.

AN OLD VINE STEM.

IN some of the more remarkable artistic treasures of Nineveh arranged in the British Museum, trellises of Vines may be seen pretty much as in many warm countries to-day, showing the great age of the Vine as a cultivated plant; but it is no less remarkable as regards the great variety of ways in which it is grown and trained—a variety of which those who see it only in our hothouse have little notion. This little cut shows an old Vine-stem after pruning in

Aulnis in the west of France. This ancient-looking stump is the opposite in character of the tree-supported Vines of the south of Italy. A series of sketches showing the various ways in which the Vine is trained would be very interesting.

Bleeding in Vines.—This is an overflow of sap, and is at times so severe that they “almost bleed to death.” The Vine is furnished with an enormous supply of sap, which begins to flow very freely and with great force shortly before growth commences, and continues until the Vine is about in full leaf. The cause of bleeding is late pruning. The pores, being naturally open for the flow of the sap, have not time to heal over and close up before the sap is in motion. The best preventive practice then is to prune as early as possible. Never prune whilst the buds are swelling. Various methods have been proposed to stop or arrest this bleeding, such as charring the cut ends of the shoots, or covering them with sealing-wax, cut Potatoes, painters’ knotting, or some of the various patent styptics. None of these, however, are quite effectual. It seems almost impossible to close these pores, or to arrest this extraordinary tide by artificial means. The painters’ knotting will check it to a certain extent, but some cases are so bad as to baffle all our feeble attempts, and these must be left for Nature herself to cure.—“Florist.”

Fruit in Italy.—We live on fruit. In every one of the little villages round about any large town in Italy are to be found in the autumn cartloads of Water Melons, Figs, Peaches, Nectarines, Tomatoes, Nuts, Egg fruit, and yellow Melons. The most beautiful are the Water Melons, with their deep green skins and rose-red frosted-looking flesh, where the big black seeds sit like ebony heads; and perhaps they are the most useful. “Si beve, si mangia, si lava la faccia,” say the Italians of these Water Melons, good for eating, drinking, and washing one’s face all at once; as the fruit is of enormous size and depth, and the proper way of eating it is to work your way steadily through a section, into which as you go on you bury your face from ear to ear. The small green Figs are now in their full perfection. These should have three characteristics: the tear of a penitent, the neck of a hanged man, the cloak of a beggar. When you get one with a drop of syrup on the point, a wry-necked kind of stalk, and a rugged, stained, and disordered-looking skin, you have got something absolutely unknown to us in England. It is like the finest kind of dried Fig, with the aroma and softness of the fresh fruit. The Peaches are of two kinds—one soft and luscious, like our best; the other hard and meaty, with the stone embedded in the flesh, and not able to be set free. But anyhow, one is thankful for fruit at this terrible time, when wine is a necessity, meat an abomination, and water alone not sufficiently refreshing.—“Queen.”

THE GARDEN-CRAFT OF SHAKESPEARE.

(Continued from p. 279).

II.—Gardens.

- (1) *King (reads).* It standeth north-north-east and by east from the west corner of thy curious-knotted garden.
Love’s Labour’s Lost, act i., sc. 1.
- (2) *Isabella.* He hath a garden circummured with brick,
Whose western side is with a Vineyard backed;
And to that Vineyard is a planched gate
That makes the opening with this bigger key:
The other doth command a little door
Which from the Vineyard to the garden leads.
Measure for Measure, act iv., sc. 1.
- (3) *Antonio.* The Prince and Count Claudio, walking in a thick-pleached alley in my orchard, were thus much overheard by a man of mine.
Much Ado About Nothing, act i., sc. 2.
- (4) *Iago.* Our bodies are our gardens, &c.
(See Hyssop). *Othello*, act i., sc. 3.
- (5) *1st Servant.*
Why should we, in the compass of a pale,
Keep law, and form, and due proportion,
Showing as in a model our fair state?
When our sea-walled garden, the whole land,
Is full of weeds; her fairest flowers choked up,
Her fruit trees all unpruned, her hedges ruined,
Her knots disordered, and her wholesome herbs
Swarming with caterpillars.

Richard II., act iii., sc. 4.

The flower-gardens of Shakespeare’s time were very different to the flower-gardens of our day; but we have so many good descriptions of them in books and pictures that we have no difficulty in realising them both in their general form and arrangement. I am now speaking only of the flower gardens; the kitchen gardens and orchards were very much like our own, except in the one important difference, that they had necessarily much less glass than our modern gardens can command. In the flower garden the grand leading principle was uniformity and formality carried out into very minute details. “The garden is best to be square,” was Lord Bacon’s rule and this form was determined on because the garden was considered strictly to be a purtenance and continuation of the house, designed so as strictly to harmonise with the architecture of the building. And Parkinson’s advice was to the same effect:—“The orbicular or round form is held in its own proper existence to be the most absolute form, containing within it all other forms whatsoever; but few, I think, will chuse such a proportion to be joynted to their habitation. The triangular or three-square form is such a form also as is seldom chosen by any that may make another choise. The four-square form is the most usually accepted with all, and doth best agree with any man’s dwelling.”

This was the shape of Chaucer’s ideal garden—

And when I had a while goon,
I saugh a gardyn right anon,
Full long and broad; and every delle
Enclosed was, and walled welle
With high walles embatailled.

I felle fast in a weymenting
By which art, or by what engyne
I might come into that gardyne;
But way I couthe fynd noon
Into that gardyne for to goon.

Tho’ gan I go a fulle grete pas,
Environyng evene in compas,
The closing of the square walle,
Tyl that I fonde a wiket smalle
So shett that I ne’r myght in gon,
And other entre was ther noon.

Romaunt of the Rose.

This square enclosure was bounded either by a high wall—“circummured with brick,” “with high walles embatailled”—or with a thick, high hedge—“encompassed on all the four sides with a stately, arched hedge.” These hedges were made chiefly of Holly or Hornbeam, and we can judge of their size by Evelyn’s description of his “impregnable hedge of about 400 ft. in length, 9 ft. high, and 5 ft. in diameter.” Many of

these hedges still remain in our old gardens. Within this enclosure the garden was accurately laid out in formal shapes, with paths either quite straight or in some strictly mathematical figures:—

And all without were walkes and alleys dight
With divers trees enrang'd in even ranks;
And here and there were pleasant arbors pight,
And shadie seates, and sundry flowering bankes,
To sit and rest the walkers' wearie shankes.

Faerie Queene, iv., 10, 25.

The main walks were not, as with us, bounded with the turf, but they were bounded with trees which were wrought into hedges, more or less open at the sides, and arched over at the top. These formed the "close alleys," "covert alleys," or "thick-pleached alleys," of which we read in Shakespeare and other authors of that time. Many kinds of trees and shrubs were used for this purpose; "every one taketh what liketh him best, as either Privet alone, or Sweet Bryer and White Thorn interlaced together, and Roses of one, two, or more sorts placed here and there amongst them. Some also take Lavender, Rosemary, Sage, Southernwood, Lavender Cotton, or some such other thing. Some again plant Cornel trees, and plash them or keep them low to form them into a hedge; and some again take a low prickly shrub that abideth always green, called in Latin *Pyracantha*" (Parkinson). It was on these hedges and their adjuncts that the chief labour of the garden was spent. They were cut and tortured into every imaginable shape, nothing came amiss to the fancy of the topiarist. When this topiary art first came into fashion in England I do not know, but it was probably more or less the fashion in all gardens of any pretence from very early times, but it reached its highest point in the sixteenth century, and it held its ground as the perfection of gardening till it was driven out of the field in the last century by the "picturesque style," though many specimens still remain in England, as at Levens and Hardwicke on a large scale, and in the gardens of many ancient English mansions and old farmhouses on a smaller scale. It was, in fact, doomed as soon as landscape gardeners aimed at the natural, for even when it was still at its height Addison described it thus:—"Our British gardeners, instead of humouring Nature, love to deviate from it as much as possible. Our trees rise in cones, globes, and pyramids; we see the mark of the scissors upon every plant and bush."

But this is a digression: I must return to the Elizabethan garden, which I have hitherto only described as a great square, surrounded by wide, covered, shady walks, and with other similar walks dividing the central square into four or more compartments. But all this was introductory to the great feature of the Elizabethan garden, the formation of the "curious-knotted garden." Each of the large compartments was divided into a complication of "knots," by which was meant beds arranged in quaint patterns, formed by rule and compass with mathematical precision, and so numerous that it was a necessary part of the system that the whole square should be fully occupied by them. Lawn there was none; the whole area was nothing but the beds and the paths that divided them. There was Grass in other parts of the pleasure grounds, and apparently well kept, for Lord Bacon has given his opinion that "nothing is more pleasant to the eye than green Grass kept finely shorn," but it was apparently to be found only in the orchard, the bowling green, or the "wilderness;" in the flower garden proper it had no place. The "knots" were generally raised above the surface of the paths, the earth being kept in its place by borders of lead, or tiles, or wood, or even bones; but sometimes the beds and paths were on the same level, and then there were the same divisions that we now use, as Thrift, Box, Ivy, flints, &c. The paths were made of gravel, sand, spar, &c., and sometimes with coloured earths; but against this Lord Bacon made a vigorous protest:—"As to the making of knots or figures with divers coloured earths, that they may lie under the windows of the house on that side on which the garden stands, they be but toys; you may see as good sights many times in tarts."

The old gardening books are full of designs for these knots; indeed, no gardening book of the date seems to have been considered complete if it did not give the "latest designs," and they seem to have much tried the wit and ingenuity of the gar-

deners, as they must have also sorely tried their patience to keep them in order; and I doubt not that the efficiency of an Elizabethan gardener was as much tested by his skill and experience in "knot-work" as the efficiency of a modern gardener is tested by his skill in "bedding out," which is the lineal descendant of "knot-work." In one most essential point, however, the two systems very much differed: in "bedding out" the whole force of the system is spent in producing masses of colours, the individual flowers being of no importance, except so far as each flower contributes its little share of colour to the general mass; and it is for this reason that so many of us dislike the system, not only because of its monotony, but more especially because it has a tendency "to teach us to think too little about the plants individually, and to look at them chiefly as an assemblage of beautiful colours. It is difficult in those blooming masses to separate one from another; all produce so much the same sort of impression. The consequence is people see the flowers on the beds without caring to know anything about them or even to ask their names. It was different in the older gardens, because there was just variety there; the plants strongly contrasted with each other, and we were ever passing from the beautiful to the curious. Now we get little of quaintness or mystery, or of the strange delicious thought of being lost or embosomed in a tall rich wood of flowers. All is clear, definite, and classical, the work of a too narrow and exclusive taste" (Forbes Watson). The old "knot-work" was not open to this censure, though no doubt it led the way which ended in "bedding out." The beginning of the system crept in very shortly after Shakespeare's time. Parkinson spoke of an arrangement of spring flowers which, when "all planted in some proportion as near one unto another as is fit for them will give such a grace to the garden that the place will seem like a piece of tapestry of many glorious colours, to increase every one's delight." And again—"The Tulipas may be so matched, one colour answering and setting off another, that the place where they stand may resemble a piece of curious needlework or piece of painting." But these plants were all perennial, and remained where they were once planted, and with this one exception—the planting of knot-work was as different as possible from the modern planting of carpet-beds. The beds were planted inside their thick margins with as great a variety of plants as possible, and apparently set as thick as possible, like Harrison's garden quoted above, with its 300 separate plants in as many square feet. These were nearly all hardy perennials, with the addition of a few hardy annuals, and the great object seems to have been to have had something of interest or beauty in these gardens at all times of the year. The principle of the old gardeners was that "Nature abhors a vacuum," and, as far as their gardens went, they did their best to prevent a vacuum occurring at any time. In this way I think they surpassed us in their practical gardening, for, even if they did not always succeed, it was surely something for them to aim (in Lord Bacon's happy words), "to have *ver perpetuum* as the place affords."

Where the space would allow of it, the garden was further decorated with statues, fountains, "fair mounts," labyrinths, mazes, arbours and alcoves, rocks, "great Turkey jars," and such like things. These things were fitting ornaments in such formal gardens, but the best judges saw that they were not necessities, and that the garden was complete without them. "They be pretty things to look on, but nothing for health or sweetness." "Such things are for state and magnificence, but nothing to the true pleasure of a garden."

Such was the Elizabethan garden in its general outlines, the sort of garden which Shakespeare must have often seen both in Warwickshire and in London. According to our present ideas such a garden would be far too formal and artificial, and we may consider that the present fashion of our gardens is more according to the type of Eden, in which there grew

Flowers worthy of Paradise which not nice art
In beds and curious knots, but Nature boon
Poured forth profuse on hill and dale and plaine.

Paradise Lost, book iv.

And none of us probably would now wish to exchange the straight walks and level terraces of the sixteenth century for

our winding walks and undulating lawns, in the laying out of which the motto has been "*ars est celare artem*"—

That which all faire workes doth most aggrace,
The art, which all that wrought, appeareth in no place.
Faerie Queene, ii., 12, 58.

yet it is pleasant to look back upon these old gardens, and to see how they were cherished and beloved by some of the greatest and noblest of Englishmen. Spenser has left on record his judgment on the gardens of his day—

To the gay gardens his unstaid desire
Him wholly carried, to refresh his sprights;
There lavish Nature, in her best attire,
Poures forth swete odors and alluring sights:
And Arte, with her contending, doth aspire
To excell the naturall with made delights;
And all that faire or pleasant may be found
In riotous excesse doth ther abound.

There he among round about doth flie,
From bed to bed, from one to other border;
And takes survey, with curious busie eye,
Of every floure and herbe there set in order.

Muicopotmos.

Clearly in Spenser's eyes the formalities of an Elizabethan garden (for we must suppose he had such in his thoughts) did not exclude nature or beauty.

It was also with such formal gardens in his mind and before his eyes that Lord Bacon wrote his essay on gardens, and commenced it with the well-known sentence (for I must quote him once again, for the last time), "God Almighty first planted a garden, and indeed it is the purest of all human pleasures; it is the greatest refreshment to the spirits of man, without which buildings and palaces are but gross handyworks; and a man shall ever see, that when ages grow to civility and elegance, men come to build stately sooner than to garden finely, as if gardening were the greater perfection." And, indeed, in spite of their stiffness and unnaturalness, there must have been a great charm in those gardens, and though it would be antiquarian affectation to attempt or wish to restore them, yet there must have been a stateliness about them which our gardens have not, and they must have had many points of real comfort which it seems a pity to have lost. Those long, shady "covert alleys," with their "thick-pleached" sides and roof, must have been very pleasant places to walk in, giving shelter in winter, and in summer deep shade, with the pleasant smell of Sweet Brier and Roses. They must have been the very places for a thoughtful student, who desired quiet and retirement for his thoughts—

And adde to these retired leasure
That in trim gardens takes his pleasure.

Il Penseroso.

And they must have been also "pretty retiring places for conference" for friends in council. The whole fashion of the Elizabethan garden has passed away, and will probably never be revived; but before we condemn it as a ridiculous fashion, unworthy of the science of gardening, we may remember that it held its ground in England for nearly two hundred years, and that during that time the gardens of England and the flowers they bore won not the cold admiration but the warm affection of the greatest names in English history, the affection of such a queen as Elizabeth, of such a grave and wise philosopher as Bacon, of such a grand hero as Raleigh, of such poets as Spenser and Shakespeare.

III. Gardeners.

- (1) *Queen.* But stay, here come the gardeners,
Let's step into the shadow of these trees.

Thou, old Adam's likeness,
Set to dress the garden, how darest
Thy harsh rude tongue sound this displeasing news?
What Eve, what serpent hath suggested thee
To make a second fall of cursed man?
Why dost thou say, King Richard is deposed?
Dost thou, thou little better thing than earth,
Divine his downfall?

Richard II., act iii., sc. 4.

- (2) *Clown.* Come, my spade—there is no ancient gentlemen but gardeners, ditchers, and gravemakers; they hold up Adam's profession.

Hamlet, act v., sc. 1.

Very little is recorded of the gardeners of the sixteenth century, by which we can judge either of their skill or their social position. Gerard frequently mentions the names of different persons from whom he obtained plants, but without telling us whether they were professional or amateur gardeners or nurserymen; and Hakluyt has recorded the name of Master Wolfe as gardener to Henry VIII. Certainly Richard II.'s Queen did not speak with much respect to her gardener, reproving him for his "harsh rude tongue," and addressing him as a "little better thing than earth"—but her angry grief may account for that. Parkinson also has not much to say in favour of the gardeners of his day, but considers it his duty to warn his readers against them—"Our English gardeners are all or the most of them utterly ignorant in the ordering of their outlandish (*i.e.* exotic) flowers as not being trained to know them. . . . And I do wish all gentlemen and gentlewomen, whom it may concern for their own good, to be as careful whom they trust with the planting and replanting of their fine flowers, as they would be with so many jewels, for the roots of many of them being small and of great value may soon be conveyed away, and a clean tale fair told, that such a root is rotten or perished in the ground if none be seen where it should be, or else that the flower hath changed his colour when it hath been taken away, or a counterfeit one hath been put in the place thereof; and thus many have been deceived of their daintiest flowers, without remedy or true knowledge of the defect." And again, "idle and ignorant gardeners who get names by stealth as they do many other things." This is not a pleasant picture either of the skill or honesty of the sixteenth century gardeners, but there must have been skilled gardeners, to keep those curious-knotted gardens in order, so as to have a "*ver perpetuum* all the year." And there must have been men also who had a love for their craft; and if some stole the rare plants committed to their charge, we must hope that there were some honest men among them, and that they were not all like old Andrew Fairservice, in Rob Roy, who wished to find a place where he "wad hear pure doctrine, and hae a free cow's grass, and a cot and a yard, and mair than ten pund of annual fee," but added also, "and where there's nae leddy about the town to count the Apples."

H. N. ELLACOMBE.

Coffee.—Dr. Attilio Lelli having met with a case in which a dose of strychnia was administered in Coffee without fatal consequences, was, the "*Lancet*" says, led to institute some experiments to determine whether it possessed antitoxic power against this drug. The animals employed were rabbits, and by comparative trials he found that a dose of five centigrammes proved fatal in a short space of time; when the same or a larger dose was given in a very strong infusion of Coffee, he found that the Coffee either acted as a complete antidote in preventing the poisonous effects of the strychnia, or that it materially diminished the violence of its action.

A Welsh Meadow.—During the last week in June Mr. James Britten and I spent three days in North Wales, sometimes walking, sometimes travelling by rail, from Llangollen to Dolgelly. Whilst at the latter place we took an evening stroll along a road leading to the foot of Cader Idris, and some three miles or more from Dolgelly we came upon a small meadow, certainly not more than an acre in extent, which appeared from the road to be almost covered with various kinds of Orchids. On a closer inspection, we found great quantities of *Gymnadenia conopsea*, *Habenaria chlorantha*, *Listera ovata*, and *Orchis maculata*, and such a profusion of many other pretty and some not very common plants, that we determined to search the place carefully, and for our own amusement to put down all the species we could find in this fertile little spot. The list soon became so large as to astonish ourselves. Probably there is scarcely another acre to be found containing not only so many species of wild plants, but so many individuals of certain species. It was the gayest little garden imaginable. At the time of our visit it was perhaps chiefly conspicuous for the Orchids and for the amazing undergrowth of Fairy Flax; but at various times other plants will be in the ascendant. The moister portions will by this time be yellow over with the fragrant Asphodel, and the drier parts will soon be blue with Scabious; whilst the pretty pink *Pedicularis* will give it a rosy tint. In all eighty species were counted, but we did not take into account the hedges or the trees. It likewise grew too dark to see any more, and we were obliged to give up our search, no doubt missing several species which would probably have brought up the list to very nearly one hundred.—ROBERT HOLLAND, in "*Science Gossip*."

SCENT-YIELDING PLANTS.

By G. W. SEPTIMUS PIESSE, Ph.D., F.C.S.

Cassie, Jasmine, Tuberose, and Violet.

I HAVE grouped together the Cassie, Jasmine, Tuberose, and Violet, because their scent can only be obtained by the enfleurage and maceration processes. They are a type of nearly all scent-yielding flowers. Kill the flower by

Section of Bain Marié, for macerating flowers.

boiling it in a still and no odour can be obtained; it is only when the flower is alive that it gives out its scent. There is nearly always a certain amount of odour in pollen

Cassie (*Acacia Farnesiana*).

which, on being put into grease, imparts to it the scent of the flower from which the pollen is taken. The odour of the Hop flower seems to be wholly due to the profuse way in which it yields pollen. In order that the operations of inflowering

and maceration should be more perfectly understood than by the brief description of the processes given in the article on "The Rose" (see p. 173), illustrations of the "Bain Marié" (used for macerating flowers) and the "Chassis en Verre et en Fer" (for inflowering fat and oil) are here given. For scenting grease with Cassie or Violet, it has to be treated by both processes: first by placing the flowers into the liquefied grease, an operation which must be repeated some ten or twenty times; then the grease has to be strained through muslin

Chassis en fer, or wired frame for inflowering oil.

every day, and fresh flowers added, finally spreading the grease when cool on both sides of the chassis, and sprinkling flowers over it, changing them as often as may be convenient. When the blooming period is over, the grease is collected, slightly warmed, strained, and put into canisters for exportation. In obtaining scent from the Jasmine and Tuberose, the grease is inflowered only, as maceration in the case of these flowers deteriorates the product. They exhale odour for a long time when shut up in a grease box, for such it is when one chassis

Chassis en verre, or framed glass for inflowering grease.

is placed upon another as they are in practice as seen in the illustration. If oil having the scent of these flowers be required, the wire gauze sash is used for the inflowering of oil upon a cotton fabric. As many as 3000 chassis are in use at one time in some laboratories.

Cassie.

Let us now glance at the cultivation of these flowers as raised on the flower farms of the Var (Alpes Maritimes). The young

Pile of framed glasses, with flowers between and grease at top and bottom.

plants of Cassie (*Acacia Farnesiana*) are raised from seed which is sown in beds, on which the best plants are left and the doubtful ones removed. In the third year they have generally reached a height of 2 ft. or 3 ft., and they are then planted out in fields, each tree requiring about 12 ft. square of land. Before planting the Cassie the ground is well dressed with manure, and deeply trenched. This plant thrives better at Cannes than in any other part of Europe. The blossoms of the Cassie are

successive, some being ready for plucking while others are scarcely formed; this is a great advantage to the cultivator,

to grow till it reaches a height of from 12 ft. to 15 ft., with branches 6 ft. long, and a stem as thick as a man's wrist.

Each full-grown tree will produce about 2 lb. weight of flowers, the value of which is from 3s. to 4s. per lb., say from £30 to £40 per acre. The annexed illustration of Cassie (p. 308) clearly shows the "successive" way in which it blooms. Flowers, however fragrant, are not of much practical use in the perfumer's laboratory unless they are produced in succession, because if they come altogether there is not sufficient time for the butter to be infloxed. It is found that better results are obtained by repeating a small quantity of flowers over the butter than by infloxing a large quantity of blossoms at one time.

Jasmine

is obtained by grafting the Spanish variety on two-year-old plants of the Wild Jasmine (*Jasminum officinale*), that which is seen in our English gardens. Spanish Jasmine thus treated produces a large blossom, the fragrance of which is intense. Jasmine needs a moist soil or to be so situated that it can be irrigated. It requires about 8000 plants to stock an acre, and they do not come into full bearing until the second year after grafting; the blossoms are produced from July to the end of October, but those of August and September yield the greatest amount of odour. Every August (the Jasmine season), the fields of the Var from Antibes to Cannes are alive about daybreak with women old and young, and children, each having a little basket suspended by a strap across the shoulders, both hands being actively engaged in picking blossoms. As each basket is filled it is conveyed to the shaded laboratory, and there weighed. An acre of land will yield about 500 lb. of blossoms during the season, the value of which is from £25 to £35. Fifty successive infloxications of fresh blossoms occupying as many days produce the finest Jasmine butter.

Tuberose.

THE TUBEROSE (*Polianthes tuberosa*), like nearly all the plants belonging to the same Order, grows best in moist situations, or if cultivated otherwise, the land must be irrigated. The bulbs are planted from 9 in. to 12 in. apart in rows 24 in.

inasmuch as one lot of blossoms is gathered and passed through the laboratory before it is time to gather others. This *Acacia* begins to flower after the third year, and continues

the plants belonging to the same Order, grows best in moist situations, or if cultivated otherwise, the land must be irrigated. The bulbs are planted from 9 in. to 12 in. apart in rows 24 in.

Branch of the Spanish Jasmine (*Jasminum grandiflorum*): natural size.

asunder, and a good plantation in suitable soil will last from seven to eight years. As to its odour, who is unacquainted with it? The poet says "it comes out when the sun's away," referring doubtless to the marked exhalation of fragrance which takes place before sunrise. The confinement laboratory is always kept dark, an artificial inducement (may I say?) for the blossoms to "work hard."

Violet.

As to Violets in England, they grow anywhere and almost anyhow; but the fierce sun at Nice is but ill borne by them; consequently cultivators plant them under the shade of the Orange and Lemon trees which abound there, or close to walls and houses. They are propagated by division, and after the young plants are set out and well established they receive a good supply of liquid manure, which has to be repeated every year about two months before they begin to blossom. If the soil be very dry the plants should be irrigated every week during the hot season. Violets are planted so as to grow in tufts or clusters about 1 ft. apart all round; this space enables the garnerers to pick the flowers without treading upon the plants. Old plantations have to be removed about every five years, and young roots substituted, planting this time in the spaces which before were vacant. An acre of land during a season at Nice will yield from 180 lb. to 200 lb. of flowers, the value of which is from 1s. 6d. to 2s. per lb. Violets may be looked upon as an under crop, as they succeed under trees. The variety best suited for yielding scent is the double Parma. About 25 tons weight of Violet blossoms are produced annually at Nice.

Hughenden House, Chiswick.

THE INDOOR GARDEN.

WINTER-FLOWERING PLANTS.

THERE is no season of the year when flowering plants in conservatories or other glass structures are more appreciated than in winter, and yet many are deterred from attempting their culture because they imagine that a temperature suitable for stove plants is necessary for them, while in point of fact a too high temperature shortens their period of blooming. There is no reason why any one having a glass house in which the temperature of an ordinary dwelling room can be maintained should not enjoy a fine display of flowers in winter as well as in summer. The temperature of our conservatory, which is, as a rule, gay with flowering plants during winter than in summer, is frequently as low as 40° on sharp frosty nights, and the average night winter temperature ranges from 45° to 50°, yet a large and varied collection, or rather selection, of plants is maintained in it in perfect health as long as they are required, or until their flowers fade and they are removed to make room for successional subjects. There is now such a wealth of exotics that flower naturally during winter that any additions to them might seem superfluous, but there are, nevertheless, a few useful groups of plants that may be made available for such purposes, either by hastening or retarding their growth, that a few notes on the most serviceable may not be out of place at the present time.

PELARGONIUMS.—Whilst our flower beds and borders are aglow with these, one fancies that we could not appreciate them again under glass, but from October to May Pelargoniums are amongst the most effective conservatory plants which we possess. Our winter stock of them, now ready to burst into flower, has been prepared as follows:—In March the required number of plants was selected from amongst those that had been cut in close the previous autumn, and which were consequently bushy plants, well furnished with side-shoots; these were potted in 7-in. and 8-in. pots, using a compost consisting of loam, rotten manure, and sharp grit. They were then set in a light, span-roofed pit, where an intermediate temperature was maintained, and as soon as they had become vigorous the principal shoots were tied down to the rim of the pot and the points pinched, with the view of inducing bushy growth. When the external temperature admitted of their removal without checking their growth, they were transferred to cold

pits and placed close to the glass. Their summer treatment consisted in giving abundance of water at the root, and a sprinkling after hot days amongst the pots in order to keep the coal-ash foundation cool and moist; a slight shade was given during the brightest portions of the day; the flowers were kept constantly removed, and the strongest of the shoots were pinched off to induce the formation of a well-furnished head of well-ripened side-shoots, which will, as soon as the pinching is discontinued, produce a display of the finest bloom, equal, if not superior, to any summer effects which are generally obtained from Pelargoniums. They must be allowed at all times abundance of air; the lights should only be used for warding off heavy rains, and should be entirely drawn off in fine weather up till within a month of the season when the plants are required to be in bloom, when stopping must be discontinued and a drier atmosphere maintained; but root moisture must still be applied in sufficient quantities to ensure a healthy development of fine foliage and sturdy spikes of flower that will, in the light, dry, buoyant atmosphere of the conservatory, last in perfection several weeks. Successional plants from spring-struck cuttings should be kept as cool as possible in order to permit them to husband their strength until required. As regards varieties, I find those of the Vesuvius type, of moderately strong growth, and of a floriferous character in summer, to be equally effective in winter; Dr. Denny's well-known varieties, too, and Mr. Pearson's, include all shades, from pure white to the most brilliant scarlet.

CHINESE PRIMULAS.—To have these in perfection from October onwards the seed should be sown in February in light, rich soil, and placed in a moderate heat. They should be pricked off as soon as they are large enough to handle, and finally potted according to the size of the specimens required. In summer their treatment consists in shading from strong sunlight, strict attention to watering, preserving a cool, damp foundation, and keeping all flower-spikes pinched out until September, when good plants will throw up from five to seven spikes of flower, and form a perfect ball of blossom and foliage. Such specimens make excellent plants for vases, or for conservatory decoration; not the least of their many good properties being that they are even more effective under artificial than solar light. We have at present coming into bloom Russell's Pyramid (red and white), *P. sinensis fimbriata*, rubra and alba, *P. sinensis Cottage Maid*, *P. filicifolia*, (red and white), *P. fimbriata striatiflora*, and *P. sinensis punctata elegantissima*.

SALVIAS.—These are invaluable for furnishing large conservatories, as their brilliant blossoms, produced in the greatest abundance, give a cheerful effect in winter, and contrast well with the large masses of foliage usually employed for furnishing such structures. We propagate a supply of young plants in March, and grow them on in moderate heat until the external atmosphere admits of their being gradually hardened off in cold frames, and by the beginning of June they should be fine bushy plants ready for shifting into flowering pots, the size of which is regulated by the size of plant required. For large specimens for central beds we use 12-in. pots, employing a rich compost; they must receive some temporary shelter until they have become well established, when they may be set in the open air, where they are sheltered from rough winds. Plenty of root moisture with occasional applications of liquid manure should be regularly given them, and they like a good syringing after hot days, to keep off red spider, which is their greatest enemy. Treated in this manner, *S. splendens* is now coming into bloom, and will continue in that condition under conservatory treatment until Christmas or even later, when *S. Heeri* will be fit to take its place. This will be succeeded in March by *S. gesnerifolia*, a dwarf variety with stout foliage and brilliant blossoms. When coming into flower, a good top-dressing of sheep or cow manure will keep the growth healthy and vigorous, and few plants are less troubled with insect pests.

TREE CARNATIONS.—These are grown both for ordinary purposes, and for furnishing cut flowers, which are extremely useful for bouquets or general decorative purposes. Spring-struck plants in medium-sized pots are best; they should be

grown in the open air after they are established in their blooming pots. By the end of September, the earliest of them will be coming into bloom, and may be removed under glass in succession. A cool, rather dry atmosphere suits them best, as damp soon spoils their blossoms. We find Miss Jolliffe (pink), Garibaldi (scarlet), La Belle (white), and Vulcan (bright red), to be amongst the best for winter; and Souvenir de la Malmaison (extra large, blush-white), to be the best for the early spring months.

CALLA ÆTHIOPICA.—This invaluable plant is greatly benefited by being planted out during the summer months in good rich soil. It delights in abundance of moisture at the root, and, in fact, it succeeds well as an aquatic. It should be lifted carefully and repotted in September, when the most forward amongst them will be showing flower. They should be placed in a cold pit and introduced as required to the conservatory, where the white flowers or spathes and highly ornamental foliage render them effective subjects. They are not liable to insect-pests, and are easily increased by means of offsets or small bulbs that form at their bases. I find them to answer best confined to a single crown in a pot. Care should be taken to get a stock that produce fine flowers; for amongst them there are some with narrow-pointed leaves that produce small flowers even in the case of strong plants, while the broad-leaved section as a rule produce flowers of good form and substance.

CYCLAMENS.—No collection of winter-flowering plants can be called complete if these be not abundantly represented. They are so easily raised from seed, and produce such fine-flowering bulbs the second year, that it is desirable to continually remove all second-rate flowering bulbs, and only retain the best. Cyclamens have been greatly improved during these last few years, and therefore care should be taken to get seed from a good stock. We do not dry off their bulbs at any time, but during their dormant season they are placed in a partially-shaded frame on a coal-ash foundation until they commence to grow, when they are removed to a light, airy shelf, and introduced in succession to their flowering quarters.

CINERARIAS.—These may be had in full bloom by the beginning of December by sowing the seed in February, and treating the young seedlings as one would do Primulas. Cinerarias will not stand forcing in their later stages of growth, therefore early preparation must precede early blooming. If kept cool they are seldom troubled with insects, but in heated structures they soon become infested with green fly.

EPIPHYLLUMS.—These are handsome plants when in flower, the season of which may be prolonged through the dullest part of the year, viz., from early in November to the New Year. After flowering we usually keep them comparatively dry and cool until March, when they are potted if necessary and placed on a shelf in the forcing-house where a high moist atmosphere is maintained. Under these conditions they make vigorous growth, and by the end of July they may be removed to a cool airy position and kept moderately dry. By introducing them to heat again in succession from the first of September onwards, a long display of the flowers produced by this beautiful succulent may be relied on.

CHRYSANTHEMUMS.—For ordinary decorative purposes these are struck early in spring, and grown on under glass until they are fit for transferring to their flowering pots, when they are plunged in coal ashes up to their rims to prevent evaporation. Good drainage is an essential part of their treatment, for if sodden the plants perish suddenly, while on the other hand any lack of moisture causes them to lose their foliage at the base, and unless well furnished with deep green leaves Chrysanthemums, however well flowered, are comparatively useless for decorative purposes. A position with a south aspect and sheltered from wind suits them admirably. Pompones from their dwarf bushy habit require no stakes, but the large-flowered kinds so effective in floral decorations require a stake to each shoot in August, after which they will form a natural-looking bush. As it is desirable to prolong the season during which they flower as late as possible, they should only be removed under glass as they come into bloom, or when danger from exposure is apprehended. A cool airy orchard-house suits them

admirably, the dry cool atmosphere preserving the blossoms for a long season.

BEGONIAS.—Many of the free-flowering varieties form excellent plants if grown freely during the early summer months, and rested in August in a cool situation; the blooms should be pinched off up to September, when a slightly increased temperature will start them into vigorous growth, and a fine display of flowers will be the result. Although usually treated as stove plants, they will continue in good health for a lengthened period in an intermediate-house.

JAMES GROOM.

Henham.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

October 1.—Potting old plants of Cloth of Gold, Golden Chain, and Flower of Spring Pelargoniums for stock. Putting in cuttings of Blue Perfection and Golden Gem Viola in sharp sandy soil, under hand-lights, in a shady border. Putting Fraser's Broad-leaved and Green Curled Endive in cold pits as they become vacant; also black-seeded Brown Cos Lettuce. Giving Strawberry beds a good coat of manure, and forking it in. Getting border under north wall ready for Calceolaria cuttings. Taking up one portion of Beet-root, and storing it away for use in case of frosty weather. Gathering Coe's Golden Drop and Reine Claude de Bayay Plums. Watering Pine-Apples throughout, and tying up the fruit where necessary.

Oct. 2.—Putting in Calceolaria cuttings under hand-lights against a north wall. Getting Camellias, Myrtles, and other plants under cover. Earthing up Celery when the ground is dry and in workable condition. Cutting off what bunches are left in late Black Hamburg house, and putting them in bottles of water in which have been placed a few pieces of charcoal. Gathering Louise Bonne of Jersey, Jersey Gratioli, and Marie Louise Pears; also Cellini, Cox's Pomona, and Stirling Castle Apples, and laying them singly on clean wheat straw in fruit room. Weeding Box edging, and cleaning the garden walks to make them fresh for the winter.

Oct. 3.—Potting rooted cuttings of Tomatoes for succession; and putting in another batch of Hathaway's Excelsior. Clearing off old Peas, and getting the ground ready for manuring and trenching. Hoeing and weeding amongst the autumn-sown Onions whilst the ground is dry and the weather fine. Turning gravel walks, and laying down new where required. Tying up Lettuces, and covering up Endive to blanch. Clearing off all decayed vegetables, and carrying them to the rubbish-heap to burn. Gathering Passe Colmar, Doyenné du Comice, Forelle, and Flemish Beauty Pears.

Oct. 4.—Potting Flower of Spring and Dr. Lindley Pelargoniums; also Hyacinths, Tulips, and Narcissi. Moving Primulas and Cinerarias to warmer quarters. Thinning Spinaach, and weeding and hoeing between the rows. Making a new Mushroom bed, and turning more manure for another. Looking over all Cauliflowers, and turning down the leaves over such as have formed heads, to protect them from frost. Gathering all Dwarf and Scarlet Runner Beans, and putting them in 4-in. flower pots, set in pans of water with a little charcoal added for keeping till they are wanted; also treating all Vegetable Marrows in the same way.

Oct. 5.—Potting Christine and Jean Sisley Pelargoniums; also a quantity of Echeveria glauca. Planting all spare borders with Wheeler's Imperial Cabbage plants 8 in. apart. Preparing temporary frames in which to prick out Cauliflower plants; also a quantity of black-seeded Brown Cos Lettuce. Giving late Peach-house inside border a good soaking with water.

Oct. 6.—Sowing Mustard and Cress in boxes placed indoors. Potting a few Lobelia pumila and dwarf Ageratums. Putting in Calceolaria cuttings under hand-lights. Getting up a large quantity of the most forward Cauliflowers, and laying them in an open shed. Clearing leaves from the pleasure grounds and walks, and rolling the same. Gathering all nuripe Tomatoes, and placing them in a sunny position indoors to ripen. Fruits in use for dessert consist of Pine-apples, Grapes, Pears, Plums, and Apples.

Railway Planting.—The Central Pacific Railroad Company are doing a good work in tree planting, having already planted 40,000 Eucalyptus trees along the line of their road. This enterprising company intend, according to the "American Naturalist," planting certain species of the Eucalyptus on each side of their right of way through some 500 miles of the valleys of California; it is estimated that 800,000 trees will be required for this purpose.—R. E. C. S.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Bulbs should now be potted without delay, especially those that are required to be in bloom early. Amongst Hyacinths, the small White Roman is the best for early flowering; and of Narcissi, the Paper White is the best early, to be succeeded by the ordinary large-flowered Hyacinths and Narcissi. The bulbs of Hyacinths collectively are inferior in quality this season through the adverse weather experienced during the time they were making their growth; but, from the appearance of the roots, some kinds have been much more affected than others; consequently I should recommend amateurs to order or select only the freest-growing varieties, as many of the more delicate sorts will this year be liable to cause disappointment. To counteract as far as possible this weak condition of the bulbs, even of the mid-season and late-flowering varieties, they should be potted sooner than usual, and not kept out of the soil after they have evinced a disposition to grow (which is shown by the prominence of the roots), for when allowed plenty of time between potting and being placed in a warm temperature to bring them into flower, it gives time for the pots to become filled with roots, which is most

genial afterwards to cause it to make favourable progress, root-pruning is best carried out in the beginning of September; but in most cases this year the summer shoots have not completed their extension until a month later, consequently it is necessary to defer the work. Like almost every other operation connected with gardening, root-pruning does not admit of universal application, not even in the case of such trees as from their over-luxuriant condition form few or no bloom-spurs, with a consequent absence of fruit. There are some growers who object to root-pruning, arguing that it is better to take up the trees and re-plant them; this may be quite correct in the case of small bush-shaped Apples, and pyramidal or hush-shaped Pears, the size of which will admit of their thus being taken up and re-planted without much mutilation of the roots, or a great amount of labour involved in their removal; but by far the greater number of trees, not only grown by amateurs, but in gardens generally that are in an unsatisfactory, unfruitful condition, have often been allowed to remain until they have attained a height of at least 12 ft., and almost as much through; and although it is quite possible to transplant them, still it is far from advisable to do so when there is no further object in view than simply to bring them into a bearing state. It is more particularly to trees of this latter description that

Minute Vegetation (see p. 313).

essential to success in the case of all bulbous plants. Crocuses, Tulips, Snowdrops, and the beautiful blue Scillas should all now be potted. The best place to keep them in until they are ready for placing in heat is a bed of ashes, with 2 in. or 3 in. of the material under the pots to keep out worms, filling it in betwixt them and over the tops to a depth of 4 in. or 5 in.; whilst here, the soil should be kept moderately moist, but not saturated. Should the weather be very wet, one or two hotbed lights or shutters may be placed over them in a sloping position, to throw off the rain. Hyacinths and other bulbs for forcing do not require so much root-room as they often receive; I have found that two or three bulbs in a 7-in. pot flower equally well as if they were put in separate pots. Plump, well-matured bulbs, the pots well filled with roots, gradual forcing, and plenty of light as soon as the crowns have got fairly inured to it, are the essentials to secure fine, stout flowers. Where the leaves and bloom-stems are of a drawn-up, weakly description, it is evident that some of the foregoing requisites have been wanting.

Root-pruning Fruit Trees.—There is scarcely a single operation in gardening during this exceptional season which it has not been necessary to delay later than usual; and amongst the rest, root-pruning. In ordinary springs, when the weather enables the growth of the trees to commence at the usual time, and is sufficiently

these remarks are intended to apply. Then, again, as to the method of operating upon the trees; here also size and the circumstances under which they are grown must to a considerable extent influence the mode of procedure. With comparatively small trees that have not been many years planted it will generally be found the best to remove the soil from above their roots, commencing at from 2 ft. to 2½ ft. from the bole, and to follow them to near their extremities, shortening them to within 4½ ft. of their whole length, spreading them out evenly in the trench that will have been made in getting to them, and keeping them well up towards the surface, filling the soil in evenly all round, and treading it firmly down as the work proceeds. The direction thus given to the roots in keeping them within 1 ft. of the top has the best possible effect upon the future health and bearing capabilities of the trees, as the roots lying comparatively near the surface are under the influence of the sun-warmed earth, which during the summer is necessarily in that dry condition which causes a cessation of wood growth, and induces the formation of fruit-spurs to an extent that cannot possibly occur when the roots are deeper down in the moist subsoil. In the case of any trees that exhibit more than usual vigour, producing thick rank shoots, it will be well, whilst the trench is open, to remove the soil right under the centre of the undisturbed ball to see if there be any strong roots descending in a vertical direction; if any be found they should be cut away

for whilst these strong tap roots exist, medium-sized trees never can be induced to bear. Larger trees in an unfruitful state such as already alluded to, and which may have been planted ten or a dozen years, or even more, without ever having their roots pruned or brought nearer the surface, will require to be treated somewhat differently. The roots of these will in most cases have extended a considerable distance, and in gardens where there is what may be termed a mixed cultivation, vegetable crops will be growing on the ground occupied by these roots; in which case it will not be found convenient to remove the soil and follow them to their extremities in the way recommended for smaller examples. Therefore a trench 15 in. or 18 in. wide should be opened on each side of the tree so as to go about half round it, at a distance, according to its size, of from 3 ft. to 5 ft. away from the bole: the larger the tree the further it will be necessary to open the trench from the bole, and that for two reasons—(1) if the roots of a large tree be cut in closely, the tree will not only be liable to displacement by the wind, but the severance of the roots too near the trunk would be so severe in its effects as to injure its health; for this reason I have found it better to reduce the roots one-half at a time as previously described; (2) if the growth be not restricted, and a sufficiently fruitful disposition secured by this first operation, then the remaining roots on the two opposite sides of the trees will require to be operated upon in the ensuing year, or at a further interval, according to the requirements of the case. In opening the trench, it is necessary to dig as deeply as the horizontal roots, and also to work under the ball and cut back any that descend more directly downwards. In shortening the roots, never leave them in a jagged, mutilated state—such as will be the case where they are chopped off with the spade—but make a clean cut with the knife: so far as possible, a fork should be used for the removal of the soil, especially with the smaller trees, where the object is more to bring the roots near the surface than to effect the greater reduction in their length. Plum and Cherry trees may be similarly treated; but it seldom happens that they are inclined to such an over-luxuriant growth that their roots become so strong as to induce an unfruitful disposition in the trees, and if taken in hand before they are too large, lifting them, so as to keep the roots near the surface, will be found the best mode of treatment for those in small gardens: this also applies to Apple and Pear trees. I cannot too forcibly urge the necessity for this root-lifting and the more severe operation of root-pruning being carried out with as little delay as possible after the present time; for where the work is done whilst the leaves are yet green, and have considerable vitality in them, I have found it not only much more effectual in inducing the formation of fruit-spurs the following autumn, but it also rarely exercises any injurious effects upon the health of the trees. The reason of this will be obvious to all who have had any experience in fruit culture, as when the operation is performed some weeks before the leaves fall, the healing up of the severed roots is greatly assisted, and the formation of new root-fibres is at once promoted: it is where root-pruning is deferred until the winter is far advanced that injury is inflicted. By way of experiment I have tried root-pruning as late as when the buds had begun slightly to swell, and the weakening influence of such treatment was so great that the trees did not recover their necessary vigour in less than two or three years. I would also impress upon amateurs that the larger and stronger the trees are, the greater the necessity for completing the work early. It will be seen that these directions only apply to fruit trees grown in gardens more or less devoted to the cultivation of culinary vegetables, where the manure used for the latter has a considerable influence in producing the over-luxuriant condition of the trees, which can seldom be induced to bear satisfactorily without either lifting or root-pruning, until they have become too large for ordinary gardens. In orchards which are dug annually, and where intervening crops, such as vegetables and bush fruits, are grown between the trees, it is often necessary to resort to root-pruning, as the trees, when kept within a moderate size, and their branches sufficiently thinned out, bear finer fruit than that produced where they are allowed to grow to their natural dimensions without restraint.

Moulds and other Minute Vegetation.—Besides the innumerable and infinitely varied forms which are presented to us by the higher forms of vegetable life, there is another and scarcely less beautiful world of plant-form which is almost concealed from the ordinary observer on account of the minute size of its members, or, when seen, presents itself in no ornamental guise. We refer to the vast group of minute, or, as they have been termed, microscopic, fungi, which present under the microscope forms of marvellous beauty and exquisite colouring. How varied is their form when thus regarded the illustration on the preceding page feebly portrays; but it cannot convey any idea of the rich colouring which microscopic

fungi frequently present. Besides such important members of this class as the *Peronospora infestans*, which is the cause of the too well-known Potato disease, the "rust" and "smut" which the farmer dreads in his Wheat fields, or the "mildew" which suggests to the housewife a vision of damp linen and to the agriculturist and the Hop-grower a form of plant-disease, the "Vine-blight," the "orchid-blight," and many more—we shall often find in our spring rambles the underside of a Violet-leaf covered with round orange spots which, when examined under the microscope, present a most beautiful appearance. The infinite variety of these objects, which may be found in all sorts of situations—not only upon the leaves of living plants but upon dead twigs, upon straw, or on decaying stems—render them readily available for microscopic examination, and their beauty and curiosity make them well worthy of more notice than they generally receive.

THE EUCALYPTUS IN ALGERIA.

CONSUL-GENERAL PLAYFAIR has forwarded recently from Algiers a report in which he states that he has been greatly impressed with the disastrous consequences of the destruction of forests in Tunis, and has given much attention to the *reboisement* of Algeria, where the same process has been going on, though not to the same extent. At the time of the conquest the whole of the Sabel and a great part of the Mesidja were covered with wood or scrub, which acted not only as a parasol to the earth, preventing the undue evaporation of its dampness, but as a means of attracting and condensing the moisture in the atmosphere, and causing it to descend in refreshing dews or rain. But the clearings and destruction of forests which began about 1845, soon had the effect of changing the climate appreciably, and the rainfall has seriously decreased. The plantation of Australian trees is the most eligible course to be adopted as a remedy; and the Eucalyptus especially, because, while growing with great rapidity, and attaining in Algeria in six or seven years the same dimensions as the Oak does in twenty, it produces at the same time hard and dense timber, and may be expected in its twentieth year to furnish such logs of timber for ship-building or other purposes as could not be furnished by an Oak tree under 100 years old. Consul Playfair mentions that a short time ago, wishing to send a Eucalyptus tree of four or five years of age to England for experiment, he found that its great length made it impossible to put it into a boat to convey it to the steamer, and the boatman decided on towing it alongside; but the moment he put it into the sea it sank to the bottom, and divers had to be employed to raise it. When properly seasoned, its specific gravity becomes less, and it then floats on the water. The Consul states that the plantation of these trees on appropriate soil in Algeria will yield a large profit. There may be also parts of Europe where they could be cultivated as well as in Algeria, but that is very doubtful, and hardly anywhere is the price of land moderate enough to allow of their being grown with a certainty of profit. As a rule, wherever the Orange tree flourishes so does the Eucalyptus. There is no doubt of its action in improving the sanitary condition of unhealthy districts, and in dissipating miasmatic influences, which made such havoc among the Algerian colonists in the first years after the conquest. Formerly it was impossible for the workmen at the great iron mines of Mokta-el-Hadid to remain there during the summer; those who attempted to do so died, and the company was obliged to take the labourers to and from the mines by train every morning and evening, 33 kilos. each way. From 1868 to 1870 the company planted more than 100,000 Eucalyptus trees, and now the workmen are able to live all the year through at the scene of their labour. Other places are mentioned in which fever has disappeared since the introduction of these trees. They destroy miasma by utilising the moisture of the soil, and thus draining marshes. The emanations from their leaves also may produce a salutary effect. They contain a large quantity of essential oil very similar to turpentine, which they emit freely, especially when stirred by the wind, and this acts, it is supposed, as a febrifuge. The Consul is convinced that no culture in Algeria offers such prospects of success as Eucalyptus, if the cultivator can afford to wait for a certain considerable time for the return of his capital; but the land must be selected with due care and judgment. The Government now encourages its plantation, and offers to share the expense with the communes.

Antirrhinums or Snapdragons.—One of the brightest spots in my garden is that occupied by a batch of Snapdragons. The plants, which are dwarf and bushy, the first year of blooming are loaded with flowers, and by picking off the seed-pods they may be induced to throw up fresh growths and spikes of flowers for a long time. Antirrhinums, though perfectly hardy, do not winter well; last winter the excessive rainfall killed a great many one-year-old plants; hence the necessity for securing select varieties by means of cuttings.—D.

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE FRUIT SHOW.

SEPTEMBER 21 AND 22.

THIS exhibition was in all respects a good one; fruit, cut flowers, and vegetables were shown in large quantities, and the arrangements were such as showed off the exhibits to the best advantage. Amongst the chief features of the show may be mentioned a large collection of Apples and Pears from the Royal Gardens, Frogmore, by Mr. Jones: and banks of cut Roses from Messrs. William Paul & Sons, Waltham Cross, and Messrs. Cranston & Co., Hereford. First-class Certificates were awarded to Mr. Turner, Royal Nurseries, Slough, for Seedling Dahlias, Charles Lidgard, and Lady Golightly; also for Potato, Schoolmaster, evidently a fine kind. To Messrs. Kelway & Sons, Langport, Somerset, for Seedling Gladioli, Marciannus, John Laing, Venulus, and Richard Dean. To Mr. Todd, Catterick Bridge, Yorkshire, for Seedling Dahlia, Rose Circle. To Mr. Keynes, Salisbury, for Seedling Dahlias, Robert Burns, Dictator, Emulator, and Marion. To Mr. Betteridge, Chipping Norton, for a Seedling Quilled Aster called Novelty; and to Messrs. Rawlings, Romford, for Seedling Dahlia, James Willing.

Fruit.—In the class of collections of twelve varieties of fruits, there were three competitors, all of whom sent excellent examples; but the best came from Mr. Coleman, Eastnor Castle. It consisted of fine Muscat of Alexandria and Black Hamburg Grapes, Barrington Peaches, Pitmaston Duchesse Pears, good Melons, Plums, and Cherries, and two well-ripened Pine-apples. From Mr. Webb, gardener to J. H. Manners Sutton, Esq., also came good Alicante and Muscat of Alexandria Grapes, Figs, and Victoria Plums. The next collection contained good specimens of Hughes' Golden Pippin Apple and Beurré Superfin Pears. In the class of six varieties, the principal exhibits of note were well-coloured Alicante Grapes and Pine-apple Nectarines. In the class of ten varieties of Grapes, there were only two exhibitors, Messrs. Lane & Son, Berkhamsted, being first; they showed remarkably well-finished clusters of Bowwood Muscat, Trebbiano, Alicante, Black Prince, and others. Mr. Wildsmith, gardener to Viscount Eversley, Hockfield, furnished very large bunches of Barbarossa, good examples of Venn's Black Muscat, and Alicantes, all well-ripened. In other classes devoted to Grapes we noticed fair examples of Golden Champion from Mr. Woodbridge, Syon House; also good Muscat of Alexandria and Madresfield Court. The best bunches of Black Hamburgs came from Mr. Adams, gardener to the Rev. R. Hudson, Frogmore Hall, who contributed large and shapely bunches, in which the berries were plump and well coloured. In the same class—that of three bunches of Black Hamburgs—Mr. Wildsmith had also good examples. Mr. Upjohn had smaller clusters, but well coloured. Of White Grapes, which were well represented, the best came from Mr. Coleman, gardener to Earl Somers, Eastnor Castle, who had very large and well-ripened bunches of Muscat of Alexandria; and fine bunches of the same variety were also shown by Messrs. H. Lane & Son. Madresfield Court was shown in good form by Mr. Earp, gardener to J. S. Sellon, Esq., and Mr. Woodbridge, but those furnished by the latter were not quite ripe. Three excellent bunches of Foster's Seedling came from Mr. Stephenson (gardener to F. Peck, Esq., Roby House, Sydenham) and Mr. Miles, Wycombe, the berries in both cases being of a rich golden transparent colour. Lady Downe's Seedling was largely shown, but most of the bunches were unripe. The best Buckland's Sweetwater which we have seen this season came from Mr. Bungay, gardener to W. Smith, Esq., Herne Hill, the berries being large and of a beautiful golden colour. Excellent stands of Alicante were shown by Messrs. Lane & Son, and Mr. Peed, Norwood. The heaviest bunch of Grapes (Syrian) came from Mr. J. Dickson, gardener to J. Jardine, Esq., Arkleton, and weighed 10 lb. 10 oz.; the next heaviest was a bunch of Barbarossa, from Mr. Peed. The best Queen Pine-apple out of eleven exhibited came from Mr. Webb; it weighed 6½ lb., and was in perfect condition. An excellent fruit of this variety was also shown by Mr. Day, Hillside, Newark. A good Smooth-leaved Cayenne came from Mr. C. Ross, Welford Park, Newbury; and a well-finished ripe fruit was furnished by Mr. Pragnell, Sherborne Castle, Dorset. Peaches and Nectarines were shown in considerable numbers; the best dish of Peaches (Lord Palmerston) came from Mr. A. Gibson, Sevenoaks. A good dish of Barringtons came from Mr. Frost, Maidstone, and Princess of Wales was shown in good condition by Mr. J. Fry, gardener to J. Baker, Esq., Pinner. Of Royal George good dishes were shown by several exhibitors. Among Nectarines the best were Prince of Wales, from Mr. Jamieson, gardener to Earl Crauford, Wigan. Hunt's Tawny, a pretty dark-coloured kind, came from Mr. S. Bolton, and good examples of Oldenburg, Pine-apple, and Violette Hâtive were also shown. Melons were exhibited in large quantities; the best scarlet-fleshed kind (Scarlet Gem) came from Mr. Goldsmith, Dorking; Mr. Coleman had the next best (Read's Scarlet) in good form and beautifully netted. The best green-fleshed Melons came from Mr. R. Adams of Frogmore Hall, Mr. Coleman, and Mr. John Day. Figs were shown in unusually good condition; the largest fruit of White Marcellais which we have seen this season came from Mr. Burnett, gardener to Mrs. Hope, The Deepdene, Dorking, and of Brown Turkey and Brunswick there were also good dishes. Morelle Cherries were shown in good condition by several exhibitors, the fruit being large, bright, and well ripened. Of Plums a fine dish of Green Gages came from Mr. J. Fry, and a very fine dish of Coc's Golden Drep was furnished by Mr. Staples, gardener to H.

Oppenheim, Esq., Chipstead, Sevenoaks. Pond's Seedling, from Mr. Walker, Thame, and from Mr. J. Bolton, gardener to W. Spottiswoode, Esq., Maidstone, obtained second and third prizes. Good fruit of Transparent Gage, White Magnum Bonum, Diamond, and Jefferson's were also shown. Apples, both culinary and dessert kinds, were shown in fairly large numbers, notwithstanding the almost general failure this year of that fruit. The best three dishes of dessert kinds came from Mr. Haycock, gardener at Barham Court, Maidstone; they consisted of remarkably finely-coloured fruit of the Melon Apple, Cox's Orange Pippin, and Ribston Pippin; the next in point of merit came from Mr. Rutland, Goodwood, who had good, even fruits of Ribston Pippin. Kitchen Apples made a fine display, owing to large dishes of each kind being shown; and several extra prizes had to be awarded in consequence of the equality of the collections. The best three dishes came from Mr. Bowles, gardener to W. Skinner, Esq., Beresford House, Maidstone, who had very large specimens of Warner's King, Stone Apple, and Lord Suffield; the next best collection was that shown by Mr. Rutland, who had Lord Suffield, Blenheim Orange, and Warner's King, all in good condition. In other collections the most noteworthy kinds were large, clean fruits of Stirling Castle, Gloria Mundi, and Emperor Alexander. Pears were sparingly shown; the best three dishes came from Mr. Goldsmith, who had clear-skinned, shapely fruits of Williams' Bon Chrétien, Beurré d'Amanlis and Duchesse d'Angoulême; Mr. Staples had medium-sized, ripe fruits of Marie Louise, Williams' Bon Chrétien (finely coloured), and Beurré d'Amanlis. Marie Louise and Williams' Bon Chrétien were the best ripe kinds shown. In the collection of Apples from Frogmore we remarked fine examples of Parker's Seedling, Wellington, well-coloured Cox's Orange Pippin, Fair Maid of Windsor (an orange-coloured kind tinted with scarlet), Wall's Seedling, and King of the Pippins. Amongst other good kinds were finely-coloured fruits of Summer Golden Pippin, Devonshire, Quarrenden, Kerry Pippin, Colonel Vaughan, Golden Pippin, and others. Mr. William Paul, Waltham Cross, also sent a fine collection of Apples, a good collection of Pears and Apples came from Mr. Wildsmith; and Mr. Killick, Maidstone also sent Apples in excellent condition. Apples, consisting of some of the most select kitchen and dessert kinds came from Messrs. George Paul; and Mr. Haycock furnished good Peaches, Nectarines, and Apples grown in pots. An extra prize was deservedly awarded to Mr. Mowbray, gardener to the Earl of Leven, Fulmer, Slough, for a magnificent bunch of Golden Champion Grapes; also to Mr. Rutland, gardener to the Duke of Richmond, for a fine dish of culinary Pears (Calebasse Grosse).

Cut Flowers.—Dahlias were shown in large quantities and in good condition. In the class of forty-eight show blooms, Mr. John Keynes, Salisbury, had the best collection; it contained remarkably well-matched and finely-coloured blooms of some of the best known kinds. Messrs. Rawlings & Co., Romford, and Mr. C. Turner, Slough, had also fine collections. The best twenty-four fancy dissimilar flowers came from Mr. John Keynes, who showed well-formed blooms, embracing all shades of colour; in the same class Mr. Seale, Sevenoaks, contributed unique blooms of some of the more popular kinds, as did also Mr. Chas. Turner, Slough. In the amateurs' class, the best twelve flowers (show varieties) came from Mr. H. Glascock, Bishop's Stortford; and well-formed blooms also came from Mr. G. H. Fewkes, Tyburn, near Birmingham. Asters were shown in large numbers, and amongst them were excellent stands of quilled blooms from Mr. Betteridge, Chipping Norton, and Mr. Wheeler, Warminster. The best tasselled flowers, magnificent blooms, striped and self-coloured, came from Messrs. Saltmarsh & Son, Chelmsford. Roses, considering the bad season here, were well represented, Messrs. Paul & Sons, Mr. John Harrison, Mr. William Corp, and others showing fairly good collections of them. In the different stands we noticed good blooms of Alfred Colomb, Baroness Rothschild, and Marie Van Houtte. Gladioli in a cut state were furnished by Mr. George Wheeler, Warminster; they consisted of kinds with well-formed flowers of great purity of colour. In the amateurs' class the Rev. H. Dombain had an excellent collection, as had also Mr. J. Sladden, Chipping Norton. Messrs. Kelway & Co., Langport, sent a large collection of seedling kinds, many of which were in size and colour of flower considerably in advance of any at present in cultivation. Mr. Charles Turner showed a good collection of cut blooms of Pomponé Dahlias, and baskets of plants of autumn and winter blooming Carnations. Mr. John Laing contributed plants and cut blooms of Begonias, among which were some beautiful varieties.

Vegetables.—These were exhibited in excellent condition, and as the number of varieties to be shown was unlimited, the collections were unusually large. Mr. Pragnell, who had the best collection, showed no fewer than thirty-eight dishes, amongst which were remarkably well-grown, clean-looking tubers of Bread-fruit and Porter's Excelsior Potatoes, Sherbourne Improved and James' Keeping Onions, finely-shaped Early Horn and Early Nantes Carrots, very large white heads of Veitch's Autumn Giant Cauliflower, Tomatoes, William I. Peas (in excellent condition), Cucumbers, Celery, and Cardoons, together with almost every other kind of useful vegetable, all of which were in admirable condition. Next in point of merit came a collection from Mr. C. Chaff, gardener to C. H. Goschen, Esq., Addington; this was in every way complete, but there was a want of finish about some of the productions. A good though small collection gained the third prize. In the class devoted to smaller collections of vegetables, there were numerous exhibitors, whose produce was of a meritorious description. Mr. J. Walker, Thame, showed samples of a new Onion named Exhibition; they were of the Banbury type, of good shape, and well ripened; they averaged 5 in. in diameter.

THE KITCHEN GARDEN.

WINTER TREATMENT OF CAULIFLOWERS.

THE last week in September or the first week in October will in most places be early enough to prick out Cauliflowers into their winter quarters, and after the moist, growing weather which we have had, the check given in moving will be beneficial to them. If during mild winters, when the plants are showing signs of a too exuberant growth, they could be gently lifted with a small hand-fork, just sufficient to disturb a few of the longest roots and then pressed down again, there would be a less tendency to premature "bolting." This might be done at any time during November or December when the weather is mild, or later if necessary. There are many and various ways of wintering Cauliflowers, all more or less well adapted to the different circumstances and conditions. Planting under hand-lights is a good old-fashioned plan for the early crop; the lights should be placed in rows about 3 ft. apart, the land should have been deeply worked and well manured, and about nine plants should be planted under each light, to be thinned out in March to four—those removed to be planted elsewhere to come on in succession. There should be 3 ft. of clear space between the lights, as in mild weather the plants will be all the better for having them lifted off, unless they have movable tops; in that case the tops only need be taken off—but at all events abundant ventilation must be secured in mild weather, either by taking the lights entirely off, or by setting them up on bricks. The latter is a very good plan, and one commonly practised where hand-lights are much used, as it economises labour. In the southern counties Cauliflowers will generally pass through the winter safely simply pricked out 4 in. apart on the lee side of a hedge with a few fronds of Bracken or branches of Evergreens laid over them during severe weather, leaving them on for a day or two after the weather has changed, in order that they may thaw gradually. In cold districts it is a very good plan to prick the plants into frames 4 in. or so apart, in beds of light, loamy soil, near the glass. In fine mild weather the lights should be drawn off; at other times they should be propped up at the back. In bright frosty weather, during the early part of the day a thin shade will be beneficial in preventing the plants from suffering from sudden extremes of temperature. Scattering dry, dusty ashes over and amongst them occasionally will keep slugs in check, and if a pure atmosphere be maintained, mildew will be kept down.

Early Cauliflowers are an important crop, and no one should depend altogether upon one sowing, as in the case of a mild autumn and winter, if sown early, they button prematurely; and if, on the other hand, they are sown late, and the winter happens to be severe, the crop must be backward, even if the plants do not perish; therefore, it is always a good plan to make two or three sowings at intervals of ten days or a fortnight, and, if possible, bring them on under different conditions. Thus a part may be put out about October 1 under hand-lights; another part may be pricked out in a cold frame; a few may be left out in the open air; and a few for very early work may be potted and grown on under glass: the latter is an excellent plan to adopt in cold, ungenial situations. When plunged in old tan or leaf-mould near the glass, the plants acquire a sturdy habit, and when turned out in some sheltered, well-prepared bed in March, I have had them superior to the autumn-planted crop under hand-lights. When one has the means of giving a little warmth in winter, if anything happen to any of the early-sown crops, or if a suspicion be entertained that the plants may button prematurely, a sowing may be made under glass any time during winter; and if potted singly in small pots, and grown on in gentle heat near the glass (a warm greenhouse shelf is a good position for them), they will, if planted out at the end of March, be as good as the early-sown batch, and I have never known such plants to button prematurely. I have sown Cauliflowers in December and January in heat, grown them under glass till the first week in April, then planted them out on a warm border, and cut good heads the first week in June. I mention this to show that no one need ever be without early Cauliflowers even if the autumn-sown plants should fail, if the precaution be taken

to sow a pinch of seed in heat under glass soon after Christmas, and under any circumstances, the plants will be sure to prove useful.
E. H.

Blanching Late Celery.—In retentive soils Celery often suffers considerably from damp lodging in and around the hearts after being earthed up, and in some places many plants are useless from this cause. This is in many ways annoying, for if reliance could be placed upon the whole crop keeping in good condition, less might be planted in order to ensure a good supply, and the land thus saved might be profitably occupied with something else. The best way which I have ever found of obviating or checking this tendency to decay is to plant on the surface, and blanch with ashes, burnt earth, or old spent tan, first tying the plants carefully up, and then placing the ashes or whatever material is used around and amongst the plants and ridge, pressing it round them with the hands. Besides reserving the crop from premature decay ashes keep the slugs and snails at a distance, and during severe weather less covering will suffice to keep out frost.—H.

Potato Crops in Kent.—Potatoes have suffered much from blight in this locality, especially second early kinds, although some are nearly free from it; early kinds, such as Myatt's, Veitch's, and other Ashleaf sorts, also Extra Early Vermont, Early Oneida, Porter's Excelsior, Alpha, and others all ripened off early a good crop, and free from disease, although not so large as usual. Some time after the disease appeared, other kinds were lifted; some were much blighted, and others have gone bad since they were stored. Last week a quantity of Late Rose Potatoes were lifted nearly all sound and a good crop. This is a valuable Potato on this soil (a light, sharp loam); it is not a late kind, although its name would lead one to think it was, but quite a second early and good in quality. Several other kinds which I have grown on trial are much blighted. I find "Salus" does not prevent disease. The latter is said to spread faster in wet weather than in dry, a fact of which I am quite aware, yet with us the reverse was the case this season, the weather being dry and hot, and the haulm nearly all dried up with disease before the rain came.—W. DIVERS, *Wiverton*.

The Potato of the Future.—We are all pretty familiar with the "Potato of the present," which requires from fourteen to twenty-four weeks from the time when the tubers are put into the ground to bring it anxiously-looked-for crop to maturity. Because of this it admits of only one crop being produced in the year. It is a plant of late years singularly liable to disease; it is subject to the attacks of spring frosts if planted too early, and to late frosts if not matured in good season; it is, in fact, a most precarious plant to cultivate. The Potato of the future must be something wholly different from this, because it must admit of being planted late enough to escape spring frosts, and to ripen its produce before the customary time of the disease. It must ripen, from the time of planting, in twelve weeks at least, that is to say, if planted on May 1, it must be ready for lifting and storing quite ripe on July 24. If such were the case, it would be lifted ere the disease appeared in any virulent form. Of course, such early-ripened tubers could not be expected to keep beyond Christmas suitable for table, and therefore it would be the business of the grower of the future so to arrange as to produce two crops in the year—thus: one from early-ripened seed planted May 1, and one from a second crop of late-ripened seed planted at Midsummer. As the disease only attacks crops that are considerably matured, and in the period comprised between the middle of July and the middle of August, the first crop would be too early and the latter too late to sustain any damage.—A. D.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Tender and True Cucumber.—This is stated by good growers to be one of the best of Cucumbers, both as regards handsome fruit and free-bearing properties. For winter culture it may perhaps be considered a rather too long-fruited kind; but for good flavour and appearance on the exhibition table it is unsurpassed. Examples of it were shown by Mr. Pragnell at Alexandra Park on the 13th inst. which far surpassed all other kinds exhibited on that occasion.—S.

Planting Cabbage.—There is no better place in which to plant Cabbage to stand the winter than in ground just cleared of Onions. It will require no digging or forking; the weeds should merely be removed, and the surface stirred several times with the Dutch hoe. The Cabbage plants may then be planted in lines 9 in. apart each way, and in winter, when Greens are scarcest, each alternate plant may be removed as required for use, leaving the remainder to form hearts in the spring.—S.

American Blackberries.—What experience I have had of the Lawton variety is more favourable than that of Mr. Tillery (p. 276). Having in my garden some wire trellises of Mr. J. B. Brown's manufacture, 8 ft. in height, I devoted about 40 yards in length to American Blackberries which were planted in 1875. In 1876 they fruited to a small extent, but the fruit was nearly all appropriated by the birds. This year the plants have covered the trellis to a height of about 7 ft.; and though the past summer cannot be said to have been exceptionally warm, we have had a very heavy crop of fine fruit, which has ripened well, and been gathered for preserving purposes. Our situation is cold and exposed, and the trellis is a self-supporting one, away from the garden walls; but it answers its purpose admirably, and I can recommend its adoption by any one who wishes to try the American Blackberries.—H. TURNER, *Stockport*.

The Selection of Young Fruit Trees.—In ordering young fruit trees from a nursery, there is a considerable advantage in being first in the field—the early planter has the pick of the stock; and although a respectable nurseryman never knowingly sends out bad trees, yet there are degrees of goodness even in things of fair average quality. In the selection of young trees for walls, or any position where a blank would be objectionable, whether maidens or trained trees are chosen, none but those worked on good, sound, healthy stocks should be planted, and the eye and judgment requires some educating to tell which trees are likely to turn out best under given circumstances. As a rule, small, spindly stocks do not make long-lived trees, even if in their early life they have a clean, healthy appearance. Strength and substance are necessary in a stock that is expected to carry a fully-developed tree and to support it when heavily laden with fruit. The recruiting officer, before he passes a youth into the ranks of the army, takes the measure of his chest, as a guarantee that he possesses the necessary stamina to enable him to perform his duties. In like manner, a strong, stout stock, if otherwise healthy, is of more importance to a fruit tree than is sometimes supposed or allowed for.—H.

Air Roots on Vines.—I agree with the statement (see p. 276) that a close atmosphere overcharged with moisture encourages the growth of air roots, but I do not believe air roots are a sign that the roots are in a bad condition, or that they are unable to supply the wants of the large expanse of foliage. During the late spring we had occasion, while erecting a temporary stage for plants in one of the late Vineries, to enclose some stems of Vines for about 1 ft. where they entered the house; consequently this portion was in a close confined atmosphere, while the rest of the Vines were under ordinary conditions. On removing the staging a short time ago I was surprised to see large masses of roots protruding from the stems. To save them, therefore, from drying up, and to give the Vines additional feeding ground, we raised a narrow border of rich soil to enclose them. These Vines were in robust health and perfected a fine crop, with less than 1 per cent. of shanked berries. I attribute the production of air roots entirely to imperfect ventilation, accompanied by excessive atmospheric moisture. The Vine being naturally a free and vigorous-rooting subject, only needs the requisite amount of moisture in the atmosphere to induce the dormant roots that exist in embryo at the base of each bud or spur, to make it as much an aerial rooting plant as the common Ivy.—JAMES GROOM, *Henham*.

Best Bedding Lobelia, Henderson's Lustrous Improved.—As no one else has directed attention to the great merits and beauty and unequalled continuity of bloom of this beautiful Lobelia, I think it but fair and just to those who sent it out (Messrs. E. G. Henderson & Sons, Pine-apple Nurseries, Edgware Road) to say a few words in its behalf, as several other varieties have been commended in the columns of THE GARDEN which I do not think at all as good as this seems to me to be. I grew for trial this summer two scroll beds, side by side, with Bronze Bicolor Pelargoniums down the centre, and a double row of the old variety, Lustrous in one, and Lustrous Improved in the other, down the whole length of the bed. For the last fortnight the former has been out of flower, and all the plants are now almost entirely withered away, whereas the Lustrous Improved is as beautiful as ever, and the greater number of the plants are so well provided with vigorous young growth that if the frost could only be kept from them they would, I am sure, continue in beauty for a month or six weeks to come. This variety is also by far the easiest to propagate of any Lobelia with which I am acquainted, affording continually an abundance of good soft cuttings which strike with the greatest ease and readiness stuck into a pan of sand and water, with all the drainage-holes carefully stopped up. They should be kept constantly well supplied with water, and they do not require any bottom-heat whatever to get them to strike. I have also grown this season Ebor, a kind unequalled for its deep shade of colour, but inferior to Lustrous Improved in compactness of habit

and continuity of bloom, as it has lost all its brilliancy at least a fortnight ago. The two best whites are The Bride, still in full beauty and of good compact habit, resembling that of Lustrous, but not quite so cushion-like (this variety was sent out this season by a Norwich firm, from whom I received it, but whose name has for the moment escaped my memory); and White Beauty, received from Mr. Quilter, of Aston Grunds, Birmingham, which is an equally pure white, and of a still more compact and dwarf low-growing habit than The Bride; it is also most free blooming, but hardly continues so long in beauty as the other variety.—W. E. G.

Travelling Seeds.—Sometimes seeds only, sometimes fruits, are thus transported by running streams and ocean currents. The fruits of Fennel are exactly like miniature boats; and Fenchal or Fennel Bay in the island of Madeira owes its name to this plant, colonized there by seeds that have safely made the voyage from the main land. In like manner, Hazel-nuts, Walnuts, and many other kinds of Nuts, have been carried by currents to a new home beyond the seas. For a long time the source of the large Cocoa-nuts that drift about in the Indian Ocean; and are finally stranded on the coast of Malabar, remained a mystery. These gigantic fruits, some of them more than 18 in. in diameter, and weighing from forty to fifty pounds, are not the produce of any neighbouring country, and the Hindoos called them "Sea Cocoas," supposing that they are supplied by some unknown plant. It has since been discovered that they are the produce of the Lodoicea, a magnificent Palm, growing on the Seychelles Islands, which lie on the eastern coast of Africa, more than twelve hundred miles from the nearest point of Indian territory. The currents of the Pacific Ocean carry out Cocoa-nuts and other fruits from the American continent to enormous distances in a similar manner. These find a resting-place on the coral ridges which are raised up from the bottom of the sea by the ceaseless labour of polyps; here they germinate, and soon cover with brilliant verdure what had formerly been a rock almost invisible to navigators.

INTERNATIONAL POTATO EXHIBITION.—This is to be held in the Royal Aquarium, Westminster, on Wednesday, Thursday, and Friday next. The schedule comprises fourteen open classes and two for amateurs. Although the season has been very unfavourable, a good exhibition may nevertheless be expected, and if those who furnish the soundest and best tubers were also to state under what conditions they were produced some good might be the result.

THE GREAT SUMMER SHOW OF THE ROYAL HORTICULTURAL SOCIETY (to be held at South Kensington, from the 23rd to 31st of May next, both days inclusive) will probably be an event of considerable importance. The schedule, which is now ready for issue, has evidently been prepared with great care, the prizes being sufficiently liberal to insure a spirited competition. There are thirty classes for plants, in which the first prizes range from £20 to £6; one, for a collection of ten dishes of fruit, with £10, £7, and £5 as the first, second, and third prizes respectively. There also ten other classes for fruit, and one for a collection of vegetables consisting of ten kinds.

NOTES AND QUESTIONS—VARIOUS.

Kœlreuteria japonica.—Allow me to inform "H. P." (see p. 292) that there is a good plant of this shrub growing in the grounds here. It flowers most years, and is, when in bloom, a very attractive object. Lovers of choice shrubs who have not got it should not fail to add it to their collections. The foliage is especially pretty when dying off in the autumn.—H. J. C., *Grimston, Tadcaster*.

Lachenalia rubida.—I have grown for several years a bulb under this name which I have failed to flower. It produces an abundance of offsets, which, as well as the larger bulb, are of a singular form, quite unlike any I have met with among the other species, being cylindrical and thickened at each end. Have any of your readers grown this plant successfully, and, if so, will they kindly enlighten me on the secret of flowering it? Gawler, in his description of this species at t. 933 Bot. Mag., does not hint that it is difficult to bloom, and it is quite possible that I have not the true *L. rubida*.—W. T. T.

The New Potato Digging Machine.—For many years people have tried to invent a machine whereby Potatoes can be dug without peeling or otherwise injuring them, and Mr. Aspinwall has at last succeeded. It was tried on Mr. Howard's farm, and answered perfectly. Its capacity with a pair of horses is from 3½ to 4½ acres per day. It leaves the Potatoes entirely on the surface, clear from the tops, and never "chokes," a fault which, we believe, it possessed last year. The Potatoes are deposited directly in the rear of the machine, without their being in the least injured, and the gatherers have not the slightest difficulty in collecting them. With respect to the draught of the machine, it is so easy that on such land as that on which it was tried at Rufford one horse would have sufficed to work it.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

IN THE INDIAN SEAS (SINGAPORE).*

AUGUST 6, 1877.—I like the climate of Singapore better than I had expected—of course from 9 a.m. to 3 p.m. it is very hot as a rule, but the mornings and evenings are deliciously cool and breezy, and the weather is so regular that very thin white clothes may be worn without any danger, so different from the sudden transitions of temperature which occur in England. The mean temperature is about 82°, and there is but little variation throughout the year. Being close to the sea Singapore gets cooler breezes than places further inland, and were the sanitary condition of the place—drainage, &c.—well carried out there would scarcely be a more desirable climate in the world. The people here are principally Chinese, but there are a great many Malays and Klings, together with a fair sprinkling of Hindoos, mainly Bengalese; of English there are but few, and they are nearly all merchants, large store or hotel keepers, shipping agents, &c.; the Chinese are merchants, petty shopkeepers, artisans, coolies or labourers, carriers, &c.; the Malays form the police and Gharry (cab) drivers; the Klings are itinerant traders or shopkeepers; while the Bengalese monopolise the washing or laundry business. Fruit and fish shops or stalls meet one at every turn. The following list of fruits and vegetables taken from a Chinese newspaper for January, may prove interesting, as showing the immense variety of produce grown by the Chinese gardeners.

List of Fruits.

Aleurites	Lemons	Pine-apples, Punt
Almonds (Bombay)	Lichees, dried	Plantaine, common
Apples, dried	Loong Ngan, dried	" fragrant
" Californian	Olives, green, Punt	Pomeloes or Shaddock
Bananas, Punt	Oranges, (Coolie) Chang	Prunes, dried
" Common	" Sweet, Sun-woey	" Amoy
Chestnuts, new	" (Mand.) coolie	Raisins, Muscatel
Cocoanuts	" Kam-kwat	Salisbury Seeds, Pak-kwo
Currants	" (Mandarín)	Sugar Cane
Dates	Papaw	Tamarinds
Figs, dried	Pears, Santoong	Walnuts
Ground Nuts	" Chefoo	Water Chestnuts, Canton

Vegetables.

Asparagus	Chillies, Mixed	Parsley, English
Bamboo Shoots	Curry Stuff, English	Potatoes, California
Beans, sprouting	Egg Plant	" new, Macao
" Broad	Garlic (bulb) dried	" Sweet
" French (Macao)	Ginger	Pumpkins
Beetroot	Greens, White	Radishes
Brassica	" Winter course	Scallions
Cabbage, white Canton	" Sprouts	Shallots
" Common	Green Peas, in shell, old	Sesamum
" Hong Kong	" young	Taro (U Tau)
" Macao	Horse Radish, Shanghai	Tomatoes
Carrots, Salt	Lettuce, Chinese	Turnips, Salt
Carrots, Fresh	" English	" Chinese
Cauliflowers	Mint	Water Lily Roots
Celery, Chinese	Mushrooms, dried	Water Cress
" English	Onions, Bombay	Yams
Cucumbers	" Green	
Obilics, Dried	Parsley, Chinese	

The fruits at the present time in the market place are Bananas, Mangoes, Limes, Pomeloes, green-skinned but delicious Mandarin Oranges, Papaws, Bread and Jack fruits, Durians, Pine-apples in abundance, Rambutans, Mangosteens, Guavas, Australian Apples (just arrived), and numerous other fruits less well known, and eaten principally by the Chinese. Green Cocoa-nuts are plentiful at 1d. or 2d. each, and in the hot weather these furnish a delicious beverage nearly as pure as water, and with a rich, nutty, milk-like flavour, to which a dash of brandy or sherry is a great improvement. A small Nut will hold 1 pint (a large one 3 pints) of this colourless milk, and here, where drinking water is often fraught with danger, it seems inexplicable that green Cocoa-nuts are not more valued by Europeans than they are. Universally among Europeans there is a shadowy misconception as to the value and usefulness of fruit as food—and nowhere is this

more evident than in Singapore, where the finest of all tropical fruits are abundant during the whole year—notwithstanding the fact that the Chinese, from the richest merchant to the poorest coolie, eat little else but fruits and vegetables, supplemented now and then with a little salt fish. The Durian is a favourite fruit here, and is the size of a large Cocoa-nut after the husk is removed, covered with stout, broad-based prickles; indeed, the fruit of the Horse Chestnut, enlarged twenty or thirty times, would be nearly the exact counterpart of a Durian in appearance; when fully ripe the fruit splits into four or five sections, each of which contains a row of from three to five large seeds, surrounded by a luscious, sulphur-coloured pulp, concerning the flavour of which there are many conflicting statements. I think the rich, creamy pulp of a good Durian—for all are not good—may be likened to Nectarine and Apricot pulp mixed, with a dash of Pine-apple, a little flour for thickening, and just the suspicion of an Onion. The tree bears two crops every year, and the earliest fruits of the season fetch as much as 4s. 3d. each, but when plentiful, as now, from 5d. to 1s. is the usual price.

The Vegetation.

Much of the island of Singapore is covered with jungle and waste patches, on which *Melastoma malabathricum* takes the place of *Ononis arvensis* or Gorse at home, our common Brake Fern (*Pteris aquilina*) being here nearly crushed out of existence (for it does grow here) by *Gleichenia dichotoma* in dense masses, and 10 ft. in height. The surface of the island itself is tolerably flat, from which rise many isolated, rounded hills, of which perhaps Bukit Timah (400 ft.) is the highest. These Bukit or hills are mostly covered with virgin forest or jungle, but clearance for cultivation is now rapidly going on. Wherever the jungle has been cleared by fires, many pretty Ferns and the commoner varieties of *Nepenthes* spring up among the young Grass in all directions, and down by the rivulets and ditches a few Tree Ferns luxuriate. Bordering the red sandy roads in all directions are patches of Bananas, Sugar-cane, Tapioca, or Indigo, fringed by Bamboo fences and Cocoa-nut plantations. Many species of Palms luxuriate here, but *Cocos nucifera* and the Betel nut (*Areca Catechu*) meet the eye in all directions and add much to the picturesque appearance of the cool, whitewashed bungalows which nestle on the hill-sides. Some of the principal streets are fringed with trees, and a week ago a splendid specimen of *Poinciana regia* near the Town Hall was a perfect bouquet of vivid scarlet flowers and fresh green, feathery foliage—a picture never to be realised by those who have only seen it starved in a pot in English hot-houses. The particular tree to which I allude is about 20 ft. high, with a rounded, spreading top, and the panicles of scarlet blossoms were so profuse that the term bouquet-like is strictly applicable.

Private Gardens.

The gorgeous *Amherstia* grows well in several gardens, and especially so in those of Mr. Whampoa, a wealthy Chinese merchant, where there are many examples in all stages of growth. Some of the older specimens had been cut back, and are now forming glorious heads of foliage, through which the scarlet blossoms here and there peep; but as an effective tree, from a floral point of view, it can never rival *Lagerstrœmia Regina*, which is just now a mass of large lilac-like panicles; the *Poinciana*, apart from being one of the best and most effective of all tropical garden trees, is also one of the most variable, a fact doubtless owing to its being generally increased by means of seeds, which are freely produced in long, pendent, scimitar-like pods. Mr. Whampoa has a large collection of Water Lilies in open-air ponds or tanks, and at the time of my visit *Victoria regia*, *Nelumbium speciosum*, *Nymphaea rubra*, *N. cœrulea*, and others were in great beauty. Roses and Magnolias were in profusion, the cool morning air being deliciously perfumed by their waxy-petalled flowers. Many curious examples of dwarfed trees and shrubs are to be seen here, as also one or two very handsome *Arecas* and other Palms. The Government Botanical Gardens are situated at Tanglin, a distance of about three miles from the town, and consist of a large, undulated plot of ground well laid out, tastefully planted, and nearly surrounded by a fringe

* Communicated through Messrs. James Veitch & Sons.

of jungle, which adds much to their apparent size. *Araucaria Cookii* here forms a distinct and effective tree, columnar in shape, and 30 ft. or 40 ft. in height. The Travellers' Tree (*Uraria speciosa*) of Madagascar also does well, and near the entrance several low trees are overrun by a most luxuriant and floriferous growth of *Allamanda Schottii*. The effect of light and fresh air on many of the plants common to English bothouses is here something wonderful, the leaves being of a much more vivid green tint, albeit exposed to a scorching sun, while the hues of the flowers are proportionately brighter. A new lattice-work Orchid-house has been erected, and is covered with such creepers as *Tecoma jasminoides*, *Passifloras* of different kinds, *Antigonon leptopus*, *Cissus discolor*, &c., the Orchids themselves being suspended inside in baskets containing coir fibre and crocks.

Chinese Gardening.

Singapore possesses an excellent climate for gardening operations, and nearly every house, even the meanest Palm-leaf hut, has its strip of garden attached, in which Onions, Sweet Potatoes, *Caladium esculentum*, Chilies, and other common vegetables are grown. It is simply astonishing to see the thrift of the Chinese, especially those of the poorer classes, in all matters relating to food or medicinal products, for scarcely a plant exists from which they do not derive food, medicine, flavouring for curries, dyes, or other advantages, and as cultivators of market vegetables they have the monopoly here just as they have in San Francisco and other places to which they have emigrated. In the narrow streets of the Chinese quarters of the town itself pot plants are largely grown in bowl-like vessels of green or grey porcelain, and these are set on narrow ledges, or other supports in front of all the upper windows. China Roses do well so treated, as do also *Caladiums*, and a bushy plant much resembling the common Rue is grown almost universally, as it has the reputation of keeping away bad spirits and ill-luck from the houses before which it grows.

Manufactures and Modes of Transport.

All heavy goods here are transported either by bullock carts or by coolies, and here again we have evidence that a diet consisting principally of vegetable substances is capable of keeping men who undergo great exertions and fatigue in a state of healthy vigour. Rice, salt fish, and fruit form the staple sustenance of the Chinese coolie, who trudges cheerfully along with a load of 200 lb. or 300 lb. on his shoulders, apparently entirely oblivious as to the great weight he is carrying. Nearly all the manufactures of Singapore are carried on by the Chinese, whose productions for cheapness and quality will bear comparison with those of any other country. Of basket work, jewellery (especially some exquisite filigree work) cabinet making, iron and tin working, and of course porcelain manufacture I have seen beautiful examples. What a pity it is that the literature of such a people is buried in obscurity! what a loss to our own artizans and art manufactures it is that the results of their skill and ingenuity are so rarely and so sparsely represented in our museums and art schools at home! This island, the mainland, Johore, and the Malayan Peninsula behind, consist of a vast tract of fertile soil destined ere long to become the

"Garden of the East."

Even the primeval jungle is rich in wealth, timber trees almost rivalling those of the West in magnitude, and of great variety suitable for many different purposes. Here also the finest Rattan Palms are obtained, and El Dorado that it is, gold and other metals await a more energetic system of mining. Over all this enormous tract the home of the pure and gentle Malay races—the Incas of the East—the Chinese are spreading like grasshoppers, trading, buying up the land where possible, and by thrift and industry aided by secret societies, they bid fair in time to extirpate the native races in Malaysia. In the hotels here there are one or two little vegetable delicacies rarely seen at home, such as "Banana fritters," which are made by peeling perfectly ripe and fresh Bananas or Plantains, covering them with pancake paste, and baking them in a brisk oven: they should be served quite hot on a clean napkin, and when well made are simply delicious. Now that these fruits

are so plentiful, and withal so cheap in the London markets this hint may be worth adopting. Another way of eating Bananas here is with cheese instead of bread or biscuit, and the modicum of salt used in the cheese adds a piquancy to the flavour of the Bananas which is very agreeable. Another exquisite and simple dish for hot weather is a plate of milk (a soup plate is best) into which a large spoonful or two of Red Currant and Raspberry jelly is placed. In tasting this combination for the first time I thought it by no means a bad substitute for the Strawberries and cream of England. I have more to relate respecting this Liverpool of the East, but I am afraid I have trespassed on the patience of the readers of THE GARDEN too much already. F. W. B.

New Worm Destroyer.—A week or two ago we received from Messrs. Rutley and Silverlock, 412, Strand, a new worm destroyer in the shape of a cake of "soap," said to be made from the seed of the Tea plant, and to be much used in China for worm killing. This new destroyer we sent to Mr. Groom, of Henham Hall, for trial, and the following is his report upon it:—The cake of soap which you sent me has exceeded my most sanguine expectations, both by its speedy action and effectiveness. I crushed, according to the directions, about 1 lb. of the soap to powder (as from its hard, dry, oil-cake-like character, it takes a long time to dissolve), and soaked it in an ordinary full-sized garden watering-pot of hot water, stirring it occasionally until it was thoroughly dissolved and cold. I then selected a plot of Grass on which worm casts were abundant, and after sweeping it clean I poured as much of the solution on it as would soak in. In less than half an hour the surface was completely covered with worms of all sizes, which all died after a short struggle. On the small space operated on (about 6 ft. square) I collected over 100 large dead worms, and the birds carried off as many small ones. The Grass looks even more luxuriant than before it was operated on, and I need scarcely add that there is no vestige of a fresh worm cast. Being so well satisfied with the results of this worm destroyer on the lawn, I resolved to try it on plants in pots and enclosed borders. I selected Roses and similar plants in pots that showed signs of having worms in them, and gave each a thoroughly good soaking, and the results were in all cases as speedy and effectual as in the case of the lawn. The worms were lying on the surface quite dead shortly after the application; but to make sure that it was harmless, even in the case of the tenderest-rooted subjects, I thoroughly soaked such plants as Balsams and young French Beans in pots, and none of them shows the slightest ill effects, although the application was repeated two or three times at intervals of two days. I therefore consider this new worm destroyer a valuable addition to our list of garden requisites, that is, if its price be not prohibitory.

Bathing in Battersea Park.—The Battersea Vestry, at their meeting held the other night, the Rev. Canon Erskine Clarke in the chair, resolved to apply to the First Commissioner of Works for his consent to receive a deputation from them on the subject of permitting bathing within certain hours in the ornamental water in Battersea Park. Mr. Durrant, a vestryman, said it was very unlikely that permission would be given, as the lake throughout was not more than 3 ft. deep. Mr. Gay, another vestryman, observed that it could easily be made deeper, and even now if well filled it would be nearly 6 ft. deep. He thought it was a disgrace to the parish that they had no public bathing place. This observation was received with applause. [We have long considered it wrong that these vast and costly London Parks should not provide bathing places accessible at all hours. There is no other want they can now, or at any other time, meet more likely to be useful than cleanly, well-ordered bathing places. It is wrong to convert a beautiful piece of open water into a bathing place, because it prevents the general enjoyment of the scene at the same time by others. But there is not one of the large London parks where an acre or two of water could not be formed that would make delicious bathing places; these could be surrounded by shrubberies in a way to increase, instead of diminish, the beauty of the park. A bathing place only open early in the morning and late in the evening is a very poor substitute for what is wanted.—Ed.]

Blechnum Spicant trinervium.—This distinct and beautiful variety of *B. Spicant* (which, by the way is, I believe, restricted to Ireland) when better known will assuredly prove a favourite. Its chief distinction lies in the lower-most pinnae, which are developed in a pinnate manner, sometimes one-third the length of the entire frond, thus giving the latter a tri-pinnate appearance. It must, of course, be planted out to reveal its true character: it thrives where the typical form does. It was introduced by Messrs. Rolliason last spring.—J. T. R.

TREES AND SHRUBS.

THE PYRENEAN PINE.

(PINUS PYRENAICA).

THE foliage of this tree is very distinct, quite unlike that of any other Conifer. The leaves are in twos, of a beautiful grass-green colour, and from 6 in. to 7 in. in length. It can easily be distinguished from other Pines on account of the deep yellow-coloured bark on its young shoots; the cones are about 2½ in. long, rather egg-shaped, on short foot-stalks, sometimes in

The Pyrenean Pine (*Pinus pyrenaica*).

twos, but mostly solitary. It was discovered on the Pyrenean Mountains, where it forms extensive forests, by Capt. Cook, by whom seeds of it were sent home in 1843. This tree is highly ornamental, especially when young; its fine, upright-growing, light green leaves, and the orange-coloured bark on the terminal shoots being its most striking and beautiful features during that stage; but when older, it assumes a coarser habit of growth; its branches become stout, wide-spreading, and straggling, and altogether its general appearance is far from attractive. It is not likely to be ever valuable

as a timber tree in this country, the wood being of inferior quality. This Pine has never been very extensively planted, on account of its scarcity throughout the trade, and the difficulty in procuring seed true to name. G. B.

CLOTHING BARE PLACES UNDER TREES.

GRASS will not grow well under a dense shade; even when frequently renewed the result is unsatisfactory. Yet, in conspicuous positions, the bare earth has an objectionable appearance, and the substitution of something of an evergreen character becomes a matter of importance. Whatever is chosen must either have a creeping habit, like that of Ivy, throwing out roots wherever the branches come into contact with the soil, thus always maintaining a clean, fresh appearance; or else like the Periwinkle, be able quickly to renew themselves from their base. Take, for instance, either the large or small Periwinkle; masses of either of these usually look worn and shabby towards the end of March, but trim off the discoloured growth and foliage, and in a short time they will be beautiful again; and if any light at all reach them, they will flower in the greatest profusion. There is scarcely anything so good as Periwinkles for covering shady banks, where the soil is of an inferior description. Even Ivy takes some time to establish itself in bad soil, but the large Common Periwinkle (*Vinca major*) will grow in anything and almost anywhere. One of the creeping-rooted St. John's-worts (*Hypericum calycinum*) will also grow well in shady positions; once get it established, and cut it back occasionally, and it will give no further trouble; but all leaves that fall upon and are buried amongst its branches, or that are drifted by the wind, if not absolutely unsightly, should be allowed to remain for the purpose of affording nourishment. *Euonymus radicans variegatus* will likewise grow in shady places, and when planted somewhat thickly, and pegged down, it soon forms a close carpet. *Lomaria Spicant* I have also seen do well in woods, where the shade of the foliage was heavy, and very pretty and interesting it looks growing in masses, and it will transplant with safety. Where a less formal growth is admissible, the common male Fern (*Lastrea Filix-mas*), or the Shield Fern (*Polystichum angulare*), looks well in summer, but the former is not evergreen, and would not suit where a covering of that kind is desired. Several species of pretty close-growing Mosses are found naturally under the thick shade of trees; and where they thrive no better carpet need be sought, as they possess the advantage of always looking fresh and green. The Woodruffe (*Asperula odorata*), when naturalised under the smaller kinds of Conifers, such as *Arbor-vitæ*, or any other close, low-growing evergreen, has a very good effect. But this, and, indeed, all other plants that may be used for the purpose of forming a close undergrowth, should be given a fair start. It often happens that the soil under large trees is thoroughly exhausted, and to plant in it without some addition would probably be useless; first break up the surface as far as can be done without injuring the roots of the trees, and then spread over it 3 in. or 4 in. of good soil; there would then be a chance of the plants used becoming established before the roots of the trees monopolised the fresh soil, and when well established they would be able to hold their own in the contest. Wherever Ivy is employed, and there is nothing that looks neater or is better adapted for making quick growth, either under the dense shade of the Cedar of Lebanon or the heavy drip of the Beech, it should be kept from climbing the trees if they are choice and valuable specimens; and where fresh soil is applied as a top-dressing in which to plant, it should be placed quite close to the trunk of the trees. E. H.

The Spiræas.—Mr. Gordon writing about the Spiræas in the London GARDEN, says of *S. tomentosa* that it is 4 ft. or 5 ft. high; that the flowers are red, and that they bloom in August and September. The plants which we have seen would average less than 3 ft.; the flower is generally rose-coloured, sometimes white—never red—and it blooms late in July. Mr. Gordon remarks at the end of the article, that the Neillias of Prof. Don are considered by some botanists, to be species of Spiræa—which reminds us that the old favourite Ninebark which is too venerable to be danced about, has been removed from the Spiræas and placed under Neillias in the first volume of the "Botany of California,"—"Rural New Yorker."

NOTES OF THE WEEK.

Vases in Autumn.—In furnishing garden vases in the open air, nearly all the right work has yet to be done. They are as stereotyped and as poor as if the plant-world consisted of a hundred forms. The most beautiful vases we have lately seen were in Prof. Owen's garden at Sheen, each filled with a very large plant of *Sedum Sieboldi*. The plant seems to thrive best lifted up in the vases, and the beauty of the leaves, each bordered with a red line, is more easily seen.

Gladiolus Saundersi.—This beautiful *Gladiolus* has been unusually fine with me this summer; the bright, fresh colour of its wide, expanded flower, its pretty white throat, and feathering on the lower lip, render it perhaps the most attractive of the genus. Its only defect is the habit it has of not holding its head upright.—H. HARPUR CREWE.

The Regent's Park.—In our recent notices of the London parks, we omitted mention of the gardening in this, which is really well and tastefully done, there being numerous graceful forms among the more ordinary subjects, and a considerable amount of variety. In this, as in all the parks, however, the aim for the future must be planting as opposed to mere temporary decoration. Instead of painting the house every year badly throughout, it is best to do one room at a time, and do it to last.

Erodiums in Autumn.—E. Manbyanum has been gay for some weeks past, and will probably continue to be so for some time to come. It has large, sometimes three-lobed leaves, and conspicuous, rose-coloured, widely-expanded flowers. I have it growing round a standard Rose tree, along with the pretty *E. pelargoniflorum*, which has large, white flowers with a purple blotch at the base of the upper petals. I am very fond of these *Erodiums*, fugacious though they are. I learnt to like them when in Rome years ago; I used to think the little pink tufts of *E. romanum* one of the prettiest of the Roman sights. Will some one send me a cutting or tell me where to get a plant of the lovely *E. incarnatum*, which I have lost for several years, and have hitherto failed to recover?—H. HARPUR CREWE, *The Rectory, Drayton-Beauchamp, Tring*.

Mr. Wallace on Colour in Plants.—We expected much interest in Mr. Wallace's papers on "The Colours of Plants and Animals" in "Macmillan," but regret to say that we find little that one who knows anything about plants can follow or agree with. Very showy flowers, we are told, are very seldom sweet, the Rose, Peony, Magnolia, and hundreds of others notwithstanding. "The relation," says Mr. Wallace, "of white flowers to nocturnal insects is also well shown by those which, like the Evening Primroses, only open their large, white blossoms after sunset"—most of the Evening Primroses, and nearly all the large and vigorous ones, being among the most showy of clear yellow flowers. Plants, and among them the "Stone Mesembryanthemum," are supposed to resemble their surroundings by the need of "protection from their numerous enemies," but nothing is said of the thousands of species of plants grazed down every year throughout the world, nor is it stated why one should be protected and a dozen unprotected.

Vegetarian Restaurants.—I wish, with you, that gardens were multiplied; but ten years' experience of vegetarianism shows me that, even as things stand, townspeople have little to complain of. For the last five years I have had a garden, but it would be far dearer to me to raise vegetables and fruit than to buy them. I find everything in the market except German Peas, the *Mange-tout* of the French. "G. A. S.," whom you quote, is so far right when he says that a single member of a family finds it difficult to live as a vegetarian at his family table. Naturally many cooks murmur at having to dress (what they call) "a separate dinner" for him; yet possibly a deeper annoyance to them is that he is sure to be far more particular that his vegetables are well dressed than flesh-eaters are; at most only one additional dish is needed. Notoriously a majority of English cooks send up many vegetables but half done, or mixed with unpleasant water. When I became a vegetarian, my present cook, already verged on the age of seventy, and certainly much wedded to her old ways, always cooked vegetables well, and to that I attribute it that from the first day until now I have never had any difficulty with her. It is as easy to make a vegetarian pie as a beef-steak pie; to make a savoury Rice, Barley, Oat, or Wheat pudding as a sweet pudding. Even to cook an omelet nicely (which needs care) I am assured is not more laborious than to make a Rice pudding, and is easier than a rich Plum pudding; difficulties in this way are only imaginary. As fast as people demand more vegetable gardens will increase. Meanwhile, my vegetarian diet feeds me, not only better than flesh, as my health attests, but the oat is less than servants' board wages amount to. But let vegetarian restaurants multiply ever so much, the expense of the house, the tablecloths and other appurtenances, and the attendance, must be double that of the

viands, if all is clean and at all acceptable; hence it will always be cheaper to feed at the family table. "G. A. S." must try to convert his messmates; a vegetarian club seems to be a step towards vegetarian restaurants.—F. W. NEWMAN, *President of Manchester Vegetarian Society*.

Eryngium pandanifolium.—This fine tropical and umbelliferous plant is thriving admirably in the neighbourhood of London. A specimen now in Professor Owen's garden at Sheen has thrown up flowering-stems over 12 ft. high, and forms one of the most striking objects one could see in a garden. The lower or leafy portion resembles the rosette of a vigorous and graceful tropical Pandanus.

The Atlas Nut (Corylus algeriensis).—This large and handsome Nut has been sent to us by Messrs. Rivers, in the form of branches full of cob-like Nuts. It seems a fine kind.

A Friend in the Tropics.—Those who may have missed Mr. Burbidge's many sketches and notes in THE GARDEN for some time back, will be interested to hear from him in the Indian Archipelago, where he has now a new and fertile field for observation. Few travellers, we imagine, ever left England whose training and knowledge better fitted them for recording impressions interesting to horticulturists. He is collecting plants for Messrs. Veitch, of Chelsea.

"**Arboretum Segrezianum**," by A. Lavelle, is a volume containing a classified list of trees and shrubs cultivated at Segrez (Seine-et-Oise), in the fine collection at various times alluded to in THE GARDEN. We hope soon to notice it at greater length.

Crinum giganteum.—Specimens of this lovely Amaryllidaceous plant are now finely in bloom in Messrs. Veitch's Nursery at Chelsea, where each flower-spike is bearing four or five large Lily-like blossoms of the purest white, and beautifully scented. Though *Crinum* as a rule do not last long in bloom, they are, nevertheless, well worth attention on account of their easy culture and their effective character when in flower.—C. S.

Potatoes in Germany.—At a meeting of the Social Science Congress which took place the other day, Mr. Caird said—"The Potato crop is becoming more and more precarious. It is costly to grow, expensive in seed and manure, exhaustive of the land, and very liable to disease, and now possibly to the attacks of the Colorado Beetle. The extent planted has declined nearly one-fifth since 1871, while the imports of foreign Potatoes in the same time have risen from 43,000 to 300,000 tons. Germany is the great Potato-growing country, whence we can always draw by a moderate increase of price whatever quantity we require. The annual crop in that country is twice as great, both in quantity and per head of population, as that of either France or the United Kingdom, but it is not exported till the price rises above the rate which it yields when made into spirits."

The Tomato Crop.—The importance of this crop for marketing purposes has increased to a marvellous extent during the past few years, and market gardeners, who formerly devoted but little space to the culture of Tomatoes, now grow them by the acre. They are grown extensively on Mushroom ridges as well as in the open ground. The former plan as a rule gives the best results, inasmuch as the fruit ripens earlier, and the chances of disease through rain in autumn are consequently diminished. This year a great proportion of the crop, which has been generally good as regards quantity, has been completely spoiled by a disease similar to that which attacks the Potato; but, notwithstanding this, the markets have been, and are still, well supplied with Tomatoes of fair quality. Some growers have individually disposed of as many as 250 or 300 bushels per week.

Distribution of Plants.—We are requested to announce that the Commissioners of Her Majesty's Works and Public Buildings intend to distribute this autumn, among the working classes and the poor inhabitants of London, the surplus bedding out plants in Battersea, Hyde, the Regent's, and Victoria Parks, and in the Royal Gardens, Kew, and the Pleasure Garden, Hampton Court. If the clergy, school committees, and others interested will make application to the superintendent of the park nearest to their respective parishes, or to the director of the Royal Gardens, Kew, or the superintendent of Hampton Court Gardens, in the cases of persons residing in those neighbourhoods, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

Gardeners' Benevolent Institution.—We understand there will probably be a liberal addition to the pension list of this Institution, as will be seen by an advertisement in our columns to day. We have reason to believe that Mr. Cutler's visit to the Carlisle show, and other horticultural meetings, have had a very satisfactory result, as much so that the committee desire him, with a view of advocating the claims of the institution, to continue his visits to important shows in various parts of the country.

SELECT EDIBLE FUNGI.

At this, the Mushroom season, we have thought it desirable to publish figures of some of the more important edible fungi, as well as of the common Mushroom, for the benefit of fungus gatherers. Much valuable food is wasted from want of knowledge of what to gather and what to avoid, and the illustrations in question may serve as a help in this matter.

True Mushroom.—The question is frequently asked, are there any infallible rules for distinguishing the true Mushroom from all

Section of True Mushroom.

other fungi? and, if so, what are the crucial points of distinction? First, and foremost, the true Mushroom (*Agaricus campestris*) is invariably found amongst Grass in rich open pastures, and never on or about stumps, or in woods. Many cases of poisoning have occurred owing to the supposed Mushrooms being gathered from stumps or in woods; it is true there is a certain variety found in woods and woody places (*A. silvicola*); but, as far as amateurs are concerned, it is best left alone. A second very good point is the peculiar, intense

True Mushroom (*Agaricus campestris*).

purple-brown colour of the spores (which are analagons to seeds); the ripe and fully-matured Mushroom derives the intense purple-brown colour (almost black) of its gills from the presence of these innumerable coloured spores. To see these spores, and so become acquainted with the peculiar colour, remove the stem from a Mushroom, and lay the upper portion, with the gills lowermost, on a sheet of writing paper; in a few hours the spores will be deposited in a thick, dark, impalpable powder. Several dangerous species, at times mistaken for this Mushroom, have these spores amber-brown, or pale amber-brown in colour, and belong to *Pholiota* or *Hebeloma*. In the uppermost figure is shown a vertical section of the true Mushroom, which differs (when the colour of the spores is taken into consideration) from almost all other *Agarics*, and certainly from all

poisonous ones. One of the principal points to be observed is the distinct and perfect collar at C, quite encircling the stem, and the edge of cap at B, overlapping the gills; in some poisonous allies, as *A. ceruginosus* (generally found on and about stumps), this ring is reduced to a mere fringe, and the overlapping margin is absent, or reduced to a few mere white flecks or scales. Lastly, the gills never reach or touch the stem A, for, on inverting a Mushroom, a blank space will be seen all round the top of the stem where the gills are free from the stalk. There are innumerable varieties of the true Mushroom (and of the Horse Mushroom), but all are equally good for the table, sometimes the top is white and soft, like kid-leather; at other times it is dark-brown and scaly. Sometimes, on being cut or broken, the Mushroom changes colour to yellow, or even blood-red; at other times no change whatever takes place. But, observe, the Mushroom *always* grows in pastures; *always* has dark purple-brown spores; *always* has a perfect encircling clothy collar; and *always* gills which do not touch the stem, and a top with an overlapping edge.

Horse Mushroom (*Agaricus arvensis*).—This species is very nearly allied to the true Mushroom, and frequently grows with it, but it is coarser, and has not the delicious flavour. It is usually much larger, often attaining a very large size, and turning a brownish-

Horse Mushroom (*Agaricus arvensis*).

yellow as soon as broken or bruised. The top in good specimens is smooth, and snowy white; the gills are not the pure pink of the true Mushroom, but of a pale brownish-white, ultimately becoming brown-backed. It has a big, ragged floccose ring, and the pithy stem is inclined to be hollow. It is a species often exposed for sale in Covent Garden Market. When young and fresh, the Horse Mushroom is most desirable; it yields an abundant gravy, and the flesh is firm and delicious. It is a valuable plant when freshly gathered, but when stale it becomes tough and leathery, and without aroma or juice. Many country-folks readily distinguish the true from the Horse Mushroom, and show antipathy to the latter, although they are always willing to put it into the jar as one of the ingredients of ketchup.

True St. George's Mushroom (*Agaricus gambosus*).—The St. George's Mushroom cannot well be mistaken for any other. The fact of its appearance in spring, and growing so freely in rings, when so very few other funguses are to be found, is almost enough to distinguish it. It has, however, very distinctive characters in itself in the thickness of its pileus; the narrowness of its gills, which are very closely crowded together; and the solid bulging stem. It grows in rings, has a strong smell, and appears about St. George's Day (April 23), after the rains, which usually fall about the third week in April. It continues to appear for three or four weeks, according to the peculiarities of the season. It is usually to be found on hilly pastures in woodland districts. Pileus thick and fleshy, convex at first, often lobed, becoming undulated and irregular, expanding unequally; the margin more or less involute, and at first flocculose; from 3 in. to 4 in. across; of a light yellow colour in the centre, fading to almost opaque white at the edges; it is soft to the touch; more or less tuberculated, and often presenting cracks. Gills yellowish white, watery, narrow, emarginate, *i.e.*, annexed to the stem with a little tooth (see section in illustration). This *Agaric* is usually

nearly white, smooth, soft, and firm, like kid leather to the touch, and, as Berkeley has happily said, "in appearance it very closely resembles a cracknel biscuit." The best mode of cooking it, according to Dr. Badham, is either to mince or fricassee it with any sort of meat, or in a *vol-au-vent*, the flavour of which it greatly improves;

True St. George's Mushroom (*Agaricus gambosus*).

or simply prepared with salt, pepper, and a small piece of bacon, lard, or butter, to prevent burning, it constitutes of itself an excellent dish.

Parasol Agaric (*Agaricus procerus*).—There are but two other Agarics that at all resemble this, and both are edible. One about the same size is *Agaricus rachodes*; but it is not generally considered so good in flavour as *A. procerus*. Mrs. Hussey, however, says plainly, "If *Agaricus procerus* is the king of edible funguses, *Agaricus rachodes* is an excellent viceroy." The other is the *Agaricus excoriatus*, a very much smaller fungus, with a more slender habit, a shorter stem, and no true bulb at the base. This elegant little fungus is also good eating. Whenever an Agaric on a long stalk, enlarged at the base, presents a dry cuticle more or less scaly, a darker coloured umbonated top, a movable ring, and white gills, it must be *Agaricus procerus*—

Parasol Agaric (*Agaricus procerus*).

the Parasol Agaric, and it may be gathered and eaten without fear. When the whitish flesh of this Agaric is bruised it shows a light reddish colour. This is one of the best of the edible fungi, so commonly passed by as useless. The pileus is fleshy ovate when young, then campanulate, and afterwards expanded and umbonate (blunt pointed), from 3 in. to 7 in. across. Cuticle more or less brown, entire over the umbo, but torn into patches or scales, which become more and more separated as they approach the margin; flesh white;

gills unconnected with the stem, fixed to a collar on the pileus surrounding its top; ring persistent, loose on the stem; stem 6 in. or 8 in. high, tapering upwards from a Pear-like bulb at the root, hollow with a loose pith, whitish-brown, but more or less variegated with small and close-pressed scales. In broiling the Parasol Agaric remove the scales and stalks from the Agarics, and broil lightly over a clear fire on both sides for a few minutes; arrange them on a dish over fresh made, well-divided toast; sprinkle with pepper and salt, and put a small piece of butter on each; set before a brisk fire to melt the butter, and serve up quickly.

Brown Warty Agaric (*Agaricus rubescens*).—This is very common all through the summer and autumn months; indeed, one of the most abundant of Mushrooms, and it is one of those species that a person with the slightest powers of discrimination may distinguish accurately from others. Pileus convex, then expanded, cuticle brown, scattered over with warts, varying in size; margin striate; gills white, reaching the stem, and forming very fine decurrent lines upon it; ring entire, wide, and marked with striæ; stem often scaly, stuffed, becoming hollow, when old bulbous; volva obliterated. The whole plant has a tendency to turn to a sienna-red or rust colour. This is very distinctly shown some little time after it has been bruised. It may be toasted, boiled, or stewed in the ordinary way, Place the full-grown Agarics in water for ten minutes, then drain,

Brown Warty Agaric (*Agaricus rubescens*).

and, having removed the watery skin, fry with butter, pepper, and salt. The ketchup made from *Agaricus rubescens* is rich and good.

Orcelle or Vegetable Sweetbread (*Agaricus orcella*).—In this Mushroom the pileus is thin, irregular, depressed in the centre, lobed, with undulated borders, from 2 in. to 3 in. across. In colour clear white, sometimes tinted with pale brown on its prominences, and occasionally with a grey centre or even lightly zoned with grey. Its surface is soft and smooth to the touch, except in wet weather, when it becomes soft and sticky. The flesh is soft, colourless, and unchangeable. Gills crowded, decurrent, at first nearly white, then pinkish-grey, taking at length a light brown tint. Spores pale brown. Stem smooth, solid, short, decreasing in size; central when young, but becoming eccentric from the pileus growing irregularly. Odour pleasant, usually compared to that of fresh meal, but Dr. Badham and others think it resembles more closely the smell of a Cucumber or Syringa leaf.

Plum Mushroom (*Agaricus prunulus*).—There has been considerable confusion, writes Dr. Bull, between the two Agarics *orcella* and *prunulus*, some thinking that we have only *orcella* in England, and others only *prunulus*, and others again that they are both the same fungus, differing only in size. Dr. Badham and some others again confuse *prunulus* with *gambosus*, the fungus of early spring, and this has arisen from the French term "*mousseron*" being often applied to both these funguses; but they are so essentially different as not to be liable in any way to be mistaken for each other. *A. orcella* and *A. prunulus* are both placed together in the annexed illustration, so that their close alliance may be seen at a glance. Fries treats them as separate funguses, "in deference to ancient authority, since their differences are chiefly in degree." These differences are, nevertheless, so well marked, that they are kept separate here. *Orcella* is a

smaller and more delicate fungus than *prunulus*. It is thinner and less fleshy, more undulated in its borders, and has a lighter and more agreeable odour. *Orcella* grows in more open glades than *prunulus*; it is usually much whiter in colour, sometimes in high situations white and glazed as an egg-shell, or even pottery. *Orcella* grows more solitary than *prunulus*, in light, scattered groups, showing an inclination for the neighbourhood of Oak trees, and where it does grow it may be found year after year in the same place, but seldom more than two or three in a spot. In 1869, when *orcella* was pretty plentiful, *prunulus* was not to be found in the situations where it

1.—Orcelle or Vegetable Sweetbread (*Agaricus orcella*).
2.—Plum Mushroom (*Agaricus prunulus*).

grows usually most abundantly. *Prunulus* is the reverse of all this. It prefers more shaded places, is larger, more fleshy, and with a strong odour rather heavy and overpowering. It grows in greater quantities together, and not unfrequently in crowded rings from 4 ft. to 6 ft. in diameter. As edible funguses they should certainly be kept distinct. *Orcella* is light and pleasant in odour, and excellent in flavour; it is so delicate and tender as to be termed, not inaptly, "Vegetable Sweetbread." *Prunulus*, on the other hand, though always good, is to many people too strong in odour, and more coarse in taste. *Orcella* being usually found in small quantities, is best perhaps when broiled and served on hot toast. *Prunulus* will yield an abundance for broiling or stewing, or both.

Clouded Mushroom (*Agaricus nebularis*).—This is common in certain places, but rare near London. It comes up late in the

Clouded Mushroom (*Agaricus nebularis*).

autumn on dead leaves in moist places, principally on the borders of woods. When gathered, it has a wholesome and powerful odour; and when cooked, the firm and fragrant flesh has a particularly agreeable and pleasant taste. Pileus from 2½ in. to 5 in. across; at first

depresso-convex; when expanded, nearly flat or broadly subumbonate; never depressed; margin at first involute and pruinose; occasionally somewhat waved and lobed, but generally regular in form; smooth, viscid when moist, so that dead leaves adhere to it; grey, brown at the centre, paler towards the circumference. Flesh thick, white unchanging. Gills cream-colour, narrow, decurrent, close, their margins waved, unequal, generally simple. Stem from 2 in. to 4 in. long, from a quarter of an inch to 1 in. thick; incurved at the base; not rooting, but attaching by means of a floccose down round its lower portion and for one-third of its length, a large quantity of dead leaves, by which the plant is held erect; subequal, more or less marked with longitudinal pits, firm externally, within of a softer substance. This Mushroom requires but little cooking; a few minutes' broiling (*a la Maintenon* is best), with butter, pepper, and salt, is sufficient. It may also be delicately fried with bread crumbs, or stewed in white sauce. The flesh of this Mushroom is perhaps lighter of digestion than that of any other.

Fir-cone Mushroom (*Agaricus (Amanita) strobiliformis*).—This truly magnificent *Agaric* grows generally in Fir plantations, but may sometimes be found in grassy hedgerows under trees; though generally considered a somewhat rare *Agaric*, it is often abundant during the autumn months. It may be known by its almost pure white colour (slightly inclined to buff), its large patches on the pileus resembling in shape the scales of Fir cones, and its thick, solid, compact flesh and stem, and large, well developed annulus. It is closely allied to *Agaricus rubescens*, and the methods of cooking this species

Fir-cone Mushroom (*Agaricus (Amanita) strobiliformis*).

will well apply to *A. strobiliformis*. It may be toasted, boiled, or stewed in the ordinary way.

Lilac-stemmed Mushroom (*Agaricus (Tricholoma) personatus*).—This is one of the commonest and best of all British *Agarics*, and there is little fear of mistaking it, when its salient characters are once known. It grows everywhere abundantly in pastures and grassy places, generally late in the autumn, and appears sometimes in immense quantities after heavy rains; at these times its flesh becomes saturated with moisture, and unfit for the table. It is said to have been sold at one time in our markets under the name of "Blewits," but of late years it has never appeared. In colour it is throughout very pale brown, almost white, or pallid buff, with the exception of the upper part of stem, which is usually tinted with a pale but lively purple shade, hence its popular name of "Blewits," or "Blueits." The pileus is smooth, or greasy and bibulous, the stem solid, ringless, and slightly scaly at the purple apex; the gills have a tendency to separate from the stems, as shown at c (p. 324); hence Fries, the great Swedish botanist, some time since removed the plant to the *Lepista* section of *Paxillus*, under the name of *Paxillus personatus*, whilst Cooke, in his handbook, following a suggestion of Mr. Worthington Smith, elevates *Lepista* to a genus (on account of its white spores, as contrasted with the red spores of *Paxillus*) and describes one plant under the name of *Lepista personata*. *Agaricus personatus* is closely allied to *A. gambosus*, and the recipes for cooking the latter apply to the former, but care should be taken to gather the specimens in dry weather, and when not sodden with moisture.

Edible Boletus (*Boletus edulis*).—This is one of the safest and most delicious, and at the same time most abundant and long-con-

tinuing, of the British edible fungi. The first crop may be gathered soon after the rains of early summer, and the growth continues till the frosts of winter have fairly set in. There are about three dozen species of Boletus in this country, but *B. edulis* materially differs

Lilac-stemmed Mushroom (*Agaricus (Tricholoma) personatus*).

from all its allies; it is probable that most Boleti are either edible or harmless, but such species as *B. edulis* and *B. aestivalis* certainly stand in the first rank. This fungus has maintained a good reputation from time immemorial, and has been consumed as a delicacy in all countries of Europe for ages; not, however, in this country; but, thanks to Dr. Badham, Dr. Bull, and others, it is at last rapidly becoming a recognised article of diet with us. To distinguish it from other Boleti, the following points must be carefully noted, and when the fungus is once known, no other species will ever be mistaken for it:—It grows in woods; the cap is smooth and of a very pure and delicate shade of pale brown, often with an edge of a lighter shade, as shown in our illustration; the under surface of the top, instead

Edible Boletus (*Boletus edulis*).

of being furnished with gills like the Mushroom, has a soft, spongy substance, composed of innumerable pores or tubes (like the pipes of a miniature organ); this spongy substance is at first pure white, then sulphur coloured, at length sulphury-green; the stem is stout and fleshy, pale brown in colour, and furnished with an exquisite minute reticulation or network round the upper portion; the flesh, when broken, is snow-white, like crumbs of bread, and the taste agreeable and nutty. It should not be gathered for the table when too young, when the tubes are white, or when too old, when the tubes are green and the plant flabby; neither should specimens be used that are mildewed or soddened with rain. They are in the best condition when the tubes

are sulphur-yellow. *B. edulis* grows to a great size, being often many inches across; it is frequently very irregular and uncomely in shape, with a swollen stem, and at times varies considerably in the colour of its cushioned-shaped top, which at times will vary from delicate fawn to dark brown. One of its best points of distinction resides in the beautiful white network round the apex of the stem. A good and simple plan of cooking is merely to remove the tubes and stem, and cut the top into slices, and fry with butter, &c., like the common Mushroom; or lay the pieces in a dish, with butter, pepper, and salt; cover the dish closely, and bake for half an hour. A few species of Boleti are either highly coloured, acrid when raw, or change to bright blue when cut or broken. Such as these, and all having the tube surface red, should be discarded.

Chantarelle (*Cantharellus cibarius*).—This grows sometimes sporadically, sometimes in circles or segments of a circle, and may be found from June to October. At first it assumes the shape of a minute cone; next, in consequence of the rolling-in of the margin, the pileus is almost spherical, but as this unfolds it becomes hemispherical, then flat, and at length irregular and depressed. When young its stalk is tough, white, and solid; but as it grows this becomes hollow and presently changes to yellow; tapering below, it is effused into the substance of the pileus, which is of the same colour with it. The pileus is lobed, and irregular in shape; its margin at first deeply involute, afterwards when expanded, wavy. The veins or plaits are thick, sub-distant, much sinuated, running some way down the stalk. The flesh is white, fibrous, dense, "having

The Chantarelle (*Cantharellus cibarius*).

the odour of Apricots" (Purton) or of "Plums" (Vitt.). The colour yellow, like that of the yolk of eggs, is deeper on the under surface; when raw it has the pungent taste of pepper; the spores, which are elliptic, are of a pallid ochre colour (Vitt.). "This fungus," observes Vittadini, "being rather dry and tough by nature, requires a considerable quantity of fluid sauce to cook it properly." "The common people in Italy," says Dr. Badham, "dry or pickle, or keep it in oil for winter use. Perhaps the best ways of dressing the Chantarelle are to stew or mince it by itself, or to combine it with meat or with other funguses. It requires to be gently stewed and a long time to make it tender; but by soaking it in milk the night before, less cooking will be requisite."

Orange-Milk Mushroom (*Lactarius deliciosus*).—There is no possibility of mistaking this fungus. It is the only one which has orange-red milk, and which turns green when bruised. These properties distinguish it at once from *Lactarius torminosus* or "necator," the only fungus which in any way resembles it. This acrid fungus (*Lactarius torminosus*) is somewhat similar in shape and size, and is also zoned; but the involute edges of the pileus are bearded with close hairs. It is of a much paler colour, and with gills of a dirty white. The milk, also, is white, acrid, and unchangeable in colour. The Orange-Milk Agaric chiefly affects the Scotch Fir-tree, and is generally to be found beneath the drip of the branches around the tree. It is also found in hedgerows occasionally, but is most abundant in plantations of Scotch Fir or Larch. Pileus smooth, fleshy, umbilicate, of a dull rufous orange, turning pallid from exposure to light and air, but zoned with concentric circles of a brighter hue; margin smooth, at first involute, and then becoming expanded; from 3 in. to 5 in. across. Flesh firm, full of orange-red milk, which turns

green on exposure to the air, as does any part of the plant when bruised. Gills decurrent, narrow, each dividing into two, three several times from the stem to the edge of the pileus; of a dull yellow by reflected light, but being translucent, the red milk shines brightly through them. Stem from 1 in. to 3 in. high, slightly bent and tapering downwards; solid, becoming more or less hollow with age; short hairs at the base; sometimes pitted (scrobiculate). The rich gravy it produces is its chief characteristic, and hence it commends itself to make a rich gravy sauce, or as an ingredient in soups.

Orange-milk Mushroom (*Lactarius deliciosus*).

It requires delicate cooking, for, though fleshy, it becomes tough if kept on the fire till the juice is exuded. Baking is perhaps the best process for this Agaric to pass through. It should be dressed when fresh and pulpy. It may be fried in slices, properly seasoned with butter, or bacon and gravy; and served up hot with sippets of toast.

Maned Agaric (*Coprinus comatus*).—This very elegant Agaric has also been called *Agaricus cylindricus*, Schæff; *A. typhoides*, Bull; *A. fimetarius*, Bolt. It is common throughout the summer and autumn months on road-sides, pastures, and waste places. It is extremely variable in size. Its general appearance is so distinct and striking, that it cannot possibly be mistaken for any other Agaric.

Maned Agaric (*Coprinus comatus*).

Pileus cylindrical, obtuse, campanulate, fleshy in the centre, but very thin towards the margin. The external surface is soon torn up into fleecy scales, with the exception of a cap at the top. Gills free, linear, and crowded, quite white when young, becoming rose-coloured. Stem of a pure white, 4 in. or 5 in. high, contracting at the top, and bulbous at the base, hollow, fibrillose, stuffed with a light cottony web. The bulb is solid and rooting, the ring movesable. The best and

simplest method of cooking it is to broil and serve on toast in the ordinary way. It may be added also with great advantage to steaks and made-dishes, to give flavour and gravy.

Vegetable Beefsteak (*Fistulina hepatica*).—Although the popular name of "liver-fungus" corresponds very well with the scientific name of this species, yet we consider the name of "Vegetable Beefsteak" (aptly given to it by Dr. Bull, of Hereford) so very much better, both as regards the shape of the fungus itself and its taste, too, that we prefer to keep it here as its popular name. The taste is exceedingly like beefsteak; but it must be confessed that a well-grown specimen more resembles a great tongue than either a lump of liver or steak; hence it is known in Italy as "*Lingua quer-cina*" or "*Lingua di Castagna*," and in France, "*Langue-de-bœuf*." This fungus, which resembles a great red tongue protruding from tree-stems, when once known can never be mistaken for any other species. It generally confines itself to old (and often prostrate) Oaks; but in Epping Forest it is not uncommon on the Beech. We have also seen it more than once on the Ash; and it has been observed on the Chestnut, Walnut, Willow, and other trees. We have tasted it from various habitats, but have never been able to detect the least difference in the flavour. Although such a large fungus, its growth is very rapid, soon appearing and again disappearing, on ancient trunks in the autumn. When cut, broken, or bruised, it distils a copious red juice like beef gravy. "When grilled," says Dr. Badham, "it is scarcely to be distinguished from broiled meat;" and Berkeley describes it as "one of the best things he ever ate, when prepared by

Vegetable Beefsteak (*Fistulina hepatica*).

a skilful cook." There is a very slightly acid flavour in the fungus when cooked, which adds considerable piquancy to the dish; it is extremely tender, succulent, and juicy. Of course, it should be gathered when quite young, fresh, and clean, and at once prepared for the table in the following manner:—Wash and dry, and cut into quarter-inch slices half-an-inch wide, soak in scalding water for five minutes, and stew with butter and herbs; yolk of egg may then be added, and serve hot; or simply stew with a good steak, adding a scallion and Parsley, salt, and pepper. For *Fistulina* ketchup, slice and macerate with salt, and, says Mrs. Hussey, serve "with a little lemon juice and minced Shallots, with a broiled rumpsteak."

Fairy-ring Champignon (*Marasmius oreades*).—Champignon is a name applied in France to edible fungi in general, or, if specifically, it indicates more especially the common Mushroom. The subject of our illustration is an early species, seldom produced in any quantity late in the season. When of a good size, and quickly grown, it is perhaps the best of all Agarics. It is so common in some districts, that bushels of it may be gathered in a day, and even on our lawns it is by no means uncommon, where, as well as in old pastures, it generally appears in broad, brown patches, either circular or forming portions of a circle. *M. urens*, the only species with which it can be confounded, the most acrid of all allied funguses, usually grows in woods, though sometimes in the fairy-ring. However, its flat top and narrow crowded gills cause it to be readily distinguished anywhere. Pileus smooth, fleshy, convex, subumbonate, generally more or less compressed, tough, coriaceous, elastic, wrinkled; when water-soaked, brown; when dry, of a buff or green colour, the umbo often re-

maining red-brown, as if scorched; gills free, distant, ventricose, of the same tint as the pileus, but paler; stem equal, solid, twisted, very tough and fibrous, of a pale silky-white colour. When cut in small pieces and seasoned, it makes an excellent addition to stews, hashes, or fried meats, but it should only be added a few minutes

Fairy-ring Champignon (*Marasmius oreades*).

before serving, as the aroma is dissipated by over cooking. It is the Mushroom used in the French *à la mode* beef shops in London.

Hedgehog (or Spine-bearing) Mushroom (*Hydnum repandum*).—There is no possibility of mistaking this Mushroom; when once seen it is always to be remembered. Its awl-shaped spines are crowded beneath the pileus; its size and colour are most marked; it closely resembles a lightly-baked cracknel biscuit in colour. "This fungus," says Badham, "occurs principally in woods, and especially in those of Pine and Oak; sometimes solitary, but more frequently in company and in rings." Pileus smooth, irregular in shape, depressed in centre, more or less lobed, and generally placed

The Hedgehog (or Spine-bearing) Mushroom (*Hydnum repandum*).

irregularly on the stem (eccentric); of a pale buff or cinnamon colour; from 2 in. to 5 in. in diameter. Flesh firm and white; when bruised it turns slightly brown. Spines crowded, awl-shaped, slanting, soft, and brittle, varying in size and length, and of a faint cinnamon tint. Stem white, short, solid, crooked, and often lateral. When well stewed it is an excellent dish, with a slight flavour of oysters. Cut the Mushrooms in pieces and steep them for twenty minutes in warm water; then place them in a pan with butter, pepper, salt, and Parsley; add beef or other gravy, and simmer for an hour.

Giant Puff-Ball (*Lycoperdon giganteum*).—Dr. Bull, of Hereford, states that the Puff-Balls are edible when young; and we consider the Giant Puff-Ball to have a great pre-eminence over all the others. It may be at once known by its great size, commonly measuring 1 ft. in diameter, its snow-white colour, and its texture like the finest white kid leather, with the skin frequently breaking into minute areas. It grows with great rapidity, and is common in rich pastures, gardens, and orchards, usually irregularly scattered, but occasionally growing in enormous fairy-rings. When the interior of the Puff-Ball is perfectly white and firm, it is fit for the table. We consider the allied species not worth experimenting upon. It generally happens that a single good-sized Puff-Ball is far too large for a single day's consumption. Should the plant, therefore, be found growing in a garden or any similarly convenient place, the better plan is to cut a few slices off the living plant, and let the bulk remain growing. By these means, as Vittadini says, one may have a *frittura* every day in the week. The best authorities agree in stating that no French omelette is half so good in richness and delicacy of

Giant Puff-Ball (*Lycoperdon giganteum*).

flavour as the Puff-Ball omelette. Dr. Curtis, of South Carolina, calls it the "South Down" of Mushrooms, and says, "it has a delicacy of flavour superior to any omelette ever eaten." Cut slices a quarter of an inch thick, and fry with butter; then spread over them Raspberry jam or jelly, or any similar sweet, and serve hot. For fritters, cut slices half-an-inch thick; dip in yolk of egg; sprinkle with pepper, salt, and sweet herbs; fry in fresh butter, and serve hot. The Giant Puff-Ball is one of the lightest, most digestible, and delicious of all fungi.

Viscid White Mushroom (*Hygrophorus virgineus*).—This species, exquisite in form and flavour, is one of the prettiest ornaments of our lawns, downs, and short pastures at the fall of the year. In these situations it may be found in every part of the

Viscid White Mushroom (*Hygrophorus virgineus*).

kingdom. It is essentially waxy, and feels and looks precisely as if made of the purest virgin wax. The stem is firm, stuffed, and attenuated, and gills singularly distant from each other; it changes colour a little when getting old, at which time it is unfit for culinary purposes. A batch of fresh specimens, broiled or stewed with taste and care, will prove agreeable, succulent, and flavorful eating, and may sometimes be obtained when other species are not forthcoming. Several allied species enjoy the reputation of being esculent, notably

H. nivens; and report speaks favourably of *H. psittacinus*—a highly ornamental yellow species, with a green stem, sometimes common enough in rich pastures (and said to be very suspicious). Pileus fleshy, convexo-plane, obtuse, moist, at length areolato-rimose; stem stuffed, firm, short, attenuated at the base; gills decurrent, distant, rather thick.

Hygrophorus pratensis is very common on downs and short pastures. Pileus tawny or deep buff, sometimes nearly white. Probably esculent. Pileus convexo-plane, then turbinate, smooth,

Hygrophorus pratensis.

moist; disk compact, gibbous; margin thin; stem stuffed, even, attenuated downwards; gills deeply decurrent, arcuate, thick, distant.

Morel (*Morchella esculenta*).—This, on account of its nutritive qualities, its fine aroma, and its delicacy of flavour, is entitled to rank high as an article of diet. It grows wild in woods, chiefly Pine woods, preferring a sandy soil. Morels may be quickly and satisfac-

The Morel (*Morchella esculenta*).

torily dried without losing any of their aroma; the plan adopted is to attach them by their stalks to a string, and hang them up in some airy place. In this way they may be preserved until the new crop makes its appearance.

Mushroom Ketchup.—Place Agarics of as large a size as you can procure (not worm eaten), layer by layer in a deep pan, sprinkling each layer as it is put in with a little salt; the next day stir them up several times so as to mash and extract their juice. On the third day strain off the liquor, measure, and boil for ten minutes, and then to every pint of the liquor add $\frac{1}{2}$ oz. of black pepper, $\frac{1}{4}$ oz. of bruised Ginger root, a blade of Mace, a Clove or two, and a teaspoonful of Mustard seed; boil again for half an hour, put in two or three Bay leaves, and set aside till quite cold; pass through a strainer and bottle, cork well, and dip the ends in resin. A very little Chili vinegar is an improvement, and some add a glass of port wine or a glass of strong ale to every bottle. Care should be taken that the spice is not added so abundantly as to overpower the true flavour of the Mushrooms.

The Vine in London.—We noticed lately a handsome wreath of Vine foliage around the inside of a window near Portland Place. The plant grew in a pot, and the leaves had assumed their rich autumn hues.

SOME TEACHINGS OF THE PAST AND PRESENT SEASONS.

VEGETABLES of all kinds have been wonderfully fine this year, even Cauliflowers, which in some soils are often very inferior. Throughout August and September they have been this year exceptionally good. This is due to the abundant rains and the cool atmosphere which generally accompanies such weather. In many gardens last year at this time everything in the way of vegetables had been so stunted and dwarfed by drought, that the supply of Cabbages even had fallen off. The chief lesson to be learned from a study of this contrast is, that it is impossible to grow good vegetables in a dry season without some better means of obtaining and supplying moisture than are commonly met with at present. No doubt better cultivation, greater depth of soil, and a more frequent stirring of the surface with hoe and fork will do much to mitigate the effects of severe drought; but where it is possible to obtain a good supply of water for irrigating purposes, better crops would certainly be obtained. Wherever there is a pond on a higher level, a pipe laid from it through the gardens would give not only a good supply of water, but also the necessary pressure for its distribution; and in such cases the outlay, in proportion to the benefits derived, would be so small, that scarcely any valid excuse can be urged for not adopting it. A small hydraulic ram by the side of a running stream or river, where the necessary weight of water could be dammed up, and where the waste water could get away on a lower level, would insure an ample supply. By these and similar means the water that now finds its way through the drains and watercourses to the rivers, and finally to the sea, might be arrested in its course and passed through the parched soil again and again. And not only is this feasible, but it would also pay; in fact, it never does pay to do things grudgingly, or half-do them; and a good supply of water and a ready means of applying it is one of the greatest essentials in gardening, not only in one department, but in all. Fruit trees, especially wall trees, do not get half enough water in a dry season. I know a case in point that often comes under my own observation. In the garden I am referring to there are two walls covered with Peach trees. One is within a few yards of a supply of water, and the other some distance off. In the one case it was possible during the drought of last summer to give the trees a fairly liberal supply of water, but in the other it was not; and the result is the trees that were well watered during the drought have carried a good crop of fruit, whilst, with one or two exceptions, the crop on the other wall was a scanty one. The inference I draw is this, that a proper supply of food during the growing season is of as much, or indeed of more, importance to the building up of wood that will produce strong healthy blossoms, than the question of its maturation—important though most fruit growers admit this to be. Vegetable physiologists tell us that plants and trees absorb or imbibe their food either in a liquid or gaseous form; and if a sudden period of severe drought sets in, when the plants are in the midst of their growth, a check follows, more or less intense according to its duration and severity. The summer of 1876, or rather I should say the month of July and the first days of August, were excellent for the intensity of their heat and drought; but where water could not be freely given and mulching applied, the growth of all things came to a sudden standstill. Then again, when the change came there was a long time of warm, damp weather, which kept everything in a state of unnatural excitement till long after the usual period for the leaves to fall. Although the blossoms of all kinds of fruit trees last spring were most abundant, it was evident to those who took the trouble to look at things closely, that they were generally small, weakly, and ill-formed, giving clear evidence of lack of nutriment at some period during their formation; and, after all, what is termed ripening or maturation is only a continuation of the building-up process and of the growth. If its early progress has been stunted and starved from want of proper and sufficient nutriment, the whole economy of the tree is thrown out of gear for that season at least. Examining closely into the condition of the fruit trees generally, there is, I think, a good prospect for a fair return next year. The trees have had a favourable time for making their growth, and we are now getting bright, breezy, ripening weather, that will plump up the buds, and mellow the foliage in a steady, regular manner, which will tell its own tale next spring.

E. HOBDAV.

Trumpet Creeper (*Tecoma radicans sanguinea præcox*).—Among the hardy climbers that deserve high rank are the Bignonias, or, more properly, Tecomas. Their rapid growing, woody stems, bright foliage, and richly coloured flowers have acquired a well-deserved reputation for beauty and practical qualities; but their very vigour, a good trait in itself, may become a nuisance unless checked and trained by systematic pruning. All species of *Tecoma* possess

both beauty and vigour, but in the quality of hardiness a decided distinction should be made. They come from all parts of the globe, and their habits vary accordingly; but my object at present is to notice only one variety of a certain hardy species. *T. radicans* is the hardiest and best known of all, and is only surpassed by *grandiflora*, because of its grander and more open flowers; in hardiness, the latter is decidedly inferior. *T. radicans* shows a bright red colour, and a narrow, straight form of the trumpet-shaped corolla, quite peculiar and distinctive. In date of blooming it differs but little from *T. grandiflora*, and otherwise comports itself like a near relative. There is, however, a variety of *radicans* called *sanguinea præcox*, the superior qualities of which have received slight recognition. Several nurseries in this country offer in their catalogues a variety of *radicans* variously termed *sanguinea*, *atrosanguinea*, and *coccinea*. I suppose this to be the same as the one to which I refer, although our name comes from Belgium. Garden varieties are frequently somewhat mixed, and botanists give but little attention to the adjustment of the names of these minor forms. I select the Belgian name as more descriptive, and hence much better, especially as those of our catalogues fail to mark two distinctive peculiarities of the climber in question—namely, that it excels all others alike in early blooming and rich colour. While *grandiflora* and *radicans* bloom in August, *sanguinea præcox* commences to display its deep red flowers early in July. This extension of the season wherein we may look for flowers on the various species of climbers, is of much importance to those wishing to increase the number of floral effects on their lawns at any given period, especially when that period is not prolific of flowers, as is the case in July. The lover of plants will thus find the study and employment of some apparently insignificant variety productive of most agreeable results.—SAMUEL PARSONS, in *Country Gentleman*. [The early variety mentioned above would probably be more valuable than the older forms in our gardens.]

Effects of the Late September Frosts.—

The sharp frosts which we had on the 23rd and 25th ults. have been productive of a large amount of damage to tender vegetables—especially Marrows and Runner Beans. The first frost, although very white, did little harm, but the latter one succeeding a very warm, sunny day, literally destroyed the Runner Beans in all directions, and cut short their productiveness for the rest of the season; although they were so full of growth and fruit that market gardeners were looking forward to several further good pickings. Marrows also were injured beyond recovery, many good fruit fit to eat having been spoiled. Here, among tender flowers, Balsams have suffered most, although not killed, and it is probable with a continuance of mild weather they will still mature seed. Curiously enough such tender plants as *Tropæolums* are scarcely injured, and Marigolds are also but little touched. The African and dwarf French kinds are a blaze of bloom, and show how very effective they are as autumn border plants. Fall grown plants of the dwarf section are about 12 in. in height, from 18 in. to 20 in. in diameter, and literally covered with large double flowers of various hues and markings. Tomatoes on walls and fences are but slightly injured by frost, but they are showing here and there evidences of the same disease that effects the Potato: the best remedy for which is planting out good strong plants as early as it is safe to do in the spring.—A. D., *Bedfont*.

Clethra alnifolia.—This sweet and graceful shrub is most valuable for flowering now, when flowering shrubs are so rare. It is a shrub that inhabits moist places in North America, is quite hardy, and too seldom seen in our gardens.

PLATE XCIV.

RIGID-LEAVED YUCCA.

(*Y. TRECULEANA*).

WE have treated so fully of Yuccas in previous numbers of THE GARDEN, that only the very remarkable merit of this fine, hardy species can justify our illustrating it. As regards habit, apart from the flowers, we believe it to be the most stately hardy plant introduced to our gardens for many years. Those who have seen the specimen, which for several years has grown in the little square garden in the Royal Exotic Nursery at Chelsea, will probably heartily agree with the above estimate of this plant. It was discovered and collected by Mr. Trecul, who travelled in Texas during the years 1848 and 1849, under the auspices of the French Government. It was introduced by this traveller into French gardens, and M. Carrière briefly described it in the "*Revue Horticole*," naming it after its discoverer; but at that date—1858—its flowers were unknown. Its foliage, however, is so handsome that M. Carrière was quite justified in giving it a name without waiting for it to produce flowers. Writing at that time he says:—

"If not the handsomest of the genus, it has at least no rival among the stemless species." It has proved to be not a stemless species, but one of the tallest of the genus. In 1859 it flowered in the open air at Charenton, in France, where it proved perfectly hardy. Vigorous young plants bore rigid leaves between 4 ft. and 5 ft. long, and the inflorescence of the plant figured was about 4 ft. long; but it had previously been imported into this country by Mr. Wilson Saunders, with whom it flowered at Reigate in 1860. The late Sir William Hooker, not being aware of M. Carrière's publication of the species, gave it the name of *Yucca canaliculata*, in allusion to the deeply channelled leaves; but this character is not so pronounced in older cultivated plants, though Dr. Englemann gives it,

Rigid-leaved Yucca (*Y. Treculeana*).

in his notes on the genus, as common to the wild specimens. I may say here that I am indebted to Dr. Englemann's notes for the bulk of what follows. Trunk tall, branching; leaves very long and very rigid, deeply concave-channelled, margin tinged with brown or reddish-brown, minutely toothed or entire, at length slightly filamentose, spiny-pointed, rough on the under surface; panicle very dense, and nearly sessile, the lower bracts large, ovate, or ovate-lanceolate, furnished with sharp, woody points, whitish in the wild specimens, the upper ones white. In its native country this species has a trunk 6 ft. to 15 ft. high, or sometimes from 20 ft. to 25 ft. high, and 1 ft. in diameter, terminating in several branches, each one bearing a crown of long, rigid leaves, and often a panicle (2 ft. to 4 ft. long) of something like 500 flowers. Leaves longer than in any other species, $2\frac{1}{2}$ ft. to $4\frac{1}{2}$ ft. long, 2 in. to $3\frac{1}{2}$ in. wide when flattened out, deeply channelled, and quite semi-circular in section. The short peduncle or scape of the inflorescence is 1 in. to 2 in. in diameter, and the bracts very large and conspicuous in the wild specimens, being 4 in. or 5 in. long, and 1 in. to 3 in. wide, and always white or whitish. The flowers vary from 2 in. to over 4 in. in expansion, and are remarkable for the taper-pointed segments. The fruit is a pulpy cylindric, or rather indistinctly six-sided, somewhat sulcate and three-lobed,

RIGID YUCCA (Y. TRECULEANA).

strongly-beaked berry, 3 in. to 4 in. long, and about 1 in. thick. It is of a bitter-sweetish taste, and much relished by the Indians, who prepare it by roasting and removing the acrid rind. Judging from the descriptions of it, both in a living and dried state, and what I have seen of young plants, there is no doubt this is one of the finest species of the genus in cultivation, or, indeed, in existence. As to its hardiness, I am not able to say that it has been fully proved; and from the position of its native country, it is not likely to be perfectly hardy in the climate of London, though it may withstand our ordinary winters. Mr. Saunders treated it as a greenhouse plant, and the specimens I have seen in the open air were protected during the winter. It is a native of Texas, from the Matagorda Bay and the Brazos and Guadalupe rivers, south and south-westward into Mexico, as far as Saltillo, Parras, and Chihuahua, on the sea beach and in the interior, on the gravelly, overflowed banks of streams, and on the stony declivities of their slopes, flowering in April and May. It has been collected in the different localities named by Lindheimer and Drs. Wislizenus and Gregg.

W. B. HEMSLEY.

Tritoma Macowani.
—Mr. A. Dean has, in a contemporary journal, under the heading of "Tritonia" Macowani, criticised the plate we published of this valuable plant, which we believe we were the first to illustrate. "A recent figure of the flower," he says, "gives a very poor idea of the size of its spike and its form and beauty, as in the plate the flower is represented almost as an inverted cone, whereas it is really the reverse, and differs but slightly from the spikes of that well-known kind, 'Tritonia' Uvaria." The plate in question, however, is not an untrue representation of the plant, which sometimes assumes the form shown in the figure late in the season. When a new plant first flowers it is not always possible to secure blooms in the best state for illustration. Ours was drawn last year, and the drawing is a perfectly faithful representation of what the introducer (Mr. Green) sent us. We felt pleasure in popularising such a remarkably good plant, and did it much better than new plants are generally done.

Sandersonia aurantiaca.—This is a great rarity and a very desirable plant. It is easily grown, but wants attention. When in a dormant state it ought to be kept beneath a greenhouse shelf, and water must be carefully withheld.—MAX LEICHTLIN.

Mignonette the Year Round.—In order to get a constant supply of Mignonette, seeds should be sown at least three times in the year—early in spring for a summer bloom, at Midsummer for an autumn and early winter cutting, and early in September, in pots, for a supply early in spring; of course the latter must be grown in frames or in a cool house, but the value of a dozen pots or so of well-grown Mignonette can hardly be over-estimated. The white-flowered kinds are the best, as the colour is much more pleasing than that of the red-flowered varieties.—D.

THE INDOOR GARDEN.

BIRTHWORTS (ARISTOLOCHIAS).

THE genus *Aristolochia* is a very large one, being represented by about 200 species, of which by far the greater number come from Tropical America. In North America, Europe, and India a few are found, and one, *A. indica*, is common to the latter country and Australia. Of late years some extraordinary species have been discovered in Tropical Africa, one of which is described below. Botanically the genus is of very great interest, but from a gardening point of view (considering its size), it is not of great importance. Many of these plants attain too great a size to be cultivated in

any but large houses, and the generally dingy colour of their flowers, together with (in many instances) their disagreeable odour, does not recommend them to the general horticultural public. We now give a list of a few select species worthy of being more widely known, with notes respecting the particular requirements of each. We have selected them from different sections of the genus, so that any one wishing to know more of these peculiar plants can choose them with flowers of very dissimilar forms.

The Virginian Birthwort (*Aristolochia serpentaria*).—A perennial herb with a short horizontal rhizome. The flowering stems are about 1 ft. in height; the entire, minutely-pubescent leaves are from 2 in. to 3 in. long, usually ovate; the solitary flowers are a little less than 1 in. in length, and are borne on rather long, flexuose stalks; the perianth is tubular, of a dark brownish-purple colour. This species, which flowers in June and July, and whose singular blossoms are more or less buried in the loose soil and dead leaves near the root, was one of the first introduced into this country, and yet it is very rarely met with. According to Aiton's "Hortus Kewensis," it was cultivated as early as

1632. In the United States it grows in moist fertile woods. At one time it was of great repute as a cure for the bites of venomous serpents, as may be inferred from its common names Snakeroot, Viperine, and Colubrine, but in such cases it is no longer regarded as of any remedial value. It is perfectly hardy, but requires a moist shady position.

The Fringed Birthwort (*A. fimbriata*).—The reniform leaves of this plant are characterised by the nerves being surrounded on the upper surface by whitish zones, this coloration being due to the presence of a film of air under the epidermis. They are quite glabrous, glaucous underneath. The outside of the perianth is greenish, interior brown-purple crossed with greenish veins. The half-climbing stems grow from 1 ft. to 2 ft. high, and the flowers are produced in July and August. Being a native of Brazil, &c., this does best in a warm house.

The Broad-leaved Birthwort (*A. Siphon*), is probably in this

The Fringed Birthwort (*A. fimbriata*).

country the best known of all the genus. It has deciduous, very large, glabrescent leaves, and small, yellow and purple-striped flowers. It is from North America, and in its wild state is often found climbing to the tops of high trees. For quickly covering unsightly objects, this is invaluable, and trelliswork, arbours, &c., can be made almost impervious to the summer rain by training over them the long branches of this vigorous climber. From the syphon-shaped flower it has received its Latin name, as also the English ones, Pipe Vine and Dutchman's Pipe.

The Snake-killing Birthwort (*A. anguicida*).—A climbing plant with long, slender, twining stems, and distant, entire leaves on rather long, slender petioles. The flowers in shape are somewhat like those of the European *A. Clematitis*, and are borne singly on peduncles nearly as long as the leaves. The base of the perianth is inflated, globose, nearly white, the rest of tube funnel-shaped, white, netted and spotted with brown. The natives of South America employ this just as the *A. serpentaria* is used in North America, for the cure of snake bites. Jacquin assures us that the odour of the root has the faculty of driving away serpents when they approach this plant, and that the juice applied to the recent bite of a serpent, or taken internally, infallibly cures the patient. Ordinary stove treatment will suit this species.

The Three-tailed Birthwort (*A. tricandata*).—An arborescent evergreen shrub with jointed branches swollen at the nodes. The deep green leaves are acuminate, from 5 in. to 8 in. long. The flowers, which are produced in August, are of a maroon-red colour outside and very dark purple-brown inside, and (as seen in the drawing)

Three-tailed Birthwort (*A. tricandata*).

the lower margin is split into three diverging subulate tails, which attain a length of 4 in., and are of the same colour as the outside of the perianth. Ghiesbreght discovered this plant in the forest of Chiapas in the extreme east of Mexico, and sent it to Verschaffelt, of Ghent. It requires stove temperature and will flower well in a small state. This species is nearly or altogether scentless.

The Bird's-head Birthwort (*A. ornithocephala*).—A large, climbing Brazilian shrub, with cordate-reniform leaves. The large perianth is a dingy whitish-yellow, marked with dark purple reticulations; the inflated tube and upper lip bear a striking resemblance to a bird's head, whence the specific name. This is much too large for pot culture; where it can be planted out in a warm house, as it is in the Palm-house at Kew, it will soon clothe pillars or rafters, and produce abundantly its peculiar flowers.

The Large-flowered Birthwort (*A. grandiflora*).—This species, figured and described long ago in the "Botanical Magazine," seems to have been lost to English gardens. Until the recent introduction of an African species, *A. Goldiana*, the flower of this plant was often quoted as next, in point of size, to the gigantic *Rafflesia Arnoldi*, which is the largest of known flowers. Like that, it possesses a disgusting odour, and the general tone of colour, too, is the same. The young buds are much bent, and have the appearance of the head and beak of a pelican when that bird is at rest. The

expanded limb of the perianth is terminated by a tail sometimes more than 18 in. in length. Dr. Lunan relates in his "Flore des Antilles" that a whole herd of swine were poisoned by eating the roots and young leaves of this plant. From this it derives its English name, Poison Hog meat. Mr. Myers was often led to compare the large, flaccid blossoms on the bushes to coloured pocket handkerchiefs laid out to dry. It is a native of the West Indies and South America.

The Pale-nerved Birthwort (*A. lenconeura*).—This is a large-sized climber, with leathery, cordate, glabrous leaves, which are seven-nerved; nerves pale-coloured on a deep green ground. The dark chocolate-purple flowers are beautifully marked with pale yellow, and are produced in clusters from near the base of the old, corky trunk. This requires a warm temperature. It was introduced into Europe from New Granada a few years ago by Linden.

Duchartre's Birthwort (*A. Duchartrei*). is a very curious and showy species, and is allied to the last-named, though it produces much handsomer flowers. It was discovered on the Upper Amazons, in 1866, by M. Wallis, whilst collecting for Linden. It is a medium-sized climber, with a grooved, corky stem, and slender, annual branches; the flowers are produced from the old wood in short racemes; the perianth extends into a funnel-shaped limb (the mouth of which is 2½ in. to 3 in. in diameter), cream-coloured, with large, irregular, purple blotches. It will succeed well as a pot plant, provided the long branches be trained up a rafter, and water be rather sparingly administered during the season of rest.

The Common Birthwort (*A. Clematitis*).—This is sometimes met with on ruins, &c., from York southwards, but is not truly indigenous to this country. It is a perennial, growing from 1 ft. to 2½ ft. high; the leaves are from 3 in. to 6 in. in diameter, broadly cordate, glaucous beneath; the small yellow flowers grow in clusters of from four to eight, from June to September. It is an excellent plant for the wild garden. Philip Miller says "it is a terrible plant for creeping at the root . . . therefore it should be planted in some object part of the garden, and it will thrive in any soil and situation."

The Glaucous-leaved Birthwort (*A. glauca*). is a Mediterranean species, which will succeed in warm, sheltered spots in the open border, though it is perhaps safer to treat it as a wall or cool-house plant. Its glaucous leaves and dark purple flowers on long, nearly straight peduncles, render this a very distinct species.

The Rev. Hugh Goldie's Birthwort (*A. Goldiana*).—Two botanic gardens at least in this country can boast of possessing this extraordinary plant, viz., Kew and Glasgow. From the latter place material for the plate in the "Botanical Magazine" was procured. The flowers are enormous, the one figured having measured 26 in. by 11 in. The perianth externally is greenish, barred and veined with maroon-red; the inside is reddish-brown, marked and splashed with orange-yellow. It is named in honour of the Rev. Hugh Goldie, of the United Presbyterian Missionary Society, and living plants were first sent to Great Britain by him from the Old Calabar River. Gustav Mann also found it near Sierra Leone. Plenty of heat and moisture are required for this plant. G.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Large-flowered Jasmine in Autumn.—This is one of the most useful of indoor plants at this season. Its pure white, sweetly-scented flowers are invaluable in a cut state, and either in pots or planted out it flowers freely if liberally treated. It is now being largely grown by London florists for furnishing cut blooms during autumn and winter, and it is highly valued in the market. Plants of it, which are best obtained by means of layers, grow well in rich sandy loam and leaf-mould, or well-rotted manure, intermixed with a few pieces of peat to keep the compost open.—C. S.

Propagating Dracenas.—The most expeditious and surest way of rooting the tops of Dracenas is to insert them in bottles of water, in a temperature of 74°. In this manner they strike root in about ten days, and failure seems impossible. Old stems, too, cut into pieces of 1½ in. in length, and inserted in pots of sandy soil, soon make shoots and form roots, if plunged in a strong bottom heat. They should be potted singly before the roots of the different cuttings have had time to come in contact, or injury on division would be inevitable.—W. W. H.

Three Good Begonias.—The most perfect white-flowered Begonia yet raised is now in good condition in Messrs. Veitch's nursery at Chelsea. Even small plants of it in 4 in. pots bear numerous spikes of pearly-white blossoms, above a mass of stiff-green foliage resembling that of *B. Veitchii*. It is appropriately named Queen of the Whites. In Messrs. Lee's nursery, at Hammersmith, are two coloured kinds well worth notice, viz., *B. Boltoni*, a brilliant crimson-flowered kind of good substance; and *B. Dodwelli*, a rich salmon-coloured variety. These three kinds are very distinct and well deserve a place among indoor plants.—S.

THE GARDEN-CRAFT OF SHAKESPEARE.

(Concluded from p. 307).

IV.—GARDENING OPERATIONS.

A.—PRUNING, &c.

- (1) *Orlando*. But, poor old man, thou prunest a rotten tree,
That cannot so much as a blossom yield
In lieu of all thy pains and industry.
As You Like It, act ii., sc. 3.

- (2) *Gardener*. Ge, bind thou up yon dangling Apricocks,
Which, like unruly children, make their sire
Stoop with oppression of their prodigal weight:
Give some supportance to the bending twigs.
Go thou, and like an executioner,
Cut off the heads of too fast growing sprays,
That look too lefty in our commonwealth:
All must be even in our government.
You thus employ'd, I will go root away
The noisome weeds, which without profit suck
The soil's fertility from wholesome flowers.

O, what pity is it,
That he had not so trimm'd and dress'd his land
As we this garden! We at time of year
Do wound the bark, the skin of our fruit-trees,
Lest, being ever-proud in sap and blood,
With too much riches it confound itself:
Had he done so to great and growing men,
They might have lived to bear, and he to taste
Their fruits of duty. All superfluous branches
We lop away, that bearing boughs may live.
Had he done so, himself had borne the crown
Which waste of idle hours hath quite thrown down.
Richard II., act iii., sc. 4.

This most interesting passage would almost tempt us to say that Shakespeare was a gardener by profession; certainly no other passages that have been brought to prove his real profession are more minute than this. It proves him to have had practical experience in the work, and I think we may safely say that he was no mere 'prentice hand in the use of the pruning knife.

The art of pruning in his day was probably exactly like our own, as far as regarded fruit trees and ordinary garden work, but in one important particular the pruner's art of that day was a far more laborious art than it is now. The topiary art must have been the triumph of pruning, and when gardens were full of castles, monsters, beasts, birds, fishes, and men, all cut out of Box and Yew, and kept so exact that they boasted of being the "living representations" and "counterfeit presentments" of these various objects, the hands and head of the pruner could seldom have been idle; the pruning knife and scissors must have been in constant demand from the first day of the year to the last. The pruner of that day was, in fact, a sculptor, who carved his images out of Box and Yew instead of marble, so that in an amusing article in the "Guardian" for 1713 (No. 173), said to have been written by Pope, is a list of such sculptured objects for sale, and we are told that the "eminent town gardener had arrived to such perfection that he cuts family pieces of men, women, and children. Any ladies that please may have their own effigies in Myrtle, or their husbands in Hornbeam. He is a Puritan wag, and never fails when he shows his garden to repeat that passage in the Psalms, 'thy wife shall be as the fruitful Vine, and thy children as Olive branches about thy table.'"

B.—MANURING, &c.

- Constable*. And you shall find his vanities forespent
Were but the outside of the Roman Brutus
Covering discretion with a coat of felly,
As gardeners do with ordure hide those roots
That shall first spring and be most delicate.
Henry V., act i., sc. 4.

The only point that needs notice under this head is that the word "manure" in Shakespeare's time was not limited to its present modern meaning. In his day "manured land generally meant cultured land in opposition to wild and barren land. So Falstaff uses the word—

Hereof comes it that Prince Harry is valiant, for the cold blood he did naturally inherit of his father, he hath, like lean, sterile, and bare land, manured, husbanded, and tilled with excellent endeavour of drinking good and good store of fertile sherris, that he is become very hot and valiant. *2nd Henry IV.*, act iv., sc. 3.

And in the same way Iago says—

Either to have it (a garden) sterile with idleness or manured with industry.

Othello, act i., sc. 3.

Milton and many other writers used the word in this its original sense; and Johnson explains it "to cultivate by manual labour," according to its literal derivation. In one passage Shakespeare uses the word somewhat in the modern sense—

Carlisle. The blood of English shall manure the ground.

Richard II., act iv., sc. 1.

But generally he and the writers of that and the next century expressed the operation more simply and plainly, as "covering with ordure," or as in the English Bible, "I shall dig about it and dung it."

C.—GRAFTING.

- (1) *Buckingham*. Her royal stock graft with ignoble plants.

Richard III., act iii., sc. 7.

- (2) *Dauphin*. O Dieu vivant! shall a few sprays of us,
The emptying of our fathers' luxury,
Our scions, put in wild and savage stock,
Spirt up so suddenly into the clouds,
And overlook their grafters?

Henry V., act iii., sc. 5.

- (3) *King*. His plaintive words
He scattered not in ears, but grafted them,
To grow there and to bear.

All's Well That Ends Well, act i., sc. 2.

- (4) *Perdita*. The fairest flowers o' the season
Are our Carnations and streaked Gillyvors,
Which some call Nature's bastards: of that kind
Our rustic garden's barren; and I care not
To get slips of them.

Polixenes. Wherefore, gentle maiden,
Do you neglect them?

Perdita. For I have heard it said
There is an art which in their piedness shares
With great creating Nature.

Polixenes. Say there be;
Yet Nature is made better by no mean,
But Nature makes that mean: so, over that art
Which you say adds to Nature, is an art
That Nature makes. You see, sweet maid, we marry
A gentler scion to the wildest stock,
And make conceive a bark of baser kind
By bud of nobler race: this is an art
Which does mend Nature, change it rather, but
The art itself is Nature.

Perdita. So it is.

Polixenes. Then make your garden rich in Gillyvors,
And do not call them bastards.

Perdita. I'll not put
The dibble in the earth to set one slip of them.

Winter's Tale, act iv., sc. 4.

The various ways of propagating plants by grafts, cuttings, slips, and artificial impregnation (all mentioned in the above passages) as used in Shakespeare's day, seems to have been exactly like those of our own time, and so they need no further comment.

V.—GARDEN ENEMIES.

A.—WEEDS.

- (1) *Hamlet*. How weary, stale, flat, and unprofitable
Seems to me all the uses of this world!
Fye on it, oh fye! 'Tis an unweeded garden
That grows to seed; things rank and gross in Nature
Possess it merely.

Hamlet, act i., sc. 2.

- (2) *Titus*. Such withered herbs as these
Are meet for plucking up.

Titus Andronicus, act iii., sc. 1.

- (3) *York*. Grandam, one night, as we did sit at supper,
My Uncle Rivers talked how I did grow
More than my brother. "Ay," quoth my Uncle Glo'ster,
"Small herbs have grace, great weeds do grow apace;
And since, methinks, I would not grow so fast,
Because sweet flowers are slow, and weeds make haste.

Richard III., act ii., sc. 4.

- (4) *Queen Margaret*. Now 'tis the spring, and weeds are shallow-rooted;
Suffer them now, and they'll o'ergrow the garden,
And choke the herbs for want of husbandry.

2nd Henry VI., act iii., sc. 1.

- (5) Unruly blasts wait on the tender spring,
Unwholesome weeds take root with precious flowers.
Rape of Lucrece.
- (6) *King Henry.* Most subject is the fattest soil to weeds
2nd Henry IV., act iv., sc. 4.

The weeds of Shakespeare need no remark; they were the same as ours; and, in spite of our improved cultivation, our fields and gardens are probably as full of weeds as they were three centuries ago.

B.—BLIGHTS, FROSTS, &c.

- (1) *York.* Thus are my blossoms blasted in the bud,
And caterpillars eat my leaves away.
2nd Henry VI., act iii., sc. 1.
- (2) *Montague.* He is to himself so sweet and close,
So far from sounding and discovery,
As is the bud bit with an envious worm,
Ere he can spread his sweet leaves to the air,
Or dedicate his beauty to the sun.
Romeo and Juliet, act i., sc. 1.
- (3) *Imogene.* Comes in my father,
And like the tyrannous breathing of the north
Shakes all our buds from growing.
Cymbeline, act i., sc. iv.

- (4) *Bardolph.* The instant action
Lives so in hope as in an early spring,
We see the appearing buds—which to prove fruit
Hope gives not so much warrant as despair
That frost will bite them.
2nd Henry IV., act i., sc. 3.

- (5) *Violet.* She never told her love,
But let concealment, like a worm i' the bud,
Feed on her damask cheek.
Twelfth Night, act ii., sc. 4.

- (6) *Proteus.* Yet writers say, as in the sweetest bud,
The eating canker dwells, so eating love
Inhabits in the finest wits of all.
Valentine. And writers say, as the most forward bud
Is eaten by the canker ere it blow,
Even so by love the young and tender wit
Is turn'd to folly, blasting in the bud,
Losing his verdure even in the prime
And all the fair effects of future hopes.
The Two Gentlemen of Verona, act i., sc. 1.

- (7) *Capulet.* Death lies on her like an untimely frost
Upon the sweetest flower of the field.
Romeo and Juliet, act iv., sc. 5.

- (8) *Lysimachus.* O sir, a courtesy
Which if we should deny, the most just gods
For every graff would send a caterpillar,
And so afflict our province.
Pericles, act v., sc. 1.

- (9) *Wolsey.* This is the state of man: to-day he puts forth
The tender leaves of hope, to-morrow blossoms,
And bears his blushing honours thick upon him:
The third day comes a frost, a killing frost,
And when he thinks, good easy man, full surely
His greatness is a ripening, nips his root,
And then he falls, as I do.
Henry VIII., act iii., sc. 2.

- (10) No men inveigh against the withered flower
But chide rough winter that the flower hath killed!
Not that devoured, but that which doth devour,
Is worthy blame.
Rape of Lucrece.

- (11) For never-resting time leads summer on
To hideous winter, and confounds him there;
Sap checked with frost and lusty leaves quite gone,
Beauty o'ersnowed, and bareness everywhere;
Then, were not summer's distillation left,
A liquid prisoner pent in walls of glass,
Beauty's effect with beauty were bereft,
Nor it, nor no remembrance what it was;
But flowers distilled, though they with winter meet,
Lose but their show; their substance still lives sweet.
Sonnet v.

With this beautiful description of the winter-life of hardy perennial plants I may well close these papers on the "Plant-love and Garden-craft of Shakespeare." They have stretched to a much greater extent than I at all anticipated when I commenced them, but this only shows how large and interesting a subject I undertook, for I can truly say that my difficulty has rather been in the necessity for condensing than enlarging

my matter, which I soon found might be made to cover a much larger space than I have given to it.

As the papers have appeared from week to week, I have had to thank many readers of THE GARDEN (mostly complete strangers to myself) for useful suggestions and inquiries; and before I quite finish them, and with the prospect of giving them at some future time a more permanent shape, I would invite any further suggestions or remarks, especially in the way of correction of any mistakes or omissions that I may have made, and should feel very thankful to any one that would kindly do me this favour.

And having often quoted my favourite authority in gardening matters, old "John Parkinson, Apothecary, of London," I will again make use of him to help me to say my last words—"Herein I have spent my time, pains, and charge, which, if well accepted, I shall think well employed. And thus I have finished this work, and have furnished it with whatsoever could bring delight to those that take pleasure in those things, which how well or ill done I must abide every one's censure; the judicious and courteous I only respect; and so Farewell."
H. N. ELLACOMBE.

A FRUIT CELLAR.

ALMOST yearly we have some "newly-discovered" principle for the keeping of fruits. I read them all and I believe what I please. While remembering a fruit-room that I once knew, I will try to describe it, and at the same time record that I ate fruit from it in October that was gathered one year before, and just as fresh as that gathered that day from the same tree. A level piece of ground, from which water could be readily drained to a depth of 5 ft., was selected. A spot 13 ft. by 21 ft. was dug out 4 ft. deep, with perpendicular sides; then posts 7 ft. long of 4-by-4-in. stuff were placed at the corners, and two between the corners on each of the longest sides. The roof was one-third Pitch Pine, with ventilators in each gable, and a door 3 ft. wide at one end. Stnds of 4-by-4-in. scantling were used in the spaces between the posts; 1-in. boards were nailed on what would be the outside of these studs before they were put in place. Before the roof was put on, these studs were boarded on the inside, and the spaces filled (packed) with sawdust. The ridge-pole and plates, 2 in. by 4 in., were then put on; the underside of the roof lined from ridge to plates with ½-in. boards; then sawdust was filled in, finishing by putting on a roof of 1-in. boards, broadly battened and projecting 1 ft. over the plates and ends. A floor of 1-in. boards was laid 7 ft. from the bottom, leaving a trap-door in the centre, hung on hinges, with a pulley-rope (to raise or lower it) in the main room. Double doors were built at one end; a passage was left 3 ft. by 18 ft., and on the sides and rear end shelves were made, commencing 3 ft. from the ground. A shelf was put every 6 in., of boards 4 in. wide, ½ in. thick, and leaving a space of ½ in. between each two boards of the shelf, and finishing by a 2-in. strip edgewise on the front of each shelf. The 3 ft. space under the shelves was left for storing baskets or barrels of fruit as brought in until they could be arranged. Before any fruit was placed upon the shelves, clean white paper was spread, the first tier laid, another paper over, then another tier, and another paper; no two fruits of any kind touched each other. I have said double doors were made. This means one door 3 ft. inside of the other, the inner door having glass in it to light the room when looking over or arranging the fruit in cold weather if necessary. The ventilators in the apex of each end were arranged to be opened or closed by a pulley cord from the outside. The earth taken from the cellar was banked up all around the house, walls being built to admit of steps down to the entrance. A thermometer was kept, and unless carelessness occurred in opening on a cold day, it was never below 34° nor above 50°. The cost can be easily calculated, and as such a house then kept fruits as they should be, I see no reason why such an one should not again do it.—"American Country Gentleman."

The Phylloxera and Sandy Soil.—In Illinois and Missouri, Vineyards located on sharp gravel or sandy soils are not affected by this pest; particularly upon the arenaceous sites along the Mississippi River. Whether, if they should come to overrun this country as they have done France, they may not also become naturalized in such soils remains to be seen. It would seem, however, that they avoid gritty soils. In California, where they are not yet much spread, they are found mostly on Vines in rich soil in low places. Gravelly hill land seems as yet entirely exempt.

SCENE IN BRITTANY.

ROUGH structures, either for shade, shelter, or rest, might be made very picturesque by a mingled mass of Ivy and Honey-suckle or wild Roses, and would not detract from the wildness of spots which it might be deemed desirable to keep as nearly as possible in a state of nature. Such is one of the ideas suggested by this pretty pastoral scene in Brittany, from a painting by Henry Girardet, which is also suggestive of the flowers of the heath and of the rocks, of Ferns and Ivy, and of Burnet Rose. These Druid stones also, enormously aged as they are and often beautifully garlanded with wild flowers and creepers, remind us that rock gardens, well formed of natural stone, would be the most enduring of all and the only ones that time could not destroy.

H. N. H.

Eulalia japonica.—This appears likely to prove a valuable and interesting addition to the hardy, ornamental perennial Grasses at present in cultivation. It is allied to the genus *Erianthus*, and is

THE FRUIT GARDEN.

CHERRIES AND PLUMS IN KENT.

(Continued from p. 304).

Cherries.

FULLER says in his "Kentish Worthies" that "Cherries were fetched out of Flanders, and first planted in this country by King Henry VIII." Probably it was the excellent sort known as the Flemish Cherry that was "fetched out of Flanders," which is, as Mr. Darwin remarks, "a very odd-looking fruit, much flattened at the summit and base, with the latter deeply furrowed and borne on a stout, very short foot-stalk." Cherries were brought to Kent by the Romans, and though some authors say they were lost in the Saxon period, and restored in the reign of Henry VIII., this appears to be an error. Kent has certainly always been famous for Cherries, and nothing can be more beautiful than a Cherry orchard in full

Scene in Brittany, after H. Girardet.

even included in it by some botanists. It is of robust growth, attaining 6 ft. to 7 ft. in height, and established plants form clumps 16 ft. to 18 ft. in circumference. The flower panicles are at first brownish-violet, with erect branches, and produce at that stage but little effect, but as the flowers open, the branches of the panicle curve over gracefully, and bear a strong resemblance to what is known as a Prince of Wales' Feather. Each of the individual flowers, which are very numerous, has at its base a tuft of long, silky hairs, and these contribute greatly to the feathery lightness of the whole. It promises to be perfectly hardy. Two beautifully variegated forms of this plant are in cultivation, one with the foliage striped longitudinally with white (in the style of the common Ribbon Grass), the other with transverse markings, and it is probable that the variegated forms will reproduce themselves by means of seed.—WILLIAM THOMPSON, Ipswich.

Gladiolus, The Bride.—This is a variety that should not be overlooked when procuring bulbs. As a border plant, and for cut flowers, it is unsurpassed; it lasts good for weeks in a cut state, and looks equally as well as many Orchids.—W. OSBOENE, Fota.

blossom, with the masses of white clusters covering the trees, which look from a distance as if wreathed with snow. Cherry trees invariably have a great wealth of blossoms, which are exposed to the proverbial changes and chances of the fickle spring season. They come into blossom in Kent about the same time as the Blackthorn—from the 6th to the 25th of April—and they require suitable weather at the time of fecundation; neither too dry nor too wet, nor too much sun. "A cold blow suits Cherry bloom," say the rustics, and this coincides with experience, and the physiology of the process of fecundation. "Moisture," writes a friend, "is absolutely necessary for the prolongation of the pollen tube. If the sun be too powerful, the stigma of the pistil is apt to become scorched, and the natural moisture being lost, the pollen tube is undeveloped; on the other hand, should the pollen grain be exposed to wet from rain just as it becomes ripe, and before it reaches the stigma, the pollen tube will be developed in a situation where it can never reach its natural destination in the embryo sac." To illustrate this: the Cherry trees were in

full blossom about the 10th of April, in 1876, when the weather was very wet, with heavy rain and snow-showers: the crop of Cherries was very short indeed. In the previous year the blossoms were in full beauty about the 22nd of April; though the weather was cold, it was dry, and a very large crop of Cherries was grown. Cherries are grown upon Grass land, principally in the eastern part of the country between Chatham and Canterbury. There are a few orchards near Maidstone, but they are becoming few and far between. The trees are planted at first upon cultivated ground, having between them Hops, fruit bushes, or Plums, which are taken out after a few years, and Grass seeds sown. The Cherry trees are set at a distance of from 27 ft. to 33 ft. apart, which would give from 40 to 60 trees per acre. In some cases the landlord finds the standard trees, and the tenant pays for the labour and finds the bushes, which soon come into bearing. The rent of Cherry orchards is about £8 per acre upon an average. Good managers never mow Grass under Cherry trees, but feed it with fatting sheep, and manure it with from twenty to thirty loads of London manure per acre. Cherries are "worked" on the "Gaskin" or wild Cherry stock, which is found in abundance in the woods. This wood is harder than that of the "Honey Red," and not so liable to gum. Pruning is done tenderly and carefully for the first two or three years, after that very little is requisite. A large grower writes:—"I am very reluctant to prune Cherry trees after the first year or two."

The chief sorts cultivated are the Adams' Crown Heart, the earliest sort, allied to the White Heart, according to Dr. Hogg, but a better bearer; the Black Heart, a very old standard Cherry; the Elton Heart, Black Eagle, also an early sort; May Duke, Turkey Heart, Frogmore, Early Bigarreau, Waterloo, also early; the Early Purple Gem, Bigarreau, a large, firm-fleshed, somewhat late, and most salable Cherry; Morello, used for making Cherry brandy; Kentish and Flemish, both of which are admirable for cooking and bottling, having a fine sub-acid flavour, and a brilliant colour. Mr. Darwin remarks upon the first-named of these Cherries that "the stone adheres so firmly to the foot-stalk that it could be drawn out of the flesh; and this renders the fruit well fitted for drying." Nothing, it must be added, can be more grateful to convalescent patients than the flavour of dried "Kentish" Cherries. Mr. Webb, in his paper on "Fruit Cultivation," remarks—"It is odd that, although our great propagators have added of late years so many excellent and useful varieties to the stock of Apples, Pears, and Plums, yet with Cherries we have had but few additions." Picking is principally done by women, who mount the tall ladders with great agility, and get from 9d. to 1s. 3d. per sieve, containing each about 48 lbs. of fruit. A large proportion of the Cherries are sold upon the trees by public or private sale in June and July to fruit buyers, who take all risks and further expenses upon themselves. Mr. Webb gives a table of prices made at sales by auction of certain well-known orchards. For instance, he states that one large orchard of 88 acres averaged £19 9s. 6d. per acre for fourteen years; another, of 3 acres, has made £37 4s. per acre for thirteen years. From trustworthy information from another source as to seven typical orchards, it is shown that the fruit growing upon one of these realised by auction £27 14s. per acre in 1874, £24 per acre in 1875, and £41 2s. per acre in 1876; giving an average of £30 18s. 8d. per acre for the three years. In another case £43 per acre was obtained in 1874, £33 10s. in 1875, and £32 8s. in 1876; showing an average of £36 6s. per acre for three years. This, it must be remembered, is for the produce, clear of all expenses of picking, packing, carriage, and commission. The expenses up to the time of sale, for rent, tithe, ordinary and extraordinary—for all fruit-land pays an extraordinary tithe-charge, varying from 6s. to 8s. per acre, in addition to the usual charge—rates, manuring, maintenance, pruning, amount to from £12 to £14 per acre, from which must be deducted the value of the Grass under the trees. For the last twenty-six years the average price made in London for Cherries grown in Kent has been about 8s. per sieve. Deducting an average cost of 2s. 8d. per sieve from this price for all expenses after the fruit is grown, a balance of 5s. 4d. per sieve is shown. The highest prices made for Cherries during the period alluded to were in 1876, and the lowest in 1875. And it is curious to

note that, in spite of foreign competition, the average price per annum obtained for Kentish Cherries during the last ten years is nearly 1s. per sieve higher than the average of the preceding decade. All Cherries, except the Flemish, Kentish, and Morello Cherries, which are used for tarts, preserves, and liqueurs, are bought by fruiterers and costermongers for retailing and hawking for eating purposes, as they do not make good jam.

PLUMS AND DAMSONS.—These are grown more or less in all the fruit-growing districts of the county. Growers in East Kent prefer the forward Orleans, Magnum Bonum, Blue Diamond, Victoria, Dauphin, Mussel, Early Rivers, and Washington. Black Plums sell the best. The trees are planted between Cherry and Apple trees, or are set in plantations by themselves with bushes under them. Greengages grow especially well in the neighbourhood of Rainham, near Sittingbourne, the fruit being very large and of a particularly fine flavour and colour. A tradition exists that £100 per acre has been made in one year on a piece of land near Chatham planted with Greengages. Plums generally sell well. The average price of Plums in London is about £19 per ton. In 1876 they made from £28 to £32 per ton; in 1871, only from £12 to £14 per ton. There is a famous Damson, known as the "Critten-den" Damson, that has been planted to an enormous extent in Kent during the last twenty years. This is propagated by suckers, or "spawn," which come up all round the trees, and yield fruit after their kind without being grafted, like the "Pershere Plum," which is general in Worcestershire. After these suckers have been planted out for two years they begin to bear. This kind of Damson is amazingly prolific, and the fruit brings high prices for jam, bottling, Damson cheese, and, as some say, for manufacturing port wine. Plum-trees, like Cherry-trees, do not require much pruning, and are inclined to "gum" and decay if the knife be too freely used. It is merely necessary to cut back any over-vigorous growth that may get too much ahead, and to clear out wood that crowds up the inside of the trees. Plum trees do not do well in exposed situations, as their roots are so near the surface that they are likely to be blown down by wind.

SEPTEMBER AND EARLY OCTOBER PEARS.

THE following, in continuation of our list of Pears (see p. 183), will be found amongst the best of their class, all of which are fit for use from about the middle of September to the end of October. White Doyenné (fig. 1) is amongst the handsomest of Pears, being perfect

Fig. 1.—White Doyenné.

Fig. 2.—Louise Bonne of Jersey.

in shape; its skin is smooth, and, when fully ripe, bright yellow, suffused with red on the side next the sun; the flesh is white and of a vinous flavour; this Pear will keep in good condition for about a fortnight after being fully ripe; we have it both in espalier and bush form; for the latter mode of training it is well adapted, as the fruit being small, the wind does not prove so injurious to it as to fruit of larger growth. Louise Bonne of Jersey (fig. 2) is a Pear well known to most cultivators, but amateurs and cottagers do not grow it nearly so extensively as they should do. We know one cottager in Suffolk who pays the rent of his cottage two seasons out of three by the produce of a standard tree of this Pear in his garden; it is one of the surest of fruiters, and in quality all that can be desired, and in a good fruit room it will keep a month in usable condition. Beurré Nantais (fig. 3) is comparatively a little known Pear; it may be described as of real Pear-shape, large, and somewhat uneven in out-

line, with a skin of greenish-ruddet; the flavour is neither rich nor unpleasant, something like a mixture of sugar and water; its greatest merit is the long time during which it continues in usable condition after being fully ripe. On the Quince stock it is very prolific. Flemish Beauty (fig. 4) in a hot, sunny season is the best Pear in cultivation, being large in size and excellent in shape, with a smooth, shining skin, which, when fully matured, is of a soft yellow colour, suffused with deep red on the side next the sun. The flesh is white and melting, and deliciously aromatic in flavour. It deserves culture on a wall of either southern or western aspect, in which case it should be gathered the moment there is the slightest indication of maturity, as if left to ripen on the trees it is soon over, and is not nearly so delicious. Brown Beurré (fig. 5) is one of the oldest, most generally grown, and in all respects one of the very best amongst the many kinds of Pears which we possess, being equally adapted for walls or standards, but well deserves a wall. Beurré de Amanlis (fig. 6) is also a well-known Pear, but not cultivated to the extent which it merits. It is amongst the largest of Pears. Its skin is greenish-ruddet, changing to yellow when quite ripe, and it has a flavour perfectly unique; this also deserves a wall. We have several

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vineries.—Grapes to keep well should before this be quite ripe. In the case of amateurs it will be frequently necessary to have some plants in the house that must of necessity receive water, but no more must be used than is absolutely required, and it ought to be given early in the morning so as to permit of any that percolates through the pots getting dried up during the day. From this time forward to the end of the year, where Grapes are hanging, the usual advice given is to light fires once or twice a week in order to warm the pipes or flues sufficiently to dry the atmosphere; but I have always found it much more effectual to keep a very little warmth on continuously, with a little air, top and bottom, also on continuously day and night. Those who have not tried it would be surprised how little heat is needed to keep up a circulation in the atmosphere, and to correct the effects of the damp external air that is admitted. As a further precaution, every bunch should be looked over once every week or ten days, as should even a single berry in the centre of a bunch become mouldy it will very quickly communicate decay to the whole.

Fig. 3.—Beurré Nantais.

Fig. 4.—Flemish Beauty.

Fig. 7.—Bonne d'Ezée.

Fig. 8.—Rousselet de Rheims.

trees of it trained obliquely as double cordons on a west wall, and they never fail to bear profusely. Bonne d'Ezée (fig. 7) is a large, handsome-looking Pear, of but third-rate quality; it is a good bearer on either the Quince or Pear Stock, and, for market growers, worthy of notice. Rousselet de Rheims (fig. 8) is a very small but delicious September Pear; it is soon over, but if gathered at varying intervals its season may be considerably prolonged. It is well adapted for growth in the form of bushes or standards. Other good kinds of September and early October Pears are St. Michel Archange, British Queen, Beurré Superfin, Autumn Bergamot, Beurré de Capianmont, and Beurré Hardy.

W. W. H.

Autumn-fruiting Strawberry.—I have this season proved to my own satisfaction that Vicomtesse Héricarte de Thury and Garibaldi Strawberries are synonymous. We are now picking good fruit from plants of this variety that were transferred to the open ground after having been forced in the spring. It seems disposed to fruit as freely now as at the proper Strawberry season. Would it not be worth while to pick the flowers off an established plantation at the proper season, with the view of inducing a full crop of fruit at this time of the year?—W. W. H.

Winter Cucumbers.—Plants raised from seeds put in a few weeks back should be moved into 6 in. or 7 in. pots as they require more room; they should by no means be allowed to remain too long in the small pots in which the seeds were sown, as from their natural quick growth the roots soon become pot-bound, after which it is difficult to get them to move freely. They ought to be kept close to the glass with a temperature never less than from 65° to 70° during night, and 5° to 10° more by day according to the weather. Where plants for winter work have to be raised from cuttings, the striking of these should not be longer delayed, otherwise it does not allow of their acquiring sufficient strength when planted out before the short sunless days retard their progress. Half the failures that occur in the case of Cucumbers that are expected to bear through January and February, the two most difficult months—are through the plants not getting sufficiently large and strong before the middle of December, and by their being allowed to bear fruit previous to that time; as when a regular supply of Cucumbers is required through the first months of the year, no matter how strong and vigorous the plants may be, no fruit should be allowed to set until near close upon the end of the year. Some soil should be got under cover in which to

grow them, so as to allow of its getting dry and mellow before it is wanted. At this season, much more than in the spring or summer, it is essential that the soil be of a good description, containing plenty of turfy fibre, as if at all of a heavy nature the roots, which in the dull autumn weather are produced much more sparingly than earlier, will make little or no progress.

Frame Cauliflowers.—A frame proportionate in size to the quantity required should at once be got ready in which to plant Cauliflowers for turning out in spring; the soil ought to be of good quality, but not over rich, as if too much manure be used it induces soft, rank growth, a condition opposed to their wintering safely; if not of a moderately light character, it should be made so by the addition of leaf-mould, or other decomposed vegetable matter, sand, or charred refuse, any of which will answer the purpose; as these plants will have to be taken up and planted out in spring, where the soil is of a heavy description they cannot be moved without breaking the roots, which often results in the formation of small heads prematurely. If a little lime and soot be also dug in and dusted on the surface it will tend to keep off slugs; put the plants in 6 in. apart, give a gentle watering, and all but close the lights for a few days until they have begun to grow, when they should be exposed to the full air by keeping the lights off night and day until there is an appearance of hard frost; a little such as we get during this and the next month will not do them any harm. Cauliflowers wintered in this way do best when near the glass; consequently a shallow frame is the most suitable, as it obviates the necessity of filling up to a considerable extent with soil, which tends to rot the wood. Previous to being used for this and all similar purposes through the winter, frames should have the glass repaired if necessary, and be well painted, so as to exclude drip, as an excess of moisture previous to a severe frost intensifies its effects. Where hand-lights or cloches are used for wintering these plants, a suitable open site, away from trees or walls, ought to be chosen and prepared. Planting and after treatment should be the same as recommended for frames. In the southern or western parts of the kingdom, where Cauliflowers will generally live out under the protection of a south wall, with a little covering during hard frost or snow, a row should be put in from 6 in. to 9 in. away from the foot of the wall.

Lettuce.—Crops of dwarf Cabbage Lettuce, such as Tom Thumb, now ready, or coming in for use, should be lifted and planted either in frames or in spaces where frames can be put over them, as we sometimes get a few frosty nights early in the autumn that affect the leaves so as to prevent their keeping well. A single or double row of late-sown Lettuces may with advantage be put in at the foot of a south wall; the check which the plants receive by moving thus late in the season induces a harder condition, that often enables them to survive a severe winter, when those that were earlier planted and in a more vigorous, free-growing condition, frequently succumb. A frame should be prepared in which to sow Cos Lettuce for planting out in spring. Choose an open, light situation, and raise the frames well at the back so as to obviate drip, as success with this crop depends upon the surface of the soil getting quite dry before winter, and remaining in that condition. Either a shallow frame must be used, or it must be filled up with soil to within 8 in. or 9 in. of the glass; make the soil quite smooth and sow broadcast, putting in enough seed so that the plants may stand 2½ in. or 3 in. apart, and if they come up closer they must ultimately be thinned. If the soil be wet a little old potting material, or anything of a similar nature that has been under cover and got quite dry, may with advantage be laid on the surface 1 in. or 2 in. in thickness previous to sowing; the soil from below will very soon communicate moisture enough to this to cause the seed to vegetate. Put on the light immediately the work is completed, so as not to allow the bed to get wet by rain; not so

much as a single shower should reach it until the severe winter frosts are over; keep the light tilted back and front day and night, except during hard weather. From the care necessary to be bestowed on Lettuces treated in this way it will be seen that they are somewhat troublesome, but where a continuous supply is required during the spring it rarely can be had except these late frame-sown plants are brought successfully through the winter.

Endive.—Continue to tie up Endive for blanching as it is required, but no more should be done at a time than will keep up a supply, as when sufficiently blanched it soon afterwards begins to decay. Through the wetness of the season this crop in many places this autumn is difficult to blanch, especially the broad-leaved Batavian, the inner leaves of which are somewhat decayed through excessive moisture, and as soon as they are tied up they have a tendency to rot. The curled-leaved varieties have suffered, but not to such an extent as the other. If boards be used for blanching the curled-leaved kinds they will be much less likely either to rot through the effects of their previous condition or to suffer from frost, but whichever way they are treated the tying up or covering must be done when they are quite dry. Any ordinary thin boards sufficiently wide to cover the plants will answer the purpose, placing a couple or more bricks upon them, according to their length, to keep them close enough to the plants to exclude light and prevent their removal by wind.

Beet should now be taken up, as it is much more impatient of frost than most things; the roots will be all the better if laid in an open shed for a few days until the soil adhering to them has got quite dry, after which they may be stored under cover in moderately dry ashes out of the reach of frost.

Potatoes that were at all affected with disease before lifting should be frequently looked over, so as to remove such as are decayed, or the whole will quickly become affected.

Peaches and Nectarines.—In planting walls with these, it is a usual practice to at first put in the trees twice as thick as they are ultimately to remain when they have acquired their full size. Where trees that have been so managed exist, and a

portion requires removal, this should be set about at once; those thus moved may with advantage be employed in filling up blanks on other parts of the wall. If taken up with care and immediately planted, they will directly begin to make new fibres, and if in a good healthy state will generally bear a moderate crop the ensuing summer; whereas, if the planting be deferred until later in the season, little fruit can be expected from them next year. Although, however, this early planting is advisable where the trees on being taken up can be at once re-planted without their roots being allowed to get dry, as can easily be done in shifting from one part of a garden to another, it must not be attempted when they have to be brought from such a distance as would involve the necessity of their being out of the ground some days, until later in the year when the leaves are off, or the bark will shrivel, which will injure them. Where Apples, Pears, Plums, Cherries, Gooseberries, or Currants have to be moved from one part of a garden to another, either on walls or in open quarters, this early transplanting is a great advantage. Where fruit trees have to be planted—the removal of which, for the above reason, has to be deferred till later in the season—I should recommend the ground to be prepared at once by digging or trenching, bringing in any new soil or manure that is needed; not only can the work be much more efficiently done before the ground gets thoroughly soaked by the autumn rains, but it will admit of the trees being planted as soon as ever they are fit to move. Where the soil is of a retentive character, it is still more necessary to prepare for, and carry out, the planting of fruit trees early in the autumn, for in some of our best Apple, Pear, and Plum-growing districts, the soil is of such a nature that unless the planting takes place in the autumn, it often happens that the land is so wet and adhesive through

A Gardener's House and Garden (see p. 337).

the winter that the work cannot be done until so late that the buds are moving, in which case a complete season's growth is lost, and the trees are often seriously injured.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

October 8.—Sowing Canadian Wonder French Beans in pots for forcing, using good fibry loam and leaf-mould and rotted manure; also Mustard and Cress in heat. Potting herbaceous Calceolarias; also a small batch of late Cinerarias. Getting pits and frames ready for Endive and Lettuce. Renovating linings round pits and frames in which Cucumbers, Radishes, French Beans, &c., are grown. Lifting Beetroot and storing it away in dry mould in an open shed. Looking over all Cauli-flowers, and doubling down leaves, where heads are formed, to preserve them from frost, and removing all those fit for use to a cool shed, heeling them in in dry soil. Covering up Endive and Lettuce to blanch with inverted flower-pots. Gathering Easter Beurré, Josephine de Malines, and Winter Nelis Pears, and laying them singly on clean straw in fruit room. Watering the Pines all through, and tying up the fruit where required.

Oct. 9.—Potting Pelargoniums from flower borders; also a batch of Hyacinths, plunging the latter 2 in. or 3 in. deep in coal ashes in cold pits. Clearing off Cauliflower stumps and Peas which are done with, and preparing the ground for manuring and trenching. Transplanting a large border of Carter's Early Heartwell Marrow Cabbage. Turning a large heap of Mushroom manure. Moving Plum trees from nursery wall to other parts of garden where required to fill up vacancies. Planting Lettuce and Endive in pits and frames previously prepared by being filled with good soil.

Oct. 10.—Potting Lobelias and Tom Thumb and Flower of Spring Pelargoniums. Getting Chrysanthemums under cover. Weeding and thinning out autumn-sown Carrots. Hoeing amongst all the autumn-planted Cabbages. Gathering Blenheim Orange, Gooseberry Pippin, and Royal Somerset Apples.

Oct. 11.—Sowing Mustard and Cress in shallow boxes placed in heat for succession. Potting Centaureas and Carnations. Looking over Pelargonium cuttings, and removing all dead leaves and weeds. Earthing up late Celery when the soil is dry and in workable condition. Lifting Peach and Nectarine trees, and root-pruning them where required to check rank growth and bring them into a bearing condition. Clearing out all water-spouts and drains before the rainy season sets in. Gathering Beurré de Capiaumont, Beurré Clairgeau, and Duchess de Angoulême Pears. Clearing up leaves, and stacking them away for fermenting.

Oct. 12.—Potting Pelargonium cuttings which have been struck in a frame. Planting a border of spring-flowering plants, consisting of Wallflowers, *Silene pendula compacta*, Forget-me-Nots, Red and White Daisies, &c. Gathering all Scarlet Runners which are of usable size, and putting their stalks in water to keep them fresh until required for use. Earthing up Cardoons when the soil is dry and friable. Erecting staging over Strawberries in pots, on which to place spare lights to throw off heavy rains and protect the plants from frost. Clearing flower borders, and digging them. Top-dressing Cucumbers with chopped turf and rotted manure.

Oct. 13.—Roping Onions during wet weather; also looking over seed Potatoes, and placing them on their ends in shallow boxes to sprout. Cleaning paint in Vineries, &c., to destroy insects. Cutting shreds, pointing nails, making labels, pegs, &c., ready for use in dry weather. Fruit in use for dessert—Pines, Grapes, Pears, Plums, Apples, Nuts, &c.

A GARDENER'S HOUSE AND GARDEN.

ANYONE who has spent wearied hours in the extensive solitudes of geometry at Versailles, and who was happy enough afterwards to cool his eyes among the rare and handsome trees, choice variety, and cool green of what is called the "Fleuriste," will probably preserve an agreeable souvenir of the spot. It is a little garden cut off from the rest of the grounds, and, like all charming gardens, remarkable by not being "laid out," in the usual sense of the word. Grass, trees, choice plants, a house and creepers, walls and creepers form the elements; but the resulting charm is quite indescribable. It is only a gardener's garden; but if kings were born to wisdom they would prefer it to the stony solitudes spread around their homes by thoughtless "landscape architects."

THE LIBRARY.

BELLOWS' DICTIONARY.*

THIS book, though not specially within our province, is, nevertheless, so novel in its way and so well done that we make no excuse for calling attention to it. The author has, with singular success, compressed into a very small, very neat, and handy little book all that is essential in a French-English and English-French dictionary. This possesses in addition several features not before found in any book:—1. The distinguishing of masculine and feminine genders by different types, or of the feminine by italic type. 2. The indication by typographic marks or signs, in French words, of the *liaison* or of its absence. 3. The arrangement of both the French-English and English-French divisions concurrently on the same page. 4. The manner of arranging the verb conjugations, and the reference by number to such conjugations from the text of the dictionary. 5. The figures showing equivalent measures or weights and their money values. 6. The indication on the maps, with the names of towns, of their distances from London and Paris, both in time and in miles, or in kilometres. 7. The translation of all words and phrases given in the following pages, which have previously appeared in no other dictionary. By the above plan well carried out there has been much saving of time, type, space, and much benefit to the reader, who is also enabled by the agreeable variety of type to find the word he seeks more quickly than when it is in a mass of uniform type. Words that are the same in both languages are explained only in French, and by this means space is also gained. The most striking feature of the little book, however, is the placing of the French part and the English part on the same page. On the upper part or half of the page there is the French dictionary with English explanations, on the lower the English with French explanations, thus saving much time in reference. The relations of weights, measures, money, and distance are exactly explained, and—what is rare in works of this kind—very clear and simple. The principles of French grammar illustrated in the commencement are carefully and systematically done. It were to be desired, perhaps, that less space were given to the verbs and more to nouns irregular in gender and number, also to the general rules which govern the foundation and accord of compound names, like *chef d'œuvre*, *arc-en-ciel*—words of which the usage is so frequent in French. The little plans at the end of the book are, strange to say, not only the smallest but also the clearest. That of London is most remarkable in this respect. If we may venture, where there is so much to praise, to say a word of criticism, it would be that a good many Gallicisms very seldom used might be omitted and the type somewhat enlarged, as a jolting traveller, least of any persons, likes very small type, and nobody would begrudge twice the space this little book takes up in his bag for one with larger type. The plan of the book is so good that a larger edition still—an octavo edition—in clear, large type would be a precious gain to the library. As it is, we have to thank Mr. Bellows for what is already done, and his work might well bear for motto a line from a great French writer—*C'est ici lecteur, un livre de bonne foi*.

Early Planting of Fruit Trees.—When the trees to be removed are close at hand so that the roots need not be long exposed to the air, I consider October to be the most favourable month of the year for transplanting fruit trees, as the soil being warm, fresh roots are at once emitted, and the trees start into growth in spring without a check; but where they have to undergo a long journey by rail, it is better to wait until the leaves are off. Last season we removed several Plums, &c., that had been temporarily planted on vacant spaces, and the growth which they have made this year is unusually satisfactory. In preparing sites for stone fruits I would warn the inexperienced against an error commonly committed, viz., filling the trench half full of manure, with the view of giving the trees a good start; the result of this is gross, watery shoots, which, necessitating so much knife-work, eventually bring on canker and other evils, from which trees planted in sound loam generally escape.—J. GROOM, *Henham*.

* "Dictionary for the Pocket": French and English, English and French. Both divisions on same page. By John Bellows. Second Edition. Gloucester: John Bellows.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY, OCTOBER 2.

THIS was by far the best meeting which has been held here for a long time, flowers, fruits, and vegetables being shown in considerable numbers. Amongst the more attractive features of the show may be mentioned a large group of *Nepenthes*, *Sarracenias*, and other plants of that kind from Messrs. Veitch & Sons; a hank of Roses from Mr. Wm. Paul; Dahlias from Mr. Charles Turner; and a good collection of Grapes from Messrs. Lane & Son, Great Berkhamsted.

First-class Certificates were awarded as follows:—

Nepenthes hybrida maculata elongata (Veitch & Sons).—A garden hybrid, the result of a cross between *N. sp.* and *N. Dominii*. It has long strap-like leaves, to which are suspended well-shaped, deep green, and bright brown or purple-spotted elongated pitchers some 9 in. in length.

Nepenthes Courtii (Veitch & Sons).—A hybrid raised by crossing *N. sp.* "Borneo" and *N. Dominii*, the result being a dwarf-growing plant, with well-formed pitchers of a deep green colour, and quite distinct in shape from those of any other kind.

Nepenthes rubra maculata (Veitch).—The result of a cross between *N. sp.* and *N. hybrida*. A compact-growing kind, with narrowish leaves, and small, well-formed, purple spotted pitchers.

Gladiolus Rhamnes (Kelway & Son).—A kind with very large flowers of a brilliant scarlet, the throat and lower petals being blotched with rich purple.

Tree Carnation Osman Pasha (Turner).—A crimson-flowered, free-blooming kind, well adapted to pot culture.

Dahlia James Willing (Messrs. Rawlings).—A large, globular flower, with smooth, rich purple and maroon petals.

Dahlia Mrs. Shirley Hibberd (Rawlings).—A cream-coloured kind, with delicate, purple-tipped petals.

Primula White Lady (Gilbert).—A free-growing kind, having large, semi-double, white flowers, slightly tinged with violet.

Primula Mrs. Barron (Gilbert).—A kind with semi-double flowers, of large size, white, suffused with delicate purple.

Primula Princess (Gilbert).—A semi-double, white flower, striped and spotted with crimson.

Stone Apple (Killick).—A very large, clear-skinned fruit, with a small crown; colour greenish-yellow, with scarlet on the sunny side.

Miscellaneous Subjects.—Mr. H. Cannell, Swanley, sent a plant in a pot of a French Marigold, named Cannell's Perfection, a kind well furnished with orange and crimson-coloured blossoms; and from the same exhibitor also came plants of *Lobelia Defiance*, a dwarf-growing, compact kind, bearing a profusion of purple blossoms. Mr. G. F. Wilson sent cut sprays of *Escallonia pterocladon*, a kind which bears spikes of ivory-white, sweet-scented blossoms. Messrs. Kelway & Son, Langport, sent some good cut spikes of seedling *Gladioli*. From Messrs. Bell & Sons, Norwich, came a group of seedling *Begonias* grown in pots, amongst which were several which differed from any we had before seen. Mr. J. Farquharson, Acton Nursery, Wrexham, showed *Viola* flowers of large size, good form, and beautiful colours. Mr. C. Turner, Slough, furnished an epergue tastefully filled with Pomponé Dahlias and Ferns, showing how effective and useful small-flowered Dahlias are for purposes of decoration. The same exhibitor also showed a collection of these Lili-pit Dahlias, which were highly commended by the Floral Committee. It comprised nearly every known kind worthy of cultivation, and amongst them were some unique both in form and colour. Mr. Turner also contributed a collection of Tree Carnations in pots, consisting of self-coloured and striped kinds, amongst which *Gloire de Lyon* is a good kind, with bright crimson flowers; *La Belle* is also an excellent white kind, and *Mazeppa* is one of the best striped varieties, and a beautiful pink-flowered kind named *King of the Belgians* attracted considerable attention. Among Mr. Paul's Roses we noted good blooms of *Louis Van Houtte*, *Madame Berard*, *Charles Lefebvre*, *La France*, and other well-known kinds. Mr. Wheeler, Warminster, sent good blooms of show Dahlias, as did also Mr. Turner, Slough. Mr. Noble, Bagshot, showed cut blooms of *Rose Queen of Bedders* in good condition. Mr. Gilbert exhibited a collection of new *Primulas* of the semi-double type, all of which were much admired. Mr. Roberts, gardener to Baron Rothschild, Gunnersbury, furnished a flowering specimen of *Odontoglossum crispum* Rothschildi, the flowers of which are large and richly suffused with violet. Messrs. Fröbel & Co., Zurich, sent a *Begonia* named *Monte Rosa*, which promises to be one of the best of its class; it is compact in habit, and the flowers, which are remarkably large, are stiff and waxy, and of a rich salmon colour, set off in the centre by a cluster of rich golden stamens. Messrs. Stewart & Sons, Dundee, showed a plant of the Purple Norway Maple, a desirable kind, which has leaves of a deep bronzy-purple, a colour which contrasts well with green-leaved trees.

Fruit and Vegetables.—Mr. William Paul contributed an excellent collection of Apples, consisting of about ninety kinds, all of which are well worth culture. Mr. Harrison Weir sent excellent examples of *Venus Black Muscat* Grapes, grown without fire heat; they were good in bunch and berry, and well coloured. Messrs. Carter & Co., High Holborn, showed a collection of *Capsicums*, amongst which some fruits of the kind named *Giant Emperor* measured from 6 in. to 7 in. long, and

from 9 in. to 10 in. in circumference. Messrs. Kelway & Sons furnished a collection of Cucumbers grown without artificial heat, and which were, considering the season of the year, of a very meritorious character. Mr. Parr, gardener to J. Sims, Esq., Harrow Weald Park, sent a brace of Parr's Prolific Cucumbers, the result of a cross between *Blue Gown* and *Telegraph*; they were of good shape, and evidently excellent in flavour. Mr. Allen, Gunton Park, sent a seedling Onion, the result of a cross between *White Spanish* and *Brown Portugal*; it is globular in form, firm, and said to be very prolific. Mr. Turner showed a seedling Potato named *Schoolmaster*; a kidney-shaped kind, smooth in the skin, and apparently good in quality. Mr. J. Loney, gardener to G. Dickson, Esq., Gothenburg, Sweden, sent a large collection of Apples and Pears, which, on account of their richness of colour, size, and general good quality, were much admired; they had evidently been grown under glass. Filberts, consisting of some forty varieties, came from the Society's garden at Chiswick. Mr. Gilbert sent bunches of *Gros Colman* Grapes, which were considered so good as to deserve a bronze medal, which was recommended. Mr. Gilbert also sent a basket of *Burghley Selected Brussels Sprouts* of a superior description. Messrs. Lane's collection of Grapes, to which allusion has already been made, consisted of excellent bunches of *Muscat Hamburg*, *Black Hamburg*, *Gros Colman*, *Trebbiano*, and *Muscat of Alexandria*, Mrs. Pince's *Black Muscat*, and the best examples of *Pearson's Golden Queen* we have seen. From Mr. Bates came *Gros Colman* Grapes. Messrs. Harrison, Leicester, sent a seedling Apple named *Lord Howe*; and Mr. Allen, Gunton Park, sent a good-looking, long-keeping Apple, named *Swanley Pippin*. Messrs. Carter & Co. sent a Melon named *Cream Pine*, a kind oblong in shape, ribbed, and scarlet-fleshed. Mr. Allen had a good scarlet-fleshed Melon named *Royal Ascot*. Mr. Bennett, Rabley, showed *Garibaldi Strawberry* in excellent condition; the same exhibitor also sent four fruits of a variety of Melon, in fine condition, named *Rabley*, a scarlet-fleshed kind, of medium size, and beautifully netted. Mr. Jones, Bently Priory, sent a well-shaped fruit of *Charlotte Rothschild Pine*, about 8 lb. in weight, cut from a plant not eleven months old. Mr. Jones, Royal Gardens, Frogmore, had three smooth-leaved *Cayenne Pines*, each weighing from 9 lb. to 10 lb. From Mr. Turner, Slough, came a collection of Potatoes, amongst which we noted good examples of *Snowflake*, *Model*, *Early Bird*, *Porter's Excelsior*, *Schoolmaster*, and other popular sorts. Mr. Shirley Hibberd, Stoke Newington, sent examples of *Watercresses*, to show how the same variety varies in different localities and under different circumstances. A box of *Goliath Tomatoes*, a large fruited kind, of good quality, was shown by Mr. Hepper, The Elms, Acton. Mr. Miles, gardener to Lord Carington, Wycombe Abbey, exhibited ripe and well-coloured *Hamburg Grapes* from the same Vines from which ripe fruit was cut and exhibited in January of the present year.

INTERNATIONAL POTATO EXHIBITION.

THIS was held in the Westminster Aquarium on the 3rd, 4th, and 5th inst., and was in all respects a success. The different exhibits showed an improvement as regards quality on those produced on previous occasions. As respects numbers perhaps little advance has been made, but exhibitors have learnt better what class of tubers is considered best by the judges, and have shown accordingly. In the premier class (open) for twenty-four varieties, nine tubers of each, there were fourteen competitors, all of whom exhibited tubers of fair average quality, although in some cases rough, uneven specimens were observable. The best collection came from Mr. Peter McKinlay, Beckenham, who had excellent examples of some of the most popular varieties, including *Bread-fruit*, *Porter's Excelsior*, the *Purple Grampian*, *Alexandra Kidney*, and the best specimens of *Model* we have yet seen, together with other good English-raised varieties, which throughout the show took the preference to American sorts. The next collection, which was little inferior to the one just named, came from Mr. William Finlay, gardener to Colonel North, Banbury. In this there were more American kinds than in the preceding; the best-shaped tubers in this collection consisted of *Snowflake*, *King of Potatoes*, *Myatt's Prolific*, *Schoolmaster*, *Perfection Kidney* (white and clean), the *purple Blanchard*, and *Princess of Lorne*, all in excellent condition. In other collections the most noticeable kinds were *Myatt's Perfection*, *Early Market*, *Henderson's Prolific*, and *Yorkshire Hero*. In the amateurs' class for eighteen varieties there were nineteen competitors; the best collection came from Mr. William Porter, Old Meldrum, N.B., who had excellent medium-sized, well-shaped tubers, with clear skins, and showing no signs of disease. Among these the most conspicuous were *Snowflake*, *International Kidney*, *Napoleon*, *Fenn's Bountiful*, and *Ash-top Fluke*. In the next collection, from Mr. Donaldson, Inverurie, Aberdeenshire, were good examples of the *Scotch Blue Dalmahoy*, *Early Handsworth*, *Turner's Union*, and *Yorkshire Hero*—old but excellent kinds. In the amateur class for twelve varieties, nine tubers of each, there were seventeen competitors. The best collection came from Mr. James Pink, gardener to Lord Sondes, Faversham, who had evenly-sized, thin-skinned tubers, the best of which were *Coldstream*, *Waterloo Kidney*, *Berkshire Kidney*, and *Bresce's Prolific*. The next collection in point of merit came from Mr. Rose, gardener to E. Eyre, Esq., Newbury, who had good samples of *Walnut-leaf Kidney*, the salmon-coloured *Garibaldi*, *Yorkshire Hero*, *Waterloo Kidney*, and other popular kinds. In other collections were good tubers of *Breadfruit*, *Prince Teck*, *Lye's Favourite*, *Carter's Main Crop*, *Schoolmaster*, and *Fenn's Bountiful*. In the class of nine varieties there were nineteen competitors, the most successful amongst whom was Mr. Richard Dean, Ealing, who showed remarkably

fine tubers of very distinct kinds; amongst them were King of Potatoes, Purple Ashleaf, Climax, and Salmon and International Kidneys. A second prize was awarded to Mr. Peter McKinlay for good examples of Ruby, Model, Snowflake, and Alexandra Kidney. The class for six varieties was even more interesting than the larger ones, the exhibits in every case being of a superior character. The best came from Mr. W. Finlay, who had finely-shaped, clear-skinned tubers of Blanchard, Magnum Bonum, Walnut Kidney, Edgcott Seedling, Snowflake, and Scotch Blue. The next best collection came from Mr. Ellington, Mildon Hall. It contained good specimens of Breadfruit, Giant King, Snowflake, Red-skinned Flourball, and King of Potatoes. In the class of four varieties (two Kidneys and two Rounds), there were twenty-three exhibitors, all of whom showed excellent tubers. The best came from Mr. F. Miller, gardener to J. Friend, Esq., Margate, and consisted of large but shapely specimens of Ashtop Fluke, Snowflake, Blanchard, and Breadfruit. Mr. S. Denyer, Beckenham, who was second, had good dishes of Model, Golden Eagle, Salmon Kidney, and International Kidney. In the class of four sorts of Potatoes not yet in commerce, or in commerce for the first time this year, there were twelve exhibitors. The best came from Mr. J. Pink, who showed Covent Garden Perfection, a kidney-shaped variety of medium size, very even surface, and, judging by appearances, of excellent quality; Superior, a red-skinned kind; and two others of a less meritorious description. Mr. Richard Dean had Bedford Prolific, Fenn's International Kidney, Radstock Beauty, and Garibaldi Kidney, all apparently good kinds. In competition for two dishes of Potatoes, there were twelve exhibitors. The best tubers came from Mr. R. Dean, who had Schoolmaster and International Kidney in excellent condition; Mr. Miller had Schoolmaster and Jackson's Improved. The prize for the best dish of any round white-skinned Potato was awarded to Mr. Robert Ironside, Inverurie, N.B., for a dish of Rector of Woodstock, remarkably even, clean, and bright, with scarcely any eyes observable. Mr. Pink gained the second award for Rounds with even examples of Early Goodrich. The best dish of round coloured-skinned kinds came from Mr. Pink, who had Red Emperor in good condition; Mr. Dean had good examples of Radstock Beauty. The best single dish of White Kidneys came from Mr. F. Miller, who had good tubers of Yorkshire Hero, and Mr. Finlay had good examples of Lapstone Kidney. The best dish of coloured Kidneys came from Mr. Evenden, Dartford, who had very large tubers of Superior; Early Vermont, from Messrs. Virgo & Sons, was next in point of merit. The best dishes of Snowflake came from Mr. Pink, and the best Ruby came from Mr. C. Ross. The best examples of Porter's Excelsior came from Mr. Pink and Mr. Ross. The best dishes of Schoolmaster (Turner) were shown by Mr. J. B. Hall, Gillingham, and Mr. E. Bennett, Enville.

Amongst miscellaneous exhibits was a basketful of very fine Schoolmaster Potatoes, from Mr. Charles Turner; and Messrs. Bliss & Sons, of New York, showed an extensive collection of Potatoes, the best amongst which were Manhattan, Standler, Centennial, and Trophy. Messrs. Kelway & Sons sent a collection of Cucumbers, consisting of new and approved kinds, said to have been grown in a cool house; the same firm also sent stands of seedling Gladioli, which were much admired. Messrs. Sutton & Sons furnished a large quantity of their Magnum Bonum Potato in good condition; and Mr. Porter, Old Meldrum, sent an extensive and superior mixed collection of Potatoes. Messrs. Carter & Co. had a large stand filled with Potatoes, Asters, Capsicums, and other vegetables of a highly meritorious description. Messrs. Daniels Bros., Norwich, had a collection of 500 varieties of Potatoes, arranged on a separate table, and associated with cut spikes of Gladioli and Dahlias. Mr. Turner had a good collection of cut blooms of Pomponé Dahlias.

Alexander Peach.—"The Alexander is evidently a desirable Peach, and its high flavour and juicy quality make it a summer fruit as much as the Strawberry, the Cherry, or the Plum. We like this variety on that account, and commend it to the attention of Peach-growers for the supply of the summer market, in good locations." I see the above in an American paper. Is this kind to be had in this country?—A. H.

Autumnal Crocuses in Turf of Spreading Plants.—I have a large stock of these, the well-earned reward of a system of cultivation that answers with many more things besides the lovely Colchicums. The secret of it is they have been left alone. I devoted a border to them, had it deeply dug and well-manured and planted with turf plants, such as the Woodruff, carpet-like Saxifrage, Arabis, Arenaria, and other plants of the like habit in considerable variety. Having begun in the spring with these, I planted at regular intervals amongst them in the autumn tufts of Colchicums in flower, securing all the varieties known to the nursery trade, and buying freely to begin with. The experiment has succeeded to perfection, and already the flowers of my autumnal Crocuses are appearing in plenty. My reason for proceeding in this way was to protect my pets from the spade, which would be sure to find them at some unhappy moment and bring them to a dreadful end. All kinds of bulbous plants that for a certain time are unseen may be grown well in this way if you begin well with them. It is not advisable, as a rule, to plant them in an old hard border, but to make a good border, and, having arranged the places for the bulbs, then proceed to finish by covering the ground with beautiful surfacing plants, and you thereby prohibit the entry of the spade and have a lovely garden every day in all the year.—"Gardeners' Magazine." [This is one of the various forms of true carpet planting, and its results are very different from the lifeless and highly coloured "patterns" to which the term is generally applied.]

COLCHICUMS BEARING SEED WITHOUT PREVIOUS VISIBLE FLOWERS.

Mr. HORSMAN, in THE GARDEN of June 30, says Colchicum bulbs received early in autumn from the Caucasus were immediately planted but did not flower; yet in the following spring the foliage appeared, and with it seed capsules containing perfect seeds. I think I can explain this without supposing "abortive and inconspicuous flowers." Doubtless the bulbs had flowered before they were sent from the Caucasus. Supposing them to have been found in a wild state, and taken up, of course, the collector would only find them by their flowers. Of these there would be no visible trace when received in England, but in due course the hidden ovary, duly fertilised, would make its appearance. I do not know the Colchicums, but we have here (in South Africa) the Gethyllis, which flowers precisely like the pretty coloured plate in THE GARDEN (see p. 549, Vol. XI.), only on a smaller scale, and the flowers are pure white with a pink or purple tinge on the outer edges of the sepals. After the bulbs have had a good roasting during our early summer months, the first good shower at Christmas or the New Year is followed on the third day by a host of these pretty, sweet-scented flowers, and as regularly as the time comes round I go out on the third morning after rain with a basket, knowing that within a few hundred yards of my house, on an open hillside, in the centre of the town, I shall find enough to perfume my house for a couple of days. About twenty years ago I took up a quantity of the bulbs in flower but leafless, and putting them away on a shelf, forgot all about them. Some months afterwards I overhauled them, and found that most of them had got shrivelled up, all the moisture of the bulb having gone to form perfect fruits; and so for the first time I learned the fact that the sweet white flower and the fruit—which children gather in May or June, and familiarly known by the native name of "kookamakanka"—were the production of the same bulb. I have no doubt Mr. Horsman's Colchicum seeds were produced in the same way.

W. C. ELLIOTT.

Port Elizabeth, S. Africa.

Water Chestnut (Trapa natans).—A few weeks ago there appeared in THE GARDEN (see p. 193) a short account of this interesting plant, which is an annual that grows in great abundance principally in the south of Europe, but as far north as Versailles; and from the climate and conditions under which it is found growing wild, I believe that it might be naturalised in this country, where it would prove not only an ornament to our swamps and streams, but even of value as an article of food. The fruit, which is of good size, is encased in a peculiar hard shell, which, when cut, discloses a white, sweet kernel, about the size of a Filbert, and in flavour resembling that of the Spanish Chestnut. It is extensively eaten in the south of Europe both raw and cooked, and Pliny tells us that the Thracians made the nuts into bread; possibly some correspondent of THE GARDEN could give a receipt for cooking it, as much depends upon that; boiling in salt water I am told is best. I believe that the plant, if once established in this country, would prove a great boon as an article of food.—A. P.

Quilled Asters.—The appellation of "German" so commonly applied to these Asters, doubtless leads to the belief that seeds of them are only obtainable from the Continent; but that is a mistake, as the finest strains are now produced from home, grown seed; Betteridge's superb flowers, now so familiar at flower shows, are probably the best of their kind anywhere to be found, and the seed which produces them is annually saved at Chipping Norton. The beauty of this form of the annual Aster is indisputable, as although somewhat formal in shape yet they are not too large to be ungainly whilst the smaller side flowers are singularly beautiful for bouquets or for table decoration. Quilled Asters are erect in habit, and need little support, and they may be grown in any good border soil, but the blooms come better and larger if specially cultivated.—A. D.

Air Roots on Vines.—These are not an indication of ill-health, but the contrary. In early forcing, for instance, where one is obliged to keep up a large amount of heat and atmospheric moisture with little ventilation, air roots are almost sure to make their appearance, although I am acquainted with places in which good crops of early Grapes are grown without air roots showing themselves. Where very early forcing is carried on, it is not a good practice to allow the evaporating pans to be always full of water, as the continual steaming loads the atmosphere with moisture, and the sashes cannot be safely opened to let it out. Hence the production of air roots. It is better to damp the floors or walls occasionally than have the house in a continual steam, producing air roots, and often causing the Grapes, when coming into bloom, to damp off. I am acquainted with Vines at this moment that bristle with air roots, and yet, as regards health and vigour, no Vines could be more satisfactory. As

a proof that a close, warm atmosphere produces air roots, I may mention that a plant of *Hoya carnosa* under my care, trained against a wall in a stove, is over run with air roots, which cling to the wall like those of Ivy, whilst another plant of the same, trained to the wall of an ordinary greenhouse, has not a vestige of an air root upon it; yet, as regards health and profusion of bloom, both are equally good. When I see air roots produced in any great quantity during early forcing, I reduce the amount of moisture and admit more air, if possible, and I find that where this is done fewer roots are emitted. Air roots, therefore, would seem to be the result of a warm, close, damp atmosphere, and the want of admission of a proper amount of air.—J. B., *West Lodge, Chapeltown, Leeds.*

NOTES ON LATE PEAS.

THE last week or two of sunshine seems to have put new life into late Peas, and shows how necessary warmth and light are to their proper development. The following notes were taken to-day (Sept. 29):—*Ne Plus Ultra*, sown June 11, is now in excellent condition and loaded with beautiful green pods, some fit to gather, others, influenced no doubt by the fine weather, fast filling; and all the ends of the shoots are covered with blossoms. June 11 is quite late enough for sowing this variety in the Midland Counties. *British Queen*, sown May 31, is still full of growth, and producing plenty of pods; but it seems to require a sunny place, *i.e.*, a higher temperature to fill up the pods quickly, and has hardly been so useful this season as the preceding. *Culverwell's Prolific Marrow*, sown May 14, is rightly named *Prolific*, for after having borne one heavy crop, it has shot out new growth from the old stems, and is now full of pods and blossoms; it is sometimes thought not to be quite first-rate in flavour, and I notice that sparrows do not take quite so kindly to it as to *Ne Plus Ultra*; but it is indispensable where Peas must be had under all circumstances. I have grown it several years, and have always found it a sort to be depended on. *Williams' Emperor of the Marrows*, sown May 14, though producing a few pods, is not so useful as any of the preceding kinds, at least not here this season. *Omega*, sown June 11, although planted in well-manured trenches, has become attacked by mildew, and the produce and growth have both been poor. I have grown several other kinds, including some of the early round sorts, but it is unnecessary to notice them further, as this year they have not been a success.

There are several matters in connection with the production of late Peas which are so important that, at the risk of repeating an oft-told tale I will briefly refer to, viz:—Never plant near trees or bushes, but in the most open and exposed positions that are to be found. Trees not only by their shade and shelter weaken the growth, but they also harbour birds, which are often very destructive to late Peas. Isolate the rows, have them five or six yards apart, if possible, with Potatoes or other crops between them. Plant thinly, in order to ensure robust growth; remember that strength and vigour react upon and encourage the roots, and cause them to get a firmer grasp of the soil than they otherwise would have, thus enabling them to bear better, and to resist to a later period the dire attacks of mildew, which is the great enemy to late Peas. Place the sticks in the rows early, so that they may never leave the perpendicular for want of something to which to attach themselves, and when the sticks are finally placed in position, the tops, instead of being close together, and crowded thicker should be several inches apart, so that tall Peas, instead of being forced out from between them, may remain inside and have the advantage of their support. When, owing to the sticks being crowded together at their upper extremities, the plants from want of the necessary space are compelled to escape from them, they are often so blown about and injured by wind that their capacity for continuous bearing is destroyed.

E. H.

Poisonous Fungi.—A few days since, some children rambling in Stanley Park, near Everton, came upon some fungi, which they gathered and ate. A short time afterwards one of the children was taken ill, and appeared to be in a fit, the other children being soon in the same state. They were taken to a surgeon's in the neighbourhood, who administered emetics and applied the stomach pump. It was not until after some two or three hours' exertion that the children had so far recovered as to admit of their removal to their homes, and they continued to suffer from the effects of the poison for some time. This is the fifth case of poisoning by fungi that has occurred in the neighbourhood of Everton during the past week.

Poisonous Fumes from Asphalte Road-making.—At the Thames Police Court, the other day, Mr. Nolan, secretary of the Limmer Asphalte Works, carrying on business at Orchard Street, Poplar, appeared to answer a summons taken out by Mr. Raymond (one of the officers of health to the Poplar Board of Works) "for that on the morning of the 10th August, and on several other occasions, there was a quantity of

vapour arising from a large cauldron on the defendant's premises, the said cauldron being used for mixing purposes, and that the effluvium proceeding from the said vapour was of an offensive nature and injurious to health." Mr. Raymond said that he served a notice on July 26 on the defendant with respect to the nuisance in question. Nothing had been done since that time to secure an abatement of it. On August 10 witness visited the works; the cauldron complained of was then discharging a quantity of vapour. In Nov. 1875, notice was served on the company respecting the nuisance caused in the neighbourhood by the effluvium from the cauldrons, in consequence of which one of them was altered in such a way as to stop the nuisance. The other might be altered in a similar way at a trifling expense. Mr. James Johnson, a master shipwright, of 29, Orchard Road, said that his house was within 100 yards of the defendant's premises. The smell of the vapour that came from the mixing cauldrons was very offensive and obnoxious, and had a very bad effect on the health of himself and his family. Dr. Samuel Ellison, medical officer of health to the Poplar Board, stated that his attention had been drawn to defendant's premises. He had seen the vapour arising from the cauldron and smelt the effluvium it threw off. In witness's opinion it was a nuisance and injurious to health. Mr. De Rutzen said he should inflict a fine of £5 on the present occasion, and if the necessary alterations for abating the nuisance were not made, and any further proceedings were taken, the penalty would be doubled, and that would go on until the fine would amount to £200.

The Late Professor Parlato.—European botany has sustained a severe loss by the death of Filippo Parlato. He was a native of Palermo, where he was born August 8, 1816, and was therefore only sixty-one at the time of his death; but for many years past he had suffered from illness, and at the time of the Congress at Florence, in May, 1874, was unfortunately prevented from taking an active part in the proceedings. His name will always be inseparably connected with the Royal Herbarium at Florence, which he may be said to have created. It was at his urgent representations that in 1842 Leopold II., the then Grand Duke of Tuscany, founded a national herbarium, and at the same time revived the Chair of Botany at Florence, which had been suppressed since 1814, and nominated Parlato professor, giving him also the directorship of the garden, then a very small affair. Under energetic management and devoted attention, in a few years the herbarium took rank among those of note, and the gift of Webb's fine collection in 1850 rendered it one of the first rank. As an author, Parlato will be best known by his elaborate "*Flora Italiana*," commenced in 1848, and unfortunately left far from completion; and his monographs of the *Conifere* and *Gnetaceae*, in the sixteenth volume of De Candolle's "*Prodromus*;" but he was the author of many memoirs and systematic papers. His early writings were chiefly on Sicilian plants, and in 1844 he commenced a "*Flora Palermitana*," which was never completed. In this year he also published a monograph of the genus *Fumaria*, and a memoir on the anatomy of *Aldrovanda*. His account of the Sicilian *Papyrus* appeared first in 1852, and the fine volume on the species of *Cotton* was published in 1866. Personally Professor Parlato was possessed of a singularly amiable and simple character, and will be universally regretted.—"*Journal of Botany*."

NOTES AND QUESTIONS—VARIOUS.

Negro Largo and Bourjassotte Grise Figs.—As an addition to our stock of Figs in pots, I last year procured plants of these excellent varieties, which, although only in 10-in. pots, produced several fruits each of exquisite flavour. I look upon these two Figs, indeed, as kinds likely to be largely grown, for, although the Fig is an ancient inhabitant of our gardens, it is but comparatively recently that home-grown Figs have become popular dessert fruits. I may add that Figs under glass have this season been exceptionally fine and abundant; but that on open walls the season has been unfavourable for their ripening in anything like first-rate condition.—JAMES GROOM, *Henham.*

Climbing Roses and Bignonia radicans.—Which are the best climbing Roses to plant against a house, already pretty well covered with Golden Ivies, Clematis, Ampelopsis Veitchi, &c.? I want a pink or red Rose, both to be continuous bloomers and free growers. I cannot flower Bignonia radicans on an east-facing wall; must it be pruned at all? and when?—J. H. W. T., *Belmont, Carlisle.* [Six good climbing Roses to plant against a house are—Gloire de Dijon, Maréchal Niel, Climbing Devoniensis, Madame Berard, Belle Lyonnaise, and Sombreuil. These all bear light-coloured flowers—white, cream, and yellow, or yellowish. The two best red Roses for the purpose are Glory of Waltham, and Belle de Bordeaux; but these, while they are free growers, bloom less abundantly and less continuously than the preceding. The Bignonia radicans is proverbially a shy bloomer; lay in some of the strongest of the one-year-old wood, as it is from this you are most likely to obtain flowers. B. radicans major is a better variety, and blooms more freely. This latter is usually "spurred" in, as you would a Vine, in winter, and it flowers freely under this system of pruning.—W. PAUL.]

American Water Weed (see p. 214).—Swans will keep down this weed, and also all other plants except Nuphar lutea. I have to put a fence round Nymphaea alba and Calla aethiopica to protect them.—ACRON.

A Redwood.—Mr. James English is still at work on the Redwood tree which he felled at Russian River Station, California, some few months ago. He has already made from it 250,000 shingles, 100 fence posts, 60.0 stakes, lumber for a dwelling house and out-buildings, and has timber left for 300,000 shingles. The tree was 14 ft. in diameter.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NEW TUBEROUS-ROOTED BEGONIAS OF 1877.

HAVING, during the summer and autumn now drawing to a close, continued my trials and comparisons of all the new varieties of the above-named highly ornamental and continuous-blooming family, and having bedded out over eighty named varieties, I have now to report as to the respective merits and demerits of the thirty-one new kinds sent to me from various sources (principally Continental), all of which I have grown in the open air and carefully compared with the fine introductions of previous years, concerning which I have had something to say at the end of the outdoor blooming season of 1875 and 1876 in the leading horticultural newspapers, which remarks I may, I think, venture to hope have been of some use in guiding amateurs in the selection of a good assortment of these beautiful flowers, which, in the opinion of all who have seen them here this summer, are quite unequalled by any other plant whatever for affording an unbroken continuance of brilliant bloom from the middle of June till the middle of September in the open ground, and for a further month or six weeks after being lifted into pots for the greenhouse before they finally go to rest for the winter towards the middle of November. Of the twenty-six novelties above mentioned eight came to me from Van Houtte of Ghent, being all seedlings raised in that establishment from which we have already received so many fine varieties. This year's lot, however, was of very unequal merit, three only out of the eight being of first-rate excellence; one other, with large and sometimes semi-double male blooms of a pleasing and uncommon deep blush colour, having faults in habit of growth of considerable gravity; the other four were either insignificant or otherwise comparatively worthless. Seven varieties, three of them double-flowered, and four single, came to me from M. Victor Lemoine, of Nancy; all of these, with the exception of one of the doubles, were very good, as might be expected from the source from whence they came. From Messrs. Thibaut & Ketteleer, of Sceaux, came six varieties, all of them raised by the gardener of a neighbouring private gentleman, Fontaine by name, and all of them of first-rate excellence, two of them, indeed, being in my opinion the most beautiful varieties yet obtained by any raiser; these are named *Lelia* and *Exposition de Sceaux*—the latter variety, however, is, I believe, not yet in commerce. Another of this set is curiously enough identical with a very fine variety sent out by M. Van Houtte in 1875. From M. Deleuil, of Marseilles, came four varieties of very fair merit indeed. From M. Vincent, of Bougival, came one very fine variety. I shall now proceed to describe these new varieties *seriatim* in the above-named order, as briefly as possible, from notes taken down as each arrived at its full development, and carefully corrected afterwards when any point previously noted was found to need correction.

Van Houtte's Varieties.

1. **James Backhouse**—A most beautiful variety, with fully-sized, light scarlet blooms, which, when fully expanded, are perfectly flat. The habit of growth is low and spreading, and the flowers, which are produced in great abundance, are well raised above the foliage. This is a really first-class kind, and one which should be in every choice collection.

2. **Laurent Descours**.—A most lovely variety, of low and spreading habit of growth, with large and handsome foliage, producing with great freedom, on slender footstalks, well elevated above the foliage, an abundance of large and perfectly-formed flowers of a clear bright rose colour, the males of which, when fully expanded, being also perfectly flat. A variety of first-rate excellence.

3. **La Baronne Hraby**.—A light-foliaged, compact-habited variety, producing fully-sized, well-shaped cupped blooms of a lovely deep shade of crimson, borne on slender footstalks, and apparently not over freely produced. This is considered by its raiser to be one of his finest varieties.

4. **Notaire Beaucarne**.—This is supposed to be a semi-double variety, and the male blooms usually have from three to five extra petals. The flowers are of large size and good substance, of a deep blush colour, produced on long and pendulous footstalks. This variety, though by no means perfect as a florist flower, yet, from its size of bloom and somewhat uncommon shade of colour, is likely to find many admirers.

5. **La Baronne Leon Legay**.—A strong, vigorous-habited, upright-growing variety, with medium-sized blooms of a whitish colour when they first show themselves, but which ultimately turn into a good clear pink colour. This, however, cannot be considered as more than a good second-rate variety, with which one of the choice unnamed seedlings, sent me by M. Lemoine, is identical.

6. **Madame Meyer**.—A low-growing, branching-habited, free-blooming variety, with small and inconspicuous flowers of a pale blush colour. It is of not more than third-rate merit, and hardly worth a place in a collection, save for its dwarf habit of growth and freedom of flowering, which may perhaps recommend it to some growers as an edging to a large bed, with taller-growing varieties in the centre.

7. **F. M. Dos Santos Viana**.—A variety with pointed, dark green, marbled foliage, in the way of *Pearcei*, with medium sized blooms, which are a dull red outside and a deep orange inside, which, however, soon tarnish on exposure to the sun, as do other inferior varieties, so can be considered as a variety of second-rate merit only.

8. **James Duncan**.—An utterly worthless variety, of a dull and washy yellow colour. How it came to be named at all, I am altogether at a loss to understand.

M. Lemoine's Varieties.

1. **Louis Van Houtte** (double).—This is of dwarf, compact habit of growth, the male blooms fully and evenly double, and of a deep shade of salmon colour. A beautiful variety.

2. **W. E. Gumbleton** (double) is of dwarf and compact habit of growth, with fully and evenly double male blooms, of a paler salmon shade than the last-named variety, borne on rather slight footstalks well raised above the foliage. The blooms are about medium size.

3. **Argus** (double) is a light red variety, with an unevenly duplicated centre to the male blooms. A variety of only third-rate merit.

4. **Incendie**.—A pleasing variety, of low and tufty habit of growth, producing medium-sized blooms of good form and substance and of a dazzling light orange-scarlet shade of colour, which, however, unfortunately burn and tarnish when exposed to the sun, which completely spoils the beauty of the blooms after they are a day or two expanded. This variety may not be thus affected when grown in pots for the greenhouse, where its great brilliancy of colour should make it an acquisition.

5. **Jules Janin**.—A really beautiful variety, with large and perfectly-formed blooms, both male and female of a deep clear rose colour, resembling somewhat those of *Diamant*; sent out by the same raiser last year, but much deeper in shade and more perfect in shape. The foliage is of a peculiar glaucous, metallic hue. This variety should be in every choice collection.

6. **Abondance**.—A compact-growing variety, producing medium-sized, cup-shaped blooms, of a dark claret colour, borne on slender, perpendicular footstalks, well elevated above the foliage, and of about medium size.

7. **W. E. Gumbleton** (single) is an exceedingly fine variety, of stout and upright habit of growth, producing plentifully on strong footstalks, well raised above the foliage, most beautifully cupped blooms of the most brilliant shade of scarlet, somewhat resembling those of a small *Tulip* in shape. This is considered by M. Lemoine as the most distinct and beautiful variety he has yet sent out. During the latter part of the season all the blooms are male.

M. Fontaine's Six Varieties.

1. **Monsieur Bienoime** is an upright-growing variety, of exceedingly vigorous habit of growth, producing an abundance of fully-sized, handsome blooms, of the same colour as the old variety, *intermedia*, but of a deeper shade and larger size, and much greater substance. The female blooms also are unusually fine and perfect in form. Were it not that this fine variety unfortunately drops about half its male blooms in an unopened bud state during the earlier half of the season, it would be of quite first-class merit.

2. **Adolphe Fontaine**.—This is a very fine variety, but is curiously enough identical in every way, save a slight variation

in the foliage, with Van Houtte's fine variety of 1875, Paul Masurel, and therefore need not be added to any collection already possessing that variety.

3. **Monsieur Pigny** is of a compact and rather hard and stiff habit of growth, with dark, hairy foliage, resembling that of Lemoine's Oriflame. Its flowers are of good form and substance, resembling in colour, but being a decided improvement in shape on those of Lemoine's C. Glijm. They are somewhat sparingly produced.

4. **Exposition de Sceaux** is a most beautiful variety, of erect-growing and free-blooming habit, producing extra large and most beautifully cupped male blooms of a lovely shade of deep and intense rose colour, closely resembling Van Houtte's fine variety of 1874 (Charles Raes) in shade, but of infinitely finer form and substance. The female blooms also are quite exceptionally fine. This is unquestionably one of the finest Begonias that has yet been raised, and, when distributed, should be in every choice collection.

5. **Lelia** is also an exceedingly beautiful variety, in habit of growth and fine form and substance of its male blooms somewhat resembling the last-named variety, though the blooms are not quite so fully cupped in shape. The colour is a most lovely deep shade of crimson, somewhat resembling Veitch's Kallista, but of infinitely finer form and substance. It is also an exceedingly free bloomer, and should be in every choice collection.

6. **Hebe**.—This variety is considered by its raiser to be one of his finest hybrids, but unfortunately did not make any healthy growth till late in the season, so that I was unable adequately to form an opinion as to the real merits of the variety. The blooms, as far as I could judge, are light red, resembling those of Vesuvius in shade, and of excellent shape and substance.

M. J. B. A. Deleuil's Four Varieties.

1. **Carnicolor** is a variety of close-growing, tufty habit, with most distinct and ornamental foliage, scimitar-shaped, and curiously crimped at the edges, and producing blooms which are almost white when they first appear, but which afterwards turn to a deep nankin outside, and a clear flesh colour within; the male blooms are of large size, but rather thin in substance. This variety is only suited for pot culture in the house, as when grown in the open air all the male blooms drop in an unopened bud state, which does not happen when grown under glass. This is an exceedingly distinct variety, being, with the exception of Van Houtte's President Schlachter, the only one yet sent out of this peculiar shade of colour.

2. **Violetta** is a variety of medium height and somewhat glaucous foliage, producing, on tall and somewhat weak footstalks, fairly-sized blooms, rather thin in substance and poor in form, but of a pleasing and novel shade of rosy-violet. A variety of about second-class merit.

3. **Cleopatre**.—A variety of spreading and branching habit of growth, with large flowers of a light red colour, of good shape, but not much substance. The female blooms of this variety are a good deal above average merit.

4. **Bayard**.—A fine variety of medium height of growth, producing large and well-formed blooms on rather pendulous footstalks, the exterior of which in shade resembles that of Veitch's fine variety Aome, the interior being of a lighter orange shade. The female blooms are also good.

M. J. Vincent's One Variety.

Reine de Bougival.—An exceedingly floriferous variety, of quite a novel and most acceptable shade of colour, the blossoms, which are of an oblong-cupped shape, being clear cream colour within, the outer middle petals being of a light red. This is admirably suited for the centre of a bed, from its upright habit of growth, and the fine contrast it forms to nearly all other varieties.

Belgrave, Queenstown.

W. E. GUMBLETON.

New Orleans is said to be built upon a forest of Cypress trees. For 600 ft. down this is the foundation! Rows upon rows of the stems of the Cypress are found growing over each other, superimposed, each of which layers it is calculated has required ages to form.

A Piece of Mahogany.—There is at present to be seen in the timber-yard of Messrs. M'Kay & Milne, Hutcheon Street West, Aberdeen, one of the largest blocks of Mahogany ever imported into this country. It has been brought from Tobasco, and at the one end it measures 7 ft. 10 in. in diameter, while at the other the measurement is 4 ft. 6 in. As usual with Mahogany logs brought to this country, it has been equared; but if it had been imported in its original form, it would have presented a far larger bulk.—"Builder."

GRAPE CULTURE AT BERKHAMSTED.

THOUGH at all seasons of the year Messrs. Lane's nursery at Berkhamsted is well worth a visit, it is probably never more interesting or instructive than in autumn, when fruits of different kinds are in perfection. In September the Grape-houses themselves are well worth travelling miles to see—houses, some of which were at one time mere sheds with glazed roofs used for the protection of fruit trees in pots and similar subjects in winter, now ranking amongst the best Vineries in England, as far as good Grape growing is concerned. The large clusters of all the most popular kinds of Grapes which have this year been seen at the Crystal Palace, Alexandra Park, and elsewhere, sufficiently attest the quality of Messrs. Lane's Grapes; but in order to acquire a knowledge of the quantity, one must visit Berkhamsted. The Vines here are well attended to, and the heavy crops of excellent Grapes which are obtained from them would surprise even our best Grape growers. The principal Vinery—a spacious span-roofed one, about 130 ft. long and 25 ft. wide—stands on a sunny slope and the Vines are planted on the sunny side of the house, their stems being trained up one side and down the other; they are planted about 6 ft. apart, and from each is carried up an extra young cane for the purpose of inarching new kinds upon, should such a course be desirable. This Vinery contains at the present time nineteen distinct kinds of Grapes, and in some cases two or more varieties are on the same root. On a Buckland Sweetwater, for instance, has been grafted the Black Alicante, and both kinds ripen their crops perfectly, the only difference observable in the fruit of the Sweetwater being that the berries are not quite so large as they formerly were. The original Vines in this house were Black Hamburgs, which were planted about twenty-five years ago; but on them have been inarched from time to time many different new kinds for trial. Should these new kinds prove good, they are retained; if inferior, they are at once cut out. The main rods are about 25 ft. in length, and are allowed to carry twenty-five, thirty, and sometimes thirty-five, bunches each, according to the variety, weighing from 2 lb. to 6 lb. Muscat of Alexandria is grown in a house by itself. The roots of this variety are planted inside in a narrow raised bed, but some of them are also allowed to ramble outside. From these Vines from twenty to twenty-five bunches of very fine Grapes are cut yearly, some of which measure quite 15 in. long, and weigh from 5 lb. to 7 lb. The culture here differs but little from that practised elsewhere, except that instead of the shoots being stopped at one or two joints beyond the bunch, five, six, or even more are left. In this way abundance of thick, large foliage is obtained, an essential point if heavy crops of fruit be expected. Abundance of air and light is at all times admitted, and even when the fruit is ripe a brisk fire-heat is maintained, with air on, to thoroughly ripen the wood. Among the newer kinds of Grapes were Pearson's Golden Queen, in good condition, a variety which Messrs. Lane think, when well established, will be valuable. Whilst the Vines are at rest, Fig trees in pots, Peach trees, cut-back pot Vines, and similar plants occupy the houses, the floors of which are covered with a thick coat of sawdust. Vines in pots are started in these houses, but as soon as the permanent Vines begin to shade them they are at once removed to more suitable quarters. In the culture of pot Vines Messrs. Lane are most successful; they grow about 2000 plants yearly, and they are all grown without bottom-heat, a circumstance of importance as regards their after well-being. After one year's growth the canes are cut back to within a few inches of the pots; next year they are started about Christmas, and the bunches which they bear—with plenty of air, light, and room, and abundance of water during the growing season—are the admiration of all who see them. Of one of these Vines, shown in London in July last, a photograph was taken, from which the annexed illustration was prepared; it represents one of six, all equally good. They consisted of four Black Hamburgs and two plants of Foster's Seedling, and collectively they bore eighty-one bunches of Grapes, some of which weighed $3\frac{1}{2}$ lb., and none less than 1 lb. The berries were large, plump, and well-coloured, and the bunches faultless in shape, and it was admitted by the Fruit Committee at South Kensington, where they were shown, that they were the best pot Vines which had ever come under their

notice. They were grown in 12-in. pots, and at starting-time were plunged in a bottom-heat of about 60°, the atmospheric night temperature being about 45°, and the day temperature during sunshine 65°. Instead of being tied to the trellis at once, as is usually done, they were twisted round stakes inserted in the pots, which had the effect of inducing them to break regularly at every joint. A moist, comparatively low temperature was maintained until the buds had bursted, when the canes were untied from the stalks and secured to the trellis near the glass, and the temperature was gradually increased. Early pot Vines here are always grown as near the glass as possible, which has the effect of thickening and hardening the leaves. During the earliest stages of growth, strict attention to watering is observed, enough being given to keep the roots moist, but not so much as to saturate the soil. After the fruit is set, copious waterings are given, sometimes twice a day; and whilst the berries are swelling rapidly, weak

A Pot Vine at Berkhamsted.

manure water, the result of mixing fresh horse-droppings and soot, is liberally given them. Indeed, this kind of stimulant is almost the only one used here in Grape growing. Messrs. Lane attribute many failures in growing pot Vines to placing them too near the hot-water pipes, or rather by making the hot-water pipes supply bottom heat, by which means no regularity of temperature can be maintained, as it is necessary sometimes to have the pipes cold and at others hot, according to the state of the weather; grown under these conditions the young fibrous roots are injured, and the crop much impaired. A gentle hotbed of moist plunging material always yields the best results. After the bunches are set the shoots are stopped at three or four joints beyond the bunch, and a little air is left on day and night, which makes the foliage harder and better able to withstand the alternations of cloud and sunshine, which we generally get in spring. A little sulphur is kept sprinkled about the Vineries during autumn as a safeguard against mildew. The soil used for Grape growing here is a heavy, sandy, yellow loam, obtained from the adjoining Common. Tea Roses, struck from cuttings in large quantities, are plunged under the pot Vines, where they succeed most satisfactorily.

Peach trees in pots are grown here extensively, in the form of pyramids, for orchard-house culture. They are potted in 10-in. pots, and in good heavy holding soil; the stocks are budded about 1 ft. above the rims of the pots, and the main shoot is trained in an upright direction by being tied to a stake; the side shoots, which are freely emitted from the main stem the second year, are allowed to grow to about 12 in. or so in length, when they are stopped. These trees in pots are grown in houses during the early part of the year, and in summer are placed in a sunny position out-of-doors. Water is plentifully supplied to the roots during the growing season, but when the leaves begin to die off it is, to some extent, withheld, and every inducement is afforded them to thoroughly ripen their wood. The shoots of such trees as are not disposed of are cut back in autumn to within three or four eyes of the main stems, thereby laying the foundation of bushy trees the following year.

The outdoor nurseries, situated on Berkhamsted Common, are very interesting at this season of the year, when thousands of deciduous trees and shrubs are assuming their varied autumnal tints, which contrast effectively with the more sombre hue of the Coniferae, of which there are here some fine specimens. The Golden Thuja and Retinosporas are just now very pretty, and the bright golden *Lawsonia lutea* forms one of the most attractive dwarf shrubs which we possess. To fruit trees many acres are devoted, and this year they have borne a fair average crop. Rhododendrons, which are grown here in quantity, succeed admirably, even in the heavy, clayey soil of the district, and they are this year loaded with bloom-buds. Of *Thuja gigantea*, a specimen from 15 ft. to 20 ft. high, is loaded with cones of a greenish-yellow tint, a colour which contrasts effectively with the deep green of the foliage, rendering the tree, whilst in fruit, unusually attractive. *Cornus Mas variegata* is grown here in the form of standards, grafted on Cherry stocks; trees of this, from 6 ft. to 8 ft. high, well furnished with good bushy heads of silvery foliage, are very effective when associated with shrubs of a green colour.

C. W. S.

NOTES FROM IRELAND.

Amaryllis Ackermanni Flowering in the Open Border.

—One of the familiar glories of the sunny borders at this season in the so-called Belladonna Lily (*Amaryllis Belladonna*). It is the only one of the genus to which it belongs that, as far as the writer is aware, has been induced to display its beautiful flowers out-of-doors. This, it appears, need be no longer the case, for a fine variety of *A. Ackermanni*, viz., *A. A. splendida*, is just now flowering freely in the open border in front of the central glass range at Glasnevin, where it forms a striking object, far eclipsing *A. Belladonna*. Here is a hint for further trials in this direction.

Hedychium Gardnerianum Flowering Out-of-doors.—

This beautiful plant is in flower now in the open border at Glasnevin, though the wet and chilly summer was by no means favourable to bringing about this result.

The Great Vine at the Viceregal Lodge, Dublin.—The great Vine at the Viceregal Lodge, Phoenix Park, may fairly claim to be the finest example of a single Vine, grown on what is called the extension system, to be found in these islands. It is possible that there are other monster Vines monopolising entire houses, and covering a larger space, but we doubt if the Finchley or any other large Vine presents such a picture of successful Grape culture as does the large Vine at the Viceregal Lodge. The crop this year is perhaps the heaviest it has yet matured, certainly the size and weight of the bunches are beyond the average. Not a few of these would turn the scale between 3 lb. and 4 lb., and the weight of the general run of bunches will be fully 2 lb. each. The number of bunches which are strung along the lines of rod with almost mathematical precision is somewhere about 500, and every one of them fit for the exhibition table. The heaviest bunches are, as a matter of course, to be found at the extreme end of the house opposite to that at which the Vine is introduced, and from which rods are conducted horizontally the entire length of over 70 ft.—“*Irish Farmers' Gazette*.”

***Yucca Treculeana* Hardy.**—Mr. Hemsley (see p. 328) need not have the slightest doubt of this plant being hardy. It may be seen growing at Messrs. Veitch's, Mr. Parker's, and various other nurseries in the neighbourhood of London, and it is as hardy as it is fine in form.—O.

NOTES OF THE WEEK.

The Tomato Disease.—We hear from M. Vilmorin that in France, as well as in England, there is much disease among Tomatoes, no doubt occasioned by the long continuance of wet weather, which has also been so destructive to Potatoes, the same disease being common to both. Large quantities of Tomatoes have been destroyed in the neighbourhood of Paris.

The Irish Heath (*Daboecia polifolia*) in Hants.—This fine and well-known plant has been found in Hampshire by Mr. M. Moggridge. We hope to publish a note on the subject by him shortly. With it grows *Erica vagans*, and not on serpentine rock, on which it is usually found.

Wistaria japonica in Fruit.—An established plant of this Wistaria in Mr. Parker's nursery, at Tooting, is now bearing numerous fruits or seed pods. In shape they resemble those of a French Bean, but are blunt at the ends.—S.

Eucharis amazonica.—We have a double row, between 50 ft. and 60 ft. long, of this lovely Amaryllid on a stage in our conservatory. One row consists of plants in 12 in. and 15 in. pots; the others are in 6 in. and 9 in. pots. Some of the plants in the 6 in. pots are furnished with four flower-stems, and on a plant in one of the 15 in. pots I counted forty-one flower-stems, and on each stem from five to seven flowers in different stages of development. The same plants also flowered well in the spring. I find those in the 6 in. pots to be very useful both for dinner table and sitting-room decoration, and when intermixed with *Dracæna terminalis* the effect is in all respects excellent.—R. C., *Towerham Hall, Norwich.*

Clematis flava.—This yellow-flowered Virgin's Bower is comparatively seldom seen; it however well deserves culture on account of its free-flowering character and the colour of its flowers, which, when associated with white and blue kinds, form a pleasing yet striking contrast. In the Exotic Nurseries, Tooting, it is planted at the foot of dead roots and posts, over which it scrambles and forms a striking object.

The Paris Exhibition Works have made good progress lately; both the Trocadero and the Palace on the Champs de Mars are beginning to assume a less chaotic appearance. The Horticultural Society has decided to hold an international congress next year at their hotel in the Rue de Grenelle, and at the same time a horticultural and botanic show. The Prince of Monaco obtained of M. Krantz a place wherein to show the floral productions, as well as the fruits and vegetables of his principality. This will not be one of the least interesting parts of the exhibition.

New Tuberose.—The new Tuberose called Pearl has a finer spike, and is dwarfier and more double than the common variety. Mr. Vertigans, of Edgbaston, from whom I purchased my roots of it, states that single blooms of it made up into little bouquets with Maiden-hair Fern meet with a ready sale. Its blooms are beautifully white, semi-double, large, and delightfully fragrant.—J. TREVOR, 59, *Wellington Road, Birmingham.* [The specimens sent seem to be a little larger than usual.]

Irises in Autumn.—In Mr. Barr's window in King Street, Covent Garden, may now be seen Irises in bloom grown in glasses like Hyacinths, and very pretty they look. A piece of Moss wrapped round the stems above the roots, prevents them from falling too far into the glasses, and forms a green base for the flower-stems. The kind grown in this instance is the charming little blue-flowered *Iris alata*; but others would doubtless succeed equally well.

Worcester Pearmain Apple.—Of this beautifully coloured and finely flavoured new Apple, Mr. Richard Smith, of Worcester, has sent me samples. He states that it crops as freely as Lord Sniffled, and that its season is from August to October. It is alike suitable for culinary purposes and for dessert, and its brilliant red colour will make it a good market fruit.

Locked Gates at Kew.—In the "Times" report of the Library Congress there are a few words which may be read with advantage in connection with the need of making the gardens at Kew accessible to the public throughout the day. Professor Justin Winsor said "that a period used to be set apart in America for cleaning, but now the cleaning is done early in the morning, and the library is open without intermission from year's end to year's end." It is a greater folly to shut up a rich garden during the best hours of the day than a library, however rich. Kew Gardens cost the people of England over £20,000 a-year, and it is unjust and unreasonable that the poorest person taxed for its support should be excluded from its use at any reasonable hour of the day. It should be opened at six in summer and at dawn in winter; numbers of persons would run out from London by an early train who have not the opportunity to go in the afternoon. The folly of opening a garden so late is all the greater from the fact that it, unlike a library, cannot be used at night. As regards Kew, nobody, so far as we know, has asked that the houses be opened before the men have had time to finish their morning work

in them, but we observe that even in cases of greater difficulty public servants can, when they wish, make institutions convenient to the public. On the same occasion, Mr. Soden Smith said "the Kensington libraries are not closed on any week days; and on three days in the week they are open till ten o'clock at night. The classification of the library was made without closing the library for a single day."

The Purple Giant Autumn Crocus.—We have seen a fine purple-magenta specimen, with Mr. Ware, of Colechicum speciosum, which is certainly a most important plant. As figured in THE GARDEN, the blooms are of a lighter colour than those under notice. This plant cannot fail to take a leading place in all gardens amongst hardy plants, and the fact that it varies so agreeably in colour makes it all the more valuable.

Pentstemons in Autumn.—Some of the newer and finer kinds of Pentstemons may still be seen in bloom in Messrs. Dicksons & Co.'s Nursery, Elmhurst. Though the flowers, individually, are not so brilliant as they have been, yet in masses they are most valuable, and, if frost keep off, will be effective for some time to come. Many of them are seedlings of an improved strain, in the production of which Messrs. Dicksons have been singularly successful.

Autumn Windflowers.—For London gardens, as has been before stated, there are no better plants than *Anemone japonica* and its varieties. Even now, amid a smoky atmosphere, these plants are flowering abundantly; indeed, in almost any position or under any circumstances these Windflowers appear to succeed, but they are of course best when planted in a deep, rich, sandy soil, and in an open situation.

Pyrus Maulei—Handsome fruit of this new and valuable shrub have come to us from Messrs. Maule, of Bristol, and Herr Max Leichtlin, of Baden Baden. The branches from Messrs. Maule are densely laden with large and singularly handsome fruit—some golden-yellow and some beautifully marked with red on one side. Peeled and cut in two, or in slices, and made into preserves like Quinces, this *Pyrus* is said by Herr Max Leichtlin to be most valuable.

English-grown Azaleas.—The demand for Indian Azaleas in our markets in spring is so great that many thousands are yearly imported from the Continent. It is, however, now thought that those of English growth can, by liberal culture, be produced at almost as rapid a rate; and, moreover, the best kinds for the purpose can be procured with greater certainty than from Continental sources. In Messrs. Low's nursery at Clapton, we remarked the other day many thousands of healthy young plants of home growth, and also thousands just grafted for succession.—S.

American Pomological Society.—The sixteenth session of this Society was held in Baltimore on September 12 and 13, and, although hardly so large as on some former occasions, consisted of delegates from twenty of the States. It was stated at the meeting that the present aggregate area in fruit culture was estimated at 4,500,000 (four million, five hundred thousand) acres, comprising 112,000,000 (one hundred and twelve million) Apple trees; 28,000,000 (twenty-eight million) Pear trees; 112,000,000 (one hundred and twelve million) Peach trees; and 141,000,000 (one hundred and forty-one million) Grape Vines. The value of the products were estimated at 50,000,000 (fifty million) dollars for Apples, 14,000,000 (fourteen million) dollars for Pears, 56,000,000 (fifty-six million) dollars for Peaches, 2,000,000 (two million) dollars for Grapes, 5,000,000 (five million) dollars for Strawberries, and for other fruits, about 10,000,000 (ten million) dollars. The entire fruit crop, President Wilder estimates at nearly one-half the value of the Wheat crop. This includes the Oranges, Olives, Almonds, and Figs of California, and the extensive Vineyards of that State.

The New House in Hyde Park.—Mr. Brithwaite writes to us as follows from 12, Sussex Gardens:—"On returning to town, after a six months' absence, I was astonished to see in the very centre of Hyde Park a newly-erected three-storied villa containing some thirteen rooms. This has, as I learn, been built for the head gardener of the Park at the expense of Mr. Albert Grant, in lieu of a lodge which was demolished at the instance of Mr. Grant, when Kensington-house was in course of erection. I also understand that a question has been asked in the House relative to the expense of this villa; and when it was answered that it had been built at Mr. Grant's expense, the subject was dropped, as if the sumptuary side of the question was alone of importance. But the expense of this wretched villa is the very smallest part of the question. I should like to ask, (1) by whose authority it was erected? (2) by what right a large house is built in the centre of a park of which we are constantly told that every foot is sacred to the public? It is both a terrible eyesore and, what is more important, occupies a very considerable space of ground. The authority that builds one house can, it may be presumed, build half-a-dozen; and what guarantee have we that in time the entire Park will not be covered with similar erections?"—"Times."

THE FLOWER GARDEN.

NARCISSUS BULBOCODIUM AND ITS VARIETIES.

THE accompanying illustration represents a charming group of Daffodils, which are exceedingly beautiful either in pots, borders, or planted among Alpines in the rock garden. They are perfectly hardy, can be readily obtained, and are easy to grow under certain conditions; nevertheless, they are rarely seen outside a nursery or botanic garden, a circumstance which I believe to be owing to bad judgment in selecting places that are not adapted for them. All the varieties of this group are natives of the south of Europe, Algiers, and other places bordering on the Mediterranean, where they receive a greater amount of heat to ripen the bulbs than in England; consequently warm, dry aspects should be selected for them, and they should be planted in sandy loam; a heavy, wet soil will not suit any of this group. But soil is of little importance; I have seen them growing freely in almost pure sand, and quite as luxuriantly in stiff loam; but the latter was in a well-drained situation and in a warm aspect. Where the soil and situation suit them, they soon form luxuriant masses of golden-yellow flowers, which are generally produced in April and May, but in some localities earlier and in some later. For edging small beds, for clumps in the borders, or for interspersing among Alpines in the rock garden, the different varieties of Hoop-petticoat are adapted. This spring I counted twelve fully-expanded flowers upon a single plant of the variety called *N. tenuifolius*, and nearly as many buds were just emerging through the ground. They not only produce abundance of flowers, but the individual blossoms last longer than those of any of the ordinary *Narcissi*. For indoor decoration in February and March they are exceedingly useful, and the Algerian varieties come in as early as January. From six to ten bulbs of them should be put into a 5-in. or 6-in. pot early in autumn, and plunged in a cold frame, bringing them indoors as they show flower. The most distinct varieties are:—

N. (Corbularia) serotinus.—This is figured in Sweet's "Flower Garden," t. 164, and is called the Late-flowering Hoop-petticoat. It has long, twisted, dark green foliage, from 15 in. to 18 in. in length, lying prostrate, or nearly so, on the ground; the flowers are larger than those of any of the following, and are of a bright golden-yellow, set on scapes 6 in. high.

N. Bulbocodium, the commonest form, has flowers similar in colour but smaller than those of the preceding. The foliage grows from 6 in. to 9 in. in length, erect, or slightly recurved, and the flowers vary (according to situation, &c.) from 4 in. to 6 in. in height.

N. tenuifolius.—This (figured in Sweet's "Flower Garden," vol. ii., p. 114) is the prettiest, earliest, and most distinct of all the yellow-flowering varieties. Its foliage is very slender, 1 ft. or more in length, and of a dark green colour, slightly glaucous. The flowers, which are numerous (from six to twelve being fully expanded at the same time upon well-established bulbs), are borne on scapes

from 3 in. to 4 in. high; they are smaller and paler in colour than those of any of the preceding, but their abundance, nestling among the slender foliage, renders this *Narcissus* the best and most showy of the group.

N. (monophyllus) Clusii.—This, a white-flowered form recently re-introduced from Algiers by the late Mr. Munby, is an old plant known and described by Parkinson more than 200 years ago, and perhaps I cannot do better than give his description of it, which is as follows:—"This Daffodill hath two or three long and very Greene leaues, very like vnto the small yellow Rush Daffodill, formerly described, but not altogether so round, among which riseth vp a short stalke, seldom halfe a foote high, bearing at the toppe, out of a small skionie huske, severall small white flowers, sometimes declining to a pale color, hauing six small and short leanes, standing about the middle of the trunks, which is long, and much wider open at the month than at the bottome: the small onter leanes are a little tending to Greene" (which I must confess I have not seen). This Daffodil is at present rather scarce, and but few have succeeded in flowering it, owing, I believe, to the bulbs being kept out of the ground too long. It commences growing early in September, and flowers in December and January, and, I think, will not prove hardy except in very warm, sheltered situations in the rock garden. Even if the bulbs will stand frost, the foliage and flowers must get injured by the weather; hence it will be necessary to grow it in pots, or

White Hoop-petticoat *Narcissus* (*N. Clusii*).

protected under a hand-light if planted out. I have plants of it at the present time growing beautifully in an open frame; the foliage is at least 6 in. high, and many of the strong bulbs have five and even six leaves, and I expect to see the greater portion of them flower this winter. These bulbs were planted in August immediately they were received from their native habitat, in a compost of one-third sand, loam, and well-decayed leaf-mould. Last year I flowered numbers of them, and when taken up the bulbs had greatly increased in size, and showed, in an unmistakable

manner, an inclination to divide as other varieties do.

A. P.

BRITISH TOAD-FLAXES.

THOUGH they will be treated of in due course in my papers on "The Garden of British Wild Flowers," I wish to mention specially some little-cared-for Toad-flaxes (*Linaria*), to which my attention has recently been directed. At the recent Reading flower show I was much pleased with a collection of over 200 flowering specimens of British plants from the neighbourhood of Henley, exhibited by Mr. Stanton, gardener at Park Place, on behalf of a botanical class, consisting, I believe, of his assistants. I had no opportunity of speaking to Mr. Stanton on the subject; but two plants especially attracted my notice. They were labelled respectively *Linaria repens* and *L. Pelisseriana*, and there can be no doubt as to the correctness of the first name. *Linaria repens* is unfortunately a rare plant in a wild state, occurring chiefly in old chalk-pits, or on walls. It is a perennial, bushy-growing plant, with small, greyish foliage, and multitudes of delicate little pale flowers of a bluish-lilac or pale violet colour, striped with a darker tint. I found it some years ago at Caversham Warren, near Reading, and it has been recorded from Wargrave, so may well be truly wild near Henley. I never saw it in cultivation

till I paid a visit a short time back to Mr. Ware's nursery at Tottenham, where, I believe, it bears another name. *Linaria Pelisseriana* is an erect, annual plant with purple flowers, wild only "near St. Ouen's Pond, Jersey." I have had a somewhat doubtful dried specimen shown me from St. Vincent's Rocks, Clifton, and I cannot, without examination, be sure as to the Park Place species, which is probably an escape, and may have been identical with a pretty, old-fashioned looking species common in gardens and on walls about here (*Hemel Hempstead*), which is, I believe, though I have no books of reference, *L. purpurea*. This is a shrubby perennial with leaves from 1 in. to 2 in. long, and racemes from 4 in. to 5 in. long, closely covered with purple flowers about $\frac{1}{2}$ in. in length. Every one knows the "Mother of Thousands," or Ivy-leaved Toad-flax (*L. Cymbalaria*), which in Italy is called "Erba della Madonna." Mr. Ruskin has pointed out how fond Bellini is of filling up the rents of the ruined walls in his exquisite pictures with its no less lovely clusters. The violet Alpine Toad-flax (*L. alpina*) is known and deservedly cultivated, whilst the Broom-leaved species (*L. genistæfolia*) was one of the prettiest things I saw at Tottenham; but I could not then help thinking of the uncultured beauty of our commonest species (*L. vulgaris*), and that, were similar attention paid to the *Linarias* they might soon rival their near relatives the *Antirrhinums*. By-the-by, I can fully corroborate what "C. S." says on the lovely show of this group at Tottenham. Their colours blend admirably, and the beds of mixed colours were, in my opinion, very beautiful.

G. S. BOULGER.
The Posting House, Hemel Hempstead, Herts.

HARDY PLANTS AT EDINBURGH.

WE always find autumn the best time for dividing our herbaceous plants, and gain a year by so doing. The soil is warm, or ought to be so, and the nights dewy; thus the divisions get well rooted before frosts come on, and in spring there is always a greater press of work that must be got through.

Tellima.—We find the flower-spikes of these very useful in the shape of cut flowers; the thin wiry stalks bearing many yellowish bells, dotted through an otherwise flat glass of flowers, have a good effect. I am so often asked "Is this a sort of Lily of the Valley?" that it is plain the plant is not much known; like Lily of the Valley, the uppermost bells should be open before cutting, else the upper part of the stalk droops, and will not stand in water: it lasts long, if cut in a fit state. At present the leaves of *Tellima grandiflora* are very prettily coloured and veined, and suit well with those of its relative *Heuchera Richardsoni*. Such I saw at Kew the other day is the correct specific name of this old favourite of ours—a plant which we cannot do without in arranging flowers, or filling up a space in a mixed border where any decided colour would offend.

Lychnis Haageana.—This is the only really scarlet flower in early summer with which I am acquainted, about 1 ft. high. It is quite as bright as the everlasting scarlet *Pelargoniums*, and in good condition before they are; once raised from seed, it is easy to save the exact shade of scarlet you wish: also white; and some have foliage and stalks as dark as those of *Lobelia fulgens*, which renders the flowers intensely red.

Libertia grandiflora.—This is another early summer flowerer, which I am always asked for. Its pure white *Tradescantia*-like flowers are very beautiful, and of firm substance. A *Libertia*, from Otago, we find well worth growing; it is a little later than *L. grandiflora*, has smaller blossoms and longer stalks, tipped with black, which gives it a distinctive character. *L. grandiflora* is, however, the favourite, I find, with non-botanical visitors.

Mule Pinks.—Beds of these last long, and by mixing young layers with old plants, a succession of bloom is kept up. We only grow the perfectly hardy sorts—some four or five—pink, rose, crimson, pure white, and (best of all) a neat little parti-coloured flower, which is lost about Edinburgh, and which I was delighted to come upon lately at Parker's, Tooting; its foliage is quite like that of a true Pink, and it is very close and compact in growth. Names of Mule Pinks seem to be local; at any rate, it is not wise to purchase by name: for instance, there is no end to kinds called *multidorus*.

Alpine Poppies.—These are charming plants; a bed of the white, yellow, and orange dotted among *Campanula trachelium* has produced flowers for four months, and there are still numbers of the pretty black-haired buds to come out. Earwigs and slugs seem to find

Poppy-flowers toothsome, soporific perchance; but it is interesting to watch the buds in water splitting up their calyxes, and extending and unfolding their wrinkled petals, and at last raising their heads; it is a slow process, and they keep good a full week in water, a remarkable time for so delicate a single flower as *Papaver alpinum*; the little double French annual one does not last nearly so long a time.

Vittadinia triloba.—This is still not sufficiently grown, judging by the queries I am asked about it and the requests for seedlings which come up everywhere (in the Box and other edgings of the walks), and seeds occasionally ensconce themselves in pots in the greenhouse. Of these truant plants we are glad, as they save us touching our little beds, and I am always anxious to encourage a fancy for a hardy plant.

Single Dahlias.—This season has proved the superiority of single over double Dahlias, as they do not require so much sunshine to open. *D. coccinea*, *aurantiaca*, the little *D. glabrata*, and *Cervantesi*, are the single sorts which we have. *Cervantesi* is a tall, graceful-growing plant, compared with other Dahlias; its fault here is its lateness in flowering, but the small, unstiff, orange flowers are very attractive, and the foliage is also small and can be cut. I got it and *aurantiaca* from Mr. Harpur Crewe. One great charm of single Dahlias is their turning to the sun, which they always do if they can, and thus form favourite resting-places for Tortoiseshell and Red Admiral butterflies, and excellent exercising grounds for numerous smaller insects; these parade round and round their yellow centres, and are, to my mind, a valuable addition. Single Dahlias are invaluable in a cut state, being free from earwigs.

Oenothera riparia.—I still maintain that this is the best, and, in fact, the only yellow evening Primrose for small beds, edgings, or as a groundwork for other plants. It becomes a mass of delicate flowers, is perfectly hardy, and goes on flowering even after the first frosts. Those plants bloom first that are left in the ground; we, however, like to be prudent, and lift a few or strike a potful of cuttings in case of accident, but in the end this reserve stock is generally given away. The old plants may be divided in spring to any extent. I have again got hold of the pretty but capricious *O. speciosa*; once it was a weed with us; we tried to keep it within bounds, and lost it for years. Only let it establish itself again in our mixed border, and it shall not be meddled with.

Erodium maritimum.—This some call a *Geranium*. It seeds freely, and flowers during seven and even eight months of the year. Late in autumn its pale lilac flowers veined with a darker shade, after the fashion of *Geraniums*, are valuable, and the buds come out in water.

Mimulus cardinalis.—This is a favourite with us, and grows beside another good plant, viz., *Calimeris Diplopappus*, whose pale lilac Aster-like flowers look well by the brick-red Monkey-plant; they grow the same height, and have both been in flower many weeks. The rose-coloured variety, which came out at the same time as *M. cardinalis*, we have lost for the present, but it must be somewhere.

Monarda didyma.—This we grow in quantity, as both leaf and flower are sweet, and therefore of use for making into nosegays for the Blind Asylum. It has flowered extra well this season, and we are quite tired of making blanks in our edging of it, and hearing "how well that handsome red flower looks in your glasses," and so our friends must have a plant. We have white, purple, and magenta varieties, but the old *didyma* (*Bergamot*) is by far the best; the red blotches at the joints and axils of the leaves are a good addition.

Scabiosa caucasica.—This is a very fine plant. Mr. M'Nab was the first to tell me how well it stood in water, and how its particular shade of lilac came out in candle light. It has a new name now, which I never can remember. It is sure, however, to be called a *Scabious* at first sight by all who see it.

Lysimachia punctata.—This is at present in blossom, and a very light, useful, yellow flower it is.

These are a few of the many herbaceous and hardy subjects which have this season shown us the advantage of not depending on bedding plants, and our hardy borders have been much envied by our neighbours. Where there is a variety of plants grown some are sure to revel in what is called a bad season, and I must say that I love to see our plants happy, even if one be rather downcast and miserable oneself.

F. J. HOPE.

Wardie Lodge, Edinburgh.

Eulalia japonica.—Will you kindly spare me room for a line, just to point out that in your notice of this plant in *THE GARDEN* of last week (see p. 333), you have made me say exactly the reverse of my intention, by the omission of the word *not* in the last line, which should read—"it is probable that the variegated forms will not reproduce themselves by seeds."—W. THOMPSON, Ipswich.

"COCKED-UP" BEDS.

AMONG the least agreeable features of our modern flower garden are beds on the top of small embankments. The fashion came first to us from Paris. It was once employed with a motive generally to secure a greater degree of heat to the more tender plants. Now beds of the freest-growing flowers may be seen fortified with these ugly banks, though no more in want of their assistance than a group of Docks. In any garden well laid out, the shape of the beds must not be obtrusive. In the gardening of the future, the plants, not the bed, will be what meets the sight. Over the whole of a large garden, the impudent bed shown in the accompanying woodcut stares at one, not when it is full only, be it observed, but when it is bare of plants. We believe the plan to be as needless as it is offensive. Given a good warm soil and good drainage, there is no need for this awkward elevation of the mass! On the contrary, there is often decided advantage in having the roots in a cool medium, not more exposed to

evaporation than need be. The gentle rise towards the centre of a bed sometimes desirable, is easily secured without raising the edge above the turf, from which all flowers should spring.

SHOW AURICULAS.

AS THIS is the season at which beginners in Auricula culture should commence to form their collections, I have thought it desirable to furnish the names of a few kinds that can be obtained without much difficulty, and which are all on the whole easily grown:—*Green edge*—Apollo (Beeston), General Neill (Trail), Imperator (Litton), Lord Palmerston (Campbell), Lovely Ann (Oliver), and Prince of Wales (Ashton). *Grey edge*—Colonel Champneys (Turner), Conqueror of Europe (Waterhouse), Privateer (Grimes), Ring-leader (Kenyon), and Robert Trail (Lightboy). *White edge*—Catharina (Summerscales), Earl Grosvenor (Lee), Ne Plus Ultra (Smith), Robert Burns (Campbell), Sir Robert Peel (Finlayson), and True Briton (Hepworth). *Selves*—Blackbird (Spalding), Formosa (Smith), Lord Clyde (Lighthody), Master Hole (Turner), Mrs. Sturrock (Martin), and Mrs. Smith (Smith). These can all be had, and they would vary in price from 2s. 6d. to 5s. each. Those who have qualified themselves, by a certain amount of success with the commoner flowers, to ascend to a higher level of Auricula culture, should endeavour to obtain such fine varieties as:—*White edge*—John Waterson (Cunningham), Smiling Beauty (Heap), Ann Smith (Smith), Trail's Beauty (a variety that is apt to come grey), and Taylor's Glory. *Green edge*—Prince of Greens, Booth's Freedom (a grand old sort, remarkable for the dense black of its body colour), Trail's Anna (very fine), Alderman Wisbey (Headly), Admiral Napier (Campbell), and Page's Champion. *Grey edge*—Syke's Complete, Lancashire Hero (Ouchtham), Alderman C. E. Brown (Headly), George Lightbody (Headly), Richard Headly (Headly), and Read's Miss Giddings. *Selves*—C. J. Perry, Lord of Lorne, Duke of Argyll, Pizarro, Petronella (Headly), Spalding's Metropolitan, Sim's Eliza, and Ellen Lancaster.

No one can expect to succeed with Auriculas unless he has a frame in which to grow them. During the winter, the frame should be under a north wall or hedge, so that the plants might face the south, and in summer it should be in a north aspect. During the autumn and winter months, the frame should be raised on a dry bottom, so as to ensure, as far as possible, freedom from damp. In the north of England—and, indeed, in the midland districts—a cold greenhouse is a good place in which to winter the plants. There should be provided a stack of fresh turf, so that it can lie by and decay, some leaf-mould, and charcoal, bruised to the size of split Peas. Charcoal is much better than sand for keeping the soil open; besides, it is of advantage as a fertilizer. The cultivators of the largest collections scarcely find it necessary to put their plants into a larger-sized pot than a 5-in. one; and some of the best kind of

pots an Auricula cultivator can keep by him are long Toms, which are deep and narrow, and which suit Auriculas well. As prizes are often offered for Alpine Auriculas, it will be well to direct attention to some of the best exhibition flowers. For the sake of convenience the Alpine Auricula may be divided into two classes, viz., the shaded and the unshaded flowers. The shaded flowers have a white or golden centre on paste, with a marginal body-colour shaded off to a paler colour, thus showing two distinct tints. An unshaded variety shows a self-coloured flower. At the National Auricula Society's exhibition at Manchester, only shaded flowers can compete for prizes; but at the Southern show, held at the Crystal Palace last April, unshaded flowers were permitted to compete. Of the shaded flowers, some of the best for exhibition purposes are Gorton's Mauve Queen, Gorton's Diadem, Turner's Bronze Queen, Turner's Dolly Vardea, Turner's Queen Victoria, Borealis, Conspicua, Turner's Novelty, and John Leech. Of the unshaded flowers, the finest are Napoleon III. (Turner), John Ball (Turner), Vesuvius (Turner), Selina (Turner), Spangle (Turner), King of Crimsos (Turner), and Diamond (Turner). As a general rule, at Auricula exhibitions the show varieties carry but one truss of flowers; the Alpine varieties as many as can be produced in good condition.

The shaded Alpines are generally grown in poorer soil than the unshaded flowers, but cultivators differ in regard to this matter. If the soil be too poor, it is said, the individual pips will be small in size and they will lack expression. The leading growers in the neighbourhood of Manchester cultivate their Alpines in good soil, and perhaps the cool, moist atmosphere which prevails there in the springtime has something to do with the exquisite shading produced on the flowers. In the north it has been found advisable to separate the Alpine flowers on the exhibition table, and they are divided into two classes, those with gold centres and those with white or mustard centres. So much preference was given to the varieties with gold centres, that fine flowers with white centres stood no chance against them. The presence of the golden centre gives a striking effect to the flowers, and it is worthy of remark that nearly all the unshaded flowers have golden centres. Alpine Auriculas are all pretty and well worthy cultivation; but he who grows a choice collection of the show kinds, with the view of raising seedlings, should not permit any Alpine varieties to be grown near them. D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Anemone japonica alba.—This is one of those hardy plants of which it seems impossible to write too often. It is a most valuable autumn flower and one that must be universally grown when its merits are better known. Small plants of it with flowers a couple of inches in diameter afford but a poor indication of what it is when thoroughly established as a hardy border plant. In a year or two, in good, deep soil, it will reach a height of 5 ft., and be literally loaded with large, pure white flowers, almost rivaling those of the *Eucharis* in purity, and measuring nearly 4 in. across. The original *Anemone japonica* is also a very useful plant and well worth cultivation, but *japonica alba* and its pink compeer, *intermedia*, are in every way invaluable.—A.

Ivy Embroidery.—It has not yet occurred to the masters of decorative gardening that the Ivies are capable of furnishing most valuable material for certain kinds of embroidery planting, which probably would tell with best effect in a large garden wherein spring flowers play an important part in the annual colouring. There are not many varieties adapted for such work, but the few that are evidently best fitted for it are conspicuously appropriate. Thus amongst the climbers we have *Marginata grandis*, which would probably be the best for forming bands of silver, and there are several others of the same section available where a weaker growth would be required, and in some soils the pretty *Marginata rubra* would develop a fine tone of red in the winter. For yellow leafage there is no climbing variety good enough, but the well-known tree Ivy named *aurea* produces a brilliant growth of orange-coloured leafage, and in a poor soil is very constant. The little *minima* is distinctly purple in winter, and Hibberd's *Emerald* would be the most useful of the green class, as it is a better colour during winter than the Irish Ivy, which is too dark for the purpose, and from March to August it presents a rich and dense growth of golden-green leafage. Others would come in, of course, as *nigra* for a very dark green, and *lucida* for glossy bronze, *tortuosa* for a neat growth of very dark, highly-polished leaves. In any case, the surest to begin with are *Marginata grandis*, *aurea*, and *Emerald*. With these to form the more distinctive outline, it would be no difficult matter to fill up with a selection of a dozen or so of the neat growers with both green and variegated leaves, because for certain parts of a pattern the silver tree Ivies would come in well. A garden boldly framed in Ivy embroidery would have a charming appearance all the winter, and if a good assortment of spring flowers appeared amongst the Ivies from March to May, the Ivies would afford, in their interest, a strong, definite, and rich foundation or setting, and quite a new and characteristic style of gardening would be the result.—"Gardeners' Magazine."

TREES AND SHRUBS.

PINUS CONTORTA (DOUGL.).

SYN.—P. TAMRAC (MURR.).

You ask for information regarding the species of Pine, the cone of which is figured in the accompanying woodcut under the name of *Pinus Tamrac*. I am sorry to say that I am responsible both for the species and the name, and I wish both to be cancelled. It was in the winter of 1868-9 that an American collector (Mr. I. Q. A. Warren) brought to this country from California a collection of objects of natural history, among which were specimens of Pine cones, shells, &c. Some of these were acquired by the British Museum, and I obtained a few of them, among which were the cones of this species. Mr. Warren informed me that it was a new species found on the route of the Pacific Railway, and that it was called by the settlers the *Tamrac*. It never occurred to me until too late that this was a mere corruption of the word "*Tamarac*," applied by the Canadians to the American Larch

*Pinus contorta.*

(*Larix pendula*), and doubtless applied by many later to this species from a fancied resemblance. I recognised it as identical with specimens sent home by Jeffrey to the Oregon Botanical Association, and which had been submitted to Sir William Hooker and Dr. Lindley, and returned as undescribed, although it was very shortly afterwards described by Newberry in the Pacific Railway Reports. On examination, his description did not seem to me sufficiently to correspond with Mr. Warren's specimens, and in a hasty moment I described it from them in 1869 as new. Four years afterwards (in 1873) I had the opportunity of seeing the trees growing in their native country, and at once saw that there was only one species concerned, although considerable variation occurred in the details of the cone. The published descriptions are misleading. Thus, Gordon says the tree is 15 ft. or 20 ft. in height. The most characteristic specimens that I saw were 50 ft. to 60 ft. in height. The scales of the cones, when handled or fallen, lose their long, projecting mucro, which, when uninjured, is one of their most characteristic features. But there is no mistaking the tree itself with its unrifted bark and other characters. Seeing that I have contributed to embroil the synonymy, I am very glad to have the opportunity of making the retraction and apology which I now do.

ANDREW MURRAY.

THE FORESTS OF ATHOLE.

THE Duke of Athole's famous plantations at Blair Athole and Dunkeld have engaged the pens of numerous writers from the period of London's compilation of the "*Arboretum*" to the present time. Mr. McGregor, who holds the office of forester on the Duke of Athole's domain, has enabled a correspondent of "*The Agricultural Gazette*" to repeat an old but interesting story. Previous to the accession of the great planter, Duke John, in 1774, two Dukes of Athole had planted Larches. In 1738 Duke James planted, at Blair Athole and

upon the lawn at Dunkeld on the banks of the Tay, on a rich alluvial sand with open channelly subsoil, sixteen Larch plants, the parents of the subsequent and famous crop which was sown on the same property. One of these original Blair Athole Larches furnished the timber for the great planter's coffin. The height of this tree was 106 ft. Three of the five Dunkeld lawn trees were also felled, and two of these which were cut down in 1809 contained, at the age of seventy-one years, 147 cubic ft. and 168 cubic ft. respectively; and the last-mentioned was sold in Leith to a company of ship-builders for 3s. per ft., or £25 4s. the tree. Baltic timber at that time was selling at war prices. The two other original Larches on the lawn still stand close to the ancient cathedral of Dunkeld, and not far from a fine group of their own offspring. They are still sound timber at 138 years old, though their period of growth had been reached some years since. The largest tree measures 98 ft. 10 in. in height, and 14 ft. 6 in. in girth at 5 ft. from the ground. The trunk is perfect in shape, tapering gradually and regularly, until it ceases to be measurable timber at about 20 ft. from the top. It is said to contain 423 cubic ft. of timber. These two companion trees are 11 yards apart, and their branches meet and interlace without injury. From this history of two Larches, which probably attained their growth at about one hundred years, we learn much in reference to the quantity of timber which may be produced on good light land with natural drainage. To continue our general history. It was by no means easy to obtain Larch plants. The sixteen just noticed were brought from London by Mr. Menzies of Migeny, who presented them to the Duke. Others were obtained by the same Duke James, who planted, in all, 1911. John, Duke of Athole, who succeeded in 1764, obtained about 1,000 plants yearly from the cones of the first planted trees upon the lawn, and added in ten years 11,400 young Larches to the growing crop. His successor, John the Planter, soon became a Larch lover and an enthusiast, but previous to determining on the general planting of his estate, he felled some of the original Larches, aged forty or fifty years, and tested their value. In a short time the Athole frigate, and a small fleet of merchant ships built of Larch timber, were afloat, and to his intense delight, he soon discovered that the timber of the new Fir from the Tyrol was equal, and in some respects superior, to that of the ancient Pine of Scotland. The greatest efforts in planting were made during the years 1816 to 1818, when 5,922,000 Larches were planted, and from 1824 to 1826, when 4,038,880 were added. The great improver died in 1830, having planted 12,974,380 Larches without mixture, and 1,122,339 Larches in mixed plantations. The following abstract account of the Duke of Athole's woods and forests was drawn up in 1829:

	Statute Acres.		Statute Acres.
Oak	1,337	Scotch	435
Larch	10,755	Mixed	3,665
Spruce Fir.....	470	Birch	30

On the Duke's accession in 1774 the total number of acres planted was about 1,250, consequently the area planted by him was 15,473 statute acres; and allowing 2,500 plants to each acre, the total number of trees planted was 24,756,000. In reality the number was considerably greater, and if ten per cent be allowed for making good the failures of plants, the total number of trees planted would be 27,231,600.

GALEWORKS.

To the genus *Myrica*, our collections of hardy trees and shrubs are not much indebted. All the species are more fitted for the botanic garden than for the decoration of the park or pleasure ground. They are widely spread over the temperate regions of both hemispheres; in North America, at the Cape of Good Hope, in Northern India, China and Japan. Some are eminently social, for example, our British Bog Myrtle or Sweet Gale, which in North-west Europe covers enormous tracts of bog country; indeed, none are found naturally, except on the banks of rivers and inundated spots. This points to the bog garden as the place where they would be of the most use and where they would best succeed; *M. Gale* is the badge of the Campbells. The leaves are bitter, but have a Myrtle-like fragrance, whence one of its common names. Formerly northern nations used this bush as we now use our Hops and in a few places in the Highlands of Scotland and elsewhere that usage still lingers. *M. cerifera*, the Bayberry or Wax Myrtle, is a shrub or small tree growing near the sea-coast of the Eastern United States. Its berries are coated with a waxy secretion, which was once largely used in the domestic manufacture of candles. A good series of specimens may be seen in a case near the door of the No. 1

Museum at Kew. The Californian Bayberry, *M. californica*, sometimes attains a height of 40 ft., with a trunk 2 ft. in diameter. *M. arguta*, of which we give a representation, was discovered in New Granada by Humboldt and Bonpland, and is described and figured in their "Nova Genera et Species Plantarum." It has rather straggling branches, with thickish rugose, oblong-lanceolate, stalked leaves narrowed at the base, edges sharply toothed, glabrous underneath, pubescent above.

Myrica arguta.

The catkins are axillary, and are generally produced in threes, the male flowers occupying the lower, and the female the upper portion of the catkins. G.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Difficult Transplanting.—Doubtless the fame of the Birch-tree which, like Picciola's flower, by a freak of Nature took root on the top of St. Stephen's Tower, at Vienna, is familiar to our readers. By order of the Municipal Council of Vienna, this tree was transplanted from its native altitude to the Rath Haus Park; but the unfortunate tree could not thrive in this low region, and has just died.

Duration of Oak Under Water.—The alteration undergone by Oak wood which has remained a long time in water is remarkable. This was observed at Rouen in 1830, in the case of pieces of Oak from an old bridge built in 1150. M. Berthier reports in a chemical work that the wood was like ebony, and the modification was found due to the presence of peroxide of iron. Another case has just been recorded by M. Charrié-Marsaines. Having occasion in constructing a discharge sluice on the Rhine, to demolish an old military dam, built by Vauban in 1681, and based on a platform which consisted of Oak wood in a cubical block of 80 metres, he found this wood to have a dark colour, quite like that of the ebony, and very great hardness, as was found on trying to cut it for re-employment in the new works. The wood then had been 146 years in a soil constantly soaked with water.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Lawns.—Should the present genial weather continue, it will, in conjunction with the more than usual amount of moisture contained in the soil, keep the Grass growing on vigorously later than ordinary; therefore, in order to preserve a neat appearance it should be kept mown, all fallen leaves should be swept up, and worm-casts removed by sweeping and rolling; the walks, too, should be kept free from weeds, and constantly rolled. Unless matters such as these are diligently carried out, the falling leaves and other indications of winter give the garden an unsightly appearance. Those who admire the beautiful tints of the leaves of deciduous shrubs and trees previous to their falling off, will do well to note what pleases them best, with the view of introducing them into their gardens now that the season for planting is at hand. Shrub-beries and herbaceous borders should again be gone over with the hoe and rake, removing from the latter all dead flower-stems; for it should ever be borne in mind that it is not extent but faultless keeping that renders a garden enjoyable.

Carnations layered early should, as soon as sufficiently rooted, be taken off and potted; it is usual to put a pair of layers together in 5 in. pots, draining them efficiently, and using good soil moderately enriched; put each layer at opposite sides of the pot and press the soil firm, so as to allow half an inch space for water below the rim, and moisten them fairly as soon as potted. They should then be at once plunged in a frame in a bed of coal ashes, with 3 in. underneath them to exclude worms; the lights should be put on and kept rather close for a few days until the roots have begun to move, after which they ought to be drawn off so as to expose the plants fully—except in very wet weather—until there is an appearance of severe frost. This of course applies to the more tender varieties of Carnations and Picotees; the more robust-growing Clove kinds, where layered early enough to be now well rooted, may at once be taken off and planted either in nursery beds or where they are to flower; such as were layered later and have not got properly rooted had better remain undisturbed for some weeks yet, or until spring.

Pinks that were piped at the proper time will now be well rooted, and a bed should be prepared for them where they can be grown together, as although desirable plants for the front or second row of a herbaceous border, still to do them justice they ought to have a piece of ground to themselves in a good open situation away from trees or walls. Where the land is of a heavy damp, character it should be raised from 4 in. or 6 in. above the surrounding level by the addition of fresh soil; and even where it is dry enough to grow Pinks well they should, after the ground is well dug with a moderate quantity of manure added, have from 4 in. to 6 in. of new soil laid on the top, and pointed in with a little more manure. In this the pipings should be planted 6 in. or 8 in. apart in rows, with 10 in. or 12 in. spaces betwixt the rows. New soil like the above generally contains wireworms, and as these, from want of something else to eat, will prey upon the roots of the Pinks, they should be trapped by means of slices of raw Potatoes thrust into the ground at intervals of a foot or so apart; or sliced Turnips laid flat on the surface will answer the purpose; these traps should be looked over every other day or so for a few weeks, and the wireworms destroyed; the same precaution should be used in the case of Carnations, whether in pots or in the open ground. These plants deserve a place in even the smallest garden; they are in no way difficult to grow, and their flowers, which are produced in quantity over a considerable portion of the summer, last long when cut either in bouquets or vases.

Herbaceous Plants.—Fibrous-rooted spring and early summer-blooming herbaceous plants, that have become too large, may now be divided; by carrying out such work at this season when the tops are dead or nearly so, the plants will bloom much better than if it were done in spring. All should therefore be removed or divided that require it, except such plants as the common White Lily, which will now be making active growth, and if the roots be disturbed it will have the effect of wholly or partially preventing its flowering next year. The majority of herbaceous plants are an exhaustive crop; consequently the ground in which they have grown, and which they are again to occupy, should be well enriched by a liberal application of manure and deeply dug; this latter is essential where, as is often the case, the roots of shrubs or trees have access to it. Where any considerable number of the plants are thus to be got up, advantage should be taken of the opportunity to re-arrange such as may require it, not only by keeping the strongest-growing ones to the back, graduating regularly so as to have the lowest growers in front, but also mixing the colours in a way that will produce the best effect.

Bedding Calceolarias require treatment different from that given to other bedding subjects; their nature is such that the some.

what dry condition of the atmosphere necessary to keep the leaves of other plants generally used for bedding from damping through the winter would be fatal to the well-being of the Calceolarias; neither will they bear so much warmth as most plants; anything above actual frost, or even a few degrees of the latter will do them no harm. Cuttings of them also do not succeed if put in early in autumn, as they get too strong and vigorous before spring, the result of which is that they are much more likely to be attacked by the root disease, to which they are liable, than late-struck smaller plants, that require less room to keep on growing until the time for bedding them out in spring. I have generally found those put in about the middle of October to do the best; a small frame should be prepared for them, putting into it some fine, moderately-light, sandy soil, about 5 in. in thickness; if this rest on a solid bed of ashes, it will be all the better, as it will prevent the roots from extending downwards; put the cuttings in 3 in. apart, pressing the soil to them, so as to make them firm, and give them a good watering immediately afterwards; put on the lights at once, admitting a little air for a few hours in the day. Calceolarias are water-loving plants, and the soil must never, from the day on which the cuttings are put in till they are planted out in spring, be allowed to get into anything approaching a dry condition. They will very soon root, when more air may be given them; mats should always be in readiness to cover them when there is an appearance of sharp frost, for although a little frost will not injure them, yet if frozen before they get fairly rooted it might do harm. A good body of litter should be prepared to put round the frame in winter and to lay on the glass, in addition to mats, during the time of continued frost.

Kitchen Garden.—Weeds have had an unusually flourishing time of it this summer, and, where cleanly gardening is not carried out, will entail much labour in keeping them down, as where not destroyed by stirring the surface with the hoe as soon as they have vegetated, many get so strong that with the damp condition of the ground they are able to re-establish themselves even after being cut up several times.

Strawberry Ground should be kept clear of weeds, and all runners at the same time should be cut away; but by no means remove any portion of the leaves whilst there is the least vitality in them, as is often done under the impression that it assists the crowns to plump up and ripen; than this no greater mistake can be made, as every leaf that is removed whilst it has any life in it has a weakening influence upon the bearing capabilities of the plants for another year. Should the weather keep dry the whole of the ground ought to be well hoed, letting it lie undisturbed for a few days; then give it another stir with the rake; if this be repeated two or three times the earth that has been removed in hoeing will part from the weeds, and they can be cleared off without the removal of any soil with them. In land of a medium character this can easily be done, but where it is extremely retentive, and of a clay-like nature (such as Strawberries succeed best in), it is so adhesive that it is a difficult matter after a wet season to get the weeds off without a good deal of soil adhering to them; in land like this it may be necessary to bury the weeds by shallow digging; this will be especially the case where a good deal of Grass has sprung up, which amongst Strawberries much more troublesome and difficult to kill than ordinary summer weeds.

Raspberry, Gooseberry, and Currant quarters should be similarly treated; it frequently happens that a few summer weeds are taken little notice of at this season of the year, under the impression that it is too late for them to do much harm; yet this is by no means the case, as they are native plants of a most persistent character that will go on flowering and producing seeds up to the end of the year, and a little inattention to them often entails a great deal of after labour. All ground occupied by winter Onions, Carrots, Lettuce, Endive, Coleworts, Cabbage, and Leeks, should have the surface hoed, taking advantage of dry weather for the purpose.

Latest Apples and Pears should be gathered as they become fit for use. Most kinds have this year kept on growing later than usual for two reasons—first, on account of the very late spring retarding the commencement of their growth; and, secondly, through the effects of the damp summer keeping the foliage much clearer than ordinary from the attacks of red spider, the result of which is that the leaves are retaining their vitality much longer than they generally do, which to a great extent prolongs the growing season of the fruit. It is not well to let these fruits remain on the trees after they are in a fit condition for gathering, for should strong winds occur part of them will be shaken off; yet it is better to lose some in this way than to gather too soon, especially in the case of late-keeping kinds, which are sure to shrivel if removed from the trees before they are quite ready to store.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

October 15.—Sowing Mustard and Cress. Putting in the last of the Calceolaria cuttings. Tying up Lettuce, and covering up Endive to blanch. Turning manure for Mushrooms. Getting manure and leaves together for making hotbeds. Gathering the last of the Tomatoes, and hanging them up in Pine stove to ripen: gathering also Glou Morceau and Knight's Monarch Pears.

Oct. 16.—Potting Echeverias; also old plants of Tom Thumb and Indian Yellow Pelargoniums. Thinning out Mignonette in pots. Salting all the flint gravel walks. Looking over Camelliflowers, and turning down leaves where required to protect the heads from frost. Hoeing among all late planted Cabbage, Endive, and Lettuce. Stacking away Carrots and Beetroot. Collecting leaves, cleaning walks, watering Pines, and tying them where required.

Oct. 17.—Sowing Canadian Wonder French Beans. Looking over cuttings, taking off the tops where required, and removing dead leaves. Earthing up Celery when the soil is dry and in workable condition. Cutting back the heads of Yews, Laurels, and other shrubs where beginning to overhang each other. Gathering Easter Pippin and Lamb Abbey Pearmain Apples.

Oct. 18.—Putting in cuttings of Pentstemons and Antirrhinums. Clearing off flower borders, and getting them ready for spring-flowering plants. Filling up all pits and frames as they become empty with Lettuce and Endive. Making another Mushroom-bed. Gathering last of Vegetable Marrows and clearing away the plants.

Oct. 19.—Potting various kinds of Pelargoniums. Planting spring-flowering plants of the following sorts, viz., Red and Yellow Wallflowers, Red and White Daisies, Iberis, Myosotis, Alyssum saxatile, Pansies, Nemophila, Saponaria, and Silenes. Fumigating Cucumbers. Clearing off late Peas and stacking the best of the sticks for another year. Gathering Uvedale's St. Germain and Catillac Pears.

Oct. 20.—Potting Hyacinths, Narcissi, and Tulips. Getting cuttings of some of the tenderest plants into warm quarters. Looking over Grapes in bottles, and putting more water in such as require it. Putting haybands round Cardoons, and earthing them up. Cleaning up pleasure grounds and rolling walks where required. Fruit in use for dessert—Pines, Grapes, Pears, Apples, and Nuts.

Rats and Climbers.—I reside in a house which once formed part of a great abbey, and is now included in the precincts or close of a renowned cathedral. Its venerable walls are clothed, and greatly adorned, by a luxuriant growth of clustering Roses, of Ivy, and of white Jasmine and Clematis, the two latter now in charming perfection, the admiration of all beholders. The Clematis, especially, regales our eyes by its wealth of blossoms immediately beneath the sill of our drawing-room window, on the first floor of the house, some 15 ft. above the level of the garden below. That birds, bees, and butterflies should hover around the creepers, and share our enjoyment of their beauty, is quite according to the best precedents, and has our full acquiescence and approval. If a few earwigs extend their walks beyond the leafy shelter, we know how to pardon such indiscretions. But we are not superior to old-fashioned prejudices against mischievous vermin of a much more formidable kind; and you may imagine our surprise, when at tea yesterday evening, to have ocular proof that rats avail themselves of our climbing plants for the purpose of invading our upper decks, and that they use them as sailors use the shrouds of their ships; in short, that the boughs and tendrils of our creepers are converted into rat-lines! The tranquility of teatime might well be interrupted when a whiskered Rodent appeared at the window, tried it with his clever paws, and, finding it closed, retired with a discomfited air! Must we really cut away our charming Clematis? Can we by no sacrifice less harrowing to our best affections place ourselves beyond the reach of renewed attacks by unscrupulous and crafty invaders.—“Science Gossip.”

A New Beverage.—Mr. O'Connor, of the British Legation in Brazil, calls attention, in a recent official report, to *Sierva-maté*, an article largely cultivated in the Province of Parana, and exported to neighbouring South American countries, but hitherto not on the list of exports to European markets, though it would, he has no doubt, be very acceptable, as it is pronounced by those who have tried it a capital substitute for our far more expensive, and too often adulterated, tea and coffee. He says it is more fortifying and alimentary and much more wholesome, and can be sold at a price so moderate as to place it within the reach of all classes. He states that the Minister of Agriculture has appropriated a small sum for the purpose of making this excellent plant known in Europe.

Emerald Green is the proper English name for the “Paris Green,” now so much spoken of in connection with the destruction of insects.

FARMERS' KITCHEN GARDENS.

A FEW farmers have provided themselves with an excellent supply of garden vegetables the whole year round; there are others who likewise obtain a good supply, but at much greater cost; a third class who have a poor and expensive supply; and a fourth, who have no kitchen garden at all. It is to the practice of the first mentioned class that we will now allude. The most successful farmers are those who practise to a certain extent what is called "high farming." Those who raise garden vegetables, procure them most cheaply and of best quality, when they pursue this kind of management—namely, with rich soil, clean culture, and with labour-saving appliances. Many have weedy gardens, because they depend on doing

Fig. 1.

Fig. 2.

the work by hand. They have thus gone into business beyond their ability to manage, by providing a large garden, which they could not properly till. It would have been better to have confined their operations to a single square rod, and given it the highest manuring and tillage, than to have attempted to take care of half an acre by means of the spade and hoe, and raised half a ton of weeds, and a multitude of seeds instead. We have repeatedly urged on those who are compelled to practise economy, to plan their gardens so as to be cultivated with a horse. If they do so, and manage aright, they may accomplish all they desire at one-tenth the cost of working by hand, and this saving in many cases is the turning point between utter failure on one hand and an abundant supply on the other. Farmers put off planning and laying out their vegetable gardens till

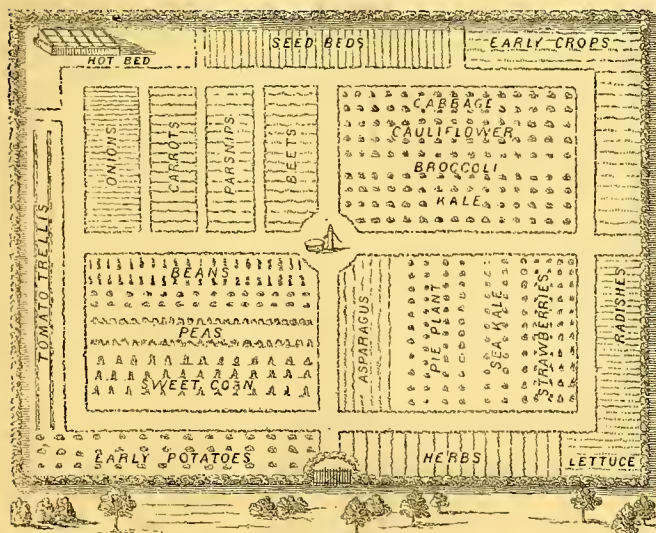

Fig. 3.

spring. This is the first mistake they make. They should begin in autumn. This will enable them to accomplish two very important objects, namely, to apply manure copiously and repeatedly before and during winter, so essential to success in raising vegetables, and to work the soil over and over with plough and harrow during autumn in intermixing this manure; but more important, to clear out and kill every vestige of weeds by this easy and cheap process, and thus save a vast amount of thumb-and-finger labour next season. The old-fashioned way was to lay out the garden with alleys, blocks, and squares, in which shape it was impossible to use a horse, but all must be worked by hand. Fig. 1 represents this mode in a simple shape, fig. 2 somewhat more complex, and fig. 3 is a large and complete kitchen garden, occupying about an acre, and

requiring at least the constant labour of one man to plant and keep it in order. Laid out and planted in the way we propose, a small

Fig. 4.

portion of one man's labour would do all the work, and it would be better done, and the crops would be better, because the owner could afford to pass over the ground oftener with his one-horse harrow or plough, or cultivator, and to keep the surface more constantly mellow and free from weeds. He could, of course, if he elect to do so, allow it to grow up with weeds, in precisely the same way that some slipshod cultivators treat their cornfields. The small plan, fig. 4, will show sufficiently how this laying out is done. Everything is in rows or drills, or in double drills; and there may be a few rows of Currant bushes extending parallel with the drills, or these may be consigned to the separate fruit garden. Small vegetables, such as Lettuces, Radishes, &c., may have a special department allotted to them, as may be convenient; but all crops of any considerable size

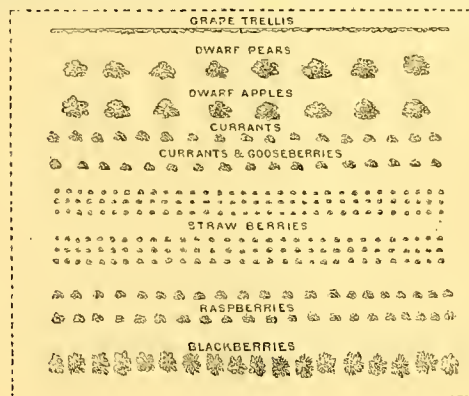

Fig. 5.

such as Turnips, Cabbages, Beets, Parsnips, Peas, Beans, &c., should be placed in straight, even drills, and receive horse culture. The rule should be never to allow a weed to grow, and this will not only be better for the crops, but considerably more economical than to fight them when well up. In order to effect this result, make it a rule to go over every piece of ground once a week, even if it be perfectly clean on the surface. This will kill any weeds that may be getting ready to come up. Do all that is possible in this way with the horse, and the rest with a steel rake. It may do to occupy a part of the ground with small fruits, such as Currants, Gooseberries, Raspberries, &c., but it would be better to give these a separate piece of ground, where they will not interfere with manuring or other operations. Such a fruit garden is represented by fig. 5, which clearly explains itself, and which is cultivated in the same easy way.—"American Cultivator."

Potatoes on Newly Broken up Land.—In ordinary garden and cultivated land where rich manures have been applied, the Potato disease has been very destructive this season; the only exceptions being comparatively high, dry situations where the soil is comparatively light, poor, and well drained, and which in seasons of drought are scarcely worth cultivating. We have also, in freshly trenched old woodland ground, where manure has never been known to be applied, an almost total immunity from disease; but of course the bulk of the crop is not equal to that of early kinds grown under more favourable circumstances. Experience, however, shows that high culture must be confined to early varieties only; late kinds, to which we look for our winter supply, will be more profitably grown on restrictive principles, as a medium crop of sound tubers is better than a bulky crop of decayed ones.—J. GROOM, *Henham*.

Mushrooms in Coal-pits.—The experiment has been tried at Borsigwerk, in Upper Silesia, of growing Mushrooms in a coal pit at a depth of 126 metres below the surface of the earth. It has proved entirely successful, the fungus growing rapidly and plentifully in an average temperature of 83 (R.). The Mushrooms thus grown are said to be of finer flavour than those developed in the open air, and are at present commanding a proportionately higher and very remunerative price in the local market.

CHAMÆROPS EXCELSA IN A CORNISH GARDEN.

The accompanying engraving of this Palm is from a photograph taken in the beautiful grounds belonging to Lamorran Rectory, Probos, the residence of the Hon. and Rev. J. T. Boscawen. It was planted by Mr. Boscawen in the spring of 1853, and has now attained a height of 16 ft. 6 in., the stem 6 ft. from the ground measuring 3 ft. 6 in. in circumference. It is a female plant, and has for several years flowered freely and produced well-developed fruits. In another part of the grounds is a male plant of the same species, about 10 ft. high, equally well furnished; both are in perfect health and luxuriance. There is no doubt whatever that this Palm is perfectly hardy, Mr. Boscawen's plants having passed through the severe ordeal of the winters of 1856 and 1860-61, when the thermometer fell below zero on two occasions, although planted but a few feet above the level of a lake which skirts the base of the grounds. The chief source of success is doubtless due here to the carefully-selected, well-sheltered situation, and fertile, well-drained soil in which they grow. Within a few yards of the Palms are some grand specimens of *Pinus insignis*, planted a year or two before them, and although cut down to the ground by frost in 1856, they threw up new shoots from the base, and are now about 80 ft. high, producing cones and seeds in abundance, from which young plants are springing through the turf. In close proximity to the Palms is a very fine example of *Saxc-Gothæa conspicua*, well-furnished, and about 10 ft. high; on the opposite side is an equally fine specimen of the Huon Pine (*Dacrydium Franklii*), 8 ft. high. But to attempt to enumerate the many rare and beautiful plants brought together here by Mr. Boscawen would occupy too much space. I will merely add that by a careful and wise selection of soils and situations suitable for each individual subject, a much more important object has been obtained than that of simply gathering together a host of subjects, however good.

HORTULANUS.

PLATE XCV.

THE SPECIES OF DAHLIA, AND THE EARLY HISTORY OF GARDEN VARIETIES.

(WITH A COLOURED FIGURE OF *D. IMPERIALIS*).The genus *Dahlia* consists of not more than half-a-dozen well

marked species, all of which are natives of the mountains of Mexico, at an elevation of between 4500 to 10,000 ft. above the level of the sea. Early in the period during which Mexico was under the sway of Spain, a certain Dr. Hernandez wrote a big book on the natural history of the country, which is illustrated by a large number of figures of animals and plants, among them two varieties of *Dahlia*. At that time botany, as we now understand it, did not exist, and the study of plants was almost limited to determining whether they were "hot in third or fourth degree," and endowing them with healing properties, depending not upon their actual tried virtues but upon some external characters. Under the name of *Acocotli*, Hernandez figures these Dahlias, and descants at some length on their medicinal virtues. It was not till towards the end of Spanish ascendancy that Dahlias were introduced into Europe, and it was by way of Spain that they reached this country. The genus *Dahlia* was founded by Cavanilles, a Spanish botanist, in honour of Dahl, a Swedish botanist, on a plant of *D. variabilis*, which flowered in the botanic garden at Madrid, in October 1789; and he published it with a figure, under the name of *D. pinnata*, in the first volume of his "Icones

Chamærops excelsa in a Cornish Garden.

Plantarum," &c., a fine folio work of seven volumes, containing figures and descriptions of a large number of plants which flowered in the botanic garden at Madrid. This was in 1791, and in a subsequent volume Cavanilles figured two other forms under the names of *D. rosea* and *D. coccinea*. *D. rosea* and *D. pinnata* turned out to be varieties of a very variable species, to which the name *D. variabilis* was subsequently applied. Humboldt introduced fresh seed to the Continent in 1804,

THE NOBLE DAHLIA (*D. IMPERIALIS*).

possibly of different varieties, as several were cultivated in Mexico.

INTRODUCTION INTO ENGLAND.—It is recorded in English books that the Marchioness of Bute introduced *D. variabilis* into this country in 1789, and after some research I have been able to prove that she sent or brought seeds of it from Madrid. Whatever the fate was of the first plants raised in England, it was not from this stock that Dahlias became dispersed over the country. In 1802, roots of the Dahlias named above were sent from Madrid to Paris where they flowered in course of time; and in 1804 coloured figures of all three of them appeared in the "Annales du Museum," probably the first coloured figures of Dahlias ever published. The coloration of the plates is not good; *D. coccinea* being of a dull red, though described as orange red; and *D. rosea* is represented of a lilac hue. Possibly the colours have faded, for *D. pinnata* is of a fine rich purple, and has semi-double flowers. Mr. Thoin, the author of the letterpress, writes very enthusiastically about them, and predicted that at some future time they would embellish our gardens in the summer. Leaving foreign literature alone, I will now give a sketch of the early history of Dahlias in England.

FLOWERING IN ENGLAND.—The first coloured plate of a Dahlia published in England appeared in Andrews' "Botanists' Repository" in November, 1801—the same year, it will be remembered, as the figures alluded to above were published in France. This is a large, single, bright purplish-red variety of *D. variabilis*, which was raised, it is stated, from seeds sent from Madrid the previous spring by Lady Holland, flowering in September and October of the same year in her ladyship's collection in the open air at Holland House, Kensington. It grew, we are told, to the stately height of 8 ft., with a circumference of 3 ft., and made a truly "specious" appearance. The notice of the plant concludes with the prediction that "there are considerable reasons for thinking that the Dahlia will hereafter be raised with double flowers." In 1805, Salisbury figured a pink single-flowered variety in his "Paradisus Londinensis," t. 16, the flower-heads of which are about 4 in. across, and have eight broad, flat ray-florets which meet at the margins, giving them the general aspect of the flowers of *Anemone japonica*. This was from the same collection as Andrews' plant, the librarian, Mr. Buonaiuti, having raised several varieties. On account of some objection to the original name, Salisbury undertook to give it "a more appropriate one," and called it *D. sambucifolia*. The first coloured figure of *D. coccinea* in an English publication is in the "Botanical Magazine," t. 762, from a drawing taken of a plant in Mr. Fraser's nursery at Sloane Square, in June, 1803. Fraser received it from France. Now that we have fixed the dates of introduction of the two original species, it may be desirable to state that *D. coccinea* is the same as *D. frustanea* of many books, and *D. superflua* is a synonym of *D. variabilis*. The reasons for giving these names, and the characters they apply to, are noticed under the brief descriptions of the species which follow.

PARENTAGE OF DOUBLE DAHLIAS.—There seems to be no doubt that *D. variabilis* or *superflua* is the principal parent of all the races of garden varieties of Dahlia in cultivation; and it is possible that it is the sole parent. It is asserted somewhere that *D. coccinea* will not intercross with *D. variabilis*, and if this be so all the varieties raised before 1840, at least, would be descendants of the latter. Such a wide range of variation is, moreover, not without a parallel in the China Aster. Whether *D. scapigera* or any other species was subsequently utilised in intercrossing I have found no positive evidence. The next phase in the history of the Dahlia in England I gather from an article by Salisbury in the first volume of the "Transactions of the Horticultural Society of London." It may be mentioned in passing that the Society was founded in 1805, though not incorporated by royal charter until 1809. The article in question was read in 1808, but not published until 1812; and among other matter new names are proposed for all the forms then existing in gardens and regarded as species. It would be waste of time and space to reproduce those names, but the substance of the article is worth reproducing.

ORIGINAL DAHLIAS VERY TALL.—Salisbury obtained seed from the Holland House strain, which he sowed in May, 1806; and

several of the seedlings flowered in October of the same year. One of these, which had obtained the height of 12 ft., did not open its first flowers until the 29th of October, but it produced a plentiful succession of bloom in the open air until the beginning of December. He does not enter into particulars respecting the variations in colour exhibited by this batch of seedlings but he mentions a yellow variety. He also states that Mr. E. J. A. Woodford introduced a variety from Paris, which flowered in his garden at Vauxhall in 1803, which would be anterior to Lady Holland's introduction.

IMPROVED VARIETIES FIRST RAISED ON THE CONTINENT.—In spite of the anticipations and predictions of writers and cultivators, little advance was made in raising improved varieties in England for some years, though a great number of varieties had been raised on the Continent, both in France and Germany, prior to 1814, as may be gathered from contemporary literature.

In 1818 Mr. J. Sabine, the secretary, read a paper before the Horticultural Society on the species and varieties of Dahlias, in the opening part of which he alludes to the splendour and richness of the varieties which surprised visitors to France after the conclusion of peace 1814. These varieties were soon imported, and previous to 1818 "splendid exhibitions of these flowers" had been held in London. In France, Count Lelieur began raising Dahlias from seed in 1808, and obtained purple, dark red, light red, yellow, and white varieties; and Otto, of the Berlin botanic garden, raised a great many fine varieties between 1813 and 1817. Even after the introduction of the Continental varieties, some years elapsed before any English raisers of note appeared on the scene. But about 1820, or perhaps earlier, the Horticultural Society began to form a collection of foreign and English varieties. Some two or three years after this date the late Sir Joseph Paxton, then an under gardener at Chiswick, was instructed to draw up descriptions and report upon the best varieties in the collection, but, leaving shortly afterwards, he never completed the task. This devolved upon William Smith, who acquitted himself well, as the report in the "Transactions" testifies; Smith's report was read in 1826, though not published until 1830. Before gleanings from that, let us take a glance at the class of flowers portrayed in the various periodicals of the period from 1815 to 1830. In the "Botanical Magazine," t. 1855 (1817), is a figure of a double variety called *rubra*, very pretty, but nothing very remarkable; and in the first volume of the "Botanical Register," t. 55, a handsome single variety called *puicea* is figured. This has rich dark crimson ray-florets of great breadth and length, and would be regarded as a very showy border plant even now. From Maund's "Botanist," vol. iv. (1831-2) we get a good idea of the degree of excellence attained at that period, better indeed than from Smith's report, which is not illustrated; it seems, however, that many of the finest varieties in the Horticultural Society's collection were not generally cultivated.

ORIGINAL CLASSIFICATION.—With a figure of a variety called *Blood-red*, Maund gives a list of twenty-five varieties, divided into two classes, namely, *Anemone-flowered* and *Globe-flowered*. In the former class the central or disk florets have lost the original yellow of the single varieties, and are of the same colour as those of the ray or circumference, but their transformation is only partial, and the ray-florets, though quilled, are still considerably longer. This variety is represented as only about 3 in. in diameter, but another of this class, named *Painted Lady*, is a little over 4 in. across. The latter is a very pretty variety, in which the florets are longitudinally striped with crimson on a rose or pink ground. *Crimson Globe*, a variety of the globe-flowered class, with heads about 3 in. across, is hemispherical, with all the florets similar in shape, the outer ones not perceptibly longer than the inner. In the letterpress is the following curious observation:—"It is thought by several cultivators, who have paid close attention to the growth of the double Dahlia, that some of those of good quality which were first introduced, are beginning to 'wear out.' At present we think this a matter of uncertainty," &c.

FIRST ENGLISH RAISERS OF NOTE.—Returning to Smith's report, we there find the first connected record of the varieties raised in this country. The Society's collection consisted of a number of Continental varieties, without raisers' names, obtained through M. Van Eeden, of Haarlem, and English varieties, with raisers' names, so that we have here a clue to

first English raisers of superior varieties. The most noteworthy of the early English raisers was Mr. Joseph Wells, gardener to Mr. William Wells, Redleaf, near Tonbridge. He succeeded in raising a strain of dwarf varieties, embracing all the principal colours, and, on the evidence of Smith, they began flowering in June, when not 1 ft. high, and continued through the summer and autumn. This was no small achievement, considering that the principal fault of most of the varieties of that date was the great height they attained. Another gardener who turned his attention to the subject at that period was David Douglas, then in the service of Lady Grantham, at Putney Hill. His name stands as the raiser of several of the best of the selected fifty given by Smith; and Miller and Middleton are the names of raisers of one or two other varieties each. Dahlia growing soon established a permanent footing, and we find the statement in Knowle's & Westcott's "Botanical Cabinet" of 1840, that a catalogue of some 1500 Dahlias had been published some years previously. It would be tedious to go through the more recent history of Dahlias; furthermore, this is very well known to those interested in it, and several of the most eminent raisers are still among us. Another thing, Dahlias are no longer fashionable, a fact not much to be regretted, perhaps, because they are now more likely to be grown for their real merits alone; and florists who make them their speciality are careful to offer a small but very select assortment only. The Pomponé or Bonquet Dahlias, a class of comparatively recent acquisition, deserve special mention, because they are very useful for decoration at a season when flowers are getting scarce out-of-doors. There are varieties of almost all the shades of colour known among the "show" varieties, and there is now a race of dwarf Pomponés. Formerly Dahlias were called Georginas in this country, and they still bear that name in Germany. All single-flowered Dahlias, with the exception of those half-reversions from double varieties one generally sees, are showy border plants, and some of the forms described below are exceedingly elegant and beautiful.

Imperial Dahlia (*D. imperialis*, Roezl).—At first sight one would not recognise this plant as a Dahlia, it is so unlike in external character anything we are accustomed to associate with that name; but a closer inspection, and a comparison with the single-flowered varieties especially, will reveal many important characters in common. It has tuberous roots, very large, tri-pinnately divided leaves, and a solid stem swollen at the nodes, growing to a great height for a herbaceous plant, and terminating in a large, loosely-branched panicle of flower-heads. The entire plant reaches a height of 10 ft., 15 ft., or even 20 ft. occasionally; usually with a single stem, which becomes naked as the lower leaves successively fall. This mode of growth renders it unfit for a small conservatory, and it does not appear to thrive so well in the open air as to make it a general favourite. Mr. Salter succeeded in dwarfing it by grafting shoots in the tubers of a Liliputian Dahlia, but his example does not seem to have been much followed; in fact, although a majestic and showy plant that has been in this country seven or eight years, and on the Continent nearly fifteen years, it has made little way. If somebody were to take it in hand, and succeed in raising a dwarf strain, there is no doubt that it would meet with general favour. And there seems to be no reason why dwarf varieties should be unattainable, seeing what has been done with *Dahlia variabilis*. The bell-shaped flower-heads are pendant, however, and therefore their beauty would be lost to a great extent in quite dwarf varieties. It is a magnificent plant when growing in a lofty house with plenty of room for development; but, as far as my knowledge goes, it does not flower freely in the open air, and I cannot say that it has been fairly tried. Roezl discovered and introduced it some fifteen years ago, but I have not been able to ascertain at what altitude it grows in its native country. As may be seen, it is not the tallest of its genus, nor the tallest ever cultivated in our gardens. Our plate of this fine species was executed from M. Riocreux's original drawing for the "Revue Horticole," from the proprietors of which we purchased it.

Tree Dahlia (*D. excelsa*, Benthams, Maund's "Botanist" t. 88).—This is the largest-growing species of the genus, considerably overtopping the tallest specimens of *D. imperialis*. It is recorded that it was first introduced into this country accidentally with some other plants consigned to Messrs. Loddiges in 1830. Perceiving that some thick stakes which were used to protect a basket of plants received from Mexico, showed signs of life, they were planted in the open ground, where they grew the first season to a height of 10 ft., but were destroyed in the subsequent winter. The plant was again

imported, both by roots and cuttings, in 1834, by Mr. William Bates, who distributed it among his friends, and sent plants to the Liverpool Botanic Gardens. There are specimens in Kew Herbarium labelled—"Tree Dahlia or Gigantic Dahlia, collected in the valley of Mexico by W. Bates, Esq., 1834. It forms a shrub 30 ft. high, covered with double or single purple flowers." The plant figured in the "Botanist" was grown in the garden of Mr. G. Ellius, of Rigby, Hall, Worcestershire. Planted out in the border of a conservatory in the spring of 1837, it had attained a height of 12 ft. in November of the same year, with a single stem, terminating in a spreading crown of exceedingly attractive flowers. But the plant has not invariably a simple stem, and a specimen in the Liverpool Botanic Garden grew to a height of upwards of 20 ft. without producing flowers. The pale purple flower-heads of this species, as depicted in the figure quoted, are not unlike those of some of the varieties of *Chrysanthemum*, in which the central florets remain tubular, and the ray-florets are distant and spreading, giving the flower-head a diameter of $4\frac{1}{2}$ in. It does not appear to be in cultivation in this country now, but about the same time (1870) that *D. imperialis* began to be known in this country, Messrs. Haber and Co., of Hyères, South France, sent a coloured figure of what was supposed to be this species, which they cultivated under the name of *D. arborea*, to the "Gardeners' Chronicle," describing it as of compact habit, forming a large well-branched clump about 7 ft. high, with large dark green leaves, and producing its mauve-coloured flowers from the end of December onwards through the winter, in great abundance. A temperature below the freezing point does not, they state, interfere with the development of the flowers, which in form resemble those of a gigantic Anemone.

The following characters are taken from Mr. Benthams' detailed descriptions:—Roots fascicled, some cylindrical and fibrous, others swelling into tubers. Stem perennial, very thick, becoming woody, growing to the height of 20 ft. or more, less branched and assuming more the aspect of a tree than any other species, hollow inside, smooth and glaucous on the surface, marked with horizontal rings formed by the broad stem clasping base of the petioles, and sometimes emitting near the base a great quantity of fibrous roots. Leaves opposite, attaining a length of $2\frac{1}{2}$ ft. by about 2 ft. in breadth, bipinnately divided; leaflets ovate or heart-shaped, toothed, nearly smooth or with a few scattered hairs of a pale glaucous green. Flower-heads on long naked peduncles, collected in corymbs of five to eight at the ends of the branches. The variety here figured is not unlike the formerly so-called Anemone-flowered varieties of *D. variabilis*, but there are specimens at Kew with double flowers.

Dwarf Dahlia (*D. scapigera*, Link and Otto).—A very beautiful dwarf species, with procumbent or trailing glabrous stems, throwing up erect-flowering branches, 1 ft. to 2 ft. high, each branch bearing one pair of leaves, from between which proceed one to three flower-heads, borne on long, slender stalks, or sometimes taller and again branched. Leaves pinnate, 4 in. to 8 in. long, borne on slender petioles. Flower-heads about 2 in. in diameter; ray-florets flat, white, meeting or overlapping each other at the margins; disk-florets yellow. This attractive dwarf perennial Dahlia is doubtless the hardiest of the genus, and certainly one of the most desirable. It grows up to an elevation of 10,000 ft. on the Peak of Orizaba, and is found in various other parts of Mexico. Whether this has had any share in the parentage of the Pomponé varieties of Dahlia I am not able to say, but I should think it not improbable. Although the flower-heads are white in all the figures and fresh specimens I have seen, it appears to be variable in this respect, for there are wild specimens in the Herbarium at Kew in which they are red. First cultivated in this country in 1838, in the garden of the Birmingham Horticultural Society, whither it was sent from Berlin. It is figured in Maund's "Botanist," iv., t. 161, and in Knowles & Westcott's "Floral Cabinet," t. 118.

Scarlet Dahlia (*D. coccinea*, Cavanilles, Bot. Mag., t. 762).—The history of the importation of this species at the beginning of the present century is given in the introductory sketch, and little remains to be said of it here beyond the fact that it is a very ornamental plant, and would please many persons more than the florists' varieties of *D. variabilis*. It is of more slender habit than the species just named, and differs in having glaucous stems, and no trace of female organs in the florets of the ray; hence the proposed specific name of *frustranea*. Usually it has brilliant scarlet flowers, but there is a yellow variety, and possibly other colours sometimes appear. It is asserted that this will not intercross with *D. variabilis*, and that it differs from it in the tubercles being united to the base of the stem by short strings or fibres; but I cannot accept either of these statements without further proof, because I have my suspicions that there is evidence of its parentage in some of the florists' varieties. The flower-heads are usually from 2 in. to $2\frac{1}{2}$ in. in diameter, and

therefore smaller than those of the single varieties of *D. variabilis*. It grows from 4 ft. to 6 ft. high, and inhabits the intermediate regions of the mountains of Mexico.

Cervante's Dahlia (*D. (Georgina) Cervantesi*, Sweet's "British Flower Garden," series 2, t. 22).—A showy species, closely allied to *D. coccinea*, but having solid, not glaucous, stems, and the leaflets are remarkable for their very deep sharp teeth. The flower heads are about 2 in. in diameter, the ray-florets crimson, and the disk yellow. Sweet had his figure prepared in 1838 from plants in the Fulham Nursery of Messrs. Brame, Whitley, and Milne, who received seeds of it from Madrid, whither it had been sent by Cervantes from Mexico. An erect-growing plant, 6 ft. to 10 ft. high, readily distinguished, Sweet states, by its numerous slender branches. He also mentions a double-flowered variety of the present species; possibly only an extreme variety of the next.

Variable Dahlia (*D. variabilis*, Cavanilles).—The supposed parent of most, if not all, the florists' varieties in cultivation; but I can say nothing positive on this point. Perhaps some of the raisers of Dahlias may be able to clear it up. The hollow stems of this are said not to be glaucous, and the florets of the ray of the single flowers are fertile, or at least furnished with a rudimentary pistil (hence the name, *D. superflua*); both characters of little value. Further particulars respecting this species are given in the introductory sketch.

Slender Dahlia (*D. gracilis*, Ortgies, "Gartenflora," 1876, t. 861).—A handsome single Dahlia, with brilliant orange-scarlet flowers, introduced by Roezl in 1873. After comparing the figure quoted and Mr. Ortgies' description with authentic specimens of *D. Cervantesi*, I am of opinion that it is the same species, differing only in the colour of its flowers, and perhaps the shape of the ray-florets.

Dickson's Dahlia (*D. glabrata*, Lindley, "Botanical Register," 1840, t. 29; *D. Merki*, Lehmann; *D. Decaisneana*, Verlot, "Revue Horticole," 1864, p. 31, with a coloured figure).—Besides the two synonyms quoted, this Dahlia is often cultivated in gardens under the name of *repens*, a name of which I have found no publication. One of the most distinct species of the genus in the winged rachis of its smooth, shining, irregularly bipinnate leaves, and the narrow, linear, outer bracts of the involucre. It grows from 3 ft. to 4 ft. high, and Lindley says it differs from *variabilis*, &c., not only in its dwarf habit and perfect smoothness, but also in its roots, which have fangs slender and uniform in size, instead of being partly large and succulent and partly resembling fibres. The leaflets are deeply and irregularly distantly toothed, and the flower-heads about 2 in. in diameter, and the broad ray-florets overlap each other. In colour this species is almost as variable as *D. variabilis*, from white, pink, through various shades of lilac and purple. Treated as an annual, Lindley states this answers remarkably well, and it is much easier to raise it from seed than it is to save its roots; and this would apply to any of the single-flowered forms, except *D. imperialis* and *excelesae*. Seeds of it were obtained from Mexico by G. F. Dickson, who presented them to the Royal Horticultural Society, and the plant was cultivated at Chiswick as long ago as 1835. The plant figured under the name of *Decaisneana* has deep lilac-purple flowers, and is reported to sometimes attain a height of 7 ft. or 8 ft.

Among other Dahlias figured or described may be mentioned *D. pinnatifolia nana* (Andrews' "Botanists' Repository," t. 483), a dwarf variety of *D. variabilis* raised in Lady Holland's garden in the beginning of the present century; it has rosy-pink, semi-double, loose flower-heads about 5 in. in diameter. *D. Barkeriæ* (Knowles and Westcott's "Floral Cabinet," t. 127) is a distinct Dahlia, with hairy foliage and lilac-rose flowers, possibly only a variety of *D. variabilis*; it was introduced direct from Mexico in 1837 by Mr. Barker, of Springfield, near Birmingham. *Dahlia crinita*, Thunberg, is *Trichocladus crinitus*, a South African shrub.

W. B. HEMSLEY.

Wood Pavements.—The report of the deputation, appointed as representatives of the Edinburgh authorities to investigate the utility of wood paving in streets, has been completed. The deputation met various surveyors of Vestries in London in which wood pavement had been laid, and afterwards examined the pavements, noting the several kinds which were in use, and the way in which they were lifted and relaid. The deputation heard the representatives of several paving companies, and obtained explanations from them as to the methods and materials employed. In that way nine surveyors were examined in London, one in Birmingham, and one in Leicester. In the course of the inquiry it was found that the general estimate given as to the

duration of wood pavement was five years, while that of granite was set down at thirty years, during which time, however, the stones required to be once lifted, redressed, and relaid. The first cost of laying wood and granite was practically the same, but the expense of maintenance varied considerably. If well laid, granite pavement did not usually require anything to be expended upon it for several years, and the outlay was stated to the deputation to vary from $\frac{1}{4}$ d. to 1½d. per yard per annum. The wood pavement companies offered to maintain their work for fifteen years, the first three years free of charge, and the remaining period at prices ranging from 3d. to 1s. 1d. per yard. The deputation, while freely admitting that a street paved with wood is a luxury on account of its smoothness and the diminution of noise, point out that in their opinion these advantages are more than counterbalanced by its cost, and the annoyance occasioned by the necessity of frequently lifting it for renewal. The deputation found, generally, that wood pavements in conjunction with tramways were unsatisfactory. After mature deliberation, and as the result of their investigations, the deputation report that in their opinion Princes' Street, Edinburgh, should not be laid with wood nor with wood and granite in combination, but that it should be paved throughout with granite of the best quality, laid in the most approved manner. [The resolution is a wise one; several of the more important drawbacks, however, with reference to wood pavements are not mentioned in the above paragraph.]

PISTACIAS AND THEIR USES.

THE common name of Turpentine trees, under which the species of *Pistacia* are usually known, is somewhat misleading, inasmuch as they have no relation whatever to the true Turpentine trees, or those which furnish the turpentine of commerce, which is produced by several species of *Pinus*, notably *P. sylvestris* in Europe and *P. palustris* in North America. From *Pistacia Terebinthus*, however, a tree growing in Southern Europe, Northern Africa, and in some parts of Asia, is obtained what is known as Chio or Cyprus turpentine. The plants vary considerably in height in different localities, ranging from a shrub to 20 ft. or 40 ft. or more. The resinous juice or turpentine is secreted in the bark, and is contained in special cells, similar to those in *P. lentiscus*, and from which Gum Mastic is obtained. The turpentine is collected from incisions made in the stem and branches, as well as by spontaneous exudation; the quantity collected from a single tree is very small, the average yearly yield of a large tree amounting to 10 oz. or 11 oz. This peculiar turpentine is used chiefly in medicine; in British practice it is nearly obsolete, but in Greece its use is more general, not only as a medicine, but for flavouring cordials and wines. *Pistacia vera*, which is the plant represented in our figure (see p. 356), is the Pistachio-nut tree, and is said to have been originally a native of Western Asia, whence it was introduced to Italy at an early period, and is now cultivated there as well as in Sicily, south of France, Spain, &c. The tree grows to a height of from 15 ft. to 20 ft., and bears compound leaves composed of from three to five broadly-ovate leaflets; sometimes, however, they are reduced to one. The fruit is somewhat about the size of an Olive, with this difference in shape—that it is more pointed, slightly concave on one side and convex on the other, mostly about 1 in. long, and of a reddish, or crimson colour. The outside pulp is very thin, and within it is a Nut which encloses a greenish-blue kernel, which, when fresh, has a remarkably sweet and bland flavour. These seeds are largely consumed in Greece and Turkey, as well as in the south of Europe, either in the raw or dried state, or for use in ragouts, confits, preserves, and various kinds of confectionery. Pistachio Nuts, though not very generally seen in this country, are not by any means uncommon; they can be obtained in London at the best Italian warehouses, and are consumed chiefly by foreigners. The species of *Pistacia* being dioecious, it is necessary in forming a plantation of *P. vera* to plant a proportionate quantity of both sexes to ensure the fertilization of the female flowers and the consequent formation of fruit. In Sicily, it is said to be the practice amongst Pistachio Nut cultivators, to gather the male blossoms and hang them on the female plants. *Pistacia lentiscus* is the Lentisk or Mastic tree, an evergreen shrub or small tree, native of the Mediterranean shores from Syria to Spain, and found also in Portugal, Morocco, and the Canary Islands. In the island of Scio in the Greek Archipelago, a good

deal of care and attention is devoted to the cultivation of this Mastic tree, for no other part of the world is considered so suitable for its profitable cultivation. In the northern part of this island Mastic is chiefly collected from incisions made in the bark of the stem and the principal branches. In these parts of the tree the resin ducts abound, so that a very slight fracture or incision is sufficient to cause the juice to flow. It is remarkable that the wood itself is entirely free from any such product. After puncturing the bark the resin flows freely, and hardens in small masses on the trunks; these pieces are carefully gathered and placed in baskets lined with clean paper. The ground beneath the trees is also kept not only clear but clean, so that all the fragments of gum that may happen to fall are not impaired by dirt. A large tree will yield from 8 lb. to 10 lb. of Mastic. The collecting is chiefly performed by women and children. The gum obtained from the branches by natural exudation is considered of the finest quality. Mastic is at the present time very little used in this country, either in medicine or for varnish making; a little is used in dentistry for stopping carious teeth. The best quality always finds its way to Constantinople, and a good quality Mastic is sent to Trieste, Vienna, and Marseilles, a small quantity only reaching this country. In the East it is employed not only for medicinal purposes, but for sweetening the breath by chewing, and also in the preparation of cordials. Of the three species here mentioned,

Fruit-bearing Branch of Pistachio Nut Tree.

P. Lentiscus is the most hardy; with some protection, or under the shelter of a wall, it will grow in this country; the other two species are too delicate for outdoor cultivation. With regard to *P. vera* the soil and climate most suitable for its cultivation may be considered as similar to those required for the Olive. It, however, is said to have grown well and to have borne fruit even so far north as Paris. J. R.

Hardy Exotic Ferns.—During the last few years I have seen a good many schedules of horticultural and floricultural exhibitions; and it is rare, very rare indeed, that one finds in them classes for hardy exotic Ferns. I cannot understand why that should be so, are they not worth growing? or are they not worth exhibiting? There are *Adiantums*, *Aspleniums*, *Cyrtomioms*, *Lastreas*, and many others with which we are all acquainted, that are in my opinion not only well worth growing, but well worth exhibiting. As the schedule of the Royal Horticultural Society's Great Provincial Show, to be held at Preston next year, is now being formed, would it not be a fair chance for all to see what these Ferns would become, by having a class for twelve distinct kinds to be shown by nurserymen, and six distinct kinds to be shown by private growers? As a lover of hardy exotic Ferns I should like to see them becoming greater favourites, and better grown than they now are.—H. E.

The American after-dinner orator in England will soon be able to say, "Speaking the same language, glorifying in the same literature, of the same blood, and subject to the same Potato bug," &c.

EARTHWORMS, THEIR FOOD AND USES.

A RECENT number of the "Zeitschrift für Wissenschaftliche Zoologie" contains an interesting paper, by Herr Von Hensen, descriptive of observations, made with true German minuteness of detail, of the habits of the common earthworm (*Lumbricus communis*), which forcibly illustrate the correctness of the views put forward by Darwin forty years ago, respecting the important part incessantly performed in the economy of nature by these humble creatures in the elaboration of soils and their adaptation to the requirements of plant life. The observations were made in a garden having a surface layer of mould overlying a yellow diluvial sand. Von Hensen describes how the adult worms come to the surface of the earth at night, and, with their tails in their holes, calmly survey the country round before they sally forth in quest of food, in the shape of leaves, twigs, &c. These they heap up round the entrances, the leaves being rolled up separately and partly drawn into the holes, where they soon become macerated and partly decomposed, in which state they are swallowed by the worms. The worm tubes were not easily traced in the garden mould, but in the sandy subsoil they were clearly distinguishable, and were found to descend to depths of from 3 ft. to 6 ft. The tubes were found to be lined with stones about the size of a pin's head, brought from the surface; and fruit kernels were also found in them. Their walls, too, contained little black masses of characteristic shape, the excreta of the worms. Besides these freshly inhabited holes were others which have been abandoned, and the cavities of which were filled up with black earth, the black matter being diffused into the surrounding sand, and these again passing insensibly into mere black streaks of mould penetrating the sandy subsoil. In about half the uninhabited tubes were found the roots of plants growing on the surface, and these followed exactly the course of the tubes, putting out their fibres through the black walls of the tubes. An extended series of observations led to the conclusion that, as a rule, the roots of annual plants can only find their way down to the moister subsoil through channels thus prepared for them by earthworms. Chemical and microscopic analyses of the contents of the intestines and of the "casts" of the worms showed them to be nearly identical in composition with ordinary "leaf-mould," such as is obtained by mixing fallen leaves and sand and leaving them for a couple of years until decomposition is complete. To ascertain the precise part played by the earthworm in the production of ordinary vegetable mould, Van Hensen placed two worms in a glass vessel filled with sand, the surface of which was strewn from time to time with fallen leaves. The worms set to work at once, and at the end of six weeks the surface of the sand was covered with a layer of mould half an inch thick, whilst some of the leaves had been carried down to a depth of 3 in. below it. The worm tubes permeated the sand in all directions—some were quite fresh, others had walls of organic matter one-eighth of an inch thick, whilst others, again, were quite filled up with mould. In short, the soil was perfectly prepared for the growth of plants. A single earthworm weighs on an average 36 grains, and is estimated to produce in twenty-four hours 8 grains of excrement. Allowing 34,000 worms to an acre, weighing together 2 cwt., this would give 37 lb. of vegetable mould in the finest state of comminution, passed through their bodies every twenty-four hours, over and above the work done in removing vegetable refuse from the surface and working and opening up passages in the soil, thus facilitating the admission of air and moisture and the passage of the more delicate and absorbent portions of the roots of vegetation. Mr. Darwin was assuredly right when he said that in tillage the agriculturist was "only imitating, in a clumsy manner, without being able to bury the pebbles or sift the fine from the coarse soil, the work which nature is daily performing by the agency of the earthworm."

Fuchsia Regalia—This is the brightest and best of the variegated Fuchsias that has yet come under my notice; Sunray will bear no comparison with it. It has a neat twiggy habit, and soon makes useful little specimens, under pot culture, for the decoration of either windows or conservatory shelves.—H.

Nelumbium aspericaule.—This has recently been in flower in the Lily-house at Kew. Horticulturally speaking, it is a slight improvement on *N. speciosum* as far as the flower is concerned; otherwise the two plants cannot well be distinguished from each other. The late Mr. Silvester, who raised it from seed, used to grow several species, so there is a possibility of *N. aspericaule* being a cross-bred.—S.

Potato Disease.—We have this season lost all our Tomatoes from a disease similar to that which affects the Potato. The plants were attacked simultaneously with Potatoes which were growing alongside of them. "Salus" was applied, but without avail. Can anyone vouchsafe a remedy or preventive, so as to counteract a similar loss in future?—W. W. H.

MADAGASCAR CHRISTMAS ROSES.

(HYDNORAS).

THESE singular Fungus-like plants, supposed to be natives of Madagascar, are known there under the name of Christmas Roses—it being stated that they bloom with almost mathematical precision on Christmas-day. Their odour is most offensive, resembling that of tainted meat. The upper part only of the blooms rises above the soil, but when fully spread out they look like a star with five points. The flower, which is of a livid colour, only lasts one day. A short time before blooming the soil is thrown up and large protuberances like great Truffles rise out of it; these are the buds. The development of the roots is so rapid and in some cases so powerful that this

curious parasite positively becomes formidable. The species of *Hydnora* found at the Cape of Good Hope is said to resemble Mushrooms and is often eaten, in a cooked state, by the natives.—“*La Nature*.”

Preserving Colour in Dried Flowers.—Botanists, to whom the rapid loss of colour in the flowers preserved in Herbaria, has been a source of regret, will be pleased to learn (according to a Vienna journal) that if plants be dipped in a warm mixture of one part of hydrochloric acid (spirits of salt), and 600 of alcohol before being placed between driers for herbarium purposes they will not only dry with greater quickness, but will retain their natural hues.

“There are but two fine things in the world,” says Malherbe, “women and Roses.”

THE FRUIT GARDEN.

BUSH OR UNDER FRUIT IN KENT.

(Concluded from p. 334).

A brief description of the various kinds of fruit known as bush, soft, or under fruit must now be given, as these form a very important part of the fruits grown in Kent.

GOOSEBERRIES.—The Gooseberry bush is planted under Filbert, Apple, and other fruit trees, and does remarkably well upon the loam, “pinnock,” and the lighter soils of the Hythe beds. It thrives best in fairly dry land, and is grown extensively in the neighbourhood of Maidstone, paying very well on suitable land. It is also grown in East Kent under Apple and Plum trees, and more largely still in West Kent. These bushes are usually set about 6 ft. apart under full standards and Filberts, or 1210 plants to the acre; and 5½ ft. apart, or 1440 plants to the acre, when put by themselves or under Plums or Damsons. Growers having short leases, or growers whose landlords decline to find standard trees, frequently make plantations of Gooseberry or Currant bushes alone, which come to bear in two or three years and pay well, if well managed, for a few years without renewal. Mr. Webb relates that a grower near Maidstone made £100 in one year, from one acre of Gooseberry bushes. The average return from an acre in full bearing, is probably about £33, from which must be deducted at least £22 for expenses of all kinds. The method of propagating these bushes is to select straight portions of the leading shoots cut off in the winter, to reduce them to about 8 in. in length, and to set them in rows in a nursery. They are kept well trimmed, and are ready for planting out in two years or so, being trained in a cup-like form, from one stem about 10 in. from the ground. All rank-growing branches are cut away every year, and a supply of moderately young wood is reserved for fruit-bearing. The land is dug in the winter, and manured with rags, shoddy, sprats, &c. It is hoed two or three times in the summer. Though the sorts of Gooseberries are legion, amounting to over 300 varieties according to Mr. Darwin, Kent growers chiefly grow the Whitesmith, Warrington, Lancashire Lad, Crown Bob, Yellow Rifleman, Velvet White, Golden Drop, and Monarch. Should the demand be good, many of the Gooseberries, especially the Whitesmith and Crown Bob sorts, are sent up green for bottling and cooking, directly they are large enough. The Warrington, a medium-sized red berry that ripens about the latest of all, being most excellent for preserving, having a sub-acid flavour, is very largely grown. Besides these qualities it has a peculiar arrangement of its thorns, which are so disposed that they serve to protect the buds in the winter from the onslaught of small birds, which are very fond of them, and do infinite mischief in plantations near woods. Bullfinches are especially troublesome in this respect, so much so, that fruit-growers set a price of 2d. each upon their heads. Red worsted is often put over the bushes to frighten the birds away.

CURRANTS.—Red, White and Black Currants are grown in great quantities in Mid and West Kent, and to some extent in East Kent. Black Currants have been lately planted to a considerable extent in the Weald of Kent. Currants are usually grown under fruit-trees: they are, however, occasionally put by themselves. The Red Currant is indigenous in this country, according to Phillips. There are not many sorts of it. Dr. Hogg mentions only five or six. The Dutch, Raby Castle, and the Scotch,—which is by far the best, though it is not mentioned by Hogg,—are generally planted in Kent. This fruit is not so profitable as the Gooseberry. The bushes are raised from cuttings, and are cultivated in the same way as Gooseberry bushes, only that in pruning them nearly all the growing wood is cut away, the fruit-buds coming on small shoots or “snags” thrown out each year from the older wood. The inside of the bush is therefore kept cleared well out to allow air and light to get to the bunches on the inner side of the fruit-bearing branches. Red Currants are in great demand for bottling, for jam, and for Currant jelly; they are packed in sieves weighing 48 lb., and make from 2d. to 2½d. per lb. White Currants are not much grown. They ripen well under even the darkest shade of standards. They are only used for

dessert purposes. The Black Currant is a most profitable fruit when the bushes are planted upon snitable soil. It is very much grown upon heavy, sticky land, which can hardly be too wet. The bushes are raised from cuttings, and their growth is very rapid. Pruners cut away the greatest part of the wood, as the fruit comes best and largest on young wood. No wood is left over two years old. The wood does not grow from a stem, as in the case of other Currant and Gooseberry bushes, but from a "stub" or stock close to the ground, like Ribes in shrubberies. Only two sorts are grown—the Black Naples and the old Black. This fruit always sells well for jam, jelly, and lozenge-making. About 3d. per lb. is the average price of it in London. An average crop of Black Currants would be at the rate of 3000 lb. per acre, though as much as 6000 lb. has been grown per acre upon land planted with these bushes alone.

STRAWBERRIES.—This fruit is largely cultivated in West Kent, and not to any extent for market purposes in other parts of the county more distant from London, on account of its perishable nature. It is not uncommon to find individuals having as many as 100 acres of Strawberries in this district, chiefly planted upon the clays of the Thanet beds, in many cases upon grubbed woodland, which suits them remarkably well. An owner of land in this neighbourhood states that poor woodland, whose underwood was never worth more than £7 or £8 per acre at twelve or fourteen years' growth, has yielded as much as £150 per acre when grubbed and planted with Strawberries; but this was in the earlier, palmy days of Strawberry growing. Clay land suits Strawberry plants best, though they grow fairly well upon sandy soils, but do not bear much fruit after three years. On the clay they come into full bearing at the expiration of three years, and continue to be fairly productive for six years or so. Strawberry plants are propagated by the long runners which cover, and strike root in, the ground in the autumn. When it is desired to obtain young plants, these runners are not cut away as usual directly after the fruit has been picked, but are left until some rootlets have been formed at their joints, and then taken up and planted. The price for these is about 5s. per 1000. The chief sorts planted are, the British Queen, one of the best Strawberries, of great size and fine flavour; Keen's Seedling; Princess Alice, an early sort; Comte de Paris, an early Strawberry and an excellent bearer; the Elton Pine; Goliath, one of the best sorts for culture on a large scale; Eleanor, described by Dr. Hogg as "able to endure drought without material injury"; and Sir Joseph Paxton, a large prolific sort. Previous to planting, the land is well manured and hand-dug to get a level surface, which ploughing and harrowing would not obtain. The plants are set in rows 2 ft. 6 in. wide, and about 1 ft. 6 in. from plant to plant in the rows, giving about 10,500 plants per acre. The rows are put thus far apart in order that horse-hoeing may be done, and some growers have lately put the plants in 2 ft. 6 in. apart each way, which would give rather less than 7000 plants per acre, in order that the horse-hoe might work in all directions, and the expense of labour be much diminished. In an established Strawberry plantation, the "runners" are cut away in the autumn, being generally used for propagation, and the land is dug by hand. In the spring the horse-hoes, and hand-hoes where the plants are set closely in the rows, are continually worked to keep down the weeds. Just before the fruit is changing its colour, the ground is covered with rough manure, or straw cut into 6-in. lengths, laid carefully under the plants to keep the fruit from the dirt, to stimulate the growth of the plants, and to retain the moisture in the soil, which is most essential for the plants. This covering of rough material also serves for manure for the next season. Strawberries for eating must be picked very early in the morning in order that they may be fresh and firm. They are generally picked by gangs of men and boys, who sally forth at 3 a.m. and leave off at 7 a.m. This matutinal fruit is put into "punnets," containing about 1 lb. weight, which are again packed in deal boxes holding about five dozen "punnets," and sent off by the earliest trains to Covent Garden. For this, which is the *crème de la crème* of the fruit, as much as £5 per box is sometimes realised, or 1s. 8d. per lb. Women do not pick the best Strawberries, as they do not like the very

early hours, and their clothes damage the fruit; but they arrange them deftly in the punnets and boxes in a shed or tent close to the field. Some growers sell the produce of their Strawberry plantations to middlemen, who pick, pack, sell, and take all risk, at an average price of £18 per acre. Others make contracts with jam makers to supply them with Strawberries at from £18 to £28 per ton. In this case the fruit is gathered at all times of the day, and sent to the jam manufactories in tubs containing 80 or 100 lb. weight of fruit. The average price of the fruit in London is about 7d. per lb. When the price falls below 3d. per lb. there is not much profit in its production. Strawberry growing is a very pleasant and a fairly profitable business when carried on under favourable conditions near the metropolis, and it seems hardly possible that home or foreign competition can interfere much with the fortunate cultivators in West Kent.

RASPBERRIES are also largely grown in this part of the county as well as to a small extent near Maidstone and Sandwich. The "canes" are raised easily and quickly from cuttings, and are planted between Currants and other bushes; or by themselves, about 15 in. distant from each other, in rows wide enough apart for purposes of cultivation, being treated as regards cultivation and manure in the same manner as fruit-bushes. When this fruit is grown on a large scale, stakes and espaliers are dispensed with, the canes are cut down in the winter to about 3 ft. in height, the old wood that has ceased to bear is cut away, and as much of the young wood as is not required. Care should be taken to retain those canes that are stoutest and have short joints. The fruit is picked by women and children, and is usually sold to contractors at from £18 to £26 per ton. It is packed in tubs in order that the abundant juices may be preserved. Some of the largest, firmest, and best fruit is sent to market in punnets for dessert, but the bulk of it goes to the jam manufacturers. The average price of this fruit for the last six years in London has been about 3d. per lb.

The details and descriptions that have been given of fruit-growing in Kent will serve to show that it is a pleasant, interesting, and fairly profitable occupation, as well as that some parts of the county are eminently suitable for this purpose in regard to soil, situation, and climate. It has been remarked that considerable improvement has been made of late years in the methods of planting, cultivating, manuring, and pruning fruit-trees, and that more attention has been given to the selection of varieties; though in these respects there is still much to be desired. Kentish fruit-growers do not use their skill, energy, and capital sufficiently in the production of high-class fruit. They are satisfied rather with the production of quantities of common kinds, such as Gooseberries, Currants, Cherries, Damsons, which do not entail much skill or care, of which fruits there is either a general glut or a general comparative scarcity in the market. Fine-grown Apples, choice dessert Pears, large brilliant Plums, are always in request and bring remunerative prices; but it cannot be expected that such fruit can be grown by the systems of management that have, as a rule, until recently prevailed. The producers of fruit have been too much mere fruit farmers, having practised the rough-and-ready ways adopted in their cultivation of ordinary crops. There are signs that all this is being changed, and that proper attention is being bestowed upon details, upon minutiae which are essential to ensure success. It is possible that foreign competition, which is increasing year by year, coupled with a largely increasing home production, may affect the profits of growing "soft" fruit and the more common kinds; but, with regard to fine dessert fruit, it is not likely that there will be too much if the growers have a due regard to the selection of sorts that will succeed each other in regular rotation, and keep their fruit at home until it is fit for market. It is too much the custom to send all fruit, that ought to be kept, away when it is gathered, on account of the trouble and uncertainties of "harvesting" at home. If the growers will not undertake this, they cannot expect the full return from their fruit land, nor will the public have a steady supply of fruit fit for the table. A very great waste of fine fruit takes place because so little is kept at home by the producers until it is ripe; and much goes to the "smashers"

that would fetch full dessert prices in its due season. Many complaints have been made lately of the scarcity of fruit in many places, and it was justly remarked by Mr. Bartley, that many of the poorer classes never taste fruit, which is so grateful and even necessary to some constitutions. This scarcity is due to the centralization of the fruit supply in London and other large towns, caused obviously by the reason that the sale of consignments is practically certain at some prices—the market-price of the day. Soft fruit in many cases will not bear a second journey, and it constantly happens in the season that the costermongers are traversing London, taking fresh fruit to the slums and alleys at the cheapest rate; for instance, selling fine Bigarreau Cherries at 1½d. per lb., while the inhabitants of the towns and villages within twenty miles of the metropolis, even in fruit-growing districts, can hardly get fruit at any price. Jam makers always stand ready to take immense quantities of all kinds of fruit in plentiful seasons, as the price is low and the jam will keep for a “rainy day.” It is true that fruit of all kinds goes from London to the largest northern towns, but the risks of the fruit not finding a market are few where the population is dense and jam manufactories exist.

Fruit-growers can hardly help to remedy this monopoly of soft fruit in thickly populated places, as the article is so highly perishable. They can, however, better regulate the supply of hard fruit, such as Apples, Pears, and Filberts, by a better arrangement of varieties in their plantations, and by forwarding to market only fruit actually fit for consumption; by doing this they would prevent a great deal of waste, and obtain far better prices for their produce.

SOME NEW GRAPES.

To Grape-growers, great and small, anything new in the way of Grapes is always a matter of interest. When a new variety comes out with high recommendations, enthusiastic cultivators cannot rest till they get it, whatever the price may be, and some, on the mere strength of a recommendation, will make room for it to the exclusion of all others. This was the case, in not a few instances, with that most erratic variety Mrs. Pince, which was sent out as the best late-keeping Grape in existence; one judge of Grapes stated, and truly no doubt, that he had kept a bunch of it in his office for a month without shrivelling, without being bottled, or supported in any way. On the strength of such recommendations it was extensively planted—in some places whole houses of it, which, to our knowledge, have since been rooted out in disappointment. Yet Mrs. Pince is a good Grape in some situations; but it is not a Grape for general planting like Alicante, Lady Downe's, or Gros Colman, which have stood the test under many different circumstances. We have seen and heard of good examples of Mrs. Pince, and there are some who say that it does better with them than any other of its class; but such cases are exceptional, and the best proof of this is that the majority of those who have tried it do not trust to it as a general cropper, while it is seldom seen in first-rate condition on the exhibition table. We have seen it under various aspects, and tried it on its own roots, and grafted on the best late stocks, which improve it considerably; but it seldom colours or keeps well. It is not so apt to damp off, but the berries shrivel, in which condition, however, they sometimes keep for a long time. With us this takes place when grown on its own roots, or when grafted. Some of our late Vines, such as Alicante and Lady Downe's are grafted half-way up with Mrs. Pince, the fruit of which never colours perfectly, and always shrivels by scores; while the Alicante and Lady Downe's, on the lower part of the same rods, get quite black, and keep till May in fine condition, and this has been the case every year since Mrs. Pince was sent out, for we procured it at once. It is, however, a better-flavoured Grape than the two named, and for that reason is preferable to them, but only when it is found to succeed as well.

Golden Champion.—This has been one of the most abused as well as the most praised Grapes ever sent out, but must now be described as a very uncertain kind, and not one for general culture. The Vine is a very vigorous grower, the berries are unusually large, with a deliciously-refreshing flavour when quite ripe; but before they get that length the bunches are decimated by spot, which may be checked greatly by giving them time to ripen and a dry atmosphere, but is seldom wholly prevented. If for nothing but its magnificent appearance, it is, however, well worth a place in a mixed collection, and should be grafted on the Muscat of Alexandria.

The Duke.—A good, large-berried, and well-flavoured Grape, but delicate, like the others, and difficult to finish. We have never

seen it so good anywhere as at Clovenfords, in the hands of the raiser. It is a desirable Grape to grow, but is not one for planting extensively.

Pearson's Golden Queen.—The great fault of nearly all the new Grapes sent out within the last twenty years is that they have some marked constitutional defect—they spot, crack, shrivel, fail to colour, or perhaps set badly; but the Golden Queen, though it is only of second-rate flavour, is at least hardy, has a good constitution, and quite equal to the Black Hamburgh or any of the old standard sorts in that respect. It is a very good grower, a free bearer, a good setter, colours well, and keeps pretty well, and may be recommended either for late or early work. The flavour is fair, but not first-rate; it is likely to become a standard variety.

Venn's Black Muscat.—This variety is so like the Muscat Hamburgh, even to its worst faults, as hardly to be distinguished from it. It possesses the true Muscat flavour, but that is all that can be said in its favour. Like the Muscat Hamburgh, it will probably be found to succeed in some situations; but hitherto we have hardly heard one good account of it. We have one strong Vine of it here in a mixed collection, all of which do well but it; and the bunches it has produced the last two years are simply miserable abortions, owing to the fruit setting so badly.

Madresfield Court.—Were it not for its propensity to split, this would undoubtedly be reckoned one of the finest Grapes in cultivation. The Vine is a good grower, and the bunches and berries are large and shapely, and the flavour excellent, but the propensity of the berries to crack and then rot before they are quite ripe frequently spoils the entire crop. For this reason it is not extensively grown. Too much water at the root is said to be the cause of the splitting; all that we can say is, that the Vine which does worst with us here is growing in the driest corner of an inside border, while another Vine which has to share in the watering with the others—and we water liberally—usually finishes pretty well. The only other difference in the position of the two is that the Vine that does best is more shaded than the others, or at least the fruit is, for it is growing at the west end of the Vinery, and receives the afternoon sun for several hours every day. The Madresfield Court should, however, be tried in every collection, and grown extensively where it succeeds. It is an early kind.

Mrs. Pearson.—We cannot say much about this Grape yet from personal experience, but so far it seems to bear out the character given to it. It is yellow in colour, described as being as large in bunch and berry as the Black Alicante and as good a keeper, and having a Frontignan flavour, a character which should insure its popularity without fail. A yellow Grape, possessing keeping qualities like the Alicante with a Frontignan flavour, would be an acquisition indeed! It puzzles me to learn how such a Grape was raised from the Black Alicante, which has nothing in common with the Frontignans.

Two other Grapes raised by Mr. Pearson are Dr. Hogg and Ferdinand de Lesseps, neither of which, however, are so good as the two first-named, but worth adding to mixed collections for the sake of variety.

We have here referred to some of what may be called the older new Grapes, because their merits continue to be discussed in the gardening papers, and very various opinions are expressed regarding them; but we have here described them, as we think pretty truly, from personal acquaintance of most of them, and a knowledge of their behaviour under very different circumstances and in places widely apart. Though excellent in many respects, none of them will do for general cropping, for which we must still rely on the old Black Hamburgh, Muscat of Alexandria, Lady Downe's, Black Alicante, Gros Colman (the latter for size of berry), and, we may add, the agreeably-flavoured Frontignans.—“Field.”

Sweet Apples.—Of forty-three varieties of Apples tested by M. A. Truelle of the Chemical Society of Paris, the red American Reinette was found to contain the largest amount of sugar.

Remedies for Injuries to Fruit Trees are mentioned by Herr Lucas in a late work on orcharding. According to him, wounds of the usual sort are best treated by cutting out the injured part, and smearing the parts laid bare by the incision with resin or tar. Washing them with water and bandaging with wet cloths, have also frequently produced good results. Wounds on the trunks of smooth-barked trees, caused by hailstones, should be smeared with a mixture of clay and cow manure. Fruit trees injured by late frosts, if the bark looks spotted and the liber assumes a reddish appearance, should be scarified at once, or the strips of bark may be cut out in the direction of the length of the trunk, and the line of the incision filled up with paste made of clay, cow manure, and ashes.

BEST CROPPING HARDY FRUIT TREES.

THE general failure of the fruit crops this year will doubtless make all those who intend to plant young trees try to find out the varieties that have borne the best crops in their different localities. To begin with Apples, the best bearing varieties here have been, amongst the early ripening kinds, the Irish Peach, Early Harvest, and Early Strawberry; of the mid-season sorts, Lord Suffield, Duchess of Oldenburgh, Cox's Pomona, Small's Admirable, King of the Pippins, and Cox's Orange Pippin; and of the late or winter-keeping sorts, New Hawthornden, Tower of Glammis, Blenheim Pippin, Lord Burghley, Dumelow's Seedling or Wellington, and Sturmer Pippin. The early varieties of Pears that have had half a crop on them have been Beurré Giffard, Clapp's Favourite (an American Pear of good flavour), Beurré d'Amanlis, and Williams' Bon Chrétien; of the mid-season Pears, Louise Bonne of Jersey, Foudante d'Automne, Doyenné du Comice, Thompson's, and Comte de Lam; and of the latest, Knight's Monarch, No Plus Meuris, Easter Benrre, and Hacon's Incomparable. All kinds of Plums have been a complete failure, that great bearer in most years, the Victoria, having only very thin crops even in the most sheltered situations. Of Cherries, although I never saw the bloom more abundant, only the May Duke and Morello on walls produced crops. There is not the least doubt that by the selection of free-bearing hardy fruit trees in planting new orchards and waste grounds, the production of fruit in this country might be doubled, and a check put to the importation of so much hardy fruit from abroad to our markets. Of course, in unfavourable seasons like the present, the foreigners, from their better climate, would always have the advantage, and the higher prices given them for fruit would compensate them for the carriage; but in plentiful fruit years here, this will not be the case. If new orchards planted with the free-bearing sorts of Apples, Pears, and Plums were substituted for old, unproductive ones, and if all waste grounds and even hedge-rows were planted in places out of the reach of the million, what quantities of fruit might be grown, and then the markets might be supplied at a cheap rate. The best cropped small orchard I have seen this year was where there had been a quarry, and where the *débris* of the magnesian limestone surface had been placed in it to fill it up. The tenant, an industrious man, had barrowed and carted all the road-scrappings within his reach in which to plant the trees, and they seldom miss bearing fine fruit.—W. TILLERY, *Wellbeck*, in "Florist."

Parthenogenesis in the Case of Maize.—We planted at regular distances apart, and with some degree of care, a large quantity of Maize plants, some with red seed, and some with yellow; also three other named kinds, each variety being kept separate, and as soon as they arrived at the flowering stage we examined them daily, and removed all the male flowers. We did not wait until these were even apparent; but, removing the envelopes surrounding them

in the bud stage, we cut away all the male flowers before they had time to open.—[So speaks M. Carrière in the "Revue Horticole," and gives this, among other illustrations, of seed being produced by Maize without fertilization, which, however, would require further confirmation, inasmuch as pollen from other plants anywhere in the same district could be easily carried to those from which the male flowers were removed by wind or birds.]

PHYSICAL GEOGRAPHY.*

THE seventh edition of this standard manual contains a large

amount of information relative to the distribution of vegetable life over the different parts of the earth's surface, which cannot fail to be both valuable and interesting to both horticulturists and botanists. Five chapters are devoted to Vegetation and its distribution over the globe. The author sets out with a concise description of the various vital processes concerned in the growth of plants, as well as of the elements which enter into their composition. The classification and distribution of plants are next treated of at some length, after which the author describes the vegetation of the different parts of the earth in detail. The plants of the great Continents are first treated of, after which the reader is taken on a pleasant botanical excursion through the Arctic and sub-Arctic regions, Great Britain, and Middle and Southern Europe. Temperate Asia, one of the most interesting botanical regions of the Old World, is next fully described, travelling botanists being reminded that for its size no country has so abundant and varied a flora as Asia Minor. We next come to the flora of the Indo-Chinese Peninsula, Indian Archipelago, and India proper. Austria and Africa come in for a fair share of attention, the vegetation of the Cape being well described, and its affinities with that of Australia being specially pointed out. The peculiar character of Australian and Polynesian vegetation is also alluded to. North and South America are deservedly very fully described; Mexico, the West Indies, and tropical America receiving special notice, the whole concluding with an account of the peculiar vegetation of Kerguelen's Sound, Tierra del Fuego, and the Antarctic regions generally.

The chapter on marine vegetation will be perused with interest by algologists. We may add that several improvements have been introduced into this edition.

THE ENVIRONS OF LONDON.†

THIS work, which is both useful and interesting, should find a place on the bookshelf of every one who desires to have something more than a mere topographical account of the towns and villages and private places of interest within a twenty-mile-circle or so round

* "Physical Geography." By Mary Somerville. Seventh Edition. London: John Murray, 1877.

† "Handbook to the Environs of London" (2 vols). By James Thorne, M.A. London: John Murray, Albemarle Street.

Maize, showing effects of parthenogenesis.

London. The principal features, historical and otherwise, of each place are carefully noted, and as a book of reference it will be of invaluable ; it may, indeed, be styled a pleasant-reading gazetteer of London's surroundings. The names of the different places are arranged alphabetically, and there is also a copious index. From a horticultural point of view, of course, little can be expected, but old and famous trees to be found in the different parks within, and even some distance beyond, the twenty-mile-circle, are briefly alluded to. Altogether, the work is one which we can heartily recommend.

EXTINCT MAMMALS OF AUSTRALIA.*

This work may be regarded as a supplementary volume to the original edition of Cuvier's "*Recherches sur les Ossements Fossiles*" (4to, 1821). In that work but one extinct species had been referred to the Marsupial Order, viz., the famous "*Didelphys gypsurum*" (vol. iii. pl. lxxi.), and the osteology of the existing species is not described as in the case of the placenta Mammalia, of which the fossil evidences are there so richly illustrated. The author of the present work has accordingly added descriptions and figures of the osteology and dentition of the existing Marsupialia to those of the fossil remains of the extinct species; the characteristics of the bony structure and teeth of the wombats and kangaroos are shown in detail. As in the great work of Cuvier, the several memoirs by which the discoveries and determinations of the fossils were first made known, are reproduced with additional matter and in systematic order. A chapter is premised on the fossil Marsupials of England, with figures illustrative of twenty-eight species, referable to fifteen genera. Of the extinct Marsupials which have left their remains in Rhætic, Oolitic, and Purbeck deposits in England, some exemplify or pre-figure, in a singular and interesting manner, genera and species of Marsupials which have left their remains in the comparatively recent drift-deposits and in the caves of Australia.

After a survey of the 522 pages and 132 plates recording these "*Researches on the Fossil Mammals of Australia*," to which the author has devoted part of his annual labours since 1836, he might well be pardoned in indulging "in the flattering thought that the chances were small of future discoveries of new species of large extinct marsupial quadrupeds in the Australian Continent." But he checks himself by the following remark:—"Warned, however, by the rate of progress of the science of palæontology since the demise of its founder in 1832, I deem it more probable that a like lapse of time after the issue of the present volumes will have been attended by such rich results to the young and ardent naturalists of Australia as to show that their predecessor at home had but 'skimmed the cream,' and given them the broad outlines of a picture of ancient animated Nature which their labours will fill in and finish."

In the descriptions and plates of the present work, devoted not only to the characteristic fossils of the extinct families, genera, and species, but also to the dentition and osteology of the still existing types, the generations issuing from the colonial schools, colleges, and universities of Australia, of whom some may be irresistibly led, like those of the present generation of Anglo-Americans, to investigate and interpret the phenomena of an envioning Nature, will find an instrument which will facilitate and accelerate their endeavours to reconstruct the strange forms of mammalian life which once traversed the Australian plains and scrubs and have long since passed away from that continent.—"*Annals of Natural History*."

[Notwithstanding the abundance of literary journals, it sometimes happens that the noblest books receive little or no notice. This will probably be the case with this great work, of which a comparatively small number has been printed.]

MUMMY WHEAT—WILL IT GERMINATE?

ON Sunday week, the Rev. C. Shakspeare, in commencing a sermon at St. Stephen's, Westbourne Park, on the words "Except a corn of Wheat fall into the ground and die, it abideth alone," referred to the somewhat common belief that the so-called Mummy Wheat found in Egyptian tombs has been known to germinate and grow on being planted, notwithstanding its burial for more than 4000 years. The preacher said that this fact, "if it were a fact," was an interesting illustration for his purpose, but he was careful not to stake an argument upon a statement which, he said, had been called in question by scientific men. Mr. Shakspeare has since received the following letter, which he has forwarded to us with the request that we would, if possible, state the real facts of the case:—

* "*Researches on the Fossil Remains of the Extinct Mammals of Australia*; with a Notice of the Extinct Marsupials of England." By Richard Owen, C.B., F.R.S. Two vols. 4to. Erxleben: London, 1877.

"A lady, who had the privilege of hearing Mr. Shakspeare preach on Sunday morning last, thought it a great pity he threw doubt over his own illustrations of the Mummy Wheat. It is a well-known fact that the experiment was tried in England, and with the most perfect success, producing a large field of corn of very large growth. More than that, a lady to whom she spoke of it on Sunday evening had herself seen the result of an experiment tried in a sunny spot in Scotland, twenty-eight years ago, at Admiral Duff's, Drum Muir Castle, Co. Bauff, and that the ears of corn were nearly as large round as her wrist, and otherwise quite unlike English Wheat. Drum Muir Castle has now passed into the possession of Colonel Gordon she believes, and probably all appearance of the Mummy Wheat may have vanished." On reading this letter, we at once recollected that the case referred to by the writer had been recently dealt with in one of our scientific journals, and the circumstances fully explained which led to the erroneous popular belief in the subject. We have the impression that the refutation was given either in the pages of "*Nature*" or *THE GARDEN* during the past year, but have been unable to refer to the file. In the interval, we have forwarded the letter to Professor Henslow, who has kindly sent us the following reply:—"The lady is evidently confounding 'Egyptian' Wheat with 'Mummy' Wheat. The former is a variety which produces several ears in a cluster on one stalk. The latter is Wheat (grains) found in catacombs of Egypt, and which has never germinated when planted. The reported cases of Mummy Wheat having grown were undoubtedly erroneous. Many years ago my father carefully examined some samples and also made careful enquiries. The examination revealed not only decidedly fresh grains, but fragments of Indian corn, an American plant! Enquiries proved that the Mummy Wheat had been put into a common corn jar of Alexandria, which accounted for fresh grains, so that whenever Mummy Wheat was 'supposed' to have germinated, it was undoubtedly recent grain mixed with it. The true Mummy Wheat is dark brown and carbonised.—G. Henslow."—"*Baywater Chronicle*."

At What Depth should Bulbs be Planted?—This is a question of some importance. My experience is decidedly in favour of deep planting for such bulbs as Winter Aconite, Crocus, Snowdrop, Narcissus, and Hyacinth. The depth should perhaps vary with the soil, being greatest in light open soils, but I have not found 1 ft. above the crown of the bulb too much in any soil. The tendency of the Crocus, where not covered with turf, is to work upwards, new bulbs forming every year on the crown of the old bulb, but probably this tendency is counteracted in their natural state. In Nottingham meadows, where the blue Crocus is naturalised, I used often to dig them up, and think the average depth is about 1 ft. The surface of the ground is probably raised there by the alluvial deposits of floods faster than the new bulbs rise, but in getting up Snowdrops, Crocuses, or Daffodils which have been accidentally left wild, I have generally been surprised at the depth of the bulbs. In fields of stiff red clay in Cheshire the common double Daffodil flowers in luxuriant clumps, which I have wished to divide, and found that the full depth of a garden spade, 18 in., does not reach the bulbs. The common autumn Crocus (*Colchicum autumnale*), which is perhaps a native there, grows nearly as deep. Again, where garden ground has been dug deeply, we see here and there a Crocus or Snowdrop which has been accidentally buried, flowering quite as well as any others, and on taking it up to restore it to its proper place, are surprised to find that not only is the bulb at least 1 ft. deep, but also upside down. The obvious advantage of deep planting in mixed borders is, that spring bulbs so planted need not in any way interfere with such plants as scarlet Pelargoniums or blue Lobelias planted over them, not to mention instances where cultivators, who have not enough to do, employ their superfluous time in autumn in digging the mixed herbaceous borders, an evil practice I have much difficulty in preventing. Of course the rule of deep planting does not apply to all bulbs, exceptions are Anemones, Cyclamens, &c. I believe that Hyacinths and Polyanthus Narcissus, where the soil is light, may with advantage be covered to a depth of 18 in.—G. W. Don, in "*Gardeners' Chronicle*."

William the First Pea.—In addition to this being the best early Pea in cultivation, it is also one of the most valuable of late kinds. It bears freely late in September, when the pods are fresh and their contents well flavoured. Mr. Pragnell showed a dish of it at the Crystal Palace the other week equal in every respect to those gathered in July.—C. S.

Small Brussels Sprouts Best.—While in England people are generally anxious to choose the largest, in Belgium, which is supposed to be the home of Brussels Sprouts, they prefer the small and firm sprouts to large ones, thinking them better in flavour.—L.

THE GARDEN OF BRITISH WILD FLOWERS.

LARKSPUR (*Delphinium Ajacis*).—An annual corn-field weed like the Larkspur, which is naturalised in Cambridgeshire, and occasionally occurs in other counties, must have many good qualities if it is to hold its own against equally hardy perennial species. New hardy *Delphiniums* are constantly brought out, growing in any soil, 2 ft. to 5 ft. high, and with flowers of nearly every colour, and few plants look better in a copse or shrubbery with *Pæonies* and other large herbaceous plants than these do; yet there is some charm of delicacy in habit and foliage which seems confined to the annual Larkspurs, and their many colours—even in a level sheet in a border, shown up by the pure pale green of their finely-cut leaves—are very attractive. The wild Larkspur is found with blue, white, or pink flowers, some-

Common Annual Larkspur.

times colouring entire fields in June and July. Its fairy-like spikes of bloom have, however, so much individual beauty that I like to see them also isolated, either on the margin of some rustic kitchen garden, or by the pebbled footpath leading to the cottage door; or, better still, growing one above the other at all levels on rockwork, some rising wholly, some in part, above the sky-line. They should be so placed that plenty of sun may show their transparent texture. The British species is distributed throughout Central and Southern Europe and North Africa, and is an introduced weed in the United States. It is interesting botanically from not being the *Delphinium Ajacis* or consolidation of Linnæus, though described under the former name by Reichenbach, and under the latter in many British floras. Among the best hardy perennial forms are *D. formosum* and *D. nudicaule*.

MONK'S-HOOD (*Aconitum Napellus*).—Though its dark-blue flowers, with the purple and white ones of its South-European congener, *Aconitum variegatum*, render the Monk's-hood suitable for such

Monk's-hood.

situations as I have just mentioned for the perennial Larkspurs, where it will grow 4 ft. or 5 ft. high, yet there is a coarseness of habit about the majority of the genus that I consider detracts considerably from their merits. As cut flowers they are not equal to Larkspurs, *Salvias*, or *Lobelias* in clearness of colour or beauty of form. They are virulently poisonous, but there can be no excuse for the carelessness which has mistaken their roots for Horseradish, and this character need not deter us from cultivating the "Monk's-hood darkly blue," as Clare calls it. It is a hardy, blue-flowered perennial, and is apparently a native of Wales, Hereford, Gloucester, and Somerset, where it grows in shady places near

streams. We have not many blue herbaceous perennials. The Monk's-hood is generally distributed eastwards to the Himalayas. The effect of a mass of this plant with the Great Hairy Willow-herb

Parts of Monk's-hood.

(*Epilobium hirsutum*) by a streamlet in some woody glen would be worth trying. The variety called bicolor might be used.

THE BANEERRY (*Actæa spicata*).—A diminutive, shrubby little plant, not often seen in gardens, and, though distributed throughout Europe and extra-tropical Asia, not common in a wild state but occurring in the copses of Yorkshire and the Lake district on a limestone soil. The Baneberry, or Herb-Christopher (*Actæa spicata*), is worthy of a corner

Baneberry.

on the rockwork. It seldom exceeds 2 ft. in height, and is not much branched; its whitish raceme of flowers, though somewhat graceful and Mignonette-like, is insignificant, and its blackish fruit is poisonous. Its one redeeming feature is its delicate, long-stalked, root-leaves, which, though sufficiently resembling those of an Elder to justify the name of the plant, are still more like those of some of the justly-popular Maples. In North America the plant has red berries, and a mixture of the two might look well in autumn.

THE BARBERRY (*Berberis vulgaris*).—The shrubby little Baneberry, with its fruit so unlike that of other Ranunculade, forms a not unnatural transition to the tribe of the Barrenworts and Barberries. Scarcely any item in the autumnal beauties of an old-fashioned garden is more beautiful than the drooping clusters of the orange-red fruit of the common Barberry (*Berberis vulgaris*). Hanging from some ruined wall, as at Buildwas Abbey, or draping rough masses of cold grey rock, as it does round the valley of Interlaken, or in the many positions where it grows wild, the Barberry is strikingly beautiful; nor is its beauty confined to autumn, for in May and June its racemes of sulphur-yellow flowers, with their curiously irritable stamens, much haunted by bees, render it a shrub which should not be over-

looked by cultivators. Though its favourite wild haunts, alike with its rugged, spiny habit, point to the overhanging limestone crag as its most suitable location, it will flourish equally well in the border, shrubbery, or hedgerow, and seeing that there are some fifty other species in the genus, besides the varieties of this species known as *lutea*, *violacea*, *purpurea*, *nigra*, and *alba*, with yellow, violet, purple, black, and white fruit respectively, the cultivator ought not to lack variety.

THE ALPINE BARRENWORT (*Epimedium alpinum*).—Though having no claims to be considered a native of Britain, the Alpine Barrenwort (*Epimedium alpinum*) has too many good points to be passed over in silence. It is a herbaceous perennial, seldom exceeding 1 ft. in height. It forms a clump of the most delicate leaves, triply divided in three or tri-ternate, each young leaflet having the texture of a Wood Sorrel, and the unusual and graceful form of a Begonia, while it is fringed with spiny hairs. From amongst its foliage rises

Alpine Barrenwort.

a loose raceme of quaintly-structured blossoms, four spreading maroon sepals in each, supporting four pale green, slipper-shaped nectaries, nearly resembling the petals of the Hellebores. This interesting plant, which is a native of Southern Europe, does best in a moist, peaty, or vegetable soil, in some shady corner of the shrubbery or rockwork. It flowers early in spring, and is propagated by dividing the root-stock. It occurs in a wild state in the Bingley Woods, six miles from North Bierley, and at Fountains Abbey, in Yorkshire, on Carrick Fell and Skiddaw, at Cleish Castle, Kinross, and Mungodoch Castle, Glasgow. The Persian species, *E. pinnatum*, grows somewhat larger, and, though perfectly hardy, requires rather warmer situations. G. S. BOULGER.

AUTUMN-FLOWERING SHRUBS.

AUTUMN is the season of fruit rather than flowers. And yet the rains of September renew so thoroughly the vivid green of the Grass, and many trees retain so entirely the beauty of their foliage, that one feels the more a lack of flowers. Nearly all the finest shrubs have bloomed in June or July, and only a few remain to continue the flowering season. It becomes somewhat important, therefore, to the amateur that his knowledge should afford every means within reach to lengthen out this season. Without pausing to dwell upon the exquisite beauties of autumn Roses, we note first the noble masses of *Hydrangea paniculata grandiflora*, plants or groups of which make such prominent objects in the landscape. What can be finer than these great clusters of white flowers, passing, as the season advances, through varying shades of light green, rose, reddish purple, and deep red? The flower is not satisfactory when plucked. A certain coarseness adheres to it, which is not lessened by the great size and sameness of structure. Seen on the lawn, however, it is difficult to surpass; indeed, it ranks with many persons, as the very best of shrubs. So grand an individual as this *Hydrangea* quite overshadows the merits of other late-flowering shrubs, not excepting even the beautiful *Hydrangeas* from Japan, such as *Otaksa*, &c., which are gradually making their way into public favour after the slow manner of all new plants. Another well known but valuable shrub for this season is the *Althæa* (*Hibiscus*), bearing large flowers often striped with white, purple, red, and pink. Both plant and flower, however, are somewhat coarse in construction and colouring, but the late-blooming property, a bright, glowing aspect, and great vigour and aptitude for growing in hedges or large masses, will always render it very important to the landscape gardener. More humble plants are the *Hypericums* (*St. John's-wort*). Most of them bloom late in summer or early fall, and their profuse, bright yellow flowers, studded over dwarf, compact bushes, present a very pleasing

effect at this season. *H. kalmianum* is especially attractive with its shining, evergreen-looking foliage and numerous flowers, remarkable for many anthers. These shrubs have been long known and esteemed, but have never received the attention they deserved. *Potentilla fruticosa* is another pretty autumn-flowering shrub, with yellow flowers and somewhat silvery or glaucous foliage; it is of low growth, but more erect usually than *Hypericums*. Two or three pretty *Spiræas* also bloom at this season, bearing more or less pink blossoms, and having the respective names of *S. Billiardi*, *S. Regeliana*, and *S. Nobleana*. The study of the various seasons of flowering peculiar to shrubs and trees should receive more attention, for there is very much that might be done in this way to render our grounds more attractive than they usually are in autumn.

SAMUEL PARSONS, in "Country Gentleman."

Violet Banks.—Violets are such universal favourites that any vacant spaces may be profitably planted with them by way of additions to the regular beds of them in kitchen gardens or forcing grounds. As a rule, we get the finest blossoms of both double and single varieties from one-year-old plants, raised annually from runners, and confined to single crowns after the manner in which Strawberries are prepared for forcing. It frequently, however, happens that there are warm sheltered banks under the partial shade of orchards, and by woodland walks, where, with good preparation previous to planting, Violets will flourish for years, and produce abundance of the finest blossoms with but little attention except that of keeping coarse weeds from overgrowing them. I have just planted such a bank under the shelter of a tall Hawthorn hedge; it was prepared as follows—the soil being stiff and encroached on by roots, was deeply cultivated, and several loads of roads scrapings and leaf-mould were added to it in the form of a top dressing, sloping it gently to the south. In this the runners of *Neapolitan*, *Double Blue*, and the *Czar* (single blue) were planted 1 ft. apart each way and kept watered until they had become well established. The *Czar*, being a vigorous kind will probably overgrow the other sorts in time, but after four or five year's existence such banks will well repay replanting, and charming combinations may be formed by adding such roots and bulbs as those of *Lily of the Valley*, *Squills*, and other plants of like character that succeed under similar circumstances.—JAMES GROOM, *Henham*.

Three Days' Shows.—The great shows of the current year being over, the framing of new schedules for 1878 will soon occupy attention; indeed, one or two are already in print, and as three days' shows, which terminate on Saturdays, seem to be the order of the day, permit me to direct attention to the great loss, inconvenience, and sacrifice which attend these arrangements, and to enquire if something cannot be done to help distant exhibitors, who are obliged to pack and travel the day before the shows open to the public, and cannot by any possible chance return before the following Monday. If large shows are to be made to pay, I am well aware that they must be attended by the masses, and we are told that Saturdays are the only paying days; but, judging from appearances, I am inclined to think that the majority of visitors could have attended the September shows equally well earlier in the week, when owners of valuable plants might have reached home with their treasures on Saturday, and exhibitors of fruit would have been able to remove their produce while it was fit for use. When I state that the three great September shows this year represented in my case seventeen day's absence from home, including three Sundays, I feel sure that the hard-working Secretaries, to whom we are indebted for every facility and accommodation, will admit that we have a grievance to complain of; and as distant exhibitors cannot be dispensed with, I trust they will endeavour to make such future arrangements as will admit of getting home before Sunday. If this cannot be done, it is more than probable that many exhibitors of valuable plants and perishable fruit will be conspicuous by their absence. Another inconvenience and annoyance with which exhibitors have to contend, is the way in which the public are allowed to elbow and impede them when they commence packing up after the exhibition is over. At the Alexander Palace Show I discovered that the majority of the exhibitors, distant and local, were strongly opposed to Saturday terminations; but no one seems to have taken the matter up, and as Societies may be labouring under the delusion that horticulturists are perfectly satisfied with their arrangements, I trust that these remarks may have the effect of bringing about a system of holding shows which will tend to the advancement of horticulture, by making the interests of promoters and producers mutual.—W. COLEMAN, *Eastnor*.

Hydrangea paniculata.—Professor Rein, a Japanese traveller, says:—"Of all the specimens of *Hydrangea*, *H. paniculata* is the most widely dispersed in a wild state, ascending to an altitude of 5,000 ft., where it forms large bushes." We need not be surprised at its remarkable hardiness.

HARVEST DECORATIONS FOR CHURCHES.

At this season, when harvest thanksgiving services are being held, a hint or two on church decoration may prove interesting to some of the readers of THE GARDEN who are, perchance, about to lend their aid in such work. As a rule, much more attention is paid to the Easter and Christmas church decorations than to those employed at this season, and this I consider a mistake, as a far finer effect can be produced with the materials now available than at either of the above-named seasons. Hot-house flowers can be obtained it is true during even the coldest weather, and lovely bouquets and wreaths are made therewith at Christmas, but as fine effects can be produced at this season with golden corn, fruit, and tinted foliage as it is possible to imagine. Where corn is employed for plume-shaped decorations, Oats are by far the most graceful; but where sharp outlines are required, I prefer Barley to Wheat, as it has a lighter effect. Letters for texts can be made of Barley or Wheat on a scarlet foundation. The prettiest plant for intermixing with corn are trails of the bright-tinted Virginian Creeper, just now in perfection; for twining up pillars and round capitals, no more charming plant can be found. If the sprays be light and liable to break, they should be supported by means of a slight wire fastened at intervals along the stem. It is best, if possible, to place the end of the stem in a pot or some such receptacle filled with wet sand, as otherwise the leaves will droop and the whole effect will be spoiled. For smaller decorations, tinted Vine leaves, and odds and ends of tinted foliage too numerous to name obtained from hedgerows, will be found most useful. In the way of coloured berries none will be found more desirable than those of the Mountain Ash, and I have used Hips and Haws before now with happy results. There are, however, many berry-bearing plants in perfection just at this season, and I have named the above merely as examples. With regard to flowers we have at present large numbers, from amongst which may be selected the following, viz., Gladioli, Asters, Lilies, Hydrangeas, Roses, Dahlias, and Fuchsias. These are best suited for bold decorations, such as large crosses and devices for blank spaces on walls, and wreaths for pillows and window-sills, smaller varieties being best adapted for the decoration of the pulpit, reading-desk, or font. Fruit should always occupy a prominent place amongst harvest decorations; it looks well intermingled with flowers and foliage round the chancel or at the base of the pulpit. Amongst the smaller flowers some blooms of Cornflower should be obtained, if possible, as they are in keeping with the Oats and Barley.

ANNIE HASSARD.

Why is the Climate of Europe Growing Colder?—A Swedish paper, just received, publishes an interesting article under this heading. The article states that in the Bay of Komenok, near Koma, in Greenland, fossil and very characteristic remains of Palm and other trees have been discovered lately, which tend to show that in these parts formerly a rich vegetation must have existed. But the ice period of geologists arrived, and, as a consequence of the decreasing temperature, this fine vegetation was covered with ice and snow. This sinking in the temperature, which moved in a southerly direction, as can be proved by geological data, i.e., the discovery of fossil plants of certain species, seems to be going on in our days also. During the last few years the ice has increased far towards the south; thus between Greenland and the Arctic Sea colossal masses of ice have accumulated. On European coasts navigators now frequently find ice in latitudes where it never existed before during the summer months, and the cold reigning upon the Scandinavian peninsula this summer results from the masses of ice which are floating in the region where the Gulf Stream bends towards our coasts.

Early Frosts in Antrim.—"A. D." remarks (see p. 328) that the frost on the 23rd and 24th of last month was very destructive in the case of certain flowers and vegetables in his locality, which was certainly bad enough at the dates named, but in this part of Ireland we had a severe frost much earlier, viz., on the night of the 3rd ult., which destroyed Dahlias, Nasturtiums, Alternantheras, Iresines, Perillias, Heliotropes, Dwarf and Runner Beans (which were late this year), and completely stopped the filling out of late Peas. The leaves of an ornamental Fig tree (a standard) were also blackened, and dropped off prematurely, and in the case of one or two Oriental Planes in the grounds, the young tender leaves were shrivelled up—in fact, the general "fall" of the leaf was, in conse-

quence of the frost, brought on earlier than it otherwise would have been. Last year we had an exceptionally open autumn with no frost to do any harm until November.—S. K.

Select Edible Fungi.—I am very pleased with the paper on this subject which appeared in THE GARDEN last Saturday. I have for some time been interested in such matters, and, living as we do in the country, the search for different kinds of fungi adds a charm to our country walks and drives. So far we have only proved the virtues of two kinds, the *Hydnum repandum* and the *Chanterelle*. Of these we all greatly prefer the flavour of the *Hydnum*, and as we have a large quantity growing in our own grounds, we have been able to have several dishes of it, which always call forth exclamations of praise from the younger branches at the table. All that has been said in favour of the qualities of the Spine-bearing Mushroom, when gently stewed with cream and butter, pepper and salt, and served very hot on buttered toast, we can fully endorse.—M. L. D.

Is Gas-tar Injurious to Trees? (see p. 287).—My experience entirely justifies Downing's recommendation of the use of gas-tar as a preventive of the attacks of rabbits upon the bark of newly-planted trees. I have used gas-tar, sometimes mixed with a little benzoline, if very stiff, for twenty-five years for Ash trees, Oak, Larch, Ivy, and other plants, without being aware of a single instance of injury. It has even been applied without injury to parts of the stem which have been already bitten and laid bare, whilst I never knew rabbits touch plants which have been so treated. I have also tarred the cuts of trees of all ages, after removing limbs close to the trunk, to keep wet from decaying the timber, instead of paint, with good effect, especially if the limbs are cut off in early summer when the sap is rising.—J. L. ROGERS, *Penrose, Helston*.

Blanching Late Celery with Spent Tan.—The soil of the kitchen garden here is very strong and retentive, and I have great difficulty in keeping late Celery from rotting during the winter months. Of late years I have used old spent tan principally for earthing it up, and find it to be one of the best materials yet tried, both for keeping the plants free from slugs and from severe frosts. During winter, when there is much rain or snow falling, I have wooden coverings placed above the plants to throw the water off the rows; these coverings are formed of old slabs or planks of little value, and are nailed together in the form of a span roof, and sufficient space must be left below the covering to give the plants plenty of air. To obviate blanching the plants too much near the surface, these wooden coverings must only be kept on during very severe frosts, or in heavy falls of rain or snow.—WILLIAM TILLERY, *Welbeck*.

NOTES AND QUESTIONS—VARIOUS.

New Giant Yellow Zillan Onion.—In what does this differ from our old Danvers Yellow Onion? I have grown them both side by side this year, and cannot discover the slightest difference between them.—D. LUMSDEN, *Bloxholm*.

Autumn Strawberries.—I exhibited a dish of Strawberries (*Viscontesae* Horicarte de Thury) the other day at South Kensington, which were gathered from a border that has furnished a continuous supply since the second week in August; I may also add that the first prize collection of fruit (eight dishes) shown by me at Norwich, on the 12th of September, contained a large dish of Strawberries of this variety.—WM. ALLAN, *Ganton Park*.

The Service Tree in France.—A tree, says a homely French proverb, earns its living, and so the Walnut, the Apple, or Service-berry is allowed to overshadow the Wheat and the Barley undisturbed. The Walnut gives a most valuable crop, besides supplying the grower with oil, whilst the Apple is sold for cyder; and of the fruit of the Service-berry is made an excellent drink, something like cyder, for his own use. It is called here (in Anjou) the sorbier, or cormier, and its wood makes excellent walking-sticks. The rich foliage of these trees, drooping low over the waving corn, has a beautiful effect; some Wheat-fields are planted with them as thickly as an orchard.—"A Year in Western France."

The Phylloxera in Devonshire.—May I ask what the disease is which effects the Vine leaves herewith sent? On the roots, too, I observe a parasite, and with the microscope quantities are visible. I have been told it is the *Phylloxera vastatrix*! I planted twenty-seven Vines in June in a new Vinery, and I observed that four or five of them had small warts on the leaves; but, not thinking the matter one of any importance, I caused them to be planted. After a three months absence from home, I returned last week, and found that every Vine was affected, and my fears that all my money and care in making a new Vine border have been wasted are in a measure confirmed by referring to Mr. D. Thomson's book on the Grape Vine, where *Phylloxera* is described. Is the nurseryman who supplied these diseased canes liable to an action? for it can be easily proved by five witnesses that these warts were on several of the canes when they were delivered to me. I note what is said in the number of THE GARDEN for January 13, but before I do anything I should wish to know whether I have got *Phylloxera* or not.—J. G., *Exmouth*. [It is the *Phylloxera* which has attacked your Vines; as regards the legal question, you must consult a solicitor.—M.]

"This is an art
Which does mend Nature: change it rather: but
THIS ART ITSELF IS NATURE."—*Shakespeare.*

A PAPER ON MODERN "TASTE."*

It appears to be generally assumed that there has been no little advance in English society of late years in regard to what is called "good taste," an expression often very vaguely used, but which we may take to imply the critical perception of the distinction between what is graceful and suitable in form and harmonious in colour in all the objects with which we surround our daily lives, and what is the reverse of all this. This movement in the direction of good taste is, perhaps, hardly as general as is sometimes supposed. As far as we can judge, it has hardly reached the mass of the trading classes at all; and perhaps there are not a few among the professedly more cultured classes who are still sublimely indifferent to the designs of their tables and chairs, their carpets and wall-papers. But even these have to swim with the stream, and this indifference to the æsthetics of house furniture and decoration can hardly be openly professed by any who have the hope of social salvation before their eyes. It would be very untrue to say that there is nothing to congratulate ourselves upon in regard to this recent outbreak of "taste." It is certainly a fact that we now not unfrequently see rooms the *ensemble* of which is harmonious and grateful to our sense of colour, and in which there is no object which can be said to be in a tawdry or vulgar taste, and this is wherefore to be thankful. It is when we come to consider these results not absolutely but relatively—relatively to the principle from which they appear to spring, on the one hand, and to the ultimate ends of art on the other hand, that we seem to meet with that which must give us pause. The theory underlying this movement, with those who think about reasons and principles at all, is what has become almost a "Shibboleth" among art critics of the day, that art and artistic feeling are as much shown in the design of furniture and other accessories as in what have been hitherto considered the higher or "fine" arts of sculpture and painting. The practical corollary to this is found in the existence of numerous establishments devoted especially to the production of what is termed "art-furniture." Now this phrase alone, so familiar to us in print and in conversation, constitutes in itself a begging of the whole question, an indication of a view of the subject radically false and unreal. A great Scotchman, John Stuart Mill, in his memorable address at St. Andrews (which suggests to us more about the true relation of art to our intellectual life than can be found in whole volumes of "art-criticism"), observed that art might, from one point of view, be regarded as the endeavour after the perfection of execution. The definition, at all events, precisely covers the section of the subject which we are just now considering. So far as relates to furniture—to the class of articles which are in the first instance for practical use, and only in a secondary sense ornamental—that is truly artistic which is made, firstly, in the best possible way in relation to the use for which it is intended, and the material of which it is constructed; and, secondly, which expresses in the best and most graceful manner, in the shape and treatment of each portion, the motive and use of the whole, and the special character of the material. We might say that when an object—a sofa, for instance—has the first of these qualities, it is workman-like; when to these is super-added that of expression, or expressive execution, it may rightly be called artistic; but, in fact, the two qualities can seldom be separated or divorced. What is truly workman-like is almost always artistic; what is unworkman-like is invariably inartistic—unsatisfactory to our sense of beauty and fitness. There is not, therefore, and cannot be, rightly speaking, any such thing as "art-furniture," con-

sidered as a separate species of article; and to go into a cabinet-maker's and ask for art-furniture is as reasonable as it would be to go into a bootmaker's shop and ask for a pair of art-boots. The request in either case would in reality be for something made for another object than that for which it professes to be made—for show and not for use. In any sense in which the expression is worth anything, all furniture ought to be "art-furniture," and if it is not it is badly made. What is actually meant by art furniture, as sold in the æsthetic warehouse, is furniture which is a copy of something else that was in fashion at some former period of our history. Much of what is now made as art-furniture, for instance, is in the style which has lately been distinguished as that of the "Queen Anne" period, which has superseded the Modern-Medieval type, though there is combined with this a taste for furniture of a simpler (and, to my thinking, better) Old English style. A good deal of the furniture of these types is far more artistic and tasteful than that which was in vogue in the last generation, so that the impression conveyed is of a more or less general improvement of taste. But that this is to a great extent a superficial appearance is shown by the fact that the bad is taken along with the good. Were there space here to go into details of criticism, it would be easy to show that while some of the furniture-work referred to is good, some of it is as bad and vulgar in taste as it well could be; but it is all alike accepted by the public, and recommended not only by dealers, but by writers and critics who aspire to guide public taste. Indolence of mind, coupled with a desire for show, is at the root of all this. That which might be rightly called artistic furniture, is valuable precisely in proportion to the thought that has been put into it; every detail should bear the impress of having been thought out in reference to the material and the use to which it is to be put. If it were usual to have furniture and other accessories so designed as to represent the thought of the workman and the individual taste of the owner, it would have a real interest; but this involves too much trouble. The manufacturer is content to take a certain style and reproduce it, and say "this is artistic," and the purchaser, instead of cultivating his individual taste, and endeavouring to gratify it considerably and thoughtfully, so as to make his dwelling-rooms a part, so to speak, of his own individuality, is content with the easier task of paying his money, and taking what is set before him, furnishing his rooms after a pattern of a hundred years back, and sitting down and flattering himself that he has succeeded in being artistic, even sometimes at the expense of common convenience. If, for instance, you drop in to afternoon tea at an "æsthetic" house, you have your tea in cups without handles. Supposing, for the sake of argument, that the tea were hot (which æsthetic tea seldom is), you burn your fingers and nearly drop the cup; and then you are told, for consolation, that it is an artistic cup. If it were, it would have a handle, for the natural and proper way of making an object that is to be held in the hand is to give one something to hold it by. Even Macbeth, at a moment when his brain was in a very disordered and disturbed state, still preserved sense enough to see his visionary dagger with

The handle towards my hand:

but then Macbeth was not æsthetic.

Even supposing, however, that the prevalent taste in furniture were logical and real in itself, there is a more serious question suggested by the importance attached to this class of work in comparison with what used to be considered the more intellectual forms of art. As was observed just now, it is almost a commonplace at present to urge that art is not confined to sculpture and painting, but should be shown in all the objects collected in a room, and that we should aim at totality of effect. If this meant that we were to bring furniture and decoration up to the level of the plastic arts, in intellectual interest, there could be nothing to be said against it, except that it is hardly possible to do so. But the theory seems practically to result in an attempt to bring down painting to the level of furniture. A painting is no longer, according to this school of critics, to be a separate creation of the imagination, having its own interest and embodying its own idea, but it is to be a means of filling a panel as part of a scheme of decoration. It is probably to this theory that we owe the existence

*Is the Prevalent Taste for 'Art Furniture' and Bric-a-Brac Indicative of a Sound or Healthy Æsthetic Culture? By Mr. H. Heathcote, St. Ham. Read at the Social Science Congress, Aberdeen.

of a peculiar school of painting which has arisen lately, in which the object seems to be to eliminate all distinctive idea or intellectual meaning from a picture, and all direct reference to Nature, and to make the whole a mere matter of decorative colouring. The most common development of this form of art is familiar to most of us in the shape of those long-limbed female figures of neo-Greek type, clad in semi-diaphanous drapery, whose handsome faces have all the same placid vacuity of expression, and by whose side always stands an "art flower-pot," out of which grows a decorative plant. Very graceful are many of them (for, indeed, some of our finest draughtsmen have lent their talents to this style of painting), and very tired we get of their grace and their meaningless poses. Their faces are all alike; but their lack of distinctive character is compensated for by writing their names beside them, always remembering to jumble the letters about so as to make the reading of it as much of a puzzle as possible. They may be either the Months, or the Virtues, or anything else you like; they will do equally well for either, and the same figure may represent either "Chastity" or "November." But if we are inclined to feel bored at this repetition of a type, we are offered as a compensation any amount of old china. A lady who professes to be artistic is not happy till she has given her drawing room the aspect of a crockery-shop. You feel afraid to move about for fear of knocking over or shaking down something which you will be assured no money can replace. You go to the theatre to see a domestic comedy, and the actors seem scarcely able to find their way amid the collection of Japanese jars and screens, and blue china, with which the stage is crowded; and, to add insult to injury, if you do not like all this you are called a Philistine. The nameless opprobrium conveyed in that phrase might seem more applicable to a man who follows a multitude to hunt *bric-a-brac* than to those who fail to find this a sufficient motive for living. But, without calling names, and admitting that every one has a right to his own hobby, I protest against the assumption that this worship of furniture and china is an indication of an advanced preception in regard to art. As with furniture itself, so with art in its widest sense, the ultimate value to us is in proportion to the thought that is in it; and it is idle to pretend that the most piquant piece of china, the most artistically-designed cabinet or wall-paper, can by possibility have the same intellectual meaning and interest as the productions of an art, which, like painting, can translate the poetry of Nature, can speak to us the language of the deepest human passion and emotion. To say that such an art as this is to be no more to us than a part of the furniture of our rooms; that upon some pretext of unity of effect our pictures are to be merely objects subordinate to a general scheme of decoration, is not to exalt art, but to degrade it, and is a view which could only be seriously held by those who have allowed their mental sympathies and perceptions to be narrowed and cramped to suit a conventional standard. One figure in which the passion or the hope, the joy or the grief, of the human soul is visibly symbolised; one landscape instinct with the light and air and the sentiment of Nature, does more to give interest and beauty to a room than all the sweepings of Wardour Street that can be collected in it. A picture that is worth anything is not a piece of decoration, but a separate poem in itself; and it is better to have such works, even in company with bad furniture, than to have a room filled with decorative furniture and piquant knick-knacks, but bare of anything that can appeal to our highest sympathies and aspirations as intellectual beings. Yet this is what is actually set before us now as the theory of an artistic dwelling, and what it is actually becoming more and more the fashion to put in practice. And the fact has an important significance in relation to social science, so far as that concerns the moral and intellectual aspect of our national life. It is a sign of something very unsound in the artistic taste and sentiment of the day that we should be exhorted systematically and on principle to rank the lower and more material forms of art, as equal to, or even above, those which appeal to our highest consciousness and perceptions. It seems a very false economical principle, so far as regards the encouragement of art, that people should be ready to give for an old jar, which may be ornamental, but which may as likely as not be ugly and

grotesque in design, as much as would procure them a dozen drawings or etchings representing a far higher intellectual effort applied to a far higher end. But what is most serious is the moral aspect of the subject,—the falsity and pretentiousness of feeling which this artificial taste indicates. What was observed in regard to the art of the theatre is only a type of what we see in society. The acting is so tame and unreal that it hardly deceives any one; but the play is admirably mounted, and the decorations got up regardless of expense; only, unfortunately, the decorations themselves are a sham. We need by no means be indifferent to furniture; on the contrary, I would like, if it were possible, to see everything in a dwelling designed with a direct relation to its purpose, its position, the style of its accompaniments, and the special fancy of the inmates. But this is hardly attempted, for this would cost thought, and people wish to be artistic without thought, and at the cost of money only. What is really done is to fix upon a particular fashion of a past generation or of another country, to brand that as artistic, and to purchase as much of it as you can afford. The phenomenon is not new. There have been other periods in the history of our own and other societies when this imitation fashion has prevailed, and they have always been periods of pretence and hollowness, of an indifference to the highest and most serious ends of life. When people are much in earnest they do not care about tricking themselves out in borrowed decorations; it is an amusement for an idle hour; and the corollary to be drawn from the characteristics of the prevalent artistic taste of contemporary society is not a satisfactory one. It was the complaint of Wordsworth, at an early period of this century, that—

Plain living and high thinking are no more.

He would hardly have considered that matters were much improved in this respect at present, when Art, which should be the expression of the highest thought and aspiration of a people, is coming to mean a mere arbitrarily chosen form of costly luxury, having no connection with the serious thoughts and problems of life, when, as it has been remarked, you may break any moral law, but you must admire blue china; when English ladies can so far forget their traditions of true dignity—so far mistake the accidentals for the essentials of refinement, as to masquerade in modern-antique costumes, which draw every eye—not, indeed, to the wearer, but to the costume. All this, done in the name of Art, is evidence not of true artistic feeling, but of a show and pretence at variance with what is best and noblest in art, which, if it were a reality, should lead us to quote again the words of Mill, to idealise not only every work we do, "but most of all our own characters and lives." This is hardly to be achieved by dressing out our life in a costume of borrowed finery, and dignifying it by the name of "art."

Note on the Dahlia.—*Apropos* of Mr. Hemsley's interesting sketch of the history of the Dahlia, it may be worth noting that there are in the British Museum Herbarium four sheets of Dahlia variabilis, from Lady Holland's garden, where they seem to have been collected in 1805. Only one is dated, but all appear to have been gathered at the same time. On one is written:—"This plant bears flowers of a deeper colour . . . the flowers are double, but only eight leaves were perfect. The petals *superius* deep purple and like velvet; *inferius* the same colour as the *purpurea* No. 1. Only two imperfect flowers appeared." On another is written:—"This plant came from seeds in 1805; the colour is stronger and dries much better: 8½ ft. high to the first top flower." There are also two sheets, labelled respectively *D. pinnata* and *D. rosea*, which bear the inscription:—"C. G. Ortega (Lady Bute)." Ortega was Director of the Madrid Botanic Gardens from 1771 to 1801, which bears out Mr. Hemsley's statement that the Marchioness sent or brought seeds from Madrid, or, it may be, had them sent to her by Ortega. There is also a specimen of *D. coccinea* from Ortega, and two from "Lady Holland's garden," which are apparently contemporaneous with those of *D. variabilis* already mentioned.—JAMES BRITTON.

Linaria repens (see p. 345).—This is well enough known near Henley, and is not so very rare in a wild state, as it abounds where it occurs; *L. Polissieriana* would not get there.—M. B.

NOTES OF THE WEEK.

The Catalpa in October.—This is the only deciduous tree that bears in October the robes of July. We speak of London, where the Catalpa trees in the parks have lately been beautiful from the freshness and greenness of their ample leaves.

Pyrus arbutifolia.—This, although one of the most beautiful of our autumn-tinted trees, appears to be but little known. We have a large specimen of it in our nursery, which at present is a gorgeous spectacle, the flame-coloured upper surfaces of the leaves being very brilliant.—ROBERT OSBORN, *Fulham*.

Bad Peaches.—A large yellow Clingstone Peach is yet coming in abundance from France, but for what purpose it is bought it is not easy to say, as anything more disagreeable in flavour has seldom left the apothecary's shop. The elements of the fruit seem to have decomposed during the long time it has been gathered before arriving at the ripe stage. If any wholesome supervision existed in our markets, the sale of such fruit would not be allowed.

Oranges from Brazil.—Among the many warm and temperate countries to which Orange culture has recently been extended, Brazil possesses one of the best fields for its cultivation. Fine examples of Oranges are now in Covent Garden from Brazil, and these are marked by their unusually large size, firmness, and great sweetness of taste. This to many will be a recommendation, but we prefer pleasantly acidulous Valencia fruit.

Apple Crops in Dorsetshire.—In this county the orchards of Cider Apples now present a striking appearance, the trees in some places being literally bent down by the weight of brightly-coloured fruit which they are bearing, and although there is almost a total absence of kitchen and dessert Apples in this county, there will be at least no scarcity of cider. Nothing can be more beautiful than these scarlet and crimson-fruited Cider Apples, and if skillfully associated with trees of other kinds in suitable situations, they would be effective as well as profitable.—C. S.

Improvements in Kensington Gardens.—We notice preparations for improvements in Kensington Gardens, particularly on the Bayswater side. We regret to see that several new walks form a part of the change; in all such cases it would be well to avoid the making of new walks, which more than anything else tend to cut up and destroy some of the most charming qualities in parks of all kinds. It is better to alter the direction of existing walks, to widen them as much as need be, than to create new ones without commanding reasons. We are pleased to note that an attempt will be made to embellish with flowers the Bayswater side of the park, and hope that the new borders there will be made as unlike those on the other side as possible, both in plan and plants.

Best Cropping Hardy Fruit Trees.—In so capricious a season as the present has proved to be for almost all sorts of outdoor fruits, it may be useful for cultivators to compare notes. Here is my experience:—Apples, with good crops, are Adams's Pearmain, Hawthornden, Passe Royal Russet, Redstreak, Box, Cornish Aromatic, Royal Monster, Slade's, Blue Pippin, Moshay Pippin, Aromatic Russet, Keswick Codlin, and Blenheim Orange; all others have failed. Pears, with good crops, are Easter Beurré, Dachesse d'Angoulême, and Crassane; all others have failed, even Marie Louise, usually a good cropper. Plums, all sorts failed. Peaches and Nectarines fair, but small. Apricots none. Gooseberries and Currants, very fair crops. J. L. ROGERS, *Penrose, Cornwall*.

A Tree Studio.—The German Ambassador, Herr von Kaudell, with a party of his countrymen, went the other day to Olevano to celebrate the taking possession of what has now become German territory in Italy. Olevano is a small town about fifteen miles distant from Valmontone, the fourth station from Rome on the way to Naples. Near it is an old grove a few acres in extent, upon which grow some of the finest specimens of evergreen Oak to be seen anywhere in the world. The spot was a favourite haunt of the artists in Rome, attracted by the wild beauty of the sight, and especially by the picturesque shapes of some of those venerable trees. The owners of the soil, who were born in the district, had made up their minds to cut down the timber and till the sacred ground. Upon hearing this, a distinguished artist from Dresden, who had frequently illustrated that wood scenery on canvas, offered to buy the property with the grand trees upon it. Having struck the bargain and paid the purchase-money, on the peasants' own terms, he offered his new possession as a present to his German Fatherland, on condition that it should become inalienable German national ground, to be held and taken care of for the benefit of the world's art.—"Times," Oct. 17.

Daboecias in Hants.—When I mentioned to you the occurrence of the Irish Heath (*Daboecia polifolia*) and *Erica vagans*, near Bournemouth, you asked for further details respecting them, which I now give. They both were found by me on a wild moor to the north of that town, and in tolerable abundance. For the former, only two

habitats are given in such books as I can refer to; the latter I had met with only on the Serpentine, in Cornwall; therefore, it was probable that they had been introduced, and further search gave plants that certainly are foreign to our isles. It is right to mention this, though it may lessen the value of the discovery; at the same time, since they are both flourishing, and reproducing without aid from the hand of man, may they not fairly be considered natives in that habitat? Among the many who may be charmed with Bournemouth is the lover of wild flowers; he may, even in August, gather the prettiest of our English Heaths—*Erica ciliaris*, *Gentiana pneumonanthe*, &c.—if he knows whither to bend his steps.—M. MOGGIDGE, S. Bina Gardens, South Kensington.

Dracæna Goldieana.—This remarkable plant (previously announced as to be sent out next year) is now being distributed. In Mr. Bull's nursery, at Chelsea, so rich in new fine-foliaged plants, it occupies a foremost place, its zebra-like markings making it not only distinct from all other plants, but also quite separating it from all the numerous and varied members of its own family now in cultivation.

Gift of a Park to Lancaster.—Alderman Williamson has written to the Mayor of Lancaster, intimating that if the Town Council will sell him absolutely a plot of Lancaster-moor, about forty acres in extent, he will undertake to apply a sum of not less than £10,000, besides the agreed purchase-money, to converting that portion of the moor into a public park, and providing a fund for its maintenance as such for the free use and enjoyment of the people for ever.

Sedum Sieboldi in Vases.—The notice of these as grown in Prof. Owen's garden (see p. 320), we desire to supplement by a few words as to their size and culture. The largest plant is 2 ft. 7 in. in diameter, and has 286 flower-stems. They have been in the vases nine years without change. In May, or during very dry summer weather, a little weak liquid manure is given. As a foundation, the vase contains 2 in. of gravel-pebbles, and on this are placed 7 in. of mixed stiff loam and rotted leaf-mould, with a good admixture of silver sand. A little dried Fern is put loosely over the plants in winter, though this is probably needless. The plants are now in bloom, and form the most elegant vase plants we have noticed. On the level ground they never thrive half so well about London.

National Rose Society.—A meeting of this Society was held at the Horticultural Club, Adelphi Terrace, on Thursday, the 11th inst., and was attended by many of our chief Rosarians, including Messrs. Baker, Exeter; Camm, Monkton Wyld; Cant, Colchester; Cranston, Hereford; Captain Christie; G. Paul, Cheshunt; W. Paul, Waltham Cross; Scott, Bond Street; Turner, Slough, &c. The Rev. Canon Hole, President of the Society, was in the chair, and the accounts of the Society were read by the hon. secretary, the Rev. H. H. Dombrain. It was decided, after a long discussion, to hold the next exhibition of the Society in London, on the last Thursday in June, and there seemed to be a prevailing opinion that the Agricultural Hall would be an advantageous site for the show; a committee of inquiry was appointed. It was thought to be desirable to hold, if possible, a later exhibition, in the second week of July, inasmuch as the midland and northern Rose growers would be excluded from the show in June.

On Access to Public Herbaria.—The public, to a large extent (and also, we fear, some paid servants of the State), consider national collections of dried plants as preserved only for the select few. These, be it well understood, must even sometimes belong to the "clique" if they wish to work with comfort and for any length of time in some of our public institutions. It would be well if the poorest and most friendless person, who desires to consult our national herbariums, would bear in mind that the officials in such are the servants of the State, and that their duty is to make the treasures at their disposal convenient and accessible to all who defer to the necessary rules. In connection with this matter we may reprint the following words from a report in the "Times" of the Librarian Congress recently held in London:—"On 'Access to Librarians,' Mr. S. S. Green, Librarian to the Public Library, Worcester, Massachusetts, observed that in every library there ought to be a cultured person with good manners who could meet people half way; he should be not merely polite, but with some effusiveness of manner, and should go forward to give people information. In a public provincial library such a man would make the collection of books a university. He then related how a public collection of books given to a certain town in America was rarely consulted. A librarian was appointed, and by going to the door and welcoming the people as they came in, &c., he increased the numbers from 7000 in the first year to 10,000, 15,000, and 27,000 in the fourth year. After what he had said about the qualifications of a librarian, he felt some delicacy in saying that he was the man appointed. (Laughter and cheers.) He admitted that it was sometimes hard to disembarass oneself of querists."

THE KITCHEN GARDEN.

DISEASE-PROOF POTATOES.

SOME say that there is no such thing as a disease-proof Potato, but I have grown the Red-skinned Flourball and Late Rose for some years, and hitherto the percentage of loss, as regards these two kinds, has been so small that they may, I think, virtually be called here disease-proof, so far as the tubers are concerned; but the disease attacks the foliage the same as other kinds. I had a plot of Late Rose which, in a few days after the appearance of the disease, had lost every vestige of green, both as regards stem and foliage, and yet, when the crop was lifted, there were virtually no diseased tubers; but, unfortunately, on our soil the two kinds I have named are not first rate in quality. They improve, however, by keeping, being fairly good after Christmas, and they keep improving in quality till June. Looking at the Potato crop as a whole, I am disposed to take a very hopeful view of matters so far as regards the future, not because I think that Salus or any other remedy will either prevent or cure the disease, but solely because I believe, by a careful selection of varieties to suit different localities, we may nullify its ravages. As regards my own case, I have never had so good a stock of Potatoes laid up in capital condition from the same quantity of land as I have this year, although the disease has been rife and much destruction has ensued all around us. I think every grower ought to try a few experiments for himself, both as regards the most suitable kinds to grow and the best way of growing them. It is better to give up cultivating Potatoes altogether than to plant, year after year, the same kinds that have always failed. There are two operations that will have an influence for good upon next year's crop and which may be set about at once and be followed up as time permits. These are, firstly, ridge up as deeply as can be conveniently done, all land intended for Potatoes next year, leaving as much surface exposed as possible; and, secondly, gather up everything in the way of wood or turf ashes, turf parings, soot, old plaster, sweepings of the potting shed, and anything else of a similar nature, to work into a compost with which to cover the sets in the drills, instead of the highly-stimulating and sometimes rank manures that are frequently used. I do not believe in planting in poor hungry soil without manure for the purpose of leaving the disease nothing to feed upon. Such a course I believe to be unnecessary, and, in truth, I have always found a badly fed vegetable to be as unsatisfactory as the beef from a lean, half-starved ox. It has been said that it is better to have small Potatoes than none at all, but I am convinced no really good cultivator will rest satisfied with the comparative failure that such an admission implies.

As regards early and second early varieties, I have no sympathy with those who submit to their loss from disease, as, by timely lifting, the crop might certainly be saved. An important matter, as it appears to me, is finding out the kinds best adapted for each particular district or soil, and the culture and manures that are most suitable for them. To do this thoroughly there must be a general "turning over of new leaves," starting afresh on new lines, and although, perhaps, the disease may never be altogether stamped out, yet I feel sure that its effects may be so far reduced as to render it comparatively harmless. I have noticed of late years a tendency in field culture to grow second early kinds more largely, such as Early Rose and Snowflake, and this no doubt is a step in the right direction; and if lifted in good time the whole crop might be saved. Probably the market salesmen and consumers generally are, in some measure, responsible for this clinging to old kinds of Potatoes, and so things go on year after year, submitting to a loss of half the crop rather than trying anything fresh. It perhaps really affects the grower less, except in isolated cases, than the consumer, for the former probably receives as much for his half crop as he would have done for a good one, in consequence of the markets being higher. This is a matter in which every Potato grower and consumer is deeply interested, and ought to be taken into serious consideration by all; for to go on year after year submitting to failure, or at the best only obtaining a qualified kind of success, is not creditable to us.

E. HOBDAY.

Salus v. the Potato Disease.—During the last two or three years, the Dunbar Regents have been so severely smitten by disease here that I had made up my mind not to grow them again; but last spring, just about planting time, I so far altered my determination as to give them another trial, for the purpose of seeing what effect Salus would have upon the disease. They were arranged as follows:—In plot No. 1, the seed tubers were dressed with Salus at planting-time, and it was also dusted a little on the soil round the sets. In plot No. 2, the seed was dressed as in No. 1, and the whole plot was sprinkled over just previous to earthing the Potatoes up; and, just before the disease made its appearance, the plants were syringed all over with Salus dissolved in water at the rate of 1 oz. to the gallon, taking care to well wet the stems and foliage. To plot No. 3 I gave a heavy dressing between the rows, just previous to earthing up. In each plot selected for experiment, several rows were left, to which no Salus was applied, for comparison. The result was that there was no perceptible difference between any of the plots, all being as badly diseased as the rows that were left undressed. In taking up the Potatoes, it was remarked that the land where the heavy dressing of Salus had been applied appeared damper than elsewhere. This was probably due to the potash or salts fostering or encouraging the presence of moisture. Although Salus is never likely to have much effect in preventing or curing the Potato disease, it may perhaps, if it can be had cheap enough, make a useful top-dressing for many crops on light, porous soils, and insects do not seem to like it.—H., Ramsay Abbey.

Coal Ashes in the Garden.—It has been long known that coal ashes have the effect of mellowing heavy soils, particularly clay. A clay may thus be greatly improved in texture. It has been held that the fertilizing properties of coal ashes are small; repeated analyses have shown this. Yet, used as they have been in gardens, without other manure, the effect has been such as to lead irresistibly to the conclusion that they develop in some way a considerable amount of fertility. All cannot be accounted for by the mechanical improvement, as in cases where this is not lacking the effect is still present, and apparently undiminished, if not sometimes increased—in this case acting seemingly as wood ashes do, requiring other (organic) fertility to aid, if full results would be obtained. I was surprised, early in the season, on seeing unusually fine Tomatoes and Beans, to learn that the only manure used for them was coal ashes, scattered in the garden to get them out of the way. This was practised for several years, and no manure other than this had been used. My own experience is confirmatory, but I find that the effect is not immediate. It is more tardy than in the case of wood ashes, whose potash and soda act promptly. I would recommend that coal ashes, instead of being thrown away, be used in gardens, removing the coarser parts; also on Potato ground, always mixing them well with the soil, and as early as the ground will admit, and to be repeated yearly, thus giving time for effect upon the soil. I find the best success where the ashes have been applied for several years. The second year is sure to tell, even where thrown upon the ground and left to lie there undisturbed, as I have abundant evidence. But the place for full action is in the soil.—"Country Gentleman."

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Potato Disease, Lime, and Salus.—It is said that if land be either dressed with gas or common lime no disease will appear. I limed a piece of land this season, planted it with Potatoes, and afterwards dressed it with Salus; but I have lost half the crop from disease.—R. GILBERT, Burghley.

Tomato Disease.—The greater part of the crop of Tomatoes, grown out-of-doors here and at several places in this neighbourhood, has this season been destroyed by a disease similar in appearance to that which attacks the Potato. Fortunately I had planted a lot on the back wall of an orchard house, which have produced a very heavy crop of fine fruits entirely free from disease.—H. H., Denne Park, Horsham.

French Beans for Forcing.—From three successions of Beans which I have, I manage to keep up a constant supply. I find none to excel Osborn's Early Forcing all through the winter. It can be grown in 7-in. pots, and it wants no staking. All Bean forcers who have not tried this variety, which is a good cropper and well flavoured, should lose no time in trying it.—R. GILBERT, Burghley.

Cucumbers in Africa.—In Zanzibar Cucumbers of many varieties grow almost wild without sowing. The people declare they become bitter if touched by the hand in selling. The Arabs make from the seeds an oil of most delicate flavour for superior for salads to the best Lucerne oil. I have asked in vain in London for "Cucumber oil"—the vegetable is probably too expensive and the seeds too small to be thus used. About Lagos, however, on the slave coast, there is a Cucumber nearly 1 ft. long with large pipe which could be sent northward. I commend the idea to those who are fond of oil.—CAPT. BOSTON.

A SMALL GARDEN NOT SPOILED BY BEDS.

In large gardens, wise people sometimes manage to get a little freedom from the tormenting beds that have been the nearly worthless stock-in-trade of the landscape gardener for centuries; small ones are nearly always ruined by them. A bed, in the sense of a body of well prepared soil, is essential, and will always remain so in gardens; but it is not necessary that beds should expose their ugly forms. The best preparation needed for shrubs or flowers may be hidden beneath the foliage it supports or unsuspected below the green turf. When men come generally to see the meaning of real gardening, they will laugh at the endless weary strainings after patterns in beds. They will not admire a garden that is laid out as men used to design wall-paper; now better things are expected even of wall-paper designers. These few remarks occur to us in connection with a pretty little garden we passed the other day, and in it there were no beds at all in the central and important parts. Here is a little engraving of the spot, with its varied trees and choice shrubs, and masses of Rhododendrons against the house. In such a garden one may have as much variety of flowers as may be desired, and one of the ways of best attaining this end is by having groups of beds, simple in outline, a little way from the central scene. All the really fine hardy plants, from Tritomas to Grasses and Yuccas, may be planted to best effect in good ground, but not in formal beds; and where a geometrical series of beds is desired, they certainly will also be best on one side in a quiet nook, and not in the centre of, and dominating, all.

Hardiness of *Yucca Treculeana*.—

In the last number of THE GARDEN (see p.343) your correspondent "O." says that "Mr. Hemslay need not have the slightest doubt of this plant being hardy." I was aware that it may be seen in some of the nurseries around London, but I could not

accept this fact as a sufficient proof of its hardiness, because I did not know whether it had stood the test of a severe winter; but since I wrote the notice of this fine Yucca, I have met with a more explicit record of its hardiness. It is to the effect that at Angers, in France, it ripens seed perfectly, and has there borne 18° and 25° of frost without injury. Very few plants will bear a greater amount of cold than they are exposed to in their native countries, consequently I felt justified in expressing a doubt as to the perfect hardiness of *Yucca Treculeana*.—W. B. HEMSLEY.

Liatris pycnostachya.—Although this is by no means a new plant, it is still sufficiently rare to justify a brief reference, as it affords an opportunity for calling attention to the value of many other species of this genus as ornaments of the mixed border. The *L. pycnostachya* grows in favourable soils from 3 ft. to 5 ft. high, with a stout, erect, simple stem thickly set with linear-lanceolate leaves, and terminated by a dense and thick club-shaped spike of flower-heads about 1 ft. in length. The flowers are rosy-purple, fewer in each head than in *L. scariosa*, *L. squarrosa*, and some others, but more effective from the closeness of the heads, and it is said to suffer less from drought than some other species, and than most other perennials. The root is a roundish corm or tuber, in which it agrees with nearly all the species except *L. odoratissima*, a plant which can also be recommended as well for its distinctness as a

species as for the remarkable Vanilla-like fragrance of its foliage. W. THOMPSON, Ipswich.

THE CULTIVATION OF THE ROSE.*

In the following paper I shall endeavour to describe some of those essential items of culture most calculated to insure a fair measure of success. Although the Rose possesses charms which enchant the senses more than any other flower, it is, on the whole, void of some desirable qualities found in other genera of less pretensions, that is to say, the habit of the Rose forbids its combination with other plants with good effect; even in such gay company as scarlet Pelargoniums and Calceolarias it neither looks dignified, nor heightens the appearance of its neighbours. It is in groups alone and in the Rose garden that its supreme beauty is displayed to advantage.

Propagation by Cuttings.

With many others, I prefer this mode of propagation for dwarf plantations, which are, as a rule, pegged down near to the surface of the soil. Plants on their own roots can be handled with more freedom, and they will not trouble the cultivator by starting up "rogues," or stock shoots, as budded plants so frequently do. Roses will root freely if operated upon in the months of September and October by selecting well-matured growths. Such growths ought to be carefully chosen, with an eye to preserving a uniform number of growths on the plant left, while those detached ought to have a small portion of the previous year's growth, which is known in the profession as "heel." In forming the cuttings, the operator has first to cut off with a keen-edged knife a portion of this old wood intended to form a "heel," leaving about one-eighth of an inch for that purpose. The cuttings are then shortened back to 8

A small Garden not spoiled by beds.

in. or 10 in. by taking off their tops, thus making them ready for insertion. In some localities cuttings root readily without the aid of protection, if planted at the bottom of a wall in a sunny part of the garden, and the weather prove favourable; but under all circumstances that process is assisted by a covering of glass. More especially is this protection essential where the place is cold, with a damp, adhesive soil, and the quantity of cuttings limited. Seeing the risk of diminishing the number is great in a cold, open aspect, it is preferable to form a comfortable bed for their reception under a glass frame or hand-glass. The bed ought to be 9 in. deep, composed of light, fresh loam, river sand, and leaf-mould, the last ingredients in equal proportions, while the loam should be present in greater quantities. Moderately beat the bed to a rather firm consistency, so that the cuttings are held secure after being inserted. Plant the cuttings in lines 8 in. apart, and 2 in. between the plants, inserting them so that three eyes are exposed above ground. Carefully tread the soil firmly around the cuttings as the work proceeds, and leave the surface trim and neat, after which give a moderate watering over the whole,

* Read at a meeting of the Scottish Horticultural Association, by Mr. A. Kerr.

and cover with the glass frame. Ventilate moderately daily, and shade when the sun shines strongly, but not otherwise. Nothing further need be said regarding the attention required, excepting that a couple of mats should be used to protect them from severe frost, but on no consideration should they be kept covered in the absence of frost. With such encouragement, most of the cuttings will root, but Tea-scented and some of the Bourbon varieties are rather stubborn in that process. However, give them time; so long as their wood retains freshness, there is vitality in them. Keep the soil free from weeds and Moss; the latter is apt to accumulate when left undisturbed by the hoe. With the first indication of returning spring, allow a judicious quantity of water to be supplied by means of a pot provided with a rose. Keep the bed moist until the cuttings have assumed the character of plants, as indicated by their strength, or by the young shoots beginning to push. When it is ascertained by their growth that they are properly rooted, lift them carefully, and plant them at wider distances; shade from the sun, and keep rather close until the roots have retaken to the soil, when shading must be discontinued, and air admitted more freely. Ultimately, the sashes should be altogether removed.

Propagation by Layers.

This is a very successful method of increasing the stock of Roses, and may be effected with great ease with plants previously laid to the ground. The proper time to layer Roses is from June to the middle of July, but it is to their advantage to have it performed early, so that the layers get rooted before autumn is far advanced, else they will continue through the winter in the same state as they happen to be in the autumn. For layering, first have the bed pointed a few inches deep with a digging fork; follow this up by sifting an inch of sharp sand over the surface. Next stir with a Dutch hoe, leaving the surface level. Have the required number of hooked pegs, and likewise a similar quantity of short stakes. Proceed then by selecting such shoots as are most convenient, choosing those which are neither too strong nor too weak, but which show a good bone of ripe wood, yet not too hard ripe. Bend the middle of the shoots to the ground with both extremities inclining upwards, then make an incision exactly at that part where the shoot touches the ground. Direct the knife upwards, making a clean cut up the centre about 2 in. long, then hollow out the soil where this incision is intended to rest. Again bend the centre of the shoot, and cause the tongue of the slit thus formed to dip into the soil. Next fix it in position securely with a hooked peg, supporting the upper extremity by tying it to a stake, then fill up the hollow made for the reception of the layer. Three months after this operation most of those shoots ought to be rooted, when they may be separated from the mother plants, and potted into a loamy mixture, giving them the benefit of a cold frame for the succeeding winter. March is perhaps the best season of the year to have them turned out of their pots and transplanted where they are to form permanent plants.

Propagation by Budding.

This operation is at once an interesting and pleasing recreation, more especially to the amateur. To be an expert budder requires much practice—not that any material difficulty attends the performance of it, but what is demanded of the operator is care not to insert the knife too deeply while making the slit in the stock, causing damage to the wood and the thin layer of cambium, whose chief functions are to form new layers, heal up wounds, and form a union with the adopted bud or graft. This important formation is most sensitive to exposure to sun or wind, which causes it to brown and form a thin bark-like skin, making a union between it and the bud an impossibility. Being furnished with the required materials, commence by cutting back all the leaves of the shoot that is to furnish buds, also displace the spines or prickles from both it and the stock. Having now determined where to insert your bud, make an upright cut about 1. in long, penetrating the inner bark and no more. At the upper extremity of this incision make a horizontal cut; let the edge of the knife-haft be carefully introduced between the bark and wood, entering it where the horizontal

and longitudinal incisions unite, and gently raise the bark sliding the knife along at the same time. Let the opposite side of the bark incision be operated upon in the same way. Scooping out a sheath of bark containing a bud comes next to be considered. This ought to be performed by a single cut of the knife, inserting the knife about $\frac{1}{2}$ in. below the bud, guiding it inwards and upwards until the edge is opposite the bud, when the knife must take an outward course, sloping the cut at top into a similar form to the one below the bud. The extraction of the wood which fills the sheath of bark thus formed requires care to prevent extracting the core of the bud along with the wood; but, to lessen this danger, cut off the sheath with as thin a body of wood in it as possible, allowing sufficient margin of bark on each side of the bud. Remove the wood out of the sheath by an easy twitch. Having inserted the point of the knife between the bark and wood, insert the bud by raising one side of the bark by means of the knife-haft and the thumb, placing the sheath parallel with the lengthened cut, then gently put in the sheath until the bud is neatly placed; the bark on the opposite side should be treated in a similar way. The bud adjusted, hold it in position with the thumb, draw the knife through the horizontal cut in the stock, cutting the upper portion of the sheath so that it fits exactly the cross cut in the stock; wrap up the bud with soft matting, being careful to cover the incision, and only allow the bud to peep out. I shall not stay to inquire regarding the different "stocks" recommended by various authorities whose opinions are divided. Some incline to prefer the Manetti, but the great majority are disposed to favour the Dog Rose, which I consider, on the whole, preferable to all others for general budding. All stocks have a tendency to generate stock-shoots more or less, but the Manetti especially, and its excessive vigour of growth is objectionable. If restrained by having weak-growing Roses budded on it, it invariably starts stock-shoots, which, if not soon discovered, have a fatal effect upon the Rose, causing it to dwindle and die. Further, it takes a practised eye to distinguish it from the genuine Rose-shoots when forming part of a mass of growths. The proper time to collect stocks of the Dog Rose is at the fall of the leaf. It is important to cut away all useless protuberances on the roots, dressing them back to the last fibres rather than allowing them to remain and produce stock-shoots. Plant in rows, after having previously trenched and manured the ground well. Cow manure in a moderately fresh condition should be preferred to all other home manures, and it is desirable not to have too much of manure in immediate contact with the roots; rather have the body of it near the bottom of the trench. The roots will find sufficient food for their immediate wants if a portion of this stimulant be incorporated with the soil. Plants intended to form standards may at once be cut back to the desired height, while those required for dwarfs must be cut back to 6 in. above the ground. In all probability the standards will furnish many growths up their stems; these should all be removed, excepting two or three selected for budding near the upper extremity. Budding ought to be done early in the summer, when it is found that the bark will rise freely, and the shoots from which the buds are taken are in a medium state of maturity. A sunless, mild day is perhaps the best for this operation. Hot, dry weather has a tendency to dry the opening on the stock in which the bud is deposited, besides causing the sheath to shrink unless expertly performed. About a month after budding, when union has been effected between bud and stock, have the wrappings cut, so that no interruption may be made to the swelling of the stems. All buds still dormant must continue to wear their wrappings until a union has been accomplished. In February following let there be a general pruning away of all rank growths on the stocks, cutting them back to a couple of eyes above the buds, which will afford great assistance to them in their first start, and will further materially assist the buds by allowing them to appropriate to their own use food offered through the reviving action of the roots, while at the same time an over-copious rush of sap will be restrained by detaching the vigorous growth of the stocks, whose powerful agency proves more than enough for inactive buds. Ultimately let the remaining part of the shoots be cut off above the buds when the latter have started a few inches.

Soil and Situation.

It is generally agreed by growers that a strong, stiff loam is the most suitable for successful Rose cultivation. Such a soil, resting on a well-drained foundation, the Rose perfectly luxuriates in, if other essential wants are at the same time supplied, the chief requirement being a genial situation—that is, a sunny opening, if possible, sloping gently to the south, protected from winds and draughts from all quarters—in short, neither windy nor shady, neither dry above nor damp below. A proper situation is of more importance than manures, soil, or anything else required. To prove this assertion, I may mention what I have been a witness to in various parts of the country. First, the old favourite Rose Cloth of Gold is well known to be difficult to flower satisfactorily, even where other tender Roses do very well. Some years ago I saw Cloth of Gold hiding a large portion of a south wall with its glorious massive blossoms in a garden called Clotfelach, in Strath Tay; such a sight I never saw before or since produced by this noble Rose. The soil all along Strath Tay is remarkably light, consisting of rotten rock in the main, showing alluvial deposit to some extent, and a large proportion of sand, intermixed with shining mica. Contrasting with the inland situation of this Strath, and very much in its climate, I shall next instance Sutherlandshire. At Golspie, near Dunrobin Castle, the Rose prospers amazingly. Here, with the sea close at hand, may be found the most splendid examples of our popular H.P. and Teas in particular. Every nook and corner about Golspie has its Rose blossoms in profusion. One plant I noted in particular—a *Gloire de Dijon*, trained on a house-front measuring 21 ft. by 20 ft., a space completely covered by well-trained growths, which were one mass of most magnificent blossoms from top to bottom. There must have been many hundreds of open and half-open blossoms on it when I saw it. In the gardens of Dunrobin the Roses were almost as beautiful as the fountain basins of *Nymphæa alba*, which leave their impression on the memory of every visitor when seen in flower. The soil in this district is of a comparatively light nature, being much mixed up with sand and large particles of grey granite.

Preparation of the Ground.

Supposing one is about to prepare a bed or border for Roses where the soil happens to be "stiffish loam," I think it would be bad judgment to apply as manure any compound of an adhesive description; for such soil the manure ought to have a contrary tendency, and at the same time unite the necessary stimulating element—such substances as stable manure, sand, leaf-mould, and lime-rubbish incorporated, and allowed to remain for some months before using. On the other hand, for soil naturally poor and light, the compound may be composed of cow-manure, old night-soil, and fresh stiff loam containing as much fibre as possible. These, with a liberal supply of liquid manure laid in a heap for a time, make splendid material for Roses when grown on light ground. In any soil the Rose is a greedy feeder, and demands annual manuring. In making a Rose garden, if the subsoil be at all stiff and retentive of water, it ought first to be properly drained, conveying the water to some distance by a main drain. Should the subsoil be sandy and gravelly, and drainage already exist—unless, as sometimes happens, there are springs which require to be drawn off artificially, thus preventing them from over-sopping the soil, in which case after draining and allowing time to draw off the superfluous damp—the ground may be well trenched, depositing at the bottom of the trench a good store of prepared compost, besides mixing the overlying body of soil with goodly portions of the same material; as the trenching process goes on, heap the surface into deep rough ridges, and leave it in that state all the winter, that it may be properly pulverised by the united action of frost, wind, and rain. Again, in March, previous to planting, let the ground be partially trenched, after a top-dressing of wood-ashes or burned clay should it be adhesive. Top-dress the light soil with the compost recommended as a suitable manure for its kind. The ground is now in readiness to receive the plants. Planting may be proceeded with; and as to the distance to place one plant from the other in the rows that depends much upon the vigour or delicate nature of the respective kinds—some require 15 in. or less between, others

as much as 3 ft. The habit of the plant should be understood as nearly as possible before its situation in the bed is fixed.

Pruning.

I believe most of us have much to learn as regards pruning Roses, scarcely a dozen kinds are alike in vigour or require the same amount of pruning. Out of a collection some are improved by close-pruning, other flourish best with scarcely any. The rule ought to be to cut weak growers more closely back than vigorous ones; for instance, Tea Roses, Bourbons, Chinese, and Neisettes all suffer by too close pruning; and, on the other hand, many of the Hybrid Perpetuals are improved by close pruning. By practice alone we can judge how best to use the knife; however, this ought at all times to be conducted with an eye to the regularity of form and the natural habit of the variety acted upon. The proper time to prune is rather a disputed subject. Some prefer the autumn, but I think the majority—and rightly, too—advocate spring pruning. In ordinary seasons I consider the beginning of March quite soon enough, and indeed, too soon in such a season as the last. The Rose suffers much by late spring frosts, and even the blighting winds of early spring when there is no frost. Further, regarding late pruning, a number of years ago, when I was in the Highlands, I had in charge a number of very old, large, and fine standard Roses growing in the flower garden. Unfortunately, the season of Roses was always past before the family came there to reside. These standards were pruned back somewhat in early March along with the early Roses, and all commenced an early and rapid growth, which induced me to experiment a little. With the object of having these standards come into bloom in the middle of August, instead of July, I had them all pruned back to dormant eyes in the hard wood in the latter end of April. For some time afterwards they looked very scrubby besides those at their base covered with promising shoots; but, ultimately, I was well repaid for my experiment, for we had quantities of grand Roses in August and September that year from these giant standard heads.

Disbudding.

This is most important if pursued systematically both as regards blooms and wood-buds, which latter in no small degree obviates the removal of what would subsequently form hurtful growth. Disbudding ought to be conducted with an eye to a symmetrical outline in the plant, thinning out all that are likely to prove useless, and preventing the free action of air and light throughout the body of the tree, which is essential to health, cleanliness, and proper ripening of the wood. Very rank growths ought to be removed when first discovered amongst others, seeing their tendency is to rob them of their share of sap, making them thin and weak, if not worthless, besides spoiling the order and regularity of the plant. Pegging down the shoots of dwarf Roses, more especially when growing on their own roots, is a vast improvement on the usual mode of conducting growth; this I experienced some years ago. For the sake of experiment I had a large bed, which centred a portion of a flower garden, planted with sixty of our most popular H. P.'s and some of the hardest Tea Roses. This bed was trenched 4 ft. deep early in March, and highly enriched by turf and stable manure; indeed, in a similar way to that in which one would prepare soil for bench potting. The Roses were then and there planted partially on their sides, the more to facilitate the layering; very little was taken from the length of the previous year's growth, a mulching of short horse manure was spread over the bed, and the shoots were pegged down over the dressing, distributing the growths in such a way as to insure the most regularity over the bed. In all respects this resulted in a perfect success, the Roses were both abundant and good; indeed, some of them prize winners, and the bed was entirely covered with young growth. In the March following the required shoots were layered, and what were not wanted were cut clean away without attempting spurring on that bed.

Insects and Mildew.

These are very destructive, at times defying all our efforts to exterminate them without sacrificing the plants also. Soap-suds form, perhaps, the best remedy against insects and mildew. I have found a constant application of soft soap dis-

solved in water (at the rate of a piece of soap the size of a hen's egg to a 3-gallon can of water) act effectually, and prove beneficial to the growth of the plants. This I have experienced with pot Roses in particular.

In monstrous growths in Roses, the pistils are developed into leaves in some instances, and in others Rose petals, along with imperfect buds of Roses clustered into a confused mass. The stamens invariably retain their natural character, or are transformed into flower-petals. This is the effect or result of some influence difficult to understand, which it should be our purpose to discover, and, if possible, prevent. In my opinion, the cause of such monstrosities is attributable to the roots being placed on a cold, damp bottom. The plant is excited into growth by the returning heat in the atmosphere after a lengthened state of inactivity; therefore its tendency is to grow, the absence of sufficient sunlight and heat prevents the perfect elaboration of its sap. I am informed by a gentleman, Mr. Scott, of Philadelphia, who has been an extensive cultivator of the Rose, both in and outdoors, for the Philadelphia market for the past thirty years, that he never once saw a green-centred Rose in America during all those years; and he was astonished, on visiting this country this summer, to witness so many existing amongst the very Roses he has been accustomed to grow in America. One thing I feel convinced of—that is, although America is subject to rigorous frosts and long winters, that country has likewise the advantage in heat over a great portion of the year, the effect of which on the Rose will be to ripen root and branch to perfection prior to the occurrence of frost. Further, an American spring is very different from ours—no periods of alternate warmth and biting winds and rains. Spring opens there with sharp frosts at night, but the days are bright and warm, and thus spring grows into summer without alternate checks to vegetation.

I have already entered at some length into the mode of striking cuttings from ripe shoots; let us note what may be accomplished by means of cuttings while they are yet green. These are in a more active state of growth, and when properly handled root quickly, but they must be put into bottom-heat, and kept rather moist at the root. These half-ripened shoots are prepared for insertion in a similar manner to other Rose cuttings. Pans or pots should be used to root them in, and the soil may be composed of two parts light loam, two parts sand, and one part leaf-mould, not too much reduced by age. The cuttings are inserted at regular distances around the edge of the pots, then the central portion is filled with the tallest of the cuttings. After pressing the soil firmly to them, the operation is completed by scattering a handful of sand amongst the cuttings. Store them away in a shaded corner in a cool house, placing a bell-glass over each pot, to prevent the waste of moisture from the soil, and at the same time to exclude air. Allow them to continue thus situated for about three weeks, by which time they will be in a proper state to be put into heat to root. I have practised another method with fair success. This applies to prunings taken from old forced Roses in November. These prunings were treated exactly similar to those last described; but, instead of being put under glasses, they were shelved in an intermediate-house used for bulb forcing, and stood facing the sun until the succeeding spring, when that aspect became too hot for them, and necessitated their removal to cooler quarters. A number of these cuttings bore moderately large blossoms in the latter end of the succeeding summer, so well did that plan succeed.

Fungi in Hotbeds.—It is said that the production of fungi in hotbeds may be effectually prevented by putting a layer of wood ashes about two fingers deep between the manure and the soil. The "Allgemeine Hopfen-Zeitung" is responsible for the statement that this method has never been known to fail wherever it has been put in practice.

Tamarinds: a Caution.—Dr. Steele recommends for a summer drink to pour boiling water on the West Indian Tamarind. Some years ago I did so, and my wife and I were immediately attacked with all the symptoms of poisoning, although we had only sparingly partaken of it. A few days after I singularly met with a similar receipt, but with a caution that the stones should first be removed, as they are poisonous. I hope that none of your readers may suffer an experience similar to mine.—"Dietetic Reformer."

TREES AND SHRUBS.

THE HOP HORNBEAMS.

THE Hop Hornbeams (*Ostrya*) are very nearly related to the true Hornbeams (*Carpinus*). There are but two species, one South European, extending into Western Asia, the other spread over North America. Both are extremely ornamental deciduous trees worthy of much more extended cultivation. The unisexual flowers are produced in separate catkins on the same plant, and develop at the same time as the leaves. The male catkins are long, drooping, made up of a number of small, simple bracts, at the base of each of which are inserted about a dozen irregularly united stamens. The female catkins are short, terminal, with small deciduous bracts; each flower is enclosed in a pair of thin involucre scales, which become enlarged and grow together, so as to form an inflated membranous covering to the fruit. These, being imbricated, afford a very striking resemblance to the cones of the common Hop—hence the name Hop Hornbeam. The pretty, serrated leaves are shed about the same time as those of the common Elm.

Hop Hornbeam (*Ostrya vulgaris*).

Some confusion seems to exist respecting the differences between the European and the American species. In the "Treasury of Botany" it is stated that the latter chiefly differs in having upright fruit catkins, while the figure given by Michaux certainly represents it with pendulous ones. Willdenow and others describe the European tree as having upright catkins, and on this account separate it from the American, which has drooping catkins. Asa Gray and De Candolle rely much for specific characters on the number of the nerves of the leaves. Karl Koch, the learned author of "Dendrologie," does not, however, attach much importance to this point. It is certain that the two species resemble each other very closely, and it may be that they are mere forms of one. The common Hop Hornbeam (*Ostrya vulgaris*) is represented in our figure. According to Loudon's "Arboretum et Fruticetum Britannicum," the old tree at Kew is probably the finest in Britain; the measurements given in the work just quoted being—height, 66 ft.; spread of branches, 54 ft.; diameter of trunk, 3 ft. Both this and the next species are usually propagated in this country by grafting, using the common Hornbeam as a stock. Philip Miller cautions his

readers against buying grafted plants, which, in his opinion, are short-lived, but the Kew specimen does not bear out this assertion. Although the tree from which the material for our illustration was obtained does not fulfil Wildenow's conditions in having upright catkins, there is no doubt of its identity. The leaves are 3 in. long by $1\frac{1}{2}$ in. broad, and on comparison with several gathered purposely from different specimens of the American species, seem to lend some weight to the distinctive characters given by Asa Gray and De Candolle, in all cases the nerves being more numerous than in *O. virginica*. The Hop-like female catkins are from $1\frac{1}{2}$ in. to 2 in. in length, the inflated involucre being covered with prurient hairs. A peculiar circumstance connected with this tree is that the withered male catkins often remain attached to the branches for months after all trace of them has disappeared in all the allied genera. This species is quite hardy in the south of England, and is one of the most handsome of all our deciduous trees. It was first cultivated in this country in 1724. The Virginian Hop Hornbeam (*Ostrya virginica*) is a smaller tree than the preceding, sometimes under favourable conditions attaining a height of 40 ft. From all we can learn it hardly seems to be so hardy as its European congener, which, however, it excels in its rate of growth, although it is a very slow grower. It was first cultivated in English gardens in 1692. In the Eastern United States it is widely distributed, growing here and there in moist fertile woods, never in such numbers as to occupy tracts of land, however small, to the exclusion of other trees. Its wood is exceedingly hard and fine-grained, and is used for mallets, wedges, levers, &c. It is sometimes called Iron wood and Lever wood. G.

Pinus Cembra.—In a recent article on this Pine, the Arolla or Swiss Stone Pine, it is said that when old it assumes the tabular form of the *P. pinea*, or true Stone Pine. This is not so; of many thousands which I have seen in their native woods, I have never found one which, except by injury or accident, varied from the closely conical outline characteristic of the species. It is not a Pine which should be planted in this country for ornament; *P. monticola*, *P. strobus*, and *P. excelsa* are far more beautiful and nearly akin to it, but from its extreme hardiness it is well suited for close planting on high, exposed land. — SALMONICEPS.

A New Late-flowering Magnolia.—In the "Gardeners' Monthly" for July, an interesting notice was given of *Magnolia Halleana* and *Thurberi*—comparatively new varieties that were brought from Japan fifteen years ago by Dr. Hall. The hardiness of these *Magnolias* is unquestionable and unsurpassed, having been tested these many years in the various nurseries at Flushing, and by hundreds of persons in all parts of the country to whom they have been sold. It is gratifying to learn that so valuable a variety as *Magnolia Thurberi* can bloom, since never before, to our knowledge, has a single flower appeared in America. In all probability, mature age is necessary in this case, to produce wood suitable for flowering. My main object, however, is to call attention to another variety, or, perhaps, species, *Magnolia hypoleuca*, which deserves consideration, not only for beauty, but extreme rarity, never having been offered for sale in America, nor as far as I know, in Europe. The merit of this variety lies chiefly in the great beauty of its milk-white flowers, which resemble those of *conspicua*, and possess a delicious Banana-like odour, surpassing that of any other hardy *Magnolia*. Bright and

attractive in foliage, the underside of the leaf is greenish-white, whence the name. *Hypoleuca* is quite hardy, having been grown a dozen years or more in New York City by Mr. Thomas Hogg. The bloom appears about the middle of June. Specimens of the flowers were exhibited by Mr. Hogg at the June exhibition of the New York Horticultural Society. Messrs. Parsons & Sons are in exclusive possession of a considerable stock of this variety, and will soon offer it for sale. They have other new and valuable *Magnolias* from Japan, obtained through the enterprise of Mr. Hogg, which they propose, as soon as propagated in sufficient quantities, to describe and offer to the trade. All *Magnolias* are so beautiful and valuable, that any real addition to the list of good kinds should be very interesting to the horticultural public.

CRYPTOMERIA ELEGANS.

AMONGST the many ornamental Conifers from Japan, this is, without exception, one of the most beautiful. It is perfectly hardy, and a free grower in almost any kind of soil and situation. The colour of its dense foliage during summer is pale-green, changing in autumn to a purplish tint, and in winter it becomes a bright reddish-brown, particularly so when planted in light soils or dry, porous subsoils; and in airy, sunny situations; but in heavy soils and damp, sunless positions, it does not exhibit its brilliant and lovely colour to such perfection. It sustains no injury from the keenest frosts or the withering influence of prevailing winds; and a deluge of rain only tends to brighten rather than tarnish its colour. When young, it has a tendency to make duplicate leaders, and to throw out straggling lateral branches; these should be pinched back, and, of course, in the case of the leaders, the most central and best formed shoot should be left, so as to form the main stem; it is also inclined to produce suckers, which should, of course, be cut off close into the stem at the base, and if the collar or neck of the plants be kept quite clear of branches for about 6 in. or even more above the ground, it will be an advantage. One more good quality this *Cryptomeria* possesses, and that is, it is not difficult to transplant, for under any ordinary treatment it rarely fails to grow after being moved. It is said to reach a height of 100 ft. in Japan, where it was discovered

in 1863 by Mr. John Gould Veitch. As an ornamental tree, when judiciously placed, it presents a striking contrast to plants of almost any other colour, and, like other Conifers of a decided outline, in which lies much of their beauty, it must have an abundance of room in which to develop its natural shape. It may be added that it is easily increased by means of cuttings.

PRUNING DECIDUOUS SHRUBS.

To facilitate matters as regards pruning, let us arrange the more common ornamental shrubs in four groups, naming each after its most conspicuous member, and then suggest the treatment proper for each. 1. The *Diervilla* Group. This includes the *Weigela* (properly *Diervilla*), *Dautzia* (single and double), *Hydrangea nivea*, *H. quercifolia*, and *H. radiata*, *Kerria* (Japan Globe-flower), *Philadelphus* (Mock Orange or *Syringa*), *Ribes* (the ornamental Currants), *Spiraea* (the shrubby sorts), *Symphoricarpos* (Snowberry and Indian Currant). All of this group bear flower-buds that will

Cryptomeria elegans.

bloom the coming summer, on wood which grew the previous year; hence care should be taken to prune them but lightly, and for symmetry only, cutting out entirely the wood that has already borne flowers. The work should be done in winter or early spring. If performed after flowering, much disfigurement will ensue from the growth of rampant side-shoots. In this group indiscriminate shearing will be sure to remove nearly, if not quite, all the flower-buds. 2. The Hibiscus (often called *Althæa*) group includes *Berberis*, *Calli-carpa* (French Mulberry), *Colutea* (Bladder Senna), *Coruus* (Dog-wood), *Elæagnus* (Silver Thorn), *Hippophaë rhamnoides* (Sea Buck-thorn), *Hydrangea paniculata*, *Ligustrum*, *Salix*, and *Tamarix lonicera* (Upright Honeysuckle). Shrubs belonging to this group need strong pruning on account of their vigorous nature. It is best, therefore, during each winter, to cut back the growth of the previous year to within three or four eyes (or buds) of the old wood, always paying due attention to the preservation of the symmetry of the plant. The flowers of this season will appear on wood grown at the time, and will be much larger and more satisfactory than if all the buds had been left on. 3. The *Amygdalus* (or Flowering Almond) group includes *Cytisus* (Broom), *Daphne Cneorum*, *Forsythia* (Golden Bell), *Genista* (Whin), *Jasminum*, *Prunus* (Flowering Peach and Plum). Although these shrubs, like those of the *Weigela* group, bear flower-buds on shoots grown during the previous year, they require a different treatment. As they are of slow growth, it is better to remove in summer all of the wood that has just dropped its flowers. This treatment, apparently severe, ensures the development of the most perfect and vigorous wood and flower-buds for the following year. Some species, such as the Flowering Almond or Plum, have a strong tendency to disease, unless treated in the manner here described. Stronger members of the group, however, may require slight modification of treatment. 4. The *Syringa* (Lilac) group includes *Calycanthus*, *Caragana* (Pea tree), *Clethra*, *Coronilla Emerus*, *Pyrus japonica*, *Daphne Mezereum*, *Euonymus* (Spindle tree or Burning bush), *Exochorda grandiflora*, *Viburnum* (Arrow-wood and Snow-balls). Careful attention to all points here indicated should be given by all who wish their shrubs attractive and finely developed. No pruning whatever is better than indiscriminate clipping; but entire neglect will always in time permit an irregular growth that gives a slovenly appearance to the grounds. In time also the uncut shrubs become crowded with old and superfluous branches, bare of flowers, and, finally, not only do they lose their best charms, but they prove a positive nuisance on account of their untrimmed condition. Of course, only a small number of the desirable shrubs are here enumerated, but any intelligent person, by watching the manner of growth of a shrub, will soon see to which group it belongs. The simple principle that lies at the bottom of all this pruning is to assist the plant to the most perfect and natural development. If curving grace be a marked trait, the knife should seek to prevent all angular growth; if, on the other hand, a regular upright form is characteristic, symmetry in this direction should receive special attention. Here, as elsewhere, education and not coercion should be our aim.—SAMUEL PARSONS, in "Moore's Rural."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Spiræa tomentosa and *Thunbergi*.—I see it stated in *THE GARDEN* (see p. 319) that *Spiræa tomentosa* has white flowers. I enclose a small piece to show you that it has red ones. I never saw a white variety of it. I also enclose a sprig of *S. Thunbergi*, which I omitted in my list.—GEORGE GORDON.

A Wild Cherry Tree in Ireland.—Mr. Balfe, in the "Farmers' Gazette," gives an interesting description of a fine Cherry tree, at Old Conna, near Bray. At 1 ft. from the ground, the circumference of the trunk is 16 ft. 8 in.; at the ground surface considerably more, owing to large, irregular, expansions and excrescences. At 5 ft. from the ground, it branches out, and here the girth is 19 ft. Dr. Moore—who has often admired its huge proportions and picturesque form—stated that in all his wanderings he never met any of its kind at all coming up to the proportions of Mr. Riell's patriarchal Cherry tree.

Sycamore Timber.—The timber of the Sycamore tree (*Acer pseudo-platanus*) is extensively employed in Lancashire in the construction of the heavy rollers used by calenders and cloth-finishers, and when of a size suitable for that purpose, 18 in. or more of quarter girth, it is in much demand, and realises good prices. The boles of four moderate-size trees, containing in all 200 cubic ft. of timber, averaging 20 in. in the quarter girth, were lately sold on the Earl of Wilton's estate, of Pilsworth, near Bury, at 2s. 6d. per ft., realising the handsome sum of £25 for the four trees, without taking into account the limbs or large branches, which are used in the manufacture of bobbins, &c., and realize a paying price when sold for that purpose.—"Journal of Forestry."

THE FLOWER GARDEN.

AMORPHOPHALLUS RIVIERI.

THIS curious plant belongs to one of the most remarkable groups in the vegetable kingdom. It is a recent introduction from the Tropics, and is rarely ever seen, owing, I believe, to the fact that it is considered a stove plant, and as such not worth growing; but when grown as a hardy plant, its value

Amorphophallus Rivieri (flower).

for decorative purposes can be easily seen. It can be grown in or out-of-doors in almost any soil or situation, its curious snake-like stems and large, Palm-like foliage rendering it a conspicuous and stately object either in beds, on the rockwork, or mixed with plants of a kindred character. It is an Aroid, producing enormous bulbs which throw up in early spring a

Amorphophallus Rivieri.

stout, erect stem from 2 ft. to 3 ft. in height, terminating with a curious blood-red spadix, partially enveloped in the spathe, which is of a rose colour spotted with green. After it has flowered, the leaf (for there is generally only one) emerges about the beginning of May, and continues to grow at a rapid rate until September, when if strong it will attain a height of 4 ft., and about the same size in diameter. The stem and petioles are of a greenish-purple, spotted and splashed in the most fantastic manner. The foliage is of a deep green colour

and slightly ribbed, while a very distinct venation adds to its beauty. It remains in flower until the first frost, which cuts it down, after which it should be taken up and stored in a dry place and protected from frost until the second week in April, when it should be planted out. If the bulb be in vigorous health it will flower in a dry state without being potted, but it would be preferable to pot it in dry soil until the roots make their appearance, which they do from the top not from the bottom of the bulb. I would recommend where possible the potting of the bulbs intended for outside planting in February or March; by so doing the plants attain a greater size much earlier than when planted in open quarters. Any ordinary soil will do, but the richer the soil and warmer the situation, the better will be the development of the plants. A. P.

The Saffron Crocus (*Crocus sativus*) flowers at this time of year, and not in early spring like the common Crocuses of the garden. The leaves also do not appear until after the flowers have faded. The corm is round and without a furrow, the leaves are 7 in. or 8 in. long, very much narrower than those of *Colchicum*, being linear, and traversed by a white midrib like those of the spring Crocus. Although the flower is very similar in shape and size to that of the *Colchicum*, it is easily distinguished by having only three stamens, which are attached to the outer segments of the perianth. There is only one style, 3 in. or 4 in. long, which is thread-like and terminates in three wedge-shaped stigmas, which are notched at the apex. The ovary, which must be looked for quite at the base of the flower-tube, is inferior, i.e., the tube of the perianth does not easily separate from it as in the *Colchicum*. Although formerly cultivated

Saffron Bulbs attacked by Fungus.

at Saffron Walden, in Essex, and Hinton, in Cambridgeshire, it has not been grown in England for commercial purposes for nearly a hundred years, and has not only ceased to be found in those localities, but is apparently very rare in botanical gardens, for we have not noticed it in either those of Kew, Regent's Park, or Chelsea. This is perhaps owing to the fact that the flowers, even though artificially fertilised, hardly ever produce seed, a circumstance which has been accounted for by supposing the plant to be a hybrid, or which may be due to long years of cultivation destroying its tendency to ripen seed. Although in scarce seasons much adulterated with the stamens and sometimes with a coloured mixture of honey and chalk, we have never seen either shreds of beef, Safflower, or Marigold petals mixed with it; occasionally, however, fragments of the perianth may be seen, but probably these have only been accidentally mixed with it; the stamens are undoubtedly the most frequent admixture. These, as well as all other adulterations, are easily detected by throwing a little of the Saffron into cold water, when anything that differs in character from the tripartite stigma will easily be recognised.—“*Pharmaceutical Journal*.” [Field mice often injure Saffron bulbs, which also suffer from several diseases. Of these, one is a kind of fungus, which, when it does not absolutely destroy the bulbs, greatly diminishes their produce. Another disease is a spot which is at first red, then yellowish, and then black, which penetrates to the centre of the bulb, and destroys it. For this the only cure is cutting it out immediately it is perceived. There is still another disease worse than either of the two just mentioned, Of this, which is very fatal, the accompanying woodcut is an illustration. It consists of a red-coloured fungus, which spreads in every direction, and soon takes possession of the whole plantation. It makes its appearance in spring, and, if allowed to get established, the only thing that can be done is to abandon the infected field, and to plant no more Saffron there for some fifteen or twenty years.]

IS LILIUM CANDIDUM AN EVERGREEN?

IN “F. W. B.’s” interesting articles on “Lily Bulbs,” he remarked (see p. 134, Feb. 17), that this Lily is the only evergreen Lily we have. To this I ventured to object, saying (see p. 261, March 31):—“We have another proof of the continued vigour of the new bulb in *L. candidum*. In the autumn, while the old stem is dying down and perishing, the new bulb is pushing up above ground a cluster of leaves, which continue fresh and green during the winter. This has given rise to the mistaken idea that *L. candidum* is evergreen; it is, however, no more evergreen than any other Lily.” To this “F. W. B.” replied (see p. 268):—“‘Dunedin,’ again, asserts that *L. candidum* is no more an evergreen than any other species, whereas the reverse of this is a well-known fact to every Lily grower, seeing that the plant bears green leaves nearly all the year.” Now, as “F. W. B.’s” object, as well as every Lily grower’s, is, or ought to be, I presume, the same as mine, namely, a desire to arrive at the truth, permit me to add a few words to what I said in several letters at that time. In continuation of my experimental researches, I lifted several clumps of the White or *Candidum* Lily, on Saturday, 30th June last, when they were in full bloom. Among the bulbs I found some very interesting specimens, but as I had to leave home on the following Monday for six or seven weeks, I placed them in a basket in my tool-house for further examination. I may here, however, add, that when I lifted them on June 30 I found that the new bulbs were, in general, somewhat larger than an extra-sized duck’s-egg, and that, in their growth, they had pushed open, or apart, the scales of the old, or parent bulbs, which were then beginning to show signs of decay. On my return home, towards the latter end of August, I opened the basket and took out the bulbs. Amongst them I found one which instantly struck me as being a more than ordinary interesting specimen. It was somewhat similar to the one I described in my paper of March 31 (see p. 260), and which I called “twin bulbs,” as they had sprung from the same source, that is, from one and the same parent bulb. Considering that these twin-bulbs had been taken up while the parent bulb was in full bloom, and that they had been out of the ground more than six weeks, they were in very good condition; the parent bulb itself had, however, much decayed. This I expected, for as the parent bulb had bloomed once—all that Nature requires—nothing remained for it but to decay and die.

On studying the appearance of this particular specimen, it occurred to me that I might be able to produce a proof, that would be satisfactory to “F. W. B.” and other Lily growers, that *L. candidum* is not in reality an evergreen. I, therefore, at the end of August, put this specimen into the ground once more, and, in about a fortnight after, I was rewarded by seeing two separate and distinct tufts of green leaves shooting up above the ground. Allowing them to grow for another fortnight, I again took them up, and now, after having submitted them for the inspection of a few Lily-growing friends, I send them to you, considering that THE GARDEN has readers who may be glad of some authoritative information on the subject. On looking at what I have sent, you will see that the green leaves do not emanate from the old, or parent bulb; in fact, they have no connection with it; on the contrary, they spring from the two new bulbs, which had no existence, even in embryo, twelve months before the parent bulb began to bloom. The parent bulb itself, with its roots, has been for some time, to all intents and purposes, dead or dying—incapable of producing a single green leaf. It has done all that Nature destined it to do—that is, it has bloomed once, like other Lily bulbs, for, as I reared it, I know that it never bloomed before. The flower-stem of the parent bulb, though now withered, still stands between the twin bulbs, and the remains of the old scales are pushed away right and left, as if they were—and rightly, too—of no further use. The fresh roots will be seen to spring from the new bulbs; the roots of the old bulb are, like the scales, either dead or dying. So far, indeed, from “seeing that the plant bears green leaves nearly all the year,” we see the very reverse, for we see that in this, as in all other cases, vitality has left the parent bulbs after only one flowering season, leaving to legitimate successors—that is, the new bulbs which spring from within the parent bulbs—the important function of yearly reproducing, with liberal culture, larger

successional bulbs, and, consequently, a more gorgeous display of their lovely and stately bloom.

We have another fallacy to contend with, and that is what is called the "dormant" season. What is thought by some to be dormancy is, in reality, decay and death. A Lily bulb is never dormant. From the instant the seed-bud is generated until it has bloomed, its growth is always increasing, more and more, according to circumstances. This is easily proved by taking up bulbs every month, winter and summer, and dissecting them. When the old, or parent bulb, has bloomed, and the foliage is beginning to wither, vitality has ceased to operate, and decay has taken its place. The new bulb has now received all the nourishment the parent bulb is capable of supplying; consequently, this is the best time, with all Lilies, for transplanting the new bulbs. October is said to be the best month for planting; but it is wrong to consider this as a general rule. The White Lily, for instance, should be replanted two months before this time, that is, before the green tufts of leaves begin to appear above the ground. If replanted in October, these tufts are generally 6 in. or 8 in. high, and are therefore apt to flag and die down; or, if they do not entirely fade away, the flowering and the foliage next season will be weak and sickly, lasting but a very short time. There are other Lilies which, if we desire to transplant them without a check, should be lifted and replanted in August and September rather than in October. It is wrong, as a rule, and damaging to many Lily bulbs, to wait until the end of October before they are taken up, to wait until they are, erroneously, called ripe or matured. It is a well-known fact, that Lilies do not all bloom at the same time. When the aboveground parts of a Lily are fading and dying down, the underground parts, that is, the old bulb and its roots, are also fading and dying. This is Nature's doings. Care nothing for the old roots, for they have done their duty; but take great care of the young roots of the new bulb. If not transplanted as soon as the parent bulb has ceased to convey nourishment (and this is known by the above-ground fading of the plant) the young roots will multiply and get strong, and if not moved before this time a serious check must be the result. The more advanced portion of the roots will decay and die, and time will be required to produce a succession, less vigorous, of course, and, consequently, very deteriorating to the bloom of the next season. DUNEDIN.

Clematis and Canary Creeper Combined.—In an old-fashioned garden in the country, I saw, during the past summer, one of the most charming combinations of climbing plants that has yet come under my notice. It consisted of the well-known Clematis Jackmanni and Tropæolum caoriense, better known as the Canary Creeper. In the garden in question was a rustic trellis, which, for some years past, has been devoted to the Clematis here mentioned, and one or two other dark blue varieties, and this season seed of the Tropæolum was sown at the foot of the trellis. The Tropæolum was allowed to intermix with the Clematis, and the result was a glorious display of the richly coloured flowers of the latter set in a groundwork of the light green leafage and golden flowers of the former. In the same garden I saw this Tropæolum most effectively employed in the embellishment of a mixed border. At a distance of 8 ft. or so apart, rustic trellises were formed with Pea sticks about 4 ft. in height, and the growth was allowed to run naturally over the branches. In the formation of these trellises, rather stout sticks were used, and the small spray out back, so that the growth could be held up firmly and present some degree of regularity. About four sticks were employed in the formation of each trellis, and they were inserted rather closely together, the tops being allowed to spread out somewhat. The soil, in which they were growing was in good heart, and as well-established plants that had been raised in frames were put out in preference to sowing the seed, the trellises were, at a very early period, covered with foliage and flowers, the effect of which was exceedingly good.—"Gardeners' Magazine."

Collomia grandiflora in Germany.—It appears from a communication made to the Brandenburg Society of Botanists, that Collomia grandiflora, a North American plant, is thoroughly naturalised and exceedingly abundant in some parts of Germany. In very stony places it grows only 2 in. to 6 in. high, and these plants bear exclusively cleistogamic flowers—that is, small, closed flowers without petals, in which self-fertilization must take place. Where they are stronger, they bear both small closed flowers and ordinary open ones, or only the latter.

PLATE XCVI.

FRÉBEL'S BEGONIA.

(B. FRÉBELI).

Drawn by MRS. DUFFIELD.

THIS fine and distinct species of tuberous-rooted Begonia was first introduced to European gardens from its native country, the Republic of Ecuador, about the year 1872-3 by M. Otto Frébel, of the Newmunster Nurseries, Zurich, to whom tubers were sent by the well-known collector, M. Rœzl. It was named B. Frébeli, in compliment to the introducer, by Prof. Decandolle, of Paris, to whom the plant was submitted immediately on its flowering for the first time in Europe. It has been described and advertised as a rival to the Scarlet Pelargonium for summer bedding purposes, but this it can never in any sense be, as its natural period for commencing to start into growth is from the end of September to the middle of October, and it commences to open its brilliant scarlet blossoms about the middle of the latter month. It will, however, be found to brighten the conservatory during the greater part of the three following dull winter months, when, owing to the

Begonia Frébeli.

great scarcity of other brilliantly-coloured flowers, it is likely to prove a most acceptable and valuable acquisition. The foliage of this plant varies considerably in the case of different specimens, some being covered with purplish, velvety hairs, and resembling the foliage of a Gesnera, while others have leaves of a much lighter shade of green, and almost devoid of hairs. There is also considerable variation in the depth of shade of the scarlet of the blooms, some being of a clear, intense scarlet throughout the entire flower, while others are a much lighter shade, sometimes amounting to almost a whitish appearance towards the centre of the flower. This plant produces seeds very freely, and the seed seems to germinate easily, the seedlings blooming towards the end of the first year of their existence, a great additional merit as regards this plant. As companions to this variety should also be grown, for the decoration of the winter conservatory, the two other specific varieties of late-blooming Begonias, also introduced by M. Frébel, and named respectively B. octopetala and B. octopetala rosea, the latter of which seems, as yet, to be rather scarce in our gardens, but which I hope to bloom a little later on in the season. It is an extremely vigorous grower, with large and handsome foliage with woolly stems, and marked with purple, somewhat like the leaves of the Podophyllum Emodi; the green ground colour of the leaf is also of a much deeper shade than in the ordinary B. octopetala. I do not

think the proper treatment of this plant is yet by any means perfectly understood, as where really well bloomed, with twenty or more flowers on a spike, as described by "J. T. P." (see p. 425, Vol. X. of THE GARDEN), it must be a really ornamental and beautiful plant, and all the more valuable on account of the late season at which it blooms. W. E. G.

Our plate was prepared from a plant furnished by Mrs. Dixon, of the Amburst Nursery, Hackney.

THE INDOOR GARDEN.

DIRCÆA REFULGENS ANOMALA.

WE have sought in vain for a botanical description of the species from which our figure represents an interesting deviation. *Dircæa refulgens* was mentioned in Van Houtte's catalogues for 1875-6, but this year it is not included. It is probably a native of Brazil. The genus was separated from *Gesnera* by Decaisne, and founded on account of the greatly-developed upper lip of the corolla; which partially closes the entrance to the flower. There are but few species, perhaps only four besides *D. refulgens*. All, though very well worth a place in any stove or warm greenhouse, are very rarely met with in gardens. We are, however, largely indebted to the natural Order Gesneraceæ, *Achimenes*, *Gesnera*, *Gloxinia*, and *Streptocarpus* being among the more familiar genera. Our present plant has a stout,

Dircæa refulgens anomala.

hairy stem, from 1 ft. to 1½ ft. high, with roundish leaves of great substance, borne on short thick petioles. The bright scarlet flowers are freely produced on vigorous specimens, and are extremely handsome and showy. The deviation from the type consists in the regularity and position of one or more of the flowers, as in our drawing, where the central one is perfectly erect and exhibits nothing of the irregularity in the form of the corolla which distinguishes its normal state. These queer flowers perfect seed freely, and if the seedlings raised from them possess the peculiarity of the parent, possibly some of our readers may soon have an opportunity of judging the merits of the plant for themselves. Any light, rich soil will suit it, and cuttings are easily struck in heat under a glass. It may also be propagated by the tubers, which must be kept dry during the season of rest. Any one who can manage a *Gesnera* can also grow this. We may remark that anomalous flowers are of frequent occurrence in allied genera.

Seedling Gloxinias.—I find these to be invaluable about this time of the year, when flowering stove plants in a good many places are scarce. From seed sown early in March we have sixty or seventy plants in 5-in. pots, with from six to twelve beautifully-coloured

blossoms on each, and several more showing, which will keep up a display of flower well into November. I also find them very useful in little vases for table decoration when low plants are required. Few flowering plants look so well under candle-light as *Gloxinias* when in good leafage and flower.—W. W., *Eaglehurst*.

PROPAGATING LAPAGERIAS.

THESE are generally propagated by means of layers, but the demand for the white variety, which is still sold at high prices, has induced raisers to try more expeditious plans of propagation; and we saw lately some 600 plants of it that had been raised from eyes; layering is, however, perhaps the safest plan. The shoots of the previous season are simply bent down around the parent plant, and pegged on a bed of peat and sand and covered over, leaving the point of the layer above the soil. Roots are formed at the joints, and several plants sometimes spring from the same shoot, springing up like Vine eyes; but the points of the shoots usually make the strongest plants. The plants of the white kind which we saw had, however, been propagated rather differently, for the ripened shoots of last year's growth had been entirely severed from the parent plant, and pegged firmly their whole length on a thin bed of peat and sand, and covered over with silver sand about half-an-inch deep, the leaf at each joint being kept for the most part above the surface, so that all that one saw of the shoot when the work was finished was just a row of leaf points sticking up above the sand. This was done early in the season, and a short time ago the young plants from the shoots so laid amounted to hundreds, the value of which represented a large sum. We noticed, however, that every eye had not produced a plant, and we were told that it was important in adopting this plan to select well-ripened shoots with good foliage, as the vitality and strength of each bud depend upon the leaf. Another plan, which we have been assured is equally, if not more successful, is to cut off the best ripened shoots, and coil and peg them on peat in a shallow pan, covering the shoots over with sand also as described above, and placing them in bottom-heat, keeping them continually moist till they throw shoots and begin to root, when they may be removed to cooler quarters. This, it will be seen is simply a modification of the plan of striking Vines from eyes; but, as we have said before, it does not insure the breaking of all the eyes along each shoot, and it seems almost worth while to cut the eyes up singly like Vine eyes, with a leaf to each, and plant them in the same way, so as to insure a plant from any bud. It can hardly be doubted, if the buried shoots strike at the joints and produce plants, that single eyes would strike also; but, of course, the propagator would need to be more particular in securing a good leaf to each bud. We find that the *Lapageria*, when established, grows and flowers best in good loam and sand, with a little peat added to it; but it is not particular, for it is an extraordinary rooter, if it has room and light and a cool house. When the *Lapageria* is propagated by seed—a plan not to be recommended, except for the purpose of raising new and better varieties—the seed should be sown as soon as ripe in a pan of fine soil, covered with a pane of glass, placed in a gentle heat, and kept moist. When the plant is grown in a light situation, it seeds pretty freely, but the earliest flowers should be selected for seed, in order that the fruit may be matured during the best season of the year. The natural flowering season of the plant is autumn and winter, but the flowers are produced plentifully in spring also, when fertilization is most likely to be successful. J. S.

Hypericum patulum.—The St. John's-wort which I mentioned as having seen at the Comely Bank Nurseries, and which I mistook for *H. patulum*, proves to be, as far as Mr. Fraser can make out, *H. oblongifolium*. Moreover, it is not a tall bush 5 ft. high, as I thought. The mistake occurred from the fact that a bush of the "Duke of Argyll's Tea tree" was growing out of the clump of St. John's-wort, which is not more than 2 ft. high. It is a very ornamental species, equally so with and closely resembling *H. patulum*, which I have since seen in flower at the Lawson Company's Nurseries. *Hypericum nepalense*, of which the writer of the article on St. John's-worts speaks somewhat disparagingly, makes an exceedingly choice wall shrub, with delicate foliage and pretty flowers.—SALMONICEPS.

Jasminum Sambac.—I have a plant of this covering about 8 ft. square of the roof of a stove, and it is now literally covered with its orange-like buds and flowers, which fill the place with fragrance. Where button-hole and other bouquets are in request, this Jasmine will be found most useful.—W. W., *Eaglehurst*.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Insects.—Where plants are grown in pots or similar contrivances, as must, for the most part, be the case when they are under glass, continuous war must be waged against insects; for it must be borne in mind that where they are allowed to become seriously infested with such parasites, it is impossible that their cultivation can be carried out with either pleasure or profit. The labour entailed in the destruction of insect pests is often such as to involve a considerable percentage of that which is required for the cultivation of the plants collectively. This is a matter that I have often found great difficulty in sufficiently impressing upon amateurs in their first attempts at gardening; sowing, cutting, striking, potting, watering, and training are operations the necessity for which is easily understood; but the continual close observation and incessant crusade against insect marauders, indispensable to success, is such that none but those who have had considerable experience can fully realise. There is no season of the year wherein it is so essential to make a successful onslaught upon the whole species of insects that infest plants as the present, when their slower increase, consequent upon the lower temperature and the lessened vitality which they possess through the dormant period now commenced, renders them more easy of destruction. In addition to this, most plants, having made and solidified their season's growth, are in a condition to bear without injury the applications necessary to kill the insects with which they may be infested. This particularly applies to mealy bug and the different varieties of scale insects. Camellias, more than most plants, are subject to the attacks of the latter, including both the white and brown species, and to the presence of these may frequently be attributed the unsatisfactory state in which amateurs' Camellias are often seen. Of the two, the white scale is much the most injurious, as well as the most difficult to cope with, where it is allowed to establish itself. In such cases it often causes the partially-developed blooms to drop, and injures the terminal wood-buds to such an extent that they fall out, engendering a debilitated state of the plants, which is often attributed to some other cause. It adheres so closely to all parts on which it gets a footing that it is not easily removed. An ordinary tooth-brush, somewhat softened by use, is one of the best implements for the purpose, but in its use too much force must not be employed, otherwise both buds and leaves will be injured thereby, although they may not show it for some days or weeks afterwards. To carry the work out satisfactorily, it is necessary to get into every crevice and inequality in the bark, as it is in these the scale partially conceals itself. After being removed by a careful use of the brush, the whole of the wood and leaves should be well washed with a sponge and soapy water, which will free the plants from any of the small fry that may have escaped brushing, and will leave the foliage in a clean, glossy condition; if the plants be seriously affected, not so much as a single inch of the wood or leaves should be left unexamined. Brown scale is not nearly so injurious, and for its removal a sponge and soapy water will usually be found sufficient; should thrips or their eggs exist, they will also at the same time be got rid of. Where hard-wooded plants are affected with white scale, it often happens that some of them are unable to bear dressing with a solution strong enough to kill the insects without seriously injuring the foliage. In the case of *Cytisus*, *Habrothamnus*, *Jasmines*, *Rhynchospermum*, *Jasminoides*, *Plumbago capensis*, *Boronia*, and similar free-growing subjects that are badly affected, it often becomes necessary to cut them back a considerable distance into the hard wood and then immerse them as far as possible in a strong solution of insecticide; I have found Stevenson's "Abyssinian Mixture" to be the most effectual, and to do the least injury to the plants; but the application must be repeated several times, at intervals of a week or two. Stove plants, upon which that most troublesome of all insects, Mealy Bug, exists, can be more effectually dealt with now than at any other season, as their young shoots and leaves will be getting fully matured. Many troubled with this insect imagine that, when once it gets a footing, it cannot be thoroughly eradicated; but that is not the case where sufficient perseverance is bestowed. No half measures will, however, suffice; on the contrary, every plant in a collection upon which it will live must have their heads either steeped in a vessel sufficiently large to hold enough of the dressing to admit of their complete immersion, or be laid down on their sides and washed with the syringe, turning them round repeatedly, so that the whole surface of both bark and leaves, from the extreme points down to the collars of the plants, is reached. The application, too, should be repeated three or four times, or so long as the slightest trace of either the insects or their eggs can be detected. The "Abyssinian Mixture" will effectually destroy Mealy Bug, and it also possesses the advantage that if it gets into the soil and reaches the roots it will not do the least harm to even those of the most tender plants.

Flower Garden and Lawn.—So long as there is not frost sufficient to destroy bedding plants it is well not to disturb them, for, although the season is too far advanced for them to be very gay with flowers, still whilst they have a fresh green appearance they look better than the bare soil, except in cases in which the beds are filled with small shrubs. If bulbs, such as Hyacinths, Tulips, and Crocuses are to be planted, the summer occupants should, in that case, be cleared off to make way for them; the ground should also be well dug over, especially where it is of a retentive character, as, when well stirred to a moderate depth, it admits of the water percolating more freely through it than it otherwise would do. Soil of this nature will be improved by giving it a liberal dressing of road scrapings, and, still better, pit or river sand mixed with some decomposed vegetable mould. This will also be of benefit to the bulbs, which should be at once planted; for keeping them out of the ground after they should be started into growth has a weakening influence on them. Crocuses and Snowdrops have a fine appearance planted somewhat thinly (say single bulbs 1 ft. or so apart) on outside corners of lawns, where it would not be unsightly to leave the Grass unmown for a few weeks in spring until the leaves of the bulbs had ripened. In no position do these early spring flowers look so well as when they are arranged in this way; Daffodils and other Narcissi may also be similarly treated with advantage. If preference be given to planting any or all of the above more closely together, say a dozen roots in a patch with more Grass space intervening, this can easily be done, but it would involve a little extra labour in mowing and the use of the shears if the Grass be kept cut without interfering with the leaves of the bulbs until they are ready for removal.

Frames.—*Pentstemons*, *Snapdragons*, *Phloxes*, and all plants of a similar character struck from cuttings put in early in the autumn should be occasionally gone over, and any which have failed to root and are decayed should be taken out, otherwise they will affect the others; give them plenty of air by drawing the lights off in the day time during mild weather; but, as these newly struck plants have yet comparatively little root, it is not well to allow them to get frozen; they must not, however, be subjected to any treatment likely to induce a soft, tender condition, or difficulty will be experienced in getting them safely through the winter.

Mushrooms.—For these more manure should now be prepared. An opinion often entertained by those who have not had much experience in the cultivation of this crop is, that the saving of manure for Mushroom growing necessitates a great amount of care in selecting nothing but droppings, and keeping them so as not to allow a drop of rain to reach them; this, however, is unnecessary, though there is no doubt that manure for Mushrooms is all the better for not being subjected to drenching rains, and if it contains an excess of long litterly material it is not so suitable; but a slight wetting, or a moderate mixture of short litter does no harm; neither is it by any means necessary to use manure exclusively, for as good crops of Mushrooms are frequently obtained from a mixture of say one-half manure to one-half ordinary loam or road scrapings as from manure alone; when a mixture of this sort is used it is necessary that the material added to the manure be used in a sufficiently dry state, as if too wet it would prevent the manure from attaining a sufficient degree of warmth to start the spawn; consequently where amateurs are not in a position to obtain horse-droppings alone in large enough quantities without incurring considerable trouble and expense, they need not, on that account, be deterred from attempting the growth of Mushrooms. A mixture of this sort is not liable to overheat so as to injure the spawn in the way that manure alone will, and therefore may be made up into a bed without so much turning and preparation as are necessary in the case of manure. Beginners in the cultivation of Mushrooms should not be disheartened through failing in the first instance, as even with the most experienced growers they are more uncertain than most crops. Their growth involves little cost except the labour in preparing the material and making up the beds, as the manure and whatever else is used is available afterwards for all purposes for which manure is needed.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

October 22.—Sowing Mustard and Cress. Getting a few Hyacinths into gentle heat. Putting a good covering of leaves and long litter on early Vine border. Pruning Vines in second early Vinery and stripping off all loose bark. Covering up Endive and Lettuces to blanch. Clearing off late Peas, and storing away the best of the sticks for another season.

Oct. 23.—Potting Ashleaf Kidney Potatoes that had been previously started in gentle bottom-heat. Laying down new turf where required, and taking up old where unlevel and relaying it. Cutting back large

FRÖBEL'S BEGONIA (B. FRÖBELI).

deciduous trees where overhanging each other, and lightening the heads, where too heavy, to prevent wind from breaking them. Turning manure for Mushroom beds, and gathering in the last of the Apples and Pears.

Oct. 24.—Washing glass and paint in second early Vinery with soft soap and hot water, and painting the Vines with a mixture of sulphur, soft soap, and Tobacco-water, to which a little clay has been added to thicken it. Looking over the fruit-room and arranging it for the winter. Roping Onions, cutting shreds, pointing nails, and making labels and pegs when the weather is wet.

Oct. 25.—Potting clumps of Lily of the Valley, so as to be ready for forcing. Dividing some old Lobelia plants, and putting them in small pots. Earthing up French Beans. Spawning Mushroom bed and moulding it over. Getting up a little Chicory and Dandelion ready for forcing in pots. Rolling down firmly all gravel walks that have been broken up or newly made.

Oct. 26.—Sowing French Beans in pots. Getting up Dahlias and placing them in open sheds to dry. Clearing off dead plants from flower borders, and planting them with spring flowers, viz., Red and Yellow Wallflowers, Silenes, Red and White Daisies, Myosotis, Iberis, Alyssum saxatile, Pansies, and Nemophilas. Earthing up Celery when the soil is dry and in workable condition. Clearing off Lettuce and Endive that are gone too far for use.

Oct. 27.—Potting off cuttings of Hathaway's Excelsior Tomato. Filling frames as they become empty with Lettuce and Endive. Getting bulbs planted, such as Hyacinths, Narcissus, Crocus, Tulips, Snowdrops, &c. Cutting back shrubs in new plantations where growing too closely together, and, where planted too thickly, removing them and filling up gaps elsewhere with them. Fruit in use for dessert—Pines, Grapes, Pears, Apples, and Nuts.

Pæonia Browni.—One of the most strikingly handsome plants, growing in California in a wild state, is this Pæony. I saw it for the first time this spring, and was immediately struck with its great beauty, and have no doubt that when brought into market it will be found one of the most desirable of novelties. Pæonia Browni is, like all other Pæonies, a perennial, the top dying down in winter, and new shoots coming up from the root every spring. It grows about 1 ft. high. The petals, which are very thick, are from five to ten in number, and they vary in size; in colour they are a dark red, the centre of each petal being almost black, the edges shading off to a clearer red. The sepals are about the same size as the petals, and vary in colour from a pure green to a bronze green. The flowers are from 1 in. to 2 in. in diameter, and are always found drooping downwards. Pæonia Browni, though spreading over a great range of station and climate, is never met with in large numbers; a dozen, perhaps, will be found together, and then you might go for fifty miles and not find another. That it will do well in any locality is evident from how it grows wild, being found on the hot plains of Los Angeles and San Diego, and also near the limits of perpetual snow on the Sierra Nevadas. It shows no preference for wet or dry soil, blooming equally well in both.—"Gardeners' Monthly."

THE LIBRARY.

KETTNER'S BOOK OF THE TABLE.*

THE author of this book might very well have added to the three adjectives which he has employed upon the title page, to describe its general scope, a number of others, such as witty, humorous, poetical, etymological, archæological, and, above all, delightful, for it can lay claim to the whole of these epithets, particularly to the last. To ourselves and our readers this latest contribution to our knowledge of gastronomy should be especially interesting, seeing that fruit and vegetables receive a large share of the author's attention, a virtue which is exceedingly rare in writers on the subject. The very first paragraph of the book is a gentle remonstrance against the needless multiplication of names in cookery, different authors describing ordinary mixed vegetable soup under nine or ten different names, such as Julienne, Printanier, Jardinière, &c., the ingredients for each being precisely the same, or at any rate differing only according to the season of the year.

The arrangement of the book is alphabetical, the cross-references being as numerous as the convenience of the reader can require. The article on the Apple is an excellent one, and is evidently from the pen of a true Apple-lover. The remarks on the necessity for flavouring the cooked Apple with spices, butter, cream, Apricots, Quinces, Cinnamon, the zest (not the peel) of the Orange and Lemon, brown sugar, &c., ought to be reprinted and distributed as a

tract amongst those conservative housewives who think that a couple of Cloves and a thick slice or two of Lemon-peel are all that is necessary to bring out the delicate flavour of the fruit.

In treating of Asparagus, the author makes some capital remarks, in which we most heartily concur, on the absurd native custom of using cooked vegetables not as dishes *per se*, but simply as adjuncts to meat or fish, except in the case of Asparagus and Artichokes. The author is inclined to think that this exception is not due to a pure admiration of the vegetables, but to the circumstance that having to be eaten with the fingers, it is necessary to put down the knife and fork in order to seize the vegetables. This may be very true as far as Asparagus and Artichokes go, but the real reason why Peas and Potatoes are never eaten alone in England is because they are, as a rule, simply boiled, and not made into dishes properly so-called. Our author speaks of Dill soup as having been such a favourite dish with William the Conqueror that he created his cook, Tezelin, who invented it, Lord of the Manor of Addington. Most people, we fancy, have only made the acquaintance of the Anethum graveolens in the form of that favourite infantine carminative, Dill-water. The article on Faggots is also good. The author does not refer to those fearful and wonderful but savoury combinations of minced entrails which are sold by thousands every night in Clare Market, Whitechapel, and other poor neighbourhoods, but to those nosegays of different herbs known to the French as *bouquets*. The poorest French woman, when buying the vegetables for her *croûte au pot*, or for the ordinary *pot au feu*, always bargains for her faggot to be thrown in. The Belleville greengrocer who would neglect to supply his customers with a *bouquet gratis* would soon find himself left desolate; it is, in fact, like the milkman's "tilly" in England, and costs the giver just about as much. Faggots are of various kinds; the ordinary French *bouquet* consists of a little bunch of Parsley tied up with a few spring Onions; to the *bouquet garni* a Bay leaf and a sprig of Thyme are added. These two are pretty well known in England, but the Ravigote Faggot is a comparative stranger. It consists of equal portions of Tarragon, Chervil, Burnet, and Chives; minced it forms an excellent garnish for salads of all kinds. Some of the faggots are minced and fried, and consist of Carrots, Onions, Shallots, Bay leaves, Thyme, Mushrooms, Truffles, Garlic, fat bacon, and ham in various proportions, and are greatly used for flavouring soups and sauces. We are obliged merely to glance at the excellent instructions for frying, which apply equally to vegetables and meat. Throwing meat or vegetables into a frying-pan containing a thin layer of melted fat, and heating them till some are burnt and others are grease-soaked is not frying; the frying-kettle ought to contain a sufficient quantity of fat to allow the thing to be fried to be completely immersed in it. What are called "fried Potatoes" in England are cold Potatoes from yesterday's dinner (one half sliced and the other crumbled) heated in a greasy frying-pan until they are partly browned. By this means they become sodden with half-burnt fat, whereas by plunging the raw slices into boiling fat or oil they become covered with a crisp, golden armour, which prevents the absorption of the smallest particle of greasy matter. Under Horseradish there are two excellent receipts for Horseradish sauce. By the way, when will English cooks learn to give us grated Horseradish instead of the stringy scrapings and shavings which are generally served up with our national dish? We cordially join with the author in lamenting the almost total disappearance of that delicious and wholesome condiment Laver, but must express our surprise that he should dismiss such important subjects as Mushrooms and Onions in so few words. Under the heading Pimpernel we receive the salutary warning that Pimpernel is not the English for the French word *Pimprenelle* any more than Primrose is the English for *Primerose*. The French *Pimprenelle* is the garden or salad Burnet (*Poterium Sanguisorba*), a harmless pot-herb, while the English Pimpernel is the poisonous *Anagallis arvensis*. Under Pumpkins, Lady Llanover's appreciative account of these useful and ornamental vegetables is quoted, but unluckily no receipts are given for their preparation. Lady Llanover tells us that the only civilized people in England, from the Pumpkin-eating point of view, are the inhabitants of the neighbourhood of Gower, in South Wales, whose cottage ceilings resemble those of the farmhouses of the Abruzzi and Campagna in their wealth of Pumpkins stored for winter use. In the article on Purées a striking contrast is drawn between French *purée de pommes de terre* or *epinards* and the lumpy mashed Potatoes and stringy Spinach which we get in England.

The article on Salad is an essay extending over a dozen pages. The description of the pains the author took to procure a properly mixed salad at a first-rate Piccadilly dining-room, such a salad in fact as would be brought to him as a matter of course at any 20 sous Paris *gargote*, is very amusing. He asked for a salad. The waiter brought a wet Lettuce cut in halves on a flat plate, half-floating in its own water; he next produced an annulated bottle full of

* "Kettner's Book of the Table: a Manual of Cookery—Practical, Theoretical, Historical." London: D. Au & Co. 1877.

the abominable compound called "salad mixture." It was hinted that this horrible concoction was not required, whereupon it was whisked away by the offended waiter, who evidently thought his customer was going to eat his Lettuce with salt like the Turks. He next asked for oil and vinegar and a salad bowl, but there was nothing of the sort in the establishment. It was explained to the waiter that a salad could not be mixed on a flat plate, whereupon he brought successively a soup plate, a slop basin, and lastly, a soup tureen, in which our author prepared his salad *secundum artem*. The extraordinary way in which we neglect the scores of delicious salad herbs growing in our fields is also dwelt upon. Cos Lettuce, Cabbage Lettuce, and occasionally a stray head of Endive are the only salad plants which are commonly obtainable, except at one or two special shops in Covent Garden. Where are the numerous "Sallets," as he writes it, which Evelyn describes with so much gusto in his "Acetaria?" The Alisander, the Artichoke, "that noble Thistle," as he justly calls it, Purslane, Lamb's Lettuce, Hop tips, Dandelion, Mallow, Sance alone, Burnet, which is thought to be so essential to a salad in Italy that it has given rise to a proverb—

L'insalata non è bella
Ove non è la Pimpinella.

Borage, Bugloss, Nasturtium leaves, Stonecrop, and a host of other delicious and wholesome salad plants are all neglected, and quite unobtainable through ordinary channels. Tomato salad, too, is almost unknown in England, except to those who have lived in the East or the United States. Potato salad is only to be seen in a few houses, and the *salade de légumes*, which may be obtained in the humblest French restaurant in perfection, is almost unheard of. Under the heading of Sprats, we learn that a friend of the author's once surprised a connoisseur in Roses, who was admiring a splendid show of *Maréchal Niels*, by informing him that they were all produced by manuring the ground with decaying sprats. With this hint to our sea-side Rose growers we reluctantly take leave of this charming book.

C. W. Q.

Underground Water.—The committee of the British Association for investigating the circulation of underground water in the new red and permian rocks has been re-appointed, and the inquiry extended to the oolites. The secretary, Mr. De Rance, read an elaborate report of the work done by the committee during the last year, and it is evident the association considers the inquiry one of growing importance. Mr. T. Mellard Reade, followed with an individual report upon the wells of south-west Lancashire, in which he analyzed the information he had collected during the last three years, and demonstrated by calculation of the water yielded by certain wells and bore holes, that the yield of a well is dependant upon striking certain fissures or channels which ramify through the sandstone, forming ducts, conveying the underground water to the pumping stations. These ducts, which may be vertical fissures or may be channels along the planes of bedding, like arteries, conveyed the water from large areas of sandstone that have absorbed the rainfall from surface percolation. He also showed that the wells are nearly all affected by local percolation, and insisted on the necessity in most cases of excluding the water from the strata immediately surrounding the well, as it is liable to all sorts of organic contamination, by water-tight cylinders or tubbing.

JEAN-BAPTISTE VAN MONS.

THIS celebrated pomologist, whose portrait well deserves a place in *THE GARDEN* on account of the good work which he has done in that department of horticulture, was born at Brussels on November 11, 1765, and died at Louvaine on September 6, 1842. At eighteen years of age he entered the service of a chemist at Brussels, and from that time his attention was devoted to the study of chemistry, natural philosophy, botany, and cultivation, especially that of fruit trees. In 1802 he founded at Brussels the "*Journal de Chimie et de Physique*," and later on he published several scientific works, to which it is unnecessary now to allude, but his labours in these respects did not prevent him from bestowing some attention on pomology. In 1819, however, his nursery at Brussels was required by the Government, and he was called upon to deliver up the ground within the short space of two months, a summons

which he strenuously opposed, but at length was compelled to give way. The time was too short for him to transfer his stock without loss to Louvaine, where he was then settled; in fact, he only saved five per cent. of his fruit trees. In 1823 he published a fruit catalogue containing no fewer than 200 new varieties together with descriptions of them, and some account of their parentage. In 1831 some nursery ground which he had acquired at Louvaine was wanted for government purposes, and a second time a large number of his fruit trees were destroyed. He, however, obtained some fresh land, and saved a portion of his collection; but in 1834 his new nursery was taken for a gas factory. Though much depressed by such an accumulation of mishaps, Van Mons was not discouraged; on the contrary, he pursued his labours in the way of culture, and the raising of new kinds of fruit

Van Mons, the Pomologist.

trees with an ardour and perseverance worthy of imitation even at the present day. In 1835 he completed "*Les Arbres Fruitiers et leur Culture*," a work which attracted much attention. Van Mons was of opinion that varieties of fruits, however good at first, would degenerate with age, and that it was necessary to continually raise new kinds, which he maintained should be the produce of seeds saved from the very best varieties. In this way, by means of successive sowings and careful selection, were obtained the many fine varieties with which his name is associated, and amongst which are the following:—*Belle Henriette*, *Beurré d'Amanlis*, *Beurré Dumortier*, *Beurré Navez*, *Beurré Spence*, *Beurré Bosc*, *Colmar d'Arenberg* or *Fondante de Jaffard*, *Colmar Nélis* or *Bonne de Malines*, *Comte de Flandre*, *Conseiller de la cour*, *de Bavay*, *Délices de Lovenjoul*, *de Spoelberg*, *de Brabant*, *Enfant prodigue*, *Espérine*, *Frédéric de Wurtemberg*, *Van Mons Léon Leclerc*, *Ne Plus Meuris*, *Rousselet de Coster*, &c. These, it will be seen, comprise some of the best varieties of the present day.

N.

THE FRUIT GARDEN.

CULTURE OF HARDY FRUIT TREES.

THE culture of fruit trees in Belgium (a country with quite as bad a climate as our own) is pursued with much success. The methods of culture successful there cannot fail to be instructive to the English cultivator, and, with a view to making these known, we have translated the more essential portions of Mr. F. Burvenich's "*La Grande Culture des Arbres Fruitières, dans les Vergers, les Champs, les Patures, les long des Routes, dans les Cours D'école, aux Façades des Bâtimens Ruraux.*" It is a very instructive little work, which deals with fruit-growing in its relation to market supply.

Growing Tall Trees.

In most civilised countries, fruit trees are cultivated on two different systems, which are essentially dissimilar, whether we take into consideration the end to be attained or the means taken to attain it. The first and least important is where fruit is grown on a small scale as a luxury by the wealthy amateur or professional grower; the second and most important is where it is grown on a large scale for sale at a cheap rate in the open market. Under the first system, the improving and perfecting of the fruit cultivated has been the main point arrived at, quality being everything, and quantity merely a secondary consideration; under the second, an abundant supply of fruit of good flavour and fair appearance for sale on a large scale for the general consumer. It is with the latter system that we have more especially to deal. Fruit trees grown in the open air are generally grafted in such a manner that the lower branches are not less than 5 ft. or 6 ft. from the ground. The method of producing such trees may be considered under two heads, the formation of the stock and the formation of the head. To acquire the development necessary for the growth of good fruit, the stocks ought to be produced from good seeds gathered from trees of a vigorous habit of growth. Fruit seeds are used with two objects, either to produce new varieties possessing different properties to those of the parent tree, or else to produce healthy stocks for grafting. Every year we see new varieties produced from seeds, and replacing inferior qualities in the market. Such varieties are liable to degeneration on account of the artificial manner in which they are propagated, so that we have lost a large number of old varieties. Others, again, which at one time were perfectly hardy and thoroughly capable of resisting the inclemency of the weather, and which could be easily grown in an open orchard, must now be grown in well-sheltered gardens, and in soil of the very richest quality. Such varieties as these are unfit for orchard cultivation, and would yield nothing but small, hard, tasteless fruit. A seedling which gives good fruit is a real treasure in an orchard. Seed sowing is generally practised for the sake of producing healthy stocks for subsequent grafting, for which reason little need be said with regard to the choice of seed, except that the parent tree ought to be well-shaped, vigorous, and healthy, and, if possible, a wildling. Although varieties do not reproduce themselves exactly always, there are a few sorts which may be depended on for propagating by seed, and when once they have become large enough to fruit abundantly they appear to act like natural species, and reproduce themselves exactly, such, for instance, as the *Pêche d'Oignies*, *Burgnon de Féligny*, *Abricot pêche*, &c. If on the other hand, we sow seeds taken from these varieties grafted on a wild stock, the seedling proves quite a distinct sort. It has been found that trees grown from seed without grafting are less liable to the effects of bad weather, and are more fitted to the ground they occupy than being so to speak natives of the soil. They are also generally stronger and healthier than grafted or imported trees. In order to keep the seeds in proper condition they should be well dried, and then mixed with damp sand or mould, the whole being placed in a jar or box, and kept in a cool place or buried in the ground so deep as to be out of the danger of being frozen. By this means the germinating power of the seed is not only preserved, but the moderate dampness by which the seeds are surrounded causes them to swell slightly, so that when sown in the ground they germinate more quickly.

Some growers keep the seeds in a thoroughly dry place during the whole of the winter, and soak them for a few days just before sowing time. This method, although serviceable in case of necessity, is, nevertheless, not to be so thoroughly relied upon as that described above. Seeds which have not been properly kept are longer in germinating, often taking a whole year before they give signs of life, or else they do not germinate at all. Trees grown from seeds which have remained too long in the ground are always sickly. The seed should be sown in sand some time early in spring, in a rich soil made into little ridges. The ground where the sowing is to be made should be kept clear of weeds during the summer by covering it with short Grass or manure, half-rotten tan, hop refuse, or dead leaves, which, by their decomposition, enrich the soil. In dry situations shallow trenches, about 4 in. deep, should be made between the paths, as shown in fig. 1. Although spring is most generally recommended

Fig. 1.

as the best time for sowing, it is equally advantageous to sow in November and December, the seeds germinating earlier and more regularly. Mice, rats, and birds may, it is true, prey on the seeds, but this objection applies equally to seed sown in spring. The long-established custom of sowing tree seeds in spring is a mere tradition, and more of a prejudice than a principle. It should be borne in mind that Nature, who ought to be our guide, sows her seeds at the end of the year, and not at the beginning. Sowing on a small scale should be practised on every holding, large or small. To begin with, the seeds of the fruits consumed at the table should be carefully preserved. A bottle or jar half filled with dry sand should be placed on the mantelpiece of the sitting room, and the seeds thrown in from time to time, the sand being well shaken up at every addition. The seeds should be sown one by one in long rows, in shallow drills, at the end of the year or early in the spring, the drills being covered over with short manure. Seed sown in this manner furnish strong stocks for after grafting.

FIRST YEAR.—If the young plants are too crowded they should be thinned out, and about a year after sowing they should be planted out, taking care to choose the healthier-looking and best-formed subjects. Tall, leggy plants should be carefully rejected, as general sturdiness of habit is a necessity, height being a merely secondary consideration. Plants which show a tendency to throw out lateral branches should also be rooted up, such subjects never forming vigorous trees. This remark applies especially to seedlings which are intended to bear fruit without grafting. For this purpose stubby young plants, with smooth, even stems, and without many side branches, should be chosen. When the young seedlings are planted out the side branches should not be pruned, as in so young a subject it would endanger its future health. The tap root only should be cut down to one-half. The best mode of planting out is that shown in fig. 2. The young trees

Fig. 2.

should be planted in rows about 18 in. or 20 in. apart, the distance between the plants being about 15 in. After the lapse of two or three years they should be thinned out so that only the plants marked O are allowed to remain. The others should be re-planted elsewhere in rows, about 2 ft. 6 in. to 3 ft. apart. The young seedlings are allowed to grow in their own way during the first year, care, however, being taken to remove the ends of any of the lateral shoots which appear to injure the main stem by too much luxuriance.

SECOND YEAR.—During the second year the side shoots should be moderately shortened without cutting them away

entirely, because they help the growth of the stem. If any of them prove too vigorous they should be pruned down close to the bark of the main stem, otherwise they will give rise to large scars if pruned down in after years.

THIRD YEAR.—If the trees have grown vigorously during the first two years, the third year should be chosen for transplanting them elsewhere, and at the same time of again reducing their tap-roots. From this time the side shoots should be pruned down close to the bark of the stem every year. The pruning of the side branches of the Apple may be commenced earlier than in the case of the Pear, which ought to be allowed to keep its lateral shoots for a year or two longer. The method of pruning the side shoots generally adopted by fruit growers is extremely defective. For fear of making too great a scar the branch is not pruned close enough to the stem, as shown in fig. 3. By not removing the swelling at the point of junction, the wound, although smaller, does not heal so readily. There is no danger in increasing the size of the wound by cutting close to the stem, such wounds healing much more quickly and healthily than those which project from the stem. If we wait until the stem be fully formed before we commence pruning the side shoots, the wounds will be too large, and the

Fig. 3.

Fig. 4

trunk will become too knotty, besides being checked in its growth. It may happen that, in spite of all our care, the stem will show a tendency to grow crooked. This must be corrected as gently as possible by means of stakes or wires, as it is an absolute necessity that a perfect fruit tree should have a straight, symmetrical stem. It should, however, be remembered that a tree which has been made straight by training is never so vigorous as one which has required no such artificial aids. If the trees have been properly chosen in the first instance, staking and wiring will be found quite unnecessary.

FOURTH AND FIFTH YEAR.—By the middle of the fourth or fifth year, the young seedling will have reached the height of 7 ft. or 8 ft. The top shoot should now be pruned down, as shown in fig 4, a few lateral branches being left to form the crown of the future tree. We must now decide whether we shall allow the young seedling to bear its own fruit, or whether we shall use it as a stock for grafting purposes. We shall also have to determine whether we shall leave it where it is for two or three years more before transplanting it to the position which it is to occupy permanently, or whether we shall graft it on the spot before planting it in the situation we intend it to remain in for the rest of its life; the latter method is the best. We may remark that the height of the stem will differ according to circumstances, and that it should be kept as

low as possible, other things being equal. It must always be borne in mind that in low and damp localities where a large amount of evaporation is always going on, and in foggy climates, it is advisable to allow the stems to grow taller than those planted under opposite conditions, on farms or roads where there is a free circulation of air. Where fruit trees are intended to be planted in school playgrounds or in open spaces or roads, it is as well to grow them with extra tall stems, in order not to lead unscrupulous fruit lovers into temptation. The same remark applies to trees planted in meadows, where cattle are apt to destroy the young branches. Those trees, which, like the Apple, have pendent branches, should have taller stems than those whose habit is more upright, like the Pear and the Cherry, although the contrary rule

[Fig. 5.]

seems to be observed in many cases, Pear trees having tall stems, while the branches of the Apple trees sweep the ground. In Holland, where so much of the land is below the level of the sea, the stems of fruit trees are not allowed to grow to a greater height than 5 ft., so as not to reach above the tops of the neighbouring dykes. By this means, they are effectually protected from the sea air, which generally exercises an evil influence on fruit trees. On the other hand, very tall trees are to be avoided, seeing that the higher the tree the more difficult it is to look after, to say nothing of the damage done to the fallen fruit and the difficulty of gathering the crop. In growing Apples, it must be recollected that one of the causes which prevents this valuable tree from holding a proper position in orchards, is the ill-proportioned height of the stem. A glance at almost any of our orchards will be sufficient to show the rarity of a symmetrically-grown Apple tree. We shall also find that the most shapely trees are those which, from one cause or other, are the shortest. The Bellefleur de Brabant Apple tree affords an excellent example of a symmetrically-shaped tree of moderate height, as shown in fig. 5.

SIXTH YEAR.—Although it is not usual to graft trees so early, this operation may be performed on healthy young subjects whose development has been unchecked by adverse circumstances, during the sixth or seventh year of their growth. It must never be lost sight of that it is rarely advantageous to begin to graft before this period, for it must always be borne in mind that the stock develops much more slowly after grafting, and that a healthy crown can never be grown on a weak stem.

Formation of Trees by Double Grafting.

The custom of allowing trees to attain their full growth in the wild state ought to be entirely given up. Both Pear and Apple trees are more easily grown, and produce straighter and more vigorous stems, with a smaller amount of training in the case of the cultivated varieties, than if their wild congeners are used. We are aware that the truth of this principle, which we have always advocated, in accordance with our own experience, has been frequently questioned, possibly because it has been but sparingly adopted by small growers, or else has been misunderstood by them. Orchard trees grown in this manner are lower in stature and more prolific, for the reason that they must be grafted twice. To grow stocks on this system, we must begin by sowing and planting out the varieties required, the wildlings being shield-grafted with those kinds which are more distinguished for the rapidity and vigour of their growth than even the wildlings themselves. The stocks

thus obtained are afterwards grafted a second time with scions of the variety and height we desire. The varieties of Pears recommended for double grafting are Cumberland, Souvenir de Simon Bouvier, and especially the Canada Pear. This latter is a local variety, and is, without doubt, the best for growing strong, straight, and, above all, healthy stocks. At one time the Bezi d'Antenaïse was thought to be the best variety for this purpose, but, as M. Burvenich has proved, the scions grown from the Canada variety are far superior in point of healthy growth. The wood of nearly every variety of Apple grows with sufficient strength and rapidity to form tall stocks; there are some kinds, however, such as the Marais, the Rambour d'Automue, the Rambour Papeleu, and the President Dufays, all excellent varieties for double grafting. Amongst cultivated Plum trees there are several which grow rapidly and yield stocks which are much softer than those of the wild varieties. The Altesse Plum is one of the best kinds for double grafting in

Fig. 6.

Fig. 7.

the case of Apricot and Peach trees. It is by no means a rare variety, and is found in most orchards. It yields a good fruit for drying, of medium size, oval in shape, and of a blue colour, the stone separating easily from the flesh. The Hazard and the Bavay Green Gage are also valuable for the same purpose. As regards the Wild Cherry, its habit leaves nothing to be desired. If, however, the subjects chosen show a tendency to grow crooked, it is well to graft them low down with the Bigarreau Napoleon, which will soon give a strong, straight stem. One advantage possessed by this method of forming tall stocks by double grafting is, that no matter how crooked, thorny, and knotty the wild subjects may be, they can always be used, provided they are healthy and strong. One year after the double graft, all the young trees, no matter how irregularly they have previously grown, have developed into uniform subjects, similar to that shown in fig. 6, their height being generally about 5 ft., or say two-thirds of their ultimate height. Wildlings of three years, and even more, which have grown irregularly, may be converted into straight subjects by grafting close to the ground, provided they are sufficiently vigorous. In fig. 7 a strong stock is shown treated in this manner, and it often happens that even during the first year the young scion will reach the height of its crooked predecessor. There is, therefore, no longer any excuse for growing crooked or knotty trees. The grafted stock is allowed to grow

to the desired height, according to the preceding rules, with this difference, that they increase in size so quickly that there is no need to take any heed of the side branches during the first three years. It is by no means unusual for stocks grown in this manner to be ready for the second graft in the fourth year, in which case the young stock should be shield-budded with the variety required.

(To be continued).

VINE MILDEW.

THIS is a fungoid growth upon the young leaves and fruit of the Vine, and was not known in this country until about the year 1847, when an account of it was given by Mr. Tucker, of Margate, where it was first observed; hence it received the name *Oidium Tuckeri*. In America, however, it had been known to exist for many years previously, although, singularly enough, the American varieties of Grapes are but little affected by it. In this country it has caused great destruction amongst Grapes, both in Vineries and in the open air, and in Vine-growing countries the entire season's crop is frequently destroyed by its agency. This mildew appears to the naked eye like a little white powder only, resting on the leaves, &c.; but by the aid of the magnifying glass, it is seen to be a true vegetable parasitical growth. It is a most insidious enemy, and requires extreme watchfulness, so as to observe its very earliest appearance, in order to check its progress. It vegetates very rapidly; from a small speck, it will in the course of a few days spread over an entire house, and if not arrested in its growth, its roots will have penetrated so deeply into the tissues of the affected parts as completely to destroy them. The mildew itself may be arrested and killed, but its effects are left, the skin or cuticle of the berry being blackened and injured beyond recovery. It seems to render the berry incapable of distending further, so that it soon splits open, and is of course ruined. The tissues of the leaves are also injured in much the same way. As to the causes of the Vine mildew, they are, as in most other diseases, very difficult to trace. Certain atmospheric conditions are favourable to its development, as to that of all fungoid growth. There is no more fertile source than cold, damp, sunless weather, with a stagnant atmosphere, and especially if this be succeeded by bright sunshine. On Vines grown in the open air, there is seldom a season in which they are not affected to some extent, but frequently it occurs so late in the season as practically to do but little harm. The prevention of mildew ought, if it be possible, to be the chief endeavour of all Vine growers; and in houses or Vineries it may be almost prevented. In the open air, it is much more difficult to contend with. As a stagnant atmosphere is favourable to its development, it naturally follows that one of the surest preventives is air—plenty of sweet fresh air—and this can be secured to a great extent by proper ventilation, and a judicious use of the heating apparatus to set the air in motion. Where this is not available, a drier atmosphere should be maintained in the house during cold weather, avoiding all unnecessary syringing or damping. In order to arrest or destroy the mildew where it has once obtained a footing, many and varied means have been adopted and recommended. The most effective, indeed the only truly effective agent, is sulphur, or certain compounds of which sulphur forms the major part. It is chiefly in regard to the method of application that the distinction between the various agents is made. Firstly, let it be noted that the sulphur must not be ignited in any way, that would to a certainty not only destroy the mildew, but also the Vines themselves. We have seen Vines so treated and so destroyed. As a preventive or safeguard, it is not a bad method to give the hotwater pipes—not a flue—a washing or coating over with the flowers of sulphur mixed with water, the gentle sulphurous fumes thereby arising being destructive to the mildew. Another very effectual method is to throw sulphur on lumps of freshly-slaked lime, which will have a like result. The most effectual and simplest remedy of all is to dust flowers of sulphur all over the Vines. This will, in the course of a few days, destroy the Fungus, when the sulphur should be immediately washed off by a forcible syringing with clear rain-water, otherwise the Grapes, being covered with the sulphur, would be spoiled. Many varieties of sulphurators have been introduced, but the simplest of all is the ordinary penny pepper-box. Various liquid compositions, which are applied by means of the syringe, have also been introduced, and are effectual in its destruction, such as Gishurst Compound and others, but as these frequently contain a proportion of oleaginous matter, their use for the destruction of mildew on Grapes is not to be recommended. Quite recently, a very effectual and excellent liquid application for its destruction has been introduced by Mr. Speed, of Chatsworth, which is stated to be altogether innocuous, and immediate in its effects. It is applied with the syringe, and immediately washed off.—“Florist.”

FLORA OF CHINESE AND JAPANESE VASES.

A SUBJECT such as is suggested by the above title may aptly be divided into two parts—the first referring to the plants grown in the vases, and those figured on them. The singular vase gardens of the Japanese formed the subject of a note in the last volume of *THE GARDEN* (see p. 223, Vol. XI.), and a few particulars regarding them, in addition to what was there stated, may be of interest. The three plants in the vase figured are three of the most popular favourites of Japan; the Conifer, indeed, can scarcely be specifically identified, but many species are much esteemed by the Japanese for vase-cultivation. Two or three years back, a figure of a variety of *Pinus densiflora* treated in this manner, which was supposed to be at least a hundred years old, but which was only a metre and a half high, was growing in a pot only half a metre in diameter: this was brought from Shiba, the site of the mausoleums of the old Tycoons of Japan, at Yedo. *Sciadopitys verticillata*, *Pinus Trassoniana*, and some species of *Retinospora* and *Thuja* are much employed in this manner. This dwarfing depends upon the prevention of an abundant flow of sap, so that, although the tree is kept alive and even healthy, its growth does not go on with its natural activity. They are planted in shallow, narrow pots, and care is taken that the roots never pass through into the ground beneath; water is but sparingly supplied, and the leading and strongest shoots are pinched off, while those that are allowed to remain are bent and twisted in various ways. The other plant in the upper vase will be recognised by those familiar with greenhouse plants as *Lagerstrœmia indica*, a native of China, and, like so many of the native plants of China and Japan, commonly cultivated in the gardens of those countries. It is at once recognised by the curiously crumpled appearance presented by the pretty rose-coloured petals; and is frequently to be noticed on Japanese porcelain and lacquer-work. The *Chrysanthemum*, which occupies the lower vase, is, as every one knows, a most popular Japanese flower; it supplies the official crest of the Mikado, and is constantly occurring on porcelain, silks, or cabinet work. One method in which the Japanese employ the *Chrysanthemum* is sufficiently remarkable, and is described by Mr. Fortune. In the tea gardens near Yedo, imitation ladies are made up out of the flowers, thousands of which are employed for the purpose; and the effect of the appearance of these figures in the little alcoves and summer houses is described as sufficiently startling to one not accustomed to such sights. The Japanese mode of grafting *Chrysanthemums* on the stout stems of a species of *Artemisia*, and then training them as standards, presents a curious appearance to English eyes.

It is perhaps not generally known that the Japanese are as fond of bouquets as they are of flowering plants, and that they construct them in a very artistic manner. This was well shown by Mr. G. A. Andley, in a lecture which he delivered in London a few years since upon "Japanese Art." According to his description, dwarf trees and clusters of large flowers are associated together without any attempt at symmetrical arrangement, this, indeed, being strictly avoided. Sometimes we find a piece of Bamboo rising straight up among the flowers, with a delicate creeper climbing round it, or a slender branch of some choice plant stuck into its side and deriving water from the hollow stem; or occasionally, if the Bamboo be a large one, its top joint is filled with earth, and a miniature Oak or other tree is planted therein. Occasionally a yet wilder effect is produced by the addition of gnarled and twisted branches to this already eccentric bouquet; these branches are sometimes leafless or have tufts of leaves at their extremities, and wander about the bouquet in a most erratic manner.

The polychrome porcelain of China has been classified according to the style of decoration which predominates in various examples. Thus, in the chrysanthemo-pæonian family, *Chrysanthemums* and *Pæonies* (*Pæonia Montan*) "invade the ground, overcharge the reserved medallions, and even appear in relief in the appendages of the vases." The bouquets with which the reserves are filled sometimes contain, besides the flowers mentioned, blades of Grass, branches of Peach or Plum in blossom, and a kind of double Pink. The *Nelumbium*, or Sacred Bean, also occupies an important place upon certain

large vases, especially in those of the "Green Family," a group which is distinguished by the presence of a brilliant copper-green colour. The greater number of plants have a symbolic as well as an ornamental value; and this explains the use of the *Nelumbium*. "We see [on one of these large vases] boats filled with young women, their sleeves turned up to the

Japanese Vase.

shoulders, about to plunge their arms into the water, not only to gather the flowers, but to pick up the stalks already laden with the ripe fruit; through an archway opening to the palace the boats return, and upon an upper terrace the superior and his family, surrounded by dignitaries, are about to make a traditional repast, composed only of the Almonds of the *Nelumbo*, and which serves to recall annually to the hundred families,

as well as to the greatest persons of the empire, the frugal life of their ancestors."—Jacquemant's "History of the Ceramic Art." The Feast of the Nelumbo is an important occasion in certain apartments of a Chinese palace, occupying much the same position as the Feast of Tulips in the residence of the Mussulman, and the preparations for it are sometimes represented on vases of the "Rose" class.

On Japan porcelain of the family first mentioned, we often find, besides the guik-mon, or arms of the flower of the Chrysanthemum, which, as has been already mentioned, is the badge of the Mikado, but also the Kiri or Dairian tree (*Paulownia imperialis*), which is more particularly his official ensign or mark of power. The Kiri is not only stamped upon the coins, and upon everything intended for imperial use, but is even impressed on the bread or cakes served in the official repasts given to the Dutch ambassadors. Some specimens of Japanese vitreous porcelain are enamelled with rare beauty. "Some," says Jacquemant, "have light bouquets delicately studied, thrown irregularly upon the milky surface—the *Begonia*, with its crimson-lined leaves and delicate flowers; the *Banana*, with its purple bractæ; the blue *Lily of Japan*. But even the ordinary blue cups in vitreous porcelain are characterised by their form, which resembles the flower with irregular petals of the garden *Hibiscus*. The creamy paste adapts itself wonderfully to the representation of vegetable fibre; strokes graven in the thickness of the porcelain render the smallest veins which radiate from the base of the petals; and the outer limb of these forms, round the cups and saucers, the most graceful edging of six lobes that can be imagined." The kind of Japanese porcelain known as Indian porcelain with flowers is especially characterised by the special nature or particular delineation of flowers, especially the *Chrysanthemum*, *Rose*, *Pink*, *Jagged Poppy*, *double Anemone*, *light*, *diminutive flowers*, *Cinerarias*, and, more rarely, the *Celosia* or *Cockscomb*.

B. J.

RIPE GRAPES LOSING COLOUR.

It is no easy matter to lay on that jet-black colour and perfect bloom which is the pride of the most successful Grape growers, and to have it disappear while the Grapes are waiting to be eaten is provoking. That best of all black Grapes, the *Black Hamburgh*, is the most subject to this change of colour; in fact, it reaches its maximum of blackness before it is fully ripe, and almost as soon as it is ready for eating it begins to lose colour, until, if kept long enough, it approaches that foxy-red state which is the horror of cultivators. Nor does there seem any sure and certain remedy for this state of things. Neither a cool temperature, nor perfect ventilation, nor water at the root will wholly prevent early *Hamburghs* from losing colour as the season advances. There are, however, one or two facts in regard to this change of colour in ripe Grapes which may probably help to elucidate its cause; and, if so, the cause once determined, may lead to a cure, or at least a mitigation of the evil. It will probably be generally admitted that the loss of colour is greater in the south than in the north; that the earlier the crop the more it is affected, and that *Hamburghs* suffer most in this respect. If so, these facts would seem to point to heat, light, and drought as the active causes of loss of colour in ripe Grapes. It may be well briefly to refer to each of these separately. It can readily be proved by experiment that heat may be applied to such an extent to Grapes as to prevent their colouring, and also to force them to lose it afterwards. If such be the fact as regards artificial heat, of course solar heat is still more powerful. Consequently if Grapes be ripe in April, May, or June, and fully exposed to all our summer and autumn sunshine after maturity, it seems alike natural and reasonable that they should lose their colour. As solar heat declines, either from a change of latitude or of season, the loss of colour is less—thus almost proving to demonstration that the loss of colour is caused by heat. Doubtless, too, light has a good deal to do with the loss of colour in ripe Grapes. Light is evidently the most active promoter of chemical changes in vegetable life and products—the maker, developer, and destroyer of colour. Comparatively few of what may be termed the vital colours of plants or fruits are fixed or permanent. Conse-

quently, the colour of Grapes, though it seems to us to be a fixed and permanent quality or quantity, is probably not so. It waxes greater and deeper till it reaches a maximum; it then immediately begins to wane until it reaches the foxy state. If this representation of the matter be in any sense the true one, and if the colouring of Grapes be less like the building up of a house than the flowing of the tide, and the loss of colour the ebbing out of the same, then it follows that the more intense the light, the sooner the Grapes would lose colour, for the light not only lays on, but also dissipates colour. Hence it is found that the shade of leaves, of clouds, or of canvas, conserves the colour of Grapes, while those most exposed to direct solar light lose colour soonest and to the greatest extent. As the sun's rays become more oblique in the autumn, their illuminating and chemical force decline; and hence late Grapes continue black for a much longer period than early ones. There may, however, also be another reason for this difference. Early Grapes probably reach a higher degree of maturity than later ones, and the change of colour, which is mostly associated with greater sweetness, may arise from the conversion of a larger proportion of the flesh and juice of the Grape into sugar, a process which would, of course, be hastened in proportion to the intensity of the light. Drought is doubtless also a cause of the loss of colour in ripe Grapes. Dryness at the roots and semi-aridity of the atmosphere render the flesh of Grapes more or less flaccid, and relaxes the tension on the skin of the berries. How far colour depends on tension and thickness of rind is one of those points that is still unsettled. Marked changes of colour, however, are found to follow changes of tension and internal condition, and as our *Black Hamburghs* become more or less foxy, they, as a rule, also become slightly flaccid or shrivelled. Assuming that drought is one cause of this loss of colour, we can understand why *Hamburghs* would be amongst the first Grapes to be affected, because they are thinner-skinned than most black Grapes. Possibly, too, the Grape rinds differ as much or more in degree of porosity as in thickness. Otherwise it would be difficult to account for the fact that that very thin-skinned Grape—the *West's St. Peter's*—never loses colour, while *Black Hamburghs* mostly do to a greater or lesser extent. Be that as it may, however, there can hardly be a doubt that the excessive dryness of earth and air, which are held to be needful for the safe keeping of ripe Grapes, causes them to lose colour. The dry air is kept in constant motion, and thus of necessity drains out much of the juice, and probably some of the goodness, as well as rubs off a great deal of the colour from the Grapes. It seems worthy of serious consideration whether all this drought at top and bottom, and this violent agitation of the air, are essential to the safe-keeping of ripe Grapes. Late Grapes, and Grapes in more northern latitudes, are kept sound and good under far less arid conditions, and with little or no loss of colour. Were the choice between a loss of colour and the loss of the Grapes by decomposition, no one would hesitate for a moment to let the colour go; but if the colour can be preserved intact as well as the Grapes by a different method of keeping the fruit on the Vines from the prevailing one of drying them up into redness, it may be wise to adopt it. Than this few subjects could be more important or timely for present discussion, for the change of colour is by no means confined to *Hamburghs* nor black Grapes, though, even were it so, it would be of immense importance; but white Grapes, and that best of them all, the *Muscat of Alexandria*, also subject to a change of colour; it proceeds from green to golden—the pledge and proof of perfect flavour in this matchless Grape. But it does not rest there; it runs into a purplish tint, in which it loses flavour, and from thence into dark brown, the prelude to decomposition. As already remarked, *Hamburghs* seldom lose flavour through losing colour; there is, in fact, at times an increase of sweetness, though not of lusciousness. But the great point is to know how to keep the colour of Grapes perfect to the last. Perhaps in the present state of our knowledge the simplest and safest plan is to cut them as soon as they are ripe, and bottle and rail them in the dark in a cool temperature of, say, 45°, and in a still atmosphere, neither too dry nor too moist. Grapes would not then be exposed to the active destroyers of colour to which I have adverted. D. T. F.

HARDY APPLES.

I WOULD recommend those who intend to plant to send orders for what they may want to the nurseries at once, if they have not done so already; and those who require fruit trees should consult the pages of THE GARDEN with a view to ascertain what those varieties are that have not suffered materially by the trying weather that occasioned such mischief to orchards and fruit gardens during the early spring months. That most useful of all fruit trees, the Apple, though it suffered less than did the earlier-blooming fruits, has not escaped; and of many sorts much less than an average crop was produced. Out of about five-and-thirty varieties growing here, Cellini (espalier on the Paradise stock) yielded abundantly, Court-pendu-plat (espalier on the Crab stock) did the same, Blenheim Orange (a large orchard tree) yielded fairly, but most of the Apples on this tree did not reach their usual dimensions. The same may be said of Waltham Abbey Seedling. A very young standard of Bess Pool had as many Apples on it as it could safely carry. But the Apple we most depend on for giving us fruit is one of native growth. I have two standards of it that have borne fruit for many years, and I may say with truth that it never fails. This Apple is little known except in the villages near Manton, where, at the beginning of this century, it was found growing in a hedge. A man named Hotchkin raised several young trees of it in his garden at Lyndon from scions taken from the parent tree. The soil about Lyndon, being a strong clay, is favourable to the growth of most kinds of Apples; but I learned from Hotchkin that this Apple did not grow so well there as it does in lighter soils; and I have found that to be the case. In size and form it resembles the Blenheim Orange; its colour is a greenish-yellow, deepening into a dull orange after it has been kept awhile. It is excellent for cooking, bears abundantly, and is very hardy, and if carefully stored will keep well till February. It is known at Manton by the name of Hedge Apple and Hotchkin Pippin. The latter name was given it by the late Mr. Wood, of Swanwich in Staffordshire, when he was curate of the adjoining village of Wing. There are doubtless many Apples superior to the Hotchkin Pippin, and many that keep much longer; but it may fairly be asked of what benefit would the very best variety be to the grower if he could not rely upon it for producing fruit with regularity and in fairly sufficient quantity? Where the soil and climate are not very favourable to the production of orchard fruit, most housekeepers would, if they were consulted, ask to have planted those sorts upon which reliance can be placed for a supply of fruit. How is this end to be accomplished? The year 1877 may help us to solve this question; and a comparison of the fruit reports sent to THE GARDEN during the autumn months will assist us in fixing upon the varieties that seem, from these reports, to be the most likely to bid defiance to the vicissitudes of seasons and recompense the grower. If I had not happened to have any one of the six varieties mentioned here, the sum of the produce of all the rest would not have equalled that of either the Blenheim Orange, the Waltham Abbey Seedling, the Cellini, the Hotchkin Pippin, or the Court-pendu-plat; and my fruit room, which is now nearly filled, would have been almost empty. All the trees were very full of bloom and I expected an unusually good yield. Some produced a few Apples, and one or two had rather more, but nothing approaching to an average crop. One tree, Fearn's Pippin, though covered with bloom, did not set a single fruit. Nothing that the orchard produces can take the place of the Apple, and any information tending to secure a regular supply of that valuable fruit will be welcomed by every one who has the charge of the domestic commissariat during the long winter months. I may add that I have just ascertained that the Hotchkin Pippin may be found in some nurseries under the name of the Rutland Foundling.

B. S.

Apple culture in Brief.—Prof. Beal, of the Michigan Agricultural College, gives the following directions for Apple growing:—"I think it a good plan to keep young trees mulched, and I am not sure that it is not the best of all ways to treat large or old trees as long as they live. Mulching prevents the rapid evaporation of moisture from the soil, keeps the surface mellow, prevents the soil

from often freezing and thawing in winter, and from becoming overheated in summer. Whether or not to cultivate the ground under trees which have become well established depends upon circumstances. I have never seen an Apple orchard which I thought was injured by too frequent shallow culture, but this may be the case in some places, especially in warm climates, or where the soil is deep and very rich. Whether to cultivate or not can be told by the appearance of the trees. If the colour of the leaves be good, and the growth all right, and the trees bear plenty of fine fruit, they are doing well enough, even if in Grass; but if the leaves are pale, the growth of the annual twigs much less than 1 ft. in length on trees twelve years planted, and the fruit small and poor, something is the matter; they are suffering from want of plough, harrow, or cultivator, or a heavy mulch or coat of manure, or two or more of these combined. The upper twigs of trees planted twelve years ought to grow from 6 in. to 12 in. or more each year."

"Does Protection Protect?"—All my gardening life have I been a sceptic on the ill effects of a low temperature when unaccompanied by wind. Several years ago when the mercury fell to 14° below zero, and the air was perfectly still, the Peach buds were apparently uninjured; but another season not nearly so cold, yet exceedingly windy, the buds were unmistakably killed. This theory has been fully demonstrated during the past spring in many instances, but in one particular case was it very convincing. A long bed was devoted to Strawberries, and this was skirted in the back by a fine Hemlock hedge. At one end of each is a building, so situated that the high north-west winds during winter were prevented from striking either for two-thirds their length, but the main portion being fully exposed, indicated when spring opened the exact line of the division between the protected and unprotected sections of both bed and hedge. In the first of these the Strawberry plants were so badly injured as to produce little or no fruit, and the hedge was so badly cut up as to need replacing. In the protected portion no Strawberries were as fine as any I have ever grown, and the hedge is a model of beauty. Along the north side of my dwelling I have a bed of Rhododendrons; at the western end where the wind sweeps around the corner, the plants were all more or less damaged, but at the other end of the bed they were uninjured. These high, drying winds, causing excessive evaporation, injures the vitality of vegetation during the season of partial rest, for vegetation is never entirely dormant. Strong, cold winds during a drought in winter are invariably destructive to all manner of plants not iron-clad, and moisture will go far toward remedying the evil. With all our boasted knowledge of plant-life and the influence exerted upon it by the weather, we are frequently puzzled to ascertain the cause of many a mishap to our choice trees and plants. Acclimatisation is a delusion and a snare, as many of our cultivators have no doubt learned to their sorrow, time after time. As a partial remedy I want to impress upon the minds of my countrymen that protection by means of screens and groups of Evergreen trees is the best investment made by any one living in the country; at least, such has been my experience and observation.—JOSIAH HOOPES, in "Tribune."

Pelargonium Trials at Chiswick.—The following is a select list of the best varieties in each class:—FLOWERS SCARLET (NOSEGAY SECTION)—Wellington, H. M. Stanley, Duke of Devonshire, and Waltham Seedling. FLOWERS PALE ORANGE-SCARLET—Triomphe de Stella, Golden Harry Hieover, Grand Duke, and Mrs. J. George. FLOWERS LAKE-ROSE—Arthur Pearson, Lawrence Heywood, and Violet Hill Nosegay. FLOWERS SCARLET SHADED WITH MAGENTA—Caxton, Argus, and A. Rivers. FLOWERS SCARLET, LEAVES ZONATE—Vesuvius, Mark Twain, Rose of Summer, John Watson, Wonderful, and Aurora. FLOWERS SCARLET WITH WHITE EYE—A. F. Barron, Harry King, Richard Dean, and Theocritus. FLOWERS SCARLET, LEAVES PLAIN GREEN—Duke of Sutherland. FLOWERS PALE SCARLET—Red King and Colonel Wright. FLOWERS CRIMSON-SCARLET—Mrs. Vincent and Rev. F. F. Fenn. FLOWERS CERISE AND ROSE—Lucius, Princess of Wales, Claude de la Meurthe, and Ianthe. FLOWERS PALE PINK—Christine. FLOWERS ROSE-PINK, LEAVES PLAIN—Mrs. Augusta Miles, Mrs. Hallibarton, and Cleopatra. FLOWERS ROSE-PINK, LEAVES ZONATE—Rose of Allendale. FLOWERS PINK, SHADED WITH PURPLE—Mrs. Turner and Amaranth. FLOWERS SALMON—Vanessa. FLOWERS OCULATE—Lucretia and Eugénie Mézard. FLOWERS WHITE—Snowdon. GOLDEN TRICOLOR—Mrs. Pollock, Countess of Ashburnham, Fair Emily, Lady Cullum, Bright Eyes, Macbeth, Home Influence, and Beautiful for Ever. PLAIN GOLDEN VARIEGATED—Golden Superb Nosegay, Robert Fish, Golden Harry Hieover, Creed's Seedling, and Crystal Palace Gem. SILVER TRICOLORS—Lase O'Gowrie, Glen Eyre Beauty, and Prince Silverwings. SILVER VARIEGATED—Little Trot, Albion's Cliffs, Miss Kingsbury, Princess Alexandra, and Silver Chain. BRONZES—The Czar, Black Douglas, Maréchal MacMahon, James Richarde, and W. E. Gumbleton.

HINTS FOR PLANTERS.

As planting forest trees will now be general, the following concise remarks on the work may prove instructive, and assist those about to engage in the operation. The ground ought to be securely enclosed with a good ring fence. Draining should be finished some time before planting begins, so that the ground has time to "drip." It should be remembered that the necessity for draining arises from water rising to the surface in springs; or, from the flatness of the ground, it is flooded with water oozing out from higher land, and also from the retentive quality of the subsoil. A superabundance of water is located in the stratum immediately beneath the surface. Stagnant water is extremely injurious to trees, and draining should never be neglected. Clearing brush and other obstacles to planting may be done any time previously to the time of planting, but moorland subject to rank heath should always be burned some years before, so that a fine young healthy sward covers the surface, which affords valuable shelter to small plants. The forester should ascertain as far as practicable the nature of the soil, subsoil, and if possible the rocky formation, to enable him to distribute his plants judiciously over the ground, giving each individual its *locale* subsidiary with correct arbori-chemical principles. It is further necessary to be thoroughly conversant with the situation, to allot such plants suitable for exposed aspects their proper place, that as the trees grow up they may be beneficial. The next consideration is the number of the various kinds of plants to form a mixed plantation, and also their size. Having examined the nature of the soil and its surface herbage, also having decided on the tree intended to form the permanent crop, these will give the best guide to go by. The hard wood need never be planted closer than 24 ft. or 30 ft. apart. Several kinds of planting-irons (tools) are recommended, but a common Scotch spade (the spade universally in use in Scotland is greatly superior to that in England or Ireland) is the best adapted for all practical purposes. In removing plants from the nursery row great care should be taken not to cause root fracture, more especially with the resinous tribe. Pit planting is very common, but every variety of pitting has some forcible objection to its use. The loosened earth admits of a greater evaporation in dry weather, and absorbs too much moisture in winter, and, being a slow process, increases the cost of planting very considerably. Slitting or notching is certainly the best system of planting. It commends itself by being the most expeditious. There are four kinds of notches, all well adapted to varying circumstances: the T (tee) form is very answerable in stiff ground; the L (ell) for small plants; the H (aitch) for a tough surface and large-rooted plants; and the X (cross) for deep surface and large plants. It is advisable to pare off the surface before putting down the tree; to do this entails very little extra labour. The planter stoops low, and with a smart horizontal swoop of his spade pares off a thin scraw, and exposes the fresh soil beneath. In making the notch the operator strikes his spade into the ground perfectly perpendicular and as deep as possible, and by again striking across the first slit a notch is made similar to one of the letters shown above, which, by heading down the handle, is sufficiently opened to receive the plant. If the incision be well made, a smart blow with the heel on each side of the plant is all that is required to firm it in the ground. Great care should be taken to see that the roots are all well under the sod and the plants straight. Much depends on the first cut. An expert spadesman amalgamates the operation of paring off a scraw with the making of a notch, and will, with a boy holding the plants, put in from 1,000 to 1,500 plants per day of ten hours. Planters should be arranged into squads of twenty or thirty spadenmen, with one boy or girl to attend two men, and one or two stronger boys carrying and supplying the planters with plants from the "stock," "sheugh," or "bed"; the whole gang to be under one foreman, whose duty is to superintend the work and see it properly performed. On laying the men ought for the work the most experienced hands should be placed at each side to act as leaders. The squad should work from side to side. Commencing in the morning at the fence, the leading man after putting in his plant moves off 8 ft., the second spade putting his plant between the leader's two, but 4 ft. behind, and each succeeding man follows inserting his plant between the preceding man's two, until the limits of the enclosure is reached, when the foreman gives the order "reverse," and each man falls back one space, puts in a plant, and without the least confusion as to places makes the spade once the rear now the leader on the return journey. By this system the foreman is able to detect the smallest irregularity, and by moving backwards and forwards can see every plant put into its place.—"Journal of Forestry."

The Late Gale.—The gale which swept over this part of Devonshire on the night of the 14th inst. has been most disastrous in its effects. Some of our finest old trees, Elm, Ash, Beech, Wild Cherries, &c., are torn up by the roots. I have just measured one of

the largest Elms, and find the diameter of its bole at the base to be 7 ft.; it has upturned a ball of soil 16 ft. high and 18 ft. wide, but barely 3 ft. deep. Many other trees of large size are also torn up by the roots, and others, varying from 1 ft. to 3 ft. 6 in. or 4 ft., are broken off at different heights up their boles. One large Beech where it is broken is a mass of splinters, like a loose bundle of laths, while tops of young Cedars, Silver Firs, &c., are broken almost clean off. Trees, the roots of which kept firm hold, are snapped asunder. We have about 30 ft. of the top of a fine Douglas Fir broken off, the broken portion being apparently rather more than one-third the height; the diameter at the point of breakage is 16 in. On Monday morning the pleasure grounds and park were strewn with broken branches of all sizes, from the smallest spray to the tops of large trees. Among the trees which suffered least are the Turkey and Lacombe Oaks, fine specimens of which occupy the most exposed situations. It would, therefore, be well for planters to use these more freely than they do as nurses and wind-screens in places much exposed. In the case of English Oaks, although very few are blown down, their heads and smaller branches are much broken. In the flower garden, Pelargoniums, &c., that were in full flower lost every blossom, and the foliage generally seemed scared and withered. Peas, Scarlet Runners, and Jerusalem Artichokes exhibited the same appearance, while many plants of autumn Broccoli were twisted out of the ground. Such a gale has not occurred here for many years.—JOHN GARLAND, *Killerton, near Exeter*. [Disastrous accounts of the gale in question have also come from other quarters. At Holme Lacy, Hereford, an old Tulip Tree, one of the finest in the country, is a perfect wreck. The havoc among Oaks and Elms is said to be dreadful. In this county, too, according to newspaper reports, no fewer than 10,000 Apple trees have been uprooted, and the destruction committed amongst fruit trees in Moamouth is also said to be very great. At Wolverhampton, in the colliery districts, much damage has likewise been done. An immense Oak and some Elm trees, the growth of centuries, have been uprooted and blown across the road close to the town. "T. M. M.," writing in the "Times" from Budleigh Salterton, states that the appearance of the gardens and landscape on rising on Monday was of a magical nature, the former being hopelessly withered up, as though baked in an oven, while the latter had all the trees browned and dried up to a dirty brown paper appearance. This dry gale, he adds, is a fit sequel to a summer of wonderful dryness here, there having been only twenty-seven days on which rain exceeding 3.100ths of an inch fell in the last 137, viz., from the beginning of June.]

Peen-to, or Flat Peach of China.—In the April number of the "Gardeners' Monthly" I referred to this peculiar variety, which, although in my collection for a number of years, had heretofore failed to produce fruit. Some two years ago I gave a friend residing in Pensacola, Florida, trees of the most promising of my varieties, and to-day (June 23) he sends me a box of the fruit with the following note:—"At the time when we received the trees you stated that they would not answer for Georgia. I can assure you that here they are a perfect success, and just the Peach for this climate. The samples I send you were taken from one tree, from which we have plucked 1200 Peaches." As this is the first instance of the Peach having fruited in the United States, it may be interesting to California and Florida fruit growers to know more about it. I add the description of the fruit. Size, from 2 in. to 2½ in. in diameter; shape, irregularly round, and very much flattened; 1½ in. thick on one side, and 1 in. on the other; a deep furrow starts on the thinnest side from the stem and ends on the apex, where a deep hollow is formed, having in the centre a deep, narrow calycinal cavity; skin greenish-yellow washed with carmine, and a deeper cheek on one side; flesh white, exceedingly fine in texture, juicy and melting, and with a delicate almond flavour; clingstone; quality very good; pit quite flat; tree a very rapid grower, of open habit; holds its leaves later than any other variety.—J. J. BERKMANS.

The Potato Beetle in Iowa.—We have received from Messrs. Cheal & Sons, Lowfield Nurseries, Crawley, Sussex, the following extract from a letter which they have received from a relative of theirs, a farmer in Iowa:—"Earlham, Dallas County, Iowa, U.S.A.—Potatoes look well here, considering the dry weather which we have had, and the Potato beetles have not damaged them seriously. You English people seem to be too easily scared respecting this beetle. Here they do not give us much trouble, though we have thousands of them. If they are picked off at first, they do not do much harm afterwards. They deposit their eggs on the under sides of the leaves, and the lady-birds eat them. Were it not for the latter, the beetles would be swarming, and I think there are more lady-birds in England than here. Paris green will kill them, and Guinea fowls will also eat them. People say if you plant three Flax seeds with every Potato, they will keep off the beetles. If the Potatoes be planted out early, they get up strongly before the beetles make their appearance, and

after the Potatoes have grown to a considerable size they keep ahead of such pests. We never plant Potatoes two years in succession on the same ground. Some neighbours did so last year, and did not get a Potato. In picking off the beetles, care should be taken not to squeeze them too tightly, as their blood is poisonous, and will raise a blister. The best way to kill them is to scald them in hot water."

A SERIES of HORTICULTURAL EXHIBITIONS will be held at Dresden, in 1878, in honour of the jubilee of the Flora Society, which was established in that city in 1828. The first exhibition will be held from March 21 to 25; the second from May 16 to 20; the third from July 25 to 29; and the fourth from October 3 to 7.

FROM Mr. Wilder's recent address at Baltimore, we learn that as long ago as 1773, when the crop of Apples had failed the previous year, English importations from this country had been made and were highly appreciated. In a letter from Michael Collinson to John Bartram, of Philadelphia, he writes as follows:—"Your American Apples have been an admirable substitute this season, some of our merchants having imported great quantities of them. They are, notwithstanding, too expensive for common eating, being sold for 2d., 3d., and even 4d. an Apple. But their flavour is much superior to anything we can pretend to, and I think even superior to the Apples of Italy."

The Belladonna Lily Under Glass.—This, the best of all the hardy Amaryllids, is at present flowering beautifully with us in Wales, planted out in ordinary soil in the bed of a conservatory. Each of its flower-spikes is about 15 in. high, and surmounted by numerous blossoms. It succeeds very well under ordinary treatment in the open air, but if the weather be wet when the blooms open they do not last so long as in a cool house under glass.—A CAMBRIAN.

Pansies and Violas.—Pansies have not a rule done particularly well this season; but Mr. Hooper, Wildcombe Hill, Bath, has sent us blooms of a few kinds which seem to form an exception, for they are as fresh and beautiful as Pansies well could be, even thus late in the year. Amongst dark sorts, the best were *Souvenir* and *Grand Monarch*, a blue one called *Remarkable*, a fiery-crimson and maroon kind named *John Cranston*, and a good light-ground sort, blotched with velvety-purple, called *Conductor*. We have also received from Mr. Paul, of Paisley, an unusually fine yellow seedling *Viola*, said to be a dwarf and free-flowering kind, and evidently an acquisition.—M.

Delphinium Cashmirianum.—This Larkspur is now growing in Mr. Parker's nursery at Tooting. Though as yet scarce, it will no doubt eventually become popular, and may probably, if fertilized with kinds of different habit, give rise to new and important varieties. The plant is found on the Western Himalayas, at altitudes varying from 12,000 ft. to 15,000 ft. The flowers, which are of a bright, purplish-blue colour, are borne on leafy stems from 15 in. to 18 in. high, which are produced freely all round the bases of the plants, and contrast effectively with the green masses of palmate leaves with which the plants are furnished.—C. S.

Ivy on Ruins and Hollow Trees.—In this neighbourhood are numerous remnants of ancient churches and monasteries that have been landmarks for ages, and in most cases they are overrun with Ivy that has sprung from the decayed mortar rubbish, both on the inside and outside walls, and which now has stems more like those of trees than Ivy, crowned with majestic heads of berry-bearing branches, that have never been either pruned or trained. On hollow trees Ivy is also equally effective, not only in garnishing and beautifying their rugged stems, but also in serving as a support for binding together their decayed portions with living bands, thereby mutually supporting each other. There is a decided, and I believe, well-founded prejudice against encouraging Ivy on such trees as are expected to grow into timber, as it is certainly prejudicial to their development. But in the case of trees of ancient aspect, that are past use as timber, it is well worth while to plant Ivy at their bases, and to protect it until it has become well established. It will afterwards well repay the trouble that has been taken with it by converting their bare stems and branches into so many wreaths of luxuriant foliage. The winter aspect of such trees would be poor indeed if divested of their covering of Ivy.—J. GROOM, *Henham*.

Violets by Post.—The season for Neapolitan and other Violets having again arrived, it may not be uninteresting to your readers to know that any one, though away from home, may enjoy them fresh every morning from October to May through the post. They are so well adapted for travelling, that a journey in a tin box of 200 or 300 miles does not in the least impair their sweetness or freshness. For Violets we have tin boxes made especially for passing through the post; they are 6 in. long, 2½ in. wide, and 2 in. deep. In these the blossoms are laid flat as they are gathered, between layers of Violet

leaves pressed down tolerably close until quite full, when a layer of wadding is put on and the lid closed tightly down; the direction may be pasted or written on the lid, and they may be relied on to reach their destination without being crushed, as they usually are in card-board boxes, and in fresher condition, as in tin they are cool and air-tight. Boxes of the size just named, when full, require three penny stamps, and hold several dozens of the finest blossoms. Boxes of this kind are equally serviceable for choice flowers, such as Gardenias, Rose-buds, Orchids, or Stephanotis; their size may be varied, according to the flowers intended to be sent in them; but I feel sure that any one staying at a distance from their own garden, and receiving from home every morning a box of fresh Violets, will find it one of the by no means small advantages which the Post Office affords. I may add that Violets look best garnished with Violet leaves, but the leaves of the Neapolitan variety are not so effective as those of the single blue, such as *The Czar*, and hardy Russian kinds.—J. GROOM, *Henham*.

Poisoning of Cows by Yew.—M. Hartenstein records an important case of poisoning by Yew, as coming immediately under his own observation. Last April a herd of seventeen cows were driven a distance of twenty-four miles in search of fresh pasturage, the time occupied by the journey extending over eleven hours. On arrival at their destination the pasturage sought for was not obtainable, and for want of better accommodation the animals were placed for the night in an empty garden, surrounded by Yew. In the morning the four finest cows were found dead, and three others died immediately afterwards; the remaining ten were quite well. On examining the garden the leaves of the Yew bushes were discovered cropped all round. Post-mortem examination showed the bodies distended, the eyes dim, the nostrils clogged with blood and mucus, the liver literally looking as though it had been thrown into boiling water, and the small intestine for a distance of three yards almost black. The rumen was discovered full of green herbaceous matter, in which pieces of Yew were easily recognised. It is supposed that the ten surviving cows, being older than the rest, had at once lain down to rest on reaching the end of their journey.

NOTES AND QUESTIONS—VARIOUS.

Autumn Pears.—We are now using the *Fondante d'Automne* Pear from an east wall, and a most delicious Pear it is—perhaps the prince of all October Pears.—R. GILBERT, *Burghey*.

Celosias for Church Decoration.—We find nothing so good for church decoration at this time of the year as *Celosias*. Their plume-like trusses of various colours are very showy and appropriate, and they are not so easily damaged as many other flowers.—S. W.

11 The *Gloire de Dijon* Rose, it is said, in the "Journal des Roses," was raised from seed by M. Jacotot, nurseryman, of Dijon, in 1849. It was first publicly exhibited in 1852, and sent out in 1853.

White Siberian Squill.—This is an early flowering plant but seldom met with; but when associated with the ordinary blue *Scilla sibirica*, either as an edging or otherwise, or by itself in patches in herbaceous borders or on rock-work, it has a pretty effect.—R. M.

Keeping Pine-apples after they are Ripe.—Pine-apples keep better after they are ripe in a cool, light room than anywhere else. Two months ago we had more ripening than were wanted, consequently the plants, pots and all, were lifted out of the bed, just when the fruit was ready for cutting, and set in a cool store room. Nothing farther has been done since, and the fruits are now as plump and fresh as on the day when they were shifted out of the stove.—A CAMBRIAN.

Electric Conductivity of Trees.—According to M. de Moncel's observations on this subject, soft woods of spongy tissue and vigorous vegetation, such as the Elm, Chestnut, Lime, Poplar, &c., are the best conductors; while the hard woods of slow vegetation are the most resistant. Birch seems to form an exception. [It appears from M. de Moncel's experiment, that the electric conductivity of living wood is generally in direct proportion to the amount of sap and other moisture which they contain.]

New India-rubber Tree.—Mr. Robert Cross publishes some interesting notes in the "Geographical Magazine" in regard to certain important trees of the Amazon Valley, and announces that the Ceara India-rubber comes from a hitherto undescribed species, materially different from any yet known. He was unfortunately unable to obtain it in flower, so that its precise position in the vegetable kingdom was not ascertained; but young plants which he has sent home to England will, he hopes, furnish the information at no distant day. The region in which the tree grows is very dry for a great part of the year, rain occurring but seldom, and in some seasons scarcely at all. It is found up to about 200 ft. above the sea-level. It is thought to be suitable for cultivation in India, where there are extensive tracts of a precisely similar character to those in which it occurs, although it is believed that the tree will not stand a temperature below 50°.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

PROPAGATION OF PLANTS BY ROOT CUTTINGS.*

THE most natural method of propagation is by means of seed; but there are many plants in cultivation which rarely produce seed, and many more which cannot be depended on to come true from seed. Moreover, we have now many hybrids, a class of plants which in all probability will be largely increased before long; as is well known true hybrids seldom seed, and those which do produce fertile seeds we often find reproducing varieties totally different from the kinds we wish to preserve. It is evident, therefore, that we must adopt other means to increase those plants, and at the same time keep their distinctive peculiarities intact. Fortunately there are many ways by which this may be done, such as by means of cuttings of the stem, grafting, budding, inarching, layering, division, and the mode which I am about to describe, by cuttings of the root. Before doing so, I may mention that it is not always easy to distinguish between stem and root; many forms of stems are often confounded with roots, such as the rhizomes of the Iris, the corms of the Crocus, the bulbs of the Lily, the tubers of the Potato, the soboles of the Couch Grass, &c., which are all forms of underground stems. The roots I mean to refer to are different from any of these, but inasmuch as they possess the power of forming leaf-buds, they are different from true roots, which, according to botanists, have no such power; one of the main distinctions between stem and root being the absence of any provision for forming leaf-buds on the latter. They appear to be intermediate, that is, can perform the functions of both root and stem if placed in favourable circumstances. The propagation of plants by means of root cuttings has been long practised, for I find that the late Mr. T. A. Knight in 1816 succeeded in growing Apples, Pears, Cherries, and Plums, by putting pieces of their roots about a foot long into the open ground. Leaf-buds are formed naturally on the roots of *Pyrus japonica*, Moutan Pæony, Plums, *Anemone japonica*, and a few others. There are many plants which possess this power of forming buds on their roots, although they remain dormant until, either by accident or design, their roots are cut and they then push buds. It is generally supposed that the number of plants capable of being propagated in this way is very limited; but, judging from my own experience, I am inclined to think that there are many more than we are at present aware of. Having got a plant which we know will increase by means of roots, the first thing necessary to be done is to shake the soil or wash it clean away from the roots; next, cut them into little pieces, generally about $\frac{1}{2}$ in. long; but some kinds, such as the *Ipecacuanha*, for example, I have found to succeed when only one-sixteenth of an inch long; others require to be about 1 ft. long. A curious fact in connection with this is, that usually no more than one bud starts, whether the pieces of root be left one-sixteenth of an inch or a foot long, all the strength goes to the bud that starts first and the others remain dormant. Having got the roots cut up, boxes or seed-pans may be prepared for them the same as for ordinary cuttings, viz., filled with light sandy soil, adding a little peat for such plants as naturally like that kind of soil. The pieces of root should then be scattered over the surface of the pans and covered about their own depth according to the thickness of the roots used; give them a slight bottom-heat, and in a fortnight or three weeks' time, the young buds will be found rising above the soil and elbowing each other for room. Spring is the best time to put them in, although they may be inserted all through the summer months. In the case of many hardy plants bottom-heat is unnecessary, unless where time is an object, which in most cases it is. Care must be taken in har-

dening off plants struck in heat, as they will be found to suffer more than in the case of stem cuttings unless gradually inured to the cold. This is the whole process, and it has several advantages to recommend it. 1st. A good supply of roots may be got without at all destroying the appearance of the stock plant. 2nd. The cuttings are more easily and quickly put in, and in the third place the results are more satisfactory; provided the roots are healthy it is rare to find a piece which will not grow. The only difficulty is to learn what plants are capable of being propagated by means of roots, and this can only be discovered by experiment, as there is nothing, so far as I can see, about the appearance of the roots themselves that would lead one to be certain whether they could be propagated in that way or not. The following plants I know, however, may be increased by means of pieces of roots. My first attempt was made with *Aralia papyrifera*, and then with *Aralia japonica*; I do not, however, yet know whether the new *Aralias*, such as *Veitchi*, elegantissima, and others of that section may be increased by roots or not; but most probably they may. In that case they would require to be on their own roots and not grafted plants. All the kinds of *Dracænas* may be propagated in this way; also *Hellebores*, particularly *H. grandiflorus* or *maximus*. *Pelargoniums* thus treated will also succeed, but not so well as by stem cuttings, with the exception of fancy *Pelargoniums*, which are often difficult to strike by means of stems cuttings. *Monsonia lobata*, another Geraniaceous plant, *Pulsatilla bracteata*, a somewhat rare *Anemone* which has fibrous roots (not a creeping rhizome like the Wood *Anemone*) may also be increased by root cuttings. *Anemone japonica* (which grows naturally from the roots), *Clematis*, and *Ipecacuanha* may also be increased by means of root-cuttings. Plants of the *Ipecacuanha* were first sent out to India in Wardian cases, but it was afterwards found that the roots alone could be successfully sent out by post, and several small boxes of them were sent out in that way by Prof. Balfour, along with printed instructions as to their propagation drawn up by Mr. McNab. The roots arrived in good condition, and on being treated as directed, abundance of plants was the result. *Drosera dichotoma*, a rare Australian Sundew, strikes readily by means of pieces of root. Cuttings of all kinds of *Bouvardias* are now commonly raised from roots, as are likewise *Rosa rugosa* and other species, and many of the hybrids, together with *Senecio pulcher*; *Scolymus grandiflorus*, *Viola pedata*, *Cephalotus follicularis* (the Australian Pitcher plant), *Passifloras*, *Melanthus*, *Greyia*, *Xanthoceras sorbifolius*, and *Venus's fly trap* (*Dionæa muscipula*). With regard to this plant it is certainly not the root that is propagated, but the bulbous enlargement formed by the old leaf-stalks, the scales of which are pulled asunder in the same way as is often done in the case of Lily scales. *Sarracénias* and *Darlingtonia californica* may also be propagated in this way, but they are clearly rhizomes, not roots, that are used for the purpose.

NOTES FROM KEW.

THE following hardy plants, in spite of frost, rain, and lack of sun, are still in full beauty. Firstly, the *Asters* claim our attention, and from the large collection the species hereafter noted are the very best of their respective colours. *Aster Chapmanni* has very pretty lavender flowers, and grows from 4 ft. to 5 ft. high. The rose and blue varieties of *A. Novæ Angliæ* are exceedingly handsome; the latter attains a height of from 4 ft. to 5 ft., but is not so tall by 1 ft. as the former. *A. patens* forms a bush about 2½ ft. high, and has rather large, light-blue flowers; *A. lævis* and *A. purpuratus* are of slightly different shades, and grow rather taller. The pretty, somewhat Heath-like foliage of *A. ericoides* and *A. Tradescanti*, together with their numberless small white flowers, and rather elegant habit, render them desirable acquisitions. *A. sericeus*, with large blue flowers, and *A. longifolius* with handsome rosy-purple ones, are among the finest of the dwarf *Asters*; as seen at Kew, both species are about 1½ ft. high. *Chrysopsis villosa*, one of the commonest plants on some of the North American prairies, merits notice on account of its close bushy growth, and its abundance of pleasing yellow flowers. *Coreopsis trichosperma* grows 3 ft. or more in height, has finely-cut leaves, and flowers of a bright yellow. *Diplopappus chrysophyllus*, by the wall of the herbaceous ground, has inconspicuous flowers, but the neat, Heath-like foliage, as well as the branches themselves, are, as it were, dusted with gold.

* Read before the Scottish Horticultural Association, October 2, by Robert Lindsay, Royal Botanic Gardens, Edinburgh.

coloured powder. *Helianthus orgyalis*, with small flowers, when its large size, 8 ft., is considered, is nevertheless extremely ornamental; its tall, unbranched stems are thickly set with linear, arching leaves, which give a remarkably graceful appearance to the plant. As a single specimen on a lawn this species would be admired anywhere. *Pyrethrum uliginosum*, from Hungary, has large white flowers, which so far have been uninjured either by frost or wet; it grows about 3 ft. or 4 ft. high, and is deserving a place in every select collection of herbaceous plants. The ample foliage and long succession of rather deep yellow flowers of *Calceolaria Pavoni* make it a welcome addition for the mixed border; it is far too gross a grower for bedding purposes; by a wall or in a suitable position it will grow 3 ft. or more in height; it is a native of the Andes of Peru. *Polygonum vacciniifolium*, the Whortle-berried Knotweed, is one of the most charming species of its genus; its numerous slender stems trail along the ground and root at the joints, the leaves often being nearly hidden by the copious spikes of bright rose-coloured flowers, which are produced almost uninterruptedly from August until November. In some parts of the Himalayas, at elevations varying from 11,000 ft. to 13,000 ft., this is frequently met with. For the front of rockwork, where it can get plenty of moisture at all times, this neat-growing little plant is a perfect gem; as a pot plant it succeeds thoroughly well in a cold frame.

Of late the Kew authorities seem to have devoted some attention to Crocuses, for, on referring to the "Botanical Magazine," we find that no fewer than eleven species have been figured in the last half-dozen volumes, whilst, during the previous quarter of a century, only two are represented. The autumnal species of this beautiful genus certainly ought to be more frequently met with in gardens. *Crocus Salzmanni* has a pretty pale violet perianth with a long tube; it is a native of olaye fields about Tangiers, and is known in some gardens under the name of *C. tingitanus*. One of the prettiest of the autumnal white-flowered species is *C. cancellatus*, from the Ionian Isles, Greece, and Asia Minor, in Greece ascending to 4000 ft. above the level of the sea; its pure white perianth and pale yellow throat are very attractive. The lilac-purple *C. byzantinus*, from Transylvania, is remarkable for the acute perianth segments, the three inner of which are only half the size of the outer; this is one of the earliest of the introduced exotic species, being figured by Clusius in 1601; in some gardens it is known as *C. iridiflorus*. *C. speciosus* has a wide geographical range (Anstria, Crimea, Caucasus, and Northern Persia being the limits given by Mr. Baker in his "Systema Iridacearum"); it has beautifully feathered blue flowers, and is one of the finest and most distinct of all the Crocuses. The British *C. nudiflorus* and the Portuguese *C. serotinus* are also in flower. On the wall opposite the Crocus beds is *Mühlenbergia adpressa*, a pretty Polygonaceous climber from Australia and New Zealand; although the greenish flowers are inconspicuous, the small cordate leaves and the elegant habit of the plant mark it as a useful screen where a gross grower would be out of place.

The most striking hardy succulent now at Kew is *Sedum spurium*, from the Caucasus; its dwarf, creeping habit, and numerous fine deep rose flowers, ought to make it welcome on every rockwork. Of all the wall plants, *Convolvulus Cneorum* is now by far the most handsome, its white or flesh-coloured flowers and beautiful silky leaves causing it to be universally admired. It was cultivated in the Chelsea Garden in 1739, and is a native of Spain and the Levant. G.

Autumnal-flowering Crocuses.—*C. zonatus* has been in great beauty with me for the last few weeks, planted out in a frame. It varies a good deal in colour, some of the specimens being almost white; and also in the shape of the petals, some being narrow and pointed, and others broad and obovate. In general habit it closely resembles *C. pulchellus*, but its flowers are a brighter mauve; it blooms a fortnight earlier, and has a much larger and more flattened bulb. It is one of the hardiest and most floriferous of the autumn-blooming species, and increases fast. Like *C. pulchellus* and *Boryi*, it has white stigmas. During the last few weeks I have flowered the following, *Crocus*, viz., *C. nudiflorus*, *speciosus*, *pulchellus*, *pulchellus albus*, *vallicola*, *Clusii*, *hadriaticus*, *serotinus*, *medius*, *oilicious* (probably a variety of *cancellatus*), *Boryi*, *levigatus*, and *tingitanus*; *C. longiflorus*, *sativus*, *Cartwrightianus*, *byzantinus*, *Orphanides*, *cancellatus*, *ochroleucus*, *Damasceus*, and *Peloponnesiacus* are just showing above-ground. Autumnal Croci are very late this year, and, as a rule, in consequence of the cold, showery, sunless summer, they are not blooming well. I mean in future to grow them almost entirely under glass, planted out in a frame. The violent showers which we almost have at this time of year dash their delicate blooms all to pieces if they are planted in the open border.—H. HARPUR CREWE.

THE KITCHEN GARDEN.

TOMATOES AND THE POTATO DISEASE.

THE extraordinary destructiveness which the Potato Fungus has displayed amongst Tomato plants, not only in the present, but also in previous years, shows that it will be necessary eventually to secure the plants from climatic influences, if they are to be expected to produce healthy, ripe crops of fruit. It is one of the characteristics of the disease as regards the Tomato, that it seems chiefly to expend itself upon this plant after all food for it, in the shape of Potato haulm, has been destroyed. I think I am right in saying that it rarely affects the Tomato until September, whilst the chief mischief is wrought amongst the Potato crops at the end of July and during August. Either, therefore, this late appearance of it in the Tomato is due to the reason I have mentioned, or else it arises from the fact that, as with the Potato, so with the Tomato, the disease does not attack the plant until it has attained a certain degree of maturity. The real matter for consideration is the fact that the disease does attack the Tomato, although not until late in the summer, and if the entire crop is to be saved, some measures must be adopted to protect the plants from the action of atmospheric moisture, as it is through this only that the Fungus is started into activity. One thing to be done is to get seed sown very early and to have plants, as strong as can be had with safety, ready to turn out directly all danger from late spring frosts is past. Single plants in 5-in. pots would be better than two starved and stunted in 3-in. pots. In any case, a good, early start in the summer is of great importance, as upon that may hinge the saving of all the best fruit of the season. Their culture should not be too gross, as that induces a needless amount of growth, which does not favour the production of fruit. A good mulching about the roots, so that the moisture might be retained, is often of much more value than a quantity of rich manure worked into the soil. The restriction of the growth is, moreover, an important point in Tomato culture, as in this way the early-set fruits are sooner ripened, and the crop secured before the autumn rains induce disease. Still there remains in all large gardens the necessity of having Tomatoes in the open air as long as the season will permit; therefore, it becomes necessary to protect them in some way. In many places at this time of the year it is possible to have a number of plants growing in large pots standing in some early Vinery from which the crop has been taken, and the Vines probably at rest. Here a fair crop may be obtained until the end of November, and if, as in some places, the back wall of a Peach-house is covered with Tomato plants, there will be a fair supply all through the winter. In gardens where this convenience for pot culture is not available, plants put into pots and then plunged in soil in a frame might be tried, clean straw being used for the plants to creep over; but perhaps the most efficacious plan would be to set apart either some low wall or fence specially for the purpose. A length of 100 ft., about 3½ ft. in height, would produce a large crop for late use if the plants were put out early in June from 3 in. pots. As long as the summer heat and drought prevailed they would need no protection, but in September, when autumn rains began to fall, it would be well to be prepared for any disease that might show itself. This would be best effected by having a protection ready to be applied in the shape of a wide glass coping. In front of the wall, which should be 3 ft. 6 in. in height, stout Oaken stakes should be driven into the ground at intervals of about 3 ft. apart, or more, as may be thought necessary; their tops should be set even, about 3 ft. from the ground, and at least 10 in. from the wall. Upon these, along the entire length, should be nailed a stout strip of wood. The glass protectors should be 3 ft. in length, and hinged to a piece of wood fastened on the wall so as to be opened or let down as required. All, therefore, that is now needed, are some small iron swing hooks to drop into eyes fixed on the front edges of the lights, one at either end, and, when thus secured, almost any amount of wind might be defied, whilst no rain could get at the foliage of the plants beneath. Farther still, if, when sharp frosts occur, mats were thrown over the glass, and allowed to hang down to the ground, it is possible that in this way the

plants might, during some winters, be kept in bearing until Christmas. The northern side of a wall of this kind need not be idle, as here could be obtained fine late crops of Red and White Currants or Gooseberries, and during other periods of the year the glass protectors might be stored away in some dry place in a small space, and, with an occasional coat of paint, would probably last for many years. A. D.

DISEASE-PROOF POTATOES.

I REGRET to find currency again being given to the exploded notion that there are disease-proof Potatoes. Some may be more robust than others, and therefore more capable of resisting the attacks of the Potato Fungus, but all are liable to its attacks. Varieties of Potatoes that are much diseased in some localities, in others are often comparatively healthy, and with the variations of seasons are also found variations as regards the attacks of the disease, making the crop to be lifted of any one kind or sort a matter of uncertainty. In my own case there has been much disease this season among some fifty or more sorts, when grown in stiff cold land, and well manured; whilst as regards the same number of kinds grown in soil of a light, porous character, with a light dressing of manure, there has been little or no disease, and the kinds might fairly have been said to be fairly disease-proof. There does not, however, exist such a thing as a disease-proof Potato. Flourball has often been specially mentioned for its disease-resisting qualities, and such appeared to be its characteristic until the trials, so widely conducted by the Royal Agricultural Society, showed conclusively that it was no more disease-proof than others. In my own neighbourhood, some four years ago, a market gardener grew a grand crop of Flourball, finding scarcely one diseased tuber. Next year he planted with the view of lifting 10 tons and got about 4 tons, the crop being terribly diseased. Another bad crop last year induced him to alter his opinion; and yet he started with the firm belief that Flourball was a disease-proof Potato. Throughout this neighbourhood, Regents were badly diseased; but, nevertheless, I have just seen a fine crop of them lifted where the percentage of diseased tubers was very small. This exemption is accounted for by the fact that this field was planted late, and the haulm had not obtained maturity when disease suddenly developed itself. A month later in planting this year saved the crop. Perhaps another year late planting might have a contrary effect, as in some seasons the earlier crops escape, and the late ones get diseased. I find, for instance, that Victoria is this year coming out very clean indeed, close by where Regents have been badly effected, but this immunity is this year more the result of a later period of ripening than owing to any other cause, as last year the Victorias were very badly diseased. It is right that Potato growers should make public the fact that this year certain sorts have produced clean crops, but next year they may have to tell a different tale. There are other considerations which should guide growers in relation to selecting sorts for planting; one kind, for instance, that may have the reputation of resisting the disease, may yet produce Potatoes that no one would care to eat, and if this be the case what gain is there in having such a crop? It may be said that a crop of indifferent eating Potatoes is better than none, but if it can be shown that a clean and sound crop of tubers of the finest eating quality can be had if the grower be content with small Potatoes, is it not better to have that than a lot of course tubers? If, however, good eating Potatoes of fair size be desired, it is not necessary to grow Flourball, or that much more uncertain kind Late Rose. Far better than either of these are Schoolmaster, Magnum Bonum, Victoria, International Kidney, and several other extra robust kinds none of which are disease-proof, but the disease attacks them lightly if planted in poor, light porous soil. The haulm is then more firm and woody, and less influenced by the Fungus than when robust. The tubers are of medium size, and of really good quality. I disagree with the assertion that a crop of small Potatoes is indicative of bad cultivation. If it be found that large tubers are generally diseased, and small ones generally sound, it is obvious that the latter are greatly to be preferred. Small Potatoes, however, need not necessarily mean mere "chats";

tubers the size of a hen's egg would ordinarily be termed small, and yet they are often excellent for table use. I am glad to be enabled to say that under the treatment just recommended I have this season lifted the best crop of medium-sized tubers I have ever had. If I had grown my Potatoes in rich land, with plenty of manure, I should have had abundance of large tubers, and also plenty of disease, but under poor cultivation I have a clean and good crop. I have further found that early lifting is of little value if the disease has once attacked the tubers. It is better to let the few bad ones rot in the ground than to have them decaying in the store and poisoning the entire stock. A. D.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Taylor's Richard Gilbert Pea.—This is a promising mid-season and late Pea, the surprising vigour and sturdy growth of which seem to give it a power of resisting mildew far above the average. I gathered a pod from a long row growing at Burghley on October 10 that measured $4\frac{1}{2}$ in. long, and contained eight very sweet, good-flavoured Peas, and there were hundreds of similar and later pods, as well as flowers, still being produced, whilst Omega, which is generally looked upon as a good late kind, growing alongside of it, was quite exhausted and overrun with mildew. Richard Gilbert grows from 3 ft. 6 in. to 4 ft. high.—E. HOBDAV.

Two Useful French Beans.—One is Flageolet, which I had sent me two years ago from Paris. In growth it resembles Osborn's Forcing, but it is more robust; when young, the pods are used like those of the ordinary French Bean; as they get older they supply the place of green Peas, and when they are ripe they may be used like Haricots; the Bean itself is about the size of Osborn's Forcing, and of a greenish-white in colour. The other, which I had sent from Hamburg, is a Runner Bean resembling the Premier in growth, but the pods are more of a seedy character; these we use in the same way as the other. The Bean of this variety is pure white, and about the same size as that of the other, but rounder. This kind continues bearing like the Scarlet Runner, provided the pods be kept picked as their contents reach the size of green Peas.—W. W., *Eaglehurst*.

Endive for Autumn and Winter Use.—In wet seasons tying up Endive is of little use, as it is sure to become rotten at the heart before it is sufficiently blanched. To prevent this I find it a good plan to double in the outer leaves and place a clean blue slate on the top of each plant; the slate is less likely to harbour slugs or vermin than wood. If the plants be on a sloping border so much the better, as the slates will throw off the rain, blanch the Endive beautifully, and make it more crisp than if tied up. Another good plan, in the case of late Endive, is to take it up with a good ball of earth and well tie in the leaves, selecting a dry day for the operation; then pack the roots in mould in a light open shed, or, better still, at the foot of a south wall, letting the roots into the ground; then place an inclining board over them. This will make them white and preserve them a long time. Endive, thus treated, will have white hearts larger than a man's fist, and these, with a little Mustard and Australian Cress, which can easily be obtained at all times, make a good salad in autumn and winter, when Lettuces and other things are scarce.—C. H. KITCHING, *Cokethorpe Park, Witney, Oxon.*

Tomatoes Grown at Burghley.—I have sent specimens of Jackson's Tomato ripened out-of-doors. The late glorious weather has done wonders for everything ripened out-of-doors in this district. Peach wood is as red as that of Dogwood, and as hard as Ivory. Strawberries for forcing are well plumped up, and showing the autumnal colouring of the foliage; we may therefore hope to have a bright year in 1878.—R. GILBERT. [The specimens sent are the finest we have ever seen at any time of the year.]

Parsley amongst Broccoli.—I know of nothing in a small way so useful as Parsely. Many take it up and grow it under glass, but no coddling is needed. When we plant our Broccoli in July, we take a little Parsely seed and sow it broadcast amongst them. The young Parsely plants grow with the Broccoli, the large leaves of which duly protect them in the winter, so that a good supply is always at hand.—R. GILBERT, *Burghley*.

Onion Juice v. Stings.—The "Berliner Presse" states that the pain caused by the sting of a horse fly may be instantly alleviated, and the swelling which often accompanies it speedily reduced, by simply rubbing the injured part with the juice of an Onion.

Snow's Broccoli.—We are just now (19th October) busily employed taking up this Broccoli, and laying it in on a west border thickly, in order to preserve the heads from frost, and clear the ground on which it grew for digging. When laid down 9° or 10° of frost do not harm it; but should any sharp weather set in we cover it up with Bracken, which makes all secure.—R. GILBERT, *Burghley*.

NOTES OF THE WEEK.

Romneya Coulteri.—Dr. Moore tells us that this fine plant is yet in flower at Glasnevin, the recent fine weather having encouraged it. It forms a bush from 5 ft. to 6 ft. high, and will probably prove a valuable plant for mild districts.

Dasyllirion glaucum.—There is now in bloom at Sadbury House, Hammersmith, a fine plant of this Dasyllirion, the flowers of which are all male. The spike measures 8 ft. in height, and is a singular yet really beautiful object.—J. CROUCHER.

A Graceful Palm.—One of the most graceful Palms to be found in the Holloway Nurseries is *Cocos australis*. Its fronds, which are from 2½ ft. to 3 ft. in length, assume a drooping habit, and are furnished with light, long, narrow, Grass-like leaflets, nearly 1 ft. in length. On pedestals, or similar supports, or for table decoration, this plant will eventually become a favourite.—C. S.

Silene Elizabethæ.—Messrs. Backhouse, of York, have received a large importation of this lovely Catchfly. In its native habitat it is found growing in shattered limestone. For cultivation, a mixture of about one-third good loam, one-third peat, and one-third broken stones will suit it admirably. It should be planted in such a position that the roots can penetrate back, say from 18 in. to 24 in., into congenial soil.—R. P.

Fruits in Covent Garden.—Large, well-ripened fruits of the Prickly Pear (*Opuntia*) are now plentiful in Covent Garden Market, and appear to be in good demand. Pomeloes and Shaddocks and Tangerine and Brazilian Oranges are also abundant. Fine examples of Marie Louise and Duchesse de Angoulême Pears of French growth may likewise be seen in several of the shops in the Central Avenue, associated with the American Lady Apple, finely-coloured fruits of which have just made their appearance. We also noticed fruits of the true Service tree (*Sorbus domestica*) exposed for sale this week. This fruit is not often met with in our markets; indeed, Philipps says that it was in his days "as rare in the London markets as the fruits of the most distant parts of the world." It is reddish-brown in colour, with small, white spots, and somewhat resembles the Medlar in flavour, but it is more austere and astringent. The tree although very handsome, is not very frequently met with. A solitary example existed for many years in the centre of Wyve Forest, in Worcestershire, but this was burnt down in 1862. The fruit is not gathered until late in the autumn; it is wiped dry and laid on dry straw, and spread out until it becomes mellow and fit for use, which is usually in about a month after it has been gathered. It is eaten in Italy and the north of France, and is considered useful in cases of dysentery.

The Colorado Beetle and its Enemies.—The Colorado Potato Beetle has at last found its match in the shape of a mite parasite. Prof. Riley, at a meeting of the St. Louis Academy of Science, exhibited a Potato Bug which was so completely covered with a mite parasite that the point of a needle could not be placed on any part of the Beetle's body without touching one of the parasites. He estimated the number of mites at 800. The Beetle has been attacked by these enemies and killed. It seems to have a number of natural enemies, such as the toad, the rook, the rose-breasted grosbeak, and domestic fowls. There are no fewer than twenty-three insect enemies that attack and kill it.

Desfontainea spinosa in Scotland.—On a lawn attached to one of the villa gardens at Danoon, Firth of Clyde, may be seen a specimen of this fine evergreen shrub, forming a dense bush, well furnished with branches; of these, some of the principal ones shoot up from the root to a height of fully 9 ft., and their spread at 5 ft. from the ground is nearly 20 ft. in circumference. It is standing within 100 yards of the sea, but protected from the breeze by a wall and a narrow belt of trees, by which it is partially shaded. The soil in which it is growing is a rich, heavy loam, and the ground is naturally damp. It is in luxuriant health, and in the fifteen or sixteen years during which it has occupied its present position, it has never suffered materially, if at all, from frost. For many years past it has flowered very profusely, beginning about the middle or end of July and continuing till late in the autumn, but it is generally at its best in the end of August. This summer it has been remarkably fine, and when I saw it on the 25th of September it was literally covered with fruit and flowers in all stages of development. For the benefit of those who are either unacquainted with this plant, or who have not seen it in flower or fruit, I may add that it was first introduced to this country from Peru nearly thirty years ago, that it grows naturally to a height of about 10 ft., and that in foliage and general aspect it somewhat resembles a Holly. The flowers, which are tubular and pendulous, measure from 1 in. to 2 in. long, and arch out; they are bright scarlet, tipped with gold. The fruit is

about the size of a small Gooseberry, and when ripe is of a bright yellow colour. Surely so beautiful and valuable a shrub as this is worthy of wide cultivation, especially in the milder or sea-side districts of the country.—OMEGA.

Ismene calathina Out-of-doors.—This plant, which used to be grown in the stove, has been planted out for the past five years at Glasnevin. It has proved quite hardy, and has flowered well this year.

Plants in Bloom at Holloway.—In Mr. Williams' nursery, at Holloway, many plants of an attractive character are now in bloom. In the Orchid-houses is a fine display of *Oncidium varicosum* and *O. Rogersi*, and the curiously-spotted *O. tigrinum*, the flower-spikes of which droop gracefully among green-leaved Palms and Ferns, with which they are associated. The large, white, sweet-scented flowers of *Dendrobium giganteum* are also very attractive, as are also those of the showy *Odontoglossum grande* and *O. Alexandræ*. Large plants of *Dendrobium chrysanthum* are furnished with strong pseudobulbs, each of which bear from thirty to forty rich golden blossoms, which contrast strikingly with those of the beautiful *Pleione Wallichiana* and *P. lagenaria* (sometimes called Indian Crocuses), and which are embedded in a mass of Clab Mosses and small Ferns. Small plants of the new *Abutilon rosæformum* are loaded with blossoms, and a bank of *Calanthes* will shortly be finely in bloom, their flower-stems being already thrown up in large numbers.—S.

The Fruits of the Service Tree.—Large quantities of these are sold in the streets of Constantinople during the autumn, under the name of *Kiziljicks*, i.e., Little Reds. They are plucked before they are ripe, that is to say, when they are bright red. The first time I tasted them, thinking from their appearance that they were cooling and luscious, I crammed a couple into my mouth expecting a treat, but was soon undeceived. In their unripe condition they are the very concentration of all that is acid and astringent, so much so that a Turkish mother will call her peevish, crying baby a *Kiziljick*. Their flowers must be something like that of the fruit Tamarind, so graphically described by Mark Twain, for my mouth, like his, assumed the form of the stalk end of a Tomato, and preserved it for several hours. With a certain amount of sugar, they make a deliciously refreshing drink for use in hot weather. They are eaten in large quantities by all the Ottomans, both Christian and Moslem, as an infallible preventive of diarrhoea. Plucked when they are just losing their bright red hue they make an excellent preserve, which the Greek and Armenian housewives consider to be a valuable cure for sore throat.—C. W. QUIN.

The Pistacia Tribe.—The *Pistacia Terebinthus*, described by "J. R." in an article on "*Pistacias and Their Uses*," in THE GARDEN (see p. 355), is a very noble tree, and, judging from the way in which it bears the winter snows and frosts on the shores of the Black Sea, the Bosphorus, and the Sea of Marmora, ought, I should say, to be perfectly hardy in England. One of the finest specimens I ever saw is on the shores of the little Bay of Therapia. It generally grows to from 40 ft. to 60 ft. high, and often reaches 8 ft. or 9 ft. in girth. The trunk and habit closely resemble those of the Oak, but the leaves are long and pinnate. As the autumn advances, the dark green leaves become thickly covered with crimson galls, which, with the purplish-brown berries, form a very pretty contrast of colour. The true colour of the fresh Pistachio kernel is not greenish-blue but yellowish-green, and the inner covering dark purplish-crimson. The shape of the Nut closely resembles that of the mussel, and is of a delicate buff. They are consumed in immense quantities in Constantinople, the ground of the numberless open-air cafés and public gardens being literally paved with their shells. They are scalded in salt and water, to cause the two valves of the shell to open slightly. The *Pistacia Lentiscus* deserves to be called the Upas Tree of Turkey, its gum being the base of the pernicious liquer called by the Greeks "*mastika*," and by the Turks "*raki*." The common raki, which can be bought at about 1s. per pint, is made by distilling raw Boston rum from Gum Mastic, Aniseed, and other herbs. Part of the gum distils over so that when water is added to the spirit it becomes milky; it is, in fact, very weak water varnish. It is the almost universal custom in Turkey to take a small glass or two of this liquer before dinner, as an appetiser, with a shrimp, a raisin, a scrap of sausage, or a pickled Gherkin added as a zest. The rising generation, both Christian and Moslem, are far too partial to this pernicious spirit, which makes an end of its victim as speedily as the French absinthe. The best quality comes from Chio, where it is distilled from the finest Gum Mastic and the lees of the famous Chian wine. The picked gum is largely used for chewing by the Turkish, Greek, and Armenian ladies, more to pass the time than for any sanitary reason. I am assured by several of the first dentists in Constantinople that mastic chewing strengthens and whitens the teeth, ladies who have indulged in the practice from childhood being rarely sufferers from toothache.—Q.

THE FRUIT GARDEN.

CULTURE OF HARDY FRUIT TREES.

(Continued from p. 383).

Grafting and Budding the Stocks.

From a practical point of view grafting consists in growing on a wildling of the same species a portion of a branch or twig or a bud of a given sort or variety, cut in different fashions according to circumstances, so that the vital parts of each come into intimate contact. To do this properly a certain amount of manual dexterity is required, which is only to be obtained by much practice and many failures. It is not necessary to begin our experiments with valuable subjects, but grafts and buds of

variety grafted is, speaking generally, in no way changed, preserving most of its special characteristics without partaking of those of the stock. The principal stocks used in grafting for the orchard are the following:—

PLUMS.—These stocks are obtained from seedlings of strong wooded varieties such as St. Catherine and the White Damson, which are generally used for grafting Apricots and Plums for every description of growth, and for standard Peaches. The Myrobolan is a short bushy tree easily grown from cuttings. We mention this stock in order to disapprove of the bad habit of growing it as a tall standard for grafting the Plum and the Peach. The Myrobolan soon reaches its proper height, which is somewhat low, but its branches are always small and as hard as iron. Grafts form on it a large ring at the place of junction. Beyond three or four years from the time

Unity in fruit-tree planting.

Wall of Easter Beurré Pears, 14 ft. high. Photographed in the Potagerie at Versailles in April of the present year. It illustrates the convenience resulting from cultivating one variety in a carefully-considered position; also, the advantage of growing, in some quantity, one variety of the highest value for late winter and spring use.

any common variety may be tried until success is attained. Grafting with almost the certainty of success is acquired much more easily than is usually supposed. If absolute precision in making grafts were really required, hardly five per cent. of those made even by the most expert grafter would succeed. Before beginning to work it is important to clearly understand that success depends on the proper choice of stocks and scions, the time for grafting, and the particular method of grafting adopted.

THE CHOICE OF SUBJECTS.—It may be taken as a general rule that the operation of grafting succeeds best the more closely the stock and scion are related to each other by natural affinity. All stories of miraculous grafting of Roses on Ivy, or on the Vine, or the Cherry tree, or on the Pear, or the Elm, are simply to be looked upon as worthless tales. On the other hand, it must be acknowledged that certain stocks seem to be more suitable to certain scions than others, although the character of the

of grafting it cannot be successfully transplanted. The Almond sown from the sweet variety with a hard shell, grafted near the ground with a Peach, will give a tree with a tall stem in warm, deep soils situated in sheltered positions. The Almond is but little used as a stock for Peaches, and it is much better to raise Peach stocks from good seed, which after all, are the best stocks for Peaches growing out-of-doors. The wild Cherry forms excellent stocks for tall standard Cherry trees. It is obtained from the seed of the wild or some good sweet cultivated variety. Stocks with pale bark are mostly chosen, the dark varieties being shorter-lived. Seedlings from the acid Cherries are generally weak and sickly. There is no need to double-graft the Cherry except in the case of ill-grown subjects.

The Quince may be grafted on its own stock when it is grown on the edges of ditches which surround many orchards. It resembles the Medlar in this respect. Its principal use is as

a stock for half-standard Pears with a pyramidal crown (fig. 8), which may be used for temporarily planting intermediately in damp situations. When trees thus grown show signs of decay, they may be partially restored to health by making longitudinal incisions in the base of the graft, which must be covered up with earth, as shown in fig. 9. As an exception, the Quince is sometimes used for tall standards with general

Fig. 8.

Fig. 9.

success, as far as regards strong varieties, provided they are grafted close to the ground. For this purpose the Portugal Quince is generally chosen.

The Pear requires a deep, dry, warm soil, and an open and airy aspect; its roots penetrate deeply into the ground, and they dread stagnant water, except the graft has been made low down on a Portugal Quince stock, which seems to thrive wonderfully in damp and even in marshy places. Pears grafted on the Portugal Quince stock are extremely rare, but from what has already been said, they may be used in situations in which ordinary subjects would speedily become sterile. Even when grown as a tall standard for temporary intermediate planting, it will be found a most useful fruit tree. Many excellent varieties, such as *Beurré d'Amanlis*, *Conseiller à la Cour*, *Beurré Sterckmans*, *Double Philippe*, and others, form strong and prolific trees when grown in this way, even in a damp soil, provided it be kept well manured. These trees, it is true, are not very long lived, but they bear early and abundantly. They ought to be planted pretty close together. By taking advantage of the peculiarities of the Pear grafted on the Portugal Quince, situations which are only fit for Osier beds may be converted into fertile Pear orchards. The wild Pear is the most frequently used for the standard Pear tree for all descriptions of soil, provided they are not too damp. Grafted on large Hawthorn stocks, the Pear lasts a long time in good soil, is a prolific bearer, and throws out but a moderate amount of shoots and leaves.

Free Apple stocks are useful for tall standard Apples.

Good varieties of Sweet Chestnuts and Walnuts may be grafted on stocks of their own varieties.

CHOOSING THE SCIONS.—This part of the art of grafting may be compared to a vast field of experiments, in which an immense number of experiments, researches, and observations are being continually carried on, but in which there still remains an immense deal to learn. The following directions must be strictly followed in the case of tall standards growing in open places, for these will receive less care, and will be more subjected to external influences than espaliers, and should, therefore, have lost as little as possible of their primitive vigour. We must not, therefore, accept the first scion that comes to hand as being fitted for every purpose. The scions should be taken from healthy trees, which, although old, are still making good wood, and which thrive well in situa-

tions away from shelter of every sort. The scions themselves should be cut from moderately vigorous shoots a year old. In case of necessity, they may be in their second year, and will often produce good trees, especially piped fruit, such as Apples and Pears. Two-year-old scions are recommended for soft-wooded trees, such as the Mulberry and Walnut. The necessity for taking scions from healthy trees only, requires no discussion, it having been proved, times out of number, that a healthy scion, taken from an unhealthy stock, will inherit the weaknesses of the parent stock. As regards the second point, the age of the scion, it must be observed that a watery shoot in which the wood is not quite mature, or scions taken from young trees, are liable to yield but little fruit. The older the tree, therefore, within certain limits, other things being the same, the more likely is the scion to be healthy and prolific. By taking this precaution, we may often obtain tall standards, bearing fruit, which it would have been impossible to obtain from scions cut from young trees, owing to their not being sufficiently hardy to bear the weather. Grafting, it should be understood, although it makes the tree more prolific and the fruit larger and of finer flavour, also leads, ultimately to decay, and the more frequently a tree is grafted, the sooner will it surely, although imperceptably, degenerate and perish. It results from this that after a certain time, a variety will degenerate through being continually grafted, and will fall away from being a choice orchard fruit to be but little cared for. The same reasoning applies to the third point. Whatever is against nature, such as cultivating fruit trees as espaliers, against walls, or under shelter, or grafted on other trees, occasions a weakening of the natural forms of the tree, and engenders weaknesses which gradually increase, and at last become incurable. As far as the choice of the most suitable kind of scion goes, a moderately vigorous shoot must be chosen, otherwise the resulting tree will be deficient in bearing properties. On the same branch we may meet with many different varieties of shoots, which will give rise to as many different varieties of trees; considerable care and judgment must therefore be exercised in making our choice. The scions should be cut from the parent tree before the least trace of growth has shown itself. They must not either be cut too early, because during the rest of the tree they are much better on it than off. The scions after being cut off, should be tied up in bundles, and stuck into the ground to the depth of $1\frac{1}{2}$ in. or 2 in. The situation should be well sheltered, but not too much so. Scions which have been entirely covered up with soil, or which have been preserved in cellars, are very tender, and it is a long time before they become acclimatised to the open air when they are grafted on the tree. The time for grafting is indicated by the tree itself upon which the graft is to be made. Grafting should be performed as soon as the sap begins to rise, which may be told by the swelling of the buds. It is not prudent to begin grafting too early, but when much work is to be done the professional grafter is often obliged to begin sooner than is advisable. The grafting of stone fruit may be begun before other varieties. Lately a fashion has come in of grafting at the end of autumn. With a view to test the value of this method, M. Burvenich has made several experiments on various fruit trees in the months of September and October. With the Apple and Cherry he was perfectly successful; in fact, he gives it as his opinion that the Cherry should never be grafted at any other time. As a general rule, however, the scion ought to be dormant, and the stock in full growth. Grafting, if possible, should never be performed when the wind is in the north or east, not only because the cold would be calculated to injure the graft, but because those winds are of a drying character, which greatly diminishes the chance of the graft taking, through becoming dried up after the operation has been completed.

Methods of Grafting.

It would take up too much time to describe all the different methods of grafting now adopted, more especially as M. Charles Baltet has published an exhaustive book on the "Art of Grafting." It may, however, be useful to describe a few of the methods applicable to fruit trees for the sake of those who have not M. Baltet's work. The most usual methods of grafting fruit trees are the following:

CLEFT GRAFTING.—This is a very old method, and, although not much practised now-a-days, ought always to be looked on as a good method of grafting. The stock is cut off level, as in fig. 9, at a certain height from the ground, taking care, however, to choose a portion which is clean and healthy. If the graft be made on the branches, the cut should be made close to the body of the tree, or if it be a low graft, it should be made from 2 in. to 3 in. above the ground. The raw surface of the cut should then be smoothed, and a slit made in it as

Fig. 10.

Fig. 11.

Fig. 12.

Fig. 13.

shown in fig. 10 with a grafting-knife, the depth being regulated by the thickness of the stock. A portion of the scion, bearing at least two good buds, should then be cut off and cut slightly thinner on both sides at the part which is to be fixed in the cleft, the upper end being cut off short, as shown in fig. 11. The cleft should be so wide as to take the scion easily without wounding it, but sufficiently tight to be in contact with it in several places. This being done, the whole is bound up to keep the two together, and to prevent the cleft from opening later on. It is not necessary to place wedges in the cleft to prevent the scion from being crushed. Instead of being of use this practice often prevents the proper union of the surfaces. Stocks of less than $\frac{3}{4}$ in. in diameter will only carry a single scion. Above that size they may be increased in proportion, as shown in fig. 13. Cleft grafting, as described above, is only applicable to pipped fruits, Plums, and Cherries. Stocks for the latter fruit should be of medium

Fig. 14.

thickness. In 1871 M. Burvenich made several experiments on a peculiar form of graft, consisting in the insertion of a three-sided scion in a corresponding cleft, as shown in fig. 14, with excellent results. This mode of grafting is not so difficult as one would suppose. One advantage is, that in this mode of grafting the stocks which have not taken may be afterwards used for cleft grafting. The triangular method is a middle course between cleft and crown grafting.

CROWN GRAFTING.—This mode of grafting may be practised later in the season than cleft grafting, for which reason it is

much used, more particularly for thick stocks and branches, especially in the case of stone fruit. Crown grafting should not be used until the bark separates easily from the wood; the branch or stock is cut off straight, or at an angle, as in cleft grafting; the wound is then smoothed down, after which a slit is made in the bark, which is separated from the tree by the grafting-knife, and the pointed scion is slipped in (fig. 15). In

Fig. 15.

some trees the bark separates so easily from the wood that the pointed scion itself may be used to effect the separation, in which case there is no need to use the grafting-knife. The scion, as shown, should be smoothed down on the side opposite to the bud, a shoulder being left at the upper end of the cut. A thin slice of bark is also cut off the scion on the side on which the lower bud is found, so that the raw surface may be in contact with the inside of the bark of the stock. If the bark of the stock be sufficiently strong, the handle of the grafting-knife may be inserted between it and the wood without making any incision; as the handle of the knife is withdrawn the properly-trimmed scion is gently pushed into its place. When the bark adheres to the wood very strongly, a piece may be cut out, as shown at *d*, in fig. 16, so as to hold the scion cut

Fig. 16.

to the same size, as shown at *B*. The whole is then tied up, but not too tightly, for fear of injuring the bark.

REGRAFTING OLD TREES.—Old trees which have not been grafted for ten or even twenty years, may be readily regrafted with varieties of a better quality than those they have borne, always provided they are sufficiently healthy and strong. From the above remarks it will be clear that the best system of grafting large branches is by crown grafting, the same method being adopted as in the case of ordinary stocks. When the trees are very old, certain precautions must be taken. As far as regards the period of grafting, it ought to be remembered that the movement of the sap and the separating of the bark and the wood taking place later in old trees, their regrafting ought to be deferred until the buds are on the point of expanding. The scions used for regrafting old trees should be young and vigorous; the number of branches to be grafted depends entirely on the age and health of the tree; this is a matter of individual judgment. Figs. 17, 18, and 19 will give an idea of how far the pruning process ought to be carried. The best time to cut the branches which it is intended to regraft is the

end of February or beginning of March, not precisely in the place where the graft is to take place, but some 10 in. or 15 in. higher up, so as to find the part of the branch which is to receive the scion full of sap when the period of grafting arrives; the branches are cut off as near the trunk as possible, as grafting on long stumps is to be avoided for several reasons. First of all, the scions do not grow so vigorous; besides which, long shoots frequently grow between the trunk of the tree and the scions, robbing them of their nourishment, and frequently becoming confounded with them. The thickness of the branch ought to determine the number of scions to be inserted; they should be at least from 1 in. to $1\frac{1}{4}$ in. apart. In grafting the scion on these thick branches, it is better to place the lower bud towards the centre of the branch instead of towards the bark, as in grafting an ordinary stock. In the case of the inclined branches, the scion should be grafted on the upper side; if there are two scions, one on each side, and all round if there are a larger number. The small branches which grow on the grafted portions of the old tree may be allowed to grow or not, according to circumstances. In the case of trees which are already well grown, and of which only a few of the branches require regrafting, it is perhaps better to allow some of the old branches to remain on; they can at any time be pruned down

Fig. 17.

Fig. 18.

Fig. 19.

if it should be thought necessary. It is always better to choose upright branches for pruning away in preference to those which are horizontal or inclined, as the former tend to starve the scions by absorbing too much sap. The year after the old trees have been regrafted, provided the scions have all taken properly, the whole of the superfluous wood may be removed. The Cherry and the Plum will bear regrafting up to an advanced age, as long as the thinner branches are selected for the purpose. Regrafting is a very practical method of renewing the health of the Apple and Pear. There is, however, a great difference between them in this respect. Pear scions may be grafted on branches fully double the size of those of the Apple tree, as large, in fact, as a man's arm.

Scions may also be grafted on trees without cutting the branches. At the proper season for crown grafting, an incision, in the form of a T, is made in the place where it is desired to graft the scion, just as in the operation of shield-budding. The scion, which ought to be a little longer than usual, and slightly curved, if possible, is, as in crown-grafting, slipped beneath the bark, tied, and luted. It would be wrong to suppose that old trees regrafted take as long to produce fruit as young ones, for we have frequently seen old trees regrafted bearing abundance of fruit within three or four years. Weak varieties of Pears and Apples, which have only been grown with an immense deal of difficulty—more particularly as regards the formation of the crown—will quite change their habit if grafted on a vigorous stock. The following varieties of Pears gain greatly by this method of treatment:—Josephine de Malines, Beurré Dubuisson, and Marie Louise; on Apple trees, the Belle Fleur de Brabant; and on Cherries, the Royal Early, as well as many others known for the strength of their growth.

(To be continued).

THE INDOOR GARDEN.

THREE ALOES.

Agave densiflora.—This is a good and distinct Aloe, of a bright, shining green-colour, and moderate as regards growth. When old the marginal spines are dark brown, but when young they are of a chestnut colour. It generally flowers in the seventh or eighth year, and reproduces itself by throwing up a new crown, which may be left intact, when it will soon take up a central position, pushing the parent stem on one side. It varies when raised from seed, and, therefore, there are in collections plants of it under different names,

Agave densiflora.

such as *A. Wolkensteini*, *A. chloracantha*, and *A. serrulata*. Plants belonging to this section of Agaves never appear to throw up suckers.

Agave americana.—This, the most common of all the Aloes, grows to a height of from 6 ft. to 10 ft., and its flower-spike often reaches from 18 ft. to 25 ft. In colour the foliage is glaucous green, but there is a variegated variety of this species, the margins of the leaves of which are yellow, and another variety, called *striata*, with yellow striped foliage; there is a third variety, too, called *mediopicta*, which has a band of yellow running down the centre of each leaf. This is, perhaps, the most beautiful form, but all four are grand plants for associating with architecture on terraces in summer, thereby giving nobility to a conservatory as well as setting off other plants to advantage. The old story that the American Aloe flowers

once only in 100 years is now pretty well exploded. Under pot culture it flowers according to the treatment which it receives, at from fifteen to twenty years of age; so long as frost is kept from it it is safe. One point regarding Agaves is important, and that is that the foliage be kept perfect; when a leaf is partially decayed, cut it off close to the root, and whenever a plant gets old and has many stumps of leaves on it, cut it quite clear off its roots in June and set it on a new tub or pot. This may be safely done, and thus the old base is got rid of and new vigour is at the same time infused into the plant.

Agave Scolymus.—This is a moderate-sized plant, of excellent habit, and beautifully adapted for vases. Its largest leaves are but 2 ft. long, and glaucous green in colour. It closely resembles *A. Verschaffeltii*; in fact, I believe the two to be only variations of one species. In a young state these two *Agaves* make excellent centres

healthy shoots, with a heel attached to them, off an old plant, which was neither useful nor ornamental; these I struck in the usual way, and I potted them in June in 5-in. pots, and grew them on near the glass in the stove, stopping them frequently until some time in July or August, when I removed them to the greenhouse, where they soon showed signs of flowering. They blossomed freely, and, from the commencement of the flowering period up to the present time, they have not ceased to form striking objects, and they still look as if they would keep in bloom for some time to come. It is therefore clear that if this plant be grown properly in 5-in. pots, or in any other size required, it will become both useful and ornamental at this season of the year, when it is difficult to keep conservatories well supplied with flowering plants. I am also of opinion that if it be kept in good shape and healthy it will make a valuable table plant, both

Agave americana.

Agave Scolymus.

for beds. Agaves, it is said, are always alike, but that is not the case, for I will guarantee that a person who saw a plant of *A. Scolymus* three years old would not know it at six, as it not only changes in habit, but the tint of foliage and spines also change, and the same thing happens in the case of other *Agaves*.

Small Plants of *Habrothamnus elegans*.—These are invaluable for autumn decoration. Some say that plants of this *Habrothamnus* are only suitable for pillars and walls; also that they should not be stopped until after the flowering season, when they can be cut hard back; but I prefer small plants for autumn use to using them as climbers, also that they should be stopped for this purpose, as it causes them to flower earlier, and keeps them in good shape for the conservatory, greenhouse, or table. Like many more, I did not value this plant in a small state until my attention was specially directed to it in that condition. I then took about a dozen

as regards duration of bloom and also brightness of colour under gas or other artificial light.—T. C.

Raising Small Seeds.—Small seeds, such as those of *Lobelia*, *Begonia*, &c., occasionally present, especially to the amateur, considerable difficulty in inducing them to germinate. This arises from the fact that, while it does not do to cover such seeds with soil, a very small amount of surface dryness is sufficient, when the seeds are swelling, to destroy them altogether. Covering the pots with Moss or sheets of glass is occasionally recommended; but both tend to draw up the seedlings, and not unfrequently cause them to damp off. Such being the case, I submit the following plan, with which I have been very successful in raising hybrid *Begonias*, whose seed is very small indeed. In most plant-houses may be found pots surfaced with a delicate growth of Moss, varying from the condition of a green felt to fully-developed Moss. On this sow the seeds. The Moss maintains a genial moisture, while its fibres retain among them the tiny seeds and prevent them from being washed down into the soil

and lost. A piece of turf (peat) kept close and moist under a bell-glass also answers the purpose, but air must be freely and judiciously admitted as soon as the seeds are up. Altogether I am of opinion that the best *nidus* for such seeds as I have named is a Moss-surfaced pot; in proof of this I may say that I have numbers of seedling Begonias amongst the various Mossy pots in my little plant-stove—some showing flower, and others not ten days old.—G. P.

Adiantum cuneatum pentaphyllum.—Under this name I received, some years ago, from the late Mr. Bewley, of Blackrock, Dublin, a very beautiful and useful Adiantum, which, as I have never seen it elsewhere, nor have been able to find it in any trade catalogue to which I have access, may possibly be unknown to some of your readers. It resembles the typical form of *A. cuneatum* in its creeping rhizome and more or less triangular fronds, which are, however, narrower in proportion to their length than in the type; the growth, too, is more upright, and the leaves are a fresh, bright green in colour, quite different from those of *A. cuneatum*, and they have no trace of the faint purplish tint to be found in the young fronds of that species. The chief distinction, however, is in the fact that in *A. c. pentaphyllum* it is only the first or second pairs of pinnæ that are again bipinnate, all the other pinnæ being simply pinnate, with the foot-stalks of the pinnules rising directly from the primary divisions of the rachis; the pinnæ are larger, more deeply lobed, and less oblique than those of the common form. From a cultural point of view, *A. c. pentaphyllum* is especially valuable, as it lasts, when cut, far better than any other form of Adiantum with which I am acquainted, the older fronds remaining unwithered for twenty-four hours, even without water; while in elegance, both of form and colour, it holds its own with any of the smaller species, such as *A. cuneatum*, *tinctum*, *tenerum*, and *Capillus-Veneris*.—GREENWOOD PIM. [Judging from the small specimen sent, this Maiden-hair appears to be *Adiantum glaucophyllum*.]

Kalosanthes coccinea.—There are few more showy, and at the same time more sweetly fragrant plants, than this. To grow and flower it well was at one time considered a creditable feat, though its culture is not a difficult matter. It is one of our oldest and finest greenhouse plants, and sometimes it is planted out during the summer in the flower garden. Cuttings of its succulent shoots struck in autumn, potted off the following spring, and allowed to grow all the summer in any light airy structure, or in a warm exposure out of doors, flower the same year. Like most of its class, it strikes freely, and the young plants may be potted singly in 6 in. pots in a compost of loam and sand chiefly, mixed with a proportion of broken potsherds and charcoal. The shoots are better not pinched; but if tops be chosen for cuttings which are just breaking into a number of shoots, as they often do, pinching will not be necessary. The great point as regards the summer culture of plants of *Kalosanthes* is to get their growth well ripened, and with this object, in the south at least, and even in the north, it is a good plan to plunge them in a warm border in front of a hothouse, where they will get all the sun and heat possible; in such a situation they do almost better than under glass. Water should be regularly but sparingly supplied, and towards August they should be kept rather dry, to induce the formation of flower buds, when they may be introduced to the conservatory and placed in a good light. The *Kalosanthes* is from the dry slopes of the Cape of Good Hope, and, as might be expected, the successful flowering of it depends very much on exposure to the sun and air, together with a limited supply of moisture. In order to increase the heat about the roots, I have seen the plants plunged in a bed of sand formed close to the front wall of a plant stove, where between the heat that struck outwards from the pipes inside the house, and the sun together, they were subjected to a temperature that would have been destruction to many other subjects, but which suited them admirably.—J. S.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Shading Todeas.—It has been found in the Holloway Nurseries this summer that shading placed from 6 in. to 9 in. above the glass, instead of being allowed to lie closely on it as is generally the case, greatly benefits the growth of Todeas. By this arrangement the sun's rays are effectually broken and a thicker canvas can be used than is usually employed, and yet abundance of light is admitted, conditions under which many other plants would doubtless be found to thrive besides Ferns.—S.

Sempervivum tabulæforme.—I find the present time to be the best for propagating this plant; cut the leaves off with a small portion of the stem adhering to each, have some shallow pans filled with soil, lay the leaves on the surface, pegging them down with small wire pegs; they should be put in a dry warm house, and must not be watered until the young plants are the size of Peas.—RICHARD NISBET, *Ascotbury Park*.

THE FLOWER GARDEN.

HEDYCHIMUM GARDNERIANUM OUT-OF-DOORS.

Nor only will this plant flower out-of-doors, but it will live through an ordinary winter without any protection. In order to enable it to do this, however, it should be planted out in May, so as to make its summer growth where it is to stand, as then it drives its roots deep down, and becomes thoroughly established before the tops die off in autumn. The soil that suits it best is a loose, sandy loam made rich by working into it a good dressing of thoroughly decomposed manure, and if this be done, and a mulching of the same applied while the plant is making its growth, with an occasional watering of liquid manure in dry weather, it will form stems at least 5 ft. high, with leaves double the size which they usually are under pot culture. For forming groups in the sub-tropical garden, this *Hedychium* has few equals, and as a plant for the backs of herbaceous or shrubby borders it is quite unsurpassed, affording, as it does, one of the most striking objects which it is possible to have in situations of that kind. Where the soil is not naturally favourable, deep holes should be dug, into which some drainage should be thrown; and then they should be either filled up with fresh loam, or the natural earth made rich and light. A heap of cinder ashes, half-rotten leaves, old tan, or anything of that kind, laid over the crowns in winter, will ensure their safety, even during the severest weather; or the roots may be lifted in autumn and wintered in any dry place along with those of Dahlias and Cannas. Those who once grow *Hedychiums* in this way, will never again be satisfied with them in pots, with their roots restricted and half-starved, as such gross-feeding plants must necessarily be, unless the pots afforded them are of unusually large dimensions. *Hedychiums* may be readily increased by dividing the roots, an operation which should be done in spring, just as they are starting into growth, as then the severed parts soon heal over, and there is no danger of rotting, which they would be liable to do were the separation effected while they are in a dormant state. In cutting the roots through, it is necessary to see that each piece has a young, plump crown attached to it, or disappointment may be the result.—S. D.

Lilium candidum an Evergreen.—Probably "F. W. B." never intended to convey more than "Dunedin" has so elaborately shown, viz., that this was the only Lily which had green foliage all the winter, and that in fact the clumps of bulbs of this variety were never devoid of green leaves. That the new growth is the product of new bulbs is, in the case of this Lily, well known to me, and the freedom with which these young bulbs are produced sufficiently accounts for the fact that this Lily is the most common of the family to be found in gardens. The golden variegated form of this variety is not as frequently met with as it should be, as in borders in winter its foliage has a cheerful and enlivening appearance. Even on that account alone, it deserves a place in every garden.—A. D.

Wintering Calceolarias.—As the best season for propagating these has now arrived, let me recommend any one who has hitherto experienced any difficulty in keeping his plants healthy through the winter to look well to the quarters in which they are placed. They cannot bear artificial heat, and therefore a cold frame is the best for them; set it on a hard foundation of coal ashes, and spread over them 6 in. of good fresh soil, consisting of sandy loam and a little leaf-mould; beat all down firmly, and insert healthy cuttings from growing shoots 4 in. apart each way. Water freely, and keep the frame close until the cuttings are rooted, after which ventilate freely on all favourable occasions, and water when necessary, as drought is injurious to Calceolarias of this class. Pinch out the points as soon as they commence to grow, and by April they will be fit for planting in beds. The roots being in a solid mass, will move in square blocks by cutting down between each plant, whereas plants in loose soil will not recover the check sustained by transplanting for some time.—J. GROOM, *Henham*.

Violets by Post.—I can confirm what Mr. Groom says (see p. 389) about transmitting Violets through the post in small tin boxes. I have done it for years with great success.—A. R.

An Ancient Rose Tree.—On the Grass near a pathway at Conington Castle is a veritable old tree of the Rose named Blairii No. 1. It is budded on the Briar about 3 ft. from the ground. I measured the stem 2 ft. 6 in. from the ground, and found it to be 15 in. in circumference, and the head through the branches was 12 ft. in diameter. It has not been disturbed for many years, and I was told that when in bloom it was a sight worth seeing. It is growing in a strong loam.—E. H.

VELTHEIMIA VIRIDIFOLIA.

THE Veltheimias form an interesting group of plants from the Cape of Good Hope, closely allied to the Tritoma; there are only two or three species, and the one here figured is the best. It is an evergreen, and has long, lanceolate, undulated foliage of a glistening deep green colour. From the centre rises a stout scape about 18 in. in height, bearing numerous, tubular, drooping flowers, which are purple streaked

Veltheimia viridiflora.

with red, and conspicuously green-pointed. It is said by many to be hardy, and may be so in very favoured spots in warm sandy soils, but from my experience I have never found it to succeed out-of-doors. As a pot plant for conservatory decoration it is valuable at this time of the year, the attractive spikes of flowers and the pleasing foliage rendering it an object of interest in the greenhouse. It prefers a good friable loam, and is readily propagated by offsets or by pulling off the leaves close to the bulb, and inserting them in a pot filled with sandy soil, when they will form bulbs at the base. A. P.

AMERICAN SENNA (CASSIA MARYLANDICA).

THIS is the showiest of the hardy Cassias, and its distinctive characteristics render it a suitable plant for the herbaceous border. It grows from 3 ft. to 4 ft. in height, and produces abundance

Cassia marylandica.

of bright yellow flowers in clusters. It is an attractive plant, and has been apparently overlooked, as it is rarely seen in catalogues, and consequently would be very scarce in private gardens. The leaves are sometimes used as a substitute for the common Senna, but the true drug is procured from Cassia orientalis. P.

TROPÆOLUM TUBEROSUM.

AMONG ornamental climbing plants for the summer decoration of our gardens few are more popular than the Nasturtiums or species of Tropæolum, and this popularity they fully deserve, for all the species are worthy of extensive cultivation. Many a country cottage and town garden are made bright by the flowers and fresh green foliage of Tropæolum majus, and many a rustic arbour, in itself perhaps a most primitive structure, is made a "thing of beauty" by the luxuriant and free growth of T. peregrinum, commonly known as the Canary Creeper. The Tropæolums, Indian Cress plants, or Nasturtiums, are all natives of South America, the species of which we give a figure having come originally from Peru. The specific name tuberosum was given to it by Ruiz and Pavon, in consequence of its root being in the form of a somewhat Pear-shaped tuber, and these tubers when cooked are a constant article of food amongst the natives. The flavour after boiling is said to resemble that of Seakale, but the pungency of the Tropæolums is still quite apparent; owing to this they have not found favour with Europeans as an esculent, for which they were proposed at one time; indeed, it was thought they might form a substitute for the Potato. The pungency in question, however, might be overcome by cultivation, as has happened in the case of the Potato, the tuber of which in its wild or original state is small and waxy, so much so that in Bolivia they are exposed, after being dug up, to the action of severe frost before they are cooked and eaten. The Bolivians treat the

Tropæolum tuberosum.

tubers of Tropæolum tuberosum in the same way, and they are said to be greatly improved. The plant was first grown in the Glasgow Botanic Garden so long ago as 1836, since which time it has been widely distributed, and is a great favourite on account of its nearly hardy character, brilliant flowers, and glabrous, dark green foliage, the leaves having each five broad lobes; the calyx is deeply five-lobed, of an orange-red colour, the upper segment prolonged into the usual spur; the corolla is composed of five petals, longer than the calyx, and of a bright red colour. The plant grows well out-of-doors in some localities, but to produce the flowers in greater perfection a slight amount of previous forcing has been recommended.

J. R.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Ricinus Gibsoni.—This beautiful bronze-leaved Castor-oil plant has withstood the severe frosts of last week better than any of the larger-foliaged varieties, and, while most of the other occupants of sub-tropical beds are quite destroyed, this is as fresh as ever. The side branches are highly effective for furnishing large-sized trumpet vases, now very popular in indoor decoration. —J. GROOM, Henham.

Androsace lanuginosa.—This is, I think, about the best Alpine rock plant with which I am acquainted; I have it in a sheltered spot facing the north-east. It is about 2½ ft. across, and completely covers the rather smooth surface of stone over which it forms a beautiful drapery. It has been in full bloom for over three months, and promises to continue so much longer. One other great point about it is that slugs do not touch it, and this is no small consideration. Will anyone devise a plan for keeping off these troublesome pests? —D. C. M., The Island, Rochestown, Cork.

Roses and Clematises Mixed.—I have on a previous occasion drawn attention to the beautiful effect produced by planting Clematises and climbing Roses together, and I cannot help still saying to those about planting for permanent beauty to try this combination, for as seen here they produce a most charming effect. Sedum spectabile for herbaceous borders or for flower beds at this season of the year is equally charming; the old Calceolaria amplexicaulis still retains the reputation of being one of the best and most useful bedding Calceolarias which we have, for when the other plants of a yellow colour have failed this is one mass of beauty. —A. OUTRAM, in "Gardeners' Record."

PLATE XCVII.

THE GENUS CLEMATIS.

(WITH A COLOURED FIGURE OF *C. indivisa lobata*.)

THERE is no class of plants which has been so prolific in varieties, in so short a period, as Clematises; and the wonderful diversity they exhibit in the size and coloration of their flowers, has materially enriched the choice of climbing shrubs, with showy flowers, produced in summer and autumn. Altogether about 100 species are known, and these are dispersed over nearly all temperate and sub-tropical countries of the earth, including the mountainous regions of tropical countries. A few occur in the tropics of America, &c., but they rank among the less showy members of the genus. Although the following enumeration includes several species requiring a high temperature, it may be observed that they scarcely deserve a place in a hothouse, where they are better replaced by

extensively planted; but, about that time, Mr. Jackman, of Woking, commenced hybridising, employing *C. Viticella* and the large-flowered Japanese sorts. Among the earliest acquisitions were the beautiful *C. Jackmanii* and rubro-violacea, and since then Messrs. Jackman and other raisers have reared an almost endless variety, and anyone who has seen the special exhibitions of this flower at Regent's Park and elsewhere must have been struck with their great beauty. Special descriptive catalogues of varieties are now issued by some firms, so that it is unnecessary to say more on this point than that every year new varieties are sent out, and intending purchasers should contrive, if possible, to see and make their own choice. The only danger is that the raising of varieties will be carried too far, and the public get tired of them as it has of several other fine florists' flowers in turn. At all events these handsome productions of the florist's art are quite able to recommend themselves, and the purpose of this article is more to point out the claims of the

Fig. 1.—*Clematis Viticella venosa*.

more brilliantly coloured flowers; but, both for the cool conservatory and the open air, Clematises are unrivalled among climbing shrubs with showy flowers. The earliest-flowering, hardy species commence unfolding their blossoms from the middle to the end of April, according to the season, and these are succeeded by other species and varieties throughout the summer and autumn, some of them continuing in bloom up to Christmas in mild localities. In colour, they present almost every shade and combination of red and blue, though pure scarlets and crimsons are still wanting. The lilac, pale blue, purple, mauve, claret, violet-purple varieties are connected by every intermediate shade. There are also yellow and many pure white-flowered species and varieties, the flowers varying from less than 1 in. to 8 in. or 9 in. in diameter. It is not only as climbers on trees or for covering walls, trellises, &c., that Clematises are useful. They trail or creep equally as well as they climb, and are also admirably suited for bedding, festooning, and other decorative purposes. With all the wealth of variety in wild species, and the Japanese varieties in our gardens in 1863, Clematises were not

species, which are likely to be lost sight of at the present time, though their uses are not the same as those of the florists' varieties. The original large-flowered Japanese kinds are all more or less tender, and in severe winters are often cut to the ground; but many of the hybrids—*Jackmanii*, for example—will bear without injury the severest frosts we ever get in this country. However, whether cut down by frost or knife, they will throw up again in the spring and flower perhaps even more profusely. They never form very thick stems, are not so suitable for permanently covering large spaces, particularly where the height is considerable, and to obtain their flowers in perfection the plants must be freely pruned. On the other hand, such species as *C. Flammula*, *montana*, and *Vitalba* grow quickly to a great height or length, especially the two last. A few species, such as *C. erecta*, *tubulosa*, and *integrifolia* are herbaceous. Characters for distinguishing the species are found in the shape and size of the flower, in the presence or absence of feathery hairs on the styles in the fruiting state, in the inflorescence, &c. Thus, in *C. Viticella* and its allies, the styles are not plumose, whilst in the *montana* and *Flammula*

groups they are. The montana group have medium-sized or large flowers, borne separately on long stalks; whilst *Flammula* and allied species have small flowers borne in large panicles. Several of the North American species have thick, leathery flowers. The New Zealand species and some others have unisexual flowers, and in a few the two sexes are borne on different plants. In popular language the parts of the flower are called petals, but here, in conformity with botanical usage, they are termed sepals. Reasoning from analogy, it is assumed that the sepals of the calyx are coloured, and the petals quite suppressed.

Native Species.

Traveller's Joy (*C. Vit-
alba*).—Under cultivation,
this species will quickly grow
to a height of 25 ft. or 30 ft.,
and if not quite so ornamental
as some of the other small,
white-flowered species, it has
its uses in covering unsightly
brickwork, &c. The feathery
carpels persist for a long time,
and give the plant a very
attractive appearance. From
this circumstance, it has got
the name of Old Man's Beard;
it is also called Lady's Bower
and Virgin's Bower. A native
of Southern and Central Eng-
land, and especially abundant
on chalky soils.

European Species.

1. Herbaceous Plants.

Entire-leaved Clematis
(*C. integrifolia*, Willdenow,
Bot. Mag., t. 65).—An herba-
ceous, erect species, with
large, oval, sessile, quite en-
tire, more or less distinctly
three-nerved leaves, 4 in.
long in some cultivated
specimens. Branches ter-
minating in solitary, nodding,
dark blue flowers, supported
on long, naked stalks. A very
hardy, free-growing and dis-
tinct, though not remarkably
showy species. It was cul-
tivated by Gerard in 1596.
A native of the Pyrenees,
Austria, and Hungary.

Erect Clematis (*C.
erecta*).—A dwarf, erect, her-
baceous plant, with pinnate
leaves, of two, or three, or
four distinct pairs, and a
terminal leaflet. Flowers
small, white, sweet-scented,
arranged in terminal, dense
panicles. A native of Central
and Southern Europe; cul-
tivated by Gerard. There is a
pretty, double-flowered va-
riety of this species, fig. 2.
It is quite hardy.

Besser's Clematis (*C.
lathryfolia*, Bot. Reg., xxv.,
t. 61).—One of the prettiest of the herbaceous Clematises, produc-
ing a profusion of white flowers in the summer. It grows about
3 ft. or 4 ft. high, and requires some kind of support to prevent it
from straggling. A native of the south-west of Europe, and per-
fectly hardy with us.

Purple Clematis (*C. Viticella*, Linn., Bot. Mag., t. 565).—
The ordinary variety of this has four reddish-purple, veined, obovate
sepals, narrowed very much towards the base, and the fragrant
flowers are about 2½ in. to 3 in. in diameter; but there are many
garden varieties in which the sepals are more numerous, and some of
them are quite double, though the single ones are certainly the hand-
somest. *C. Viticella venosa*, fig. 1 (see p. 400) has six reddish-purple

sepals, which are broader and more prominently veined than in the com-
mon variety. There are also some very showy hybrid varieties of this
type, all profuse summer and autumn bloomers. This hardy species
is a native of the South and West of Europe, and was in cultivation
by Hugh Morgan as early as 1569. *C. campaniflora* does not materi-
ally differ, except in the less spreading sepals and its blue flowers.
C. Hendersoni, with purple-blue, bell-shaped flowers, is probably a
hybrid, and *C. Viticella* one of its parents.

Evergreen Clematis (*C. cirrhosa*, Willdenow, Bot. Mag. t.
1070).—This species has an involucre of short bracts almost close
under the sepals simulating a
true calyx, so that at first
sight one might imagine
them to belong to a Rosaceous
shrub, especially as the upper
part of the peduncle between
the bracts and the sepals is
of the same colour as the
latter. A very tall species
with simple, entire or toothed
leaves, climbing to the top of
high trees by means of short
stout tendrils. The white
bell-shaped flowers are soli-
tary on short stalks in the
axils of the leaves, and about
1½ in. in diameter. In a
greenhouse it flowers from
December to February, but
it is quite hardy in the
warmer parts of the kingdom,
and in the open air it flowers
in March and April. In un-
usually severe winters it is
sometimes cut to the ground.
A common plant in the Medi-
terranean regions, varying
considerably in the lobing and
toothing of the leaves, which
are ternately divided in a
variety called *balearica*. It
is stated in Aiton's "Hortus
Kewensis" that this species
was cultivated by Gerard in
1596, but there appears to be
some mistake on this point,
as he says that he found it in
the Isle of Wight, and in a
wood near Waltham Abbey.
However, it was in cultiva-
tion in Phillip Miller's time,
who states that it stood out
in the open ground in the
Chelsea Physic Garden for
forty years without injury.
The name *calycina*, has been
given to this species in allu-
sion to the calyx-like invo-
lucre, and it is perhaps better
known by this name than
any other. The flowers are
useful for cutting, as they
hold well.

Fragrant Clematis
(*C. Flammula*).—This small-
flowered and small-leaved
species is valuable for the
delicious fragrance of its white
flowers, which are produced in
great profusion from July to

October. It is deservedly one of the commonest in cultivation, being
perfectly hardy, and continuing in bloom until late in the autumn.
For many purposes it is preferable to the larger-flowered kinds, as
it is not so much injured by rough weather. A widely dispersed
plant in the South of Europe and Syria, cultivated by Gerard in this
country in 1596. Its small pinnate leaves are very elegant and orna-
mented independently of the flowers.

Indian Species.

Hardy Shrubby Species.

Spring-flowering Clematis (*C. montana*).—One of the best
hardy species, flowering towards the end of April and beginning of

Fig. 2.—*Clematis erecta* fl.-pl.

May, when few other species are in bloom. It is a vigorous, rapid-growing climber, forming quite thick stems in the course of a few years. The leaves are ternately divided, and the white flowers are clustered in the axils of the leaves, each one being borne on a stalk longer than the leaf. The variety in cultivation has white fragrant flowers about $2\frac{1}{2}$ in. in diameter, but there are wild varieties in which the flowers are tinged with pink or yellow, and sometimes as much as 4 in. in diameter. A native of the Himalaya Mountains, ascending to 12,000 ft. above the level of the sea, introduced in 1831. This deserves a place in every collection.

Edgeworth's Clematis (*C. barbellata*, Bot. Mag., t. 4794).—From the same region and probably equally as hardy as *C. montana*, and flowering at the same time. The flowers are of a dull purple, the sepals margined with yellow and less spreading than those of *C. montana*. It was introduced to the Dublin Botanic Garden by Major Madden in 1854. A pretty species to contrast with its congener. The specific name is in allusion to the bearded anthers. It appears to be very rare.

Nepal Clematis (*C. nepaulensis*).—A slender climber with white flowers, not unlike those of *C. montana*, from which it is easily distinguished by having two connate bracts on the flower-stalk. In cultivation in this country in 1835, but I have seen it only in a dried state.

Old Yellow Clematis (*C. orientalis*, Bot. Mag. t. 4495, under the name of *C. graveolens*).—A pretty yellow-flowered climber, forming stout stems and woody branches. Leaves once or twice pinnate, smooth and glaucous; sepals ovate acuminate. Flowers about $1\frac{1}{2}$ in. in diameter, yellow, or sometimes mottled with purple in wild specimens, borne in large panicles. A widely dispersed and variable species, ranging in temperate regions in Asia from Persia to Manchuria, and ascending to an altitude of 14,000 ft. in the Western Himalaya. A hardy summer flowering and very desirable species. Although introduced as long ago as 1731, it appears to be rare.

Lindley's Clematis (*C. graveolens*, Lindley).—A greenhouse species, closely resembling *C. orientalis*, differing mainly in the sepals being elliptic and obtuse instead of taper-pointed. It is also more slender in habit, and the yellow, strongly-scented flowers are somewhat larger. In foliage it is not unlike *C. Flammula*. A native of the Himalaya Mountains at an elevation of between 6000 ft. and 11,000 ft., introduced in 1845. It is doubtless hardy in the warmer parts of Britain, at least from the higher habitats, if not the lower.

Stove or Greenhouse Species.

Hore's Clematis (*C. hedysarifolia*, Bot. Reg., t. 599).—A shrubby species with ternately divided rather thick leaves, climbing by means of its twisted petioles. Flowers small, white, in large terminal and axillary pendulous panicles. A stove plant cultivated by Messrs. Colvill in 1821; native of Pegu and Concan, and first collected by Mr. Hore.

Smilax-leaved Clematis (*C. smilacifolia*, Bot. Mag. t. 4259). A fine greenhouse climber with large ovate or cordate thick leaves, sometimes as much as 1 ft. in length by 6 in. or 7 in. in breadth. Flowers rather small and curiously coloured, scarcely exceeding $1\frac{1}{2}$ in. in diameter; the sepals thick and finely reflexed, dull brown and hairy outside, purple inside. A native of the sub-tropical regions of Borneo, Java, the Malayan Peninsula, and North India, introduced from Java by Messrs. Veitch in 1846.

Herbaceous Species from North China.

Hyacinth Clematis (*C. tubulosa*, Bot. Mag., t. 4296).—A handsome hardy herbaceous species, growing to a height of 3 ft. or 4 ft., and flowering late in the autumn, when few other things are in bloom. It has ample, ternately divided glossy leaves, and terminal panicles of small pale blue flowers, bearing a strong resemblance individually to those of a large single Hyacinth. A native of North China, cultivated in this country as long ago as 1846, but still rare in private collections. *C. Davidiana*, "Revue Horticole" 1867, p. 90, scarcely differs except in its hairiness.

Dusky Clematis (*C. fusca*, Gartenflora, t. 455).—A singular species in the colour of its pendulous tubular flowers, which are densely woolly, and of a rich dark brown suffused with violet. They are about 1 in. in depth, with the sepals slightly reflexed at the tips, and disposed singly on short stalks in the axils of the leaves. Stem erect and herbaceous, or woody and climbing in different varieties inhabiting North-eastern Asia. This species, according to Dr. Regel, is very attractive, and possesses the additional merit of being perfectly hardy even in the rigorous climate of St. Petersburg—that is to say the shrubby varieties. In Kamtschatka it becomes herbaceous.

Narrow-leaved Clematis (*C. angustifolia*, Will.; Watson's "Dendrologia Britannica," t. 112).—A dwarf, erect, half-shrubby species, with rather stout stems. Leaves pinnate, with three to seven distant, long, narrow leaflets, the upper ones usually undivided. Flowers white, about $\frac{3}{4}$ in. in diameter. This is a very distinct and very hardy Clematis, native of Siberia and North China. It should be treated as an herbaceous plant.

Cut-leaved Clematis (*C. aethusefolia*, Turez).—The typical variety of this Clematis is an herbaceous plant, or, in mild seasons half shrubby, the lower part of the stems becoming woody and persisting through the winter, with very slender stems and finely-dissected leaves, resembling rather those of *Adlumia cirrhosa* than those of Fool's Parsley, the lobes being often much narrower than in the accompanying figure (fig. 3). Altogether, this is one of the most

Fig. 3.—Cut-leaved Clematis (*C. aethusefolia*).

elegant, if not the most elegant, of the herbaceous Clematises, bearing a profusion of its yellowish-white, bell-shaped flowers, which stand up clear of the foliage during the latter half of the summer and the beginning of autumn. In a good soil it will climb to a height of 6 ft. or 8 ft. in one season, and its light and graceful foliage, and pretty, though not showy, flowers, recommend the plant more than any praise I could bestow upon it. Regel ("Gartenflora" (1861), t. 342) figures and describes a variety under the name of *latisepta*, in which the divisions of the leaf are broader. It is described as a tall, shrubby, slender climber, having white flowers. Both forms are perfectly hardy; the latter was introduced from Japan to the Amur country, by Maack, into Russian gardens, and the herbaceous form is from North China, by whom introduced I have not ascertained.

Japanese Species and Varieties.

Large-flowered Japanese Clematis (*C. florida*).—This species is regarded by botanists as being the parent of all the gorgeous florists' varieties of the lanuginosa, patens, cornelia, and other types. Although the extreme forms imported from Japan are very different from each other, there appears to be little doubt that many of them originated in Japanese gardens. How far they may

have been intercrossed it is impossible to say; but whether they have actually descended from one wild type or from more than one, is of little importance from our stand-point. They are very distinct and beautiful, and although not quite so hardy as some other species here enumerated, they are practically hardy, especially against a wall; and if they are out down by frosts they will shoot up again from the root, and flower as well as ever in the succeeding summer. The first variety was introduced just about a century ago, and is the one to which the name *florida* was originally applied. It has leaves consisting of three or five oval leaflets, and white flowers faintly tinged with blue, and about 3 in. in diameter. A semi-double variety appears to have been first introduced. Later came the *C. Sieboldi* having white flowers, with a purple violet centre; and several others were considered as varieties of *C. florida*. In 1836 the *cœrulea* or *azurea* type was introduced. This has large, widely expanded flowers 5 in. or 6 in. in diameter, composed of about eight sepals in the single varieties. The flowers are of a pale blue or lilac or white. Among early varieties of this type, "*Amalis*" and "*Sophia*" may be mentioned. The former has pale violet flowers, and the latter

Fig. 4.—*Clematis cœrulea odorata*.

very large deep lilac-purple flowers, each sepal traversed longitudinally by a greenish band through the centre. Another name for this type is *patens*. *C. lanuginosa* has usually simple, broad, heart-shaped leaves, and even larger, pale blue flowers. It was introduced in 1851. A variety called *pallida* has flowers not less than 9 in. or 10 in. across. *C. Fortunei* is a handsome double variety of more recent introduction. What these Japanese Clematises, intercrossed with others, have given birth to in this country is touched upon in the introductory part. *C. cœrulea odorata*, fig. 4, has handsome reddish-violet fragrant flowers. None of these varieties form very stout woody stems.

New Zealand Species.

Forster's Clematis (*C. indivisa*).—A splendid greenhouse woody climber, quickly covering a large space, and blooming most abundantly in the winter and early spring. It is a native of New Zealand, and is common throughout the islands, festooning lofty trees, especially on the outskirts of forests, having stems 6 in. thick. The trifoliate leaves are leathery in texture, and either glabrous or slightly downy, and the white, fragrant flowers vary in wild specimens from 1 in. to 4 in. in diameter. The leaflets are usually undivided, hence the specific name; but there is a variety with lobed leaflets, a coloured figure of which accompanies this. It bears the name of *lobata*, and different plants vary considerably in the extent

of the lobing, the present one being no more than coarsely toothed. Introduced about forty years ago, and deserving of all praise, being unsurpassed for embellishing a large greenhouse or conservatory in early spring.

Colenso's Clematis (*C. Colensoi*, Hooker; syn.—*C. hexasepala*, Lindley, "Botanical Register," xxxii., t. 44, not the true *C. hexasepala*).—A native of New Zealand, having ternately divided leaves, and small, greenish, but very sweet-scented, flowers. It is of slender habit, and the leaves are often very much divided into very small leaflets. Unlike the other New Zealand species, this has hermaphrodite flowers.

South African Species.

Masson's Clematis (*C. brachiata*, Bot. Reg., t. 97).—An evergreen, shrubby species, with dark green, ternately or quaternately divided, glossy leaves, and medium-sized white flowers with yellow stamens. Flowers in axillary, bracteate clusters of three or five. A greenhouse plant, climbing to a considerable height and flowering freely. It appears to have been first cultivated in this country by a Mr. Middlemist, nurseryman, at Shepherd's Bush, early in the present century. I do not remember having seen it in a living state.

American Species.

1. Hardy Shrubby and Herbaceous Species.

Long-flowered Clematis (*C. cylindrica*).—This is one of the most showy of the North American species, having bell-shaped flowers nearly 2 in. in depth, the sepals of a dark indigo-blue on the outside, light blue inside and on the margin. The flowers are thinner in substance than those of either *Viorna* or *reticulata*. It was in cultivation in the beginning of the present century, and is figured in the "Botanical Magazine," t. 1160. Native of Virginia and southwards, shrubby in its warmer habitats, but the stems are annual with us. A variety called *Walteri* has very narrow leaflets.

Leather Flower (*C. Viorna*).—Herbaceous or slightly woody at the base, with pinnate leaves, and thick, leathery, purplish, pendent flowers. A pretty species treated as an herbaceous plant, when it will grow to the height of 4 ft. to 6 ft. The yellowish, plumose styles of the fruit are very conspicuous. Leaves pinnate, or the uppermost ones simple. Flowers solitary, terminating the branches, and axillary. Andrews figured a Clematis, to which he gives this name, with flowers of a dark, almost indigo-blue, but this is probably *C. cylindrica*. The species was cultivated in this country in 1830. It is a native of North America, growing in rich soil from Pennsylvania and Ohio southwards.

Netted Clematis (*C. reticulata*).—A greenhouse species closely allied to *C. Viorna*, but the leaves are prominently net-veined, and the purplish flowers are somewhat larger and thinner in texture. Watson, in his "Dendrologia Britannica," vol. 1, t. 72, represents the fully expanded flowers as 3 in. across. A native of the southern States of North America, cultivated by Messrs. Colvill, of King's Road, Chelsea, in 1822. It possesses no special decorative merit.

Pitcher's Clematis (*C. Pitcheri*).—Near *Viorna* and *cylindrica*, but the styles of the fruit are not feathery. It has dull, purplish flowers, on long naked stalks. A native of Illinois, in the Mississippi. There is a very beautiful Clematis in cultivation under this name with handsome orange-red flowers.

Virginian Clematis (*C. virginiana*).—A slender climbing shrub, with ternate leaves, and coarsely toothed leaflets. Flowers small, less than $\frac{1}{2}$ in. in diameter, greenish white, arranged in axillary panicles. A very hardy species, ranging from Canada southwards. In cultivation in this country in 1761.

Creamy Clematis (*C. ochroleuca*).—A dwarf herbaceous species, with entire sessile leaves, and solitary terminal yellowish-white flowers. A rare North American plant cultivated by Messrs. Loddiges some years ago, and figured in their "Botanical Cabinet," t. 661. It is a plant of little beauty.

2. Stove or Greenhouse Species.

Houston's Clematis (*C. dioica*, Linn; syn. *C. americana*, Will.).—A very variable and widely-dispersed tropical American species, of tall, climbing habit. Leaves ternately divided, leaflets entire; flowers small, white, in large panicles. It was introduced by Houston before 1733, but it is not a particularly ornamental plant in comparison with many of the greenhouse species.

W. B. HEMSLEY.

Amarantus is a Himalayan crop, but it gives a poor and indifferent food. It forms an ornamental feature, both yellow and red varieties, when in flower on the terraced hillsides up to about 8,000 ft. or more.

THE LIBRARY.

ELEMENTS OF AGRICULTURAL CHEMISTRY AND GEOLOGY.*

ALTHOUGH this well-known work was specially written as a scientific guide to the agriculturist, it will prove none the less valuable to the practical gardener who wishes to make intelligent progress in the art of horticulture by studying the principles upon which it depends. To be successful, the horticulturist, just as much as the farmer, ought to become acquainted with the connection which exists between the art which he practises daily and the sciences of chemistry, geology, and physiology. The scientific principles involved in the growth of a bed of prize Roses are precisely similar to those which govern the cultivation of a 10-acre field of Wheat or Turnips.

The revision of the present edition of this important work has been entrusted to Dr. C. A. Cameron, the Professor of Chemistry to the Royal Agricultural Society of Ireland, who has been long and favourably known as a laborious and successful writer in this particular branch of science. The old arrangement of subjects has, for the most part, been strictly adhered to. We are first of all told in that lucid style, of which the late Dr. Johnston was such a thorough master, what are the objects of applying the sciences treated of to the improvement of husbandry in general. We are next instructed in the general principles of chemistry, after which the elementary constituents of plants, both vegetable and mineral, are fully described, and their sources traced to the fountain-head. A chapter on the physiology of plants, and another on their proximate constituents, such as gum, fat, sugar, gelatine, &c., bring this, the purely theoretical portion of the book, to a close. We now enter on the more practical division of the subject, with an account of the composition and properties of soils, and of the methods usually adopted for their improvement. These methods are discussed at full length, the reasons being given why different means are employed under the ever-varying vicissitudes of soils, climates, seasons, and the crops to be grown. This part of the book ought to be carefully studied by the horticulturist, who is more at the mercy of these changes even than the farmer. The chapters on manures and manuring will also repay attentive perusal, the "why and the wherefore" of the matter being discussed with great clearness. The article on the storage and application of manure is a peculiarly valuable one, and will be read with great profit by every cultivator who has access to a cow-shed, a stable-yard, a piggery, or even a fowl-house. After this follow half-a-dozen chapters on crops, cattle food, and dairy produce, which are but of slight interest to the horticulturist. The book concludes with a chapter on food and dietaries, which will be read with advantage by everybody.

The work is well and clearly printed, but we regret to see a few misprints amongst the chemical formulæ, which, although perfectly obvious to the practised chemist, will, it is to be feared, sorely puzzle the tyro who, as a rule, has an unreasoning dread of chemical symbols. About fifty additional pages have been added to this edition, and the index has been greatly enlarged, as well as divided into two parts—one referring to the authors mentioned, the other to the subjects treated of. We are glad to see that Dr. Cameron has adopted the latest method of nomenclature for chemical substances throughout, a glossary being added for the sake of those who find the new names strange to them. We cordially recommend this book to all those of our readers who wish to carry out horticultural operations on a truly philosophical basis.

An excellent instance of the nature of scientific knowledge properly applied is cited by Dr. Von Klenze in the "Country Gentleman's Magazine" of the present month. In the year 1869, in Upper Bavaria, some 1400 acres of swampy Grass land and lake were laid dry by proper draining at a cost of £74,000, and taken into cultivation. The owners of the reclaimed land expected it to prove as fertile as the water-washed banks of the Nile. It was accordingly tilled and sown, but not a single ear of Wheat or Barley reached maturity, and the scheme fell through. After yielding nothing but coarse Grass for five years, Dr. Von Klenze was induced to analyse the soil. He did so, and speedily discovered that the cause of its sterility was the absence of phosphorus and potash salts. The proper manures were applied to the land in 1874, and in the following year the crops were as heavy as any in the district, some of the produce carrying off the first prize at the Munich Agricultural Exhibition. Had the owners of the land laid out a few *swanzigers* on the purchase of the German translation of the book we have been reviewing, and studied it attentively, they would not have lost the interest of their capital and the value of the produce of their land during the six years that both were lying fallow.

* "Elements of Agricultural Chemistry and Geology." By the late Professor Johnston, of Durham, and Charles A. Cameron, Professor to the Royal Agricultural Society of Ireland, &c. Tenth Edition. W. Blackwood & Sons. 1877.

TREES AND SHRUBS.

RETINOSPORA JUNIPEROIDES.

THIS Cypress, according to Carrière, is a native of Japan. It forms a round-headed, Heath-like shrub, from 3 ft. to 5 ft. high, and has numerous erect, much-divided branches, covered at and towards their extremities with rather stiff, narrow, sharp-pointed leaves, from $\frac{1}{4}$ in. to $\frac{3}{8}$ in. long. They are arranged in opposite cross pairs (decussate—hence the name *R. decussata*, by which it is best known), and are of a bluish-green colour in summer, changing in autumn (in Britain, at

Retinospora juniperoides.

least) to a violet-purple. This colour at once distinguishes it from its congeners. We have blue-green, reddish-brown, and dingy-brown Conifers, but none of them at all approaching violet-purple. Its size, habit, and colour will at once suggest a befitting place for it in the ornamental garden. But it is as a winter bedding plant that I would more particularly recommend it, for which purpose its striking colour and neat dwarf habit highly fit it. It grows well in any moderately good soil, but it must be rather moist, as in dry or sandy soil it is subject to the attacks of red spider.

GEO. SYME.

THE HUON PINE (*DACRYDIUM FRANKLINI*) AT LONGLEAT.

THIS elegant Conifer, which is a native of Van Dieman's Land, was named in honour of Sir John Franklin, who discovered it growing in abundance on the banks of the Huon River, where it is said to form a lofty tree, many attaining a height of 100 ft., with a proportionately large girth of stem; its timber is considered valuable in that colony, and is much used by the natives in the construction of ships and boats. The annexed woodcut, prepared from a photograph, is a true representation of a specimen of it in the pleasure grounds at

Longleaf, and is probably the largest example of it to be found in the open ground in Britain. It measures 30 ft. high. In habit it is pendent and graceful, and singularly distinct from all other Conifers; its flexible branches, too, are clothed with pretty, whip-cord-like spray of a lively green colour. A more fitting and becoming memorial evergreen tree with which to adorn a cemetery could not easily be found; it would also be a suitable tree to plant in a rock or wild garden, or to place on a sloping bank to add picturesque contrast among trees and shrubs of wide-spreading and of less graceful forms. It is not, I think, generally known that this Pine is quite hardy in England, for I have often seen it in nurseries pent up and half starved in pots, and kept under glass during winter, instead of being treated as a hardy plant, and allowed to remain in the open ground, and so get hardened in its earlier stages of

The Huon Pine (*Dacrydium Franklini*).

growth, to enable it to withstand severe winters when planted out permanently. Some few years ago I bought a plant of this Conifer; it was in a pot, and had evidently been kept under glass previously; I, however, turned it out of the pot, and planted it in the nursery here; the first winter it got slightly injured by frost, but since then it has not suffered in the slightest degree through severe weather, and it may now be seen in the form of a healthy, well-grown tree.

GEORGE BERRY.

A Gravel-walk Metal-scraper Mat.—This is an iron grating-like mat for placing at entrances, the bottoms of steps, &c., approached by gravel walks, and convenient for removing gravel, snow, or sand from the feet. It is made by Messrs. Tidcombe & Son, of Watford, of the width of an ordinary step; and, being placed directly in the path, is convenient for use. Mats of this kind will probably be found very useful at hothouse doors.

THE TREES IN KENSINGTON GARDENS.

THE decayed condition of these ancient trees when contrasted with those of Hyde Park, shows at once an utter neglect of public taste and feeling, as regards the invaluable freedom of access of so extensive a scope of park and gardens, conjoined in an open expanse, and exceeding 800 acres. The sunken boundary of the ha-ha is unobtrusive and hardly perceptible; but the order and trim condition of Hyde Park, with its well kept borders, its accurately cut edgings, and its noble trees at once demonstrates a careful superintendence; whilst the other, from the decaying palace to the park boundary, discloses only utter somnolence, waste, and neglect. Originally there were three glades running from the round pond in a western, north-western, and south-western direction; these, as laid out by Repton, still exist, and present beautiful, healthful, and effective openings from the old palace, which was founded on the western wall; but in the intervals, and upon all the open spaces of the whole area, stand trees of nearly 200 years' growth, as at first planted; now of great altitude, many of them bare poles, many dead at the top, and nearly all in deadly conflict for freedom of "branchage." When we examine the position and space left for each tree, we find 8 ft. and 10 ft. to be the ordinary interval; but in many instances these giant-trees stand at intervals of only 5 ft., 4 ft., or even 3 ft. apart! In very many cases the tops are dead, but in most the stems grow up in nearly bare poles. How can it be otherwise when there is no space for lateral expansion? The branches interlace and conflict for freedom, which is, in fact, unattainable in a space so constricted. It is now certainly too late to redress the evil of too close planting, but still, by cutting away damaged and deformed trees, room might be secured for lateral expansion of the survivors, and thus the aspect of a forest of masts would be less repulsive, whilst the woodland would be more agreeable for light and shade, and in a few seasons more naturally branched. Of the standing timber, a full fourth part might be cut down, which would amply repay expenses of improvements, and at the same time much benefit rambblers who, when frequenting the woods, are much incommoded by the splashy nature of the subsoil. Is there no authority to inspect and rectify the defaults and growing decay of timber trees in Kensington Gardens? In Hyde Park there is a ranger, with a mansion and twenty acres inclosed; and that in the most valued centre; but there are also here various offices, repositories, stores, and cottages, together with a guardhouse, with an accumulated population, annually on the increase. Such is the freedom of open park and public liberties! As this is the season for clearing off and cutting down timber trees, this notice of waste and decay is given before the trees shed their last October leaves, and in order that remedial measures may at once be taken.

"T. H. H.," in "Builder."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Deciduous Cypress (*Taxodium distichum*).—There is now standing in the grounds at Conington Castle the finest tree of this kind I ever remember to have seen. It is 70 ft. high, and very symmetrical, and 6 ft. from the ground the trunk measures 7 ft. in circumference. It is growing in a strong loam resting on clay not far from a pond.—E. HOBDAY.

The Parasol Acacia (*Robinia Pseud-acacia umbraculifera*).—This, one of the most distinct of Acacias, is generally grafted standard-high, but, when on its own roots, it forms a moderate-sized bush, with a wide-spreading, roundish head, full of spray and entirely destitute of prickles. It has never yet flowered in England, as far as I know, although cultivated in this country for more than fifty years. It is the same as the *Robinia inermis*, and in some of the nurseries it is known as the Mop-headed Acacia.—G.

Mountain Bamboos.—*Arundinaria falcata* is only found in the Himalayas below 6,000 ft. or thereabouts, the higher Bamboo growing up to 10,000 is not *A. falcata* (as long supposed), but *Thamnochloa spathuliflora*, the latter being distinguished by its sheaths (which abruptly narrow into a subulate apex) and also by the beautiful transverse venation of the leaves, easily seen on holding one up to the light. There are various species of small Bamboo in Nepal and Eastern Himalaya, whether these two species extend so far east we are not aware.

Curious Seed-bed for Bamboos.—The finest group of Bamboos perhaps in the three kingdoms has been growing until last year at Fota; but they are now dead—seeded themselves to death, in fact. Interpered through them on the island on which they were growing were some other plants, among them being two Tree Ferns (*Dicksonia antarctica*). On the stems of these a quantity of the Bamboo seed lodged, and from this young plants have sprung up and are growing freely. It is certainly somewhat of a curiosity to find the Bamboo in the character of a parasite, and it would be a point of still greater interest if the plants were let alone to learn what the final result would be. Perhaps it may not be out of place to mention here that a large stock of young Bamboos has been raised at Fota (whether from home-saved seed or not I am unable to say) to take the place of those which have died. It is intended to place them between the old plants, and as soon as they have begun to grow freely the old stools will be removed.—"Gardeners' Record."

THE HUNTINGDON NURSERIES.

THESE, as might be expected, contain good collections of the choicer kinds of hardy plants, together with many beds of useful hardy bulbs, some of which, at the time of my visit, were full of bright flowers. The Colchicums, for instance, in the shape of some six or seven different varieties, double and single, were in great beauty, as were also several beds of *Sternbergia lutea*. There is a freshness and beauty about these autumn bulbs that ought to recommend them to all who love flowers. I also noticed several groups, among the *Rhododendron* beds, of *Lilium auratum*, each furnished with several fine spikes of handsome blooms. The following showy hardy plants were in flower, viz., *Rudbeckia Newmanni*; *Asters*—*Amellus*, *dumosus*, *ericoides*, and *Novæ Angliæ ruber*. *Erigeron bellidifolius*, a dwarf Aster-like plant, was likewise very pretty, as was also the dwarf yellow masses of *Chrysocoma Linosyris*, or Golden Locks, as it is commonly called. *Centaurea acanthifolia*, a hardy plant with white foliage, will, in certain phases of ornamental gardening, be useful; *Plumbago Larpentæ* was still pushing up trusses of bright blue flowers, and *Solidago villosa* and *mexicana* had just expanded their yellow inflorescence: *Statice latifolia* is a useful autumn plant; and, among the *Tradescantias*, *congesta* and *subaspera*, although past their best, were still pretty. *Malva moschata alba* was still in flower, as was also *Oxalis floribunda alba*. A bed of *Tritoma Uvaria glaucescens* was particularly striking and handsome; this, in my opinion, is the most useful of the genus. A bed of *Marvel of Peru* had stood out all winter, and was in full flower, but it occupied a sheltered corner. I noticed a good stock of *Yuccas*, especially of that best hardy kind, *Y. recurvifolia*; *Delphinium formosum*, *Belladonna*, *magnificum*, *nudicaule*, &c., are grown here in considerable numbers, but their beauty was over. *Potentillas* are a class of plants that deserve more attention than they usually receive, especially the double varieties, many of the flowers being very large and showy; *P. Escarbonelle*, *Aurora plena*, *Etna*, *Dr. Andre*, *aurea*, *marginata*, and *flammea* are all good.

In the *Dahlia* quarter, from which many first prize collections at local shows have been cut this year, the following were the very best, viz., *Mrs. Stancombe*, yellow-tipped fawn; *John Neville Keynes*, chrome yellow; *Flag of Truce*, white tipped lilac; *Sarah McMullen*, mauve pink; *Vice-President*, bright orange; *Ovid*, puce; *Cremorne*, yellow, tipped red; *James Cocher*, purple; *Miss Henshaw*, white; *John Standish*, scarlet; *Queen's Messenger*, purple; *James Service*, dark crimson; *Leah*, yellow, tipped rose; *Rev. Dr. Moffet*, dark mulberry; *George Goodall*, scarlet, shaded orange; *John Bennett*, yellow, tipped crimson; *John Laing*, scarlet; *Maggie Fairbairn*, pale lilac; *Royal Queen*, white, tipped peach; and *Eccentric*—this last is rightly named, for often several flowers of different colours may be cut from one plant.

Although the proprietors of this nursery, Messrs. Wood and Ingram, grow almost everything that is likely to be in demand, yet they have their specialities, and amongst these may be named *Carnations*, *Picotees*, and *Pinks*, of which the following are the names of the best, viz., *Scarlet Bizarre Carnations*—*Achilles*, *Dreadnought*, *Gorgeous*, *Duke of Grafton*, *Garibaldi*, *Howard*, *Lord Derby*, and *Prince of Wales*. *Crimson Bizarre*—*Alderman*, *Chairman*, *Eccentric Chap*, *Sybil*, *Isaac Wilkinson*, *Wm. Henfield, Esq.*, and *Lord Hinchinbrook*. *Purple Flakes*—*Squire Frew*, *Mayor of Nottingham*, *Miss Mills*, *Ada*, and *Lord Sandwich*. *Rose Flakes*—*James Merryweather*, *Lady Florence*, *Miss West*, *Lady Jane Repton*, *Lady Mandeville*, *Mr. Woodruffe*, *Mrs. Hurst*, *Pallida*, *Rosabel*, and *Rose of Stapleford*. *Scarlet Flakes*—*Adrian*, *Douglas*, *Superb*, *Guy Mannering*, *James Cheetham*, and *Splendour*. *Picotees*, *Red-edged*—*Ada Mary*, *B. J. Bryant*, *Delicata*, *Duchess of Bedford*, *Forester*, *Lizzie*, *Minnie*, *Mrs. Brown*, *Mrs. Ormsby*, and *Wm. Summers*. *Purple-edged*—*Edmund Papworth*, *Lady Elcho*, *Lady Sandwich*, *Mary*, *Mrs. Little*, *Robin Hood*, and *Mrs. Summers*. *Rose and scarlet-edged*—*Beauty of Plumstead*, *Dolly Varden*, *Edith Dombrain*, *Mrs. Fordham*, *Rev. H. Mathews*, and *Prince of Orange* (yellow ground). *Pinks*—*Arabella*, *Bertram*, *Charles Turner*, *Devise*, *Emily*, *Excelsior*, *Fanny John Balls*, *Marion*, *Minnie*, *Minor*, and *Victory*.

There are also here collections of the best double *Pyrethrums*, *Pentstemons*, and *Phloxes*; likewise large beds of *Scillas*, consisting of six or seven kinds, which give quite a character to the place in spring. *Cyclamen europæum* and its white variety were, at the time of my visit, full of flowers and very showy, and among beds of specimen shrubs I noted several bushes of *Magnolia grandiflora* (Exmouth variety) unfolding its large, pure white, sweet-scented flowers, whilst close by was a long border of *Daphne Cneorum*, with many of the plants precociously in flower.

Of the glass houses and their contents, I do not intend to speak in detail. Amongst other things for which this firm has obtained a reputation may be named herbaceous *Calceolarias* and *Cockscombs*, both of which are grown largely for seed purposes. Heaths of all the usual winter and spring blooming kinds are well grown, as are also *Epacris*, *Azaleas*, *Camellias*, and other hard-wooded plants. I also noticed a good batch of *Euphorbia jacquiniæflora* much better furnished with branches than usual; that useful plant *Abutilon Boule de Neige* was also plentiful, and *Poinsettias* (both double and single) were likewise abundant. Amongst Ferns were thousands of seedlings of the Bird's-nest Fern, which will, of course, be distributed amongst the trade. Of Zonal *Pelargoniums*, I selected the following as being both good and distinct, and useful for pot culture, viz., *Lord Zetland*, pink, white blotch in upper petals; *E. Davis*, purplish-crimson; *Corsair*, orange-scarlet; *Mr. Jacoby*, salmon-rose; *Lady Bosworth*, pink; *Mrs. Lancaster*, pink; *Laura Stratton*, salmon; *Dr. Koch*, scarlet; *Wonderful*, scarlet; *Double Vesuvius*, a good winter-bloomer; *Jessica*, dark crimson; *Jealousy*, yellowish-salmon; *Huntingdonia*, white; *David Thompson*, dark crimson, white eye; *Elise Sisley*, double white, and one of the best, but like all the others the flowers die off pink. Amongst novelties I noticed a good specimen of Harrison's hybrid Musk beautifully in flower; this is destined to become a favourite with growers for market, and, indeed, with everybody who has a window or a square yard of border. In this nursery many thousands of bedding and decorative plants are raised and sent out annually. All the best kinds of *Show*, *Fancy*, and *French Pelargoniums* are largely grown here, as are also *Fuchsias*, and the still popular *Tricolor Pelargoniums* are grown by the thousand; even such good old *Pelargoniums* as *Rollisson's Unique*, an admirable kind for furnishing cut bloom, may likewise be found here, and many scented-leaved kinds, which everybody should grow for mixing with cut flowers and for making button-hole bouquets. In order to give some idea of the extent of the trade done here in bedding plants, I may mention that last year this firm sold 15,000 of *Centaurea candidissima* alone, all seedling plants, the produce of seeds sown in August or September.

As soon as the bedding plants are cleared out, the houses which they occupied are planted with Cucumbers for seed purposes, and I noticed, amongst other kinds, a good crop of *Rollisson's Telegraph*. When true this is a long, handsome fruit; I have grown it 28 in. in length, although from 20 in. to 24 in. may be taken as the average length. Like many other good things, it is sometimes difficult to obtain seeds of it, and other sorts are frequently substituted for it, causing much disappointment. I have often induced the formation of perfect seeds by tying a ligature round the fruit 4 in. or 5 in. from the end; this generally causes the end to swell up into a club-shaped protuberance, from which seed may be obtained, when fruits grown on in the usual way are seedless.

In what are called the Brompton Nurseries belonging to this firm, many thousands of *Roses* are grown, a large proportion being standards. The soil is a rather stiffish loam, as far as I could see, adhesive and sticky in winter, but porous and inclined to suffer from drought in dry summers, like most of the loams overlying the oolite clays. On such a soil *Roses* do not make so rapid a growth as on some of the best *Rose* soils in Hertfordshire, Sussex, and Herefordshire, but the wood is built up firm and compact, and such plants are always well furnished, and move better than where the growth is over-luxuriant. At the time of my visit (October 1), the following were still in good condition, viz., *Maurice Bernardin*, *Elizabeth Vigneron*, *Madame Boll*, *Madame Charles Crapaudet*, *La France*, *Baroness Rothschild*, *Camille Bernardin*, *Marie Baumann*, *Paul Neron*, *Jules Margottin*, *Countess of Oxford*, *Abel Grande*,

Captain Christy, Marie Finger, Hyppolyte Jamain, Princess Louise, Baron de Bonstetton, Madame Lefebvre, Bernard, and climbing Victor Verdier. Many Teas and Noisettes were also in bloom, and last, but not least, I must mention a plantation of the old pink and crimson Chinas, as bright and as full of flowers as a bed of Pelargoniums in August.

In answer to my questions as to what kinds of fruit trees were most in demand in this and the neighbouring counties, Mr. Sims, who has been manager for Messrs. Wood & Ingram for many years, has furnished the following lists:—Apples—Histon Favourite (a local variety), Wellington, Lord Suffield, King of the Pippins, Blenheim Orange, Juneting White and Red, Celine, Keswick Codling, Royal Pearmain, Quarrenden, Everlasting Pippin, Warner's King, Stamford Pippin, Bess Pool, Scarlet Pearmain, Ribston Pippin, Sturmer Pippin, and Huntingdon Codlin (a local variety). Pears—Autumn Bergamot, Gansel's Bergamot, Glou Morcean, Beurré Bose, B. de Amanlis, B. de Aremborg, B. de Capiaumont, B. Diel, B. Rance, B. Superfine, Citron des Carmes, Duchesse d'Angoulême, Crassane, Jargonelle, Josephine de Malines, Louise Bonne de Jersey, Marie Louise, Ne plus Muris, Seckel, Winter Nelis-Hasel, Williams' Bon Chrétien, Stilton Swan's Egg (a local variety), Van Mons Léon Leclerc, Passe Colmar, and Vicar of Winkfield. Plums—Victoria, Diamond, Orleans, Early Prolific, Cox's Emperor, Goliath, Pond's Seedling, Prince of Wales, Green Gage, Transparent Gage, Kirke's, Coe's Golden Drop, Jefferson, Washington, and Reine Claude de Bavay. Sixty or seventy acres are devoted to the culture of fruit trees, and they are in all stages, from what are termed maidens to those several years trained; various kinds of stocks have also been tried, and are still in use, for Apples, Pears, and Cherries.

Conifers of all the best kinds are plentiful, and amongst evergreen and deciduous shrubs I noticed the Golden Catalpa and the Golden Elder, both wonderfully bright and handsome; also *Euonymus latifolius*, clothed with scarlet berries, and the Carolina Allspice, producing freely its bronze, singular-looking, scented flowers. Here I likewise noticed a useful kind of evergreen [Honeysuckle (*Lonicera grata*), which everybody ought to grow; it is very robust in habit, and nearly always in flower; when I saw it on October 1 it was quite gay. Amongst Hollies, both green and variegated, I noticed good examples of *Wateriana*, Golden Queen, Handsomithi, alba marginata, aurea marginata, Weeping Milkmaid, and Silver Queen, the latter especially well covered with berries. Among park trees, the Carolina Poplar (*Populus quadrangularis*) is a handsome, free-growing tree, with large, noble-looking foliage; *Populus nivea argentea* is another handsome Poplar that is now being sought after, and it is one that is calculated to give a distinct feature to park scenery. *Populus canadensis nova* is also good, and the Eagle's Claw Maple has a novel appearance, with its claw-like foliage. How beautiful at this season are the scarlet American Oaks! Truly we are a conservative people, or else we should use more freely the good things in the way of trees which our enterprising nurserymen bring home to our very doors. Tulip trees again, though very handsome, are not planted in very great quantities, and yet they grow as freely as the Oak. Then again among the Planes, the Western, or Occidental, is an especially handsome tree, and one that is now in brisk demand, although, for some purposes, the Eastern or Oriental is preferable to it.

E. H.

The Mediterranean Flora.—From personal observations in Italy and Greece, with the aid of literature bearing on the subject, M. Fuchs comes to the conclusion that the so-called Mediterranean flora, so far as represented by evergreen woody plants, and plants of the Sage, Thyme, Lavender, and Rosemary Order therewith always associated, occurs, at least in France, Italy, Greece, Southern Russia, and Northern Asia Minor, exclusively on calcareous formation, while soils with little or no lime (granite, gneiss, flysch, sandy and muddy alluvia of rivers) in the whole of that region, and south to Sicily and Morea, bear exclusively deciduous foliaceous trees, and in general, a vegetation hardly differing from the ordinary central European flora. We are not, however (M. Fuchs says), to conceive the phenomenon as if the former class of plants required the lime as nutriment; the correct view rather is, that the southern evergreen flora is better able to press northwards on the drier and warmer

calcareous formation, than on the damper and colder clayey soil; and he finds support of this view in the fact that, in the Azores, Madeira, and the Canary Islands, with a truly sub-tropical climate, an evergreen shrub vegetation, closely agreeing with the Mediterranean flora flourishes on various kinds of soil.

THE UPAS TREE.

Few plants are more popularly known than the Upas tree (*Antiaris toxicaria*), and there are few that have had more exaggerated stories written about them. Everybody has read or heard of the extreme virulence of this tree, how that in the valleys of Java no living creature, whether human or belonging to the brute creation, could resist its evil effects, even for the shortest space of time; that birds in their flight, unconsciously approaching within a certain distance of the trees, instantly fell dead; that criminals sentenced to death were certain to meet their fate if they were compelled to go within three or four leagues of a Upas tree, and that within this radius the ground was strewn with dead bodies and blanched skeletons.

Antiaris toxicaria.—A. male flower-head; B. female flower, showing two-parted style.

All these fabulous tales emanated from a Dutch surgeon, who had travelled in Java, and afterwards recorded all he had heard from the natives regarding the *Antiaris*. These stories became diligently circulated by every writer who took up the subject, and the supposed virulence of the Upas tree even formed the foundation for a lengthened series of lines in Darwin's "Botanic Garden." The greater facilities of exploration, however, and the spread of civilisation, which since that time has developed itself, have proved all these startling accounts to be, to a large extent, fabrications, the fact being that the Upas tree inhabits the hot, damp, and low valleys of Java, where carbonic acid gas is generated in great abundance, besides which sulphuric vapours are emitted from the craters of volcanoes connected with the valleys, so that the Upas tree was at one time credited with these poisonous effects. Notwithstanding all this, however, the tree contains a very virulent poison. From incisions made in the bark a white or yellowish juice exudes in great abundance, and soon becomes concrete in a black, resinous mass; this resin, mixed with other ingredients, is used as an arrow poison, both for the chase and in warfare. The inner bark of the young trees, which is very fibrous, is used for making articles of clothing, but on account of the poisonous resin contained in it it is said to cause great irritation to the skin of those wearing such garments. The Upas tree is one of the largest forest trees of Java, rising to a height of from 60 ft. to 70 ft. It is monœcious, the male flowers being very numerous and enclosed in a hairy involucre of several divisions, turned or rolled inwards; the female flowers, which are solitary, grow in the axils of the leaves, in close contiguity to the male flower-heads, and, as they mature, give place to a fruit of an ovoid, succulent, drupe-like form. The plant is not uncommon amongst tropical plants in botanical collections, but beyond its historical interest it has little to recommend it. R.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Planting Fruit Trees.—Where fruit trees have to be planted, that operation should be commenced as soon as the leaves have fallen and the trees are in a condition to move. Nothing is more fatal to successful growth during the ensuing year than late planting; it frequently happens that frost sets in about the close of the year, and then no opportunity is afforded for planting until the buds have begun to move; and in open winters, on heavy, retentive soils, the land is frequently so wet that the soil, when compressed closely about the roots, adheres in a compact mass, and is in the worst possible condition for the development of young fibres; consequently an effort should be made to complete the work as early as possible. "If you plant trees before Christmas they will grow of themselves, if planted afterwards, you will have to make them grow," is an old saying, and one which applies to Apricots, Peaches, Nectarines, Pears, Apples, Plums, and Cherries. "First come, first served," is the way in nurseries; consequently the first purchasers have the advantage. To

old borders in which wall trees are grown, I should recommend new soil, where it can be got, being added; from 6 in. to 12 in. will be of the greatest possible benefit to the trees; if well mixed with the already dug ground, this will be better than the most liberal use of manure. Where walls are not to be altogether re-furnished, but only here or there a tree put in, or young ones

planted betwixt others that have shown signs of failing, a spit of the old soil may be removed for a space of 6 ft. or 8 ft., and new material added. There is nothing more uneconomical than bare wall space. I should, therefore, recommend amateurs to furnish every available

wall with fruit trees, not only such as belong to the garden proper, but also those of dwelling-houses and out-buildings; on both the latter, fruit trees can often be grown when they fail on garden walls; the greater height of the wall of dwelling houses, with the warmth communicated from the fires inside, will frequently ward off frost, so as to preserve the bloom in spring when it is destroyed on low garden walls; and again, especially in the case of Pears, there is plenty of room for the trees to attain height, a condition favourable to fruit bearing. This season throughout half the counties in England I have noticed that the best crops of Pears have been on trees on dwelling houses. Apricots, Peaches and Nectarines should have a southern aspect, although, in the more favoured localities, they will frequently do well on an east or west wall. Amongst the many varieties of Peaches and Nectarines that are offered for sale, some of which are new, amateurs are often perplexed as regards what to buy; there is, however, one Peach—Hale's Early—that has everything to recommend it; it is very early, and the fruit is large and excellent in quality. This should be planted to come in first, and Grosse Mignonne will succeed it. Royal George is still one of the very best of Peaches in every way. Noblesse is large and excellent in quality, but deficient in colour, which detracts from its appearance. Téton de Venus is a

late kind of good quality not sufficiently known. Late Admirable will come in a little later. Of Nectarines, Lord Napier is a real acquisition; it is very early, large, beautiful in appearance, and excellent in quality. Elruge, a good old kind, will succeed the last-named; and Violette Grosse a little later. The above half-dozen Peaches and three Nectarines may be relied upon as being the best amongst these fruits. The finer kinds of Pears also succeed best on a southern aspect, and where east or west walls are furnished with this fruit, I should recommend early or second early kinds being chosen, such as Jargonelle, Dunmore, Williams' Bon Chrétien, Louise Bonne, and Marie Louise. Plums and Cherries will generally succeed well on east or west walls; of Plums I would recommend Rivers' Early Prolific, a free-bearing purple kind; Green Gage; Jefferson, a very fine yellow variety; Kirke's, a large purple sort, excellent in quality; and Reine Claude de Bavay, green. To these may be added Coe's Golden Drop, a yellow sort of the very best quality, especially when allowed to hang late. Of Cherries, May Duke is excellent and a free bearer, and Frogmore

Bigarreau, Bigarreau Napoleon, and Black Tartarian are all good kinds. North walls may be furnished with Morello Cherries, Gooseberries, and Currants; even though they should not be more than 4 ft. high, the two latter will succeed on them; Gooseberries are not nearly so often planted in this way as they deserve to be, for, when thus grown, they are easily protected from birds, and they will hang upon the trees so as to furnish dessert for many weeks beyond the time they are generally obtainable from trees in open quarters, and walls covered in this manner look much better than when bare. All fruit trees, especially standards and pyramids, planted in the open

ground, should have such support as they require placed to them immediately they are planted, as, if their heads be allowed to be swayed about with the wind, the roots are sure to be injured.

Endive.—A little more should now be put to blanch; boards, such as have been already described, are at this time, when there is danger of frost, preferable to the ordinary tying up; where the latter is practised, and the soil of a light, open character, a little may be drawn up to each row of plants after they are tied up; some dry litter or Fern (the latter where obtainable is preferable) should be kept in hand to throw over Endive that is thus tied up when there is an appearance of frost; or a sufficient number of empty 9-in. or 10-in. pots may be kept near the rows, dropping one over each plant when there is likelihood of frost; the labour entailed in putting them on or off is not more than five minutes for a moderate supply, and by their use I have been able to keep Endive in ordinary seasons without being frozen up to Christmas. It is not well to leave the pots over the plants in the daytime, as I have found when the light was excluded the Endive decayed much sooner than it otherwise would have done.

Celery.—All, except the very latest for spring use, should be

A Flower Market and City Square in one.

The new central flower market de la Cité in Paris, with plantation of Paulownias for shade. The scene, as drawn and engraved for us, represents the appearance of the market very early in the morning.

sarthed up, as after this we might have sufficient frost at any time to injure the tops, in which case it does not keep well.

Winter Onions.—Where there is an inclination to grow these as large as they are capable of becoming, a piece of ground should now be deeply dug and heavily manured, getting the manure well down to the bottom of the trench, say 15 in. or 18 in. deep, and on this some of the autumn-sown Onions should at once be planted; they must not be dragged up in the way sometimes practised, by which many of their fibres are broken, but carefully lifted with a planting trowel so as to retain all their roots uninjured; for planting use either the trowel, or an ordinary dibber, but whichever is employed see that the fibres are not doubled up, but put in straight down in their natural position; plant them in rows 1 ft. apart, and 4 in. or 5 in. asunder in the rows, this will admit of every other being drawn for use in the spring, allowing the remainder to grow to their full size. I have tried both autumn and spring planting with this crop, and find that the present is much the best, the roots attaining a larger size when moved at this time than in the spring, when they are making more active growth; another advantage is that the check which they now receive has the effect of rendering them hardier and better able to stand a severe winter, should such occur, than those that are allowed to remain in the seed bed.

Winter and Spring Broccoli should at once be laid, turning their heads to face the north; in this position, the sun, when it does shine, does not injuriously affect the frozen hearts by thawing them in the way that often happens when it shines directly upon them. This laying process, as regards winter Broccoli, has a twofold effect: it checks luxuriant growth in a way that imparts to the plants a harder condition than if they were allowed to go on growing undisturbed until suddenly arrested by frost; and the stems, being partially covered right up to the leaves, also receive additional protection. On dry land, in open, unconfined spaces, laying is not so necessary, as in small, confined gardens where the plants, by being more or less sheltered by walls and fruit trees, are in a more tender condition, especially where the soil is of a moist, retentive nature, particularly if the plants have been grown somewhat too near together, as this, more than any other cause, incapacitates them for withstanding severe frost. Veitch's Autumn-flowering Broccoli, or Walcheren, now fit for use or forming heads, are deserving of a little extra attention; any that are ready may with advantage be taken up and heeled-in closely in spare pits or frames, or they will do well thus heeled on the floor of an open shed, placing some soil upon it for the purpose; where such a position is available, a mat or two thrown over them at the time of keen frost, will be sufficient protection up to the end of the year. If no convenience like the above exists, the plants may be put close together in a sheltered position under a south wall, where they can be protected with mats or straw; but wherever placed, the soil with which the roots are covered must, at the time they are put in, be well watered, so as to make it sufficiently moist; without this, the plants flag, the result of which is to make the heads tough and unpalatable. The way sometimes advised of taking up Broccoli and hanging it in sheds or buildings until required for use, I have found to have the effect of making it so tough that when cooked it was always indifferent in quality.

Parsley.—Some roots should now be taken up and replanted in a frame; if they have been grown large and strong by treatment such as advised through the season, each crown will furnish as much as half-a-dozen of the ill-grown examples resulting from overcrowding. The plants ought to be put sufficiently near together for their leaves to just touch. In the removal, their roots must be no more broken than unavoidable, and they must have a good soaking with water as soon as planted; if a glazed frame be available, it will afford the best protection from snow and frost, but the lights must be kept completely off until there is an appearance of such weather. If a frame of this description be not at hand, some boards nailed together, so as to form the back, front, and ends, with a slight framework across to carry mats during hard weather, will be the best substitute.

Castor-oil Leaves and Grasshoppers.—A farmer in California has been experimenting on the leaves of the Castor Bean, and reports them as being deadly poisonous to grasshoppers. He had some trees which the hoppers were destroying, and he scattered leaves of the Castor Bean under them, and adds:—"So remarkable was the result, that an actual count of the number killed under one tree showed 498 dead ones and about 20 in a dying condition. Only a very small portion of the leaves were eaten; and, judging from the effects of the small portion consumed, I believe there was sufficient material left to have killed ten times as many." He suggests that hedges of the plant be grown around farms, and an occasional row in vegetable gardens.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

October 29.—Sowing Mustard and Cress in boxes placed in heat Potting off Sweet Basil into 6-in. pots, and placing them in a warm house to give a supply during winter; also potting Tomato cuttings to grow on for early fruiting. Putting a good coat of long litter round the shoots of Globe Artichokes. Clearing off old Rhubarb and Seakale leaves and manuring the ground. Filling pit with manure and leaves that had previously been well prepared for pot Vines. Getting a little Chicory and Dandelion into the Mushroom-house to blanch.

Oct. 30.—Potting a late batch of Primulas and Cinerarias. Removing Pelargoniums from cold frames into Vineries. Nailing up Ivy, Roses, and other climbers on walls, to prevent them being injured by wind, and to give them an orderly appearance. Turning over a large heap of manure, and adding 20 lb. of salt and 1 bushel of soot to the cartload. Putting some new stakes to young trees where blown off by wind.

Oct. 31.—Removing Cinerarias and Primulas from cold pits to warmer quarters. Stirring the soil among Spinach, Endive, Lettuce, Cabbage, and Cauliflower plants. Cutting for use Veitch's New Autumn Self-protecting Broccoli, which is now in fine condition. Mowing, cleaning up leaves, and rolling gravel walks.

November 1.—Taking up August-sown Cabbage plants, and planting borders with the small plants, placing them 6 in. apart, for spring planting. Turning a large heap of leaves and manure for making hotbeds, and covering up Seakale and Rhubarb. Earthing up late Celery when the soil is dry and in workable condition. Getting manure on the ground whilst it is dry.

Nov. 2.—Sowing French Beans in pots and placing them in heat Covering up Endive, and tying up Lettuces to blanch. Clearing out Melon-frames, and preparing them for wintering Endive and Lettuce. Cleaning leaves off the walks, and getting them all rolled down. Giving Leeks and Cardoons a final earthing up. Looking over the Cauliflowers, and turning down leaves where required, and placing some of the forward ones in an open shed.

Nov. 3.—Potting Lily of the Valley for forcing. Planting Daisies Wallflowers, and Myosotis. Getting up Dahlia roots, and storing them away in a dry room. Clearing away Scarlet Runners, and storing away the best of the sticks for the earliest crop another year. Spawning Mushroom bed and covering it with mould. Watering the Pines all through that require it. Fruit in use for dessert:—Pines, Grapes, Pears, Apples, and Nuts.

CULTIVATION OF MEDICINAL PLANTS AT HITCHIN.

THE neighbourhood of Hitchin is one which is interesting on many accounts. The spot which Dickens has immortalized as Tom Tiddler's Ground is within a few miles of the town. The geologist will notice here the out-crop of the London basin, and the antiquary will meet with much to examine in the way of flint implements and other ancient relics. The botanist will find in the spring abundance of the rare *Anemone Pulsatilla* within a few miles of the town, and cannot fail to admire the row of ancient Box trees, with trunks fully 1 ft. in diameter, and about 20 ft. high, which are conspicuous by the roadside near the centre of the town. These are probably the largest and oldest Box trees in England. The plant, which is most extensively grown in the neighbourhood Hitchin, is the Lavender (*Lavandula vera*). The cultivation of this plant was commenced in 1823, by Mr. Perks, and at the present time is carried on by his son, and also by Mr. Ransom, who commenced its cultivation in 1847. It is to these two gentlemen that our readers are indebted for most of the interesting facts which are embodied in this paper. Both these gentlemen have received medals for the excellence of their productions, Mr. Perks for oil of Lavender, and Mr. Ransom for essential oils and pharmaceutical products generally. The crop at present grown is much affected by the presence of a disease which attacks the plants just as they are beginning to flower, and causes them to wither away by degrees. This disease occurs not only at Hitchin, but also at Mitcham (in fact, it appeared at Mitcham before it was known at Hitchin), and so far as I have been able to ascertain at all the localities in which Lavender is grown. To such an extent has it occurred at Market Deeping in Lincolnshire, that Mr. Holland, who formerly cultivated Lavender there, has now ceased to grow it. The disease prevailed to a considerable extent this year, and on this account, and by reason of the smallness of the crop, the price

of oil of Lavender will probably be unusually high. The history of the cultivation of Lavender reveals some curious facts which may perhaps throw a little light on the probable cause of this disease. Formerly the plant was propagated by slips taken from the branches, for the plant does not ripen seed. Whether or not it has lost the property of ripening seed through cultivation, as has been the case with the Rhubarb plant at Banbury, I have not been able to ascertain. In the winter of 1860, owing to a very severe frost, nearly all the Lavender plants were killed, and to secure a crop for the next year instead of taking slips, the roots were parted; and, from that time to the present, the same mode of propagation has been continued. At this time (1860) the disease first appeared. Plants which are obtained by parting the roots of one-year-old plants are much more vigorous and less liable to the disease than those obtained by dividing the roots of those of two years' growth. The first appearance of the disease is indicated by the leaves of one or more branches drooping and withering away; and the remainder of the plant becomes affected by degrees. When the root of a diseased plant is pulled up, the rootlets appear fewer in number than in a healthy plant, and the woody portion from which the rootlets spring is often covered with a white filamentous mycelium, but sometimes only presents a dark colour and wet appearance internally. The appearance of the disease just as the plant has begun to flower, and the fact that the plants now come to maturity in about three years, whereas they used to last five or six years, seems to indicate that the tendency to produce flower and foliage has been stimulated to a greater degree and caused a greater demand upon the root than it is able to meet. The vitality of the plant has probably been lowered by years of reproduction from the stem instead of in the way that nature has appointed, viz., by the seeds. The method of propagating, at present adopted, is certainly one that is very likely to continue the disease, since it may be latent in the divided root of apparently healthy plants. That the disease is not likely to be owing to difference in soil, is shown by the fact that fresh soil or otherwise, manure or no manure, make no difference in its appearance. The method of cultivation is as follows:—The harvest of Lavender flowers is rarely over until the middle of September, so that it is not possible to get the ground cleared and ready for the fresh plants before the end of October or beginning of November. The ground which is to be planted is generally manured beforehand with thirty to forty-five tons of stable manure per acre, but manure is not applied afterwards until a fresh planting takes place. The roots of the old plants are parted sometimes from two, but preferably from one-year-old plants, and the sets dibbled in rows about 18 in. apart. The young plants make a start in growth in March, if the weather be mild with gentle showers, and increase considerably in size in April and May, so that the tufts become on an average about 1 ft. in diameter. If, however, there occur heavy rains so that the leaves are much splashed with soil, the growth is somewhat stopped. In hollows, or where the damp is liable to remain, the young flowering stems, if there be frost in May, are frequently nipped, and the plant either dies or does not send up fresh flower stalks until the end of June, making the harvest a late one. Black frosts do not, however, injure the plants. The sets, if made by parting the roots, flower the first year; if, however, slips from the branches are taken, they are not allowed to flower the first year, lest the young plants should be weakened thereby, but the flower shoots are clipped down close to the stem. In the second year every alternate plant is removed in the autumn and planted elsewhere, leaving the others one yard apart. The second year the plants attain a diameter of about 15 in. to 18 in., and in the third year the tufts are from 2 ft. to 2½ ft. across. Shade has a pernicious effect upon the plants; under the shadow of trees they become starved and produce scarcely any flowers. The growth of other plants between the rows also injures the crop; weeds, too, have to be kept down. In order to prevent injury to the roots of the Lavender plants while removing the weeds, Mr. Perks uses an instrument of sufficient width to pass easily between the rows, and composed of a number of hoe-like blades, the upper portion of the instrument being like a plough. By means of this apparatus he is enabled to cut off the weeds just below the surface of the ground, and

at the same time to avoid injuring the tender roots of the Lavender. The plants grow best and produce most blossoms when they have plenty of room and sunshine. If too crowded, flowers are only produced from the centre of the tufts, and not from the sides where the plants come in contact with each other. The weather has considerable influence upon the yield of essential oil. If the days are bright and sunshiny during June and July, the yield will be a good one, but if wet and dull, very often not half the average will be obtained. Mr. Perks informs me that a 200-gallon still will yield about 1½ lb. of essential oil in a good season, but in a bad one, as in the present year, barely 12 oz. The time at which the flowers are gathered also appears to modify the yield, Mr. Ransom giving as the result of his experience that the product is very much reduced if gathered after the first week in September, the largest quantity of oil being obtained about the middle of August. In collecting the harvest, which usually begins about the first week in August, the flower-stalks of one plant are grasped as far as may be with one hand, and a sickle is used with the other. They are (by Mr. Ransom) then packed in 8-bushel sacks, and carried direct to the still, about fourteen sacks going to a 1000-gallon still; or they are tied up in bundles, weighing about 22 lb. (by Mr. Perks), and as much as possible of the stalks afterwards cut off, and the still then filled up with the flowers. The distillation is commenced at four or five o'clock in the morning, and the still is filled four times a day, the men leaving work at ten p.m. The distillation of each quantity takes about two and a half hours, the largest portion of oil coming over during the first hour and a half. A considerable time is, of course, taken up in filling and emptying the still. The flowers are trodden down in the still by boys, who, for the first day or two, are often severely stung by the bees, which cling most pertinaciously to the blossoms, and appear to be quite intoxicated with the honey of the Lavender, especially towards the end of the season. The water which comes over with the oil during the first hour, being slightly impregnated with oil, is returned to the still, but that which comes over afterwards is allowed to run away. The oil which comes over after the first hour and a half is either redistilled, or sold as inferior quality. The refuse when removed from the still is thrown into heaps, and, when decayed, is returned to the Lavender field. In a good year the Lavender yields from 4 to 6 Winchester quarts of essential oil per acre, and as about 53 acres altogether are cultivated, the average yield of oil for the whole of Hitchin is about 240 Winchester quarts per year. The quality of the oil is said to be affected by the soil and situation in which it grows, so much so that Mr. Ransom informs me he can distinguish the oil obtained from different fields by the odour alone. The oil is improved by keeping up to three years, after which it begins to deteriorate, unless mixed with spirit. Redistillation also improves the quality of the oil, but unless conducted by steam-heat, the loss sustained is not compensated for by increase in commercial value, the loss being nearly £1 in the gallon. The stems are not distilled, as the oil obtained from them is of very inferior quality, and is so small in quantity that it does not pay for labour and fuel.

Belladonna.

About 8 acres are grown of this plant, from which extract is made on the spot. The plants are raised from seed, and, being perennial, are grown on the same ground from seven to ten years, when they are replaced by fresh ones. The crop is not cut the first year, but in the middle of June of the second year, and again at the end of September. The plants usually attain the height of rather more than 2 ft., but if heavily manured they will grow much larger. It is found, however, that in plants which show large leaves and grow rapidly the medicinal properties are less powerful in proportion, even the odour of the plant being weaker. This is somewhat analogous to what is known of the Cinchona trees, in which, as a rule, the smaller the leaves the larger the yield of alkaloid. About 5 lb. of extract are obtained from 1 cwt. of herb.

Hemlock.

Very little Hemlock is grown, the wild plant being preferred. It is said to be plentiful in the neighbourhood, nearly

20 tons of it being sometimes made into extract in one year by Mr. Ransom. From 4 lb. to 6 lb. of extract are obtained from 1 cwt. of herb.

Squirting Cucumber.

Only 2 to 3 acres of this plant are grown every year, there being comparatively little demand for elaterium in this country. The plants are earthed up in winter like Celery, and require plenty of manure applied annually. The yield of elaterium depends much upon the weather, very little being obtained in a wet season. If the month of August be fine and dry, the yield is not only larger but of superior quality. The drug, as prepared by Mr. Ransom, is of a fine ash green colour, and comparatively sweet odour. This result is obtained by pouring off the superabundant liquor as soon as possible after the elaterium has deposited. If this be not done, fermentation is soon set up and the product depreciated in quality. Although Mr. Ransom probably grows more than any one else in England, the demand is so small that some wholesale houses have often not purchased more than 2 oz. in twelve months. That which is exported goes chiefly to Russia.

Henbane.

About five or six acres of the biennial Henbane are grown on the average; but the quantity varies much, being almost a total failure in some years. Mr. Ransom's experience corresponds with that of Mr. Usher, of Banbury, as regards the uncertainty attending the appearance of the plant from the seed. Indeed in one of the fields at Hitchin, in which Lavender plants two years old were in blossom at the time of my visit, only the biennial Henbane had come up, which had been sown before the Lavender was planted there. A small quantity of Marsh-mallow is also grown by the river side, where it does well.

The above are, I believe, the leading medicinal plants which are grown in the neighbourhood of Hitchin. Mr. Ransom produces at his extensive laboratory a very large number of extracts, essential oils and liquors, and many of these in very large quantity, using as much as 40 tons of Dandelion root per annum. Some of the extracts are such as are rarely asked for in retail shops, but for which there must be local demands. Among these were noticeable the extracts of Sarsaparilla, *Actæa racemosa*, *Chelidonium majus*, *Datura Tatula*, *Saponaria officinalis*, Wormwood (*Artemisia absinthium*), *Angelica* (*Archangelica officinalis*), Centaury (*Erythræa Centaurium*), *Pulsatilla* (*Anemone Pulsatilla*), Blessed Thistle (*Carduus benedictus*), Walnut (*Juglans regia*), White Horehound (*Marrubium vulgare*), Buckbean (*Menyanthes trifoliata*), St. Ignatius's Bean (*Strychnos amara*), Senega, and the alcoholic extract of *Belladonna* and *Ipecacuanha*. The extract of Ignatius's Bean is used for epilepsy, and goes chiefly to Australia and China. To give an idea of the extent to which some of these uncommon extracts are used, it may be stated that as much as thirty or forty pounds of extract of *Ignatia amara* is turned out annually. All these extracts are made in steam evaporating pans, the juice being in many cases expressed from the plants or roots under an hydraulic pressure of 300 tons.—*Pharmæutical Journal.*

New Insect Destroyer.—It would almost be an act of selfishness not to bring under the notice of THE GARDEN so great a boon as Bridgford's Antiseptic Liquid has proved to be to us for destroying insects. After trying various compositions with only partial success, we commenced to use Bridgford's, and have now discarded all others. It possesses the power of dissolving the oily coats of Mealy Bug and Scale, and effectually removes them; it also enters cracks and crevices where a brush could not go, and makes such places most uncomfortable quarters for any insects that may have taken up an abode in them. A great point in its favour, too, is that it does not in any way damage the foliage of even the most tender plants.—F. W. MOORE, *College Botanic Garden, Dublin.*

Japanese Persimmon in California.—This has lately been introduced into California, and promises to be a great acquisition to choice fruits there. It is of a bright yellow-orange or reddish colour, and is considered equal to the Peach or Pear. It grows to a large size, and is most delicious to the taste. The flavour reminds one of both the Plum and Apricot. Its season is from October to February or March. When dried, it resembles the Fig or Date. There are about forty varieties in Japan, differing in size, shape, colour, and flavour.

OBITUARY.

THOMAS RIVERS.

THOMAS RIVERS, one of the deservedly best known of horticulturists, died at his home at Sawbridgeworth, the scene of his long and most useful labours, on the 17th inst., aged seventy-nine. He was among those whose work is their best record, the fruits raised by him being known to every good fruit grower, not only in England, but in America and all English-speaking lands. We cannot perhaps now say anything more fitting respecting his life and work than repeat what another horticulturist, who worked in the same garden of Roses with him—Canon Hole—said in THE GARDEN on the occasion of publishing his portrait in Vol. III. :—

"In carrying out for THE GARDEN a Portrait Gallery of those Horticulturists who have given special proofs of their love and skill, whether in their work at home, in their exquisite specimens of superior culture shown at our exhibitions, or in the instructive results of their experience, communicated through the public press—who have most distinguished themselves in the great object of our brotherhood, namely, in their endeavours to amplify all things pleasant to the eye and good for food, to reclaim and restore, to make the desert smile, we shall not find much delay or difficulty in resolving the question of precedence. We want to know who has given, so far as horticulture is concerned, the greatest happiness to the greatest number, and there is no need to appoint committees, or to send abroad commissioners, before we can attain our wish. We have not to seek our hero in "scientific" schools, we shall not find him poring over elongated Latin, over the herbarium, or the "hortus siccus"; our wreath of Laurel, with which we propose to crown him, is not mixed with Botany Bays; we shall not discover him even amid those distinguished men who have made one branch of our gentle art their peculiar study and success; we cannot give the Golden Apple to Venus, because we want something more than beauty; but we must bestow the Palm upon one who has achieved greatness, both in flowers and in fruits, who some forty years ago, found Love asleep among the Roses, roused him, trained him, made a pleasant, popular, man of him—who wrote the first descriptive catalogue of Roses ever published, and the first reliable guide for amateur Rosarians, an excellent manual, now in its tenth edition—who introduced the use of the Italian "Manetti" Rose as a stock on which to bud and graft the more lovely varieties, both French and English; and an admirable nursing-mother it has proved in many cases, where rough old Briarens has failed to rear a family—who subsequently invented orchard houses, and who has originated new varieties of our most luscious fruits. Yes; to Thomas Rivers we must give in our gallery the third welcome, the most conspicuous position, the most favourable light. That light falls on just such a head as one would expect to see above the shoulders of a man who had lived long and laboured heartily among the most beautiful works of the Creator; it falls upon a handsome, thoughtful, kindly countenance. When he who writes was only an entered apprentice in one of the most distinguished lodges ("Rose Croix") of Free and Accepted Gardeners, he would sometimes amuse himself with imaginary speculations as to the personal appearance of his worshipful master at Sawbridgeworth. There must be, he thought, a freshness, a frankness, a rudeness, a benevolence, a gentle, generous goodness, beaming in the face of one who has such a sympathy for sweetness and beauty. And when we met, pupil and master, this picturesque vision, instead of misconducting itself, as bright dreams will, was realised in broadcloth and flesh and blood. As Stanley walked up to the great explorer, and said 'Dr. Livingstone, I believe,' so could the student in Roses have addressed the professor, without an introduction, 'Mr. Rivers, I've known you for years.' With the place of honour, let us give him also the assurance of our affectionate respect. And surely there must be brightness for such a man in the nightfall of old age, to think how much happiness he has diffused amid his fellows by inducing them to love, and helping them to improve, their flowers and fruit trees; for generations, when the bloom shall be upon the Peach, and the blush shall be upon the Rose, his memory shall live. Mr. Rivers's history is that of most men who have achieved success in their undertakings by constant and unremitting attention to their work. He inherited a small property, and a business in which his enthusiastic love of plants enabled him to foresee a great development. When he began to turn his attention to his profession, Rose cultivation was in a very different position from what it is at present. Standard Roses being principally imported from France, and in small quantities, he determined to visit France and examine the French mode of Rose culture for himself. The success of his earliest literary effort, "The Rose Amateur's Guide," established him at once as an English cultivator fully equal to the French in love of the flower and in skill in its cultivation. The book, in manuscript, was submitted by him to one of his earliest Rose

friends, Professor Jones, of Haileybury College, then one of the most profound scholars of the day. Dr. Jones's approval was at once accorded, and "The Rose Amateur's Guide" was received by the public as it was received by Dr. Jones. While pursuing his Rose researches, the pyramidal mode of fruit-tree training, as universally practised in French and Belgian gardens, attracted his attention—always keen on matters likely to prove of general utility—and the "Miniature Fruit Garden," modest and small in its infancy, inaugurated a new era of fruit cultivation in English gardens. Although for years practised in France and Belgium, pyramidal fruit tree training does not appear to have been much employed in England until Mr. Rivers drew public attention to the extraordinary facilities given by this mode of culture. The frequent failure of the fruit crops led him to devise some simple and effective means of protecting fruit, and he hit upon the system of growing trees in pots. By very small degrees, and with constant experiments, extending over some years before finally giving the culture a name, he perfected the "Orchard House." Like the "Rose Amateur's Guide," and the "Miniature Fruit Garden," the "Orchard House" began at the beginning. During the time occupied in developing his ideas on these heads he was constantly occupied in studying and forming large collections of fruits, and nearly every Continental new fruit found its way to Sawbridgeworth, and most of them eventually to the fire heap. Mr. Rivers was at one time a most ardent cultivator of ornamental trees and herbaceous plants; his collections of both were at one time very large, and he was quite as enthusiastic a lover of these as of Roses. London gave him the benefit of his vast knowledge, and took great interest in his various collections; in one tribe, that of the Oaks, his collection was unusually extensive. He has made good use of the "Orchard House" to endeavour to improve the varieties of Peaches. The few sorts selected as worthy of naming have been taken from more than 1500 seedlings, and it may give some idea of the work done when it is stated that these were all grown under glass. Mr. Rivers has been a large employer of labour; a small agricultural village has, by the continued employment of the capital required in carrying out his ideas, all of which necessitated labour, been benefited by the large sums annually spent. Seventy-six years is a long measure of life for a man, but few men can look back with greater satisfaction than Thomas Rivers can on a life worthily spent and deserving in every way of the commendation that, as far as lay in his power, he has been a good citizen of a great country."

• We cannot do better than conclude this very imperfect record, written four years ago, of a long life of interesting and useful work than with the following short extract from a letter just received from Canon Hole:—"It pleased God to amplify the happiness of His creatures through the instrumentality of Thomas Rivers. Many a home was made brighter, and many a heart lighter, by those flowers and fruits, 'pleasant to the eye and good for food,' which he loved, and led others to love so dearly. I hope in my heart, and pray from my soul, that he has gone from Paradise Lost to Paradise Regained."

FLOWERS ON GRAVES.

(A PAGE FROM AN OLD BOOK.)

I HAVE read with much pleasure the papers which have appeared in THE GARDEN on Shakespeare's flowers, and I thought that the following passage from Weaver's "Funerall Monuments" might not be unacceptable to your readers. "The Romanes," says he, "had an order that within some while after the obsequies, they would strew divers flowers, and sweet odours, upon the sepulchre, as the people did on the funerall monument of Scipio: and also they accustomed yearly, to garnish, deck, and adorne, the tombs or graves of the dead, with poesies, crownes, and garlands of all sorts of flowers. 'Husbands (saith Saint Jerom) were wont to straw, spread, or scatter over and upon the graves and sepulchres of their deceased wives, Violets, Roses, Lillies, Hyacinths, and divers purple flowers.' But above all flowers in these ceremonious observances, the Rose was in greatest request, and had the sole pre-eminence. 'The Romans,' saith Kirkman ("De Funeribus Romanorum"), 'loved Roses to such an extent, as sometimes to have ordered as a last injunction—that their tombs should be strewn with them. Legacies were sometimes bequeathed for that purpose, to which there was often this stipulation attached (as we read in the inscription of Ravennatus that every year they should bring Roses to his tomb and hold a feast there).' To which Paseratius, in his "Rosa," thus alludes—

Unto the tombes and spirits of the dead,
The Rose is grateful, of all the flowers the head.

And Anacreon, in praise of the Rose, thus sings in one of his Odes (Weaver uses a Latin translation; I replace it by a modern one):—

What's the garden's grace and glory?
But the Rose, but the Rose?
Giving gods and mortals pleasure,
'Tis the Rose, 'tis the Rose!

The ancient Ethnicks did hold the springing of [the flowers, from the grave of a deceased friend, an argument of his happiness: and it was their universall wish, that the tombe stones of their dead friends might be light unto them: and that a perpetuall springtime of all kinde of fragrant flowers might incircle their verdant graves."

W. NEWTON.

Keeping Late Apples from Shrivelling after they are Gathered.—There is often a great loss arising from late Apples and Pears shrivelling after being gathered. Sometimes the cause may be gathering too early; in other cases the fruit-room may be unsuitable for keeping late fruit; and there are some kinds of Apples, such as Court Pendu Plat, that will shrivel almost under any circumstances, if managed in the ordinary manner. The best way of keeping late Apples that show a tendency to shrivel is to pack them in jars, boxes, or barrels, and strew dry sand amongst them, taking care, of course, that both in gathering from the trees and in packing no bruised or bird-pecked fruits are placed amongst that which is sound; they should be stored in a dry, cool place, and not disturbed until required for use.—H.

Garden Labels.—I have given the subject of garden labels a good deal of consideration, and now send you one which I consider to be the best of all. I have had it in use for over three years. It is easily made, and the material (wood and iron combined) is cheaper than the ordinary wood tally, 6 in. long. The board of which the labels are made, is first planed and then cut into strips, and these are afterwards cross cut; the holes are made with a sharp bradawl, and the galvanized wire stuck in. They last many years, and they can be taken up and put down close to the plants without injuring the roots.—D. Mc. C. MAHONY, *The Island, Rochestown, Cork*. [The label sent is in the form of a T, only it has two supports instead of one. The head is deal and the supports galvanized wire.]

Testimonial to Mr. Robert Foulis.—Mr. Foulis, gardener forester, and estate overseer at Fordel, was entertained to dinner the other day in the Albert Hotel, Edinburgh, and presented with a gold watch and a purse of sovereigns, on the occasion of his having completed his fiftieth year in the service of Mr. G. W. M. Henderson. He was also presented with a handsome gold brooch for his wife. In returning thanks, Mr. Foulis said it was gratifying to him to think that, after having lived amongst friends for fifty years, at the end of that period he was esteemed and respected by them. He felt that the merit attached to the position in which he was now placed was principally due to Mr. Henderson, who had proved a most excellent, kind, and indulgent employer, and one who had done a great deal to improve his estate. Although he had been a long time at Fordel, he had not attained to the length of service of his predecessor, who was gardener and forester there for sixty-three years—113 years in all between them.

NOTES AND QUESTIONS—VARIOUS.

Mandevilla suaveolens Variegata.—I should be much obliged if any of your readers can tell me if there is a variegated form of *Mandevilla suaveolens* in cultivation, because amongst a batch of seedlings raised in the spring I have one beautifully variegated!—A. BARLETT.

Hoop-petticoat Narcissi.—"A.P." in his remarks on these (see p. 345) says, "they are perfectly hardy, and can readily be obtained." Will he kindly say where *N. Bulbocodium serotinus* (true), is to be had, for I cannot get it anywhere? He seems to be more fortunate than others with *N. Clausii*, but I should like to know how his bulbs are for blooming this autumn? My experience is that the blooming improves the bulbs, and that a succession of flowering roots must be kept up.—A. R.

A Town Vine.—The Vine on the house, 18, Merriion Square, North, is just now maturing a goodly crop of fair average-sized bunches. In fact, it is one of the best crops we have noticed any year on this citizen Vine.—"Farmer's Gazette."

Keeping Gourds in Winter.—Keeping Squashes in winter seems to be attended with considerable difficulty. They cannot be kept where it is damp, as in most cellars, or where frost can reach them, nor will they keep so well where it is very warm. The best conditions for keeping them seem to be where the air is cool and dry, yet safe from frost. An attic chamber until winter, then a closet near the chimney where the frost cannot reach, or the temperature does not rise very high, is the best most families can command. Extensive market gardeners often keep them in houses built for the purpose, when they can maintain an even temperature by the aid of fires and ventilation.—Mass. Hort. Report.

Mr. Raskin will, during the present term, give a course of lectures as Slade Professor at Oxford, on landscape painting. The course is to consist of twelve readings from his "Modern Painters," and the passages which Mr. Raskin thinks are likely to be permanently useful will be collected. The lectures will commence on November 6th.

"This is an art
Which does mend Nature: change it rather: but
THIS ART ITSELF IS NATURE."—*Shakespeare.*

POTATOES FREE FROM DISEASE.

I FEAR that we shall never be able to cheat the Potato disease in the manner suggested by "A. D." (see p. 315), as I am now pretty well convinced that the haulm is quite as susceptible as regards the attacks of its great enemy in its earlier stages of growth as when it is approaching maturity. My reason for this belief rests upon the result of an experiment made here this summer. Some sets—which had been kept over for the purpose, and which were set with those short green spurs upon them which the Potato-grower so loves to see at planting time—were put into well-prepared ground, in an open, sunny aspect. When the disease appeared in this district, they had made about three weeks' growth, and were vigorous and healthy; they, however, suffered as badly, and even worse, than those which were upon the point of completing their growth; they were, in fact, swept entirely off, the change being effected in a few days, there remaining but blackened leaves to mark the spot where they had been. This I consider pretty conclusive evidence that late planting will never guarantee immunity from the ravages of the disease; neither have I any faith in preventing or stamping it out. In fact, I consider that too much stress has already been laid upon the efficacy of preventives and curatives, and the raising of disease-proof Potatoes. In order to ensure us against the wholesale destruction of the Potato crop, we shall have to place reliance upon some more systematic and intelligent mode of culture than that at present practised. Speaking from experience, I feel warranted in making the assertion that any one possessing ordinary intelligence may secure a crop of Potatoes sound and free from disease; and this result may be obtained not occasionally and in favourable seasons, but even when the disease appears in its most virulent form. The method which I advocate is that of cutting off the haulm, a system which, although almost as old as the disease itself, is but seldom practised with success, and about which many hazy, undefined notions prevail. I have often heard the assertion made that cutting off the haulm does not prevent the tubers from going bad, neither will it if the operation be delayed until the fungus has established itself. One or two days delay will often suffice to render the removal of the haulm almost useless; the tuber itself may appear perfectly sound and healthy and to the eye untouched by disease, but the fatal virus has already descended and established itself therein, to show itself later in the season. In order, however, to carry out this system, and reap the full benefit from it, certain points in reference to the general culture of the Potato must receive greater attention than they now do in a general way. There are many painstaking growers who do not shrink from any amount of labour or care which may be necessary to insure the well-being of the crop; but, as a rule, Potato growing is apt to be conducted in a rough, hasty manner. In the first place, the sets must receive more careful preparation than is now generally accorded them; they should be kept in such a way that they do not lose any of their vitality, and may therefore be depended upon to come quickly and strongly into growth. The soil should be of the very best description, so as to insure a healthy and vigorous development. By preparing the sets they may be planted considerably later than is generally done, thereby decreasing the danger of a check from spring frosts, and, the soil being adapted to their quick growth, the tubers will naturally be developed rapidly. The great point to be kept in view is to promote and accelerate the growth of the tuber as much as possible, so as to get a fair crop by the time when the disease appears, on the faintest approach of which the haulm must be immediately sacrificed. This system was explained and practically demonstrated to me some twenty years ago. I have since had considerable proof of its efficacy. Last season the

approach of the disease was heralded, as it generally is, by warm, moist weather. The haulm of a portion of the crop was cut off close before the disease appeared, and of these not a tuber was diseased at lifting time. The remainder, with the exception of a few roots, were cut down, or rather the haulm pulled up as soon as the first indications of disease appeared, and of these a good percentage were diseased; but of those which were left to their fate fully two-thirds were found to be rotten. To ensure perfect immunity, I believe that a little loose soil should be drawn over the tops of the cut stems. It may be urged that the cutting away the haulm will prevent the proper maturation of the tuber, thereby depreciating it in quality—but what happens when the crop is attacked by disease? no growth can take place when thus paralyzed, and it unfortunately happens that the largest and best tubers suffer the most. At the worst it is better to secure a crop, even if somewhat deficient in quality, than to get none at all. How many of the working-classes, to whom the Potato is one of the mainstays of life, would this year have been glad to secure their crop upon those terms. Let me briefly summarize my ideas as regards the culture of Potatoes for the future. 1. Prepare the seed; 2. Plant upon well-prepared ground; and 3. Cut off the haulm on the approach of the disease; or, better still, as soon as a fair crop is seen to be formed. By following these rules a sound crop of fair-sized Potatoes may be ensured. Those even who might not care to treat their whole crop in this way, might at least operate upon a portion of it by way of experiment.

JOHN CORNHILL.

Byfleet.

THE CHINESE YAM.

(DIOSCOREA BATATAS).

WHEN this Yam was brought prominently into notice, during the great Potato failure some thirty years ago, it was thought by some that a trustworthy substitute for that valuable esculent had been found. Various difficulties, however, chiefly of a mechanical character, soon stood in the way of its extended culture. A root that buries itself in the ground 2 ft. or 3 ft. deep, however much favour it might find in China, where labour is plentiful and cheap, could scarcely be considered suitable for this country. Prizes were offered for specimens of it at some horticultural exhibitions, but its culture, nevertheless, fell off almost before it had received a fair trial, or obtained credit for the good qualities which it really possessed. There are, however, still a few gardens in which it is grown and appreciated. It must have a deep soil, and if a sufficient depth cannot be obtained in any other way, it should be thrown into ridges 3 ft. apart, and the sets planted on the top 1 ft. asunder. When the crop is taken up, the small roots should be reserved for sets; the crowns, and the long, tapering necks of the large roots can be preserved in sand till spring, when they can be cut into suitable pieces, with one or two buds each, for planting. There need be no difficulty either as regards its propagation or cultivation; all that is required is a deep, leamy soil, and the exercise of some care and patience when taking up the crop, as, unlike most of our cultivated roots, the thickest end is at the bottom; hence the necessity for opening a good trench and getting well under it. This Yam has a slender, twining haulm, which, in good soil, will grow 5 ft. or 6 ft. high. In order to encourage a rapid development of the root, the growth of the top should be assisted by having a row of stakes (Pea sticks will do) placed amongst the plants, up which they will climb and take possession. When fully developed, the plants produce freely in autumn long racemes or clusters of small white flowers, which are by no means unornamental. The best way of cooking the roots is to bake them whole.

H.

EARLY ASPARAGUS WITHOUT ARTIFICIAL HEAT.

LIGHT, movable, glazed frames have done, and are still doing, much to forward such crops as Asparagus early in the season without the litter and inconvenience attending the use of fermenting materials. All that is required to be done is to remove the old stems at once from the permanent beds (if not already done), give a light sprinkling of salt and guano, loosen up the surface with a fork, and place the frames over the beds at once. If the latter run north and south, span-roofed frames will be the best, with the lights made to hinge on the ridge piece; they can be made any length and width that may be desired, by any carpenter, and some bethouse builders make a specialty of such protectors. By putting on the frames now, and keeping the lights close, the warmth that is still in the ground will be, in a great measure, retained and husbanded, and the result will

be good-flavoured Asparagus, fit to eat at least a month or six weeks before it can be obtained from exposed beds. After Christmas, a covering of mats on cold nights will still further accelerate growth. If the cutting be not continued too long, and the growth during summer be encouraged by liquid-manure, there is not much danger of prematurely exhausting the beds. A very light crop of Radishes may be sown the first week in January, or now, without doing much harm, if thinned out well and the whole drawn as soon as they are fit for use. When the frames are removed from the Asparagus bed they may be used as ground Vineries, or for growing Cucumbers or plants in pots, as well as for many other purposes; in fact, there is room for a very considerable extension of this kind of gardening.

E. H.

FRENCH BEANS THROUGHOUT THE WINTER.

WE have still a fair supply of French Beans out-of-doors, but they cannot last much later than November 1. By that time, those which were planted in a low pit about the middle of August will be ready for use. These are followed by a later-sown batch in the same pit, and after they are done, those sown in pots come in. The earliest in pots are just about 6-in. high, and will be fit for use by the first or second week in December. Another sowing will be made at once, to succeed these, and to come in at Christmas, and after that, sowings will be made every three weeks until the middle of March, which will give a constant supply of Beans until after Easter. French Beans are not difficult to force. For some time I have always sown the seed in 4-in. pots, and when the young plants were about 6 in. high, shifted them into 8-in. ones. With six or eight in a small pot, I found that they became very much crowded before they were many inches high, and that the pots became so full of roots that they required water nearly every hour in the day, and if they chanced to become the least dry it checked their growth very much; but now I never start them in small pots, but sow the seed at once in the pots in which the plants are to remain. Several dozen of 8-in. pots are cleaned, and about 1 in. deep of crocks is placed in the bottom of each; the soil, which consists of one-half loam and the other half leaf soil, is then placed over these to the depth of 3 in., and made very firm. Seven or eight Beans are laid on this, and covered over with 2 in. of the soil; this is also made firm, in order to prevent its becoming quickly dry. The pots are then placed in a house, where the heat is about 50° at night and 70° during the daytime. No water is given until the green leaves appear, then they are never allowed to become dry. Just before they come into flower they are top-dressed with a rich mixture, and at the same time twigs are put into each pot to support them when the Beans become heavy. Liquid manure is never given until the pods are visible. As one batch is exhausted another takes its place. Osborn's Forcing is the only one we use for forcing; it is a compact-growing kind, and each pot will produce from six to eight dozen pods. Canadian Wonder, although excellent out-of-doors, grows too tall to cultivate under glass.

CAMBRIAN.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Fine Tomatoes.—We have recently weighed a sample of Tomatoes grown by our correspondent Mr. Gilbert, of Burghley Gardens, some of which weighed twelve and a-half ounces each. As may be imagined, these formed a striking contrast with such fruit as are obtainable in the market at this season. If anything like such produce were obtainable for general use, taste for this vegetable would grow even more rapidly than at present.

Early Snowball Cauliflower.—Although when grown with all other sorts of Cauliflowers at Chiswick, this variety was classed as similar to the Early Dwarf Erfurt, the earliest of all kinds, yet it enjoys a better reputation as the Early Snowball, and truly the milk-white character of its heads renders it thus fitly named. Originally obtained by us from Denmark, it has remarkably well maintained its character for earliness, dwarfness, and purity of colour. From plants raised from seed sown in June, I am now cutting heads of the finest quality; comparison with any kind almost fails to describe the delicate tenderness of the heads, which are of medium size, and very firm. It is a first-class kind.—A. D.

Disease-proof Potatoes.—The sorts that have fared the best during the season as regards disease, and that come nearest to the idea of "disease-proof," are the following:—Ruby, Climax, Model, Alexandria Kidney, Salmon Kidney, Scotch Blue, Schoolmaster, Snowflake, King of Potatoes, Taylor's No. 1, King of the Kidneys (Covent Garden Perfection), Sedilla, McKinlay's Pride, Radstock Beauty, Early King, Magnum Bonum. In order to separate the goats from the sheep I made a note of the sorts that enforced the most from disease on my ground in the past season. They were Emperor, Blanchard, Ashtop Fluke, Porter's Excelsior, Purple King, *Crimson Walnut Leaf, *Breadfruit, Early Rose Garibaldi, Lye's Favourite, Grampian, Brownell's Superior, *Purple Ashleaf, Early Don. Those marked thus* were the worst.—F. McKINLAY, in "Gardener's Magazine."

MY TOWN GARDEN.

As all agree in having flowers, but differ most widely as to the extent to which their culture ought to be carried, I propose to limit my observations, as regards what I have to say respecting my little garden, to hardy border plants, believing that my remarks may be of use to many who are in possession of but a limited extent of ground, or who can afford from their professional pursuits but a limited portion of time for the practice of what must be regarded as the most healthy employment and most delightful recreation in which any one can be engaged. To none, however, save the idle, the curious in botany, or the apprenticed who must know their calling, can the enormous lists of plants and flowers—grassy and fibrous, bulbous and tuberous, annual, biennial, and perennial, hardy, semi-hardy, and tender, indigenous and exotic—without, in most cases, a word on culture—be otherwise than confusing. To reduce this apparent chaos into something like reasonable bounds, adapted to the requirements of many who live in the suburbs of large towns, I shall only name and describe those hardy plants to which I have myself taken a liking, on account of their beauty and easy culture, out of all I have tried during a period of more than thirty years. As my garden was planned and laid out in 1843, and approved by good horticulturists, it may be useful to some if I describe its form before going into the details of the flowers that are planted in it. The house itself is a detached villa containing ten rooms, with the windows of the drawing-room opening into the garden through a small conservatory; the aspect being south-west. The garden is entered at the middle by going down two stone steps, on the right and left of which is a light iron railing, along the edge of a paved portion extending to the walls on both sides. The piece of ground set apart as the flower garden is 36 ft. wide by 130 ft. in length. This is entered by a straight concrete walk 6 ft. wide, which, at the distance of 22 ft., comes to a fountain or small fish pond, 9 ft. in diameter, in which the *Nymphaea alba*, or White Water Lily, has bloomed luxuriantly for nearly thirty years. I had other aquatics, but the White Lily bloomed so beautifully, and for so long a time every season, that I allowed it to appropriate the whole of the water to itself. The centre walk here opens out into two parts, 4 ft. wide, and passes round the pond, meeting again at the other side; passing on straight, with the 6-ft. width, for 24 ft. further, it comes to a small rockwork or nidus, about 3 ft. high and 10 ft. in diameter, on which grow some fifty or sixty Alpine plants. I should here state that from the commencement of the walk, along the railings and the boundary walls, until we pass the pond, there is a 4-ft. border, and between the borders and the walk, on each side, there are plots of Grass 11 ft. wide and upwards of 30 ft. in length. After passing the pond, on each side of the walk, there are two very fine *Araucarias* 23 ft. high. At the rockwork, the 6-ft. walk again divides into two, 5 ft. wide, going round, and then straight on, with the 6 ft. width, for 24 ft. more, when it reaches a round bed, 9 ft. in diameter, with a sun-dial in the centre. On both sides of the walk from the pond, round the rockwork, and on to the sun-dial, there is a limited but choice collection of dwarf Hybrid Perpetual Roses on Manetti stocks; and, behind them, clumps of Lilies are planted alternately, that is, quincunx fashion, a clump of Lilies being planted behind each of the spaces left between the Roses. Behind the Lilies there is a good collection of evergreens, forming a shrubbery, the tallest being placed next the wall. The planting of the sun-dial bed has been done in accordance with the instructions given in "Hardy Flowers" (page 12). Round the dial pillar is planted a circle of *Tritoma grandis*; around that a ring of the white *Anemone Honorine Jobert*, and *Rudbeckia Newmanni*, mixed plant for plant; and outside of that again is a circle of the herbaceous *Sedum spectabile* (sold and known as *S. Fabaria*). The walk having rounded the dial-bed goes on 27 ft. further, when it reaches a summer-house, on both sides of which there are raised mounds, containing a good collection of hardy Ferns, shaded by four Lime trees, which I keep within bounds by careful pruning. Next the walls, between the shrubberies and the Ferns, there is another 4 ft. border, and between them and the walk in the centre, are two more plots of Grass 11 ft. wide, and about 35 ft. in length. Let us now advert to the borders I have mentioned,

which, in their turnings and windings, extend a length of upwards of 300 ft., and includes hundreds of hardy plants, which I shall now more particularly describe :

Larkspurs.—These constitute an invaluable class, varying in height from 2 ft. to 5 ft., with colours composed of every shade of blue, from azure to deep indigo, and almost black. At present we have in our garden *Delphinium Wheeleri*, bright Prussian blue, with a black eye; *Prince of Wales*, azure blue, with white centre, very effective; *Hendersoni*, pale clear blue, with a white eye; *Nahamah*, violet blue, very large flower; *Beauty of Peronne*, peach, shaded with blue; *Triomphe de Pontoise*, pale blue; *Barlowi*, deep blue; *Bicolor grandiflorum*, brilliant blue, with a white eye; *Belle Alliance*, porcelain blue; *Madame Jacotot*, very fine, clear pale sky blue; *Beauty*, bright gentian blue, with a white eye; *Herman Stenger*, white eye, inner petals violet and pink, corolla bright blue; *Formosum*, brilliant Prussian blue, tinged with purple, eye white; *Belladonna*, sky blue, with a white eye. *Madame Rongier*, brilliant blue, with white centre; *Alopecurioides*, deep blue, and one of the finest. As regards their culture, very little need be said, as they are a very accommodating class of plants. They will succeed in any ordinary garden soil, but they are improved by being liberally manured, giving them plenty of water during all stages of their growth. They are easily increased by dividing the roots late in autumn or early in spring; and if lifted and transplanted every two or three years they will grow more vigorously and keep longer in a healthy state than they otherwise would do. Their style of growth is bold and striking, and if a little care be taken to move the flower-stems as soon as they have bloomed, they may be kept in flower for a very long time.

Phloxes (*Decussata*, or late-flowering section).—These form another equally valuable class, concerning the merits of which too much cannot be said. We have some in our garden now in full bloom. They form magnificent pyramidal bushes, from 18 in. to 3 ft. in height, the colours varying from pure white to all shades of crimson, red, and purple. Their culture does not differ from that recommended for Larkspurs. Our favourites at present are:—*Venus*, silvery white, with bright purple eye; *Liervalli*, dark rose, striped with white; *Countess of Breadalbane* (now in bloom), brilliant crimson lake; *Flora McMah*, a delicate rose-pink, with a brilliant magenta eye; *Madame Delamere*, salmon-crimson; *Doctor La Croix*, bright crimson, with a deep coloured centre; *Jules Roussel*, French white, with a purple eye; *Edmond About*, rosy self; *Madame Nouvellet*, rosy lake, with a deep crimson eye; *Lothair*, scarlet lake, shaded with purplish, violet; *Amabilis*, rosy-salmon, with a purple eye; *La Candeur*, pure white, with a large cerise eye; *Madame Verschaffelt* (now in bloom), bright salmon; *Madame Fontaine*, salmon-pink; *Mrs. Grundy*, puce and white, with a fine eye; *Froment*, white, with a purple centre, shaded with deep blue on the edge; *Queen of Whites*, pure white, very fine truss; *Anais Forel*, white, suffused with purple; *Géant des Batailles*, salmon-orange; *Monsieur Guldenstuck*, rose, violet, with purple scarlet centre; *Madame Crouse*, brilliant self, as large as a florin; *Captain Speke*, light pink; *Mrs. Laing*, delicate rosy-lilac, profuse bloomer; *Le Lion*, crimson-lake, with a large-brilliant crimson eye, and corolla tipped with same colour; *Souvenir de Mons. Berryer*, crimson with a purple centre; *Edith*, white, with a crimson eye; *Madame Damage*, white, with large carmine blotch in centre; *Brilliant*, rich vermilion, with a carmine eye; *Gladstone*, rosy lake, truss very large and attractive.

Pyrethrums (*Double-flowered*).—These constitute a very showy and distinct class of herbaceous plants, well deserving of culture in every garden. They are neat and compact in habit, and produce their large and beautifully-formed Aster and *Chrysanthemum*-like flowers, varying in colour from pure white to brilliant crimson, in profusion from early in May to late in October. They are thoroughly hardy, and are unsurpassed for mixing in the shrubbery, or for the middle or background of borders. Their cultivation is somewhat similar to that recommended for the last two classes, but in dry weather they require a more than ordinary supply of water. Under a burning sun they flag very much, but a quart of water poured over the roots will make them spring up again almost instantaneously. The varieties which we have at present are the following, viz., *Boule de Neige*, white, slightly tinted with rose; *Carneum plenum*, bluish white; *floribundum plenum*, rosy-pink; *Galathee*, light rose; *Gloire de Stalle*, rich glowing purple-carmine; *Hermann Stenger*, rosy-lilac; *imbricatum plenum*, rich purplish-carmine, tipped with white; *Modele*, bright rosy-crimson; *multiflorum*, rosy-crimson, with an orange centre; *Nemesia*, lilac-carmine; *niveum plenum*, pure white; *Prince Teck*, brilliant crimson, with an orange centre; *Progress*, rich crimson, with an orange-brown centre; *Rev. J. Dix*, rosy-carmine; *Roseum album*, rosy-purple, with a white centre; *Roseum perfectum*, outer petals pale red, centre delicate rose, spotted with white;

Rubrum plenum, outer petals rosy-purple, centre deep rose; *Solfaterre sulphur*, with golden-yellow centre; *Titiens*, delicate rosy-pink, with orange-yellow *Anemone*-formed centre.

These three classes of plants, with their varieties, would of themselves be enough to fill a good-sized suburban garden with a blaze of beauty during a great part of the year; but we have others to which I shall allude on another occasion.

L. E. X.

NOTES FROM KEW.

In the Orchid House there are several good plants in flower. First on our list, if rarity can entitle it to that position, is *Ione palearea* of Lindley, a native of the Himalayas. This is the first time we have seen *Ione* represented in any collection of living Orchids, and a long search for it through many catalogues, English and foreign, has been unsuccessful. The genus numbers seven species, all tufted epiphytes with pseudo-bulbs, bearing a single coriaceous leaf, and a radical scape ending in a spike of white, violet, or purplish flowers. The species above-mentioned has long membranous sepals slightly veined with purple, very small lateral petals, and a large dagger-shaped purple lip, terminating in a tongue-like, thickened point. The very pretty little *Saccolabium Calceolare* is worth notice; it was introduced to Chatsworth from the East Indies in 1837 by Gibson, the botanical collector of the then Duke of Devonshire. It grows on the Rhoosea Hills, at an elevation of about 4000 ft. above sea-level, and seems to shrink from much light. The small, compact growth, and neat spikes of yellow flowers, recommend it to those who do not always look for size and glare among their floral pets. *Pleurothallis Grobyi* is a perfect little gem in its own way; it was imported to this country from Demerara by Mr. Bateman, and is one of a section in which the creeping rhizome is very nearly suppressed, consequently the tiny leaves are produced in a dense tuft. The Kew plant is grown on a small block suspended from the rafter; the leaves are perhaps from 1 in. to 1½ in. in length, and the flower-scapes hardly 3 in. The little flowers are yellow, dashed with reddish-brown. *Lockhartia elegans*, from Trinidad, has a most peculiar style of growth. The flat stems are clothed with numerous closely-placed distichous, equitant, very obtuse leaves, and appear totally unlike those of any other Orchid we can at present remember. The individual flowers are small, but the much-branched, graceful inflorescence, and the number of the yellowish-white flowers, make up somewhat for deficiencies in other respects. *Oncidium triquetrum*, introduced by Rear-Admiral Bligh from Jamaica in 1793, is a very pretty and easily-grown species; it has no bulb; the laterally-compressed triquetrous leaves rise immediately from the root, are few in number, distichous, and 4 in. to 6 in. long; the petals are white, tinged with pale green, variously spotted with purple. Among the *Lælias*, the prettiest is *L. Perrini*, an easily-cultivated species from Brazil. There are several specimens in flower, somewhat varying in merit. When growing, a high, moist temperature must be maintained, and a liberal supply of water given at the root. When at rest, this species must be kept dry in a temperature of about 45°. *Cattleya maxima* is represented by several plants of various worth. One is of a flesh colour, and not to be compared with its neighbour, a fine pink flower, with a coarse network of beautiful crimson veins. As a species, this comes very near *C. Mossii* and *C. labiata*, but differs from them in its long, channelled pseudo-bulbs and its very convex, wavy petals. It is very impatient of water on its leaves, but wants a good supply at the root during summer. *Celogyne fimbriata* has a three-lobed crested and ciliated lip, but the rather dingy yellow and brown flowers do not take the fancy of most Orchid growers. It was introduced into this country from China. *Restrepia antennifera* is a beautiful species of a most singular genus. It is a New Grenadan epiphyte, and was first discovered by Humboldt. The stems are tufted, simple, 2 in. to 4 in. high, clothed with loosely-imbricating sheaths, which are whitish, spotted with red. The ovate leaves are shortly stalked, about 3 in. long; the scapes are longer than the leaves, very slender, and one-flowered. The dorsal sepal is 1½ in. in length, and tapers into a filiform tail with a purple, club-shaped end; the lateral sepals are united into a serrulate blade as long as the upper sepal, and towards the base have a subulate appendage on each margin. The whole groundwork is yellow, thickly dotted with close-set rows of large red spots. *Dendrobium Johannis*, discovered by Mr. J. G. Veitch on the coasts of North Australia, has peculiar twisted flowers, which exhale a very agreeable odour of honey; the colours are brown and yellow, streaked with orange. Several *Oncidiums* are in good condition, among them being *O. Rogersi* and *O. verrucosum*. There are also *Epidendrum purum*, *Burlingtonia decora*, *Gongora odoratissima*, and several *Cypripediums*.
G.

NOTES OF THE WEEK.

The Pitmaston Pear.—Very fine specimens of this may now be seen in Messrs. Webber's window in Covent Garden. It will be remembered that we published a figure of this remarkable fruit at p. 284, Vol. XI. It is the best English Pear raised for many years—probably the best ever raised with us. It is, we observe, offered for sale under different names.

Dracæna fragrans.—A fine specimen of this is now in flower in Mr. Wills' nursery, at Brompton; the flowers are remarkable for their fragrance, but we think the plant more valuable for its stately port. A well-grown specimen like this is one of the noblest of fine-foliaged plants.

A Pretty Effect in our Orchid-houses.—One of the best effects in the Orchid-houses at Messrs. Veitch's results from a mixture of profusely-flowered plants of the golden *Oncidium varicosum*, *O. Rogersi*, and the winter-flowering *Calanthe Veitchi* and *vestita*. Several gracefully-drooping spikes of the chocolate-coloured *Oncidium crispum*, and other brightly-coloured flowers of Orchids on blocks, are also in beautiful condition.

Bouvardias in Autumn.—The charming white and scarlet sweet-scented flowers of *B. jasmiflora* and *B. Hogarthi* now form a striking feature in Messrs. Low's nursery at Clapton. Several large houses are entirely devoted to them, in which hundreds of plants are now in bloom. Contrasted with a rich profusion of bright green foliage, their clusters of flowers present a sight seldom to be met with.

A Violet-scented Winter-blooming Orchid (*Oncidium tigrinum*).—This fine, large, and free-blooming species is worth growing for its Violet scent alone. It is now in abundant bloom in Mr. Bull's nursery, both in pots and on blocks. It is a cool house kind, a native of Mexico. The flowering shoots grow from 3 ft. to 4 ft. long, and the house in which it grows is scented like the vicinity of a Violet-bed.

Allamanda Hendersoni.—I have a plant of this here now beautifully in bloom. It is growing in a 12 in. pot, and covers the upper part of a span-roofed house, 18 ft. long by 14 ft. wide. It began to flower late in April, and has now over 100 blooms expanded upon it. It is four years old, and promises to continue flowering until the Poinsettias come in.—A. OFFER, *Felcourt, East Grinstead.*

Orchids at Drumlanrig.—There are, in the East Indian Orchid-house at Drumlanrig, a plant of *Cypripedium Roezli*, which has borne, on six flower-stems, fifty-eight blooms, and a plant of *C. Sedeni* which, on three branched flower-stems, has produced seventy-five blooms. These plants are in glazed pots, and, as the flower-stems are not yet exhausted, they will produce a good many more blooms. In the cool Orchid-house there are about thirty spikes of *Odontoglossum Alexandræ* in bloom and coming into that condition.

Chrysanthemums are fast coming into flower in the London nurseries, and there is a pretty good show of them already to be seen in the Temple Gardens. Tree Carnations are also beginning to flower. *Bouvardias*, *Cyclamens*, and *Epiphyllums* are likewise now opening in great beauty. A few years ago November saw almost the end of the greenhouse flowers of the year; now it is the beginning of a beautiful season in well-furnished greenhouses.

Finely-flowered Oncidium Rogersi.—A remarkably fine specimen of this beautiful autumn-flowering *Oncidium* is now in bloom in Dr. Ainsworth's collection at Manchester. It is growing on a block, and two spikes are produced from the one growth, one with 165 expanded flowers, and the other with 44. The lip is unusually fine, being $1\frac{1}{2}$ in. across. This *Oncidium* needs no recommending; being both a free grower and bloomer, it should be in every collection.—W. C. Jr.

Locked Gates at Kew.—During a recent meeting held in reference to this subject at Richmond, the chairman read the following letter, which he had received from the First Commissioner of Works:—"Catmose, Oakham, Oct. 21, 1877.—MY DEAR PEEK,—Thank you very much for your letter and the local papers you were good enough to forward, giving an account of the meetings which were held at Kew with reference to the question of opening the Gardens at an earlier hour. You may be sure it will always be my anxious desire to meet the wishes of the inhabitants of Richmond when it is possible, and when I can do so without detriment to the public service. The opening of Kew Gardens at an earlier hour would enormously increase the expense of their maintenance and materially interfere with the duties of the men employed; but the matter, you may rely upon it, shall be carefully considered. I think, perhaps, that on the Bank holidays some changes might be made, so that the public might have the enjoyment of the gardens for a longer time than at present; but, of course, I can at this moment give you no definite promise.—Believe me, yours very truly, GERARD NOEL."

How the opening of the gates at an earlier hour would "enormously increase" the expense of the maintenance of the garden, it would be interesting to learn! In a garden where over £50,000 are spent on one hothouse, there are considerations as to the means required for opening the gates at reasonable hours. We repeat that many persons are prevented from using the Garden, especially in winter, when the darkness falls a few hours after the gates are open. To establish a national garden at a cost of over £22,000 a year, and then shut the gates on all the beauty and interest of the collection during the best hours of the day, is surely most unwise. The Gardens should be opened at the latest at 9 o'clock. The houses no one wishes to interfere with, as the passages are not free owing to the necessary work.

Dendrobium album.—This beautiful white *Dendrobium* is now in flower in Mr. Bull's collection at Chelsea. It has a rich and somewhat peculiar scent. There is also a fine variety of *Lælia præstans* in the same house.

An Ornamental-leaved Pear Tree.—The autumnal tints of the Doyenné Bonsoch Pear are now rivalling those of the Virginian Creeper, and the excellence of this variety as regards size, flavour, and productiveness enhances its value as an ornamental tree. My only specimen grows on the Quince stock, and is trained to a wall with a western aspect.—B. S.

Vriesia brachystachya.—This is a very bright-flowering little plant allied to the *Bilbergias*. It is of easy culture, and flowers more freely than most of the older plants of the same family in cultivation. The inflorescence is bright scarlet and yellow, and the habit dwarf and neat. It is now in bloom in warm houses in some of the principal nurseries.

A beautiful Winter-flowering White Orchid.—A fine variety of *Pilumna fragrans* is now in flower in the Exotic Nursery, Chelsea. It is a white Orchid of remarkable beauty and peculiarly grateful odour, especially in the morning. Lovers of white flowers cannot dispense with it.

Sternbergia lutea.—It is surprising that this lovely autumn flower has not long ago become a frequent ornament of our gardens, instead of being confined almost to collections, nurseries, and botanic gardens, as at present. Its numerous rich green and graceful leaves of themselves recommend it. They grow about 1 ft. high, the beautiful clear yellow flowers growing about half that height, so that when the tufts are strong many of the flowers are half concealed among the leaves.

Salvia Bruanti.—This new kind reminds one of *Salvia splendens* as regards habit, but it has even more vividly-coloured flowers. With it is a curious species, unnamed, with the inflorescence variegated white and red.

Dendrobium bigibbum superbum.—This pretty Orchid in colour, and somewhat in shape, reminding one of a rich, lilac-coloured Primrose, is now blossoming in the Victoria Nurseries, where a goodly number of plants of it have been received from Torres Straits.

Sonerila Hendersoni.—This, though generally grown for the sake of its foliage, is one of the most beautiful of winter-flowering plants, its delicate mauve-coloured blossoms forming a striking contrast with the prettily-marbled leaves. It likes a warm, moist temperature.

Todea barbara.—A remarkable example of this *Todea*, which has been recently imported by Mr. B. S. Williams, is to be seen in fine health in his large conservatory at Holloway. Its trunk is about 5 ft. high, is triangular in form, and measures from 9 ft. to 10 ft. in circumference at the top. It has seventeen crowns, which are furnished with healthy green fronds measuring from 3 ft. to 5 ft. in length. The plant forms a striking feature in the conservatory, and would form a noble object in a rockery or some similar position.

Orchids in Flower.—Among those now in flower at Messrs. Veitch's are *Vanda coerulea*, *Cattleya marginata* and others, *Oncidium ornithorhynchum*, *Masdevallias*, *Calanthes* (including a remarkable and beautiful new hybrid not yet named), *Pleiones*, *Colax jugosus*, *Pilumna fragrans*, *Cypripediums* in great variety, *Odontoglossums* in variety, *Dendrobium bigibbum*, *Burlingtonia fragrans*, *Oncidium crispum*, and others.—N. S.

Primula capitata.—Seedling plants of this East Indian species, the produce of seed sent to Chiswick by Mr. Elwea, are now flowering there for the first time. It is, in its present youthful stage, a most charming Primrose, with foliage resembling that of *P. farinosa*, and scapes of flowers resembling those of *P. denticulata*. The blossoms are, however, of a deep lavender blue, much darker than those of *P. denticulata*, and their being produced at this time of the year renders them doubly attractive. It will be exhibited at South Kensington next Tuesday.—A. D.

THE FLOWER GARDEN.

FLOWERS ON WALLS.

THERE is a way of growing flowers on walls in various countries which deserves more attention than it has received with us. It consists of leaving the upper portion of a terrace or other wall hollow, and using this for flowers. The crest of the wall is, in fact, a narrow flower border; but though narrow, with a space for 2 ft. or 3 ft. of soil from 1 ft. to 2 ft. through, thus giving ample root-room for the production of a vigorous and graceful vegetation. The architect or builder can easily arrange for such wall-vases. The accompanying illustration shows the effects obtained in the slender wall of a small garden pavilion. We have often seen very charming effects produced in this way on the Continent, even in poor

Flowers on Walls.

houses where little evidence of other beauty was to be seen. By adopting the principle of variety instead of repetition in such cases, a beautiful garden of flowers might be grown on the crest of many a barren wall near, or part of, a town house.

HARDY PLANTS AT EDINBURGH.

HYPERICUM ASCYROIDES or *orientalis* is not included in the list of St. John's-worts given in *THE GARDEN* (see p. 280). Nevertheless, this is one of the most distinct and pretty of the group, forming here a bush 3 ft. high, with numerous bright flowers 1 in. across. It is late in coming into flower. The anthers turn from yellow to white after the second day, and the blossoms are more like single yellow Banksian Roses, than those of a St. John's-wort. The foliage is delicate and useful for cutting, and when young, has a bronze tinge. At present (Oct. 31) our plant is covered with flowers. *H. Androsæmum* makes a famous bed. We have a reserve one for cutting from 12 ft. by 4 ft. At all stages, *H. Androsæmum* is of use and is ornamental; yearly there is a sod of seedlings around the bed, and these make the most equal bed to begin with; there are the bronzy young points in spring, and a profusion of flowers which are interesting, even when the yellow petals fall, as the young capsules in the centres of the starry calyxes are prominent and interesting. These increase in size and vary in colour the whole summer. At present, the bed is a mass of bunches of capsules of all ages, varying from green to red, brown, and black (when ripe) and always glossy. There are still flowers coming out, and the seed vessels remain on all winter. Thus, those of 1876 and 1877 are both represented now. A note is always made of this bed, but I have never seen any save our own; it is equally good in all weathers, every season, and is no trouble, forming of itself a good shape. The only other *Hypericum* that have ornamental capsules, that I am aware of, are *H. asperum*,

H. grandulosa, and a *Hypericum* from Mr. Ellacombe, like *H. Androsæmum*, which I saw at Kew. This last is a native species; and has, however, the finest seed vessels.

Erigeron alpinus is at present in bloom for the second time, in fact, a stray flower can be got from it all the summer. In July its clear lilac flowers contrast well with those of the bright yellow *Ceroopsis lanceolata*, and the two plants suit in height and also as regards Composite flowers. *E. purpureus* would make a useful, neat bed, inasmuch as it is in flower from May until severe frost sets in, and, like many kinds of Daisy, the old blossoms are nearly as good as the fresh ones; they are of a pinkish-lilac, and the plants grow in tufts, the flower-stalks being 12-in. high.

Lythrum alatum is another neat, erect-growing plant, which requires no stakes, and takes up but little room. The flowers, which are but sparingly produced, are bright magenta in colour; they begin to appear late in summer, and continue in succession until frost sets in. Still, the foliage and habit are so neat, and the red stalks so pleasing, that a bed of it mixed with white *Phlox Drummondii*, or a white *Campanula* of the height of *C. carpatica* or *Hosti*, would look well. This *Lythrum* stood out here last winter; we got it from Mr. Niven, who stated that it was hardy; certainly our soil and climate are superior to those of the Botanic Garden at Hull.

Polygonum Brunonis.—This keeps its bright pink flower-spikes very long, and when faded to rich brown they are no eyesore, but quite the contrary. *P. vacinifolium* is at present a mass of flowers; a miniature of *Brunonis*, but far more attractive; as an edging, or to hang down from or over stones in a rock garden, it is admirable. In the Edinburgh Botanic Garden it is just now one of the principal plants that catch the eye in the form of fine, large patches.

Crocus speciosus and *Colchicums*.—Different sorts of these are flowering well, and we find that when supported amongst fine-foliaged plants, they do not get broken by wind and rain, as they otherwise would do. *Pyrethrum Tschischewii*, for instance, makes a pretty groundwork, with its very dark green, cut foliage, and white, Daisy-like flowers, for the single lilac *Colchicum*, and *Saxifraga pentaphylla* for the white variety of autumnale. *Crocus speciosus* does well associated with the double *Matricaria Chamomilla*. In planting this *Crocus*, one must make up one's mind never to get rid of it again in the spot in which it is placed. Trenching merely spreads it, and if too weakly to flower one year, it will appear in beauty three or four years afterwards. We have transplanted our original patch entirely three times, but the result is that we have three strong colonies, in spite of us, instead of one. Where planted in a bed on Grass, I observe this *Crocus* running into the turf. We shall be careful not to let the Grass-cutter go near the verge until the *Crocus* foliage fades. I fancy planting *Colchicums* and these naked *Crocuses* among low-growing plants is the best plan, as the flowers are supported by the foliage of the *Saxifrages*, *Campanulas*, and *Pyrethrums*, amongst which they may be planted; they certainly look much prettier amongst green herbage than on the bare soil; nor do I think this plan going against Nature, as, although devoid of their own foliage when in flower, they naturally grow in Grass and amid foliage, and support is thereby provided. Inveterate, as regards extension, as *Crocus speciosus* is, I doubt our ever seeing it as one does *Colchicum autumnale* abroad. Passing through Germany in autumn is a treat, and *Colchicum* flowers seem to be the principal ingredient in the fodder or Hay that is being scraped off the little patches of Grass land.

Rudbeckia Newmanni.—This has been a very gay bed—to too staring, perhaps, for the taste of some, but we like bright flowers. To make up for its autumn flowering, blue-branched Larkspur is planted alternately in the same bed and pegged down. Its cut foliage lightened up that of the *Rudbeckia*, and it comes early into flower. When both plants are in bloom they look well, although this drenching August did not suit annuals.

Achillea tomentosa.—This is a most useful plant, growing, as it does, close and compact. It has bright yellow flowers, which are never an annoyance even when faded, although we regularly remove such as are past their best in order to ensure a constant succession of flower for six or seven months. One must step occasionally on the borders, and we use this and similar plants set at intervals apart as stepping-stones—a gentle kick in dry weather, or rain in wet, will put all to rights again. *A. aurea* is beautiful, but not so easily increased as *tomentosa*; it has long bright foliage, and clear yellow flowers; it grows about 1½ ft. high, and is beyond the stepping-stone line. *A. Millefolium rosea* is also good, but it is rather straggling in habit for choice borders. We grow many *Achilleas*; no weather injures them, and they are useful even when faded. The dwarfest which we have is *A. tomentosa*; the variegated form of the

native *A. Millefolium*, which has a beautiful leaf, is the tallest; *A. ægyptiaca*, is 2½ ft. *A. Ptarmica* fl.-pl., a desirable variety, has double flowers, and is pure white. *A. Clavennæ*, which has hoary foliage, and which is a dwarf grower, we use as an edging alternately with another wild plant named *Meum athamanticum*. By cutting off the flower-shoots and a portion of its leaves we secure the beautiful feathery foliage of this Umbellifer during the whole season. Naturally after flowering it dies down, and the edging is gone. It is impossible to exhaust the countless hardy plants that crowd on one's memory, and possibly our borders—none of which can be cast out; all have much interest and beauty, and the variety is endless—that, perhaps, is the greatest charm of such plants. F. J. HOPE.

Wardie Lodge.

PINKS OLD AND NEW.

ABOUT a century ago there was a Pink called Major's Lady Stoverdale, a kind raised from seed by a Mr. Major, who resided in the southern parts of England, and which that fine old florist, James Maddock, of Walworth, regarded as the first flower that deserved to be classed among such as are now held by florists in esteem. It was the first Pink possessed of that irregular and beautiful ornament called lacing, which is a continuation of the colour of the eye, round the white or broad part of the petal, and which gives the flower such an elegant and attractive appearance. About the same time, or soon after, a laced Pink named Duchess of Lancaster was raised in Kent; and another highly-esteemed laced variety was Green's Queen. This change in character, which added so much beauty to the Pink, gave the first impetus as regards its better cultivation. Mr. Thomas Davey, of the King's Road, Chelsea, an enthusiastic admirer of the Pink, introduced an improved class of flowers, which were distributed under the name of rose-leaved Pinks, and consisted of such varieties as Davey's Queen, Davey's Duchess of Devonshire, and Eclipse, flowers which were highly thought of at the time, and which were followed by several other raisers' productions of equal merit, for the cultivation of the flower was by no means confined to London; on the contrary, it spread with great rapidity all over the country, and from the years 1830 to 1850 the Pink was one of the most popular of florists' flowers. About 1850 Maclean's Criterion, Maclean's Narborough Buck, Turner's Nonpareil, Fellowes' Optima, Hale's Queen of England, Kirtland's Prince Albert, Keynes' Magnificent, Looker's Lord Norry's, &c., were regarded as the leading flowers, and were much prized for exhibition purposes. The Pink, as is tolerably well known, is a thoroughly hardy plant, and the invariable practice is to plant it out at the end of September, and at any time during October, to stand the winter. The usual practice is to plant in beds raised from 6 in. to 9 in. above the ordinary level of the ground, in order to escape any excess of moisture during winter. In order to have good laced blooms the soil must be rich. A good yellow loam of a fibry nature, some well-decomposed manure, leaf-mould, and rough river sand make an excellent compost, which should be well mixed and spread on the surface of the bed after the subsoil has been well loosened and broken to pieces. The bed should be made up in August, and kept forked over until planting time has arrived, in order to thoroughly mix the materials and sweeten them.

Some plant threes and some pairs, but in both cases they should be from 12 in. to 18 in. apart, according to the robustness of the plants. It is a good plan to pot some of the earliest-rooted pipings, in order to get the roots well established in the soil before planting out; but if the plants be carefully lifted from the piping-beds, with some soil adhering to the roots, they can scarcely receive a check, especially if a little light sandy soil be thrown among the roots to give them a start. Weakly stock of scarce or valuable kinds may be potted as the surest mode of preserving them through the winter. If the weather be dry at the time of planting, a good watering may be given. One great advantage in planting about the end of September is that time is afforded for the plants to get well rooted into the soil before winter sets in, so that they are seldom thrown out by the frost. If frost loosen the plants, or they are displaced by the action of worms, a gentle pressing into the soil will soon set them right. During autumn, the surface of the bed should be stirred, to loosen the soil rendered close by rain; and if the bed sinks, as will sometimes happen, some fresh soil should be added as a top-dressing. Early in January the plants will be greatly benefited by a mulching of horse-droppings and rotten leaves, placed over the bed to the depth of 1 in., and, at the same time, a few sprays of Spruce Fir should be stuck in between the rows of plants, which, standing as a kind of fence a little above them, protects them from the cutting winds and hoar frosts of January, February, and March. This protection is much more necessary in the north than in the south. In

April, when the plants begin to break into growth, the sprays of Fir may be removed.

As regards varieties, the following will be found to be a good selection, viz.:—Annie (Maclean), Annie Chater (Hooper), Attraction (Maclean), Bertram (Turner), Blondin (Turner), Charles Turner (Maclean), Constance (Maclean), Diadem (Turner), Dr. Masters (Turner), Edwin (Turner), Excellent (Turner), Godfrey (Turner), John Ball (Maclean), Lady Craven (Hooper), Lord Kirkaldie (Turner), Minnie (Turner), Mary (Anokland), Picturata (Turner), Princess of Wales (Turner), Rev. George Jeans (Kirtland), Shirley Hibberd (Turner), Superb (Turner), and Victory (Hooper). D.

Large Grass Isolated in Turf.—Some of the more vigorous hardy Grasses are well suited for isolated planting or in association with groups of fine-leaved hardy plants. They afford graceful effects from their foliage alone, and long before the period of flowering. Among the kinds of Grasses desirable from the grace and vigour of their foliage apart from their flowers, which are nearly always beautiful, may be named *Arundo conspica*, *A. Donax*, *A. D. versicolor*,

Bambusa in var., *Elymus arenarius*, *E. condensatus*, *Erianthus Ravenne*, *Gynerium argenteum* and its varieties, *Poa fertilis*, *Saccharum ægyptiacum*, *S. cylindricum*, *S. Maddenii*, *Zea Mays*, *Andropogon argenteus*, *A. formosus*, *A. Sorghum*, *A. squarrosus*, *Gymnothrix latifolia*, *Holcus saccharatus*, *Erianthus violaceus*, *Panicum bulbosum*, *P. altissimum*, *P. virgatum*, *P. maximam*, *Sorghum halepense*, and *Pennisetum longistylam*.

Late-blooming Antirrhinums.—Plants of these hardy biennials in a large bed, cut over a few weeks ago in order to secure a crop of seed, have now thrown up large numbers of side shoots, and are yielding an abundance of richly-coloured flowers. How useful these are at a time when there is little else in bloom out-of-doors those can best estimate who have to find flowers somehow, and who are only too glad to have any useful plant from which to cut. The plants in the bed in question are from seeds sown indoors early in spring, the seedling plants being pricked out into boxes until strong enough to be planted out in rows in the open ground. These dwarf kinds produce a much larger proportion of striped and fancy-coloured flowers than is usually found in the tall strains, and the bed, when in full bloom, was indeed worthy of admiration. What a beautiful mass of bloom may in this way be had at the cost of a few pence for a packet of seed, and, if merely wanted for cutting, the plants might be grown in any out-of-the-way place for that purpose. —A. D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

White Siberian Squill.—"R. M." mentions (see p. 388) with honour a white variety of *Scilla sibirica*. Will he tell us where he found it? The white variety of *S. bifolia* is not unfrequent, but I never saw, or met with anybody who had seen a white *S. sibirica*. I have looked for it in vain for years.—H. HARPER CREWE.

Double Colchicums.—How very fine in comparison with the single forms are the double Colchicums, especially the striped kind, which produces flowers of great substance. One just gathered I find to possess fifty petals, and they bloom quite as freely as the single varieties. These and the smaller kinds of autumn Crocuses are far too seldom met with in gardens. Patches of these naked autumn flowers should have a surface clothing of some of the dwarf Sedums, such as *Lyodium* or *glaucum*; and, when grown in pots, *Selaginella denticulata* would form a good base for them.—A. D.

THE HIMALAYAN LILAC.

(SYRINGA EMODI).

THIS shrub, which flowers in July and August, is frequently named *Syringa indica*, and Royle, in his "Illustrations of the Himalaya Mountains," erroneously represents it as having purple flowers, whereas they are white. It forms a robust, dense bush from 6 ft. to 10 ft. high, with oblong-elliptic leaves, sometimes 8 in. or 10 in. long, deep green above, glaucous beneath, tapering much to the

Syringa Emodi.

base, pointed, on long foot-stalks, and quite smooth. The flowers are arranged in rather large terminal thyrsoid panicles, and have rather a disagreeable odour. The fruit or capsules are somewhat large and almost cylindrical, and the shoots are spotted with white.

GEORGE GORDON.

Brambles.—There is a fine collection of the British and other Rubi in a living state in the Cambridge Botanic Garden, grouped happily in a large bed, or rather plot. Such culture is legitimate work for a botanic garden. Mr. Mudd propagates these Rubi by taking off the extreme points of the shoots and inserting them upside down in pots.

New Forests in France.—It is stated that several million acres being unproductive in France for farming purposes, the proprietors are taking measures to grow forests on these lands. It is estimated that in that country of high prices of timber, the lands will thus net 10s. per acre per annum in profit, and that there are enough of such lands in France to give an increase in productive profit of £5,000,000!

Ephedras at Cambridge.—These plants, usually found only in botanic gardens, are not without beauty when well grown, and seem to be quite hardy. A little group of them in the Cambridge Garden is at present very graceful; they grow from 2 ft. to 4 ft. at Cambridge, and somewhat resemble Conifers in habit.

The Late Gale.—We are told that by the recent gale many trees were blown down in Kelston Park, and that amongst them was one which had been planted by Queen Anne. Five hundred trees at Badminton, and 300 at Dyrham Park were also blown down.

THE INDOOR GARDEN.

THE GOMPHRENAS, OR GLOBE AMARANTUSES.

THESE pretty and easily-cultivated stove or greenhouse plants—for they are either or both—have somehow dropped very much out of cultivation of late years, though they are among the most useful plants we possess for decorative purposes. The more popular varieties are those of the *globosa* and *pulchella* sections, which are annuals. The character of the flowers which they bear will be apparent from the annexed illustrations. Their colours are bright red, rose, and white.

Gomphrena globosa.

Some of the South American varieties, such as *G. perennis*, are herbaceous plants, and this sort introduces a pale yellow colour into the genus, of which *G. villosa* is an evergreen shrub, with striped blossoms. The whole of the flowers of the Gomphrenas are not only ornamental while living, but almost equally showy when dead—and there are few dried flowers more useful and showy with which to form bouquets, along with other Everlastings and dried Grasses, than those of the Gomphrenas. Their colour, in comparison with those of most other dried flowers, may be said to be fast. To grow the annual Gomphrenas well they should be treated very much in the same way as *Celosias*; that is, sown in a hot bed. The soil, however, should be light, and the drainage perfect, as the young plants are far more liable to damp off than those of either the pointed or crested Cockscomb. The seeds are also

Gomphrena Hoveyana.

of quite a different character, and require a deeper covering of earth. The surface of the pots should be placed near the glass, in order to prevent the young plants from being drawn up weakly. If a hot bed be not available, a shelf near the glass in a plant stove, intermediate house, or a Vinery at "work" is a suitable place in which to sow the seeds. As soon as they are fairly up the young plants should be pricked off, three or so around the side of a 3-in. pot. If at this stage the pots can be plunged in a bottom heat of 60° or so, the plants will be all the better for such nurturing. They will, however, succeed if placed on a shelf near the glass, and slightly shaded from the noon-day sun until they have become quite re-established. From the first it is very important to guard against drawing up the plants in a spindly manner. The tendency of

Gomphrenas is to rise rather than spread, unless kept compact by full exposure to light from the first; they look best from 1 ft. to 18 in. high, and about 9 in. through. As soon as the plants have become well rooted they should be potted off singly into 3 in. pots, and treated as before. When these are filled with roots shift them into the size in which they are to flower, 6 in., or, at the most, 8 in. pots; 6 in. is the best size, unless special and forcing culture be adopted. Gomphrenas look best in the form of single specimens and in small pots, and good plants of them for narrow shelves may be grown even in 4 in. pots. For such plants the soil must be light. A compost consisting of equal parts loam and leaf-mould, with a sixth of silver-sand added, suits them admirably; 1 in. at least of drainage is needed in a 6-in. pot, and over the drainage a few pieces of rough leaf-mould will be found useful. In potting care must be taken not to bury any portion of the stems of the plants. In the case of Celosias and Balsams, the practice of burying part of the stem is a handy method of at once securing a more compact habit, and, at the same time, increasing the number and vigour of the roots. But this ruins Gomphrenas, as, sooner or later, it causes them to rot off. If Gomphrenas be grown in proper quarters and skilfully cultivated, they require no training; it is a useful plan, however, to nip off the first blossoms that show themselves on the tips of the stronger shoots, and it may also be desirable at times to stop a few of the stronger branchlets, or any that may get much ahead of the others. When fully grown and coming into flower they may be placed in the conservatory, in which they will do well if neither overwatered nor placed in a cutting draught. A cool stove, however, or intermediate-house suits the Globe Amaranthus best; in tolerably warm quarters the colour is brighter than it otherwise would be, and the plants continue to produce a longer succession of bloom. The Gomphrenas succeed well in sitting-rooms, in window gardens, and in other positions indoors, and the red and rose-coloured varieties, well grown and flowered, form chaste material for the decoration of the dinner-table.

To preserve the flowers in a dry state in good condition for the longest period of time, it is important to cut them with a good length of stalk just before the flowers are fully expanded; the stems will then retain their stiffness and the flowers their form and colour. Slow drying in the shade is the best and surest preparation for perfect keeping afterwards. One sometimes sees heaps of Gomphrenas and other so-called Everlasting flowers lying on shelves and stages to dry like cut Grass in swathe in a Hay-field. But those who collect and dry Grasses for ornament adopt a widely different method. There are few better modes of drying Gomphrenas than gathering them in small, loose handfuls, with, as I have said, as long stalks as is practicable, and placing them in small empty jars or pots, setting them in a shady part of the kitchen or other dry room until fully harvested.

Gomphrenas may be sown at any time from January to July; the most common months for sowing them are March and April. It is, however, a good and useful practice to make a late sowing in June, as if plants the result of this sowing be well managed they will be found most useful for enlivening the warm conservatory or cool plant stove during the two most flowerless months in the year—October and November.

D. T. F.

Standard Pelargoniums.—Where these are desired, few kinds will be found better adapted for the purpose than the double-flowered Ivy-leaved varieties which have been lately introduced; they may be grafted on strong-growing scarlet kinds, seedlings being the best. The stocks should have a clean stem, which is easily obtained by removing the lower leaves until they reach the desired height; then in spring a piece of the kind to be grafted should be taken off with a heel, then with a sharp knife make an incision about 6 in. from the top of the stock, and large enough to admit the scion. Tie tightly with matting, so that the external surfaces come into contact, and there need be little fear about their becoming united. A few leaves should be left at the top of the stock to draw up the sap, but when the graft has taken fairly they may be removed gradually, ultimately cutting the stock off down to the graft. By putting four or five good branchy pieces of any of the Ivy-leaved varieties on to one stock good plants may soon be obtained; as they grow they

naturally assume a drooping habit, and when in flower are very effective. Mr. Kingsbury, of Southampton, grows them successfully in this way, and finds them useful for decorative purposes of many kinds.—S.

THUNBERGIA LAURIFOLIA.

THIS strong-growing stove climber, from Malacca, bears, through the summer and autumn, quantities of pale blue, or rather lilac-coloured, tubular flowers, that spread considerably at the mouth, and that are produced freely from the points of

Thunbergia laurifolia.

the young shoots. Its foliage is ample and bright green in colour. It thrives well in either peat or loam, with which has been incorporated a good sprinkling of sand; the latter is essential to success, as, from its free habit of growth, the plant needs a plentiful supply of water. It is better grown in a pot than planted out, as when its roots are allowed too much space it becomes unmanageable. It is better suited for a stove of considerable size, where it can be trained loosely under the roof, than a small house, as in the latter it has not room to exhibit its true character. After it has ceased to flower in the

autumn, it should be cut in freely, and kept much drier at the root than when in active growth; but it should never be allowed to get too cold, even when at rest, or it will most likely die. It strikes freely from cuttings made of the half-ripened wood in summer, or in spring from young shoots about 6 in. in length, taken off with a heel, and inserted in small pots in sandy soil; they should be covered with a bell-glass, shaded, and kept moist until they have formed roots, when they should be gradually inured to the air and given more pot-room as required. So quickly does it grow that cuttings of it struck during the spring and grown on without stint of root-room, will cover a large space the ensuing year. It should be kept

Flower of *Thunbergia laurifolia*.

well syringed overhead during the growing season, in order to keep in check red spider, to which it is somewhat liable if the atmosphere be too dry. B.

Seedling Gloxinias.—Like W. W., Eaglehurst, I find these to make the best of flowering plants for rooms or for table decorations. I sowed two small packets of seed on February 20, and when the plants were large enough to handle I had 230 dibbled into small pots, and put on a front stage in an early Vinery, potting them on as they required it into 5 in. pots. The best plants commenced flowering the first week in July, on the 14th of July I had sixty in flower, and every one quite distinct. Some of the plants measured 20 in. across, and some of the flowers 4 in., and since that date I have not been without Gloxinia blossoms. Early in September I moved eighty plants into the stove, twenty of which are now flowering, and the remainder will come in in succession so as to keep up a supply till December.—W. W. PARKER, Broad Oak, Accrington.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Panicum plicatum Self-sown.—This handsome, broad-leaved, and large Grass grows freely alongside the pathways and under the benches in the warm houses at the Cambridge Botanic Garden. It is very graceful and luxuriant thus grown, and, moreover, useful for cutting.

Finely-bloomed Lapageria rosea.—About the middle of September this beautiful climber produced in our conservatory 900 blooms. The border in which it is planted is 3 ft. long and 1 ft. wide, and the top covers 81 square ft.—A. S., Wellington.

Bougainvillea glabra in Autumn.—This often undervalued species is of great use at this season, when it blooms profusely under good treatment, and proves very useful for cutting in late autumn. It is best planted out in a warm house, and freely trained over the roof.—H.

Melaleuca rigida.—It will be a good thing for indoor gardens when plants are trained in a picturesque or graceful manner, instead of in the usual rigid and monotonous style. So we thought the other day when looking at a plant of *Melaleuca rigida* in a cool house in the Cambridge Botanic Garden. It is gracefully pendent and weeping in habit, and very dense in growth.

SOME USEFUL AND PECULIAR VARIETIES OF THE GENUS CITRUS.

THERE are few genera of plants to which so much attention has been given, and so much written upon, as the genus *Citrus*, not on account of its being rich in species, for only five are contained in it, but rather on account of the extraordinary abundance of varieties, the interest and peculiarity in the forms of some of the fruits, their importance as an article of consumption, not only in Europe, but also in various parts of the world, and their ornamental character as conservatory plants. The Orange is certainly one of the most attractive and striking of fruit-bearing trees; whether in flower, fruit, or only for the foliage it is worth cultivating. Large plants group well in large collections, and the smaller pot plants are always attractive, on account of their shining green foliage. The strong perfume of the flowers is also another feature in these plants. Regarding the early history of the Orange a good deal rests upon what is the true and original form whence sprung our numerous cultivated varieties; all those included as Bitter and Sweet Oranges are referred by some botanists to *Citrus vulgaris* (Risso) a native of Northern India; indeed, it is supposed that a wild form which occurs in Gurhwal, Sikkim, and Khasia, is the origin of all our cultivated forms. It has further been considered that the Citron, Lemon, Lime, and Shaddock, and even the Orange, are all referable to a species indigenous also to the forests of Northern India, in the valleys of Kumaon and Sikkim, and perhaps specifically identical with *Citrus medica* (Risso). Upon the hypothesis of this being the original form of the now widely-cultivated Orange, we learn from Theophrastus that it was plentiful in Northern Persia, and cultivated by the Jews in Syria during the Roman dominion. Though it seems that the fruits found their way into Rome at a period anterior to the Christian era, the tree appears not to have been successfully cultivated in Italy till some time in the third or fourth century. However widely diffused the plant may have been in Western Asia, recent travellers have not found it in a wild state in Persia. In China it is cultivated, having no doubt been introduced from an early period. At the present time the growth of the Orange extends over all warm countries, and it is cultivated successfully in several of our colonies. In America it yields most abundant returns.

Having said so much on the early history of the Orange, we shall purposely refrain from any remarks on its subsequent cultivation in England, this matter having been so ably treated by the Rev. H. N. Ellacombe in his excellent papers on the "Plant-lore of Shakespeare" (see THE GARDEN, vol. xi., p. 525). On the literature of the Orange much might also be said, numerous works, some of a most elaborate nature, having been prepared on the subject, the principal of which have been the work of foreign authors, notably amongst these being Risso's "Histoire Naturelle des Oranges," a splendidly-illustrated work published in Paris in 1818, with life-size figures of over 100 kinds. Besides the many varieties of Orange known in commerce there are numerous forms grown which are never so seen, and the same may be said with regard to the Lemon. In considering some of the varieties of the genus *Citrus* we think it best to disregard any previous arrangement that has been made in classifying the different kinds, and to review them more in the sequence by which they are usually placed in the popular mind. Thus the first to claim attention will be the

ORANGE (*Citrus vulgaris*—Risso).—Under this head may be placed both the Sweet and the Bitter Orange. By those who do not so class them, however, the former is often referred to *C. Aurantium* (Risso), and the latter to *C. Bigaradia* (Duhamel). The Sweet Orange has ovate, oblong, acute leaves, the edges somewhat serrated, and the stalk with larger or smaller wings, the presence of which is a characteristic mark of the genus. The white, fragrant flowers are too well known to need any description. The principal difference in the numerous varieties described is in the form of the fruit; thus we have the ordinary Sweet, or St. Michael's Orange, with its somewhat small, golden-yellow fruit, with a smooth but thick skin enclosing a sweet, rich, yellow pulp, divided into from nine to eleven cells, and containing roundish seeds. This is one of the most extensively cultivated varieties, on account of its great productiveness. The tree is said, however, not to come into full

bearing until it attains the age of twenty-five or thirty years. The Blood or Malta Orange has a fruit which is round, somewhat rough, and very thin-skinned, and as it ripens becomes of a reddish-yellow colour, the pulp itself being tinged with red, which deepens as the fruit matures. It is from this fact that its name is derived. This variety has very few seeds, which are barren; it is a choice variety, the pulp being very sweet and juicy. Another choice variety is the Mandarin Orange; this bears a small fruit, somewhat flattened, with a very thin rind, which separates from the pulp as the fruit ripens, and when fully ripe hangs loosely around it; it is of a very rich and sweet flavour. This variety is extensively grown in China, where the fruits are much prized as presents to the Mandarins. It has been introduced in comparatively recent years into Malta and St. Michael's. The Mandarin Orange was at one time considered a distinct species under the name of *C. nobilis* (Lour). It seems, however, to be simply a variety of the common Orange, as is also the Tangerine, which produces small, somewhat flattened fruit, with a thin rind, and a sweet, delicious, fragrant pulp.

These are the principal or choicest varieties of the Orange known in the markets. There are numerous other varieties described, the fruits of which vary, some being more or less round or compressed, rough or smooth-skinned, and some even ribbed, horned, or variously deformed; these varieties, however, are seldom cultivated. The Oranges usually sold in the streets or in the shops in the poorer neighbourhoods of our

Horned Orange (*Citrus vulgaris*—Risso, var.).

large towns, are mostly the produce of inferior kinds, with thick, often warted rinds, and tough, woolly, juiceless pulp. Amongst Bitter Oranges, the most important, either in a commercial point of view, or on account of the peculiarity of their fruits, are the following:—The common Bitter or Seville Orange (the *Bigaradier* of the French), a fruit with a thick rind, and a rugged, uneven surface of a reddish-orange colour; the rind, flowers, and leaves are more distinctly aromatic than those of the Sweet Orange, and the pulp has an acid, bitter taste. It is the fruit of this variety that is used for making Marmalade, and the peel is used for candying and making medicinal tinctures. The rind is removed from the ripe fruit in long, spiral strips by a sharp knife: if removed without the white under-skin it is the more valuable. Besides the peel removed from the fresh fruits after arrival in this country, it is also imported in considerable quantities, especially from Malta. The foreign dried peel is not so valuable as that removed in this country. The tree is of a small size, and is extensively cultivated in the warmer parts of the Mediterranean region, more particularly in Spain. This variety and the Chinese Bitter Orange, or Chinois (the *Bigaradier Chinois* of the French), are perhaps the only two cultivated purposely for the fruits. This latter has a thick rind; the fruit is small

and spherical, and is often preserved in syrup. Many of the fruits, however, of the Bitter Oranges are very singular in form, notably the Horned variety (*Bigaradier à fruit corniculé*). As will be seen by our figure, the fruit is large, somewhat flattened, and ribbed, covered with a thick, wrinkled rind, some of the carpels being prolonged with horn-like or clawed appendages. This variety grows into a good-sized tree, and is cultivated in the south of Europe as much for the sake of its fragrant flowers as for the fruits, which were at one time, and may be still, used for flavouring or seasoning meat. A double-flowered variety, the *Bigaradier à fleur double* of the French, comes nearest perhaps to the Horned variety, resembling it in the form and size of the tree; the fruit varies in form, but is mostly double, containing, so to speak, one within another; the flowers are gathered for the sake of their perfume. Another variety, *Bigaradier Violette*, bears leaves and flowers of two different colours on the same plant, some being of a violet hue, and the others of the ordinary colour; the fruits also in an immature state have a violet tinge. One pretty little form never attains a greater size than that of a small shrub. The leaves are pointed, of a fine green colour, somewhat resembling those of the Myrtle; the flowers are small, white, racemose, bearing numerous blossoms on the same peduncle; the fruit is not unlike that of the Chinois, but is somewhat smaller.

LEMON (*Citrus Limonum*—Risso; *C. medica* var. of some authors).—Of the Lemon a very large number of varieties are known even in cultivation in this country. In all, however, the fruits contain a very acid pulp, distinct from any other species or variety of the genus. A very large-fruited variety is described by Brown as having been introduced and much cultivated in Jamaica, from a single fruit of which a pint of juice has been obtained. The common Lemon is a tree from 10 ft. to 15 ft. high, frequently seen in gardens in many sub-tropical countries, but specially cultivated as an article of commerce on the coast of the Mediterranean between Nice and Genoa, as well as in Sicily, Calabria, Spain, and Portugal. As seen in cultivation, the Lemon, unlike the Orange, is of irregular growth, with sparse foliage. The flowers are partly hermaphrodite, and partly unisexual, and the corolla is purplish on the outside and white within. Their fragrance is more delicate than, and not so clinging as, that of the Orange. The trees blossom during a great part of the year except the actual winter. The fruit of the ordinary Lemon is too well known to need any description, and the uses are also familiar to all. The Lemon assumes many peculiar forms: thus, the Fingered Lemon of China is amongst the most singular. This fruit grows to a large size and is almost solid, with little or no pulp; at the apex of the fruit the segments become absolutely divided into five or more long, cylindrical lobes: hence the name of Fingered Lemon or Citron. Such singular shapes, however, do the fruits of the different varieties of Lemon assume, that there seems to be no limit to their probable multiplication. Amongst those noted for their free-flowering and abundant fruiting is the Clustered Lime or Lemon (*Limonia à grappes* of the French). The leaves of this variety are oval-oblong, and the flowers, which are borne in corymbs, are succeeded by clusters of roundish-oblong fruits often somewhat warted on the surface, the rind being thick and shining, and the pulp very acid, and containing only few seeds. This variety produces fruit abundantly during a great part of the year, and is cultivated largely in Southern Europe. It is well shown in the accompanying figure (see p. 423).

CITRON (*Citrus Medica* (Risso) Cedrat of the French).—As stated at the commencement of this paper, this species is now usually retained as the origin of all the fruits previously considered. It has always been applied to the Citron, and in the present state of our knowledge is still specially applicable. The Citron occurs in fewer varieties than either the Orange or the Lemon. The most common is the large Citron (*Cedratier à gros fruits*), of which we give a figure (see p. 423). In this the leaves are thick, oval, oblong, and of a glaucous green, and the flowers are large and white, and very numerous; the fruit also is very large, covered with a very thick, irregular, or wrinkled rind, at first of a reddish-purple colour, becoming green as the fruit enlarges, and finally changing to a coppery hue. It is for

its thick rind that the Citron is valued, for the purpose of candying or preserving in sugar for use in confectionery; for this purpose the peel is salted, and shipped in this state both to England and Holland. The fruits themselves, which often weigh several pounds, are seldom eaten raw. Though several

Clustered Lime or Lemon (*Citrus Limonum*—Risso, var.).

varieties have been known in cultivation in this country, they have been known only very rarely to ripen their fruits. According to Fluckiger & Hanbury's "Pharmacographia," the Citron appears at the present day to be nowhere cultivated extensively, the more prolific Lemon tree having generally taken its place. It is, however, scattered along the Western Riviera, and is also grown on a small scale about Pizzo and

Large Citron (*Citrus Medica*—Risso).

Paola, on the western coast of Calabria, in Sicily, Corsica, and the Azores.

BERGAMOT (Bergamottier of the French).—*Citrus Bergamia* of some authors, though modern botanists consider it not sufficiently marked to make it a distinct species from those preceding. It is a small tree, in flowers and foliage not unlike the Bitter Orange; the fruits are nearly spherical or somewhat Pear-shaped, very often crowned at the apex by the persistent style; they have a smooth, thin skin, of a pale yellow colour, and this skin contains a large quantity of essential oil, of a peculiar but well-known fragrance. It is for this oil (the oil of Bergamot of the shops) that this variety is valued, being culti-

vated on low grounds near the sea at and in the neighbourhood of Reggio, in Calabria, where Lemon and Orange trees are often mixed with it, and the ground beneath their shade well cropped with vegetables. The essential oil is expressed from the fruits by specially-constructed machinery, by which the fruits are made to revolve in a kind of dish or saucer, at the same time coming in contact with a series of metal ridges, which fracture the rind and thus set free the oil. From 2 oz. to 3 oz. of this oil is so obtained from every 100 fruits, and about 7000 fruits are thus treated by a single machine in one day. After the oil has been extracted the fruits are again pressed for the sake of the acid juice contained in the pulp, which is concentrated and used in the manufacture of citric acid, and the residue, after the final extraction of oil and juice, is used as a cattle food. The oil is always known in commerce as essence of Bergamot, and is imported chiefly from Messina and Palermo. Its principal use is in perfumery. Like all other fruits of the Orange tribe that we have described, the Bergamot has its varieties with fruits of singular formation. One, for instance, in which the fruit is flattened to where there is a circular opening, discloses a number of irregular prominences. On cutting one of these fruits across a series of about twenty cells filled with pulp are seen around the circumference, and in the centre a number of irregular cells agreeing with the external prominences. Of the Lime, usually described as *Citrus Limetta* (Risso), and of the Shaddock (*Citrus decumana*, L.), we need say but little, as they are so well known. Of the former, several varieties are cultivated. The chief use of the Lime is for the juice, which has a great reputation as an antiscorbutic. The fruits of the Shaddock are known under distinct names according to their size; thus a full-grown fruit is very large and weighs from 10 lb. to 20 lb.; they are then called Pompelmousses or Pampelmousses, while those of the smallest size are known as Forbidden Fruit or Pomeloos. Of the remaining species of the genus Citron we have little or nothing to do, as their fruits are of little importance economically, nor are they of interest structurally; one exception, however, we must make, and that is to *Citrus japonica*, (Hib.), a native of Japan, the fruits of which are about the size of a large Cherry and quite spherical, with a thin rind, and a very sweet, agreeable pulp. It is known as the Kumquat, and the fruits preserved in syrup are often to be obtained at the best Italian warehouses at the west-end of London. The plant is in cultivation in this country, and has produced fruit with us. JOHN R. JACKSON.

VINE DISEASES.

Spot.—In some cases this appears to be constitutional, or at all events some varieties of Grapes are much more subject to this evil than others. It may be noted that where it is regarded as "constitutional," the connection between the affected parts and the seeds and axis of the berry may be traced. In other cases it is more superficial, and apparently accidental, or the result of bad health. It is sudden in its action, and sometimes very injurious. Muscats are perhaps more subject to spot than any other class of Grapes. On its first appearance, which is when the Grapes are young, tender, and swelling fast, a small irregular, whitish mark is seen on the side of the berry, as if it had been bruised in some way; the pulp beneath dries up, and a sort of contraction occurs, the berry soon assuming a one-sided, irregular form. In cases where the berries are much affected, they should be cut out. As to the cause, it is at times difficult thoroughly to ascertain its origin.

Scalding.—This is a term applied to Grapes which appear as if they had been scalded. It generally occurs when the berries are about half-grown; sometimes it is but a few berries here and there which are affected, but frequently the entire side of the bunch is damaged, and we have seen cases of nearly the entire crop being lost, the berries being completely destroyed, as if scalded or parboiled. This is caused through late or imperfect ventilation on some bright, sunshiny morning, whilst the internal atmosphere and even the berries are saturated with moisture. The varieties most subject to this affection are Muscat of Alexandria and Lady Downe's Seedling.

Warts on the Leaves.—These are merely small green warts that form on the backs of the leaves, a sort of granulation or extravasation of sap through the skin of the leaf. They are injurious to the leaves, no doubt, as affecting respiration, &c., and are the outcome of some fit of ill-health on the part of the Vine. This affection may be caused by a too close, warm atmosphere saturated with moisture. Vines badly affected take a long time to recover.—"Florist."

PLATE XCVIII.

THE JAPANESE ANDROMEDA.

(PIERIS JAPONICA.)

Drawn by Miss DUFFIELD.

Among the groups of plants which deserve to be more extensively employed in our gardens and shrubberies than is now the case, the Heath tribe (Ericaceæ) holds a prominent position. We are, indeed, in no danger of losing sight of this beautiful family so long as Rhododendrons hold their own in the shrubbery and Azaleas are conspicuous in the greenhouse, but a much greater variety might easily be presented than is at present the case. One of the most beautiful shrubbery beds at Kew is that devoted to plants of the Heath tribe; this is situated in the pleasure grounds, just outside the wire fence, on the left hand of the Syon vista, and is well worth a visit at various seasons of the year—in early summer on account of the glowing colours of the hardy American Azaleas, and in late autumn for the various white-flowered Clethras and allied plants, which are then specially attractive; the St. Dabeoc's Heath (*Daboecia polifolia*), too, is then very ornamental, flowering late on into the winter.

Flowering branch of *Pieris* (*Andromeda*) *japonica*.

Among these Ericaceous shrubs, various species, which are popularly known as Andromedas, take a prominent position. The most recent authorities, however, restrict this name to the pretty little pink-flowered shrub (*A. polifolia*) which is familiar to those who wander on the turf moors of our more northern counties, and which is found in similar localities throughout the temperate and sub-arctic regions of the northern hemisphere. The white-flowered species are by Bentham and Hooker distributed among various allied genera, all of which are worthy of attention, as including handsome and desirable garden plants. Many of them are placed in *Pieris*, a genus established by Don for three or four of them, including two of those which are about to be noticed. As now defined, *Pieris* includes ten species of smooth or pubescent trees or shrubs, with slender branches, and alternate stalked, entire, or serrulate evergreen leaves; the short-stalked white (or rarely red) flowers are disposed in short or elongated axillary or terminal racemes. These species are natives of the Himalayan region, the Malayan Peninsula, Japan, and eastern North America; they are distributed into sections, the subject of our plate with two others forming the section *Portuna*. The characters distinguishing the sections are mainly technical; but the three species agree in having leathery serrated leaves, and white

flowers in simple racemes, which are axillary or paniced at the ends of the branches. The following descriptions will assist in the discrimination of the species.

Japan Andromeda (*Pieris japonica*) is a tall, smooth shrub, with pointed, lanceolate leaves about 2 in. long, which are serrated or waved at the margin, and narrowed at the base, and numerous drooping branched or paniced white, waxy flowers. It is a native of shrubby places in the mountainous region of Japan, where it was discovered by Thunberg, who figured and described it in his "*Flora Japonica*," t. 22 (published in 1784), and specimens from whom are in the British Museum Herbarium. A variety, having narrower leaves, occurs in a wild state, as well as one having the foliage margined with white. Although at present scarce, this most graceful plant bids fair to become a most useful addition to our stock of spring-flowering shrubs; it is said to be even hardier than *A. floribunda* and is much more ornamental than that species. Our figure is from a plant that flowered in Messrs. Thibaut & Ketleer's nursery, at Sceaux, in March last. The living specimens from which the plate was made were sent by post from Paris to London, so that the artist did not see them in their best state. A more lovely shrub, when seen veiled over with pendent racemes of white waxy bells, it would be difficult to imagine, and we hope it may soon become frequent in gardens.

American Andromeda (*Pieris floribunda*).—This is a very handsome North American shrub, sometimes attaining in its native country a height of 10 ft. It is very leafy, the leaves, which are about the size of those of *A. japonica*, being narrow and oblong, and the very numerous handsome, white flowers being placed in crowded panices of dense, naked racemes. The individual flowers are urn-shaped, and conspicuously five-angled; they are formed in autumn, and remain throughout the winter unopened, expanding the following spring, usually about April. A handsome winter bouquet may be formed by cutting off a branch and placing it in water in a warm room, when the flowers will open in a few days. It has been in cultivation in England for a considerable time, having been introduced by Lyon, in 1811, and is figured in the "*Botanical Magazine*," t. 1566, and the "*Botanical Register*," t. 807.

Indian Andromeda (*Pieris formosa*).—This is a native of Sikkim and Nepal, ascending to the height of 7000 ft. to 10,000 ft. in the mountainous regions. It has long, crowded, pointed, serrulate, evergreen leaves, from 2 in. to 3 in. in length, with large terminal panices of drooping rose-coloured flowers, in delicately-pubescent racemes. This species attains the dimensions of a small tree, and like the two preceding species, is exceedingly handsome. It is figured in the "*Illustration Horticole*" for 1858, t. 162; and in Wight's "*Icones Plantarum Indiæ Orientalis*," iv., t. 1200. Loudon says that *P. floribunda* is difficult to propagate; but more recent authors say that all of these Andromedas are easily cultivated and propagated. They will grow readily from seeds, when these can be obtained, if these are placed in pots or pans of moist earth, their germination being facilitated by genial bottom heat. Layering is, however, a more usual and more ready method of increase, the old stems being headed off, and the bases of the young shoots being then covered with soil. They grow best in sandy peat, with a little loam; and cuttings planted in sand and placed under a bell-glass will readily take root. It is more than probable that useful hybrids will be produced between the species described and others allied to them.

JAMES BRITTEN.

The Carrageen Crop.—To the great majority of people, Carrageen, under the more familiar name of Irish Moss, is known chiefly as the basis of a pleasant and wholesome drink for the sick room, or as an article of use in the preparation of delicacies for the table. Comparatively few are aware of its wide and varied use in the arts, or that the thousands of barrels of it employed annually by our manufacturers of paper, cloth, felt and straw hats, &c., and by brewers, is not an Irish, but an American product, and strictly speaking, is not a Moss, but a seaweed. Carrageen (*Chondrus crispus*) is to be found, more or less abundantly, all along the northern coast of the United States, ranging between the low water line and the depth of 40 ft. or so; but, as a rule, its fronds, which correspond to the leaves of air plants, are so numerous inhabited by small mollusca that they are spoiled for other use. The clean-growing article seems to be limited almost wholly to certain ledges in the neighbourhood of Scituate, Massachusetts—a section of coast guarded by the celebrated Minot Ledge Lighthouse, and famous for its danger to shipping. Here, where the waves of the Atlantic dash with full force upon the rocky coast, the Carrageen grows in perfection; and wherever it escapes the spawn of mussels and other shell-fish, is gathered during the summer season in vast quantities.—"*Pharmaceutical Journal*."

THE JAPAN ANDROMEDA. (A. JAPONICA)

THE FRUIT GARDEN.

FIELD CULTURE OF HARDY FRUIT TREES.

(Continued from p. 396).

GRAFTING WAX.—After grafting, it is necessary to protect the graft against the effects of the air, the wind, rain, and damp, insects, and birds. For this purpose the whole of the wounded parts are covered with grafting wax as soon as the scions are in their proper places. The compositions used for this purpose are various; the following is one of the best:—Black pitch, 30 parts by weight; white resin, 30 parts; mutton fat, or any other grease, 30 parts; yellow wax, 10 parts. The resin may be left out, double the quantity of black pitch being used in its stead. In case of necessity the wax may be replaced by double the quantity of tallow. Some growers add wood ashes, and red or brown ochre to give it body, but these substances do not seem to influence the quality of the wax one way or the other. Grafting wax should be made of such a consistency as not to melt in a hot sun, or run into the cracks of the tree. This is best avoided by keeping down the amount of tallow in the mixture. Dutch growers use a compound made of 120 parts, by weight, of resin, melted with 60 parts of lard, which must be melted together and well stirred. When wanted for use, it must be dropped into warm water and kneaded to the proper consistency with the fingers, which ought to be well greased or oiled, otherwise the composition will stick to them. In order to prevent the young scions from being broken by birds or the wind, they ought to be tied to an

Fig. 20.

Fig. 21.

arched support, as shown in fig. 20. In re-grafting strong trees, and in crown grafting generally, the scions ought to be protected against the wind by allowing their shoots to grow as shown in fig. 21. By degrees, however, the young shoots of the stock may be pruned down gradually, in proportion to the development of the scion. As for those on the scion itself, they must be pruned in accordance with the form which we desire the tree to take. It is not well to begin the formation of the crown of a tree by grafting too many scions on the same stock. Caterpillars, ants, and spiders do great harm to freshly-grafted scions, and should be kept down with a strong hand.

Shield budding has one advantage over the other methods of grafting, that it causes no serious injury to the trees, so that it can be used with young wildings; besides which, certain varieties of Apricots and Peaches will only take when grafted in this manner. Besides these advantages shield-budding may be performed at almost any season. We shall see farther on that this method of shield budding, which was formerly employed for growing dwarf fruit trees and for ornamental plants, plays, now-a-days, a very important part in the growing of standard fruit trees. When shield budding is practised in summer, that is to say, before the end of June, it is called shield grafting with a growing bud. This method is not much

used, seeing that very little is gained by it, the same end being obtained by shield budding when the bud is at rest, besides which the operation, when performed in June, is much more difficult. Shield budding with the bud at rest is performed from the beginning of July onward, and is continued as long as the bark separates easily from the wood. It does not do to begin indiscriminately with any species of fruit tree. The best trees to begin with are piped fruit, continuing later on with the Apricot, Plum, Cherry, and finishing with the Peach. The earliness or lateness of the stock must also be taken into consideration; thus a Peach may be grafted earlier on a Plum than on an Almond, the Pear upon itself sooner than on the Quince, because this last named tree keeps its leaves until a late period, and has but little sap at the beginning of the summer. It is erroneous to say in this case that if the shield graft does not take it has died for want of nourishment. The choice of shoots for shield grafting is the same as for the other kinds of grafting. Strong shoots

Fig. 22.

Fig. 23.

Fig. 24.

Fig. 25.

should be taken, furnished with good buds; the herbaceous shoots, the extremities of which have been pruned down to about 1 ft. in length, always furnish the best grafts, their wood being mature and their buds healthy. As soon as they are cut off they should be stripped of their leaves and their stipules, preserving one petiole only, as shown in fig. 22. If they have to be kept for any length of time before being used, they should be wrapped up in Moss or damp cloths, or their ends should be stuck into a piece of Cucumber, Potato, or other succulent vegetable or fruit. It must be borne in mind that in choosing scions for shield grafting the bark must be tender and not too thick. Neglect of these precautions has frequently led to great discouragement. The trees to be grafted are prepared three or four weeks beforehand by relieving them of their superfluous wood, by which means their growth, which has been momentarily checked, has had time to recover itself. The early part of the season is best for shield grafting; and in cases of necessity, it may be confined to a single week. In shield grafting there are four separate operations to perform. 1st. Cutting the shield. 2nd. Cutting and loosening the bark of the stock. 3rd. Fixing the shield graft in its place. 4th. The tying up of the graft. To cut the shield scion properly the shoot should be raised by the left hand, the grafting knife being placed about $\frac{3}{4}$ of an in. below the bud which is going to be cut, cutting through the bark in a downward direction from $\frac{3}{4}$ of an in. above the bud. The shield should be held between the trunk and the grafting knife in order to cut away part of the wood as shown in fig. 23. The wood ought to be cut away so as not to remove the heart of the bud. For this reason a thin strip of bark is torn off either from above downwards, or *vice versa*, according to the tree operated upon. If it be too late to remove the wood of the shield bud it may be allowed to remain without injury, taking care, however, to remove as little wood as possible. In a smooth place, which has been previously cleaned by rubbing it with the hand, an incision is made in the form of a T (fig. 24), and for stone fruit trees a second incision in the form of a reversed T should also be made as shown in the figure. It should always be done when shield grafting is begun early in the season, although the method is more troublesome than when a single incision only is made. The two corners of the bark where the incision has been made are then gently separated from the wood with the spatule of the grafting knife, but only just sufficient to

allow the bud to be easily slipped into its place. When there is much wood to the graft, the bark should only be partially separated from the stock, and the edges of the scion itself should be used to force its way into the proper position. One great point is to slide the graft into its place as gently as possible. The graft should be held in the left hand by the petiole as shown in fig. 23, and placed in the cross incision, and then quickly slid down the longitudinal slip. The scion is then bound up with worsted, thread, or some other elastic ligature. The cross slit should be well bound, the longitudinal incision requiring less care. If the petiole falls off two or three days after the graft has been made it is a sign that the graft has taken. The operation of shield grafting should never be performed in rainy weather, nor when the weather is very dry, except the number of grafts are few, in which case they may be kept fresh by watering them. The stocks which bear dormant grafts should not be transplanted. When spring sets in the stock should be cut down to within 3 in. or 4 in. of the graft, and the ligatures should be loosened unless the swelling at the point of junction has not already necessitated this operation.

SHIELD GRAFTING FRUIT SCIONS.—For some years past fruit-growers have been in the habit of using the mature shoots of Apple and Pear trees as grafts; by this means it is easy to fill up vacant spaces and, so to speak, force the trees to bear fruit, and in many cases put fruit on a vigorous but unfruitful tree.

Fig. 23.

Fig. 27.

Fig. 28.

It affords, also, an easy means of trying the hardiness of a particular variety whose qualities in this respect are, as yet, unknown, before planting it in the open air. Many orchardists have an absurd fancy for growing four or five different varieties of Apples or Pears on the same stock; this kind of fancy grafting ought to be given up, seeing that, when adopted, it only results in producing trees of irregular growth. By shield grafting with a fruit-bud, a stock may be made to produce several different varieties of fruit without compelling the tree to bear branches of varying vigour, direction of growth, and fertility. This method of shield grafting provides us with an excellent mode of gaining a knowledge of different varieties of Apples and Pears without being obliged to plant a large number. Strong, hardy, free-growing trees may be easily used as sample growers. The proper method of cutting a fruit-bud is shown in fig. 26. If the bark does not separate easily, the mode of cutting figured in the next cut must be adopted. On a branch (a) a small piece of bark is cut with a layer of wood attached to it, and the grafts (b and b) are fitted into the vacant space. The best season for shield grafting is from the end of July to the end of August. Before this period the fruit-buds are not formed, and cannot be cut away with their own wood attached. They are also more difficult to be distinguished by an inexperienced eye.

Permanent Planting.

ORCHARDS.—These ought to be so situated that they may be open to the beneficial influence of the sun and air, a condition of growth which is absolutely essential. A low and damp situation, in which the air is continually surcharged with moisture, through not being able to circulate and renew itself freely, exercises a very baneful influence on trees and fruits, as well as animals. Fruit produced under such conditions is generally watery and wanting in flavour, especially when the summer has been cold and damp. The truth of this is proved by the enormous difference in flavour between an Apple which has

ripened on the sunny side of a tree, and one which has come to maturity in the shade. Strong sunshine makes the wood healthier and harder, and increases the number of fruit buds. The orchard consequently ought to be open to the south or south-east, and it will be an advantage if the northern or north-eastern sides are protected from cold winds and hurricanes by buildings, hilly ground, or other trees; it must, however, be borne in mind that the shelter must not be so thick as to impede the free circulation of the air. For instance, an orchard cannot be planted with its back to a thick wood, or even too near to it, without the trees of both plantations eventually injuring each other. Small orchards surrounded by thick hedges often fail to bear proper fruit on account of the air being constantly stagnant. Perhaps the best protective surrounding for small orchards is a wide deep ditch. It may be argued that a large amount of space is lost by this means, but as the trees can be planted up to the very edge of the ditch the argument is fallacious. These trees, being exposed to the full action of the sun and air bear as well as the others, whereas when the orchard is surrounded by a hedge, the trees near to it are generally less productive than the others. Where no natural shelter exists the same end may be easily attained by planting the sides which require protection with tall Walnuts and Chestnuts. It is also an advantage to choose a situation which has a slight inclination from north to south, or it may even be produced artificially when the ground is being prepared for the planting of the trees. Such an inclination is necessary in the case of damp ground, and should not be less than 2 in 100, a gradient which, although imperceptible to the eye, exercises a great influence on the health of the trees. There are but few localities in which the soil is fitted for the growth of every variety of fruit tree, some kinds flourishing in places where others are perfectly barren. When the soil is only of middling quality, the grower should confine his attention entirely to those varieties which thrive best on a moderately rich soil, for it is a difficult and costly operation to wholly change the nature of the ground by the addition of the missing materials, which are necessary for the growth of each particular variety. When we come to speak of the different species of fruit trees, we shall enter into the consideration of the aspect and soil most fitted to each of them, and shall show that if the soil be not of a high degree of excellence it is seldom profitable to plant a large number of varieties. For the same reason we shall point out the particular kinds which ought to form the bulk of the plantation. The position and nature of the ground are in direct relation to the extent of the orchard. The less fitted the soil may be for the growth of fruit trees the smaller should be the orchard, for, on a large scale, the cost of planting and after cultivation would be too great, and the chances of success too small, even if the best methods be adopted. We may remark, however, that, as a rule, orchards in this country are much too small, although the advantages of fruit growing as a profitable investment of capital and labour are becoming better known and appreciated every day. We may, however, notice an instance of the power of prejudice and routine in the case of certain fruit growers. Formerly the orchard was limited to the space comprised around farm buildings, and cultivators are loath to see fruit trees elsewhere. Who, however, can deny the great advantages of large pastures planted with fruit trees in the immediate neighbourhood of a farm, the fruit trees being at first planted as mere accessories frequently turning out to be more profitable than the pasture itself. On the occasion of M. Burvenich's visits, as a member of the jury, to certain provincial fruit shows, he rarely found an orchard which had been purposely planted for the sake of profit of any great size. Amongst over sixty orchards barely ten were larger than half a hectare.

PREPARATORY WORK.—The ground needs careful preparation, according to its peculiar qualities. The portion set apart for an orchard ought to fulfil two essential conditions before the operation of planting is commenced. The subsoil ought to be tolerably porous, and covered with a pretty thick layer of fertile soil. Permeability is a property which all soils ought to possess, whatever may be their nature. This important point in successful fruit-growing is too frequently neglected, growers being generally satisfied if the young trees grow well and bear an abundance of wood during the first few years.

It is evident that a young tree ought to show vigorous growth if we wish to obtain good results from planting it; but it must always be borne in mind that trees grown in a cold, damp soil bear late and yield fruit of an inferior quality. In the first chapter we explained how necessary it was that the air should have free access to the roots. A soil which is of a sufficient consistency to prevent the rain from percolating freely through it is rarely sufficiently pervious to the air. All operations, therefore, which are undertaken with a view to increase the permeability of the soil and improve the drainage should be commenced at the very outset. These operations are of various kinds. We have already remarked that it is of advantage to give the ground a slight incline, but this is not sufficient when the soil is damp and heavy, or in a low situation. In the first case, the following method must be adopted:—The ground is divided into portions equal to the distance at which we wish to plant the trees from each other, as shown in fig. 29. Deep and narrow drains are dug in the direction of the incline, at the bottom of which faggots or sticks are placed, in order to facilitate the drainage. Elm is an excellent wood for this purpose, as it bears damp without rotting better than almost any other wood. A layer of straw is placed on the top of the faggots, so that the soil may be well pressed down and not fall through the branches. The earth should be well trodden down, so as to form an impermeable mass. Bramble, Furze, Heath, or Fern may be used instead of the faggots or sticks. The plots are formed into ridges in such a manner that the part in which the trees are to be planted shall be the highest. If the soil be very damp, the trees should be planted on little mounds. This matter will be more fully explained in the chapter on planting. A piece of ground, situated in a very low position, may be improved by digging trenches

Fig. 29.—Dotted lines, Drainage; O, Trees.

as just described, with this difference, that they must be dug much wider. These trenches may be filled with any waste vegetable matter. Dug in this way, these trenches afford the amount of soil necessary for raising the surface, and, of course, act as efficient drains. This method may also be adopted in cases where the layer of vegetable mould is comparatively shallow. When operations are carried on on a large scale, the trenches need not be filled up. Open trenches, however, have this inconvenience, that the edges of the plots are constantly falling, on account of cattle and sheep continually grazing on the Grass which borders them, thus necessitating frequent attention. In certain cases this mode of drainage is to be recommended, especially if the plan shown in fig. 30 be followed out. The trenches should be dug at least 3 ft. in depth, and should be partially filled with clinkers. The rain-water not only percolates through the clinkers, but in its passage it acquires fertilizing properties, as is abundantly proved by the trees which have been planted along the sides of roads macadamised with this material. By following the directions given above, we may form an orchard in a meadow in a heavy soil, and situated in a low position. Taking fig. 30

as our guide, we dig trenches 30 ft. apart, 2 ft. 9 in. wide, and 3 ft. 3 in. deep. They should be filled in with clinkers to the depth of about 10 in. or 1 ft. All round the meadow a trench should be dug slightly deeper than those between the ridges. The earth taken out of this trench may be used for heightening the plots. Glass-house waste, the refuse from blast furnaces, or any similar material may be used for filling in the

Fig. 30.—A, Trenches; B, Trees.

trenches. In heavy clayey districts, the dampest land may be effectually drained by following the above directions, more especially in the manufacturing parts of the country, where the materials mentioned may be had for the asking. Drain pipes are not to be recommended for orchards, for in spite of every care, the roots penetrate the joints, and speedily put a stop to the flow of the water, except where very large pipes are used; even then the method of forming trenches just described is to be preferred.

Planting Out.

Although it is better to choose varieties which are adapted to the soil instead of trying to adapt the soil to the trees, it must not be supposed that an orchard can be established on a piece of ground that has received no previous preparation. The ground must be dry, and manured superficially at least. In former days, the method of planting fruit trees consisted in digging a hole in the ground, cramming the roots into it by force, filling up the interstices with the earth which had been dug out, and finally treading the whole level with the surrounding soil. The importance of a proper method of planting is, however, fully recognised now-a-days. It is very false economy to spare pains and expense in preparing the ground for an orchard; on the other hand, an unnecessary amount of labour may be easily incurred by the inexperienced. It is seldom necessary to dig the ground as much as two spits deep except in the case of an old Osier bed, or Lucerne field, or a cleared wood. If the land be arable or meadow, it is only necessary to dig well round the spot which each tree is to occupy. If the soil be somewhat poor it should be dug along the whole length of the strips to be occupied by the trees. The trenches between the strips should be made as wide as the size of the ground will allow, and should not exceed 3 ft. or 3 ft. 6 in. deep. Many planters err by making the trenches too deep, under the idea that the roots will bury themselves more deeply. The good earth taken out of the holes or trenches is placed on one side, while that which is sandy or clayey may be thrown on the pathways. The holes having been dug out, they are filled in first with waste cuttings or turf, and then with the soil taken out of them, which should be first mixed with good manure, if it be easily procurable. The soil should be lightly filled in so that the air and rain may percolate through the mass. The holes should be filled in some time previous to the trees being planted, in order that the soil may settle down to its proper level naturally.

ARRANGEMENT OF THE TREES.—The order in which the trees are planted should be such as should give the effect of an avenue from several points of view. The different varieties, also, should be so placed that trees of different heights may not be intermixed. Plantations may be made in squares, as

shown in fig. 33, or in quincunx, as in fig. 34; the latter method is to be preferred, inasmuch as the crowns of the trees grow with a greater amount of freedom. It may not be out of place to describe the method of planning a quincunx plantation, such a piece of work being only too frequently badly executed. Suppose that the trees are to be planted 25 ft. apart. A line

is marked out with pegs 25 ft. apart, A, B, C, D, E, as shown in fig. 35; a string, 25 ft. long, is then attached to the peg A, and a circle described round A as a centre; the same is done with the other pegs, and the points where the circles intersect on both sides of the line are the positions in which

Fig. 35.

the other trees are to be planted. The two new rows are thus taken as starting points, and the same operation is gone through until the plot is completed. There is another method of planting which, although not to be recommended, may often be found useful. It consists in planting two rows, side by side, in alternate order at a distance of 16 ft. or 20 ft. apart, leaving between each double row a space of 40 ft. or 50 ft., which may be used for planting vegetables or for other purposes; the space between the double rows is favourable to the growth of the

Fig. 36.

trees. This method of planting is shown in fig. 36. Whatever plan may be adopted, it should always be borne in mind that it is better to plant those varieties in the same row which ripen about the same time. By this means we shall keep apart those kinds which are apt to injure each other, besides which the gathering of the fruit is much facilitated, and each variety can be planted in the aspect most suited to it. The most open position should be given to those trees which flower late, and which are, consequently, less liable to the influences of spring frosts and cold winds. The following rules will help the grower in choosing the best situation for each kind of tree:—For Apples a slightly shaded situation is rather an advantage than otherwise, for it may often be remarked that those of the Apple trees which are the most seldom visited by the rays of the sun are the most vigorous. The Apple must not, however, be exposed to winds from the north or east, otherwise the bloom will be injured. Its best place is in the middle of the orchard, where it is protected by other fruit trees. Late varieties should be planted on the outside as much as possible. The Pear, whose bloom seems to suffer less from cold than that of the Apple, may be planted on the north and east sides of the Apple orchards, by which means the Apples will be sheltered completely by the taller and thicker-leaved Pear trees.

Cherries and Plums do not last long in heavy ground; they require plenty of air, and thrive best on the west and south sides of the orchard. They may be planted in the kitchen garden, for the crowns and roots, developing but slowly, they do but little injury to vegetables growing between them. Peaches and Apricots succeed badly when grown in open quarters, except in exceptionally favourable situations. The Walnut and Sweet Chestnut soon attain their full development, giving plenty of shelter and shadow. The best place for them is on the north and east sides of orchards, or in avenues at a distance from gardens in arable fields. When grafted they grow more slowly, but yield a larger quantity of fruit. The Mulberry likes a fresh, deep, fertile, and well-drained soil. It gives plenty of shade; its wood is hard, but rather brittle—hence it suffers from high winds. It ought to be placed under the lee of a building, as it will not resist the severity of a northern climate if planted in an exposed situation.

(To be continued).

OCTOBER PEARS.

THERE are so many excellent kinds of Pears that ripen during the month of October that it is difficult to make a selection, but, in

Fig. 1.—Duchesse d'Angoulême.

continuation of our illustrations of some of the best kinds, the following must have a prominent position:—Duchesse d'Angoulême (fig. 1), one of the largest of Pears, is handsome both in shape and

Fig. 2.—Helene Gregoire.

appearance. In warm seasons the flesh is buttery and melting, but, as a rule, it is coarse-grained and gritty. It is a grand exhibition Pear, but to ensure its always being good, it should be grown on a south or west wall. It is a free bearer in any soil or aspect. Helene Gregoire (fig. 2) I have not seen grown in England, except in a garden in Hants. It was obtained from Van Houtte, of Ghent, and is grown in the form of cordons on a south wall. The fruit, which is excellent, has a strong aromatic flavour and is very juicy, and it will keep for a month after being fully ripe. The tree is a vigorous grower, a free bearer, and worthy of a place in the most select collections. Red Doyenné (fig. 3) is a well-known little Pear that is always good. I find it to succeed admirably grown in the form of bushes, kept well pinched in, and at the same time fed

liberally with manure, or manure water. The pinching cripples growth and makes it fruitful, whilst the manuring feeds the fruit. Marie Louise (fig. 4) is too well known to need a word either of description or recommendation. I may say, however, that its season may be greatly prolonged by not picking all the fruit at one and the same time, but a portion only, at intervals of a week or ten days; that first gathered will ripen proportionately earlier than the last. Conseiller de la Cour (fig. 5) is a handsome, finely-coloured Pear, of large size and passable quality; it is, however, very much overrated, for, at best, the flavour is never more than second-rate. It is a productive bearer, and on this account may be worthy of the attention of market growers. Durondeau (fig. 6) is one of the most beautiful of Pears, the skin being a shining russet streaked with deep red on the side next the sun, whilst the shaded side is, when fully ripe, a pale yellow; the flesh is most delicious, and the tree an abundant bearer. It is worthy of a wall and the most liberal culture. Calebasse Tongard (fig. 7) is also a large,

wood; they are trained with three upright stems, three shoots instead of five. The old fan training generally employed takes too long to fill the walls, which, in fact, seldom get filled at all, and much valuable space is thereby lost. I have also got Cherries trained in like fashion, and intend, as my Pear walls want replenishing, to do the whole in like manner.—R. GILBERT, *Burghley*. [No doubt the upright way is the way for the future. The engraving to which Mr. Gilbert alludes was from a photograph taken to show the length and size of the wall, and therefore it makes the trees appear closer than they are; but they are really so spaced that both trees and branches have ample room for full development. The high wall allows of a fair growth to the branches, which can exhaust themselves in fruit-bearing, and need not be continually cut back to repress their vigour. A fine crop was gathered off this wall even during the past bad season. It consisted of about ten Pears to the square yard, and the fruit was both large and good; such as bring high prices after Christmas and in early spring.]

Fig. 8.—Délices de Lovenjoul.

handsome-looking Pear, of excellent quality; it is one of the few kinds that ripen best on the trees, but it requires to be used as soon as it is gathered, as it soon rots deceptively at the core; if gathered before it is ripe, it rots before it becomes in any way usable, except for stewing. Délices de Lovenjoul (fig. 8) is a very excellent medium-sized Pear, of the Doyenné type. It is suitable for growing as bushes or as small standards, as recommended in the case of the Red Doyenné. It is extremely productive and hardy, and therefore specially adapted for small gardens. W. W. H.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Josphine de Malinse Pear.—With us, this, is one of the most satisfactory Pears grown, either on walls, espaliers, or pyramids; on walls we have a fine crop of fair-sized fruit for dessert; on espaliers and pyramids it is generally russeted, but quite equal, if not superior, in flavour to those on walls. This variety has a very distinct habit of producing flower buds on the terminal growths; therefore, in pruning, these should be cut off, if it be wished to extend the shoot down to a wood bud.—J. Gaeox, *Henham*.

The Vintage is not yet terminated in the Hautes-Pyrénées. The Vines are, so to say, inexhaustible. Everybody is seeking in all directions for casks. Never, in the memory of man, has such a rich crop, as far as quantity goes, been seen. As for quality, it will rival that of 1865 or 1870, and many people believe it will surpass them. No stoppage in the sap has taken place. They are full of juice, and the skin is fine and bright-coloured.

Cranberry Imports.—At the general meeting of the German Pomologists, mention was made of the shiploads of Cranberries exported from Ohio to England and Hamburg. All this is very interesting, but it would be more interesting to know what becomes of all these Cranberries. Do the wine merchants know anything about them?

The Pear Walls of the Future.—In the very excellent woodcut (see p. 393) the Easter Beurré Pears appear to me to be crowded. I should much like to know the distances at which the trees stand apart. I feel quite persuaded that the training represented is that which will fill our fruit-room shelves with Pears. Four years ago I planted a wall with Plums, the varieties being Prince of Wales and Victoria, and the wall is now entirely full of good-bearing

HOUSEHOLD HORTICULTURE.

As all of us cannot have a Kew garden of our own, we must needs content ourselves with something less comprehensive. But even Kew's capabilities are limited. It cannot cultivate every herb which, as the poet saith, "sips the dew," even if, perchance, it could get them all. For yet stronger reasons, our own private collection must be still choicer and more select. The vegetable kingdom is vast, while our means and appliances may be exceedingly restricted. How, then, under such circumstances, is the passion for gardening, which is innate in so many human breasts, to be gratified? The problem admits of easier solution than at first sight may be obvious. As it is impossible that you should make a familiar friend of every plant which exists on *terra firma* as well as on earth which is not firm, not to mention aquatics which grow in water, you have only to decide which you prefer. A man cannot keep up even a bowing acquaintance with every one of the four millions who dwell in London, but confines his friendship to a favoured few; and so must it be with your horticultural pursuits, whether merely household or on a larger scale. You must decide what line of cultivation you will go into, which does not exclude the heterogeneous and the miscellaneous—the odds-and-ends line of horticulture. Household horticulture is undertaken either for show and display, by which is meant a most laudable means of domestic decoration, or else with personal and private study or recreation for its principal object. In both cases the choice of subjects will depend whether the preference is given to foliage or flowers, to form or to colour, to the phenomena of growth and development, or of inflorescence. The fine foliage class may be made to include many plants possessing, in addition to their ornamental merits, great botanical and economic interest. Although not a few plants, uniting commercial value with good appearance and even beauty—the Nutmeg, Coffee, Cinnamon, Black Pepper—must have a hothouse to do well in the United Kingdom, others will thrive in the temperate atmosphere of our houses. Want of space forbids our giving more than a hint which, as a word to the wise, may direct attention to what will be found a delightful branch of horticulture. Some people, too, may like to grow plants which not everybody else possesses. The Black Tea (*Thea Bohea*), is a handsome shrub with evergreen leaves, producing small white flowers in September. Green Tea (*T. viridis*), resembles it, but is of taller stature, and has narrower leaves. It should be mentioned that the Chinese Tea-plant is vulgarly confounded with *Lycium europæum* and *L. barbarum*; the latter the Duke of Argyll's Tea-tree, a coarse, hardy, unprepossessing, trailing shrub, which has the merit of making hedges and arbours in the sandiest and most sterile soils. There are also persons who boast of growing their own Coffee in the open ground in Flanders; but they only do so through a like misnomer. Their vaunted Coffee plant is a Lupine, whose seeds, roasted and ground, furnish the pretended Mocha. Whether the beverage so obtained is better or worse than that from Hunt's once-famous roasted Wheat, I cannot say, for I have not tried it and don't intend to do so. I do however, propose trying to cultivate in my study, as you would a Myrtle—another most desirable pot-plant—the Camphor Laurel (*Laurus Camphora*), all parts of which exhale their special odour, and which is included by nurserymen in their temperate-house catalogues. The Castor-oil plant (*Ricinus*), common enough in gardens as an annual, and suffered to perish in autumn, becomes a tree in warm localities where it never freezes. Grown in a large pot or tub and kindly treated, the *Ricinus* becomes a handsome object when two or three years old, deserving a place in summer on a lawn (with its pot plunged and hidden in the ground), as a semi-tropical specimen. The Australian Blue Gum (*Eucalyptus globulus*), of whose fever-absorbing powers so much has been said, and respecting whose possible hardness in Great Britain unfounded hopes have been held out, makes a handsome and striking pot-plant, notwithstanding that it rapidly grows out of all bounds, and will not conform itself to pruning or pinching operations. Its sea-green leaves, covered with a whitish bloom, give out when crushed a balsamic odour, which is a combination of Camphor, with the resinous scent of a Pine-grove. A liqueur resembling Chartreuse has recently been distilled from them in France. Seedling-plants are cheaply obtainable. For the first two or three years, with regular waterings, they make charming pot-plants. When they reach the ceiling and find they cannot get through it, they may be transferred for experiment to believers in acclimatisation, and their place supplied by fresh-raised youngsters.

Fine-foliaged plants include the whole long list of Ferns. A few Palms in their young state may also be grown in sunny apartments, without causing any great disappointment; but although unquestionably things of beauty, they cannot continue to be joys for ever, because, if alive and well, they would eventually outgrow, however slowly, the space which can be accorded to them. The most recommendable household Palm is *Latania borbonica*, with shining green leaves, from which the dust is easily wiped; *Raphis flabelliformis*

makes a formidable rival to it, on account of the greater lightness of its foliage; *Chamærops sinensis* and *humilis* are more sombre in their hues. *Corypha australis*, with *Phoenix reclinata* and *sylvestris*, furnish a sufficient variety of this set of vegetable forms. But the catalogues of the leading nurserymen, British and foreign, contain more information than is possible even to glance at here. Nevertheless, I make bold to say that, valuable as they are in other respects, they are not always absolutely sure and certain guides as to temperature and atmospheric humidity, and, in consequence, as to probable adaptability to household culture. Nothing but an actual trial of plants can determine exactly what they will stand in living rooms. One would expect that all plants assigned to "cool-house, greenhouse, *serre froide*, *serre tempérée*," might live and flourish in ordinary apartments under suitable conditions of light, &c. But no; many charming things, so classed, pine in rooms after a more potent stimulus to their vitality. I have had *Blechnum brasiliense*, and not a few other foreign Ferns, lingering for a couple of years in a continuously ineffectual struggle for existence, before I could resolve to consign them to the cemetery of plants, *i.e.* the manure heap, there to be converted into sustenance for a fresh generation of favourites. 'Twas disappointment long drawn out. And yet an excellent catalogue, by a first-rate horticulturist, makes *Blechnum brasiliense* a *serre froide* tenant. I can only say that all *serre froide* tenants are not, with me, suitable for living rooms; which does not prevent others from trying their luck or their skill with the like. When once you know your own mind, and have agreed with yourself what you like best, now is a good time to buy plants in pots, both for immediate service and to come in for winter use. I make no mention of annuals or of things that are good only for the season, and that a short one. Any one can purchase a pot *Mignonette*, *Omphalodes linifolia*, *Maritime Stock*, and such like, and throw it away when faded and done with. That is not horticulture, either household or open air; although buying the seeds of annuals, and flowering them yourself indoors, is a proof of considerable cultural ability. The lady who can show a pot of well-grown Ten-week Stock, or that dear little Everlasting *Rhodanthe Manglesii*, is no mean house-gardener. A great point is to select, for spring and summer show, plants that will give as little trouble as may be to get through the winter. Splendid while they last are many of the Cactuses, especially *C. speciosus* and *C. speciosissimus*, and the numerous hybrids obtained from them. Certainly they are ugly enough when off show. Cactus or *Cereus flagelliformis*, the old Whip Cactus, is characteristic when perched aloft on a sunny bracket, and allowed to droop naturally; which is better than training it into fans or on vase-shaped wires, however readily it may lend itself to the plan. The Night-blooming *Cereus*, *C. grandiflorus* (of which six or eight varieties exists), requires more heat and space than living rooms can conveniently afford. A generation or two ago it used to be an excuse for jovial suppers in amateur succulent houses, to witness the expansion of its large handsome flowers. The guests who sang and practised "We won't go home till morning" might also witness their fading too. *C. peruvianus* has a variety, monstrous, which grows into the shape of a dark-green bit of Japanese rockwork, and the older it is—thirty, forty, fifty years—the more strange and eccentric its aspect becomes. For a long time nobody knew what it was, until, flowering in 1814 in the Montpellier Botanic Garden, it betrayed to M. de Candolle the secret of its identity with the Taper of Fern. It is a curiosity of the easiest culture, which you may stick out of the way when you are tired of its sight and bring back again when you wish for another look at it, observing, however, that it must neither freeze nor rot with too much watering. It is the very thing to set in the sunny front of an old-style druggist's shop, for it is sure to impress the multitude with the belief that it is the source of some potent and priceless specific elixir. All the Cactus family submit more or less to this free and easy mode of treatment; a smaller species, *C. or Mammillaria Ottonis*, shaped like a plump, deep-ribbed pin cushion, gives as little trouble as the preceding, and annually produces a crop of brilliant-yellow crimson-centred flowers. Most of these, even when out of flower, are useful to stop a gap in a window when other occupants are on leave of absence.

A most handy, pleasing, showy, and easily managed family of plants for summer display are the tuberous-rooted Begonias, both typical species and hybrids from them. Their foliage is bright and fresh; their flowers, produced in long succession, continue to appear from the first day of blooming until the date of their winter rest (which the majority of this section strictly observe), while a few go on flowering through the very dearest season of the year. Their colours are white, yellow, red and vivid scarlet, comprising intermediate hues of buff, orange, and pink; sometimes with delicate shadings and contrasts in the petals of the same flower. But their great recommendation to household horticulturists is, that the varieties which hibernate do so frankly and completely. Even young cuttings raised during the season follow in this the example of their parents. These

latter may be purchased late in bloom, showing their qualifications and what they can do. About November they will flag, and their stems will spontaneously part from the root, as if they were dying. It is no such thing; they are only going to sleep. Then is a good time to repot them (in light rich soil, half leaf-mould or spent Cucumber-bed and half fresh loam) in larger pots, if required. The plants increase in beauty with age and with the increasing size and strength of the tubers. You thus get specimen plants with just pretensions to exhibition. The quality and freshness of the soil are mentioned on account of their importance, although in large cities it is often easier to procure new plants than good earth to repot old ones in. If no other source be available, it must be obtained as a favour from some benevolent nurseryman. When repotted, let them take their repose in any snug corner or shelf where it does not freeze. Light or darkness is all one to them then. Keep them dry rather than moist, but not absolutely dry as dust. Too damp, they may rot; while excessive dryness will retard their starting in spring. The judicious amateur will hit upon the happy mean; which reminds me of the late M. Van Houtte's recommending for *Genethyllis tulipifera* (a greenhouse shrub, with Box-like foliage, bearing large cream-coloured flowers striped with red) plenty of air and "intelligent waterings." There indeed he hit the mark, and gave to the world a golden rule. By "intelligent" measures great things may be done in the plant way as in other matters. In March or April take your potted tubers out of their retirement; give them plenty of sunshine and moderate moisture. If they make numerous shoots, you may remove the superabundant ones when 3 in. or 4 in. long, detaching them at their junction with the tuber, and plant them in small pots separately. They will strike root, forming tubers of their own, like *Dahlia* shoots (as will cuttings taken from the main stems during summer), flower the same season, die down in autumn, and so take their rest. There is no need to repot them till the following spring after they have started, leaving their old balls of earth unbroken while shifting them into a larger pot. The tuberous *Begonias* now are legion, and before long will be scores of legions. The good old *B. discolor* deserves a place for the sake of "auld lang syne;" besides, it is hardy in the open border in ordinary winters; and besides that, its large red-veined leaves are very effective seen from within doors, especially under sunshine, a point not to be lost sight of by window gardeners. It is this property of semi-transparent colouration which gives great value to sundry plants with inconspicuous flowers, such as *Achyranthes Verschaffelti*, the dark-leaved varieties of *Ricinus*, and others. It is from a red vegetation like these that the planet Mars, astronomers tell us, derives his fiery hue. Don't patronise *Coleuses*, in spite of their beauty, unless you have a hothouse in which to winter them. Free bloomers, not new, but inexpensive, are *Begonias Weltoniensis* and *Chelsoni*, hybrida, and *B. bolivensis*, a striking species, the parent of many varieties present and to come. Great things were expected of *B. octopetala*; but I have not yet been able to get it to flower, perhaps for want of sufficient heat to start it earlier in the spring.

To M. Lemoine, of Nancy, has been awarded a first-class certificate for his new double-flowered, tuberous-rooted *Begonia Gloire de Nancy*, of a brilliant vermilion red. We shall see whether doubleness in *Begonia* blooms, which is fast coming on, be an improvement or not. Every flower is not the better for that change. To my mind the single *Snowdrop* is more graceful than the double; the same with many *Fuchsias*; while double *Petunias* are often mere wisps of coloured rags and scraps. *B. balsaminiflora*, a double-flowered *Begonia* with light-green foliage and a compact and low habit of growth, is well worth attention. The blooms, of a pleasing shade of light red, are produced in the proportion of one double-flowered male between a couple of female blooms, which latter are invariably single.

Carpet-bedding being all the fashion, I don't see why chamber gardeners should be deprived of that mode of charming the eye. Consequently I am trying my hand at a portable carpet-bed, a sort of toy garden, made principally with cuttings, which really promises to exhibit the prettiness of a dish of *salmagundi*. I take a round earthen pan, like those used for raising seedlings, but with upright sides, 4 in. deep. The only pattern this admits is concentric circles; in a large circular vessel a star might be worked. My outer circle is composed of the small *Spiderweb Houseleek*; the second, of *Golden Variegated Lemon Thyme*; the next, of *White Variegated Thyme*, producing a ring of gray; then come sprigs of *Achyranthes*, with a plume of *Golden-Feather Pyrethrum* in the middle. There! You may set it on your dinner table. I have seen ornamented cakes and tarts considerably larger than this experimental piece of plant confectionery. One advantage which it possesses over beds in a parterre is, that if you don't like it you can throw it away. It ought to have contained a circle of white, but the *Centaureas* are too big. With a wider diameter I could have employed *Gnaphalium lanatum*.

Cultivators obtain great results by the application of bottom-heat in their frames and houses. During the fine season, plants in the open ground profit by the same healthy stimulus. On a summer's afternoon thrust your hand into the earth of a sunny border, and you will feel what sort of temperature it is which enables roots to perform their functions. Window plants are rarely allowed to enjoy the comfort of having their feet kept warm. Even in a south window, the pots, being considered unsightly, are usually placed out of view, below the line of the sash's woodwork, so that the sun's rays never fall upon them; or they are incased in pretty envelopes of card-paper, wood, or porcelain; or they are so crowded as to shade each other from the vivifying influence of sunshine, except for a brief moment. The plants suffer accordingly from a never-ceasing chill at the roots, especially if too freely watered. The obvious remedy is to raise the pots sufficiently to let the roots (the plant's purveyors) bask in the sun, as well as the foliage and the flowers. If the window-sill or shelf do not lend itself easily to this purpose, a simple mode of raising the pots, that need exposure to warmth is to set each pot on another empty pot of the same size inverted. This plan involves no fixtures, and allows changes of plants to be made as often as is wished. Carrying out the same principle, water always with tepid water, never with water colder than the air of the room in which the plants are growing. Earthworms are a great nuisance in a flower-pot in which a plant is well established; and it is easier to let them get in than to get them out. Often they are introduced with the soil when the plant is potted; search should therefore be made for them (as well as for even more destructive larvæ) during that process. But they are inquisitive as well as curious creatures, and if a pot be left standing on the open border, they will wriggle themselves in at the hole made for drainage, to try whether its contents are to their taste or not. To prevent this intrusion pot-plants set out-doors should be placed on a board, or on bricks, on a layer of dry cinders. Not only do worms disfigure the surface of a flower-pot, but they rob the plants. Like every other living creature, they must feed on some thing; and their diet is earth, which they afterwards reject impoverished of some of its nutritive elements. The better the worms are fed, the worse will the flowers fare. They may often be dislodged by a sudden fright. Perhaps in changing the place of a pot you may give it a slight blow quite unintentionally, and a bright-red tenant, of whose presence you were unaware, will emerge in all haste to escape from fancied danger. Present him immediately as a treat to your gold fish. By tapping the pot or disturbing the earth with a stick the worm will sometimes show his nose above ground. Seize him, and pull him out firmly but gradually; for if he breaks the remaining half will form a new head, and become a perfect worm. If he succeed in drawing himself back unhurt, you will not easily play him the same trick again. Suddenly dosing a pot with quite warm water, but not hot enough to injure the roots, will sometimes make a worm shift his quarters for fear of being scalded the next time of watering. The aphid or fly "our little green brother who lives on the Rose," if a single one be permitted to live, soon multiplies into an annoyance. Fumigating the plants infested, as they stand in your window, is useless except in affording a lady a pretext for permitting, perhaps asking, a gentleman to puff his cigar in her presence. Green fly can be effectually smoked off only in a well-closed greenhouse, or, for want of that, in a large chest in which the plants may be shut up with a little smouldering Tobacco. Branches badly attacked may be smeared, and thereby cleared, with a brush soaked in a strong infusion of Tobacco; but it discolours for a while the shoots to which it is applied, and, moreover, stains fair fingers. Slighter visitations of the insects may be kept down by continually brushing them off with a small clean painter's brush kept for the purpose. Take care, however, that each aphid dislodged has no further chance of rising in the world, and that "when he falls, he falls like Lucifer, never to rise again." For, feeble as he looks, he has sufficient claws and energy to justify the naturalist who referred him to the Hookey-Walker genus. Brown or turtle scale is a still more displeasing insect-pest, to which Orange-trees, Camellias, and even evergreen Ferns are liable, often caught in and brought from infested greenhouses. Therefore when buying such plants, look sharp to see that they are clean. If you discover that your Orange or Lemon-tree is thus disfigured, paint all its leaves and stems with a mixture of soft soap and Tobacco-juice; wash it off next day with a sponge and tepid water, and watch closely, for some time afterwards, that none of the culprits have escaped to leave behind them lineal descendants. What a heap of trouble! Certainly; but in household horticulture the trouble constitutes part of the pleasure. Gardening operations may have a beginning, but they have no end. A good and hearty cultivator can never say, "I have done now; everything is finished off for the present; there is nothing more to bother me for to-day, to-morrow, or the day after; I can run away for a week or go to sleep for a fortnight." Cultivated plants are insatiable.

Not a few houses (more perhaps in provincial towns than in London) have a back yard, at the bottom of which is some sort of outbuilding—scullery or wash-house—to which the family often go to and fro. By promoting this appendage to the rank of a back or second kitchen and connecting it with the house by a lean-to covered passage with glazed roof and front, in the first place the real kitchen is relieved by an annexe which the mistress can visit and inspect without catching cold; and secondly, the glass corridor will render good service as a greenhouse. The warmth from the house and the back kitchen will keep out ordinary frosts. In summer you may make it as gay as you please with the whole list of conservatory flowers to choose from, and it need not be anything like bare in winter. I have seen excellent Grapes grown in such a passage, whose utility is obvious while its beauty is acknowledged at very first sight. The longer and broader it can be made, the more effective it becomes. —“London Society.”

Sculpture and Rock-gardens.—The accompanying beautiful engraving shows the groups of sculpture embowered in the fine piece

Sculpture and Rock-gardens

of rock-gardening at Versailles, in the Bosquet des Bains d'Apollon. It is not for its statuary we are interested in it, but for the rich garlands of vegetation over its rocks. Sculpture has even in gardens a very few noble uses, but few will admire these costly groups—at least as part of any garden scheme; but Ivy and Polypody, trailing shrubs, rock and hardy flowers, that fringe the grottoes for the groups, cover many sins. The rock surface is large and picturesque and well backed by trees. On the whole, it is the most interesting scene in the large gardens of Versailles, and simply because of the living wreaths above alluded to.

Floral "Marriage Bells."—At American weddings the bride and bridegroom during the ceremony often stand beneath a bell formed of exquisite flowers. The idea is so pretty that a contemporary recommends it to those who may be busy decorating a church or a house on the occasion of a marriage. No expense or trouble is spared, the choicest blooms being used; and these bells cost sometimes as much as £20. In Denmark, for instance, charming oval wreaths are formed of the long fronds of the Filix-mas Fern, the points meeting at the top, while the stalks are hidden at the base by flowers of vivid colour, contrasting well with the green leaves which seem to spring from them.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Fuchsias.—Where glass accommodation is limited, a little space may be gained by clearing out Fuchsias which have done flowering. In the case of such as are required for future use, the soil should be allowed to get almost dry, and they should be cut back freely, when they may be stowed away under a greenhouse stage, or in any place where they will receive a little light; under such circumstances it is better to keep the soil through the winter half dry, the effect of which will be that the buds will move slightly, but not so as to make much growth, which latter should not be encouraged while they are in a half dark situation; but the advantage gained in not drying them up so as to force them into a totally dormant state, is that when required to be started towards the spring they will move much quicker than when quite dried off. When they have to be wintered in cellars, or any place that is totally dark, the soil must be allowed to get so dry as to cause complete cessation of growth; even if these old plants be not wanted longer for pot culture, it is well to keep them and treat them in the way now recommended, as in the spring, after

danger from frost is over, they may be planted out in beds or borders, where they will make a fine display through the summer. The apparently insatiable craving after something fresh in bedding plants has caused Fuchsias to be all but dispensed with; whereas, with the least possible attention, even in indifferent situations, they form the most graceful and continuous blooming subjects that can be grown for summer decoration. Where young plants of them were struck in the summer, as at the time recommended, these are much to be preferred to old ones; but to have them in flower early in spring, this can only be done where means exist for keeping them at a temperature something near 50° at night through the winter. Where they can receive this they must now be placed close to the light, and if the small pots in which they were put when first struck, are full of roots they should be moved to others, an inch or two larger, placing a neat stick to the main stem of each, and if they do not show a disposition to branch freely the points ought to be pinched out in order to induce them to do so.

Chrysanthemums.—Those who have still retained some of the early autumn varieties of Chrysanthemums, a class of plants that unfortunately of late years have been discarded, will, in a season like this,

when the later kinds are so unusually late, see the advantage of growing some of them. Where on a south wall there are any means of protecting the late ones with a few loose lights overhead and canvas or mats hung in front during the night time, but taken down during the day, so as to give them the advantage of a full admission of air, they will be much better until the flowers are beginning to open, than if crowded in a plant house. If the buds have not yet been sufficiently thinned, more should at once be removed. Where there is an empty Vinery, in which the leaves are off the Vines, it will prove a suitable place for Chrysanthemums, placing them sufficiently far apart and elevating them on empty inverted pots, so as to get their heads near the glass. Thus situated, they can receive a full complement of air during the day, and also at night, when there is no appearance of frost. They may remain here until they have done flowering, or when in bloom they can be moved to a conservatory or greenhouse.

Solanums.—Where berry-bearing Solanums were planted out and lifted and potted as recommended some weeks back, if they be yet in frames, they must not be set too close together, as when overcrowded, the leaves are almost sure to get injured and fall off, which gives the plants an unsightly appearance; and it will be found much better to discard some than to attempt growing more than there is convenience for. Solanums require a good supply of water; much more, indeed, than most plants cultivated in pots. If they be kept in good healthy condition, they produce a very good effect in the greenhouse intermixed with a front row of dwarf-flowered Chrysanthemums; or a few of their berry-clad branches mixed with Chrysanthemum flowers, and the bright shining leaves of Berberis aquifolium, form lasting materials with which to fill vases.

Cyclamens.—Those who have got a pit or house that can be kept at a temperature of 48° or 50° through the night during the winter season, and have followed the hints given from time to time on the cultivation of these plants, will now have them coming into flower from seed sown fourteen or fifteen months ago; a portion of the earliest may be moved to a greenhouse, where they can occupy a good light position, without which they become drawn, and the flower-stems elongated and weak, with a disposition, in those that are just springing up from the crown, to damp off. Cyclamens that were sown about the end of August, or the beginning of September, must not be allowed to remain in the seed-pans until they are so crowded as to cause the plants to draw up weakly, they should be pricked out 1½ in. apart in pots or pans well drained, and filled with good turfy loam, broken for these young plants small, to which add a fifth or six of leaf-mould and some sand; keep them as near the glass through the winter as means will allow. Cyclamens are subject to green fly, and by those who have not had much experience in gardening it often escapes detection, as it almost invariably confines itself to the under sides of the leaves, a position in which it is difficult to kill by fumigation; I have found dipping in Tobacco water the most effectual remedy.

Lilies.—*Lilium eximium* that has been kept cool through the spring and flowered late often retains its tops in a green state all through the summer, precluding the possibility of potting, without serious injury, until the present time. The different varieties of *L. speciosum*, late-flowering plants of auratum and others that have been late in dying down, should now be potted before the young roots have commenced to move, which they do soon after the tops have died down. It is not only necessary to repot in good time when there is division or separation of the bulbs, consequent upon their being too many in a pot, but also when merely larger pots are needed, and nothing further is wanted than removing as much of the old soil as can be got away without injury; this should be done without any hesitation or fear of doing harm by disturbing the old roots, as these, when once the season of growth is completed, never make further progress, but gradually die away, giving place to new fibres which are emitted by the bulbs. These latter, if moving, are extremely sensitive, and should by no means have the old soil they have already penetrated removed from them. In the case of large masses of bulbs that have become overcrowded where no young roots have begun to move, it is best to take them out of the soil altogether, putting three, four, or half-a-dozen together according to their kinds, and the size of the pots used, remembering that in all cases the more room they have the stronger they will bloom. Place the bulbs tolerably deep down in the pots, always pressing the soil pretty firm; good, turfy loam, moderately enriched with rotten manure, is best for them; to it must, however be added enough sand to maintain sufficient porosity for the water to penetrate freely, as when in full growth they will require a very large supply; on the other hand, the potting material must not be made too light and open, as the roots like a tolerably close soil; be careful not to use the material in potting in too moist a state, as it would become an

adhesive mass, into which the roots could not penetrate freely. After potting, keep the soil through the winter rather dry than moist; if they could be set on an earthen floor, or any absorbent material, the moisture communicated from it through the pots would prevent the necessity for giving much water; such conditions as these are sometimes available under a plant-stage; but, if placed in a position of this kind, care must be taken that the water supplied to the plants on the stage above does not drip on the Lilies, or they will be seriously injured. Wherever wintered, they should not be kept warmer than the temperature of an ordinary greenhouse, for, although such kinds as *L. auratum* and *L. eximium* may be had in flower during spring by subjecting them to heat, still the bulbs are much weakened by it.

Flower Garden.—All bedding plants should be now cleared away where any flowering subjects are to be put in the beds, as these may be expected to bloom much better when they are placed in their winter quarters some weeks before the bad weather sets in; if, as advised in the spring, at the time this description of stock was moved to the reserve garden, all that then required division were so treated, they will have made plenty of healthy roots; the comparatively moist season will have favoured them in this respect, and they can be taken up with little injury; the larger the ball, and the less interference with the roots, the better they may be expected to do. Even if the plants are individually larger than requisite, it is not well to divide them at this time, as the season is too far advanced for them to recover the check they would thus receive. As to the description of plants used, it is simply a matter of choice; the tallest growers should, of course, occupy the centres of the beds, as also the most central beds if the flower garden consists of any geometrical design. Nothing is more appropriate or more effective than the different colours of spring-blooming Violas, Red and White Daisies, Aubrietias, and Arabis; in addition to these, any compact-growing, free-blooming plants that flower sufficiently early, so as to make a display for some time previous to the summer occupants being placed in the beds may be used. With such things as the above, bulbs of any description, such as Erythroniums, Tulips, Hyacinths, Crocuses, and Narcissi may be intermixed, giving variety and succession, as well as often producing a more pleasing effect than massing the bulbs alone.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

November 5.—Earthing up French Beans in pots with loam and manure. Grubbing out old Apple trees, and preparing holes for young ones. Getting ice-house cleared out ready for refilling the first opportunity. Getting frames and lights cleared and washed ready for painting before bad weather sets in. Clearing off flower borders and forking up the ground for fresh flowers. Clearing up leaves, &c., in pleasure gro

Nov. 6.—Potting on a batch of Dracænas and Crotons for table decoration. Looking over Calceolaria cuttings and removing any that are damping off, taking off the lights whilst the weather is fine. Hoeing among growing vegetable crops. Taking up and stacking away Salsify and Scorzoneria in a cool shed in dry soil. Pears in use for dessert:—Frederic de Wurtemberg, Gansel's Bergamot, and Marie Louise. Looking over Grapes in bottles, cutting out decayed berries, and filling up the bottles where required.

Nov. 7.—Putting early potted Hyacinths into gentle bottom-heat to get them forward. Moving large trees from nursery into pleasure grounds, and planting them in prepared holes. Nailing up Ivy and Roses on walls where blown down by wind. Pruning and nailing Morello Cherries on north walls. Turning over Mushroom manure to sweeten.

Nov. 8.—Sowing Mustard and Cress; also French Beans in pots. Planting out Daisies, Silenes, Myosotis, and Wallflowers. Looking over all Cauliflowers, and turning down leaves where required, to protect them, and removing the forwardest into the shed. Covering up Endive and tying up Lettices to blanch. Turning over leaves and long manure for making hotbeds.

Nov. 9.—Looking over fruit-room and clearing away fruits that have begun to rot; also looking over seed Potatoes and removing any that are diseased: Washing plants and paint. Roping Onions, and making labels and pegs.

Nov. 10.—Getting tender plants from pits into Vineries, and placing Strawberries in pots into cold pits. Clearing the leaves off the pleasure ground walks, and rolling the gravel down firmly. Weeding Box edging, and cleaning kitchen garden walks. Nailing Fig trees on walls closely, and covering them over with thatched hurdles, to protect them from severe frost. Watering the Pines all through and tying up any that may require it. Fruit in use for dessert:—Pines, Grapes, Pears, Apples, and Nuts.

ON SEX IN FLOWERS.*

By THOMAS MEEHAN.

It will be remembered by those who took part in our Salem meeting, that I there introduced some novel suggestions in regard to the laws of sex in flowers. I then said "that where the reproductive forces are in operation, it is the highest types of vitality only that take on the female form." As the proposition was opposed to current belief I was not surprised that it did not at once receive general assent. Indeed, I myself regarded it as but a provisional hypothesis and said, "I do not urge this view for adoption; my object is to excite investigation by other observers." After the succeeding year I found that not only were my views strengthened by others, but that two distinguished observers, Dr. Spruce, the South American traveller, and Dr. Moore, of Glasnevin, had some just claims to sharing the credit of the discovery with me. At our Troy meeting I endeavoured to advance a step further, and show that it was varying powers of nutrition that probably determined sex. Eight years have now elapsed, and I have met with nothing of my own to lead me to distrust my earlier impressions, and with only one objection in print. Allow me, therefore, to present this proposition to my fellow-students in science as a truth—that the production of a female flower requires a greater expenditure of force than does a male flower. The objections I referred to relate to Indian Corn or Maize, in which male and female flowers often change places, and very often it is in quite weak stalks that grain is found in the tassel; hence, says the objector, vigour has no relation to the female sex. But the vigour intended in the objection—gross vegetable growth—is not the vigour that I mean. I have been always careful to explain that the vital power I mean is the power which shows the greatest hold on life, and this power is often exhibited to a greater degree in a branch of moderate growth than one possessed of great luxuriance. In two branches on a tree exposed to the same severe conditions, we may find one die and the other live. The one which endures has, I apprehend, a higher vital power; and this is the sort of vigour I claim for the female sex. Life is but food transformed, and that which has the greatest power of assimilation will have the highest vital power. In the earliest development of the nucleus it may be either male or female. If it has higher powers of assimilation it finally becomes a female; if lower, a male. Now we shall see that these aberrant cases of Indian Corn really support this view. But I must first remind you that the tassel and ear—the male and female parts of the flower—though so apparently different, are formed on the same plan. If you draw the branches of the tassel upwards closely, you will see that if they were to dorsally unite, and gain succulence, there would be an approach to an ear. But greater vital power was drawn to the ear. It alone had the power to concentrate, consolidate, and build. The male has less vital power; it dies long before the female; its work is sooner done; it has not, in fact, the same vital power. Now, when we find a tassel producing a large amount of grain, we see no (or very little) attempt to form ears on the side of the stalk. The stream of nutrition, usually so great in the female direction, has been turned into the channel usually male, and grain, instead of male flowers, with a considerable union of parts, results. Here are specimens illustrative of this point: in one the male has become so nearly consolidated that only a few barren tips of branchlets remain of its original plan. I consider these Indian Corn examples conclusive as regards my views respecting the origin of the female sex.

Professor Edward D. Cope said the paper just read by Mr. Meehan was one of great value to geologists and botanists alike. He regretted, however, that Mr. Meehan had not gone more into details. He admitted that with the specimens of Indian Corn, as exhibited, a very strong case had been made out, but he was not sure that the facts were not espable of a different explanation. He thought that a difference ought to be made between growth force and reproductive force, as the laws operating in one case were often distinct from those operating in the other.

Mr. Meehan remarked that he had condensed his paper as much as possible in order not to take up time unnecessarily. He recognised the difference suggested by Professor Cope; indeed, he thought the insisting on this distinction was an important part of his own efforts. He thought the paper itself, though, perhaps, too brief for a reading, would be its own witness should it find its way to print, that Professor Cope's objection had been anticipated therein.

BEST TIME FOR FELLING TIMBER.

In alluding to the complaints that are made now-a-days as to the quality of wood employed for building and similar purposes, the "Breslau Landwirth" remarks that the causes of its inferiority are sufficiently simple, though, unfortunately, but little understood. Most of its faults, such as its tendency to decay and dry-rot, are wholly due to the timber having been felled at improper seasons, and to its subsequent injudicious treatment. To fell trees in March, April, and even in May, as is now often done, is absolute folly. Timber intended for builders, or for the use of coopers and wheelwrights, should never be cut except in December or January, when the circulation of the sap is arrested. November, even, is too early, and February too late to insure its durability. Its subsequent treatment, too, greatly influences the quality of the wood. The tree should be freed from all branches and shoots immediately it is cut

down, and sawn into planks as soon as possible, so that these may at once be seasoned by exposure to the air. In this way alone can we obtain wood that will keep well, and every purchaser of timber should insist upon its being prepared in accordance with these directions.—[These remarks are undoubtedly correct in principle, but it would be utterly impossible to cut all the timber that is necessary on a large wooded estate in two or even four months in the year. It would, however, be conferring a boon and a saving to consumers of timber if the producers would make a rule to cut as much timber as possible during the winter months, or say from the end of October to the end of February. It is an indisputable fact that all kinds of timber are more durable, and also less liable to decay and dry-rot, when cut while the sap is comparatively at rest than when cut while it is in active circulation, i.e., when the trees are in leaf. The subsequent management of timber, too, after it is cut, by preventing it from being exposed to extreme moisture and dryness before it is thoroughly seasoned, is scarcely of less importance than the proper season at which to cut it. As a rule, the producer of timber has little or no interest in it after it passes into the hands of the timber merchant, and the latter has perhaps still less regard for durability, so long as he can effect sales with profit; indeed, the less durable timber is, the greater the demand, and, of course, the result is in favour of the timber merchant. It is, therefore, hardly likely that he will trouble himself to inquire whether the timber is cut in winter or summer. The consumer, being the sufferer and most interested party, should buy, so far as is practicable, timber only that has been cut in winter and seasoned. This is the only remedial check that can be suggested to a great evil in woodcraft.—GEORGE BERRY, Longleat.]

ACREAGE OF ORCHARDS, MARKET GARDENS, &c.

ACCORDING to a Blue Book return, just published, the following is the acreage under orchards, market gardens, nursery grounds, and woods in each county in England, Scotland, and Wales, in 1877:—

COUNTIES.	ORCHARDS, &c. Acreage of arable or Grass lands, but also used for fruit trees of any kind.	MARKET GARDENS. Land used by market gardens for vegetables and other garden produce.	NURSERY GROUNDS. Land used by nurserymen for growing trees, shrubs, &c.	WOODS. Coppices or plantations, excepting Gorse, land and garden shrubberies.

VEGETARIAN SOCIETY'S ANNUAL MEETING.

THIS was held at Manchester on the 24th ult.; there was a large attendance both of members and associates, and when it is mentioned that a considerable proportion of these came from remote parts of the United Kingdom, it may be inferred that no slight interest is taken in the Society's proceedings. The report, which was read by the Rev. C. H. Collins, M.A., was of the most satisfactory character, showing that the area of the Society's operations continues to enlarge itself and its supporters to increase. As regards the latter fact, it may be mentioned that whereas the subscriptions received from contributors in 1870-71 amounted to 125 only, the number for the year 1876-77 was 1458. The income, too, of the Society from all sources indicated the same remarkable development, for whereas in the former year it amounted to £62 8s. 4d., the figures for the latter year are £612 5s. The report is much too long to attempt even a summary here, but the following pertinent observations on the subject of the food supply will have an interest for our readers:—"The food supply has assumed great political significance, and the more extensive growth of fruit continues to be especially called for by considerations of national economy and advantage. It is hoped that the decay of orchards, which has been a painful feature of some counties, may now be arrested, and that the reported increase of area under fruit culture may continue. The present crisis brings into prominence some remarkable facts. That a large part of land admitting of cultivation is still devoted to the production of Barley, Hops, &c., which are afterwards destroyed by conversion into intoxicating drinks, is a fact which has frequently been brought under public attention. That other large portions of our land remain still uncultivated

is a matter of equal notoriety. That a further and very considerable area remains under pasture, yielding a minimum of food to the nation's want, employing a minimum of labour, and affording but slight return to the proprietor or cultivator is another fact which, thanks to Mr. Mechi, the world has been often told, and needs to be told again and again. More than ever, therefore, has it become timely to plead, along with the horticultural press, for the wide extension of the industry of fruit culture, from the point of view alike of the artisan, the labourer, the economist, the politician, and the moralist." The report brings into special prominence the exertions, during the year, of the Rev. C. H. Collins, Mr. Joseph Wilson, and Mr. W. Gibson Ward, and forcibly urges all members of the Society to emulate the intelligent and well-directed efforts of these gentlemen in securing a wider hearing for its benevolent principles. The afternoon meeting, as usual, gave rise to a good deal of discussion upon important features of the movement. The necessity of providing in every large town a vegetarian restaurant was pressed upon the Executive; but as this resolves itself into a question of finance, and is surrounded with elements of difficulty, the subject, for the present, must rest rather in the hands of local societies than with the central management. One enthusiastic adherent to the Society's principles demurred to the restaurant idea, contending that an Apple stall and a baker's shop should suffice any ordinary vegetarian for a decent dinner. The same speaker went so far as to deprecate the idea of "gross feeding" in vegetarianism, and hinted that he had heard that the Society's banquets were not altogether free from the accusation. It was obvious, however, that this gentleman was speaking without the card, and, as was subsequently pointed out to him, with some force, the vegetarian movement is a practical reform, aiming at a change in the dietetic habits of the people, and is not comprised in the questions of upon how much, or upon how little, a vegetarian can make a dinner. The importance of vegetarianism as a therapeutic agent was referred to, and a suggestion thrown out to the Executive to collate and publish in pamphlet form the various extraordinary cases of cure from vegetable diet to be found in the works of Dr. Lambe Graham and in the pages of the "Vegetable Messenger." Mr. Gibson Ward detailed a case of extraordinary recovery from epilepsy under his own immediate care, the patient being placed by Mr. Ward upon a Celery diet. Information was given by several delegates of what was doing to promote vegetarian practice in various parts of the kingdom, notably at Leicester and Liverpool. After tea, the usual public meeting was held, at which the chairman, Mr. W. Gibson Ward, in an able speech, dwelt upon the extreme grossness and impurity of the diet that formerly obtained in England, and quoted from a very old bill of fare of the Corporation of the City of London showing that the porpoise was then eaten as a delicacy. The conclusion to which these remarks tended was that leprosy and the plague with which the people of this country were afflicted, were the natural outcome of such gross and unnatural feeding. Among the speakers who addressed the meeting were Professor F. W. Newman, Rev. C. H. Collins, Rev. — Molesworth, Rev. W. Clark, and Messrs. Foxcroft, Kingsley, and Skinner. Amongst the Resolutions submitted to the meeting, the following more particularly concerns THE GARDEN:—"That this Meeting invites the attention of all earnest politicians and patriots, and of all holders and occupiers of land, to the importance of the cultivation of fruit as an auxiliary food supply, and urges the planting of suitable fruit trees in all gardens, hedgerows, and waste lands as a profitable, productive, and healthful industry; and in these times of scarcity of food, diseases among cattle, and great national distress, would especially commend to landed proprietors and public corporations—on the grounds of both utility and beauty—the planting of fruit trees along railways, roadways, riverways, and canalways, and in hedgerows wherever practicable."

Kew, Syon, and Chatsworth Conservatories.—In speaking of these conservatories in THE GARDEN of Sept. 15 (p. 246), their relative sizes are given as follows:—Kew 24,000, Syon 7785, and Chatsworth 15,276 square ft., whereas Chatsworth contains 1,131,596 square ft., and I cannot help thinking that the conservatories at both Kew and Syon are larger than your correspondent has stated. Chatsworth conservatory is 276 ft. by 123 ft., and the height is 67 ft.; the span of the transept is 70 ft. There are two rows of metal columns 23 ft. high, from which the span springs. The cubic contents of the transept are 457,729 ft.; the central part, inside the columns, 376,320 ft.; bottom roof to the columns, 317,547 ft. = 1,131,596 ft. There are 70,000 square ft. of glass in the roof. It is heated by hot-water pipes in combination with flues. The hot-water pipes, 5½ in. bore, if placed in a continuous line, would extend six miles. I am of opinion that a judicious combination of flues and hot-water pipes is the most economical mode of heating, as I have long been convinced that more heat is utilized by this than by any other mode of warming; for, use what boiler you will, the heat leaves the boiler at as high a temperature as the water in the boiler at the time of its exit, and by passing it into a flue round the house you utilize instead of wasting it up the chimney. This is all clear gain, and will more than compensate for the extra outlay in making the flues, &c. That this is a most economical way of heating will be admitted when I say that we have only here two 12 ft. saddle boilers, one 8 ft., and an old 6 ft. tubular boiler that has been in use twenty

years, and this is only used in very severe weather. But with the first three named we can usually command a temperature of from 48° to 50° at night, and without the flues we should doubtless require much more boiler power than we have.—THOMAS SPEED, *Chatsworth*.

Flowering of *Chamærops Fortunei* at Alderley.—This species, indigenous in Japan, is the most hardy of all the Palms. I find that several have flowered in the open air in the neighbourhood of London without any protection; but for it to flower so far north as Manchester is probably very uncommon, though I hear it has done so at York. The plant in question has stood out-of-doors about twenty-five years, and has never been covered up in winter. It is about 6 ft. high, and has always seemed very healthy; but this summer, for the first time, it threw out a racemose male flower. The position is well sheltered from east and north winds; indeed, the garden generally is extremely well protected. The species of *Chamærops* have a special interest from having been found fossil in the Miocene of Europe, and even in very high Asiatic latitudes. Besides *C. Fortunei*, both *C. excelsa* and *humilis* are common in England in cultivation. *C. excelsa* is only half hardy, and requires protection in winter; *C. humilis* is a South European species, but flourishes out-of-doors at Osborne, though it requires protection in the shape of matting in cold weather. All the kinds of *Chamærops* grow in temperatures comparatively low when compared with that required by other Palms. According to Hooker, *Chamærops martiana* grows at 8000 ft. in the West Himalayas, where they are annually covered with snow.—“Proceedings of the Manchester Philosophical Society.”

Plant Cures for Hydrophobia.—A Fellow of the Royal College of Physicians writes, in reference to this subject, as follows:—“Some of the correspondence on hydrophobia is so likely to excite vain hopes in the public mind that it becomes a duty to call attention to the following facts. The *Datura Stramonium*, a plant belonging to the Natural Order *Atropaceæ*, is familiar to every member of the medical profession in this country; indeed it is included in our national pharmacopœia. Its properties are due to the presence of an alkaloid, *dataria*, and have been thoroughly investigated. They resemble those of the Deadly Nightshade (*Atropa Belladonna*) in kind, though not in degree. Far from exciting profuse perspiration, *dataria* would rather tend to check it. Even if it were a sudorific, this would not, as some appear to imagine, increase the likelihood of its curing hydrophobia. The truth is, and it cannot be too generally recognised, that all the resources of the ‘*Materia Medica*’ have long since been tried, and tried in vain, against this terrible disease. There is no evidence worth a jot to prove that a single case has ever been cured, either in man or in one of the lower animals. A new remedy starts into notice every year; it sinks into discredit even before another is ready to take its place. The last of these claimants is the *Xanthium spinosum*, a plant which grows abundantly in Southern Russia, where hydrophobia is common. It was introduced to the notice of Prof. Gubler, of Paris, by Dr. Grzymala, of Podolia, and excited some attention from the mass of evidence adduced on its behalf. But careful experiments (made, I believe, at the Veterinary School of Alfort) soon dismissed it to the limbo where its predecessors lie forgotten.”

Magnolia Campbelli in Ireland.—We forget how long it is since this *Magnolia*, a mere stripling, was planted out at Lakelands, Co. Cork, but little more, we should think, than six or seven years. So rapid has been its growth, that when we saw it this autumn it was quite a tree, and, in its noble leafage and aspect, one of the most imposing we have ever met with. Merely regarded as a deciduous tree of fine proportions and faultless symmetry, and in its summer clothing decked with foliage exceptionally large and fine, the Lakelands specimen speaks forcibly of its value. But what, if in addition to this beauty of form and leafage, we take into account that in spring, before the leaves appear, it is the wont of *Magnolia Campbelli* to have its every branchlet decked with glorious cupped flowers, measuring from 6 in. to 10 in. across, varying in colour from white to deep rose or crimson, and exhaling an agreeable fragrance! The Lakelands specimen has not yet flowered, but it will not be very long now, we apprehend, till it will afford the first opportunity of recording its flowering in these islands. We have heard doubts expressed, and read of them, too, from time to time, as to this *Magnolia* being sufficiently hardy for our climate, and this may in some measure account for it being yet so rare in our grounds. Is there any valid ground for the supposition? We rather think not, taking into account that its home is among the outer ranges of the Sikkim Himalayas, where it is found, according to Sir Joseph Hooker, in abundance as a great forest tree at an elevation of from 8000 to 10,000 ft., and further, that more than twenty years ago Sir Joseph did not hesitate to express his undoubted conviction that it would “prove

hardy in England.” Our own experience of its behaviour out-of-doors in this country goes a good way to show he was right in forming that opinion. With regard to soil and situation, it must be remembered that, unlike some of its American congeners, its home is the mountain side, not the oozy river bank or lagoon islet. We throw out the hint merely to suggest the probability of a somewhat open and elevated situation, and a lively soil, rich withal in vegetable matter, being more favourable to its wood ripening and early flowering than if planted in low and closely sheltered quarters, with a peaty or heavy soil to grow in. Those who have facilities for doing so would do well to put this matter to the test by planting one or more in these different situations. The Lakelands specimen is admittedly growing in a rather close and sheltered spot in companionship with an almost equally large example of *Idesia polycarpa*.—“Irish Farmers’ Gazette.”

Preserving Fence Posts.—There are paints, washes, and heterogeneous steeps recommended for preserving posts, but each are comparatively costly, and only partially successful. One great objection to the application of solutions externally rests on the fact that the sap, being confined, accelerates decomposition in the interior. Most foresters must have observed this. What I would recommend with fencing posts is that the materials, when felled be directly sawn into posts and stored under sheds thoroughly ventilated, where they will remain at least a year exposed to sun and wind. The neck, or part between wind and water, of each post should be slowly charred over a strong fire—slowly, because our principle means heating the timber thoroughly to the heart, so as to extract any moisture which may be still lodged at the centre, and hardening a crust on the surface of the posts. Afterwards, to prevent the posts absorbing water, they should be well coated with coal tar, having its acid destroyed with fresh quicklime. The tar should be thoroughly boiled to evaporate all watery matter, and applied boiling hot. A large tank holding the posts set on end, and filled with the scalding tar from a boiler, answers the purpose very well. Of course the upper half of the posts can be painted when placed *in situ*. I am convinced that coal tar, properly applied to thoroughly seasoned timber, is far more effectual in preserving posts than creosoting or kyanising.—“Journal of Forestry.”

NOTES AND QUESTIONS—VARIOUS.

Coloured Vine Leaves.—These ought to be made serviceable for decorative purposes, such as harvest festivals, or for churches. Amongst them are lemon-yellows, orange, claret, and deep red with veins of orange, all of which produce a gorgeous effect.—J. PEAR, *Norwood*.

Propagating the Virginian Creeper.—What is the best method of propagating the Virginian Creeper? I have tried cuttings of the variety called *Ampelopsis Veitchi*, and have not been successful.—M. H. [*Ampelopsis Veitchi* (or *cuspidata*) is easily increased by cuttings or layer; the cuttings may be put in at this season.]

***Enonymus japonica* in London.**—This, together with its various varieties, is probably the most useful evergreen yet brought to our gardens. To sea breezes or London smoke it seems to have, of all plants, the least repugnance. A collection of the variegated forms of it, planted alternately against one of the low walls in Mr. Wimssett’s nursery, in the Kings Road, is now very attractive. The foliage looks as bright and fresh as that of evergreens in country gardens. All the varieties make admirable wall plants.

Substitute for Farm-yard Manure.—I have a garden into which it is very difficult to get farm-yard manure. Could artificial manure be used instead for the growth of vegetables, small fruits, and Grapes? and, if so, which sort and how much should I use, and when should I apply it?—K.

Pelargonium Pioneer.—We find this to be a capital variety for late autumn blooming—in fact the best in a collection of some scores of varieties. Small plants of it in 6 in. pots are now each producing from eight to twelve large trusses of beautiful magenta-scarlet flowers. The plants were struck last autumn, and potted into their blooming pots in June. During the summer they were grown in a cold pit, the light only being put over them to throw off excessive rains. They were put in a warm light greenhouse three weeks ago; for making a front row to a bank of *Chrysanthemums* they answer admirably.—H. J. C., *Grimston*.

Tawdry Splendour.—An unfortunate gentleman in the north-western district, not content with one or two of the mirror-globes of the French gardens, has made himself an avenue of them of various colours. Each huge globe reposes in a vase, and the avenue, from the gate to the house, is bordered on each side by a line of the mirrors. The effect is as good as could be desired for a Shoreditch theatre.

Mr. Legg, late gardener at Clapham Park, has, it is said, been appointed to take charge of the Duke of Lenster’s garden at Carton. If good gardening justifies such an appointment, nobody who knows Mr. Legg’s work will doubt his fitness for this, one of the most important of Irish Gardens.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE REDWOOD IN ENGLAND.

MR. SYME states, in his interesting notice of this tree (see p. 295), "that it has not done very well in this country except in a few favoured localities in which shelter from cutting winds is afforded." This is true, no doubt, to a certain extent, especially in the northern counties of England and Scotland, but it can hardly be applied to the southern and western counties of England; neither can it apply to Ireland, for there this tree grows most luxuriantly; the humid climate there, and the deep soil, full of vegetable matter, are just what it delights in, and I think it is the place of all others to plant it exclusively with a view to produce timber, and where colossal butts of it may be anticipated in the future. My opinion of this tree is that it will prove to be the fastest producer of timber amongst all the Conifers, the *Sequoia gigantea* not excepted. The latter will probably grow to a greater height, as it is not so liable to lose its leading shoots by rough winds as the *S. sempervirens* is; but it is not likely to make so bulky a butt of timber, as its stem tapers more rapidly. I base my opinion on observation of several specimens growing in the south of England. Let me now mention a few of the largest specimens of *Sequoia sempervirens* with which I am acquainted, in order to show what rapid growth this tree has made since it was brought to this country in 1843, for such was the date of its importation, though it was probably not generally introduced into commerce until 1845 or 1846. At Bowood there is a specimen remarkable for its large girth of stem; it measures in circumference, at 5 ft. above the ground, 8 ft. 7 in., and contains, probably, about 80 ft. of timber. At Hatfield I measured a beautiful specimen recently; it girthed 8 ft. 6 in. at 5 ft. up the stem, and its height is fully 60 ft. At Strathfieldsaye, Mr. Bell informs me that the largest tree there is 62 ft. high, and girths, at 5 ft. in height, 6 ft. 1 in. At Mells Park, Somerset, there is a good specimen 54 ft. high, clear of branches for about one-third its height; the stem carries its girth well up to near the top, the girth of which, at 5 ft. up, is 5 ft. 10 in. The best tree which we have at Longleat is growing in a deep black vegetable soil on the Oxford clay; it has not quite so large a girth of stem as the two largest mentioned above, but it is one of the highest and best specimens in this country. The situation in which it is growing is sheltered on the side of the prevailing winds. I may mention that the site occupied by this tree is a portion of the pleasure-ground; in 1845, it formed part of an Oak coppice, from which the trees and underwood were grubbed out in the winters of 1846 and 1847. This tree, with several others, amongst which was the *Dacrydium* (see p. 405), was planted in this newly-grubbed ground during the following winter of 1848 or the spring of 1849; it is now 62 ft. high; it measured 63 ft. high last year, but, unfortunately, during last winter its leader was broken off by a gale of wind; the girth of its stem at 5 ft. up is just 8 ft., having increased 1 ft. in circumference of stem since it was measured last winter; the cubic contents of timber in the butt, exclusive of bark, are 73 ft. There are several other specimens of Redwood here in perfect health and growing vigorously; some are planted in thin, poor, green-sand soils in a plantation, but they are doing so well that they are keeping pace with the Larch of the same age and time of planting. There is no doubt that this tree succeeds best and grows most rapidly in deep, moist soils, and when protected from rough winds, like all other fast-growing Conifers; but, at the same time, I maintain that in the south and west of England and Ireland it will thrive in almost any situation; on the other hand, I have seen it in the North Riding of Yorkshire present a miserable appearance, so battered and disfigured by storms that one could scarcely recognise it; so much does difference of locality affect trees. The heart-wood of the *Sequoia sem-*

pervirens will, I think, prove valuable for furniture-making and for other constructive industries, where a richly-coloured, fine-grained wood is essential; it is also susceptible of high polish. I have in my possession a piece of the stem of this tree, about 6 in. in diameter; the heart-wood is of a reddish colour, close and fine-grained, while the sapwood is white, soft, and probably not durable, and of little value.

Longleat.

GEORGE BERRY.

Commemoration Trees.—At a recent party at Eridge, some of the guests (we learn from the papers) planted commemoration trees. "On Tuesday, the company assembled in the north Pinetum, to plant commemoration trees. The Premier planted a *Picea nobilis*, from California, and the Lord Chancellor planted a *Picea Lowi*, also a fine specimen of the Silver Fir. Mr. Hardy's tree was the Japan Spruce. Sir W. H. Dyke planted a magnificent Douglas Fir, a tree which attains over 300 ft. in height." If they had planted a group of the best varieties of the British Oaks, or even a group of Hawthorns, these trees would be very much more likely to be commemorative. It does not show much real knowledge of trees, and the conditions under which they each attain perfection, to plant avenues of the Californian ones in country seats in all sorts of positions; but as commemorative trees, many fashionable Conifers are still more unfitted.

The Weeping Hemlock Spruce.—The "American Agriculturist" publishes a figure of this, which we imagine does not do justice to the plant. The most beautiful of American evergreens, the Hemlock, has produced several interesting forms. The Small-leaved Hemlock (*Abies canadensis microphylla*) has very small foliage, while the Large-leaved kind (called *macrophylla*) runs to the opposite extreme. There are one or two very dwarf forms, but the most beautiful of all is the Weeping Hemlock (*Abies canadensis pendula*). This variety has its branches positively pendulous, even the leading shoot bending over upon itself. This has been grafted upon tall stocks; but, so treated, it is not satisfactory, the trees being far inferior in beauty to those in which the branches start from the base. This form was discovered, if we mistake not, near Fishkill-on-the-Hudson, by Mr. Sargent, and is now in the hands of Messrs. Parsons & Sons, at whose nursery, at Flushing, we saw some fine specimens.

Tree-felling by Electricity.—The patentees of this process are Mr. H. Hope Parkinson and Mr. W. H. Martin, both of Bombay. The plan is simple enough. The two ends of the copper wires of a galvanic battery are connected with platinum wire, which, of course, instantly becomes red hot, and while in that state, it is gently sawed across the trunk of the tree to be felled. The plan was tried the other day by way of experiment, but it turned out that the thickness of the thickest wire that could be got was that of a crochet-cotton. It was, therefore, at once seen that a wire of such thinness would be consumed before the tree was half severed from its trunk. However, the attempt was made. The burning wire performed its task very well so long as it lasted, but, as was anticipated, it continually broke, and at length there was no wire left. There can be little doubt that with a stronger battery—the one used was only a twelve-chambered one—and a thicker wire, the experiment would have been entirely successful. As it was, the tree was sawn one-fifth through. It is calculated that under proper conditions a tree, which at present takes two hours to fell, will come to the ground by this process in fifteen minutes. It is almost needless to add that there is no waste of wood, no sawdust. The process is one worth the attention of all persons engaged on forest clearing.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Hardy Smilaxes.—Little attention seems to be paid to the hardy species of Smilax. Several species, however, thrive freely on good warm soils with us, and are quite distinct in habit from anything else we have. They are also handsome, and most suitable for walls, hanks, or for trailing over a low stump. We saw an effective group of them in the Cambridge Botanic Garden a few days ago.

Fir Trees in a Northern Aspect.—So much does a cold situation influence the growth of the Fir, that trees grown on the northern side of a hill are superior to those grown on the southern side.—"Family Herald." [Just so; trees on a northern aspect grow less rapidly than those on the sunny side of a hill. The timber on the former would be, as a rule, more durable than that grown on the latter, and the trees would not be so liable to injury from frosts; indeed, many diseases are induced, perhaps aggravated, by the sap being checked during early spring, on a south or south-eastern aspect.—G. B.]

THE WESTERN ALLSPICE

(CALYCANTHUS OCCIDENTALIS).

THIS is rather tender for the open border in the neighbourhood of London, but it makes a fine plant for training against a south wall, where it flowers freely during the summer and autumn. It forms a robust deciduous shrub, 5 ft. high, with large, broadly-ovate leaves, pointed and rounded at the base, downy on the midribs on the under sides, smooth on the upper surfaces, entire on the edges, and on rather long foot-stalks. The flowers, which are somewhat large, are terminal, solitary, or clustered on stout foot-stalks, and of a deep lurid purple, the calyx and petals being of the same colour, and nearly scentless. The wood and leaves have the same aromatic scent as the

Calycanthus occidentalis.

other species of Allspice. It is a native of the Sacramento Mountains in California, and was first introduced by Hartweg, who gave it the name of *C. macrophylla*.
GEORGE GORDON.

TREES IN GRAVEYARDS.

A MATTER of some interest to horticulturists recently came up for discussion by the Southampton Town Council upon the complaint of a lady that the roots of a certain tree had penetrated into, and were greatly damaging, the brickwork of the vault in the cemetery containing the body of her husband, some twenty years deceased, and she applied that the tree should be removed. As the tree in question was a very ornamental Weeping Birch, some 30 ft. in height, the Council declined to agree to this suggestion. A dispute of this kind naturally opens up the somewhat important question of the planting of trees in graveyards to be recommended, seeing that, however ornamental they may appear at first, or may ultimately become, it is just possible that if due care be not exercised such complaints as that mentioned above may be of frequent occurrence. In this case it was contended that if a site for a vault or grave be selected so near to a growing tree as that in question, the result that now followed must, at some time or other, be inevitably looked for; but it was afterwards shown that the tree was not planted until after the vault had been made, and therefore the lady had a fair cause for complaint. That trees should be found in graveyards who can doubt, but that they should consist of giant forest trees—Elms, Oaks, Beech, Scotch and Spruce Firs, Larch, &c.—no one will maintain. Ornamental trees, or such as are strictly in keeping with the surroundings, might well be planted, and not too sparingly, in a newly-enclosed space that was previously devoid of trees, because the nakedness thus displayed renders the graveyard repugnant to the relatives of those buried there; but it should be a matter of careful ad-

justment in the planting, that as the trees develop a gradual thinning should take place, a gloomy grove of overgrowth being as bad on the one hand as comparative nakedness on the other. To many there is a strong attraction towards the vicinity of a tree as a burial-place, and if it be intended to be a humble grave, that may remain again unopened for a long term of years, a tree can hardly prove objectionable. It is, however, possible that in digging such a grave some main root of the tree may have to be severed and considerable harm done to it, or if that does not follow, the severing of the roots will but produce, when the excavated soil is replaced in the grave, a perfect mass of small rootlets, and these will take possession of the disturbed soil, rendering it specially difficult to re-excavate at any other time. The lady in question, however, had an additional complaint to make, viz., that the sap exuded from the leaves of the overhanging tree was washed down upon the stonework below, and so much discoloured it as to make it the reverse of ornamental; thus it is seen that evils which can only be cured by the elastic remedy of cutting down some beautiful tree will follow upon the placing of vaults and graves in too close proximity to trees; and perchance the relatives, who have been at considerable expense in the raising of memorials over their dead, will come to wish that they had not courted the vicinity of trees at a time when it was not too late to alter the position. In some not well-governed graveyards it is the practice to allow relatives to plant memorial trees at the head and foot of graves, and as these, though small when planted, inevitably grow into size, the graveyard eventually assumes a nondescript appearance, as there is neither plan, taste, or arrangement to be seen. Flowers in abundance may well be invited, but the planting of trees by such persons should be strictly prohibited. Flowering plants, Ivies, hardy Creepers of various kinds, the beautiful varieties of Clematis especially, might well be used to cover graves, instead of the grass that is ever untidy, or the expensive stone that soon discolours and decays.

A. D.

Anti-malarial Properties of Eucalyptus.—On this subject Prof. Bentley says that "the evidence that has been adduced from Australia, the native country of the Eucalyptus, and from all parts of the world where it has been introduced, and which are favourable to its growth, in testimony of its anti-malarial properties, is so strong, that, allowing for exaggeration in some cases, it can scarcely be doubted that this tree does produce a most beneficial effect by destroying the fever-producing miasm of marshy districts; and that it should consequently be introduced into all countries and districts where the climatic influences are favourable for its development, and where such miasmatic emanations are to be found." Special interest (says "Nature") attaches to the introduction of the Blue Gum Tree into Italy for this purpose, and it is confidently hoped that by its means the problem may at length be solved of destroying the noxious malaria which has in recent times rendered the level country round Rome so unhealthy in the summer season. The mode in which the trees act in influencing the climate is open to controversy. The popular idea is that the efficient cause is the odorous and antiseptic emanations from the leaves. It is quite likely that some influence is exerted in this way, but it seems most probable that the chief effect produced is by the action of the roots on the soil. This function of trees is often greatly overlooked. The effect of the planting of forests in decreasing the rainfall is frequently erroneously stated to be due to the attractive force of the trees on the moisture in the air, similar to that exerted by a range of mountains; but it is difficult to conceive that the small mass of the entire foliage of a forest can exert any appreciable influence in this direction. The mode in which trees mainly act is by their roots arresting the rainfall, which would otherwise escape by the natural drainage of the country; the combined forces of capillarity, osmose, and transpiration then cause the ascent through the tissues of the tree of the water thus arrested, and the larger portion is eventually given off into the air through the stomata of the leaves. In this way a forest tree will, in a very short time, give off into the air its own weight in water, which must eventually condense, and be again deposited as rain or dew. It is quite possible, however, that the effect of the planting of trees may be apparently the reverse of this in swampy countries, where there is no natural drainage.

Bedding Out.—Mr. Punch offers a humble suggestion to the authorities who are about to beautify the Bayswater side of Hyde Park. If beds of flowers are to be made up, will the bed-makers be good enough to allow them to look somewhat like old-fashioned parterres, whereas those on the Park Lane side resemble nothing so much as lobster salads and open tarts. "Hear, Nature, hear our prayer! Dear goddess, hear."

AN ENEMY TO FRUIT TREES.

(YPONOMEUTA COGNATELLA.)

ONE of the causes, although by no means the only or the chief one, which have contributed to make the fruit crop this season so scarce and dear, has been the attacks of the small moth, *Yponomeuta cognatella*, which is figured in the accompanying woodcut. All Londoners are familiar with the work of its ally, *Yponomeuta padella*, the larvæ of which envelop the young shoots of the Hawthorn hedges in spring with its unsightly webs. The larvæ of *Y. cognatella* does not force its webs quite so obtrusively upon our attention, which is partly due to its preferring the Apple and similar food plants, which are not so universally grown as the Hawthorn, and partly, of course, to the much greater multitude of the Hawthorn grown as hedges than the single plants of any kindred species. The reader may not see miles of hedges denuded by the larvæ of

*Yponomeuta cognatella.*

Y. cognatella, and blackened by its *débris*, as he must often do in the neighbourhood of London by *Y. padella*; but he will see plenty of single plants of fruit trees every spring terribly injured by this species. For many years past it has been a severe scourge in the neighbourhood of London and in many other parts, and has, no doubt, contributed very materially to the loss sustained by the market gardener during the present year. The moth slightly resembles *Yponomeuta padella*, but its upper wings are entirely of a pure white, without the least bit of a lead colour; they also are marked with about twenty-five small black dots. It is hatched at the same time, and the caterpillar has the same habits; it lives upon the Apple tree, and sometimes upon the Hawthorn and Service tree, never upon other trees. When it is quite young, in the beginning of May, the larva is of a yellowish-white, with little raised blackish spots; the head and the flat part of the first segment are of a blackish-brown. When it is full grown, at the end of June, it is of a velvety-grey, with two dorsal rows of quadrangular spots of a deep black. The head, the flat part of the first segment, and

the scaly feet are of a dull black. After this caterpillar has established itself on the orchards or rows of fruit trees it gives them the appearance of having the leaves burnt, and the branches enveloped in a net-work of white silk, resembling at a distance innumerable spiders' webs, by which the whole tree seems to be invaded, and all hope of a crop annihilated.

ANDREW MURRAY.

Propagating Harrison's Musk (*Mimulus moschatus* Harrison).—Those who wish to get a good stock of this Musk, and have only a few plants, should adopt the following method, which I have practised with success, namely:—Take all the points of the shoots off the old plants at the third or fourth joint; these should be cut again at the second joint, put into 3-in. pots, and plunged in bottom-heat. That portion which is cut off the cutting should be treated as follows:—Remove each leaf with a "heel," and dibble them into a compost of leaf-mould and sand, when they will readily strike root. I had two plants by post about six weeks ago, and I have now struck three dozen and a half by the method I have just indicated; not one has failed.—T. W. S.

Plants Fed or Injured.—Cultivators have probably much yet to learn with respect to the safe and profitable application of particular manures to particular crops. Every carefully-conducted experiment tends to show that it would be almost as absurd to attempt to feed all animals on the same food as to attempt to nourish all plants on the same manure. It is often said that "What is food for one is poison for another," and the same may be said with equal truth respecting the vegetable world. The fact has never yet received the attention which its importance merits. Dr. Gustav Mark has lately been showing this in a way that may be commended to the notice of all concerned in the subject, more particularly as the plant experimented upon is one universally known, and all but universally cultivated. He set apart a plot of the common Kidney Bean and left it unmanured, and he selected other plots for treatment with kainit, nitrate of soda, bone dust, superphosphate, gypsum, guano, and farmyard refuse respectively. Of those various foods, he says that bone dust proved most nutritious, the crops supplied with it having been by far the heaviest. Next in value to bone dust was superphosphate. But the most important fact announced by Dr. Mark is that some of the manures tried not only failed to produce any increase of crops, but proved positively mischievous. Thus for many crops guano, one of the richest and most valuable forms of manure, proved worse than nothing, and the same was the case with farmyard manure, another material which few persons would hesitate to apply indiscriminately to any crop they wished to improve. The yield of Beans under the influence of both guano and farm refuse, as well as that of guano with bone dust, kainit with nitrate of soda, and kainit with gypsum, proved worse than the plot left entirely unmanured. Of course no one will find anything new in this; but there are many who are seriously interested in the subject to whom authoritative experiments of this kind cannot but prove useful.—"Globe."

Over-Decoration.—The external decoration of buildings has been overdone since the Gothic revival; as much carved foliage, for instance, is often found on a modern hotel as would have sufficed for half-a-dozen Mediæval cathedrals. It is the natural tendency of revivals to go to excess in the use of things good in themselves, and this kind of excess in decoration, which in external architecture people are beginning to recognise as a mistake, and as involving a certain degree of bad taste, seems to be now extending itself to interior decoration. It is not sufficiently borne in mind that one of the great sources of decorative effect is contrast; not only contrast of colour, but contrast between plain surfaces and decorated surfaces. At present there seems to be too great a tendency to make every available surface throughout a house an occasion for decoration of a more or less elaborate description; to let nothing alone. There is a sense of a profusion about a house thus treated which is rich in effect, no doubt, but which also becomes a little cloying to the eye and the mind. We find in a dwelling thus treated designs on the window-glass, and over all the walls and ceilings of every room; the doors have conventional vegetation in bright colours over-running the panels; decorative carpets are on the floors, of many hues; decorative china is placed in every available place; and each piece of furniture constitutes a separate study in decoration. The result is not infrequently to produce a spotty effect and a want of repose which is at variance with the best taste in decoration.—"Builder."

Michaelmas Daisies.—Among the many kinds of these ornamental autumn-flowering Asters, few are more graceful in habit than *A. pendulus* and *A. ericoides*. Isolated in light open places, these two kinds are now very attractive. The flowers are, of course, much inferior to such kinds as *A. Amellus*, which is now in bloom, but this loss is amply substituted by the profusion in which they are produced, as well as their longevity.

NOTES OF THE WEEK.

Pomegranates.—Of these often mawkish fruits there are now some of good flavour in Covent Garden—the well-browned sound fruit—sometimes suggesting what the fruit may be when in perfection in the warm south.

Bomarea Carderi.—A large specimen of this comparatively new plant, in Mr. Bull's nursery, has been yielding a succession of flowers ever since July last, and now bears large trusses of pendent pink blossoms. For planting out in a cool house, to cover walls or rafters, this *Bomarea* will, therefore, be found valuable; and it also makes a good pot plant.—S.

Epiphyllums in Winter.—Few plants are more effective at this season than are the many varieties of *Epiphyllum*, all of which are plants which any one having a warm house can grow. Grafted standard high, or in the form of pyramids, they are equally interesting. Grafted on stocks about 6 in. high, they droop over the pots, and form excellent plants for vases for room decoration.

Lady Henniker Apple.—We have lately had an opportunity of seeing in Messrs. Ewing's well-cultivated and well-stored Nurseries at Norwich, good specimens of this cooking Apple, which merits all that has been said of it. It is a handsome and large fruit, with a fine acidulous flavour, and, numerous as are the varieties of kitchen Apples, deserves a place among the best.—H.

Two Well-flowered Orchids.—At the meeting of the Royal Horticultural Society, on Tuesday last, Sir Trevor Lawrence showed one of the best examples of *Oncidium crispum* which we have seen this season. The plant, which was growing in a wooden, upright basket, bore six flower-spikes, each furnished with no fewer than forty-six richly-coloured chocolate flowers. Associated with this was a *Vanda cœrulea*, from Mr. Smith, Henley-on-Thames, with two stems, each bearing three flower-spikes, the blossoms on which numbered in all eighty-nine, and these were very large, and of a rich, dazzling blue colour.—S.

A Useful Berry-bearing Plant.—Seldom do we see the orange-fruited *Physalis Alkekengi* well grown in our gardens, and yet it is one of the most ornamental of berry-bearing plants. It is used to some extent in one of the London parks as a shrubby edging, but in such positions the leafy bladder, in which the fruit is enclosed does not assume that rich orange colour which forms the chief merit of the plant. In sunny places, in good soil, the berries become very large and ripen perfectly, and if, when the leaves have died off, the stalks be hung up in any dry airy place, the bladder-enveloped berries will keep sound and form useful material for Christmas decorations. Grown in pots, this plant will also be useful for winter decoration. By some the seeds are supposed to be poisonous, but we are told that in Arabia, Germany, and Spain the fruits, which have a slightly acid taste, are eaten.

Market Garden Notes.—All winter greens and roots promise to be as abundant as Potatoes promise to be scarce. With such a wealth of winter greens, Turnips, Parsnips, and Carrots, it might reasonably be expected that Potatoes would not realise very high prices, but it is a fact that the consumer regards Potatoes as second only to bread, and will not be without them for the mid-day meal if it be possible to obtain them. Great as are the breadths of Potatoes grown, a thoroughly healthy crop would only suffice to satisfy the usual demand for this valuable esculent. When, therefore, a grower in a large way says of his crop that he is lifting daily more bad ones than good, it is evident that only a very high price can recoup him or keep the demand in anything like reasonable check. The white Turnip crop is most abundant, and the bulbs being of quick growth, are excellent in quality. Of course, the Turnip cannot in any way be put into competition with the Potato as an article of diet, but it is a delicious vegetable at all times, and specially so from the 1st of September to the end of the year. No greater mistake can be made than to grow Turnips to a large size. Small and sweet, large and coarse, is exactly the characteristic of the Turnip. As a rule, growers thin out too much, whilst if left thick the plant would bulb sooner, and instead of putting some half dozen big ones in a bunch, they could put twelve of medium size that would be far more delicious eating, and be ready for market at least a fortnight earlier. The first one or two pullings would give the remainder all the room they require, and this would save much labour and expense in hoeing and thinning. The summer rains and the abundance of moisture that has since prevailed have produced a luxuriant growth in winter greens, and growers begin to bewail their great abundance. Of Coleworts, one of the earliest of market greens, immense breadths have been put out, and they must be sold at some price or other. Small as the amount often is paid to the grower, it, however, becomes a high one ere it reaches the consumer, and so it will continue until the grower brings his produce more immediately before his best customers. A neighbour recently said, that having been foolish enough to decline 9d. per

bushel on the road to town for small cabbage heads he found when he got there that he could only get 4d. per bushel for them. Yet these would be retailed out at about 2s. per bushel, or even more. White and purple sprouting Broccoli, Brussels Sprouts, Savoys, and other Cabbages, Coleworts, and Scotch Kale form the staple winter green crops of our market fields; winter Spinach also forming a valuable and invariably a paying crop. All of these products, with Turnips, Parsnips, Carrots, and winter Onions now fill the gardens.—D.

Gazania splendens.—This is an excellent late autumn-blooming plant on warm sandy soil, blooming with great beauty long after hardy natives of more northern climes have succumbed to wet and frost.—V.

Begonia Starlight.—This is a very pretty and free-flowering white kind, now covered with white drooping blossoms. It was raised by Colonel Trevor Clarke. Many plants of it are now in flower at Chiswick.

Helleborus niger maximus.—This large-flowered variety of Christmas Rose now forms one of the most attractive of hardy plants. Its large, saucer-shaped, waxy blossoms are just now greatly appreciated in the London markets, and large importations of roots, well furnished with flower-buds, are being made by London nurserymen.—S.

Improved Pelargoniums.—At the Royal Horticultural Society's meeting on Tuesday last, Mr. Cannell showed stands of cat flowers of Zonal Pelargoniums of an unusually pleasing character. Whilst scarlets of the common type are being raised by hundreds, it is satisfactory to find flowers which in colour are of a decidedly distinct character.—C. S.

Double Colchicums.—This season has been anything but a favorable one for these lovely autumn flowering plants; but a few of them may, however, still be found in good condition. The best of them is the double-flowered variety of *C. autumnale*, the large pure white blossoms of which are doubly valuable on account of the resistance which they offer to rain, and their lasting longer in flower than other kinds. Mr. Parker, of Tooting has a bed of this, variety beautifully in bloom.—S.

Hardy Cyclamens.—These, where planted in proper positions, are now very beautiful. Under the shelter of trees in Mr. Barr's Nursery, plants belonging to the Ivy-leaved section of the genus growing amongst the Grass, and undisturbed for years, are full of bloom apparently secure from rains and frost. Many such places in gardens might be rendered beautiful in autumn by means of these and similar bulbous plants, provided they were planted in sufficient quantity to be effective.—S.

Chasselas de Fontainebleau Grape.—Mr. Barron, of Chiswick, who has perhaps had as numerous opportunities of judging Grapes as any one, says that when he wishes to eat a Grape himself he gets, if he can, the Chasselas de Fontainebleau. Fruit raisers, as a rule, compete too much with the sugar bowl, and many will agree in the preference for a fruit of a refined and delicate flavour over the common sugary ones. In the pursuit of merely rich flavour in fruits we fear many having better qualities still have been thrown away. Some day people will begin to ask the grower for delicately-flavoured wholesome fruit.

Hardy Plants at Tooting.—In Messrs. Rollissons' Nursery may be seen several interesting hardy plants not frequently met with. One is *Eryngium Serra*, a Yucca-like Sea Holly with broad, deep green fleshy leaves, and very ornamental when growing on raised positions. Another is *Neja gracilis*, a pretty little rock plant with dark green long hair-like foliage, and bright yellow Daisy-like blossoms, which are freely produced from autumn to spring. To these may be added several new and beautiful *Echeverias* and *Sempervivums*, all of which are likely to become popular.

Royal Botanical and Horticultural Society of Manchester.—The council of this society have purchased the large Azalea house at Manley Park, and it will shortly be erected in the Botanical Gardens and used as a show house. A large permanent iron framework is to be put up over the exhibition ground.

The Veitch Memorial Fund.—The trustees of this Fund have not, during the past year, offered any prizes at horticultural exhibitions, and the consequence is they have a considerable balance in their favour; they have therefore decided this year to offer ten prizes, consisting of a Veitch commemoration medal and £5 each, to be given at ten provincial exhibitions as follows:—Belfast—For twelve new Roses, cat blooms, sent out since 1873, inclusive. Brighton—One bridal and one ball bouquet. Olney—One dish of Peaches and one of Nectarines. Dublin—Three bunches of Muscat of Alexandria Grapes. Exeter—Collection of twelve vegetables, distinct. Hereford—Twelve new Roses, cat blooms, sent out since 1873, inclusive. Manchester—Specimen Orchid. Reading—Three stove or greenhouse plants. Woodbridge—Three stove or greenhouse plants. York—Three bunches of Black Hamburg Grapes.

THE INDOOR GARDEN.

NEW DOUBLE PRIMULAS AT BURGHLEY.

I HAVE just had an opportunity of seeing Mr. Gilbert's double seedling Primulas, and very beautiful they are. They are growing mostly in $4\frac{1}{2}$ in. and 6 in. pots—just the handy kind of decorative plants which everybody requires at this season for a drawing-room stand, or occasionally for the dinner-table. Many of these little plants are each carrying from four to six robust trusses of flowers, well thrown up above the foliage—and such flowers! Imagine one of the largest fimbriated strains of Primulas, with blossoms as double as a Carnation and not much inferior in size, and you will have some idea of those at Burghley; indeed, in the case of an individual flower, especially of the striped or blotched varieties, a double Carnation gives one a very fair idea of its size and substance. I do not wish to exaggerate. There is no doubt Mr. Gilbert grows Primulas well; he puts all the size and substance into them of which they are capable; but, with all due allowance for this, he has originated a strain of Primulas that must become popular when distributed. Some people may say they are difficult to propagate because they are more robust and a trifle less branching than the smaller-flowered kinds, but any one who can grow and propagate the old sorts will find no difficulty with these. This, however, is a matter that does not affect the quality of the flowers. There are half-a-dozen varieties of varying shades between a bright red and a pure white, to which Mr. Gilbert has affixed the following names:—Princess, Mrs. A. F. Barron, Marchioness of Exeter, White Lady, and Ne Plus Ultra. The largest of these—a bold striped flower, Mrs. A. F. Barron—measures 2 in. in diameter; the smallest—a delicate blush, called Princess— $1\frac{1}{2}$ in. Mr. Gilbert informs me that he has counted sixty-six fully-expanded blooms on one plant of White Lady, and it must be borne in mind, too, that these plants are yearlings, mostly in $4\frac{1}{2}$ in. pots. Some of them have been exhibited, and have obtained certificates from the Royal Horticultural Society.

E. HOBDAV.

Cissus porphyrophylla.—This is a free-growing stove climber with variegated leaves, which may be usefully employed for clothing a pillar, rafter, or wall. It succeeds well in a pot in either peat or loam, but, like most plants of a similar character, should have room proportionate to the space which it is intended to occupy, as, if

it has too much liberty at the roots, it will need cutting in more than is desirable; the soil, when exhausted, can easily be renewed in the spring before growth commences, as, in common with the other cultivated species, it sustains no injury from the roots being interfered with.—B.

A FEW SWEET-SCENTED STOVE AND GREENHOUSE PLANTS.

THESE are not very numerous, if we include those species only that are strictly greenhouse plants, but the list may be extended by the addition of a few outdoor subjects that force easily. Those named here are all highly fragrant.

Jasminum grandiflorum.—This is a delightfully scented variety of the Jasmine, not very unlike *Jasminum Sambac*, the popular stove variety, in the flower, but it is much easier to grow, and flowers far more profusely. It succeeds either as a climber or pot plant, and thrives in the greenhouse all the year round. Propagation is effected by cuttings in spring under a bell-glass, and in a little heat; but as the plants can be bought so cheaply at the nursery, and at this season coming freely into flower, let me recommend no one to propagate their own. Loam, peat, or well-rotted leaf mould, sand, and a little Standen's Manure make a good compost for it; and potting should be performed in spring, before the summer's growth is much advanced. Pot plants will require cutting back a little when straggly, after which their growth must not be interfered with, as the flowers are produced in trusses at the ends of the shoots, and continue to unfold in succession for some months. Climbers may be pruned also before starting into growth, and if they are allowed space to grow, and light, and are not hampered too much by tying and training, they will make a good quantity of fresh wood, and produce abundance of flowers. It is one of the best sweet-scented greenhouse plants—not much inferior, indeed, to the *Stephanotis*—and is little troubled with insects or disease.

Daphne indica odorata.

—There are few greater favourites than this. Its odour is just a little too powerful at times perhaps,

when the plant is kept in a room, but for the conservatory it is unsurpassed. In the south of England the *Daphne indica* grows and flowers well in the cool conservatory when placed in a favourable situation—at least, we have known large handsome bushes of it in such places, that flowered most freely; but in the north it is usual to give it a little heat during the summer while making its growth and forming its flower-buds, or until it is about coming into flower, when it is transferred to the conservatory where the flowers unfold slowly throughout the winter and spring, and last a long while. The back shelf of a Vinery or Fig house is an excellent situation for it during the summer—the shade and the heat just suiting it. *D. indica* is often grafted on a hardier stock, but it is doubtful if grafting

Cissus porphyrophylla.

be of much advantage to it. It strikes by cuttings also, but, like the Jasmine, it can be had cheaply from the nursery. It grows freely in loam, peat, and sand; but the pots must be well drained, and the plant should not be over-watered, particularly in the winter time—the half-succulent leaves and stems not requiring so much moisture for their support as those of some other greenhouse plants.

Luculia gratissima.—It is but seldom that this beautiful conservatory shrub is seen in perfection. It is both showy as a flowering plant and sweetly fragrant, and the sight of a plant in full bloom at midwinter, or during spring, never fails to arrest attention. It is hardly worth one's while attempting to grow it in a pot; but, planted in good loam, at the sunny, warm end of a conservatory, where the light is not excluded in the least, young plants soon grow up and form large bushes, and flower unfailingly. Large plants are hardly procurable, and are very expensive to buy. In the whole range of conservatory plants, there is no more worthy subject than the *Luculia*, and few that grow more vigorously or require less attention; but it must have a good place, and a minimum temperature of 45° in winter. A conservatory or greenhouse is warm enough to produce a good growth of wood on the plant; but it requires a mild midwinter temperature to bring it into bloom perfectly. When young, the plant need not be pruned in too closely, if it be desired to get up a good bush quickly; but afterwards the shoots are better pruned in after flowering almost as close as the Vine. New growths are produced freely, and the shoots attain a length of 2 ft. during the summer, and the flowers are produced at their extremities; consequently, no such thing as summer pinching must be practised. Copious waterings at the root and fumigating for green fly are the only attentions which it needs during the summer and winter.

The Orange.—In many gardens a plant or two of the Orange is grown for their fragrant flowers. The common Orange does as well as any, and produces plenty of flowers, if planted out or grown in a large pot in the greenhouse, and in a compost of good loam. The less pruning it receives the better.

To the above may be added, among others sweet-scented greenhouse subjects, exclusive of bulbs and Lilies, several sweet-scented Pelargoniums of the Oak-leaf class and the old *Citriodora* type, the *Diosma*, and the scented *Verbena* (*Aloysia citriodora*). Of the latter, it is always advisable to have several large bushes, and it does well planted out in the horders during the summer, and even stands the winter in some places. Among bulbs we would specially mention the Hyacinth and Narcissus, and of the latter *N. poeticus*, single and double, may be recommended for extensive culture, as they are cheap and easily grown. Of forcing shrubs, the common hardy *Azalea* rank first, for they are a host in themselves, and are both showy and delightfully scented. Considering how easily they can be forced, it is a wonder that they are not far more extensively used for conservatory decoration. The nurserymen are careful to anticipate the demand for forcing plants—that is, plants set with buds—every autumn; but the best way is to keep a stock of one's own by planting them extensively about the shrubberies, and lifting a certain number of plants every summer. In this way the stock is kept up with very few losses. The *Azalea* makes a multitude of small roots close to the stem, and consequently lifts easily, and if the plants are potted in leaf-mould and loam or peat, about November, and placed in an early Vinery or Peach-house as wanted, a display of flower may be had from Christmas till May. Among seedlings and named sorts there are various shades of colour—white, yellow, and red—and all are good growers.

Violets.—These force easily in the early autumn and throughout the winter and spring. The two most useful sorts are the Neapolitan and Czar. The former requires to be grown on in pots for the purpose, and is the most difficult to grow; but the latter may be lifted in clumps from October and onwards, and forced most successfully in a greenhouse or any half-cool structure. No doubt others of its class would do equally well. The flowers, when forced, generally open all at one time, and are comparatively soon over; so, to keep up a succession, it is better to lift the plants at different times, and introduce the batches according to the demand for flowers.

Stove Species.

We need only name a few of these. One of the least known, most deliciously fragrant, and showy is the *Pancratium fragrans*. The flowers, which are large, pure white, and delicate-looking, are thrown up on stout stems like an *Amaryllis*, to which it is allied, and they are quite as powerfully scented as the *Lilium auratum*, but more agreeably. It is an easily-grown plant, and the best way is to afford it moderate pot room, good strong sandy loam, a stove temperature, plenty of light, and not to shift it too often. It is better to top-dress it occasionally than to repot it annually; our plants never fail to flower freely under these conditions. It is one of the best stove plants which we possess.

Stephanotis floribunda.—It is not generally known, we believe, but it is a fact nevertheless, that there are two varieties of the *Stephanotis*, one which is a profuse flowerer, and the other not. We at one time possessed large plants of both, and grew them under the same conditions and, while one flowered profusely, the other scarcely flowered at all. Nurserymen profess to distinguish between the two varieties by their leaves, but we never could discern much difference in that respect. There is no doubt, however, of the superiority of the one over the other for flowering, and buyers should take care they get the right sort. The *Stephanotis* does well in pure loam and sand, and a little well rotted manure mixed, and likes a stove temperature, but will succeed nearly as well in an intermediate house.

Nymphaea odorata.—This is a beautiful and sweetly-scented aquatic. We have seen it grown most successfully in a shallow pan of good loam and manure placed in a large basin of water on the front shelf of a Pine stove, just above the hot-water pipes, but not in contact with them. The roots are partially dried off in the winter time, and kept in a proportionately warm temperature.

Gardenia radicans and florida.—These are the two best. The *Gardenia* is a plant that is not generally grown well, for the reason chiefly that it is very subject to mealy bug and scale, and needs continual watching. It also requires a high stove temperature and a moist atmosphere during its season of growth, for which reasons cultivators generally give it a house or pit to itself, where it can also be plunged in bottom-heat. When these conditions can be afforded, it is well worth growing. It succeeds best in a compost of peat, loam, and sand; it should be potted in spring, or after it has done flowering, and at the same time it may be pruned back a little at the top, if the branches are inclined to be straggly.

Jasminum Sambac.—This is not unlike the *J. grandiflorum* before spoken of, but is of a more trailing habit, and requires heat. It is best trained against the wall of a stove, or on a trellis near to the glass, and pinched as it grows, in order to encourage it to flower more freely. In spring, when growth commences from the previous year's wood, it flowers profusely. As to soil, &c., it requires the same treatment as the greenhouse one.—“Field.”

BOUVARDIAS AND HOW TO GROW THEM.

THESE beautiful plants have become great favourites within the last few years; but, like many other subjects, they have been sadly mismanaged in many instances, as the many weedy specimens one meets out of Covent Garden in private establishments would amply testify. *Bouvardia Vreelandi* and *Hogarthi* are the most popular varieties, the one being a pure delicate white, and the other a bright scarlet; they come into flower about this season, and continue to flower till after Christmas. The finest plants in every way that we have seen, this year and last, were grown out-of-doors, plunged in ashes before a low Beech hedge, and lifted and taken in in the autumn; and their beauty, especially of *Vreelandi*, at mid-winter, when they were green and fresh and flowering profusely, was greatly admired. Their leaves were as green and vigorous as a freely-grown *Deutzia gracilis*, and the flowers perfection. They far eclipsed anything I have ever seen grown in frames or in a greenhouse all the summer. They were grown thus:—The plants were propagated either in autumn or spring—I forget which—and pushed on in a gentle growing temperature till the warm weather set in, when they were removed to a cool frame; and, after being hardened off, were left exposed to the weather, and now they are green and bushy and abundantly set with flowers. A number of my own plants, treated in the same way, are just in the same condition at the present time. It is not necessary to propagate fresh plants every year, as the old plants, pruned in well and started, make the best specimens. It does not appear desirable, however, to prune the plants long before they start into growth—*Vreelandi* at least, as according to my experience the plants go off, just as Sage plants sometimes do that have been cut over-late in the season. Of two dozen plants which I bought last winter to add to my stock, and which were pruned when I came, the half died before March. They died back from the tops while standing in a comfortable temperature in the greenhouse; but those that survived did well after growth did commence, though they had died back to the surface of the pot, every one of them, *Hogarthi* suffering the least. For these reasons, I deem it unwise to prune before potting time comes round. The *Bouvardia* is easily propagated by cuttings of the young or half-ripened wood in spring, with the assistance of a little heat—like bedding plants, in fact; but it is better if they can be protected by a bell-glass, which must be tilted up slightly on one side to admit air. They must not be over potted, and they succeed well in loam and peat and sand well drained. 5-in. and 6 in. pots are a good size in which to grow compact, tidy, little specimens 1 ft. or

18 in. through. Though they prefer the greenhouse to the hothouse in the winter, still they must have an airy, dry temperature of from 45° or 50° to 55° in order to bring the flowers out in perfection.
J. S.

THE TURK'S CAP.

(MELOCACTUS COMMUNIS).

THIS is a plant which some have had much difficulty in growing, owing to its being generally imported in an aged state. Being a native of the West Indies, it likes more heat than other Cactuses. It may be grown from seeds, which are contained in quantity in the cap, but they must have a shelf in the stove during winter, and be kept

Melocactus communis.

growing. When they are imported in a large state, they should be placed in the full sun and kept dry; but after the flowering head is formed, they make no more growth. A great source of failure is allowing the cap to get wet, for, being so woolly, the water gets at the heart, and quickly rots it.
J. CROUCHER.

Tritonia aurea in November.—This, grown in pots for conservatory decoration, or plunged in the open air, is unsurpassed by any other plant at this season of the year. With us its masses of brilliant orange flowers are produced freely from October to the middle of this month in the open air, but it should be stated that it is a good deal sheltered from the south and west winds. It luxuriates in a compost of light turfy loam, with about a sixth part each of well-decayed cow manure and leaf-mould, to which should be added a good sprinkling of river-sand. Some recommend leaving it undisturbed for years, but with this I cannot agree, as I find that by repotting it annually in fresh compost, the flowers and flower-spikes are at least twice the size of those on plants left undisturbed. When it has done flowering, I remove the pots in which it is grown to some shed, secure from frost or damp. I give no water until the old flower stems come easily away from the bulbs, and by that time the young shoots for flowering the following autumn, will be making their appearance. The pots should then be removed to a greenhouse or

frame, where they will get plenty of light, and, as the shoots grow all to one side of the pots, leaving the other side without any at all, it is best to let them grow from 4 in. to 6 in. above the soil before they are shaken out of the old compost, when the shoots can be placed at equal distances apart in the pots. They should then be placed in a little heat, to encourage them to grow, for a couple of weeks, and afterwards removed to a cool house or frame until April, when they may be set in some sheltered place out-of-doors until the middle of May. After that, they should be fully exposed, and given copious supplies of water and liquid manure occasionally. Any one who once grows this plant well will never afterwards be without it.
—THOS. SPELMAN, *Derry Castle, Killaloe.*

Kew, Chatsworth, and Syon Conservatories.—After the startling statement in THE GARDEN of last week (see p. 435), any one might be excused for thinking that Mr. Speed's notions of square measure are very hazy. Why, if we take his figures, the splendid structure of which he has charge has a superficies of nearly 26 acres! Mr. Speed evidently confuses cubic with square measure. The comparative sizes of the three large houses, as given in THE GARDEN for Sept. 15, are, I find, identical with those given in a published report of the late Sir W. J. Hooker, and, in my opinion, there is little reason to doubt their correctness. According to Oliver's "Guide to the Royal Botanic Gardens and Pleasure Grounds, Kew," the dimensions of the great Palm stove are as follows:—Entire length of structure, 362 ft.; centre, 100 ft. wide and 66 ft. high; wings, 50 ft. broad and 30 ft. high; there are about 45,000 square ft. of glass in the building. At Chatsworth, Mr. Speed says there are 70,000 square ft., but that is easily explained, when we remember that at Kew the "ridge and furrow" system does not obtain, and that at Chatsworth it does, unless my memory greatly deceives me.—G.

Gesnera exoniensis from Leaves.—For the decoration of the stove or dinner table, this is one of the handsomest winter flowering plants with which I am acquainted. The flowers are deep orange scarlet, with golden throats, and they are produced close together in masses 6 in. or 8 in. through. The foliage is of a dark rich velvety texture, and covered over with minute red hairs. The tubers which are large are sparingly produced, but the plant is easily propagated by means of leaves in the same manner as Gloxinias, or ornamental leaved Begonias. If the leaves be put in any time before October they make fine tubers for flowering the following season. For flowering in midwinter the tubers should be started in a gentle bottom heat in April, and grown on in a strong moist heat until September. After that they should be kept somewhat drier and cooler for two months, keeping them well up to the light, but shaded from sunshine. Afterwards they may be introduced to the stove, giving them a good soaking with weak soot water twice a week, which will greatly improve the colour and size of the blooms, which will continue in good condition up to Christmas.—THOS. SPELMAN, *Derry Castle.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Torenia Fournieri.—Mr. Barron had the happy idea of putting this new plant alternately with the old *Torenia asiatica*—both being grown in baskets. The result is that *T. Fournieri* proves as good a plant as the old one, and with the addition of another colour—the strain of yellow. It is charming as a basket plant in a warm house.

Ivy-leaved Pelargonium L'Elegante.—This is grown largely at Connington Castle for winter decoration. Large etrong plants of it well supplied with water, and placed on a shelf in a strong light near the glass, will acquire a pink tinge that makes the foliage lovely for many forms of decoration by candle light. The leaves are suffused and edged in a most charming manner with pink.—E. H.

Saving Old Plants of Dracaena anstralis.—When the Dracaenas, now becoming common in our houses, become too tall for their quarters, and must be cut down, there is a way of saving the crest of the plant, by making an incision in the stem, and placing a pot with soil and Moss kept moist around it; after a time roots are emitted in the pot, and then the stem may be severed, and the base used for purposes of propagation or cut down. There is an interesting example of this mode of propagation in Mr. Wimssett's Nursery at Chelsea, where a very tall and fine *Dracaena* is being thus treated.

Beaucarnia longifolia Suspended.—Somewhat young plants of this look very well suspended in Mr. Williams's winter garden, at Holloway, the foliage streaming down for a length of 5 ft. or 6 ft. They are in pots, and would also succeed in baskets in a young estate. This plant may, therefore, be effectively used in all stages of its existence.

Ficus repens as a Curtain Plant.—Large numbers of plants of this are grown in Mr. Wimssett's nursery at Chelsea, to a length of 4 ft. or so from the pot. In small 5 in. pots, these are placed along the edges of the central beds and hang down to the ground, gracefully draping the walls. Being easily moved, they are also useful for forming similar curtains in rooms.

ROSES.

FORCING MARECHAL NIEL IN POTS.

In order to have *Maréchal Niel* Roses early, there is no better plan than that of growing a few plants for very early flowering in pots. The idea of experimenting with "stocks" on which to grow this Rose is now out of the question; it should be grown from cuttings on its own roots, and those who have raised pot Vines from eyes successfully cannot do better than follow the same principle in the case of this Rose, with very slight modification. There must, of course, be a beginning to every project, and, just as the pot Vines are started and grown with a view to fruiting at a certain time, so should canes of this Rose be worked in order to enable the grower to have flowers at the time best adapted for his particular purpose. To make certain of strong healthy canes, cuttings should be taken not later than the end of May or beginning of June, selecting for the purpose shoots of medium growth, as these are most likely to thrive under the course of treatment to which they must be subjected in order to attain the desired end; there is no time to be lost; in fact, after success depends on quick and healthy development of root and branch. If the cuttings be selected with care and inserted from three to six in a 5-in. or 6-in. pot, or singly in smaller pots, and placed in a smart bottom-heat, they will root readily and grow with amazing rapidity. A hotbed on the decline, as regards heat, I consider to be the safest and best place in which to propagate; there is a sweetness and a growing atmosphere within a well-managed frame on fermenting material that all soft-wooded cuttings like, and, under such conditions, I find Rose cuttings to thrive amazingly. When well rooted they should be potted off in pots varying in size according to the individual strength of each plant, and again returned to the cutting frame till growth is established, after which they may be removed to any house or pit that can be conveniently spared, and trained up the wires like a Vine. All growths emanating from the base of the plant should be immediately stopped, in order to concentrate the whole strength in one single rod. It would also be well to keep the canes always growing in a perpendicular direction, as the best and simplest preventive against the production of side shoots, which often make their appearance when the flow of sap upward is arrested. Occasional fumigations will be required to keep green fly in check, and daily syringings will also encourage growth and assist in the way of cleanliness. When the plants show symptoms of growth having exhausted itself, more air and less water should be given, in order to harden the young wood and render it fit to be turned out of doors. The very fact of the roots being restricted within a 12-in. pot will cause early maturation, and rest should be attended to for some time afterwards. If there be any danger of premature excitement, steps should be taken to obviate such a contingency by removing the plants from exciting influences and keeping their roots in a quiet (not a dry) state. If the young laterals with the future embryo flowers are in an advanced state, the plants must be re-taken indoors, where they will have the shelter of a cool house, before early frosts make their appearance. They may be started gently any time after Christmas, but the longer forcing can be postponed, and the more gentle it is carried on, the better it will be for the future Rose harvest. Roses grown in this way should be treated exactly as pot Vines are, viz., a fresh stock should be raised every year and thrown away after flowering. This is a plan which, with ordinary intelligence and care, will be found to give satisfaction. W. HINDS.

Otterspool.

THE ROSE ANNUAL.*

THE *Rose Annual* for 1877-8, by Wm. Paul, just published, contains coloured plates of the climbing Hybrid Perpetual Red Dragon; Rosy Morn, a seedling from Victor Verdier; Magna Charta, a fine variety which Mr. Paul thinks may prove to be a Hybrid China; and Perle des Jardins, a pale yellow Tea resembling Perle de Lyon, but, nevertheless, different from that kind, and stated to be one of the

best yellow Tea-scented Roses in cultivation—equally good in pots, under glass, or in the open ground. In addition to the letterpress descriptive of these plates, there are also chapters on the Current Year, New Roses, Roses for Garden and House Decoration, Roses for Exhibition, the Rose Shows, and Correspondence relating to Roses. From the latter we select the following remarks by Mr. Arthur W. Paul on "Roses on Their Own Roots."

At the present moment, perhaps, more than at any other time, the opinion of the Rose-growing public seems setting in strongly in favour of plants which have never been budded or grafted. Dazzled for a long time by the extraordinary vigour and celerity of growth of plants worked on the Manetti, and also by the enormous size of the flowers produced under careful and generous cultivation, to the mass of Rose growers own-root Roses were a long-forgotten thing of the past, which the mind associated only with the idea of the old Gallicas, Hybrid Chinese, and other favourites of a bygone generation. Valuable, indeed, as the Manetti stock is, on account of its easy adaptability to soils and climates generally considered unfavourable to the cultivation of Roses, and granted also the excellence of the seedling Briar as a dwarf stock, especially when Rose flowers in autumn are a desideratum, it is, nevertheless, we think, a matter of congratulation that more attention is being paid to plants on their own roots. It is true that they take longer to establish themselves, and do not, therefore, make large plants so rapidly or yield such a quick return of quantities of flowers as budded plants, but without taking into consideration the fact that certain kinds, such as *Maréchal Niel*, are best suited to this mode of growth, this is more than compensated for by the longer duration of the plant's existence, and by the exemption from the plague of suckers and offshoots which require constant watching for on worked plants, but which we so often see developed through neglect in private gardens to such an extent as to imperil the existence of the Roses themselves. We are also of opinion that there is generally a refinement and finish about the blooms on own-root plants which contrasts favourably with the coarseness and roughness apparent in so many of the flowers cut from worked plants, especially when produced on maiden or one-year-old plants. It is often taken for granted that if worked plants be planted sufficiently deep as to ensure the burying of the junction between the scion and stock, the former will throw out roots, and by taking the plant up at the proper season, and cutting away the stock, a plant on its own roots will be the result. By this means the end aimed at would of course be attained, but we are rather sceptical as to the adaptability of the mass of varieties to this treatment, and are of opinion that it is better to start at once with plants that have been struck from cuttings or layers. In making a bed for Roses on their own roots, perfect drainage is indispensable. The perfection of soil may be described as a medium Rose soil, neither so heavy as the Briar delights in, nor so light as the soils for which the Manetti is so highly valued. A rich loam, not too heavy, with which has been mixed some river or road sand and some leaf-mould will be found to answer admirably. As with any other Roses, a good proportion of well-decayed stable manure, mixed with the soil in planting, will be found to yield greatly improved results, both as to growth and the quality of the flowers. Cuttings struck in the open ground, as well as layered plants, are best planted out at the end of October, or early in November, but many of the finest varieties, especially among the Tea-scented class, are too tender to be struck in this way, and have to be rooted in heat, and subsequently cultivated in pots. Such plants, and, indeed, all pot-grown Roses of every description, should never be planted out-of-doors later than the beginning of September, as after that time, and throughout the winter and early spring, the ground is so soft and saturated with water, that it sinks away from the more solid earth which composes the ball of roots of the plant, and the result is a vacuum or loose soil which becomes speedily filled with either water or cold air, and, by causing the roots to rot, is extremely prejudicial to the well-doing of the plants, causing, in fact, a high rate of mortality. It may be desirable, for various reasons, to procure pot-grown plants during the autumn and winter, but they should remain in their pots in a cool frame, or under a hedge, or in some other sheltered position, until the warm weather approaches; they may then be planted out at any time from May till August. For the first few weeks they will require a little attention; watering must be carefully looked to when necessary, and when first planted it is well to shade them from the sun's rays, if too powerful. Treated in this manner, they will root freely and be well established in the ground by the winter. As a rule, plants on their own roots, especially when pot-grown, are not so large as worked plants of the same age, owing to their slower growth; for this reason, also, they are rather apt to try the patience when first planted out, but when once established, they grow so well, and are so little trouble, that the extra time they take in their early stages is easily forgiven and forgotten.

* "The Rose Annual for 1877-8." By Wm. Paul. Published by the author, Paul's Nurseries, Waltham Cross, Herts.

THE FLOWER GARDEN.

CANTERBURY BELLS IN MASSES.

I HAVE just filled a border, about 120 ft. in length and 7 ft. in width, with nearly 300 strong plants of this fine hardy biennial. That such a mass of it will give a rich and varied effect next summer I have no doubt. The only drawback is the hot, dry weather that generally prevails in June and July—the blooming period—which is apt to affect this *Campanula*. It is therefore well to give the individual plants plenty of room, in order that they may have all the moisture possible when most required. If seed be sown in pans or boxes in the month of April, the young plants so produced will develop fine compact heads of foliage, and in this way will be quite ornamental in the borders during the winter. The flowers of the Canterbury Bell are most useful for house decoration, and, being borne individually on stems from 4 in. to 6 in. in length, are specially adapted for cutting. Some of the blooms are drooping, but in a good strain, where there is an abundance of the double forms of flowers, the blooms are more erect, and work well into nosegays, or are useful for any purpose. It is not difficult now to obtain some twenty or more distinct hues of colour in a number of plants, ranging from pure white to blue and purple, the rose-coloured tints especially being exceedingly handsome. The plants also lift into pots easily, and when so treated, and plenty of water given them, will hold their flowers for a long time. When in pots, they are exceedingly ornamental for the decoration of verandahs, corridors, halls, and other cool places. Of *Campanulas* there are now a great variety. The best, perhaps, of the taller-growing kinds are *C. grandiflora*, *C. persicifolia* and its white variety, *Van Houttei*, and the one now under notice; and of the smaller varieties, *C. carpatica* (both blue and white), *C. nobilis* (both the reddish-purple and the white), *C. pulla*, *C. Raineri*, *C. garganica*, *C. pumila*, *C. p. alba*, *C. Hendersoni*, and the old *C. rotundifolia*.

D.

HOSE-IN-HOSE POLYANTHUSES.

THIS section of hardy spring flowering plants would seem to be amongst the earliest of all to flower, as several kinds are now more or less in bloom. Golden Gem, a remarkably effective yellow kind, is a very robust grower, and will, without doubt, prove to be a fine spring bedding plant. The flowers are large, and, like a true Hose-in-Hose, are produced on the stems in couples of rows of petals separated by a short interval. This is a pin-eyed variety, but this naturally detracts nothing from its decorative qualities. Golden Queen is the duplicate of the former, except that the flowers are thrum-eyed and a shade richer in colour. Cloth of Gold is a deeper hue still, but this is also pin-eyed. The finest white Hose-in-Hose is Avalanche, the flowers of which are large, pure in colour, and borne in large, compact trusses; it promises to make a grand white bedding kind. The old white Hose-in-Hose has large flowers of a French white tint, and is a most valuable hardy spring flower. I had conceived this kind to be very scarce, but last spring I was fortunate enough to light upon a garden where it was grown in great abundance. Perhaps one of the most effective kinds for massing is the

crimson Hose-in-Hose, as dark rich hues are in great request in the early spring garden. This is also a very robust grower, and stands the summer drought well. The fancy section of Duplex Polyanthus gives a great variety of novel and curiously-marked flowers, all of which are exceedingly attractive whether used in beds or planted singly in borders. It will probably soon be possible to select at least a dozen good distinct bedding kinds of these early Hose-in-Hose varieties.

BEDFORD.

Hypericum olympicum.

Home-saved Stock Seed.—When visiting a nursery this season, in which there was growing a beautiful collection of summer stocks, I made the enquiry as to what amount of seed was saved; but was informed that no attempt was made to save any, as it was understood that home-saved seed was of no value; and, therefore, all the seed was obtained from the Continent. That a sort of tradition has long existed as to the superior value of Continental-raised seeds of Balsams, Stocks, and Asters, there can be little doubt; and it is difficult to dispel the illusion. With reference to the Balsam, Messrs. Smith, of Dulwich, and other growers, have long shown that no strains can or do excel theirs saved from seed of home growth. I have long found that Victoria Asters of the best quality can be raised from home-saved seed; and Messrs. Betteridge, and other growers, have also long shown what excellent quality can be obtained in the Quilled Aster from home-saved seed. Of Stocks, we know what our own seed will produce in Bromptons, Queens, East Lothians, and Intermediate, all of which, if of good strains, produce 50 to 60 per cent. of double flowers; and of summer kinds, the beautiful pyramidal Mauve Beauty is a fair evidence of what sort of quality home-saved seed of these will produce. I have grown this Stock continually for the past ten years, and through all those years, it has never varied from its regular average of about 75 per cent. of double-flowered plants.—A. DEAN.

The Olympic St. John's-wort (*Hypericum olympicum*).—This is certainly one of the most showy of this extensive

family, and the best of all the hardy species. Numbers of them are exceedingly pretty, such as *H. balearicum*, *ægyptiacum*, *ericoides*, *reflexum*, *glandulosum*, and others, but then these are not hardy in the ordinary sense of the term, inasmuch as they require to be planted at the base of a south wall, on rockwork, and similar places, and even then they are apt to suffer during severe winters. *H. olympicum*, on the contrary, will grow in any situation and in almost any soil, and, during two or three months, forms a conspicuous and showy object. When well established it does not exceed 15 in. or 18 in. in height, and forms a neat symmetrical bush from 18 in. to 24 in. in diameter, composed of numerous slender stems, yet of sufficient substance to maintain their position. The foliage is small, ovate, elliptical, with pellucid dots. The flowers are produced in terminal clusters of from four to eight on each stem. They are about the size of a florin, and when in full bloom form a complete bouquet of golden-yellow blossoms. Among others of this family worthy of cultivation might be mentioned—*H. decussatum*, *tomentosum*, *Burseria*, *Nummularia*, and the old favourite Rose of Sharon (*H. calycinum*).—A. P.

Hoop Petticoat Narcissi.—I shall be most happy to show "A. R." (see p. 345) *Narcissus Bulbocodium serotinus* (*Corbularia serotina* of some), and also to send him flowers of the different varieties as they appear. It is too late now to remove them from the ground, owing to their being in full growth, and having leaves from 4 in. to 5 in. in length. The foliage of this variety is longer than

that of *Corbularia conspicua*; the flowers, too, which are larger, come into bloom about a fortnight later. *C. tenuifolia* flowers first, *C. conspicua* second, and *C. serotina* last. *N. Clusii* is now pushing its flower-buds through the ground, part of the same that flowered last season; I cannot say whether the identical bulbs that bloomed last year will flower this, but next season I shall be able to speak upon this point, for I will mark a number of flowering bulbs and keep them by themselves, in order to see if they will flower the following season; I see no reason why they should not, provided they are planted early and grown well. The chief cause of failure in the case of this plant is late planting. August I consider the best time for planting it; if dormant bulbs of it be planted in November or December, they will, in all probability, lie in the ground for a season, and then make a miserable attempt to grow, pushing up a solitary leaf and no flower, and the following season will entirely disappear.—A. P.

BEDDING PANSIES AND VIOLAS.

FEW plants are more useful for keeping up a display of colour throughout the season than the different races of bedding Pansies and Violas, which are, indeed, intimately allied, all belonging to the same botanical family, *Viola*, but the former evolved out of the improved garden forms of *V. tricolor* and its allies; while the latter, those at least of a purplish hue, partake more directly of the blood of *V. cornuta*, and those with yellow flowers of *V. lutea*. The two latter especially are very persistent bloomers. The following notes, from memoranda made at Chiswick, and extending over the last year or two, may be regarded as descriptive of some of the more distinct and beautiful of the varieties there grown, selected either for their compact dwarf habit, the profusion and continuity of their blossoms, and their useful and effective colours, just the points which give their value to Pansies as bedding-plants. All of the following have won certificates as bedding-out plants:—

Flowers Mottled—*Magpie*.—An old, but useful variety, striking in appearance from the strongly contrasted colouring of its flowers; vigorous, hardy, and an abundant bloomer; flowers blackish-mulberry, with a large wedge-shaped spot of white at the tip of each petal; the spotting sometimes runs out, when for a time it becomes self-coloured.

Flowers Purple.—*Dean's Mulberry*.—Dwarf-growing and of compact but spreading habit, free-flowering; flowers dark reddish plum-purple with very small yellow eye; the flowers well displayed. *Dean's Lothair*.—A showy variety, with a dark compact habit of growth; flowers large, deep purple, with small yellow eye; and broadish bronzy spot just below it on the lower petal; a distinct and rich-looking flower. *Dickson's The Tory*.—Of free and vigorous growth, blossoming abundantly and continuously; flowers large, deep bluish-purple, with white eye, in the front of which is placed a bilobed mulberry spot; good.

Flowers Bluish-mauve.—*Dean's Blue Bell*.—A very showy variety, of compact, spreading, and free-blooming habit; flowers numerous, medium-sized, mauve-purple, with a small yellow eye pencilled with dark lines. The individual flowers are not equal to the average Pansy in shape, as they partake much of the Carnation type, but the effect of the mass is good, and it is a continuous bloomer. It is probably the best bedding *Viola* in existence. *Blue Perfection*.—Of compact, free-blooming habit; flowers medium-sized, of a deep reddish mauve with yellow eye; a fine effective self-coloured variety.

Flowers Lilac.—*Dean's Lilacina*.—A charming variety, of dwarf compact spreading habit, free-growing, and very distinct; flowers of moderate size, the upper petals of a reddish-lilac, the lower ones bluish-lilac, with small yellow eye; an exceedingly pretty and taking flower. *Dickson's Queen of Lilacs*.—A variety of free bold habit, forming close, vigorous tufts; flowers reddish-lilac, paler at the edge, and very freely produced; a soft, neutral colour, effective, and useful for grouping.

Flowers Yellow.—*Dickson's Sovereign*.—Of close growing habit, dwarf, free, and prolific of blossoms; flowers moderate in size, bright golden yellow, with a pencilled eye; very effective. *Dean's Bedford Yellow*.—A free-growing, compact-habited sort; flowers large, bright golden-yellow, with pencilled eye; good. *Dickson's Golden Gem*.—A variety of dwarf spreading habit, and a free bloomer; flowers large, deep yellow with deeper eye, over which occur dark pencillings; good.

Flowers White.—*Dickson's Queen*.—A variety of free compact habit, an abundant bloomer, but rather later than some others; flowers large, white, with yellow eye and pencilled lines. *Dean's White Swan*.—A fine variety, of close tufted habit; flowers of moderate size, pure white, with pencilled eye, of good substance, and very chaste-looking; fine.—T. Moore, in "Florist."

Godetia Lady Albemarle.—From a bed of this sown during summer I recently lifted a few late dwarf compact plants that were too late to produce seed, and I placed them in pots, and put them into the greenhouse. They have bloomed most freely, and are singularly beautiful, quite exceeding all that could be expected of them under

such circumstances; the flowers have expanded well, and are of that deep rich colour so peculiar to this kind. As an experiment I should recommend the sowing of a small quantity of seed of this *Godetia* about midsummer, pricking out the young plants, and growing them in the open air until the middle of October when they might be put into the house under glass; the flowers only slightly contract at night, but do not close.—A. D.

Pyrethrum aureum laciniatum.—To those who prefer fine-foliaged plants for the distinctive hues of colour which they give when used for bedding purpose, this new *Pyrethrum* will scarcely prove satisfactory, as there can be no doubt that, looked at from that point of view, it is decidedly behind the old and well-known kind. That mere effectiveness in colour is all that fine-foliaged plants, even hardy ones, should possess, will not perhaps be the opinion of everybody, and, therefore, some will be pleased with this new *Pyrethrum* because of the beauty of its delicately-cut leaves. I have found it to possess one other useful feature as regards yearling plants, viz., these do not run off to flower so soon as the plants of the old kind do, and they are more even and regular in growth. Where, in bedding arrangements pleasing contrasts are required without having too much colour, Osborn's *Pyrethrum* will afford entire satisfaction.—G. H.

White Chrysanthemums.—I have a row of some fifty strong plants, chiefly of Mrs. George Rundle, the rest being Madame Damage, that are now full of buds, and many are bursting into flower. Judging by these, I should think that *Chrysanthemums* will not be so late in flower this year as is generally anticipated. These two kinds are undoubtedly the purest white ones, and, the flowers being of medium size and fairly solid, are most acceptable when cut for bouquets, as well as for the many and various uses to which flowers are put in a cut state. I planted these out last April, being obtained from early cuttings, and, as the soil was made good with manure, they have done remarkably well. *Chrysanthemums*, however, flower so late that the chances of getting good clean blooms is almost out of the question, and therefore I am about to try the experiment of lifting these plants and replanting them thickly in a bed in the centre of a large, airy, span-roof house. If I can accomplish this successfully, I shall then have secure from the weather all the beautiful blooms now expanding, and under glass they will not only be quite clean, but will also be even of a purer white than if left in the open ground. The *Chrysanthemum* is not a difficult plant to lift with a good ball of earth, as its roots are literally one mass of fibres, and these hold the soil well together. To have the soil fit for working, frequent soakings of water have recently been given to the plants, but now that heavy rains have fallen the ground is in the best possible state for lifting. A trench will be thrown out at 10 in. or 12 in. from the row, and then each plant will be carefully cut out with a good ball of earth and carried singly into the house.—D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Hardiness of *Hyacinthus candicans*.—This has proved to be perfectly hardy on the Continent. I saw some plants of it the flower-spikes of which reached 4 ft. in height, and they had withstood as much as 2° Fahrenheit.—MAX LEICHTLIN, *Baden-Baden*.

Hardiness of *Yucca Treculeana*.—Reading in THE GARDEN notes respecting the hardiness of this fine *Yucca*, I may mention that about five years ago Mr. Bain, late curator of the Dublin College Botanic Gardens, planted two specimens of it in a border there; and that without any special protection since, they are now in robust health.—JOHN ADAMS, *Dublin*.

***Mandevilla suaveolens* Out-of-doors**.—This is generally grown in this country as a greenhouse climber, and not infrequently it is to be found in a stove. This summer I was surprised to see it doing well out-of-doors against a south wall. It was bearing great trusses of flowers, and certainly seemed quite at home.—F. W. MOORE, *Botanic Garden, Dublin*.

Planting Water Lilies.—The best mode of doing this is to procure some old, shallow, flat baskets, such as nurserymen use for packing plants, and in these to plant the thick, fleshy rhizomes, using strong loamy soil, and ramming it in firmly. Then drop the basket into the spot where the Lilies are intended to grow. This can be done at any time during the resting season—say, from November till April—during open weather. This is a better plan than attempting to sink the stems into the muddy bottom by means of stones or other heavy weights.—"Florist."

Oxalis lobata.—This is a little gem for rockwork. It has been in flower here since June, and its numerous golden-yellow flowers, the size of a sixpence, show very well above the bright green foliage. It is quite hardy.—MAX LEICHTLIN.

SCENT-YIELDING PLANTS.

By G. W. SEPTIMUS PIESSE, Ph.D., F.C.S.

Orange, Bergamot, Lemon, Citron.

Of all scent-yielding plants none has a value at all equal to that of the Orange. It is a mine of perfume in itself. The blossoms yield, according to their mode of treatment, two distinct odours, one having the true scent of the flower, the other a scent called Neroly. Orange peel, too, furnishes a delightful perfume, with which all of us are familiar; and lastly the leaves give a scent inferior only to the true Neroly. Here then we have from one plant no fewer than four perfumes. Orange stocks are raised from seeds or pips, and in the third year they are grafted either with the Sweet Portugal or Bitter Bigaradier. In the fifth year they should be planted where they are to stand; the soil in which they are to be placed should be trenched at least 4 ft. deep, and well manured, inasmuch as fifty years, nay, even a century afterwards, the results of good early treatment will be apparent. Orange trees require fifteen years to reach maturity, but they will produce both flowers and fruit in four or five years. When in full vigour each tree yields on an average 25 lb. weight of blossoms annually. Many plantations of Orange trees at Nice are more than a hundred years old. At Fontainebleau there may now be seen Orange trees bearing flowers and fruit at the same time, that were planted by an ancestor of mine two hundred years ago. At Nice a public market exists for the sale of Orange-blossoms during the season when the trees are in bloom. The bitter Orange-flowers fetch 3d. per lb., those of the sweet Orange 2d. At Nice the market season for such flowers generally lasts upwards of a month, and during that time there are sold from 15 tons to 18 tons of flowers daily! A ton of flowers will by means of distillation yield say 40 oz. of Neroly Otto, worth 20 guineas; and the residuary water—Orange-flower water—five guineas. Orange-flower fat, or butter, and oil are manufactured to a large extent by the enfleurage and macerative process; it requires about 8 lb. of blossoms to enflower 1 lb. of grease, the operation being divided into about thirty repetitions of a small quantity of flowers over or in the same grease. By digesting this Orange-flower grease in the proportion of 6 lb. to 8 lb. in one gallon of rectified alcohol, there is obtained the extract of Orange-flowers, a handkerchief perfume which is surpassed by no other scent; it is exquisite in itself, and, when blended with extracts from other flowers, it composes what is termed a "bouquet."

The Otto of the Orange fruit is procured from the peel by what is called the 'Ecuelle process. The 'Ecuelle is a tinned-copper bowl, furnished with concentric rows of short spikes or teeth, and a hollow handle with a gutter from it to the edge of

The 'Ecuelle.

the bowl, through which liquid from the hollow handle can be poured. In order to obtain the Otto, the fruit is rolled by hand over and over the spikes, thus breaking the peel in such a manner that the Otto spurts out into the 'Ecuelle, and finds its way into the hollow handle, which, when full, is emptied into another vessel. An inferior quality of Otto is procured by rasping and slicing the peel and then pressing out the juice; and this, and the better process just described, are those by which the fruits of all Citronworts are divested of their scent-yielding properties, operations which are put into practice to a great extent at Messina, in Sicily.

The Citrus Bergamia or Bergamot Lemon, is a plant of great

value as a scent-yielder; its perfume is so much in demand that its annual production in Italy has never satisfied the market. The Messina dealers and their allies carefully adulterate the true Bergamot Otto with Lemon Otto, thus spoiling an article worth from 30s. to 40s. per lb., in order to sell it at 10s. One hundred fruit will yield about three ounces of Otto. The name of this variety of Citronwort is derived from the city of Bergamo, in Lombardy, from whence, so far as we can ascertain,

Bergamot (Citrus Bergamia—Risso).

the Otto was first sold. The Otto of Bergamot, of the finest quality, is obtained by means of the 'Ecuelle, but about four fifths of it in the market is a distilled product, or one expressed from the rasped rind of the fruit. About 40,000 lbs. weight of Otto of Bergamot are annually imported into England.

Among one of the Leeward Caribbees is Montserrat, a little island on which Citrus Limetta grows most prolifically, and in almost an indigenous manner. Under the care of Mr. Joseph Sturge, the Montserrat Company, of which Mr. Sturge is director, annually produce no less than 1000 lb. of the true Otto of Citron, all by means of the 'Ecuelle process, and it is so pure that it is worth twice its present price in the market, but the products of Sicily, which are by no means good, compete with it to its disadvantage. Mr. Sturge states that "his Orange orchards consist of about 500 acres, and that each acre contains about 200 trees. It takes seven years from the seed for them to come into full bearing; they flower more or less whenever they get heavy rain, and the fruit ripens in about four months after the flowers appear." He therefore gets fruit all the year round, but the chief harvest is from September to January.

The importation of from 85,000 lb. to 90,000 lb. weight of Otto Lemon annually into England proves that Britannia has a great liking for this scent, which is extracted by rasping the fruit and afterwards expressing the pulp so produced of the Citrus Limonum. The Otto of Lemon in the market is principally from Messina, where there are hundreds of acres of Lemon groves; indeed, the extraction of the Ottos of Lemon, Orange, and Bergamot, constitutes the chief industry of Sicily, particularly in the vicinity of Palermo. Here, instead of the 'Ecuelle for breaking the peel, a drum spiked inside is employed, and in this 100 fruit or more are operated on at one time; no doubt, sooner or later, steam will be employed to rotate these drums, and thus we may expect the supply of these scents to be kept up equal to their demand; nevertheless, as the land of Italy is already occupied, there is ample room in European markets for similar Ottos, should they be produced in Australia.

Floral Decorations.—Mr. Wills has now in his various nurseries two acres and a half of glass houses, mainly devoted to the growth of fine-foliated plants, &c., used in his plant decorations; but, in addition to these, over £10,000 worth of cut flowers, &c., have to be purchased yearly from other growers.

PLATE XCIX.

SELECT CATTLEYAS

(WITH A COLOURED FIGURE OF *C. DOWIANA*).

The different species of the genus *Cattleya* must always be highly appreciated, not only by Orchid growers, but also by every one who admires flowers possessing bright colours and fine forms. So great, however, is the influence of fashion, even amongst plant growers, that the members of this family, handsome though they are, have been somewhat neglected of late years, the more recently-introduced and more popular species of *Odontoglossum* taking their place. We really cannot blame those who have become infatuated with the mania for the latter genus, and if only two genera of Orchids could be accommodated, we would at once say, select *Cattleyas* and *Odontoglossums*; our province, however, is not with fickle fashion, but to bring into notice plants of sterling merit; amongst which must be classed the species of *Cattleya* now represented.

Cattleya Dowiana, is probably the largest-flowered and most gorgeous member of the genus; and, up to the present time, extremely rare; it is not a recent discovery, for Warsowicz first found it many years ago, but failed to introduce it in a living state, and it was not until the year 1864 that it arrived in this country; it flowered the following year, for the first time in Europe, in the collection of Messrs. Veitch & Sons, of Chelsea. It undoubtedly belongs to the *C. labiata* section in habit, although perfectly distinct; it is easily recognised by its stout, club-shaped pseudo-bulbs, which are deeply furrowed, and attain a height of from 12 in. to 18 in., supporting a single, broadly oblong, obtuse leaf, which is very thick in texture, from 6 in. to 12 in. long, and of an intense deep green colour. The peduncle is from three to six flowered, the individual flowers measuring from 6 in. to 7 in. in diameter. Sepals and petals spreading (the latter much the broadest), and of a beautiful, clear, bright nankeen colour. Lip large, the middle lobe very prominent and spreading. Colour rich, deep and velvety, veined and laced with thread-like lines of gold. Our figure is from the "Revue Horticole."

C. exoniensis.—This is a garden hybrid, and a bold, free-growing plant, the club-shaped pseudo-bulbs of which produce a single oblong, obtuse, fleshy, dark green leaf. Peduncle from three to six-flowered. Sepals and petals deep flesh colour, tinged with lilac. Lip large, middle lobe golden-yellow at the base, deeply margined with bright crimson purple. It blooms during autumn and winter. Its parents are *Cattleya Mossiæ* and *Lælia purpurata*.

C. superba.—This plant is of a wholly different character from those previously named; its somewhat terete pseudo-bulbs are furrowed, and bear a pair of nearly round, thick and fleshy, deep green

leaves. Peduncle from three to six-flowered, the individual blossoms measuring from 4 in. to 5 in. in diameter. Colour, in both sepals and petals, an intense, deep purplish-rose. Lip rich magenta-rose and yellow at the base; when vigorous, it will sometimes make two growths in a season, and produce flowers from each; oftener, however, only one growth is sufficiently strong to bloom. The flowers are very fragrant, thick and fleshy in texture; and, consequently, last long in perfection. It must be grown upon a block and placed in the warmest end of the Brazilian house. Native of British Guiana and Rio Negro.

C. amethystoglossa.—This, which belongs to the *C. guttata* section, produces tall, slender pseudo-bulbs, bearing upon their summits a pair of dark green, oblong lanceolate, and obtuse leaves. Peduncles from four to six-flowered. Sepals and petals thick and wax-like, tinged with rose, and beautifully spotted with distinct spots of rosy purple (in some varieties the spots run into each other and form irregular blotches). Lip rosy violet. It blooms during spring and early summer, and should be grown in a pot. Native of Brazil.

C. Mossiæ.—This is one of the best known and largest-flowered species in the whole genus; it is, however, seldom seen so well developed as it might be, if ordinary care were taken in watering it, and not roasting it, as is frequently done. It is a plant of close, compact habit and a profuse bloomer, the flowers often measuring 6 in. in diameter. In colour it varies greatly, its varieties being exceedingly numerous; the normal colour, however, in the sepals and petals, is blush or lilac, the lip being rich orange at the base, and deep rosy or violet-purple in front. It blooms during the summer months. Native of Brazil about La Guayra.

C. labiata.—This species, which is nearly allied to *C. Dowiana*, very much resembles that kind in habit and general outline; the flowers, however, are quite distinct. Peduncles three to six-flowered. Sepals and petals broad and rounded. Colour clear rose. Lip large, intense velvety-crimson. It blooms only during the autumn months. Native of Brazil.

C. labiata Warneri.

—This varies greatly in the colour of the flowers; but all the forms of it are extremely beautiful. It is compact in habit, and has broad, somewhat flat, bright green leaves. Peduncle from three to five-flowered, the individual blooms measuring from 5 in. to 6 in. in diameter. Sepals and petals broad, deep rich rose. Lip large and beautifully frilled in front, where the colour is intense, deep crimson; base yellowish-white. It blooms during the summer months.

C. Trianae.—This is also a very variable species; as regards habit of growth and size of the flowers, it resembles *C. Mossiæ*; but all the varieties bloom in autumn and winter, so that by a judicious selection, a grand display of these gorgeous flowers may be had for many months, if not, indeed, throughout the year; the sepals and petals vary in colour from deep rose to pure white; the lip is usually yellow or orange at the base, the front portion changing from rose to intense deep purplish-violet. Native of New Grenada.

C. Wagneri.—By some this is considered to be a distinct species,

Flower of *Cattleya Trianae*.

GOLDEN-PETALED CATTLEYA (*C. DOWIANA*).

but by many only to be a variety of *C. Mossiae*, a species with which it is often found growing, and has even been frequently sent home unawares along with importations of this old favourite species or its varieties; it is, however, very beautiful; the sepals and petals are broad and pure white; lip white, stained with pale yellow towards the base. Although introduced some years ago it still remains a rare plant in collections.

As regard cultivation, *Cattleya Dowiana* does not differ from other *Cattleyas*, viz., its surroundings must be kept sweet, fresh, and clean; if grown in a pot it should have a good fibrous peat and Sphagnum Moss in about equal parts, taking care that ample drainage is provided. It, however, does best upon a block, although in this way more care and trouble are required to keep the roots duly supplied with moisture. It should be firmly fixed to the block, and its base should be covered with living Sphagnum only. *Cattleyas* like a plentiful supply of moisture when growing, and even when at rest it should not be wholly withheld. They should not, however, be syringed overhead, because the large sheaths which envelope the young growths catch such a quantity of water that they are often thereby seriously injured. This applies more particularly to *Cattleyas* in pots; when grown upon blocks, their position enables them to throw off any superabundant moisture, and the young growths in that case suffer no injury. *C. Dowiana* is a native of Costa Rica, and requires more warmth than *C. Mossiae*, *C. Trianae*, and many other nearly allied species; it should, indeed, be placed in the warmest end of the *Cattleya* or Brazilian house. It blooms early in autumn, and continues in full beauty many weeks if the flowers be not sprinkled with water. W. H. G.

Garden Design: What to Avoid.—How callous to any true taste some people may be who lay out gardens in the "natural style" is well shown in the accompanying slight sketch. A portion of artificial water, with a too formal margin, is followed by a walk,

and that by a road, all side by side. It is an actual scene, and, though it would be hard to equal it, the habit of running a formal walk beside a piece of water is far too common. In connection with this may be named the curb-stone put round the Serpentine, and which is at this moment several feet above the water.

Tritoma grandis.—This takes a prominent rank amongst *Tritomas* because it keeps so late in flower. I have a plant of it here, not very large, which has flowered ever since September, and even at present it is in full beauty, being furnished with some ten spikes, and still a lot of buds are coming out. The colour is also bright and fine, and the spikes are a little larger than those of *T. Uvaria*.—MAX LEICHTLIN, *Baden-Baden*.

Spanish Moss as a Window Plant.—The *Tillandsia usneoides*, or Black Moss, is used very effectively as a window plant by Mrs. Jackson Dawson, at the Bussy Institution, Jamaica Plains. Suspended from an iron nail just over the window, and as seemingly careless as if it were a bank of worsted, or string, without even a stick to attach itself to, is a 4-ft. long festoon of this delicate Bromeliad, and it is in the most thrifty and growing condition; it bloomed freely during the past summer. Twice a week Mrs. Dawson takes it from the nail, dips it in a pail of water, and then lets it drip outside till nearly dry, when she returns it to its position in the window. During bright sunshine the blinds are closed, not with a consideration for the Moss, but as a domestic duty, and though this drapery has been for the past two years subjected to this treatment, it is as living and as life-like as if depended from an Oak, near a Florida swamp, whence it originally came.—WILLIAM FALCONER, *Botanic Gardens, Cambridge, Mass.*, in "Moore's Rural."

ORCHIDS.

SEASONABLE NOTES.

In commencing Orchid culture a selection of species should be made which will bloom at different periods, so that a succession of flowers may be had all the year round, and this should be done with some degree of partiality for those which display their charms through the dull months of winter.

Amongst the best which bloom at this time of the year may be named *Oncidium varicosum majus* and *O. Rogersi*; of these the first has been introduced most abundantly, and amongst them many are now in flower that differ considerably in the size and brilliancy of the labellum, but all are beautiful and specially valuable for winter decoration, for with a little management as regards retarding, a few plants will produce a harvest of flowers from October to Christmas. *O. varicosum* may be grown in a pot or in a basket, and suspended from the roof, whichever way is most convenient; it matters not which as far as the plant is concerned, provided all its surroundings are sweet and clean, and the atmosphere sufficiently humid. Some say that they get tired of *Oncidiums* because they are all yellow, but *O. incurvum* is a charming kind the flowers of which are white and rosy pink; individually they are small it is true, but they are produced in great abundance upon long branched spikes; it is now opening its delicate flowers, which will last till January, if not sprinkled with water by the syringe.

In *Laelia autumnalis* we have a perfect gem, which is throwing up dozens of spikes, each bearing two, three, and five blossoms, which are of large size, measuring 3 in. or 4 in. in diameter; the colour in the sepals and petals is deep rosy-purple, and the lip rose and white with a stain of yellow in the centre. What can be more charming for the decoration of a lady's hair for a ball or evening party, or for cutting for vases? they last long used for either purpose, and in addition to their pleasing colour, they emit a delicate perfume; as regards treatment all that is needed is good drainage, good peat, and living Sphagnum Moss to retain moisture at the roots; plenty of air, too, when growing must be given, and the plants must be placed in such a position that the sun will shine upon them in the morning.

Pleiones, or as some term them Indian Crocuses, are now, and indeed, have been very gay for at least a month past. A beautiful succession of these may be kept up by placing some in a cold house. The brilliant contrast of colours in *P. lagenaria* and *P. maculata* is truly charming, whilst the tints of *P. Wallichii* are soft and rich. These plants begin to push up their young growths immediately after flowering: therefore, when the blooms fade, repot them at once in order that the new growths may reap the full advantage of the fresh soil.

The beautiful *Odontoglossum Alexandrae* must ever be a favourite with Orchid growers; its large flowers never fail to elicit admiration. Of this *Odontoglossum* there are numerous varieties, but amongst the whole of them a bad one could not be found. It is now pretty generally known that this *Odontoglossum* succeeds best under cool treatment. *Odontoglossums* like abundance of air, but it must not be admitted irrespective of external conditions, for if that were done, they would become starved and shrivelled. The Sphagnum should be kept in a living state upon the surface of the pots, and should never be allowed to become dry at any season; a few plants of this species will keep up a succession of flowers during the winter months.

Calanthe Veitchii is another winter-blooming plant, totally different from anything previously described, and extremely beautiful. It is, however, far too often starved, and consequently does not produce that abundance of flowers which it otherwise would do. The pseudo-bulbs are from 12 in. to 16 in. high, partially deciduous, or, perhaps, quite so; still it sometimes retains its foliage until after it has bloomed. The flower-spikes measure 2 ft., 3 ft., and 4 ft. high, and bear numbers of rich rose-coloured blossoms. After blooming the plants should be allowed to rest for a short time; then they should be re-potted, using for the purpose loam, leaf-mould, peat, and cow manure in equal parts interspersed with some Sphagnum, and during the growing season they will be benefited by applications now and then of weak liquid manure. W. H. G.

Odontoglossum Rossi majus.—This sturdy and charming little Orchid is now very attractive in various collections.

Angraecum sesquipedale.—A large plant of this remarkable Orchid is showing fine spikes in the Exotic Nursery, at Chelsea. It will form a fine object between the present time and Christmas.

Goodyera Rolissoni.—This is one of the most beautiful of ornamental-leaved Orchids. It possesses a robust habit, and its leaves are of a deep green colour, striped and blotched with creamy-yellow, the under sides being of a rich velvety purple.—S.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Pruning Vines.—Amateurs seldom attempt forcing Vines early, and, as a rule, it is better that they should not do so, for, unless a considerable amount of skill and practical experience were brought to bear on the matter, failure would be likely to be the result. Even in the case of thoroughly established, strong Vines in fruitful condition, Grape-growing that entails the necessity of starting the Vines even at the close of the year, is a very different operation, requiring a great deal more skill and watchful attention than what we may term accelerating the natural spring growth by the application of fire-heat towards the end of February or during March, when the vital forces are naturally more disposed to move with less artificial heat. Nevertheless, now that the leaves will have all, or nearly all, fallen, and where the fruit has all been cut, it is better to prune at once. Moreover, I should recommend amateurs, in all cases, never to delay Vine pruning longer than can be avoided. It is through deferring this operation from week to week that the mishap, known amongst cultivators as bleeding, or a copious exudation of the sap at the points where the shoots were severed, takes place, which is one of the most provokingly unmanageable occurrences that can happen, for despite all that is said about the means of stopping it by means of searing it with hot irons, Collodion, painters' knottings, and other styptics, which no doubt, to some extent, tend to mitigate the evil, still, if Vines be pruned at only a short interval before the sap begins to move, it is next to impossible to prevent its loss to an extent that does more or less harm. To make sure in a way that gives the wood sufficient time to heal up the cells severed in pruning, two months should elapse before the Vines are either excited by fire-heat, or come on of their own accord. Another advantage gained by early pruning is, that plants wintered in the houses under the Vines receive so much more light by the removal of the shoots. In the matter of pruning, two distinct methods are practised; one is known as the long rod system, and the other the spur; the former consists in taking up one or two young canes from near the base of the Vine each year, which, at the time of pruning, are shortened back to from two-thirds to one-third of their entire length, the crop being borne on the young rod or rods from the bottom up to where they are cut back, and on the old cane that has produced them above where they were severed, except in cases in which it was cut away as soon as the fruit was removed; in that case the young one is generally left nearly the entire length of the rafter; but this method is now comparatively little practised, and never had very much to recommend it, although by it larger bunches are often produced than by the other system. Amateurs are more likely to succeed under the spur system, though the Vines in time, owing to the length which the spurs assume in the course of years, have a less sightly appearance. This is a fault which can, however, be avoided by yearly cutting from each rod a few of the spurs completely; young shoots will spring from the base where these have been removed, and will take their place, though it often happens that such shoots do not show fruit freely the year after they have been formed. It is, however, always better to prune with a view to a crop than for mere appearance sake, and I should not recommend any bearing wood ever being shortened closer than to where a good plump eye can be retained, even should this be the second above the base of where the current season's shoot had sprung, and in no case to sever the shoot too near the eye that is retained. The advantage of pruning in this fashion is, that the second eye may produce a good stout bunch, wherein the usually weaker bud at the base of the shoot may show no bunch, or one that is a sort of half bunch, half tendril; and if the lower eye shows fruit satisfactorily, then the shoot from the second eye can be removed altogether. Where Vines are strong enough to bear freely, there is little to be feared in their showing a sufficient crop, provided the wood has been fully ripened, unless where over-cropping has been practised, or they have been so grossly neglected as to allow them to become a prey to red spider or thrips early in the season, long before the leaves had fulfilled their allotted functions; neither is it likely that Vines started with the assistance of fire-heat last winter or spring, a considerable time before they would have moved naturally, will be deficient in the wood being well ripened, as the length of time which they have had to make growth and harden up during the recent fine weather, will be almost certain to have secured a fruitful condition. Not so Vines that were allowed to come on of their own accord with solar heat; these, as might be expected from the exceedingly late season, notwithstanding the favourable autumn, have not had enough time to mature the wood whilst the leaves were green and retained their full vitality, for when the wood is not sufficiently matured to produce a crop before the leaves begin at all to lose colour, the case is all but

hopeless, and from what I have seen in many parts of the country, more late started Vines in the hands of amateurs are in this state than usual; in this respect it has been one of the very worst seasons that I can recollect.

There is one other point to which I would direct the attention of amateurs in Vine pruning, and that is not to retain too many spurs on each rod; it is a common occurrence to see a spur retained at the greater number of the joints of the rods first made, which is much too close, crowding the roof with small half-developed leaves; whereas, if the spurs be from 1 ft. to 15 in. apart, they are quite near enough.

In the case of Vines that are pruned now with a view to their being started more or less early during the winter, it will be as well to give them their winter dressing at once. Before applying this, it is usual to strip off some of the outer bark, but in this operation I would especially urge amateurs to be cautious, and only take off such as is quite loose and hanging in a dead, stringy condition; the unnatural practice of close scraping, so as to remove the whole of the outer covering almost down to the living inner bark, polishing the rods off smooth like a knotted walking stick, is fatal in its effects of preventing the Vines ever growing and thickening as they ought to do. This scraping process I am aware is often done with the intention of removing the eggs of red spider, thrips, and other noxious insects deposited in the inequalities of the bark, but, in this case the cure becomes worse than the disease. After removing just the loose outer portion as above described, dress at once with the usual mixture of clay, sulphur, a little Gisharet and soot, and fresh cow manure, the latter to help the dressing to stick, stirring all well together, and using it about the consistency of thick paint, brushing it in thoroughly to get it into every crevice, especially about the base of the spurs. After they are dressed the rods may either be tied up in their places under the rafters, or across the house over the front path, if there happens to be one; in this way most light will be admitted to whatever plants occupy the house during the winter.

Where pot Vines are intended to be forced, starting them some time after the commencement of the new year, these should at once be cut back to the required length. It is not well to make them too short, at the same time they are somewhat inconvenient to deal with if left over long; a length of 9 ft. or 10 ft. will generally be found sufficient. It will be well, also, in their case, to dress them over with the sulphur mixture recommended for the permanent Vines; after this, until required for starting, they may be set anywhere in a cool airy house or pit, not allowing the soil to get too dry, nor the opposite extreme of being saturated with moisture. Where Vines have to be bought for either forcing or planting, I should advise their being got in at once, and kept where the roots will neither be subjected to frost nor too much moisture. A too prevalent opinion, entertained by those who have not had much to do with Vine culture is, that if they be kept through the winter where frost cannot reach their roots they are all right, which is anything but correct, as an excessively wet condition of the soil is equally destructive to them as frost. I have frequently seen strong, thoroughly-ripened young pot Vines that, though treated during summer in such a way as to insure their showing plenty of fruit, fail through being placed out-of-doors and exposed to excessive rainfall, which rotted the roots. In the case of Vines for permanent planting in spring, the evil is only so much less that no fruit in the current year is expected from them, but the progress they make through the summer, when their roots are in the state described at planting time, is not more than half of what it otherwise would have been. Even if the pots be laid down on their sides and covered with litter, it frequently happens that the soil gets much too wet through moisture communicated by absorption through the pots. It is a very common occurrence to meet with amateurs whose Vines are a source of continual annoyance to them, going on year after year bearing but very little fruit, and what they do produce of an inferior description, through shanking, a condition which may generally be traced to an unsatisfactory state of the roots, which have got too low down in damp, ungenial soil, or where there is an accumulation of stagnant moisture. In all such cases, instead of dallying with them and looking season after season for more satisfactory results, that are not realised, I should recommend the roots at once to be lifted, and a new preparation made; in the first place there should be sufficient drainage, which may consist of 8 in. or 10 in. in thickness of broken refuse—bricks, burnt clay, clinkers, stones, or anything of a similar nature that is most easily obtained; on this lay a bed of good ordinary new soil, of not a too light sandy character, and, if very heavy and retentive, add a sufficient quantity of sand, lime-rubbish, or burnt clay, to make it sufficiently porous without being too open. It will also be an advantage to add to the soil $\frac{1}{2}$ in. or 1 in. of crushed bones at the rate of about a bushel to every three or four superficial yards of the border. In the absence of these, if the soil be not naturally rich, a

moderate quantity of good, rotten manure should be added. The work should be commenced by removing the soil at the furthest part of the existing border away from the front of the house they occupy, using forks for the purpose, so as not to mutilate the roots, which must be carefully dealt with and taken up as entire as the nature of the operation will permit; all the existing outside border ought to be removed, if there be an inside border as well, and if it be ascertained on examination that there is a fair amount of roots in the inside; if the border be all outside, about 3 ft. or 4 ft. of the portion nearest where the Vines are planted should be left undisturbed, as if the whole length of root were lifted so late in the season as this most likely they would not bear much next year, and lifting the lower extremities of the roots and placing them sufficiently near the surface in new soil will generally be found effectual. Before replacing the roots, they may be shortened to about half the length that has been taken up, spreading them out evenly, and bringing them to within 8 in. or 9 in. of the surface; when the work has been completed, on the top of all, 8 in. or 10 in. of litter should be laid, so as to throw off heavy rains and keep out frost, as if the soil were congealed down as low as the roots the latter would be seriously injured. If there happens to be any spare frame lights, wooden shutters, or, failing these, an old oil sheet or anything that will ward off excessive rain, it will be a still further advantage. Many people are deterred from interfering with the roots of unfruitful Vines, and re-making the bed in which they are grown, under the impression that it involves a serious amount of cost and labour; yet such is by no means the case, as there is little difficulty in the matter when new soil can be had without considerable expense. I have found that the best time for lifting Vines is at the close of August or beginning of September, whilst the leaves are fresh and green; but in most cases with amateurs who do not start them early, they are bearing more or less of a crop either ripe or approaching maturity at that time; consequently the work has to be deferred until later on, often till the present season. Vines that are thus lifted should by no means be hurried in the spring, but left to come on with little, if any, excitement beyond that resulting from solar heat.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

November 12.—Digging large pits and filling them three parts full with maiden loam for Peaches, Nectarines, and Apricots. Covering a bed of Seakale with leaves and manure previously prepared for it. Cutting down Asparagus stalks and clearing the weeds off the beds. Covering up Endive and Lettuce to blanch. Washing the lights and paint in the early Peach-house.

Nov. 13.—Shifting herbaceous Calceolarias. Getting early Peach house pruned, and the trees painted with the usual composition for keeping off insects. Giving Cucumbers a little earthing with new loam, adding a little charcoal to keep it open and sweet. Clearing old Raspberry canes off wire trellis. Clearing leaves and rubbish off borders in pleasure grounds, and getting them forked over.

Nov 14.—Earthing up Beans. Turning manure and leaves for hot-beds. Giving Asparagus beds a light forking, and covering them with rotten manure. Making a new Mushroom bed. Tying out the trees in early Peach-house, and otherwise getting it ready for starting. Getting all Endive and Lettuce under glass as fast as room can be found for them.

Nov. 15.—Sowing Mustard and Cress. Potting on late Primulas. Getting into the potting-shed a good supply of different sorts of mould. Emptying Melon pits and giving them a good coating of hot lime. Trenching early Pea border, turning in a good coat of manure that had been previously mixed with salt and soot. Commencing to lay down one-half of the Broccoli heads to the north, and covering up the ground between the rows with half-rotten manure.

Nov. 16.—Potting off Hydrangea cuttings. Getting in 100 pots of French Beans. Turning manure for Mushrooms. Getting Strawberries for forcing into cold pits as fast as they become empty. Looking over Cauliflowers, turning down leaves to protect the heads where required, and moving the most forward ones into an open shed. Raking up leaves in pleasure grounds and collecting them for hot-beds.

Nov. 17.—Looking over Verbena and other cuttings, removing all dead ones and decayed leaves. Cleaning the walks in the pleasure grounds and getting them all rolled down firmly. Getting all rubbish burnt up. Clearing off late Peas, and storing away the best of the sticks. Getting for fruit trees a quantity of loam from the deer park. Cleaning up the kitchen garden walks. Fruit in use for dessert—Pines, Grapes, Pears, Apples, Medlars, Nuts, &c.

NOTES FROM KEW.

SEVERAL good plants of *Begonia natalensis*, a very useful species for cutting from during the winter months, are in bloom in the stove. The flowers are pure white; leaves and stems rather succulent, yellowish-green, tinged with copper. Palisota Barteri, first discovered near Fernando Po, by Barter, the botanist to Dr. Baikie's Niger Expedition, is attractive on account of its short, thick racemes of beautiful red fruits; it is a stemless, herbaceous plant, with lanceolate leaves from 1 ft. to 2 ft. long, narrowed at the base into a short stalk, the whole being more or less covered with silky hairs. The flowers are pale purplish or white, and are not of themselves very showy.

In the Cactus-house there is a fine specimen of a very striking Bromeliaceous plant, *Paya grandiflora*, from Mexico. It has a thick, woody branching stem, with dense heads of hard, leathery, recurved leaves, 2 ft. to 3 ft. long, the margins of which are beset with large, hard, pungent spines. The panicles are 4 ft. or 5 ft. in length, and bear very many flowers, which in bud greatly resemble the beak of a bird; and, when fully mature, are more than 5 in. long; the petals are greenish-white tinged with purple, and the sepals, bracts, and almost every portion of the inflorescence, are covered with numberless reddish-brown stellate hairs, which make beautiful objects for the microscope. *Crassula rubicunda* is a very fine Cape succulent, with large heads of red flowers. In addition to its welcome colour, its compact habit and the property it has of remaining so long in bloom, render it a desirable acquisition to our stock of winter-bloom-plants. Two *Ceropegias*, *C. Gardneri* from Ceylon, and *C. elegans* from the Neilgherries, are also in flower. These very strange Asclepiads have twining stems and opposite leaves; their bent corollas suddenly narrow into a tube about 1 in. long, then again enlarge and divide into five segments, which unite at the top (in some species forming a large umbrella-shaped head). The tips of the corolla segments of *C. elegans* are deep green, then comes a blotch of chocolate-red, followed by a deep band of white; the tube is greenish-white spotted with brown. *C. Gardneri* has purplish-coloured flowers.

The Gesneraceous collection, for the most part in one of the warm compartments of the New Range, is also worth a journey to see. It seems strange that plants exhibiting such brilliancy of colours, and being so very floriferous, should not be more extensively cultivated for the decoration of our stoves at this dull period of the year. Besides nearly all are of the easiest culture; they simply require good rich loam and leaf-mould, and perfect drainage; during the season of rest the tubers can be kept in dry sand in any cool, dry place. The following *Nægeliæ* have all been raised and distributed by Van Houtte, at whose nursery considerable attention is paid to these very beautiful plants. In addition to the varied colours of the flowers, the foliage is in many instances very handsome. *N. Leichtlini* has a pure yellow flower shaded at the top with deep red; *Morgenlicht* is a very fine golden-yellow variety; *Madame Paul Boutez* has pretty speckled flowers, in which bright yellow, pink, deep scarlet and a bluish tinge are all represented; *Sapho* has a white corolla lightly tinted with rose, throat canary yellow. Intense vermilion and citron-yellow struggle for the mastery in *Grand Mogol*. *Chair et Capucine* has magnificent foliage; the flowers are a warm, flesh-colour bordered and spotted with red. The Mexican *Eucodonia Ehrenbergi*, perhaps better known as *Scheeria lanata*, is very attractive. The robust, erect stems, as well as the leaves, are more or less covered with soft, whitish hairs, and the lilac-pink white-throated flowers, veined with purple, mark it as a most desirable stove plant. *Plectopoma triumphans* is an abundant bloomer of good habit with lilac flowers, the interiors of which are white and citron-yellow spotted with purplish-red. *P. Colibri* has charming rose-coloured corollas, but its habit is not so good as that of the last mentioned plant. A large-flowered *Tydaea*, *T. Vesuvius*, raised by Thibaut and Keteleer, has dark red flowers barred with black.

Perhaps the freest winter-flowering Bromeliad is one called *Pitcairnia muscosa*, the smallest member of the genus to which it belongs; it has tufts of narrow leaves, from amongst which spring the panicles of red flowers. Another Bromeliad, *Chevalliera Veitchi*, introduced this year to cultivation by the enterprising firm after whom Professor Morren has named it, is a real acquisition, not only for its novelty, but also for its intrinsic worth as a stove plant. It has a dense, basal rosette of leaves, 12 in. to 15 in. long, by 2 in. broad; the scape, about 1 ft. high, is surmounted by an oblong flower-head, 4 in. long and somewhat less than 2 in. in diameter. The closely-set, bright scarlet, horny, toothed bracts, from the bases of which spring the flowers, last a long time in full beauty, and are much more showy than the flowers themselves. It is well figured in the "Botanical Magazine" for the current month, where, however, *Chevalliera* is only admitted as a section of the large genus *Æchmea*.

The prettiest *Amaryllid* of which Kew can at present boast is *Urceolina aurea*, from Peru; it has heads of charming, pendulous,

yellow flowers, about 2 in. long, the cylindrical green tube is 1 in. long, then comes the ventricosely bell-shaped upper portion, the mouth of which is contracted, and has short, reflexed, green segments.

In the *Mesembryanthemum-house* one of the most beautiful species of the genus is now in flower; it is *M. fragrans*, and well does it deserve its specific name. The fine bright yellow blossoms are 3 in. across, and are deliciously fragrant; the leaves are few in number, extremely fleshy, and keep close to the 'ground. Very similar is *M. grandiflorum*, which, however, has flowers only half the size of the last-mentioned species. *M. felinum* is a pretty dwarf yellow-flowering species, and the leaves are furnished at their edges with formidable-looking teeth.

G.

PARK GATEWAYS.

EVERY one who is fortunate to appreciate the picturesque of effect and of association, knows how much of either kind of interest is contributed by the entrance gateways of old family estates which form incidents in a drive along an English country road. These are mostly in more or less classic taste, for it was only in post-Gothic times that the domestic landscape, as one may call it, of the private park, came into being as an essential feature in connection with a country residence—an appendage of the "mansion" which succeeded to the "castle." There are instances where attempts have been made to preserve the castellated style, the outer signs of feudalism, when the reality is extinct; and very unfortunate is the effect. If thoroughly

carried out, the structure has a forbidding and inhospitable aspect; if badly and insufficiently done, it looks simply futile; but the old classic park entrances exhibit a great deal of variety, and it is surprising how well they seem to group with English park scenery and foliage. We find sometimes a solid and dignified structure, like the one (no matter where) which suggested these desultory remarks; a mass of solid ashlar masonry on either side of the gateway, variously grey and green with Lichen Moss, divided out into regular cubes by the thin black lines of jointing,

from which the pointing mortar has long disappeared; heavy solid-looking half-columns, with Ionic capitals, forming the main decorative feature in either block; and through this framework of masonry we look down the vista of a long, straight drive, thickly bordered with trees in the rich tints of autumn foliage, or interspersed with dark evergreens. The house to which it leads is concealed from view, so that there is about the effect something suggestive to the fancy—a pleasant touch of theatrical unreality; the road may lead anywhere—to some enchanted palace if we like. The columns seem to form a kind of proscenium ornament, and we might expect to see the hero and heroine of the romantic opera pass across between it and the back scene. But perhaps we are getting a little too fanciful; all we mean to say is that the effect is very charming, both to the eye and mind, and that it is worth while to notice how much may be made out of such merely necessary facts as a gateway and a road to an house; and, in fact, the associations connected with these specimens of gateway architecture are really domestic rather than melodramatic. The family arms, the family motto, more or less ingeniously introduced on the piers, or in the design of the gate, constitute not a little of the picturesque sentiment connected with them; but there is a great deal of variety of architectural treatment and design to be met with amongst them. One shows a heavy and massive pediment with an arch under it for the gateway. Another aims at elegance and grace, not without a certain stateliness, too, and the gate is flanked by a light, open colonnade, on a semi-circular plan, terminating in the gate piers, the cornice and blocking of which are

carried also round the semi-circle, and form at either extremity of it the pedestal for a couchant stag, which will probably be found to be better carved and more artistic in feeling than one would at first expect. This semi-circular type of entrance, providing a wide space between the public road and the gate, is a not uncommon form, and is always effective in general appearance, giving a look of spaciousness and dignity, whatever may be thought of the details. In another we find a different, a more homely but still dignified character imparted by a heavy rusticated architectural treatment, not so refined and stately certainly as the columnar architecture, but having a character of its own, peculiarly English; heavy piers crowned by an urn and a wreath, or a nondescript dog or lion with a shield, and more picturesque no doubt in its weather-stained green and black and grey condition than when fresh from the mason's hand. Yet in most of these show structures there is a largeness of scale in the detail, and a sort of execution entirely the reverse of "scamped," which gives them a satisfactory and thoroughly architectural expression, and the sculptured accessories generally are by no means despicable in style and execution. In regard to this last point we certainly have not improved upon our ancestors in decorative treatment of entrances, except in some special case in which ability of a high class has been employed upon the sculpture, and truly at this moment we hardly recall any such case. We do not recall instances in which the efforts to do something unusual in the way of sculptured decoration in such positions has resulted in the most dire vulgarities, though it is right to add that these are probably not

chargeable upon the modern architect, but rather result from the desire to try how he can be dispensed with. It is a trifle off the line suggested by our title, but we cannot help noting a contrast between old and new taste in the matter of gateway decorations which may be seen in the once classic ground of Regent's Park. The older terraces along the east drive, parallel with Albany Street, exhibit a good deal of the old classic and not over-convenient formality of design, but they are not without dignity of arrangement; and in the case of Chester Terrace, which stands back from the road, there

Ivy: a sketch by A. De Bar; Auteuil, 1877.

is something really effective in the large entrance archway, flanked by classic columns, through which access is obtained at either extremity to the terrace drive. A little way below Chester Terrace, with its pediments, and "orders," and "attics," according to rule, is a large terrace of new houses, of a would-be-Gothic type, staring and obtrusive in style, also with its drive and its entrance gateways, on each of the piers of which have been set three wonderful females, back to back, in classic drapery, and depicted with what has evidently been intended for a smile of welcome on their lovely countenances; but, whether owing to the carver's (we cannot say sculptor's) innate vulgarity of conception, or his inability to realise his intention, the smile takes the form of a leering smirk of enticement, which certainly would be, as we heard a lady resident of the neighbourhood complain, "absolutely improper," if it were not a little too ridiculous for that. Such a piece of vulgarity as this would, at all events, have been impossible in the period when the gateway designs of which we have been speaking were produced.

In recent days we have taken more to Gothic entrances, and these have this advantage, that if there is a house flanking the gate at either side, it can be obviously shown as a house or cottage, and not disguised behind a screen of classic podium and column and cornice. The Gothic entrance may be said to be more domestic in character, and no doubt it may be so designed as to combine dignity with this, but too often it is but a mean and characterless erection, wanting in largeness and breadth of treatment; an impression still further emphasised by the effect of gates of elaborately twisted and spiked

ironwork, which have an appearance quite out of keeping with the traditional sentiment of an English country mansion, importing into its environs suggestions of Birmingham, and an appearance of ostentation and unrest, a desire to be handsome, which is what the old style of gateway seldom or never suggests. The entrance gateway is an opportunity for much that is novel, and at the same time graceful and dignified in design; and towards realising these qualities in the approaches to modern mansions there is a good deal to be gathered from the study of those of the last and the early part of the present century. We may not imitate their details or the faded character (artistically speaking) of the ornamental accessories; but in regard to general treatment they afford much suggestion. Two things are to be observed in contriving park entrances—that they should always be so planned as to give a wide space in front of the gate and throw the latter well back from the road; and that if an arch is thrown over the gateway, necessitating a somewhat large erection, it should be flanked in its immediate vicinity by walls sufficiently high and important to give something like an adequate support to the entrance, and give a kind of reason for the arch. A

countries and nations, which would afford opportunities for a fresh point of departure in the architectural embellishments of an entrance; but those of our own country merit more attention than they have received, and often afford very pleasing specimens of purely artistic architecture.—“Builder.” [Like the man who listened to a somewhat long-winded song, and preferred the last note to all the rest, we think the writer of the above interesting article has put the whole gist of the matter into the sentence we have italicised. Nothing can be more ridiculous than to plant a magnificent arch gateway fit only for some baronial castle, by the side of a country road, flanked by low hedges on each side.—Ed.]

THE FRUIT GARDEN.

OCTOBER AND NOVEMBER PEARS.

THE list of October and November Pears is almost endless; the following are illustrations of a few of them, and, as the notes concerning

Fig. 1.—Dr. Lentier.

Fig. 2.—Soldat Laboureur.

Fig. 4.—Delices d'Hardenpont.

Fig. 4.—Nouveau Poiteau.

Fig. 5.—Beurré Clairgeau.

Fig. 6.—Alexandrine Douillard.

lofty arch set up to drive under, with only a low fence or wall on either side of it, looks absurdly pretensions and unreal, unless it be a *bona fide* triumphal arch. The addition of a lodge or house on either side as part of the design, and incorporated with it, gets over this difficulty, and furnishes the requisite *appui* to an arched entrance; but it is hardly justifiable to make houses which are not really wanted for this purpose of mere effect, as we sometimes find them. On the whole, except in cases when the thing is done on rather a large and stately scale, it is perhaps well to let a gateway be simply a gateway, and trust for effect to the way it is arranged and lead up to, and the manner in which the architectural details flanking it are treated. By way of a new idea, however, for this kind of design, we have sometimes thought that the Indian gate-pyramids afforded a suggestion worth working out in another form, and with another class of detail. Such an idea would be only suitable, of course, in connection with the grand entrance to a large and stately domain, in which case the pyramid might have an architectural meaning, as serving to indicate from a distance the position of the main entrance. There are many other forms of gateway design existing in the architecture of various

them are made from personal observation, those who may be contemplating the formation of a collection may derive assistance from them. Dr. Lentier (fig. 1) is a moderate-sized fruit, regularly Pear-shaped, and very handsome; skin shining and pale yellow when fully ripe, flesh white, slightly aromatic, buttery, and melting. We have it growing in the form of bushes on the Quince stock, conditions under which it is most fruitful; it generally ripens about the middle of October. Soldat Laboureur (fig. 2) is a large and very handsome Pear; skin smooth and russety, with a tinge of red on the side next the sun; flesh very rich, sugary and juicy if caught at the proper time, but the fruit soon rots at the core, and will not keep a week after it is fully matured, which is generally about the end of November. The tree is a free grower and of good habit. Delices d'Hardenpont (fig. 3) may be classed as equal to such kinds as Marie Louise, Doyenné du Comice, or Winter Nelis, and therefore worthy of a place in every good collection. It is of moderate size generally, but occasionally large; skin green, covered with patches of russet; flesh melting and highly perfumed, and the fruit will keep for a long time after being fully ripe, a consideration

of great importance in the case of any Pear. Its season is about the middle of November, but we have had it 'at Christmas. It is most fruitful on the Quince stock, but it also does well on the Pear. Nouveau Poiteau (fig. 4) is a large Pear of exquisite quality, but it possesses the great drawback of not keeping well, in this respect it is most deceptive, and therefore not to be recommended, though the tree is of fine habit and free growth. Beurré Clairgean (fig. 5) is a grand market growers' Pear, being productive and excellent as regards appearance; flesh second rate in flavour, being sweet, but gritty and coarse grained. It does well either as standards, bushes, or espalier fashion. It ripens generally from the middle to the end of November. Alexandrine Douillard (fig. 6) is in every respect an excellent Pear. It is one of the most certain bearers with which I am acquainted, the fruit is large; skin greenish-yellow, suffused with red on the sunny side; flesh white, melting, and richly perfumed. Its season of maturity is November, but it will keep for a considerable time after being fully ripe. The tree is a free grower and well adapted for training in the form of bushes or pyramids.

W. W. H.

FIELD CULTURE OF HARDY FRUIT TREES.

(Continued from p. 428.)

DISTANCES AT WHICH TO PLANT.—As a rule, tall fruit trees are grown too close together. They require plenty of air and room, otherwise they only bear fruit on the ends of the branches. The following table will give the proper distances apart for planting the ordinary kinds of fruit trees in different situations in soils of ordinary character:—

Sorts.	Planted in single lines.	Planted in rows.	Planted in orchards.	Planted in cultivated fields.
	ft. in.	ft. in.	ft. in.	ft. in.
Apricot	16 3	19 6	26 0	32 3
Apple	26 0	32 6	39 0	48 9
Chestnut (grafted)	26 0	32 6	29 3	29 3
(ungrafted)	32 6	39 0	26 0	26 0
Cherry (sweet)	19 6	22 9	29 3	39 0
(Morello)	16 3	19 6	26 0	32 6
Mulberry	29 3	20 9	29 3	29 3
Walnut (grafted)	26 0	32 6	29 3	29 3
(ungrafted)	32 6	39 0	35 9	35 9
Pear	22 9	29 3	35 9	45 6
Peach	19 6	22 9	29 3	39 0
Plum	16 3	19 6	26 0	32 6

We must also take into consideration various other circumstances which modify the rules laid down above, such as the richness of the soil, its relative dryness, whether it is situated in a hollow or in the open. In any case, it is better to err on the side of too much room than too little, for it has been shown that, with half the number of trees planted in a given area, a much larger yield of fruit is obtained than from double the quantity crowded together in the same space.

MIXED PLANTING.—The large spaces between the trees should not be allowed to remain unoccupied, as smaller or less vigorous varieties may be planted in the vacant ground, as shown in fig. 37. If the plantation has been made in quincunx,

Fig. 37.

the extra trees may be disposed as shown in fig. 38. Of course, as soon as there is any danger of the new trees hurting the

Fig. 38.

old ones, they should be transplanted to another situation. The extra trees are marked with an x in both the cuts. The Pear grafted on a dwarf Quince is very suitable for growing in this way. During the first few years vegetables of all kinds

may be planted between the trees, more especially if they require copious manuring from time to time. Spergula, Lupins, and similar forage plants may be sown between the trees of a new orchard, and dug in when in full growth, with great benefit to the land. In dry and poor soils this method is often surprisingly successful. In the case of poor or worn-out soils, in which it is desired to plant young trees, Potatoes, or some of the plants mentioned above, should be planted and dug in during the first year. Wherever trees are found to be injurious to herbaceous plants, it is entirely on account of their being planted too closely together. When at a proper distance apart, the shadows of the trees do not fall continuously, and the herbage receives alternately the benefit of the sunlight, the shade, and the air. It is really only when fruit trees form a thick shade overhead, so that there is an insufficiency of light and air, that they prevent the growth of herbaceous plants. The cultivation of fruit trees in fields and meadows undoubtedly diminishes their yield; the space between the trees should, therefore, be greater under these circumstances than when grown in orchards. In such situations, Apple and Pear trees should not be planted closer together than 45 ft. or 50 ft., the distance for other fruit trees being in proportion, according to the table on this page. Grown in arable land, in favourable years the yield will be large, and the fruit finer in flavour, than those grown elsewhere, owing to the soil being well manured and ploughed periodically. In meadows, the fruit will not come to such perfection, for obvious reasons. Plantations made on the borders of arable land, are deserving of attention, and might well replace the useless trees now so much in use for making hedges. Lines running east and west give the best results, as the trees receive an equal amount of sunshine on both sides, besides which they mutually shelter each other from the northern blast. It may also be borne in mind that the trees cast no shadow on the south side. In planting avenues, the tenderest varieties should always be planted on the sunny side of the line. Winter Pears, for instance, and trees whose fruit is prone to drop, should be sheltered as much as possible.

MANURE.—The best manure for fruit trees in general, is stable manure mixed with vegetable refuse, weeds, meadow earth, rotten turf, river and ditch mud, &c. These materials should be piled in heaps some time before they are required, and constantly stirred and watered with liquid manure of some sort. Pure animal manures should not be used at first, as they are liable to cause the tree to grow too fast at the expense of its roots. An exception may, however, be made in favour of bones, horns, feathers, hair, wool waste, &c., which are slow and gentle in their action. This kind of manure cannot be used too largely; for instance, some trees planted in poor land gave wonderful results by being manured with woollen rags, at the rate of 5 or 6 lbs. per tree. Lime is, perhaps, too little employed in the cultivation of stone-fruit trees, apparently from its nature not being so fully appreciated as it ought. Lime works a most beneficial change in heavy, cold, and damp soils; it renders them lighter and warmer. Being strongly alkaline in its nature, it acts as a caustic on other manures, causing them to be absorbed more easily. It also attracts, mechanically, the gases in the air and otherwise greatly influences the health of the tree and the yield of fruit. Lime has the same effect on clayey soils, especially when well worked in. Lime is also of great value in destroying the growth of Moss round the roots of orchard trees. It is impossible to grow fine qualities of fruit in soils which are deficient in lime. All districts famous for their fruit, are more or less calcareous in their geological structures. No fruit tree should ever be planted without mixing a couple of good shovels of lime with the soil in which it is to grow. Old plaster and mortar, so much recommended as manure for fruit trees, owe their efficacy to the lime which they contain. Wood and coal ashes are also valuable in their way as auxiliaries. Old-fashioned growers have an evil habit of filling the hole in which the tree is to be planted, with a large quantity of manure, as if they intended to supply the tree with manure for the whole of its natural life; but manure buried in this way at a great depth, and out of the way of air and moisture, does more harm to the tree than good.

CHOICE OF TREES.—Trees for permanent planting should have crowns of two or three years growth. The bark should

be smooth, the stems strong and straight, thicker at the bottom than the top. Trees which have a circumference of say $4\frac{1}{2}$ in. or 5 in. at 3 ft. from the ground, and are from 7 ft. to 9 ft. high, give good results. It is, however, difficult to procure young trees of this size, most of them in the market being much smaller. The planting of old trees present too many difficulties for description here. The amount of wood shown by the tree should be quite a secondary consideration, the real points to be regarded are the height and form of the stems, the suitableness of the variety, and its general healthiness. At one time as long as a tree looked strong, and had a good bushy crown its other merits were unregarded.

TRANSPLANTING.—This operation is generally carried on with great carelessness, the roots being wounded and bruised, or even chopped off as if they were a mere secondary consideration. To transplant a tree properly, a circular trench should be dug deep enough to reach the lowest roots, so that the tree may be lifted without any large amount of force being necessary to free them from the surrounding earth. As much of the earth adhering to the roots as possible should be procured, and the place to which the tree is transplanted should be as near as possible, so that the tree may suffer as little as may be. If necessary, a tree may be transplanted before it has lost all its leaves, if the precaution be taken to pull them off immediately before or after transplanting. The best way is to pull them off at intervals before the tree is removed; it is, however, best to wait until the tree has shed its leaves of its own accord. When young trees have suffered during their journey from the nursery they should not be planted immediately. The roots should first be dipped into a thin lute formed of clay and cow manure, and put aside in a pretty dry airy place. In the case of trees which have been planted in the same place for several years, a hole should be dug round the tree the year before the plantation is to take place, cutting the ends off the roots, and caving under the tree itself. The circular trench thus formed should be lightly filled up with earth. In consequence of the ends of the roots being cut off, the tree will throw out a number of small radicles. The next year the rest of the earth is removed, and the tree may be transplanted under the best conditions. All strong healthy trees, especially Apple trees, will bear transplanting up to the time they are eighteen or twenty years old. If intended for transplanting, the larger branches should be allowed to remain intact, the smaller ones only being thinned out from the centre of the crown.

TIME FOR PLANTING.—Trees which bud early should be planted from the end of October to the end of November in light and dry soils. As for trees which bud late, especially Mulberries and Walnuts which have fleshy roots, as well as for trees which are intended to be planted in strong, damp soil, spring plantations may be equally recommended. In spite of the advantage of late autumn planting it is always better to stretch a point, and plant at the beginning of the year rather than defer it for a whole season.

Before planting, the whole of the exposed portions of the roots should be examined, the rotten parts pruned away, as well as those which show a tendency to descend. The creeping roots, on the other hand, should be preserved intact. Clean cuts soon heal, and form large quantities of fibrous rootlets. In the case of old trees, or of trees which show but little tendency to ramification, it is often advantageous to make annular and longitudinal incisions in the roots, in order to provoke the formation of new ramifications. The ground being well prepared, it will be necessary to dig a round hole, the bottom of which should be raised in a conical form, so that the roots may be easily put in their proper positions. A puddle of clay and cow manure should be used in the case of all trees, whether young or old, as it greatly encourages the growth of new roots. The tree being placed in its proper position, the roots are spread out and covered with rich soil, which will facilitate the growth of the new roots and rootlets, the hole being filled up with earth, beneath which a layer of manure has been placed in such a position as to be only a few inches below the surface. This part of the work should be performed by at least two workmen in order to ensure complete success. Manure for fruit trees should never be turned under the roots, but over them, and as near the surface as possible. The trees should be moved backwards and forwards several times while the earth is being

filled in, otherwise cavities will be left between the roots. Great care should also be taken to pull out the roots to their fullest extent. They should be laid as flat as possible, and near the surface of the earth. The soil should also be frequently trodden down with the feet during the filling in. The amount of sinking which takes place after heavy rains should be allowed for, otherwise the roots will ultimately become buried too deeply. The point of junction between the roots and the trunk should always remain above the surface; deep planting is most injurious for all descriptions of tree, no matter how good the soil may be in which they are planted. This is a very important matter in the case of heavy ground in low situations, where it is necessary to plant on hillocks. Mr. Van Houtte adopted a system of planting which appears to have its advantage. It consists in leaving a drum-shaped hillock in the middle of the puddle in which the tree is to be planted. The hillock is lowered below the surface of the soil, the top being flat. If the earth is light it should be well beaten before digging so that the hillocks may be as hard as possible. The tree is then placed sitting as it were on the top of the hillock, the rest of the operation being finished in the usual manner. The roots being placed in this position do not descend, but spread parallel with the surface of the earth. Planted in this position they act as supports to the tree from the very first day of planting.

PLANTING ABOVE THE LEVEL.—One of the greatest improvements lately introduced into the art of tree planting, whether for use or ornament, is that of planting on hillocks or mounds, raised more or less above the level of the soil, according to circumstances. When we attentively consider what goes on in Nature, we shall find that trees, placed on slight elevations, are always more vigorous than those sunk in hollows, even when the former have part of their roots exposed. When, for any reason, the lower portion of a tree above the root is covered up with earth, the tree always suffers: except, indeed, it belongs to one of those varieties which have the power of emitting roots from the trunk when it is covered with earth. On the other hand, where the ground is lowered and the earth round the tree is shaped into the form of a hillock, the tree does not suffer, or if it does, only during the first year. Loudon in his "Villa Gardener," tells us that deep planting is the cause of the decay of numberless fine trees in old gardens. Baron H. E. Von Manteuffel, a large forest proprietor, has shown the advantage of the system of planting on mounds, especially in filling up empty spaces in forests. In hillock planting, the only thing to be feared is that the tree will grow crooked during the first few years; but this may be easily avoided by proper staking and training. No matter what system of planting be adopted, trees must be properly staked and trained, so that the only objection which has been raised to hillock planting vanishes immediately we come to consider the subject. The ground must, of course, be levelled before commencing to plant by this method; after which, the trees are placed in the position they are to occupy, the roots being covered with rich earth, turf sods, a layer of manure, and a final covering with ordinary soil. Frequent treading down must on no account be omitted.

AFTER OPERATIONS.—Immediately after the plantation is finished, the surface of the earth round the tree should be covered with rough straw or stable manure, which must be kept up during the whole of the winter following, so as to preserve the roots from frost, as well as to ensure their re-striking as soon as possible. This protection may be renewed year after year with great advantage, even in very dry situations. Straw may be replaced by Grass cuttings, water weeds, decomposed tan, Hop waste, or Flax and Hemp refuse. In the farmyard, where fowls are apt to lay the roots of trees bare by constant pecking, they should be protected either by brick or tile paving or by covering the lower portion of the trees with faggots, branches, Rushes, &c.

The Formation of the Crown of the Tree.

Although a well formed crown need not be perfectly symmetrical, and may, to a great extent, be allowed to grow in a natural way, certain rules ought to be observed in helping the tree to form a mass of branches suitable later on for bearing productive shoots.

FIRST PRUNING.—By properly pruning the principal shoot, two, or better still, three, buds should be left at equidistant spaces round the stem, as shown in fig. 39. They should not be too near the graft, otherwise they will produce a large nodosity, which is equally objectionable to the sight, and prejudicial to the tree. For this reason, we should have but a single shoot to each graft. Commence the graft upon this at a distance of from 4 in. to 6 in. above the place where the graft is inserted. The pruning of the graft for the formation of the first main branch of the tree, should be performed in a parti-

Fig. 39.

cular manner, as shown at *a* fig. 39. In cutting the principal shoot, in order to obtain the first main branches, it is necessary to preserve three shoots (*b*, *c*, and *d*). Three well-placed buds are chosen, and the top of the shoot is cut down to within 4 in. or 5 in. of the uppermost bud, the buds between being rubbed off. By this means, a small shoot is left above the last bud, which is cut off the following year, during the winter pruning. This little shoot forces the upper shoot to grow vertically instead of horizontally, and it also prevents the latter from becoming stronger than the other branches. The three first branches of the crown ought always to be of equal vigour, and placed in a triangle. By paying a little attention, it will soon be perceived that when trees are pruned immediately above the bud, which ought to develop into the first shoot (see fig. 39), generally grow in a flattened form, in which case it is extremely difficult to induce the shoots to grow. The formation of the first branches by this method of cutting, is of great practical value, whether we want to grow only a few young trees, or to produce a large number for the nursery.

(To be continued).

Best-bearing Apples and Pears.—Lord Suffield, on the Crab stock, bore this year a full crop of fine fruit, as did also Manks Codlin on the same stock, and likewise Cellini; on Hawthornden there was a fair crop, but spotted; Wyken Pippin bore a full crop, as did also Warner's King and Russian Apple, the last a very pretty early Apple, but not first-rate; on Northern Greening there was a full crop. The above are all dwarf bushes. Calville Blanche, on the Paradise stock, on a south wall, ripened a full crop of fine fruit. Of Pears, the best were Duchesse d'Angoulême, on the Quince stock, in the form of a pyramid; Benrre Hardy, on the same stock; Seckel, on a wall with an east aspect, bore a good crop; as did also Winter Nelis, on a wall having the same aspect. Pears, with these exceptions, have been a failure, there being only odd ones here and there on the trees. On pyramid Pears that were well protected, there was a good show of bloom, and fruit set, but it all fell off. Josephine de Malines, Gansel's Bergamot, Beurré de l'Assomption, Beurré d'Aremberg, Knight's Monarch, Marie Louise, Doyenné du Comice, Pitmaston Pear, Durondeau, Leopold IV., Loniee Bonne of Jersey, Bergamotte d'Esperen, and Benrre Clairgeau, although well protected with hoops and Spruce boughs, all failed.—DAVID LUMSDEN, *Bloxham Hall, Lincoln.*

New Vine Disease.—At the last meeting of the Woolhope Club (Oct. 4), M. Maxime Cornu, of Paris, described a new Disease of the Vine, which had been brought under his notice in plants from the neighbourhood of Narbonne. It is there called Anthracnose, because it appears like dark burnt spots on the leaves and branches of the Vine, and even on the Grapes themselves. In the first or condions stage the spots are white, and in the second stage they

present the blackened and charcoal-like appearance that has given the popular name to the disease. It belongs to a fungus named by Berkeley and Curtis *Phoma nivalis*. Its third condition is yet to be observed. The disease has been introduced into France with young plants from America, and has now been observed in several places. The Vines are also attacked by another fungus named *Cladosporium viticolum* of Cæsati, which is recognised by its dark brown velvety spots, which have been known for some years; and now it has been pointed out by Dr. Farlow, at Boston, that the French Vines in America are attacked by an ally of the Potato fungus in *Peronospora viticolum*, which attacks the young shoots and branches in the most destructive manner. M. Cornu dwelt on the importance of the most careful attention to the study of these diseases, and called for the assistance of English mycologists in their observations. The remarks were illustrated by most carefully executed drawings of the fungi named above, and their effects on the leaves, stems, and fruit of the Vine.—“Florist.”

Erect Training.—Mr. R. Gilbert having expressed some doubts as to the distance being sufficient between the branches of the Pear-trees figured on p. 393, we may point out that the photographer, wishing to show the wall in its length and height, placed his apparatus

too much at the side to allow of the spaces between the branches being fairly represented in the engraving. The accompanying cut from a much lower, but also remarkably well-furnished wall, gives a better idea of the spacing of the branches. It is from a photograph taken in April last.

Casimiroa edulis Fruiting in Ireland.—This so-called Mexican Apple has recently been fruited in the gardens at Kylemore Castle, Galway, the seat of Mitchell Henry, Esq., M.P. The gardener, Mr. Garnier, states that the plant, which was sent out by Mr. Bull some nine or ten years ago, is now a tree about 10 ft. high, with a clear straight stem and a beautifully-formed head, about 5 ft. through. It seems to require some years before it produces fruit. Two years ago it showed some small fruits which did not come to maturity, but others produced this year grew to the size of a good specimen of a St. Michael Orange. The tree is said to be very prolific. Mr. Garnier considers it the best of all the tropical fruits with which he is acquainted. It begins to grow at the end of September, just as the fruit is gathered, and swells very rapidly, soon completing

its full growth. The fruit is borne on the two-year-old wood, not in the axils of the leaves; it is of a greenish-yellow colour when ripe, and has a delicious melting flavour, like that of a Peach. At Kylemore it is grown in rich, perfectly-drained friable loam, mixed with a little peat, and in a large, lofty span-roofed tropical house, which is never heated much beyond an intermediate temperature. Though it has received the name of Apple, the Casimiroa is more strictly an Orange. The foliage and the outer part of the flower are studded with transparent oil-cysts, as in the Orange, but the leaves are digitate, and the flowers are less conspicuous than those of true Oranges. The tree is a native of Mexico, where it is found in a wild and cultivated state; it has also been widely distributed through various parts of America. Seemann, in the "Botany of the Herald," says it has a remarkable tendency to accommodate itself to different climates; it grows from the lowest coast region to an elevation of 7000 ft., producing everywhere an abundant harvest. The fruit is said to produce a somniferous effect, and the seeds are reputed to be dangerous, so that caution is needed in the use of it. It seems likely that in many parts of India, the Cape, and the Australian colonies it would prove a valuable introduction.

Cure for the American Blight.—I find that this troublesome Apple-tree pest can be readily exterminated by the use of common train oil. Some of the best kinds of dessert Apples are here trained to a low wall, with an east aspect, and had, for several seasons, been much infested with American blight, while several remedies had been resorted to, without, however, effecting a cure, or at all mitigating the evil. Early in March last the trees were unnailed from the wall and pruned as usual, but before they were again secured to the wall, they were thoroughly painted over with train or fish oil. This was applied with an ordinary paint brush. The trees had much the appearance of having been varnished, and some apprehension was felt as to the safety of the bloom-buds, which were considerably developed at the time at which the oil was applied. The trees were, however, again secured to the wall, and the result has proved all that could be desired. Not a bud appears to have been injured; the trees have a clean and healthy appearance; not a vestige of the blight is to be perceived; and the fruit which they have borne this season has been finer than usual.—"Florist."

Keeping Apples.—The superb samples of Apples that Mr. Ford, of Leonardslee, so often exhibits in the month of March, at South Kensington, are the admiration of all who see them. They are not only fine examples of fruit, but are also shown in the finest state of preservation. No doubt soil and perfect ripening have much to do with the matter. The tissues of the fruit are well developed and fully matured, and thus there is a firmness and plumpness that is not always found in large fruit. Mr. Ford asserts that all his fruits are stored on shelves, in a large, airy, yet cool, Apple-house, and that they are never sorted over, or in any way handled until wanted for use; even any that may go rotten are not picked out specially. Whatever this let-alone practice may have to do with keeping fruit, no doubt his chief reliance is plenty of air and a regular cool temperature. Apples, like Potatoes, are much weakened by sweating, and although it is, to some extent unavoidable during dull, muggy weather, or on the break-up of frost, yet it is alleviated if plenty of air can be given, and the moisture soon dried up. Potatoes are almost as difficult to keep as late sorts of Apples, but even the earliest sorts will keep sound and plump a long time after the usual period for planting, if exposed on a dry shelf to plenty of air and a cool temperature. I have seen and eaten excellent samples that had been kept for more than a year, but, of course, these had not been exposed to the external air, but were wrapped in paper and laid on shelves, or kept in dry sawdust. The great point is to secure an equable temperature, as it is the fluctuations incidental to our seasons that so severely test the keeping qualities of both Potatoes and fruit.—A. D.

Extra Growth in Apple and Other Trees.—Those who were dissatisfied with the excessive rainfall last year will, I think, admit that the extra vigour of their hardy fruit trees has fully compensated them. In this locality the rainfall has had a marked effect on the growth of all trees. In the gardens here, some very old Apple trees, whose growth has been of a stunted character for years, appear now to have taken a new lease of life; some of their shoots are quite 3 ft. long, their usual growth being from $\frac{1}{2}$ ft. to 1 ft.; the bright sunny weather which we have lately had, too, has ripened the wood wonderfully, which augurs well for next year's crop. Some trees of Ribston Pippin and Blenheim Orange, whose fruits usually come speckled, and never keep, have this season borne a fair crop, of excellent quality, clean, and large; in fact, some of the Blenheim Oranges measure 14 in. round. The roots of these trees must be down in the subsoil, as they are growing in the kitchen garden, which, though trenched 2 ft. deep last year, not a trace of roots could be found.

Whether or not they have been cut off by former trenchings, I cannot say. The great quantity of rain that fell last year must have washed the substance of the manure down to the roots in such abundance as to cause the extra growth in question. Apricots on walls appear to have been equally benefited, judging by the gross appearance of their growth, which is ripened and well set with buds. Fruit trees, however, are not the only ones that have been benefited by the excess of rainfall last year, for forest trees have also made extraordinary growth, which, I have no doubt, many will find by the increased quantity of leaves which they will have to clear away—a source of annoyance to some, but of benefit to many who, like ourselves, have to make manure of every scrap of vegetable refuse which they can find.—W. W., *Eaglehurst*.

IMPROVING WEAKLY FRUIT TREES.

LORD BACON, in one of his admirable essays, wrote—"If you will have a tree bear more fruit than it hath used to do, it is not anything you can do to the boughs, but it is the stirring of the earth and putting new mould about its roots that must work it." Well-managed trees are always a redeeming feature, even when other matters in the garden furnish evidence of niggardiness or neglect. No doubt cold springs and other unfavourable climatal conditions exert at times a prejudicial influence, but well-managed trees, that have a sufficiency of healthy roots, are never permanently crippled, however much they may be temporarily checked by unfavourable weather. Keep the roots in a healthy, growing condition, and the branches, if properly cared for, will soon recover their natural vigour. There is no better way of keeping trees in health than by, as Lord Bacon says, putting new mould about their roots; and November is the best month in which to do such work. It often happens if a watchful eye be kept on the trees, and the first symptoms of failing health noted, that some new turfy mould placed about their roots brings them into a healthy fruit-bearing condition, instead of going from bad to worse until, ultimately, they have to be removed to the rubbish-heap. It is only another example of the truth of the old adage "A stitch in time saves nine," and not only so, but it saves a good deal of heart-burning besides, as it lowers a man not only in his own estimation but also in the estimation of others, to have his trees in bad health from causes that ought to be under control. There are some places where new turfy mould is difficult to obtain but something might be done—some effort made—at least to shift the responsibility of failure—if failure there must be. A very large number of fruit trees die annually, or are removed incurable, that might have been restored to health if new turfy mould had been placed round their roots in time. But the work should be done carefully and, if possible, without unnecessary exposure. In carrying out the details of such work, one must be guided in some measure by the condition of the trees, the position which they occupy, and the quantity of new mould at command, but the more of the exhausted soil we can remove, supplying its place with fresh, the better will it be for the trees, and the longer will they live and bear good fruit. I need hardly say that all bruised, broken, or unhealthy roots should be pruned away. E. H.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Storing Apples and Pears.—I agree with "H." that Apples should be stored in sand to keep them from shrivelling, provided the sand be perfectly dry. This, indeed, is one of the best ways of keeping Apples all the year round. I have even known the French Crab to keep in sand for two years, and then appear quite plump and fresh. Pears may be kept in the same way. Catillac, in particular, I have seen kept for twelve months in sand when the fruit was sound when stored, as one bad fruit will cause the sand to get damp and will destroy a great many.—W. W., *Eaglehurst*.

Autumn Strawberries.—I have 'no Héricart de Thury (or Garibaldi) Strawberries in my garden, but I have this day (Nov. 5) a small dish of ripe Strawberries on one plant. I send you a sample, and shall be glad to know the name, as the bed is made up of various sorts. Is it Souvenir de Kieff? As a proof of "the mildness of the season" you need not quote Devonshire or Cornwall, but refer to Boston, in Lincolnshire, five miles from the sea, on the east coast.—C. W. [Too much crushed in transit to be recognisable.]

The Best Bearing Apples.—Although this part of Hampshire is not a noted one for Apple culture, yet a great many sorts are grown hereabouts which are good croppers. Amongst dessert kinds I find the following to be about the best, viz., Summer Golden Pippin, King of the Pippins, Cox's Orange Pippin, Gooseberry Pippin, Golden Winter Pearmain, and Red Russet. The best kitchen sorts are, Manke Codlin, Winter Codlin, Blenheim Orange, Ecklinville, Hawthornden, Northern Greening, Profit, and one or two local sorts for which I cannot find names.—W. W., *Eaglehurst, Fawley*.

THE KITCHEN GARDEN.

DISEASE-PROOF POTATOES.

I ADMIT that this term is not a well chosen one, but granting its inappropriateness generally, something might be said for it in the strictly-limited and local sense in which I applied it. If I, or any other cultivator, in the course of experiments extending over a considerable number of years, find certain varieties to invariably give satisfactory results, one may be excused for looking upon them as disease-proof, although, as I have said, the term is not a good one, and I thank "A. D." for calling attention to it. I cannot, however, help thinking that the position which he has taken up as regards small Potatoes will ultimately become untenable, for no matter from what point of view we examine this question, whether we look at it in a broad national sense, as forming not only a great industry, but also an important food supply, or whether we take a narrow view, restricting the case to ourselves individually, the conclusions arrived at must be the same, viz., that a crop of small Potatoes is in every sense a failure. Of course size, like everything else, is comparative; but if "A. D." occupied a position as gardener in a private establishment, or even if he sent his produce to market, if he had nothing larger than hens' eggs to show, the result would neither be pleasant nor profitable. The truth is, if we are to hold our own in competition with foreigners, we must in some way grow a fair crop of good-sized tubers—a crop, in fact, that will pay. I suppose all will agree that cold, heavy land is not so suitable for Potatoes as land of a lighter character; but it is possible in garden culture so far to modify our practice as to obtain a good crop on such land, even in bad seasons. Perhaps there is no better plan, at least I have not yet seen a better, than to throw the land now into 4-ft. ridges, rather steep, and in the spring round the crest of the ridge a little; draw drills along the top, 6 in. deep, and plant the Potatoes, covering them in a good depth. The rows will be 4 ft. apart, which will be none too much room for strong-growing late Potatoes. In June a row of late Broccoli could be planted in each furrow; and, when the Potatoes were lifted, a row of Lettuce or Spinach might be planted on the top of each ridge. Of course, the following year the Potatoes would be planted elsewhere, and this plot will come in for Celery, Turnips, or late Peas. Any one accustomed to watch the seasons, can generally tell, by the heavy oppressive atmosphere, and other indescribable symptoms, that the disease will break forth in a few days, and it is at the beginning of this period that the crop must be lifted if it is to be saved, or the less radical measure of cutting off or pulling up the tops may be adopted to gain time till the whole can be taken up. The term "manuring" ought to be amplified and extended; at present, with a good many people, it simply means digging in so much farmyard refuse mixed with decayed straw; but a moment's reflection ought to convince any one that a much wider signification should be given it, especially in dealing with Potatoes on heavy land. In the latter case phosphates, burnt earths, the bottoms of charcoal heaps, the gritty material that is obtained from the edges of roads, soot, lime—in short, anything that will supply what the crop requires in the way of stimulants, and strengthen and harden the growth at the same time. The whole art and mystery of manuring, I take it, is to obtain a clear perception of the deficiencies of the land, and the requirements of the crop, and, as far as possible, to supply what is lacking in the former that the latter needs. Manuring is too often a very haphazard proceeding. E. HOBDAV.

PREPARATION OF GROUND FOR RADISHES.

It is absolutely necessary that some considerable pains should be taken to insure a free and moist root-run in well-enriched ground if Radishes are to be grown in perfection. It is often customary to sow them and other salading indiscriminately in any piece of ground which may happen to be in readiness or become vacant. This is, however, a mistake, as the soil, from being partly exhausted by a previous crop, and perhaps become somewhat lumpy and sour, is in a very unfit state for the reception of the seed. It would be much better if, at the close of the year, a spot of ground were selected and

retained for this purpose alone during the ensuing summer. It could then receive careful preparation, and would always be in readiness. This latter point is not the least advantage which would accrue to the grower from an early preparation of the soil, as a break in the supply will sometimes occur through not being able to sow in time. Whilst the ground is being prepared the seed should be sown. The most suitable soil for the Radish is that which can at any time be easily and freely worked with the fork; a light and somewhat sandy soil, that has been well enriched with rotten manure, will best promote that free root-action which it is so necessary to secure, and without which tender and well-flavoured Radishes cannot be grown. If the soil should therefore be as above described, it will be easily sweetened and pulverised by well stirring it with a fork; it will then only be necessary to afford a liberal supply of nutriment during the growing season. This is best accomplished by working in a good portion of thoroughly-decomposed manure; that which has been used for hot-beds, and which has been turned over several times, is admirably suited for the purpose. Lacking this, short stable manure may be employed, removing the straw thoroughly, breaking all lumps, and working it in to at least the depth of 1 ft. Should the soil be of a stiff, tenacious character, add a good portion of leaf-mould, wood ashes, or any light material which may be obtainable; about this time of year it should be ridged up, and should remain in that condition during the winter. In February, manure should be added, and it should then be half trenched, burying the top 6 in., and bringing about the same quantity up in its place. This should be laid up as roughly as possible, in order that it may become thoroughly sweetened by the time when it is required for use. Manure may again be added at discretion. A good depth of free, well-prepared soil will thus be secured, and the extra pains bestowed on its preparation will not be regretted, especially if a hot summer ensue. In shallow or unsuitable soils, a few days' hot sun burns up the fibres, and watering is almost useless. This is mainly the cause why hard, dry, sticky Radishes are more the rule than the exception. Where a good deep root-run is provided, water may be given with beneficial effect, and a good soaking now and then will suffice to keep the plants growing without check. It is from the beginning of June onwards up to the end of August that the greatest difficulty is experienced. It is, however, comparatively easy to have good tender Radishes at any time, provided the requisite precautions have been taken to promote free root-action. Frequent sowing is, of course, indispensable, and this operation must be so conducted as to preclude the possibility of failure in germination. If the weather be hot and parching, the best way is to well water the ground at night, and early in the morning sow the seed thereon, which should have been previously soaked for twenty-four hours, and mixed with sand, to admit of its better distribution. Cover with some light soil, which should be firmly pressed down, and then lay some boughs or old Pea-sticks over the bed. Quick and free germination will thus be secured. If sown broadcast, 4-ft. beds are the most convenient size, as the plants can then be easily thinned and weeded; or they may be sown in drills about 9 in. apart. Of the two methods, sowing in beds is, however, rather the best, as the Radishes can there be more easily drawn when fit for use.

JOHN CORNHILL.

Byfleet.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Over-grown Brussels Sprouts.—We have lately examined a sample of unusually large and seemingly very fine Brussels Sprouts, of which, however, about one in four proved decomposed inside. They were, therefore, although freshly gathered, quite unfit for use. M. Vilmorin had good reason to remind us that the Belgians, who ought to know something of their own Sprouts, always prefer the very small Sprouts.

St. John's-day Drumhead Cabbage.—In the interesting trial of Cabbages at Chiswick, there is a very neat little kind of Drumhead grown under the above name, which Mr. Barron thinks very highly of. It was received from Messrs. Vilmorin, Andrieux, & Co., of Paris. No doubt somebody will take it up and re-christen it, giving it a new name as an English variety. This has already been the fate of several well-known Continental kinds.

Stott's Monarch Rhubarb.—He who has not tasted this Rhubarb has a treat to come, for without exception it is the most delicious as well as the finest Rhubarb grown. Its stalks and leaves are of size growth, and as a plant for covering large surfaces it will be found most useful.—W. H. CULLINGFORD, Kensington.

A Substitute for Potatoes.—A note going round the papers says that "a company has been formed for the importation and cultivation of the French Haricot Bean in this country; the promoters of the new Haricot Planting Company believe that the old prejudice against foreign vegetables has died out, and that the Haricot Bean will be gladly accepted as a welcome substitute for the Potato." This strikes the horticultural reader as somewhat odd work for a company.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 6.

AMONGST the most attractive subjects shown on this occasion were groups of Orchids from Messrs. Veitch & Mr. Ollerhead; and a collection of cut flowers of hardy herbaceous plants from Mr. Parker.

First-class Certificates.—These were awarded as follows:—

Sarracenia chelsoni.—A beautiful bronze-leaved hybrid, of free-growing habit, the result of a cross between *S. rubra* and *S. purpurea*.

Primula capitata (Horticultural Society's Gardens).—An interesting Alpine plant, bearing trusses of bluish-purple blossoms.

Dicksonia Berteroana (Veitch).—A graceful-habited Tree Fern, perfectly distinct from any yet in commerce.

Melon Exquisite (Peyle).—A green-flesh variety, thin-skinned, and excellent in flavour.

Miscellaneous Subjects.—Amongst Messrs. Veitch's Orchids were good examples of the winter-flowering *Calanthe*, and a beautiful new hybrid, the result of a cross between *C. Veitchi* and *C. vestita*, the flowers of which are very brightly coloured, rendering it a valuable addition to winter-flowering Orchids. The same firm also showed some good *Oncidiums* and Indian *Crocuses* (*Pleiones*), and a garden variety of *Adiantum cuneatum* named *Lawsoni*, a kind with long slender fronds and remarkably light and elegant perianth. Good plants of *A. speciosum* and *Vriesea brachystachys* were also shown in good condition. Mr. Ollerhead furnished good flowers of *Dendrobium formosum giganteum*, flowering plants of *Cattleya Dowiana*, *Miltonia Moreliana*, and good examples of *Calanthes*. Mr. H. B. Smith, Ealing, contributed a group of well-grown *Cyclamens*, the flowers of which were unusually large and well-coloured. Mr. Parker showed *Viola* Sir W. Scott, a kind with large, well-formed flowers of a rich blue colour, surrounding a yellow centre; good blooms of *Helleborus niger maximus*, *Michaelmas Daisies*, *Tritomas*, and others. Good examples of Japanese *Chrysanthemums* in a cut state were contributed by Messrs. E. G. Henderson & Son, Pine-apple Place; and Mr. Davis, Park Nursery, Plumstead Common, sent finely incured varieties of the same useful flower. Sir Trevor Lawrence furnished a remarkably good specimen of *Oncidium crispum*, and Mr. W. Smith, gardener to W. C. Lane, Esq., Henley-on-Thames, sent a finely-flowered plant of *Vanda cœrulea*. Mr. Cannell showed cut flowers of *New Life Pelargonium* in good condition, also an excellent collection of cut blooms of *Zonal Pelargoniums*, amongst which were some new kinds of decided merit; the best whites were *Jean d'Arc* and *Fairest of the Fair*, the latter having, however, a bright salmon centre. Of other kinds there were *Heartsease*, a rich scarlet suffused with purple, and *Lizzie Brooks*, a large-flowered sort, good in form and brilliant in colour. Mr. R. Dean exhibited a good potful of *Godezia Lady Albemarle*.

Fruit and Vegetables.—Examples of Mrs. Pince's Black Muscat Grapes were exhibited in good condition by Mr. Harrison Weir, who also showed Muscat Champion from a 20-ft. rod grown in a ground Vinery. Two bunches of Muscat of Alexandra were shown in excellent condition by Mr. Atkins, gardener to Colonel Lloyd-Lindsay, Wantage; each bunch weighed some 5 lb. or 6 lb., and the berries were large, even, and of a rich golden colour. Good examples of Golden Hamburg came from Mr. J. Hudson, Gunnersbury, and Mr. Wildsmith sent Gros Colman in excellent condition. Pine-apples of good quality came from Mr. J. Dinsmore, gardener to F. Blackwell, Esq., Harrow Weald, and from J. Hudson, Esq. Mr. Tillery, Welbeck, contributed fine examples of the Salway Peach. Selected Brussels Sprouts came from Mr. Gilbert, Burghley, and good Autumn Giant Cauliflowers from Mr. Wilson, Clayton House. Collections of Potatoes were shown by Messrs. Hooper, on behalf of Messrs. Bliss & Sons, New York, and a large collection of fine tubers also came from Messrs. James Carter & Co., High Holborn. Of Turnips, a collection came from the Society's Gardens at Chiswick. Mr. Bennett contributed a punnet of Garibaldi Strawberries in good condition, considering the season.

From Mr. R. H. Hampson, Egerton Mills, Stockport, came an example of his Imperial Horticultural Shading, a cotton net-like material and very elastic.

Parisian Improvements.—That portion of the garden belonging to the Hotel de Luynes which has been cut into by the new Boulevard St. Germain, and in which some fine trees are growing, is to be preserved as a square, at the junction of that boulevard with the Rue du Bac.

Carpet Gardening.—It is probably a matter of taste, but we are inclined to think that geometrical and carpet gardening have been carried to an extreme. We should like to see a little more of the primeval in some of the gardens with which we are acquainted. We miss those quiet little nooks and shaded spots which speak of Nature, and Nature only—spots which do not immediately set one thinking out a problem of Euclid or remind one of the working of a "sampler." Very glorious and beautiful and charming are those circles, and arcs, and squares, and octagons—all formed of growing flowers in their loveliest tints; but they are all suggestive of work—planning, designing, and contriving—a never-ending round of labour.—"Figaro."

SCOTTISH ARBORICULTURAL SOCIETY.

THE twenty-fourth annual meeting of this Society was held in the class room of the Royal Botanic Garden, Edinburgh, on Tuesday last. The Right Hon. W. P. Adam of Blairadam, M.P., president, occupied the chair; and there was a numerous attendance of landed proprietors, nurserymen, practical foresters, and others interested in arboriculture.

The President opened the proceedings with an address, in which he referred to the gradual, steady, and sure progress which the society was making, not only in the number of its members, but in the influence and authority with which it spoke to all connected with arboriculture. He urged all landed proprietors interested in rearing woodlands, and all foresters engaged in that most interesting pursuit to become members of the society. One claim to the position in which he had been placed was, that he came of a race of planters and foresters. He was now the fifth in succession who had specially devoted himself to improving the estate of Blairadam, more by planting than by anything else. He had this advantage over many other races of landed proprietors who had devoted themselves zealously to this occupation, that the planting of Blairadam had become classical through a touch of the magic wand of that enchanter, Sir Walter Scott. Blairadam, in its original and unimproved state before the planting was begun, was a wild unsheltered moor, lying from 500 ft. to 700 ft. above the sea, with a certain amount of natural beauty, and with fine views of the plain of Kinross, Lochleven, and the Lomond Hills. But it must have been cold and bare; it was covered with Heather and coarse Grass, and had only one enclosure, and one tree—an Ash—which, though it still grew vigorously, was far out-topped by the younger generation. He knew of no instance in the improvement of waste land that more thoroughly illustrated the value and advantage of judicious, continuous, and persistent planting than the estate of Blairadam. Silver Fir had always flourished luxuriantly, and was the most remarkable species of tree on the estate. There were four still living, of which he had the girths in 1811, in 1851, in 1862, and in 1877. No. 1 was 8 ft. 4 in. in 1811, 13 ft. in 1851, 13 ft. 6 in. in 1862, and 13 ft. 9½ in. in 1877. No. 2 was 8 ft. 1 in. in 1811, 12 ft. 1 in. in 1851, 13 ft. in 1862, and 13 ft. 3½ in. in 1877. No. 3 was 10 ft. 5 in. in 1811, 12 ft. 11 in. in 1851, 13 ft. in 1862, and the same in 1877. No. 4 was 9 ft. 2 in. in 1811, 11 ft. 5 in. in 1851, 12 ft. in 1862, and the same in 1877. These trees were planted about 1754, and others probably planted about the same time measured 15 ft. 3 in. in girth, 15 ft. 1 in., and 14 ft. 8 in. Five measured between 13 ft. and 14 ft., six or more between 12 ft. and 13 ft., and a great many others between 11 ft. and 12 ft. Three very remarkable Hemlock Spruces were planted about 1757. He did not give the exact girth, as two of them divided into separate limbs near the ground, but one had a girth before dividing of about 12 ft., and the other two of about 10 ft. He was afraid that these trees had almost ceased to grow, and that their gradual decay might now be looked for. He had dressed some of them with compost, but without producing any perceptible advantage. The right hon. gentlemen went on to refer to the necessity for something being done to establish a school for forestry in this country. It was the duty of the society to awake intelligent interest in this question, and he for one should be glad to do all that he could in and out of Parliament to further so praiseworthy an object. The necessity for good schools of forestry was illustrated by what was taking place in India. The wanton destruction of forests in that country had been going on for years. And who could say that the terrible famine which was now devastating some of the fairest provinces of that country, might not be directly traceable to the improvidence of man denuding the country of its natural vegetation, and so altering all the climatic arrangements of nature.

Mr. McGregor, Ladywell, gave in the report on the essays submitted for the usual prizes. A silver medal was granted to Mr. C. F. Amery, forest department, North-west Province of India, for Report on Indian Forests; silver medal to Mr. J. Hutton, Mackintosh Estates, Kingessie, for Report on Woods and Soils on which they Grow; bronze medal for Report on Use of Dynamite and Tonite in Forestry, by Mr. D. F. McKenzie, Murthly Castle; silver medal for paper on The Movement of Fluids in Stems, considered in Relation to the Felling and Seasoning of Timber, by Professor W. R. M'Nah, College of Science, Dublin; gold medal for Collection of British Woods, by Mr. James Duff, Bayham Abbey, Tunbridge Wells; and silver medal for Rustic Work, by Mr. Jas. Springour, Hopetoun House.

Mr. Robert Baxter, forester, Dalkeith Park, read a paper on "Woods for Making Different Kinds of Charcoal, and the Modes of Preparing it." Almost any kind of wood that grew in this country made, he said, very useful charcoal, with the exception of Poplar. Scotch Elm, Spanish Chestnut, and Lime tree he did not regard with much favour, owing to their peculiar bark offering great resistance to the charring process. Beech, Plane tree, Ash, Thorn, Oak, Hornbeam, Birch, Alder, and Laurel could all be employed as charcoal producers. The Yew and Holly made very superior charcoal, as they were very heavy, held well together, and had good lasting qualities as fuel. In conclusion, he entered into an elaborate description of the different processes for making the charcoal.

Mr. Malcolm Dunn read a paper on "Cryptogamic Plants Injurious to Forest Trees, and Their Remedies." He noticed at length instances of the attack of a fungus on the roots of *Wellingtonia gigantea*. The spawn of the fungus had completely choked up the sap wood, and thus killed the trees. The fungus had arisen from the decaying roots of old Elm trees which had been allowed to remain in the ground. The remedy for such attacks was the thorough preparation of the ground before planting, the removal of all dead or decaying wood likely to produce fungi, with careful attention to drainage, and timely and judicious prunings and thinnings.

THE LIBRARY.

FOOD: SOME ACCOUNT OF ITS SOURCES, CONSTITUENTS, AND USES.*

ALTHOUGH professedly forming one of the series of excellent guides which are being published by the Committee of Council on Education, for the use of students visiting the Art and Science collections at South Kensington and the Bethnal Green Museum, Prof. Church's little book may be read with both profit and pleasure by those who are prevented by circumstances from examining the objects of which it treats.

A large portion of the work is devoted to a description of the various vegetable substances constituting the food of mankind. The first vegetable product treated of is Starch in its different forms, a valuable warning being given that the various kinds of amylaceous foods sold under the names of arrow-root, sago, corn-flour, Maizena, &c., are not nourishing in the true sense of the word. Starch is simply a heat-giving food, and cannot produce much blood, muscle, nerve, or bone. Much misconception on this subject still exists in the minds of nurses and mothers who are often too prone to accept the statements put forward by certain advertising manufacturers of the edible starches. The late Dr. Lankester, who, as Coroner for Middlesex, had ample opportunities for observation, boldly affirmed that more than half the deaths of children under six months old, at any rate among the poorer classes, arose from their being fed with corn-flour and other varieties of starchy food. Sugar, from various sources, is next described. We should, however, have been glad to have heard a little more about the cultivation of the Beet in England as a sugar-yielding plant. Prof. Church simply tells us that it has been raised successfully in England on a small scale, but does not explain why the experiments were discontinued. Oils, fats, gums, cellulose, albumen, and caseine are next described, and, skipping an interesting chapter entitled "A Day's Rations," we come to Part ii., which contains nearly 80 pages of information about vegetable foods, beginning with cereals and ending with Nuts and the Dica Bread of the West Coast of Africa. The remarks of the author on the wholesomeness of salads are most excellent. He says that in order to be juicy and crisp, Lettuces, salads, and Cucumbers should never be gathered when they are wilted or drooping after a hot day. Many amateurs, and, indeed, professional gardeners, do not pay sufficient attention to this important point. We are also told that salads and Cucumbers should be cut and trimmed under water, so as not to expose the cut stem or leaf-stalks to the air. The plants will then, if left in the water, imbibe sufficient of that fluid to swell out their tissues to the desired state of crispness. The accounts given of the different kinds of fruit are good, and their dietetic value is dwelt on at great length. Amongst the poorer classes an immense deal of prejudice prevails against the use of raw fruit, on the ground of its unwholesomeness, and many a poor child whose system has been crying out for acids, has been cuffed for spending its farthing on green Apples. In the fourth part ("Food Adjuncts") we have descriptions of the various vegetable spices, condiments, herbs, and colouring and flavouring materials, Tea, Coffee, Cocoa, Tobacco, and Opium. The fifth and last part ("Of Food and Dietaries") will be found interesting to the general reader. The index is hardly sufficiently copious, but this defect is made up for by the systematic way in which Prof. Church has arranged the various subjects of which he has given us so interesting an account. C. W. Q.

WEATHER WARNING FOR WATCHERS.†

IN spite of its somewhat affected title, and sensationally illustrated cover, this little book contains an immense amount of information on the science of meteorology, and the instruments used in its pursuit. The work is divided into six heads—calorification or heating, evaporation, rarefaction, condensation, motion, and electrification. Under the first heading we have an account and engravings of no less than twenty different kinds of thermometers, their construction and the way to use them. The chapter on the Barometer will no doubt be the most useful to the generality of our readers. The author seems to favour the use of the aneroid-barometer where extreme accuracy is not required. According to such enthusiasts as Admiral Fitzroy, Mr. Glaisher, Sir Leopold Mc Clintock, and others, the aneroid is quick in showing the variation of atmospheric pressure an appreciable time before the mercurial barometer shows any signs of the change. The aneroid ought therefore to be a more valuable instru-

ment to the gardener than the more accurate, but less sensitive, mercurial instrument. Before recommending the use of that old-fashioned instrument, the storm glass, the author should have read Mr. Charles Tomlinson's researches on the subject, in which he proves that the changes taking place in the form and position of the floating crystals are due to differences of temperature, and not to variations in the height of the atmosphere. The Barometer Warnings are most useful, showing what kind of weather may be expected according as the fall in the mercury is shown as rapid during a high wind, or a calm, and so on. If such information as this were placed on the dial plates of our barometers instead of the words generally found there we should not be so frequently surprised to see the index pointing to "set fair" when it is promising rain, or *vice versa*. The explanatory card, compiled by Admiral Fitzroy is also given, and should be hung up beside every barometer. The article on clouds contains a large amount of weather lore, which our readers would do well to make themselves acquainted with, a remark which applies with equal force to that on the winds, in which rules are given by which we may calculate with more approach to accuracy, the direction of the wind for two or three days to come by taking note of its previous variations and intensity. The relations between the direction of the wind, and the highest and lowest points of barometrical pressure, are very singular. For instance, let us suppose that in the case of the British Isles the barometer is lowest at Valentia, and highest at Yarmouth. In this case the direction of the wind would be from north to south, nearly at right angles to a line drawn between the two points; that is to say, an observer with his back to the wind will have the highest pressure at the spot on his right and the lowest on his left. We give the above as only one specimen out of many such interesting items of weather lore. The index is absurdly meagre, one hundred references to ninety-six pages crammed with facts is a very poor allowance. The letterpress and cuts are well and cleanly printed.

We have received an interesting account of the new plants introduced to European gardens during the past year, under the title of "Enumeration Methodique des Plantes Nouvelles ou Interessantes qui ont ete Signalees en 1876 par André de Vos." It is well done, and is an extract from the "Belgique Horticole." The author (unlike certain of his contemporaries in England) includes the plants figured in THE GARDEN in his lists.

NOTES AND QUESTIONS—VARIOUS.

Jasminum Sambac.—Would "W. M." (see p. 377) kindly tell us how he manages this plant so successfully? I have grown it for half-a-dozen years, but have always found it a most unsatisfactory plant, owing to its dropping its blooms almost immediately they open. It flowers freely in a pot in the stove or greenhouse, but certainly best in the latter. As to its perfume, I cannot say a word in its favour.—T. SPELMAN, *Derry Castle*.

White Squill.—I observe in the last issue (see p. 418) a note from a correspondent in reference to what I called a white variety of *Scilla sibirica*, and, as I only saw it casually, it is just possible that the variety to which I referred may be a white variety of *S. bifolia*, and not of *S. sibirica*; should I happen to see it again, I will forward a piece of it, if possible, in order that this matter may be set right.—R. M.

Evergreen Hardy Ferns.—What is the best time for planting these in the open ground? and kindly furnish me with a few names of kinds such as will flourish in town gardens.—S. [Hardy evergreen, as well as hardy deciduous, Ferns may be planted at any time of the year, if the weather be not frosty, but if there be one time better than another, it is just before the new fronds rise (April for most hardy kinds). The following evergreen hardy British Ferns are all dissimilar, and fit for planting in suburban gardens, viz.:—

<i>Asplenium Adiantum-nigrum</i>	<i>Polystichum aculeatum</i>
<i>Trichomanes</i>	angulare
<i>Ceterach officinarum</i>	granulidens
<i>Lastrea dilatata</i>	lineare
<i>spinulosa</i>	proliferum Footi, or
<i>cristata</i>	proliferum Wocklastoni
<i>Filix-mas paleacea</i>	Elworthy or Wakleyanum
<i>cristata</i>	cristatum
<i>Bolanderi</i>	<i>Scolopendrium vulgare</i>
<i>crispum</i>	crispum
<i>Polypodium vulgare cambricum</i>	undulato-lobatum
<i>omnicolorum</i>	digitatum
<i>crenatum</i>	fissum
	laceratum
Evergreen thoroughly hardy Exotic Ferns.	
<i>Cyrtomium falcatum</i>	<i>Lomaria alpina</i> , or its var. major
<i>Lastrea intermedia</i>	<i>Polystichum acrostichoides</i>
<i>Goldiana</i>	angulare Branni
<i>marginalis</i>	vestitum proliferum
<i>Sieboldi</i>	setosum
<i>Lomaria chilensis</i>	munitum

Mr. W. Stevens informs us that it is Mr. Knowlton, of Trentham Gardens—not Mr. Legg—who has been appointed to Carton.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

A FEW WORDS ON HARVEST DECORATIONS.

WE live under the shadow of a church truly worthy of our old historic town. It is a building of the fourteenth century, though parts of it belong to a much earlier date. It is in fine preservation, and was restored some twenty years ago by Sir G. Scott. As a work of art it is nearly perfect; it has been the glory and pride of thousands, and will be, no doubt, in ages yet to come, a delight to all who can value a "thing of beauty." We are in the habit of decorating our church at Easter and Christmas, as well as at the annual harvest festival; but this year, when this feast was fixed for October 11, some of the wisacres in the parish shook their heads. "There will not be a flower in the gardens; the frost will have caught the Dahlias; there are no berries this year, and the Corn is black." In spite, however, of these prophecies, and others quite as depressing, our old church never looked more lovely than it did on this particular day. Flowers and Corn were abundant, and they were arranged with the greatest taste. The gas standards (they are very artistic, being some of Skidmore's best work) were gracefully wreathed with Oats, Wheat, and Barley, having sprays of Ivy and bunches of berries tied in at intervals. The desk was adorned with a fringe of Oats and Barberries, these last looking like spikes of coral; and small bunches of Grapes and leaves were added. Below, on the ground, the desk seemed to stand on a small bank of Moss planted with Ferns and flowers. Dahlias, Roses, Tritomas, Chrysanthemums, scarlet and white Pelargoniums, almost appeared to be growing. The pulpit, of carved Oak, also stood in a bed of Moss, into which were sunk pots of Fuchsias, red Pelargoniums, and Ferns. The supports of the pulpit were wreathed with Ivy; above these hung a fringe of Oats 1 ft. deep. The pulpit itself is divided into five compartments; into each of these was inserted a slender framework of wood, which was covered with Oats, and a large bunch of Grapes ornamented the middle panel. The Oak screen is an excellent preservation, and particularly deserves to be noticed. Above it stood a large cross covered with red and ornamented with Ivy; a thick wreath of Barley hung upon it, and on each side were sheaves, one of Wheat, the other of Barley. Depending from the arch of the chancel door was a deep fringe of Oats, like the one which was upon the pulpit. The screen belongs to the rectilinear or perpendicular period in architecture, and its graceful open arches were wreathed with ears of Barley and red Berries, and fringed with Oats. The space at the base of the arches was filled with plants in pots, such as Dracenas, Fuchsias, Pelargoniums, and Palms; these appeared to be planted in Moss, while sprays of Ivy were trained over the lower part of the screen. The tall gas standards on each side of the altar were decorated with Corn, Ivy, and Dahlias, the rails being wreathed with Corn and Dahlias. The reredos is divided into three compartments, the one in the middle being the highest. "Giving thanks always" (the letters formed of Corn on a blue ground) was the appropriate text for the middle division. The two sides bore the word "Alleluia." These inscriptions were placed on the top. The middle compartment was filled in with gold paper, with traceries of leaves. Each side compartment contained six panels, three above and three below; these were likewise filled in with gold, and upon this was a design in light blue paper. This design was traced in Berberis leaves, now turning red; in the centre of each design was a cross, or a double triangle, or a medallion of flowers. The crosses were particularly beautiful; they were made of yellow and purple Dahlias, but the background was composed of leaves of purple Beet. These looked like thick velvet, and had a very fine effect. The triangles were of Corn and the berries of the Mountain Ash. The flowers used for

the medallions were Gladioli, Pelargoniums of different colours, and Roses mixed with Ferns. The stately spikes of the Tritoma looked very well when planted in Moss. This is the very flower for autumn decorations on a large scale, and I always wonder that it is not more generally used. On the altar were three vases of flowers beautifully arranged, the middle one entirely white, the side ones white and scarlet. The background for the flowers was formed of large Ferns. Besides the vases of flowers two antique chalices were filled with Grapes, and the sprays of the Vine tendrils looked very graceful hanging from the bunches. I must not forget to mention that small bunches of Grapes were placed in the middle of the triangles.

I would here strongly advocate the use of natural in preference to conventional modes of decoration in our churches and chapels; most of us are tired of the eternal double triangles, monograms, and other symbols, and would fain exchange them for flowers artistically and yet naturally grouped. The most effective of our devices on the reredos were the medallions of flowers on the lower compartments; they looked as if they were growing; their stalks had been carefully wrapped in wet Moss, and this kept them fresh for days. The rich orange blooms of the Gladioli, contrasted with purple and white Asters and supported by Ferns, looked particularly well, as did also a similar design of pink and white Pelargoniums. The employment of the red and golden leaves of the Vine, the Virginian Creeper, and those of the Berberis (which are just now very beautiful), may be particularly recommended; the rich brown and red leaves of the latter showed well on the blue ground. The leaves of the Ribes sanguineum are also very effective; I have seen them of many different shades of grey and brown, all very lovely. This sober splendour of the fading year, beautiful in its decline, chimes in well with our own thoughts at this time; far otherwise is it with us in spring,

In whose coat armour richly are displayed
All sorts of flowers, the which on earth do spring
In goodly colours gloriously arrayed.

Then everything is fresh and bright. The natural world, awakening from its winter's sleep, hastens to put on a livery of green; but in autumn, when the dark, dull days are approaching, our feelings assume a tinge of sadness. The youth and the prime of the year are gone, and we thankfully accept and cherish all that is left of summer's lavish gifts.

Such is a short account of our harvest decorations. I did not see them on the day of the festival, but, going into the church the next afternoon, I was quite struck with the alteration which brilliant colour lends to a building whose only fault is a certain coldness; it was like giving to a marble statue the hues and the warmth of life. It had been a dull autumnal day, "The rocking winds were piping loud,"

The yellow leaves
Hung on those boughs which shook against the cold.

But, once inside the church, all was changed; a few late gleams of sunlight struggled in and fell on the painted windows—"Rich with many a prophet and many a saint."—and brought out into fine relief the exquisite carving which the hand of time had touched but to adorn. The floral decorations added grace and colour to what was already so beautiful. The rich Oak screen, with Corn and "Ivy canopied and interwove," the fair form of the grand church, gloriously arrayed in her festal robe of flowers; this was a vision of delight which I shall not soon forget.

Every year ought to witness some progress in this matter of church decoration. It is not long since the only thing done in that way here was managed by the clerk, who stuck a few of what he called "boughs" into holes drilled on purpose in the high-backed pews, carefully arranged, as old Weaver describes them, "high and easie for the parishioners to sit or sleepe in." I remember the first time that an attempt was made to have something more artistic in the way of Christmas decoration in our parish. Wreaths of Holly and Ivy were made, and put up with some little regard to what was the beautiful; the boughs were to vanish, as the high-backed pews had done some few years before. "The old order" was to change, "yielding place to new." Persons of taste hailed these changes; they did not, however, give universal satisfaction. I happened to come

across our parish clerk on Christmas eve, just as the decorators were putting the last touches to their work. He was wandering about in a desultory manner, contemplating in mournful silence the changes which were taking place. "Well, Verges," I remarked, "this is an improvement on our old doings. What is your opinion? I never saw the church look so well before." I could hardly have said anything more *mal apropos*. He turned round and replied sternly, "Well, sir, I was satisfied with things as they was; as for these ere wreaths and such like, taking of 'em altogether, I consider 'em as nowt but innovations." W. N.

THE FLOWER GARDEN.

LARGE-FLOWERED CHRISTMAS ROSE.

(HELLEBORUS NIGER MAXIMUS.)

THIS, in addition to being larger and finer than the ordinary Christmas Rose, is certainly an earlier bloomer, and for those who value cut flowers, or flowering-plants in pots, during winter, and who have but a limited amount of heated glass structures, I do not know of a more valuable plant than this; it only needs the protection of a glass covering to keep its blossoms from being dashed by heavy rains, and it will be in full flower during the dullest and darkest days of the year. Last season I procured half-a-dozen clumps of this variety, and planted them on a well-prepared border, in two rows, in such a way that an ordinary two-light frame would cover them. They have already produced blooms in abundance; there are large quantities of buds yet to open for succession; and, owing to the favourable weather which we have had, no protection has as yet been required. They are admirably adapted for furnishing vases, as, if cut in the bud state, they readily expand in water, and last as long as any flower with which I am acquainted. I would recommend any one beginning to grow this useful plant to give the soil a good preparation, choosing an open, sunny aspect for it, where the crowns can be well ripened, and every season the plants will produce great quantities of flower. If well trenched and manured they would not require re-planting for at least seven years; but a top-dressing of well-decayed manure, and a little liquid manure, might be given during the growing season when the plants are making their foliage, as upon the size and substance of the leaves will depend the size of the flowers. If required for pot culture, care should be taken to protect the foliage from injury; when the blooming season is over, they should be protected by a frame until genial weather permits them to be plunged in the open air. Hardy subjects like the Christmas Rose frequently suffer when removed from under glass, for although hardy enough to withstand our severest winters when continuously exposed, their growth, made under more exciting circumstances, will not withstand any sudden variations of temperature. For this reason it is advisable to keep them in as cool a position as possible when in flower, so that the growth of young foliage may not be excited before its natural season.

JAMES GROOM.

Henham.

Violets.—This has been a favourable season for Violets, many of which are now flowering freely in the open ground, and promise, weather permitting, to do so all through the winter. A fairly moist summer, and a cool autumn have kept the plants well in leaf, and have induced the early formation of blooming crowns. The earliest single kind, and at the same time the finest and most valuable, is Lee's Victoria Regina, a variety that ought to be grown in every garden, and would be, did people fully understand what a grand Violet it is. The earliest and best double kind, undoubtedly, is Marie Louise; it is a greatly-improved Neapolitan, earlier, hardier, and has flowers of a rather deeper hue of colour. Both of these kinds will furnish an abundance of flowers during open weather through the winter, but it would be well to lift a number of strong plants and put them into a large two-light frame, keeping them close to the glass. Thus treated, and with a slight amount of protection in bad weather, flowers could always be had. If plants be lifted for this purpose now, the side-shoots and runners should be taken off them, and they should be pricked out thickly in a bed for the winter. By the middle of April these will all be well rooted, and can be re-planted in

beds from 9 in. to 12 in. apart, where they will develop into strong blooming plants by the ensuing winter. There are few hardy plants more easily cultivated than the Violet, and few better repay any extra care that may be bestowed upon them. On the other hand, however, if there be out-of-the-way spots where other useful plants cannot be got to grow, it is very probable that Violets will do fairly well, always furnishing a good covering of leaves, and in due season a fair sprinkling of flowers, although not so fine as those produced by younger plants.—A. D.

Phlox Drummondii grandiflora.—Nothing can exceed the beauty and usefulness of this Phlox, either as a border plant or for bedding purposes, and it is also invaluable for furnishing cut flowers. Its colours, which are varied and brilliant, are far superior to those of the older varieties, and they are not injured by bad weather or frost like those of many other flowers. Here, on the mornings of the 17th, 18th, and 19th ult., when the thermometer stood at 30°, 26°, and 28°, and when there was ice one-sixteenth of an inch in thickness, this Phlox was not injured in the least, although many other flowers near it were completely destroyed. Since then I have cut an abundance of flowers, and the plants are still (Nov. 10) in good bloom, which consists of twelve or more distinct colours. Although this Phlox is generally treated as an annual, it strikes freely from cuttings at this season; these come in usefully for pot culture and early spring bloom in the conservatory or greenhouse.—W. D., Winton.

Bedding Violas in Autumn.—The great importance for bedding purposes, of the many and ever-increasing varieties of Violas, particularly in the cool soils and comparatively damp atmosphere of Scotland and the north of England, as well as many parts of Ireland, is now so generally acknowledged that it is unnecessary to take up space by enlarging upon it. These gems of the flower-garden have been, during the autumn months, unusually fine in the neighbourhood of Edinburgh. On visiting the nurseries of Messrs. Dicksons & Co., about the end of October, I was struck with the beauty of two long borders planted with the following sorts in rows, which were covered with bloom, and quite as gay as one could wish to see them in the spring and summer months. There were many others more or less known and appreciated by cultivators, but the following seemed to commend themselves specially for their late-blooming qualities, viz.:—Alpha, deep bluish-purple, with a dwarf and branching habit of growth; Canary, golden-yellow, prominently pencilled; Grievii, bright yellow, singularly effective; Sovereign, rich yellow, habit dwarf and branching; Stricta aurea, flowers small, clear yellow, but wonderfully plentiful; Stricta alba, waxy white; Lilacina, flowers large, rich lilac, habit dwarf and branching; Multiflora, lavender, centre purple, with golden eye.—H. F.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Unlifted Dahlias.—We never take up Dahlias in winter. When cut down by frost, they are covered with coal ashes, and in April they are taken up and planted on a hot-bed with no glass over it. When the shoots are about 6 in. high, the roots are divided, and only one shoot planted in each place, prepared for it by being dug, two shovelfuls of manure being added to the soil for each Dahlia. Dahlias thus managed have been particularly good this year.—C. M. O.

Effective Flower Beds.—*Coleus Verschaffelti* and *Alyssum variegatum* may be planted in innumerable ways with the best results. Two round beds here, 12 ft. across, were planted with them as follows:—The centre (3 ft. wide) consisted of *Alyssum*, then a band 3 ft. wide of *Coleus* with eight star points, each point extending to the edge; the remainder was filled in with *Alyssum*. These have been very effective, and to my mind such simple patterns are more pleasing than the many complicated designs now introduced into carpet flower bedding—design being apparently of more importance than the flowers themselves.—W. W., Eaglehurst.

Salvia Bruanti.—I do not know the *Salvia* mentioned in your Notes of the Weik (see p. 416), but I have little doubt that the unnamed bicoloured species mentioned with it is the old *S. tricolor*, the flowers of which are white and carmine, occasionally varied with another streak of red, and then a true tricolour. It is a beautiful little plant, which I rejoiced last year to recover.—H. H. CREWE.

Crimson China Rose.—This, planted in front of shrubby borders or herbaceous beds, and kept pegged low, is invaluable at this time for cutting. We have only a small line of it, but we get a handful of Roses from it every other morning. The blooms, though not large, are brilliant in colour. It requires little attention after being started.—A. H., Thoresby.

Tropaeolum tuberosum, described in THE GARDEN, October 27 (see p. 399), is very effective in autumn, when planted so as to climb through spring-flowering and other shrubs, such as *Pyrus japonica*, *Ribes*, &c., in a sunny position. If planted rather thickly, near the edge of a clump of *Rhododendrons*, it looks like a bank of orange and red flowers, till they are cut down by frost. This *Tropaeolum* is quite hardy here; the tubers are taken up, divided, and replanted in spring, and require no further trouble.—C. M. O., Dublin.

NOTES OF THE WEEK.

"The Garden."—This week we publish our 100th coloured plate, without reckoning the *Xanthoceras*, *Lily*, and other plates which were published before the regular issue in January, 1876. Since then we have not once failed to issue a coloured illustration. This was more than some of our best friends hoped for us. The general reader may understand the difficulties in the way of producing good coloured illustrations when it is stated that, apart from the original water colour drawing, and the subsequent drawing on stone necessary to print each colour, the plates in their production have to undergo from eight to thirteen separate printings. Of late we have not used less than 6000 per week—sometimes considerably over that number.

Gilbert's New Double Primulas.—Of these we have received specimens which fully bear out all that Mr. Hobday said last week (see p. 441) in their favour. The flowers, which are white, rose, or pink, are of good form, and, being double, they possess the merit of lasting long in perfection in a cut state. For conservatory decoration, during the winter months, these Primulas will be found most valuable.—S.

Iris alata.—This lovely Iris, sometimes called *I. scorpioides*, is now in bloom in the Hale Farm Nursery, Tottenham. Although hardy in some places, it will be found to succeed best in a cold frame along with *Narcissus Clusii*, *Leucojum autumnale*, and similar plants, blooming beautifully at this time of the year. If grown out of doors, the blooms should be protected by a hand-glass.

Melanthus major in Ireland.—This plant, usually grown for the beauty of its foliage, is just now in flower here in the open border. It receives no sort of protection even in winter, and it could not be more vigorous than it is. Few seem to know its hardiness, and that treated thus it forms a far more beautiful bush than in a greenhouse, where it is apt to get too much drawn up.—F. A. NICHOLSON, *Meath*.

A New Eranthemum.—As indoor winter-flowering plants, the Eranthemums are well known, *E. pulchellum* being usually grown in every garden on account of its bright blue flowers, which are so attractive at this season of the year when associated with *Chrysanthemums*, scarlet *Salvias*, and other conservatory plants. It is therefore satisfactory to find that a valuable addition to the genus has just been made by Messrs. Veitch. In habit it is branching and compact, and the leaves, being smooth, are easily kept clear of insects. Its flowers are rich violet-purple in colour, large, and well formed, and are produced in great abundance. It is named *E. laxiflorum*.

Cypripedium Sedeni.—Amongst the numerous Lady's Slippers which have been raised of late years, probably few are more useful or attractive than this. It grows freely, and has long leaves of a deep green colour. Its flowers are produced in great numbers upon branching spikes, which continue to grow and flower for months in succession. Where out flowers are needed, this *Cypripedium* might be profitably grown for that purpose, for, in addition to a long succession of bloom, the flowers last for several weeks in perfection if their stalks be inserted in wet sand. We lately saw a specimen of it, in one of the London nurseries, bearing nearly twenty spikes of flower.

Imported Pine-apples.—Importations of St. Michaels Pine-apples to the London markets during this autumn have been very small indeed, and English-grown Queens have fetched unusually high prices. This week, however, heavy consignments of Smooth Cayennes have been received; they have arrived in excellent condition, and many of them weigh from 6 lb. to 7 lb. each, and in flavour are by many pronounced to be quite equal, if not superior, to that of home-grown fruits. They may be bought at much cheaper rates than English growers could possibly produce them.

Pelargoniums for Winter Decoration.—Few plants are capable of furnishing such a diversity of colour as the Zonal and Neesegay sections of Pelargonium, and, in addition to their attractions during the summer and autumn months, under good management, a fine display may be made with them all through the winter. Mr. Cannell has, at the present time, hundreds of plants bearing flowers from 2 in. to 2½ in. across, the petals of which are of the richest shades of colour, and, the different kinds being judiciously mixed, a striking display is the result. For flowering, in autumn young plants are started early in spring, and grown on for that purpose; for winter flowering, older plants are used; these are cut back in autumn, after their wood has become well ripened, and when subjected to a little heat and abundance of air and light, they throw up a succession of brilliant flowers all through the winter and spring months. Such plants would render the conservatory or greenhouse much more attractive than it ever could be made by the plants which are usually found

in such structures. In the nursery in question we noted plants of Pelargonium Dr. Denny yielding large trusses of rich orange-crimson-eyed bright purple flowers.

White Lapageria.—The flowers of this beautiful greenhouse climber, being much prized by London bouquet makers, florists are planting it largely with a view to meet the demand. Though hitherto scarce, it will be seen by our advertisement columns this week that considerable quantities of it, as well as of the red kind, are to be sold by auction at various places.

Remarkable Growth in Cycas revoluta.—A large specimen of this ornamental plant, in Mr. Ley's conservatory, at Croydon, a short time ago produced over seventy large handsome leaves at one time.

American Apples.—Good specimens of Newtown Pippins, the best of all American dessert Apples, may now be bought in Covent Garden Market. It is a remarkable fact that, whilst good fruits of the best English dessert Apples can be bought for 2d. and 3d. each, Newtown Pippins realise 4d. American Lady Apples, too, are now abundant, and are equally valued for their bright appearance and good flavour.

Cyclamens and Primulas.—The thousands of Cyclamens and Primulas which the Messrs. Sutton & Soes grow for seed at their London Road Nurseries, Reading, are now in great beauty, and worth inspection by all, and especially by lovers of these classes of plants. Visitors to their Root show, which takes place on the 24th inst., should also make a point of visiting the Nursery.—W. W. H.

Cattleyas in Flower at Chelsea.—Cattleya Dowiana, of which a coloured illustration was given in THE GARDEN last week (see p. 448), is now finely in bloom in Messrs. Veitch's Nursery, in the King's Road. Like most kinds of Cattleyas, the flowers of this vary considerably both in colour and form; one may, therefore, reasonably hope that, when it comes to be crossed with other species, some valuable hybrid varieties may be obtained from it. In the same house, *C. exoniensis* is beautifully in flower; it is the result of a cross between *Lælia purpurata* and the Syon House variety of *C. Mossiae*, and is, without doubt, one of the best hybrid Cattleyas in cultivation. It has a well-defined, rich purple lip, and golden-yellow throat, its large, exquisitely-formed petals being of a handsome, transparent, violet-pink colour. *C. labiata*, *C. Dominiana*, and *C. Fausta* are also in good condition.—C. S.

Vesuvius Pelargonium Sports.—This Pelargonium is universally acknowledged to be the most useful scarlet-flowered kind in cultivation, either for border or pot culture, and, in consequence of its remarkable propensity to sport, we may yet be indebted to it for many new and entirely distinct kinds. In Mr. Cannell's nursery at Swanley we had, the other day, an opportunity of seeing several sports obtained from Vesuvius. One, a nearly pure white, is as yet unnamed; another is the scarlet semi-double sort called Wonderful, the flowers of which are so valuable at this season of the year for cutting, on account of their lasting properties. New Life, a scarlet and white and salmon striped flower, is also a sport from Vesuvius; and another we noted was coral-coloured, marbled with salmon. All these sports possess the same habit and free-blooming qualities as the parent, and will, on that account, doubtless be largely grown.—S.

Flowers in Covent Garden.—Whilst in gardens November is usually looked upon as a comparatively flowerless month, it is far from being so in Covent Garden Market, for just now the shops in the Central Avenue are as gay as they possibly can be with bouquets of the choicest kind. White Lilac from France has made its appearance, and Roman Hyacinths are not only plentiful in a cut state, but are freely employed for furnishing edgings for wicker-work baskets containing Primulas, Solanums, and other attractive plants in pots. Camellias, Tuberoses, and Eucharis amazonica, together with choice buds of the Niphetos and Isabella Sprunt Roses, occupy a foremost place among the choicest light flowers. The white blooms of the graceful Japanese Chrysanthemums are now favourably thought of, and are being used extensively in floral arrangements; flowers of Orchids, Carnations, and Benwardias, too, are plentiful, and the useful blue Cornflower (which has been coming to market all through the summer), Stokesia cyanea, and Neapolitan Violets, are the best blue flowers for bouquets.

Large Brussels Sprouts.—The aim of some growers of this vegetable seems to be to produce the Sprouts as large as possible; but large Sprouts do not seem to be appreciated in Covent Garden Market, for whilst large loose examples are being sold there at cheap rates, much higher prices are asked for firm young Sprouts about the size of Walnuts. Good Brussels Sprouts should be of such a size as to admit of their being cooked and eaten whole; but if they are half stalk, and have to be cut up like Cabbages, they are comparatively worthless.

VENICE AND ITS GARDENS.

HAVING recently visited Venice, after an absence of eleven years, I am glad to report favourably on the great improvement everywhere observable in the cultivation of plants in and around that city. The departure of the Austrians, and, consequently, the large increase of Italian residents and visitors to this most attractive of cities, may be the chief cause, but doubtless the taste and beauty displayed in the many superb gardens or villas about the Italian lakes have contributed to the increased love of gardening in Northern Italy. Many of the open places are now ornamented with rich clumps of Conifers and evergreen shrubs; of the former, there are fine specimens of Deodars, Cypressess, Junipers, Retinosporas, and Yews, which combine well with tall Neriums, Euonymus, and Pomegranates, many good bedding plants filling up the interstices of the margin. On entering the Botanic Garden I found that it was no longer a Government establishment, but had become a thriving nursery ground. Among the Conifers I noticed tall Cypressess, Roman Pines, Taxodiums, Piceas, and varieties of Cupressus Lawsonia, &c. My old friends the male and female Ginkgo trees (*Salisburia adiantifolia*), which formerly flanked the entrance gates, have now become large specimens, assuming a rotund form; but probably their situation, open to the winter winds from the Julian snow-capped Alps, has prevented their growing tall and pyramidal, their normal type in England and other countries. It was from the female tree that I brought to England, some thirty years ago, the ripened fruit, the first that ever arrived; this season (October) the seeds were not matured enough to be of any use. There is also a large collection of succulent plants of all climes—Aloes and Agaves, Caoti in great variety, *Mesembryanthemums*, &c., which attain a vigorous growth in this sunny region. A very striking group of grand Cypressess is in the garden of the Seminario, attached to the Church of the Salute, and also Orange and Lemon trees, Pomegranates, species of *Chamærops*, Date and other Palms, Dracænas, and Yuccas, which are often seen together with Pinus Pinea, towering above the red crumbling walls of the garden. The Cistat, or Parsley Vine, I first saw in Venice; it is still met with, and other Vines rambling over the walls and trellises, but the Grapes are not good in Venice. At the time I left large boats were arriving at the markets filled with huge baskets of dark Grapes piled up in pyramids and secured by open netting; these came from the islands and mainland. Peaches and Figs were brought in the same manner, but the season for these is now over. The Zucchini, or huge Gourds, some long-shaped and others smooth, and of a flattened form or grooved, present a rich and glowing mass of colour, especially when cleft open to invite the purchaser; these, spread on the riva or piled up in the boats at the great vegetable markets, close to the Rialto and the earliest church in Venice—San Giacomo—present one of the most striking scenes in Bella Venezia. I regret that I could not, on this occasion, visit the Botanic Garden at Padova (said to be the earliest established in Italy), but I hear that it is not so well kept up as it deserves. E. W. C.

Glen Andred.

East Lothian Stock.—This is one of the very best hardy flowering plants which we possess. It has many good qualities to recommend it, being pretty in colour, sweet-scented, and of easy culture. When cut it will last eight or ten days, provided the water is changed occasionally. A good bed of it is most useful where cut flowers are in request. We have a row of it on each side of a central walk in the kitchen garden, consisting of about 300 plants, all of which are, at the present time, one mass of bloom, and they have been in that condition since July, notwithstanding that baskets of flowers have been cut from them for decorative purposes. The seed was sown in boxes in February and put into heat; when the seedlings were well up they were removed to a warm, light pit, and gradually hardened off until May, when they were planted out about 15 in. apart, alternate plants being of different colours, consisting of scarlet, white, and purple. They soon established themselves, and grew rapidly until July, when they met in the rows, and began to bloom profusely, with scarcely a percentage of single ones among them. They now look like a dwarf hedge, 18 in. high and as much across, and, as has just been stated, they are a blaze of flowers, and have the appearance of continuing in blossom till Christmas, should the weather keep open.—W. W., *Eaglehurst*.

Juniperus Sabina.—The most perfect specimen of this shrub that has come under my notice, is to be seen growing on the lawn at the Rectory here. Its height is 5 ft., and its circumference 72 ft.—RICHARD NISBET, *Aswarby Park, Ffolkingham*.

HALL PLACE, TONBRIDGE.

THIS, the residence of Mr. Samuel Morley, is a new building in the Elizabethan style, erected in a situation for which Nature has done much; and Art, too, has materially helped to enhance the many fine landscape effects which present themselves within the domain. A glance at the annexed plan, with its various tree and shrub masses and other objects of interest carefully shown, will give a good idea of the general appearance of the grounds. An effective feature is the lake, which has been introduced into a valley on the north side of the house. At the west end of the lake is a boathouse and rustic bridge, associated with a picturesque old Spanish Chestnut and other trees and shrubs, and in the foreground is a handsome specimen of *Picea Pinsapo*. Westward from the house is the carriage-drive, leading to Penshurst. It passes by two or three fine groups of trees, and ultimately leads up to the lodge-gate, through a straight avenue of young Horse Chestnuts, which will doubtless furnish a noble feature in years to come. The chief entrance to the domain is, however, on the road leading from Tonbridge, and in the drive therefrom occur some fine park scenes, through which, at certain points, excellent views may be obtained of the mansion. A large parterre forms a good foreground on the east terrace, the mid-distance consisting of groups of timber trees, and beyond come into view the hills in the neighbourhood of Sevenoaks, Knowles, and Tonbridge. In the parterre, which is overlooked from the drawing-room, mop-headed Acacias, Standard Portugal Laurels, Pyramidal variegated Golden Hollies, Golden Arbor-vitæ, &c., are very effectively used. From the south terrace, glimpses may be obtained of the hills about Redleaf, Bidborough, and Penshurst, the square-towered church, half hid amongst Lombardy Poplars, Oaks, and Beeches, being especially noticeable. The reservoir mound is planted with Elms, Thorns, Scotch Firs, *Cupressus macrocarpa*, Double Furze, and many other trees and shrubs; within it is a large reservoir for water in two divisions, one within the other, containing collectively upwards of 20,700 gallons, for the use of the house, and for distribution over the gardens and pleasure grounds by means of hydrants placed wherever needed. The water is obtained from a well in the valley, and forced up from thence into the reservoir, an elevation of 30 ft., by means of a turbine wheel. On the large tower of the mansion there is also a tank which contains 20,703 gallons, and in other positions a fire tank holding 4,875 gallons, and tanks for the reception of 30,000 gallons of rain water. On the walk running westward to the Rose garden, and parallel with the sunk fence and balustrated low wall dividing the dressed grounds from the park, are obtained many attractive views, one of which is a full sight of the south side of the mansion, to which the eye is particularly attracted by the rich and abundant display of hardy climbers and shrubs, suitable for wall decoration, with which it is clad. Here are also numbers of fine Conifers, consisting of *Picea cephalonica*, *Pinus insignis*, *Wellingtonia gigantea*, an excellent *Taxodium sempervirens*, Deodars, Menzies' Spruce, *Pinus excelsa*, and *Araucaria imbricata*. From this part of the grounds may also be seen many picturesque old trees of fine growth, and, after passing the Rose garden, which is furnished with some of the best varieties in cultivation, the walk terminates at a picturesque old lodge and an arched gateway, now disused. A portion of the south lawn is occupied by fine-foliaged and other ornamental trees and shrubs, such as *Abies Douglasi*, *Thuja Lobbi*, cut-leaved Weeping Birch, Weeping Arbor-vitæ, *Paulownia imperialis*, *Magnolia grandiflora*, *Pampas Grass*, and also three circular beds containing *P. ygonum Sieboldi*, *Aralia Sieboldi*, and similar plants. Within a portion of the outer boundary, consisting of a large grove, are effectively-planted masses of hardy Ferns and other plants, so as to constitute a wild garden or wilderness. In many of the houses the old Vines have been entirely uprooted and replanted, after the border had been drained, concreted, and replenished with a suitable compost, and, although this is their first season after the severe ordeal through which they have passed, they have borne a good crop, showing no symptoms of shanking, to which in former years they were liable. Amongst new Grapes, Golden Queen is very highly spoken of as regards quality, and also as a late keeper. G. T.

GARDEN IN KENT, BY MR. MARNOCK.

THE INDOOR GARDEN.

VERBENAS IN POTS.

It may be thought by some that it is a mere waste of time and energy to grow Verbenas in pots, because they do so well generally in the open air; but probably most of those who think so have never seen Verbenas thoroughly well grown in pots. There are certain districts, notably in the west of England, where Verbenas are exceedingly well managed in pots. At Trowbridge, in Wilts, for instance, on the occasion of the annual exhibition which took place during the last week in August, the Verbenas in pots were so well grown as to surprise, by their excellence, frequenters of London exhibitions. The pots in which they were grown appeared over large—they averaged from 10 in. to 12 in. in diameter; but the plants carried from fifty to eighty trusses of bloom. The branches were tied out or trained to oval wire frames, which slanted somewhat, so as to present a face to the spectator; and in this way the whole of the trusses of bloom were well displayed, and not only were the trusses numerous, but they were large, and the individual pips hold and finished. The mode of culture adopted may be shortly described. If plants for early exhibition be wanted, say the end of June and beginning of July, the cuttings are struck as early in February as possible. The strongest cuttings are selected from healthy plants, and are struck in coarse sand, or sand and light mould. They are planted in a moist bottom heat of about 65°, and in ten days or a fortnight are nearly rooted. If the plants be not required for show till the end of August, the middle of March is considered early enough to strike the cuttings; and they are then placed in pans of sand and water in a gentle heat, but very near the glass, to prevent them from becoming weakly. When sufficiently rooted, they are potted singly in small 3 in. pots. The cultivator is particular as regards compost; what he uses consists of one barrow-load of well-decomposed manure, half a barrowful of rich yellow loam, half a barrow of leaf-mould, and a peck or so of sand. Some growers use a little finely-broken charcoal to keep the soil open. When the plants are potted, they are returned to the place in which the cuttings were struck, and set near the glass, particular attention being paid to watering and shading. Green fly is vigilantly watched for, and a fumigation with Tobacco smoke given when necessary. The slightest neglect in this particular is often fatal to the strength of the plants. In about three weeks the plants become fairly established in their pots. The next operation is to pinch off the leading shoots to the third eye from the pot; this not only induces strength, but also causes the plants to break out into five or six leading shoots. When they have made shoots 2 in. in length, a little air is given in order to impart robustness of constitution. By the middle of March they are shifted into 3-in. pots, kept close for a few days, and then air is given them by degrees, watering freely all the while. They are again stopped some three weeks afterwards, and by this time they are making rapid growth and are filling their pots well with roots.

The plants intended for exhibition are now shifted into 8-in. pots and placed in a pit or frame where there is a gentle heat, and by the end of May, if not stopped further, they show for bloom. If plants are required for exhibition in July or August they are stopped several times to induce a shrubby habit of growth. In order to have good bushy specimens, exhibitors do as the growers of specimen Cinerarias for show do, they put three plants in a pot, and so make large bushes. The usual plan is, when bush specimens are wanted, to put the plants in 11-in. pots, using such a compost as that already recommended. Great care is required to keep the plants clean and healthy, for Verbenas are prone to attacks of green fly and red spider. Fumigation is attended to at every stage, and plenty of air is given in hot sunny weather; the lights of the frame are raised back and front 6 in. or so, so that the air can circulate freely, and with a covering of Tiffany, or some such light shading material, thrown over the frame from ten o'clock till three o'clock, according to the weather.

The fineness of the flowers, and their brilliancy of hue is induced by administering liquid manure about twice a week. That made of fresh cow-manure is found to answer best. It

is difficult to have good symmetrical plants for exhibition purposes unless they are trained to some kind of frame. This may be of any pattern to suit the exhibitor, and so long as the flowers can be displayed to the best advantage. Some good Verbenas for pot and exhibition purposes will be found in the following selection:—Annie, white and carmine, a pretty striped variety; Apollo, blush; B. A. Hallam, deep mauve; Crystal Palace, rich shaded crimson; E. W. Badger, glossy crimson; Geant des Batailles, deep crimson; James Birbeck, shaded pink; Jupiter, lavender; Magnificus, rosy lilac and crimson; Mons. H. Stenger, white, striped crimson; Queen of Whites, pure white; Rev. C. Peach, pale purple; Rose Beauty, shaded rose; William Hillman, deep black; and Wonderful, bright plum. At Trowbridge, the exhibitors of Verbenas used some seedlings of their own, to have the peculiar qualities wanted in exhibition sorts. They do not trouble to name them, and, except that they get into the possession of local cultivators, are not heard of beyond the district in which they are raised.

D.

BOTTOM-HEAT FOR POINSETTIAS.

THE fact has been far too much overlooked that the size of the gorgeously-coloured bracts of this most valuable winter-flowering plant is chiefly determined by the size of the upper leaves on the stem. Let these be large, wide-spreading, of a deep, dense green colour, and the bracts will be fine in proportion. Of course, the size and quality of the upper leaves will bear a certain and constant relation to the vigour and thickness of the stem. The latter, again, will have been formed and almost finished by this time by previous culture, so that it is now too late either to add to or sensibly modify these; but, taking the plants as we find them now, just on the eve of flowering, it is not too much to affirm that the size of the coloured bracts may yet be almost doubled by plunging the pots in a bottom-heat of 75° or 80°, and keeping their heads within 1 ft. or 2 ft. of clear glass, and in a temperature of 65°. Also keep the roots liberally watered with house sewage or guano water, and syringe the plants overhead once a day in the morning, unless they are dewed over with the condensed moisture from the sources of bottom-heat. Equal parts of manure and leaves form the best plunging bed for Poinsettias. The same treatment also suits the valuable double variety admirably. There does not seem, in fact, any constitutional difference in the two varieties, except that *P. plenissima*, or double kind, is rather more compact, and perhaps slightly more slender in habit than the ordinary variety; but the bracts are piled one above the other in the double sort in the most gorgeous manner, and they are infinitely more persistent, each bract continuing on the plant for a much longer period, and the new ones being developed in succession. While this system of bottom-heat develops the bracts to the utmost on old plants, and infuses into them the most intense brilliancy, it is also specially adapted for the full development of those dwarf single-stemmed plants, produced by the late-rooting of the terminal points of strong shoots. Pot these in 4-in. or 6-in. pots; plunge to the rims in a genial bottom-heat, and water with guano-water, and very large single bracts will be produced. The colour may also be much intensified by raising these plants to within a few inches of the glass. Not only will the bracts be of the utmost brilliancy, but the upper tier of proper leaves will often be largely infused with the same colour, as if part of the tints of the bracts had been absorbed by the leaves.

D. T. FISH.

White Chrysanthemum Blooms at Christmas.—The experiment as regards lifting a quantity of white-flowered Chrysanthemums from the open ground into a bed in a greenhouse, referred to last week (see p. 446), has already proved most successful. The plants were lifted on the 29th of last month, and now, just a fortnight from that time, they are covered with expanded flowers of snowy whiteness, and of a most useful size for cutting. Mrs. George Randle is by far the best kind to grow for this purpose, as it produces flowering branches more freely than any of the others; its flowers are of the purest white when fully expanded, and as each branch produces from two to three side buds besides the central, and, of course, largest flower, its incurved character admits of the entire truss being expanded, and forming a neat, compact head of bloom before it is needful to cut it. The bed in question is about 5 ft. in width and 24 ft. in length, and I find that I could have easily found room for some thirty or forty more plants. What the value of the flowers now produced from the fifty plants will be of course I cannot say, but certainly there will be several hundreds of trusses available for cutting during the present month. Madame Damage is several

days later. Its flowers, which open of a pinky hue, become pure white when fully expanded; these are reflexed or tasselled, and are very handsome, but produced less freely than those of Mrs. George Rundle. It seems quite possible to secure a late succession of white flowers if plants of Madame Damage were put out behind a north wall during the summer, and lifted as soon as the flowers of Mrs. George Rundle were all cut, and put into the same place to bloom. This would give a continuity of flower for outting up to Christmas, and, of course, the value of the blooms would be greatly enhanced at that late period of the year.—D.

CEREUS CANDICANS.

THIS is a vigorous growing kind, the stem of which, when about 5 ft. high, is often 3 ft. round, and the angles large and shallow, rendering the plant solid and heavy looking. The spines, which are in sets of from twelve to twenty, are yellow, from 2 in. to 4 in. long, and very

Cereus candicans.

acute. It may be increased by offsets, which it produces freely from the base, and it is easily grown in almost any soil. The flowers, which are pure white, are but sparingly produced; but it is the spines, rather than the flowers, which constitute the chief beauty of this species. J. CROUCHER.

Flowering Stephanotis in Small Pots.—Few sweet-scented flowers are more appreciated than those of the *Stephanotis*, either in a cut state or on the plants, and to have them in abundance on plants grown in 6-in. pots is desirable. This may be accomplished by obtaining strong young plants and growing them on in a moderate temperature, where they can obtain abundance of light, sun, and air. In summer they may be placed out-of-doors in a sunny spot, where the wood will get well ripened. The side shoots should be spurred in to within 1 in. of the main stem, and, when bad weather sets in, the plants should be removed indoors and their shoots tied up to a trellis near the glass. If a little heat be applied in November, shoots will be emitted at every joint, all of which will flower profusely. In this

way Mr. Ley, of Croydon, grows hundreds of small plants, the stems of which early in summer are full of bloom from top to bottom, making admirable subjects for indoor decoration. Large plants may of course be treated in the same way; all that is required is to treat them exactly as one would Vines on the spur system, and abundance of flowers will be the result.—S.

Allocasia metallica.—This is one of the most distinct and beautiful of fine-foliaged stove plants, striking in the form of a large assecimen, and equally serviceable and effective as a small vase or table plant, the young foliage being especially lustrous and handsome. For very large specimens, we select five or six of the strongest crowns or root-stocks, and taking some 15-in. pots, fill them one-third full of crocks, over which is placed a good layer of fresh Sphagnum Moss, to keep the soil from being washed down and blocking up the drainage, as, during the growing season, abundance of water, both at the roots and overhead, is required. The compost which we use consists of fibry turf, peat, charcoal, broken potsherds, and chopped Sphagnum Moss. The crowns or root-stocks, which are long in shape, are raised well up in the centre, packing the soil amongst them, so as to form a cone. If potted in February, they will throw up a quantity of flower-spikes before the foliage, but these should be broken off as soon as they appear, in order to direct the whole energy of the plants to the formation of fine foliage. Smaller crowns, placed three in a 6-in. pot, make fine vase plants in autumn and winter, and single crowns in 3-in. pots are also highly effective in table and plant stands, their polished, shield-like leaves contrasting well with whatever they may be associated. A moist stove temperature suits them best, and when contrasted with golden-leaved *Gymnogrammas* and *Crotons*, few plants are more effective. They may be increased rapidly by means of small root offsets. They are not liable to attacks from insects, but a sponging occasionally ensures cleanliness, and greatly enhances the beauty of their leaves.—J. GROOM, *Henham*.

Torenia Fournieri.—This is a new and exceedingly beautiful plant, and when the length of time during which it continues in flower is taken into consideration, it may well be thought worthy of a place in every collection of decorative plants, however select such collection may be. The plant is of easy culture, and is readily increased by cuttings. Those under my care, however, were raised from seed, which was sown in a propagating house about the first week of April last. Some of them were in bloom by the beginning of the following June, and the plants have all continued in full flower ever since that time, and are now, nearly the end of October, in great beauty, and appear likely to continue so for some time to come. Most of the plants are growing in pots some 6 in. in diameter, and the soil used is the same as is generally employed for *Pelargoniums* and other soft-wooded plants. But, remembering something of the habit of growth assumed by the old *Torenia asiatica*, a few of them were potted into pots made for the purpose of being suspended, and these hung up from the roof of a cool plant-stove, or rather an intermediate house, have succeeded well, and are still very beautifully in flower. The habit of the plant, however, does not render it quite suited to the purpose of being suspended, as it is somewhat erect in its habit of growth, and readily forms a dense bush, and does not require much assistance in the form of stakes. The flowers bear a considerable resemblance to those of the *Torenia asiatica*, but they are more beautiful, and produced in greater abundance. To secure the production of seed, it is necessary to have recourse to artificial fertilization.—P. GRIEVE, *Culford*, in "Florist."

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Remarkable Growth in England.—Some of us may have heard of the vigorous growth of certain trees in the Tropics, and the following instance of growth in England may be worth recording:—A Bamboo growing in the conservatory at Syon House sent up a shoot in August, which is now about 6 ft. high and 24 in. round the stem. The Bamboo is *Bambusa arundinacea*, or one of its forms.

New Zealand Flax in London.—This plant, which may not be enjoyed much out-of-doors about London, should be more frequently grown in pots than it is, being so useful both in houses and out-of-doors. A line of specimens in small tubs, in front of Mr. Wills's fine winter garden at Brompton, is very effective. This Flax is admirably suited for London houses, inasmuch as it could be very effectively wintered in large halls or rooms.

Tropeolums for Winter.—Where cut flowers are in demand, few plants are more serviceable than the scarlet-flowered *Tropeolum*. Pots are unnecessary, as by planting out vigorous young plants in summer, and training them under the rafters of any cool house, abundance of flowers may be gathered from them throughout the winter. In addition to their value for yielding cut-flowers, the plants themselves, when well studded with blossoms, have a bright appearance at a season when good flowers are scarce.—S.

ORCHIDS.

PLEIONES, OR INDIAN CROCUSES.

FEW, if any, of our smaller-growing Orchids are more beautiful than these little gems when well grown, and at this season of the year they are more deservedly popular, on account of the scarcity of bloom in our stoves. They not only form valuable decorative plants, but they are also very useful for furnishing cut flowers. They are plants of easy culture, provided they get the proper treatment, and as the price of them now is within the reach of every one, they might be equally plentiful as the old and beautiful *Dendrobium nobile*, which is everybody's Orchid. It is not necessary to have special houses for them, as they will grow well in any ordinary stove in which there is a winter temperature of from 55° to 60°. I have found them to succeed best in a mixture of fibry peat, chopped Sphagnum, and a little Cocoa-nut fibre, sufficient sand being added to keep it open. Many cultivators recommend the addition of a little loam, but they are better without it. The pots should be perfectly clean and dry (if new, they should be soaked and dried previous to being used), and should be filled three-quarters full of clean-washed crocks, upon which should be placed a layer of Moss, to prevent the compost from being washed away. Being free surface-rooting plants, the bulbs should be planted well above the level of the pot, say 1½ in. higher in the centre, gradually coming down to the level of the rim. It is very desirable that Moss should be grown on the surface, as it keeps a wholesome moisture about them, in which they seem to delight. They should then receive a gentle watering, to settle the soil, and be placed on a stage or shelf near the glass, and, until they get fairly hold of the soil, the supply of water should be very limited; after they have got established, they may receive almost any amount, taking care to keep the Moss on the surface in a growing state. In the spring and summer months, they will be greatly benefited by being syringed overhead twice or three times a day. This will keep down red spider, to the attacks of which Pleiones are liable. Everything should be done to induce them to make vigorous growth, upon which depends the production of fine blooms. The larger the bulbs, the finer are the flowers. As regards kinds, *P. concolor* has a pure white lip, beautifully fringed; *P. Reichenbachiana* has rose-coloured sepals and petals, and a white lip, streaked with purple and crimson; one called *Hookeri* is in the way of maculata, but this I have not seen. The four commoner species are *P. Wallichiana* or *præcox*, as it is often called, on account of its early-flowering properties. This is the largest of the whole species, its flowers frequently measuring from 4 in. to 5 in. across, and their colour is a rich rose, the margin of the lip being finely serrated. *P. lagenaria*, which is a little later in blooming, is the commonest of the genus, and perhaps the easiest to cultivate. *P. maculata* is, however, the prettiest of the whole genus, its pure white sepals and petals contrasting beautifully with the white, yellow, and magenta lip. The last to flower is *P. humilis*, which is deservedly a favourite. Its sepals and petals are a delicate lilac, and the lip is margined with white, and exquisitely fringed. All the above are well worth growing; and if amateurs only knew the ease with which they may be cultivated, these Pleiones would, I am sure, become just as universal as a *Hyacinth* or a *Tulip*.

Pendleton.

W. C.

SEASONABLE NOTES.

ODONTOGLOSSUM MEMBRANACEUM and its varieties have been somewhat depreciated by many; they are, nevertheless, charming plants, and amateurs who do not possess them should do so without delay. They are now pushing up their blooms, and may, with care, be kept in full beauty for two months. The variety named "*decora*" is the finest marked and largest, but this is both new and rare. Other winter *Odontoglossums* consist of *pulchellum majus*, the flower-scapes of which bear numerous thick fleshy flowers, which, with the exception of a slight stain of yellow on the lip, are pure white; it is delicately perfumed, and lasts long in full beauty. *Odontoglossum Inaleayi* *Leopardinum* is often called an autumn-blooming variety, and in a general way it may be so considered; this year, however, it is only now beginning to push up its flower-spikes, so that its rich-

coloured blossoms will only be open about mid-winter, a circumstance which greatly enhances their value.

Cælogyne cristata, which stands unrivalled for the snowy whiteness of its large blooms, is now beginning to push up its flower-spikes; and where more than one specimen is grown, some should be removed to a cold house in order to retard them, thus obtaining a succession of its beautiful flowers. There is a variety of it having a pale lemon blotch upon the crests of the lip, which naturally blooms later than the normal form, and which is specially valuable for maintaining a succession of flowers; and this year a summer-flowering variety has made its appearance, so that it will not now be a matter of much difficulty to have plants of this *Cælogyne* in flower for about nine months. They should not be over-watered at any time, but it should be borne in mind that when they are removed to a lower temperature less will be required than when they are in a higher one.

Calanthe vestita, and its varieties, now opening their flowers, should receive the same treatment previously recommended for *C. Veitchii*; they produce abundance of blooms, which are very valuable for bouquet making.

Sophranitis grandiflora, a veritable floral gem, bears scarlet flowers, which last in perfection for many weeks; the blooms on different plants, however, differ greatly, some measuring as much as 2½ in. in diameter.

Cattleya Loddigesi may be said to be almost a perpetual bloomer; its flowers, too, are large, thick, and waxy in texture, therefore they last a long time in perfection, and their colour rose—or rose and white—is chaste and pretty; nothing, indeed, is more charming than a bloom of this *Cattleya* and a frond of *Adiantum* for the decoration of a lady's hair, or for a button-hole bouquet, and with but a few plants of it blooms may be had in spring, summer, autumn, or winter. *Cattleya marginata* is now quite a gem, its large rose and purple flowers being developed to most advantage under cool treatment, and thus managed the growths are not drawn out so long as when placed in strong heat, but resemble more imported pseudo-bulbs, and every growth blooms. Of *C. Trianae* the varieties are legion; they are now pushing their blooms through the spathes, and will soon be a blaze of beauty; those who do not possess *C. Trianae* or its varieties should take advantage of this, the blooming season, to add it to their collections, selecting the particular shades of colour which they prefer. They may be obtained having rosy sepals and petals, and intense deep purple lip, through all gradations of these colours up to pure white.

Oncidium ornithorhynchum, like *O. incurvum* is quite an exception to the predominant colour in this genus; its scape, which is branching, produces in great abundance flowers of a soft rose colour, which yield a grateful perfume, somewhat resembling that of *Heliotrope*. These qualifications, added to its compact habit, and easy management in a cool house, should recommend it to all lovers of winter blooming Orchids.

A careful search should now be made amongst Orchids, especially those which have been repotted or newly surfaced with Sphagnum, for the Onion snail (*Zonites alliaria*), which seems to be unusually prevalent this season. It not only eats the points of the roots off, but also attacks the flowers when in the bud. Beetles are also great destroyers of Orchid roots and flowers, and a continual war must be waged against them. Care should also be taken that nothing suffers from drought, i.e., through over-drying; avoid, however, the opposite extreme, for too much water about the house on a cold night will bring about disastrous results. Look well after red thrips and white scale, pests which are very apt to increase rapidly during the dry season. To destroy the former, dust the axils of the leaves with Tobacco powder, allowing it to remain undisturbed for a few days; the scale must be removed by washing with soft soap and tepid water.

W. H. G.

Cattleya gigas a Winter-flowering Plant.—We have a plant of this *Cattleya* with twelve fully-expanded flowers upon it. It is deliciously fragrant, the perfume being compared by some to a mixture of Violets and Prim-roses.—RICHARD CARR, *Taverham Hall*.

Wintering *Disa grandiflora*.—Last July I purchased a plant of this Orchid, then in a greenhouse. I grew it on in a Wardian Case until May, when I put it out with *Sarracenias* under a handlight. In August I found that the main growth had either died down or been eaten off by slugs (I fancy the latter); but suckers were growing freely. I then plunged it in cocoa-nut fibre in an open, shady border; and now I find the main stem developing itself again, so that it has had no rest. Ought it to die down altogether? What shall I do with it now? The small pot seems full of bulbs. I have no greenhouse, but can either grow it out-of-doors in a frame, or indoors in a large Wardian Case as before.—A. J. [*Disa grandiflora* should not die down entirely, nor should it be dried up to induce rest. It will commence growing now, and may be grown in a frame or Wardian Case if kept tolerably close; a cool greenhouse would be best if available.]

ROYAL NURSERIES. SLOUGH.

APART from their importance in a commercial point of view, the Royal Nurseries at Slough possess considerable interest. Here may be found many effective arrangements, in the way of trees, shrubs, and flowers, entirely devoid of that formalism which more or less necessarily characterises nursery gardens. Good illustrations of spring and summer gardening are yearly carried out on borders and beds on each side of a central promenade running through the middle of the grounds. Mr. Turner's house, of which the annexed is an illustration, is one of which any nurseryman may justly feel proud. Its verandahs and walls are clothed with gracefully-hanging festoons of *Wistaria sinensis*, from which, throughout the summer and, indeed, until winter sets in, depend large clusters of bluish-lilac flowers; and, even late in autumn, the various hues of the fading foliage combine to make an effective display. Contiguous, but almost hidden by the *Wistaria*, is a small house devoted to winter flowering Tree Carnations. As

ornamental shrubberies, containing Golden Thujas, graceful Deodars, and other choice plants, interspersed with standard Acacias, *Cornus Mas variegata*, and variegated Hollies laden with berries. Large patches of the neat pyramidal habited *Thuja Vervaeana*, clothed to the ground with bright golden foliage, contrast effectually with plantations of the bronze tinted *Cryptomeria elegans* and the bright green of the Deodar. *Cotoneaster microphylla* here forms effective plants grown in the form of standards. They are grafted on clean 4 ft. or 5 ft. stems of a strong growing kind; the branches are allowed to assume their naturally drooping habit, and isolated on lawns or allowed plenty of room in front of shrubberies, such plants would be very attractive at this season, when studded with bright coral-coloured berries. I noted good specimens of the large-leaved Azorian Laurel (*Cerasus lusitanica azorica*) a kind upright in habit, and bolder and more striking in appearance than the common Portugal Laurel. Roses constitute a special feature in this nursery; to their culture many acres of

Wistaria on Mr. Turner's House at Slough.

fast as the plants in other quarters show bloom, they are brought here and placed on a stair-like stage, with which the house is provided, and a succession of beautiful sweet-scented blossoms is thus kept up throughout the winter. Among some of the best kinds may be enumerated Sir Garnet Wolseley, a full and distinct flower with buff ground, striped and edged with bright scarlet; Scarlet Defiance, a free blooming kind, with vivid scarlet smooth-petalled flowers of good substance; Rose Perfection, and a beautiful white flowered variety named Guelder Rose. Many others, possessing equally good qualities, raised by Mr. Turner, are to be found in bloom, although, of course, the best of the season for the display of their bright colours is now over. Preparations for spring gardening are now being carried on. Small and effective plants, in conjunction with dwarf ornamental Conifers, are planted on small banks and borders. Ordinary shaped beds, in the centre of which are standard Paulownias, Yuccas, and Golden Catalpas, are planted with Daisies, Auriculas, and other spring flowering plants with good effect. Surrounding these are

land are devoted, and although at this season the trees are all but leafless, the large fields of Briers which were budded with new and popular kinds in summer, are by no means uninteresting. New Roses are, as far as can be arranged, planted near home in order that they may be more frequently seen, and their merits and demerits more accurately determined. The removal of Roses has this year been deferred later than usual on account of the dry state of the soil; but now, as it is getting moist, they are being removed in large quantities daily. Among late flowering kinds Mrs. Baker has been one of the best, and even late in October could be seen several of its lively carmine buds and flowers. On plants of Duchesse de Vallombrosa, too, were observable some really good blossoms. To Maréchal Niel and other Tea Roses a wall 500 ft. to 600 ft. long and 12 ft. high is devoted; the plants are remarkably strong and healthy, no signs of mildew whatever being observable, and in early spring they are loaded with blossoms. The aspect of the wall is due south, and on the top is Ivy which, no doubt, greatly preserves the buds from early spring frosts. The plants were budded on the

Brier stock, and are growing in soil of a rather stiff clayey character. During summer, the surface of the border is heavily mulched, which keeps the roots cool and moist, and enriches the soil. Pot Roses, as is well known by those who have visited our London Rose shows, are well grown by Mr. Turner. The plants this year have made extraordinary growth, and have assumed unusual proportions. These, after having flowered, are potted, and placed in an open position out-of-doors to ripen their wood, and a few are pruned and placed indoors at one time according to the period at which they are required to be in bloom to suit the shows. Pinks, Carnations, and Picotees are made specialties of in this nursery both for growing in beds and for pot culture. To obtain plants a large stock is grown in 8-in. or 9-in. pots, the surface of the soil being several inches from the rim of the pot, in order to allow of earthing up. When well established, the side shoots of the plants are pegged down, and 1 in. or so of good sandy soil is placed round their bases. When well rooted these are taken off and potted in small pots, and placed in frames or in the open air. By this method the young plants are found to make stouter and harder growth than when layered from plants in open borders, and are considered in much better condition for planting-out or growing on for flowering in pots. Auriculas constitute one of Mr. Turner's specialties, but of course, at this season, very little flower is to be seen on them. Long ranges of pits and frames filled with healthy plants of them were, however, observable, and which in spring will evidently make a fine display. Standard Aucubas, loaded with berries, are grown here by hundreds, also all kinds of plants suitable for small gardens and window decoration during winter. The Pampas Grass is grown largely here in pots plunged in the open ground; thus treated the plants are easily removed, and if planted out of pots are more likely to succeed than if transplanted from the ground at once, as is too often the case, and the cause of the death of many good plants of this ornamental Grass. Strawberries are extensively grown here, both in the open ground and in fruiting-pots; the latter are selected from the strongest plants which can be got, and grown on liberally in rich loam in an open situation, where they make stout leaves and crowns, an important point as regards the production of fruit. To supply plants for border planting, the earliest runners from permanent plantations are pegged to the ground, and when they have taken root are lifted and replanted 3 in. or 4 in. apart in a bed of good soil; here they get hardened, and emit fresh roots and make strong plants, when removed to their permanent quarters, much sooner than lanky, soft-rooted plants. The kinds most favourably thought of here are President, Vicomtesse Héricart de Thury, and La Grosse Sucrée for forcing, and Sir Charles Napier and Sir Joseph Paxton for later fruiting.

The indoor department of this nursery embraces all kinds of popular garden plants. Chrysanthemums are just now, of course, among the most striking plants coming into bloom. Hundreds of all the best kinds are grown in the form of standards. Their stems are from 1 ft. to 3 ft. high, and they are furnished with neat, well-shaped heads covered with bloom-buds. To obtain these standards, cuttings are struck early in spring and potted on in good soil; the main shoot is allowed to grow to the desired height, and then stopped. Side shoots are then soon produced, four or five only being retained near the top of the stem. When the wood of these becomes firm, shoots from other kinds are grafted on them, and thus several sorts are produced on one head; of course, to carry out this method perfectly such kinds as are well known to bloom at the same time are only used together. The soil in which they are grown consists of rich loam, and a surfacing of sheep manure is given them as soon as they have formed their bloom-buds. For vases indoors or for conservatory decoration nothing surpasses these standards, and their pots can easily be hidden by a few drooping Grasses, Ferns, or Ficus repens. Other Chrysanthemums are grown with a stem 6 in. high and cup-shaped heads, consisting of eight to twelve shoots, but none of the one-stemmed plants, 6 ft. high, which are too often seen, are here to be found. Under cover of a shed in a northern aspect, I noticed about 3000 plants of white-flowered kinds being kept back for a display at Christmas. In keeping back Chrysanthemums it is necessary that the bloom-buds should be formed

before placing them in such a position as the one described, otherwise they are apt to go "blind," or the flowers would be very few indeed. The specimen Azaleas are uncommonly fine this season, every shoot being furnished with bloom-buds. Camellias, too, are full of buds; the plants have just been housed, having been out-of-doors, together with many other hard-wooded plants, during the summer. Camellias here are potted entirely in peat and sand, and both in colour of foliage and general health they are equal to any which I have ever seen. A very good plan is here adopted for shading hard-wooded plants during the summer months. A series of lines of Poplars are planted from 20 ft. to 30 ft. apart, more or less, and between these are placed the plants on beds of ashes. Whilst the Poplars shade the plants from the scorching rays of the sun, they do not offer too much shade, and they allow air to circulate freely among them. Pelargoniums have always been grown well at Slough, as any one who has visited the London shows can testify; the plants this year look very strong and healthy; they are grown in lean-to houses near the glass. After flowering, they are placed out-of-doors, to ripen their wood, and then they are cut back to some three or four eyes or more, as the shape of the plant may require. When they break into leaf again, they are shaken out of their pots, and have their coarse roots cut back, and potted in rather stiff loam and manure, afterwards shifting them on until they are in their flowering pots. New kinds are grown on yearly to succeed the old ones, and seedlings are annually being raised; these are allowed to flower, so that their merits may be decided upon, and if found inferior, or only as good as existing kinds, they are at once thrown away, keeping only such as are considered a step in advance of such existing kinds as they most resemble. I noticed in a range of frames the finest batch of the useful flower-garden plant, *Polemonium coruleum variegatum* (Variegated Jacob's Ladder), which I have ever seen. The chief reason, it is said, why people cannot propagate this plant readily is because they divide it in the autumn instead of in the spring. Here the plants are taken up on the approach of frost, potted, and wintered in frames. In spring they are divided and potted separately, subjected to a little more heat, and they appear to grow as freely as Scarlet Pelargoniums. In a ridge and furrow-roofed house, devoted to hard-wooded plants, are very fine specimens of Lamarque and Gloire de Dijon Roses budded on the Manetti stock; these, together with *Lapageria rosea* (now in full bloom), cover the whole of the roof, rendering shading unnecessary, and they yield hundreds of valuable Roses in spring and summer. Verbenas are here largely grown. A whole lean-to house is devoted to stock plants, which are grown expressly for that purpose in pots. The more leggy the plants are, the better they are liked, as they resist damp and mildew better than compact leafy plants would do. In a house filled with Ferns I noticed a plan which might be more frequently adopted with advantage; the house is a span-roofed one, with a stage each side, and a path running through the centre; under the stages are placed stones, clinkers, and soil, in which are planted Ferns, Lycopods, *Panicum variegatum*, *Fittonias*, and other dwarf-growing, ornamental-leaved plants. A board is placed on edge to prevent the heat from the hot-water pipes drying them up too much, and here they thrive luxuriantly, and not only produce a grand effect, but utilise space and furnish abundance of material for cutting for bouquets, &c. *Libonia Penrhosiensis* is a plant largely grown here; it is of more compact habit, and has larger leaves than the well-known *L. floribunda*; its flowers, too, are larger, and they are produced in greater abundance.

Plants in flower are of course just now scarce, but one little house, devoted to such plants as are in flower, was very gay with *Ericas*, *Bouvardias*, *Fuchsias*, and the bright scarlet *Salvia splendens*. Among *Ericas* the most beautiful in flower were *E. verticillata rubra* and *E. mammosa*, two kinds which ought to be more extensively grown than they are on account of their large, delicate pink and bright scarlet blossoms, which last in perfection for a long time during the winter months. In a large house full of healthy-looking *Crotons*, *Dracenas*, and other ornamental stove plants, were noticeable good flowering examples of the effective *Pancratium speciosum*, the pure white flowers of which are so much prized for bouquets, table

arrangements, &c. Pot Vines by thousands, and, indeed, all imaginable nursery stock, appeared to be grown here in the best possible way, not excluding the Potato Schoolmaster, which Mr. Turner has exhibited so successfully this season.

S.

ROSES.

NEW ROSES OF THE PAST AND PRESENT YEAR.

Of the novelties introduced in 1875-6, the following have commended themselves most to our judgment; *Hybrid Perpetuals*: Abel Carrière, Avocat Davivier, Duc de Montpensier, Duchesse de Vallombrosa, Gustave Revilliod, Jean Liabaud, Madame Ferdinand Jamin, Madame Prosper Langier, Marguerite Brassyac, Monseigneur Fournier, Oscar Lamarche, Sultan of Zanzibar, Triomphe de France. *Tea-scented*: Madlle. Marie Berton, Maréchal Robert, Souvenir de Madame Pernet. Of the Roses of the present year (1876-7), the following seem to us the best:—*Hybrid Perpetuals*: Madlle. Emma All, Marie Louise Pernet, Marquise Adèle de Murinais. *Tea-scented*: Comtesse Liza du Paro, Madlle. Lazarine Poizeau, Souvenir de Georges Sand, Triomphe de Milan. We do not describe these varieties, because their full descriptions may be seen in one or other of the leading Rose catalogues, which all lovers of Roses will be sure to possess. Of Roses not yet in commerce, but which will probably be sold in the spring of 1878, May Quennell (Postans), Penelope Mayo (Turner), and Mrs. Laxton (Laxton) have been shown good during the present year.

Of new Roses coming from France this autumn, the following announcements have reached us up to the present time, but this list will, no doubt, be considerably augmented:—

Alfred K. Williams (H.P.), carmine, changing to magenta, large and full, imbricated; Amena (H.P.), bright rose, reflexed with violet, centre carmine; a seedling from Victor Verdier; Angèle Fontaine (Bourbon), carmine rose, large and of perfect form; opening well and very perpetual; growth vigorous; Barthélemy Joubert (H.P.), very bright cerise, large and full; growth very vigorous; Dames Patronnesses d'Orléans (H.P.), deep crimson, large and full, very free; growth vigorous; Edouard Pynaert (H.P.), bright Gooseberry red, shaded with carmine, large, full, and globular; a seedling from Antoine Ducher; Evêque de Luxembourg (H.P.), deep purple, shaded with violet, centre velvety crimson, large and very sweet; growth very vigorous; Fontenelle (H.P.), bright carmine red, very large, full; growth very vigorous; flowers in clusters; La Toulousaine, (N.P.), flesh colour, changing to rose, of medium size, full and finely formed; growth very vigorous; Louis Richard (Tea-scented), coppery rose, sometimes with deep red centre, large and full; growth very vigorous; Madame Alexandre Bernaix (Tea-scented), flowers rose colour, edges of petals shaded with white, large and full, very distinct. A Silver Medal has been awarded to this variety at a Flower Show in Lyons, June, 1877. Madame Anna de Bésobrasoff (H.P.), very bright cerise, changing to purple, large and finely shaped; growth vigorous, very perpetual; a seedling from Charles Lefebvre; Madame Chignard (H.P.), bright clear red, large and full; growth very vigorous; Madame de Laboulaye (H.P.), pale rose, with bright rose centre, large and full; growth vigorous; very perpetual; Madame Doria (H.P.), bright cerise, shaded with purple, large and of good form, foliage fine; growth vigorous; Madame Gabriel Luizet (H.P.), satin rose, petals large and of great substance, flowers very large and full; growth vigorous; Madame Jeanne Bonyer (H.P.), pink, the colour of the China Rose; very large, full, and of fine petal; growth very vigorous; Madame la Marquise d'Hervey (H.P.), velvety red, shaded with carmine, very large and full; growth very vigorous; Madame Louis Donadine (H.P.), flesh colour, with deeper centre, very large and full; a sport from Countess of Oxford; Madame Maurice Kuppenheim, salmon yellow, sometimes rosy, reverse of petals slightly coppery, large, full, and of fine petal; growth very vigorous; Madame Roger (H.P.), very pale rose, almost white, large and full; growth very vigorous; Madame Théobald Sernin (H.P.), currant red, shaded with carmine, large, full, and finely shaped; growth vigorous; Madlle. Anne Marie Danloux (H.P.), white, centre slightly rosy, of medium size, full and finely formed; growth very vigorous; Madlle. Blanche Durrachmidt (Tea-scented), flesh colour, tinted with rosy salmon, changing to white; growth very vigorous; a seedling from Madame Falcot; good for massing. Awarded a silver medal at a flower show in Lyons, June, 1877. Révérend Trautmann (H.P.), bright carmine, with rosy centre, reverse of petals lake red, large, full, and finely formed; Robusta (Bourbon), velvety fiery red, changing to purple, of medium size, full, flowering in clusters; growth very vigorous; Rose à Bois Japé (H.P.), flowers bright cerise, large, full, and globular; growth vigorous; the wood of this variety is very remarkable, being banded with yellow, green, and red, forming together a strange

variegation; Souvenir d'Adolphe Theirs (H.P.), brilliant red, shaded with vermilion, extra large, very free; growth very vigorous; a seedling from of Countess of Oxford; Souvenir de Mlle. Marie Detry (Tea-scented), pale salmon rose, sometimes bright rose, large, full, and finely formed; growth very vigorous.

Of my own novelties, the following extract from the "Journal des Roses" will, perhaps, be more acceptable than anything I can myself say concerning them:—"Of Messrs. W. Paul & Sons new Roses, May Quennell obtained a first-class certificate; it is a beautiful well-formed Rose, with very close petals of a bright crimson colour, becoming magenta on the outer petals; it is one of the best Roses yet sent out by Mr. Paul. Another new kind, named Masterpiece, has flowers very large, full, and globular, perfect, in short, in form; its colour is pink, shaded with carmine; this variety is one which cannot fail to become popular, both as an exhibition kind, and for ordinary cultivation. A charming little Moss Rose, called Little Gem, is also a kind which will do credit to the Waltham Cross collection."—Paul's "Rose Annual."

THE BEST FORTY-EIGHT ROSES.

I HAD thought that the ultimate result of the poll—I mean the best forty-eight Roses—might be compared with some degree of interest with the best forty-eight selected by a rosarian across the Atlantic. Accordingly I wrote to Mr. Ellwanger, of Mount Hope Nurseries, Rochester, New York, to whom those who have been desirous of seeing the age of Roses and the raisers' names are, as well as myself, very deeply indebted; and I now place side by side his forty-eight in order of merit and the collective election forty-eight:—

The Election List.

1. Marie Baumann
2. Alfred Colomb
3. Charles Lefebvre
4. La France
5. { Maréchal Niel
6. { Baronne de Rothschild
7. François Michelon
8. Louis Van Houtte
9. Étienne Levet
10. Marquise de Castellane
11. Madame Victor Verdier
12. Duke of Edinburgh
13. Marie Rady
14. Comtesse d'Oxford
15. Dr. Andry
16. Sénateur Vaisse
17. Xavier Ollivo
18. Mdle. Eugénie Verdier
19. Edward Morren
20. Catherine Mermet
21. Horace Vernot
22. Marguerite de St. Amand
23. Emilie Hausburg
24. Ferdinand de Lesseps
25. Dupuy-Jamain
26. Camille Bernardin
27. John Hopper
28. Reynolds Hole
29. Victor Verdier
30. Prince Camille de Rohan
31. Marie Van Houtte

44. Madame Berard
45. Madame Trifle
46. Maurice Bernardin
47. Reynolds Hole
48. Marie Finger

Mr. Ellwanger's list is placed in order of merit, and it will be seen that in his selected forty-eight he has named twenty-nine of those selected by the various electors. His list, as compared with ours, is chiefly remarkable for the Tea element, for, counting Maréchal Niel, there are eleven as against six in our list. Mr. Ellwanger further adds that he has bracketed Charles Lefebvre and Ferdinand de Lesseps, because, "though not the same," they "at many times strongly resemble each other, and I couple them as being of equal value." He also further adds—and the remark is of interest, touching the effect of climate on different yet similar Rosos—"In relation to Mdle. Eugénie Verdier and Marie Finger I would say they are with us quite distinct sorts; the former I consider decidedly the more refined and beautiful."—"Journal of Horticulture."

NOTES FROM KEW.

THIS week there is not much of interest to record concerning outdoor plants, the only one being the South European *Medicago arborea*, which is in bloom by the wall of the herbaceous ground. *M. arborea*, the Cythens of the ancients, ought to be planted wherever a sufficiently-sheltered spot can be spared; as, in such positions, it is seldom found without a number of its lovely yellow flowers. It is the only species in the large genus *Medicago* that can strictly lay claim to being a shrub, by far the greater proportion being trailing annuals. According to London, this plant abounds about Naples and in several islands of the Greek Archipelago, where the Turks use the wood to make handles for their sabres. In the greenhouse (No. 4) is a pretty South African Polygalaceous shrub, *Maraltia Heisteria*, introduced from the Cape by Masson in 1787. The Gorse-like compact growth is studded with charming little purple flowers; and, as no special care or skill is required in its cultivation, this should be more largely grown as a decorative greenhouse plant, particularly as it can be had in bloom nearly throughout the year. The Palm-house contains a few plants that merit present mention. First in beauty and exceeding richness of colour, comes the West Indian *Rondeletia speciosa*, one of our very best winter-flowering stove plants. The vivid scarlet blossoms are freely produced, and with the habit we are all well acquainted. *Goldfussia isophylla* is a dwarf, bushy Indian *Acanthad* that makes a good show at this time of the year, with its fine blue flowers. *G. glomerata* is a species with larger flowers and broader leaves than the last-named; both surfaces are covered with red-dish-purple hairs, which look very beautiful when seen in a proper light. *Gomphia Theophrasta*, with its acutely-serrate leaves about 1 ft. long, and its large panicles of golden-yellow flowers, is a handsome member of a large and beautiful genus, of which, however, but few species have found their way into cultivation; the present one was introduced some years ago from South America by Linden, of Ghent. *Schaueria calycetricha* is a fine free-flowering *Justicia*-like *Acanthad* from Brazil, the bright straw-coloured corollas and exserted yellow stamens affording a pretty contrast to the foliage below them. The fine blue of *Plectranthus amethystinus* and the peculiar form of its flowers are well worthy of notice. *Clerodendron splendens* in the stove is a grand, evergreen, close-habited climber, from the woods of Sierra Leone; the large clusters of splendid crimson flowers are very effective. In the cool compartment of the new range, there are a number of specimens of *Nerine flexuosa* and *N. crispa*; both have rosy-white flowers, the former being much the larger of the two, and lacking the pleasing undulations which render the flowers of *N. crispa* so charming. Among the Orchids which we noticed, the following are the most striking:—*Epidendrum evectum* is one of a section in which the stems are leafy and elongated; sometimes, as in the present case, growing to a length of about 9 ft. The terminal inflorescence is made up of about twenty or thirty deep, rosy-purple flowers. *E. equitans* has yellowish flowers, and a habit resembling, in a remarkable degree, many of the Irids. *E. ellipticum* from Rio de Janeiro, grows about 2 ft. high, and has pretty heads of rose-coloured flowers. *E. ibaguensis* is rather deeper in colour and grows somewhat larger than the last-named. *E. glumaceum* derives its name from the long pointed scales—like the glumes of Grasses—out of which spring the racemes of flowers; in habit and sweet odour it is like *E. fragrans*, but the labellum is convex and striped with pink. *E. paniculatum* var. *racemosum* differs considerably from the type; instead of the pretty pink flowers generally seen in some collections, this variety has much reflexed sepals, which, together with the lower part of the column, are green; the upper part and lip are white, the latter variously marked with deep red-purple. *Sigmatostalix radicans* is a very neat-growing little plant with narrow Grass-like leaves, elongated pseudo-bulbs, and little panicles of small flowers, in which yellow, white, green, and reddish-brown, combine to make a pleasing show. The unopened flowers of *Sarcanthus pallidus* are very like the head and beak of a duck in miniature, and the branched panicle bears a profusion of small flowers. G.

PLATE C.

THE GENUS EURYCLES

(WITH A COLOURED FIGURE OF *E. AUSTRALASICA*).

Drawn by MRS. DUFFIELD.

A SMALL genus of Pancratioid white-flowered *Amaryllideæ*, formerly referred to the genus *Pancratium* itself, but subsequently established as an independent genus, on account of the small corona, which is cleft, nearly to the base, into six segments. Mr. Benthams ("Flora Australiensis," vi., p. 456) puts all the known forms under two species; but, from a horticultural point of view, there are three easily distinguished forms. They require warm greenhouse treatment, and succeed well in a compost of loam, leaf-mould, and sand. After they have made their growth, the usual rest in a dry state should be given. The horticultural public is indebted to Messrs. Veitch for the re-introduction of the fine species of which a coloured figure is given in this number of THE GARDEN. Although the same species had been in cultivation in this country before, the Floral Committee of the Royal Horticultural Society awarded Messrs. Veitch a first-class certificate for this plant when they exhibited it at one of the meetings last spring;

and they also received from the Royal Botanic Society a certificate of merit. These recognitions of its value as a decorative plant, are a sufficient recommendation, but I may add a word of praise from having seen the living specimens.

Amboyna Lily (*Eurycles amboinensis*).—This was the form cultivated by Philip Miller at Chelsea, nearly 150 years ago, and it is decidedly the most ornamental. If we separate *E. amboinensis* from *E. australasica*, then the plant figured should bear the former name, and if the two are combined as one species, then, according to the rules of priority of names, *amboinensis* should be selected to designate the species, as Mr. Benthams has done in the work quoted above. Unfortunately, the plant has been certificated and mentioned in the gardening periodicals as *E. australasica*, and by this name it will doubtless continue to be known. The distinctive character of the Amboyna Lily is in the deeply cordate base of the leaf, numerous flowers (usually more than a dozen in each umbel, and

Brisbane Lily (*Eurycles australasica*).

sometimes as many as a score), and in the large size of the flowers. Whether this form extends to Australia, I cannot say; but from a record of a locality (Island of Cairncross, Queensland, Veitch) in Benthams' "Flora Australiensis," it is possible that this locality was the source whence Messrs. Veitch obtained their stock. The original introduction into Europe was effected by the Dutch, probably from one of the islands of the Malayan Archipelago. Specimens exist at Kew from the island of Zebu, one of the Philippine group, and from Malacca; and it is also a native of the Island of Amboyna. And, according to Labillardiere, it was abundant in 1793 in the vast forest of Mount Panangana, Java, growing under Teak trees. Vigorous plants have nearly spherical brown-coated bulbs about 2½ in. in diameter, long-stalked, prominently-ribbed leaves, the blade of which sometimes exceeds 1 ft. in breadth, and the flowers are from 2½ in. to 3 in. long. Salisbury ("Paradisus Londinensis," t. 84) figures the same plant under the name of *Pancratium nervifolium*; and, among its other numerous synonyms, *Eurycles sylvestris* may be mentioned. The flowers appear a little in advance of the leaves, especially in a wild state, or at the same time; but this depends probably upon the season. Allan Cunningham states that the Australian species vary in this respect.

Australian or Brisbane Lily (*E. australasica*, Bot. Reg., t. 715).—This is near the last, but smaller in all its parts; the leaves are scarcely at all cordate at the base; the umbels about eight or ten flowered; and the segments of the perianth are narrower. It was in cultivation at Kew in 1821 from bulbs sent home by Allan

THE BRISBANE LILY (*EURYCLES AUSTRALASICA*).

Cunningham from Cairncross Island, where they grew in a chalky soil under the shade of trees near the sea-coast. It is probable that this and the foregoing are connected by intermediate forms, and the same locality being attributed to Veitch by Mr. Benthani—if the source of the plant here figured—it is possible that both are found in the Island of Cairncross. Whether this be the case or not, it is worth knowing of the existence of inferior varieties.

Cunningham's Lily (E. Cunninghami, Bot. Mag., t. 3399).—Very distinct from the others. Bulbs about the size of a Walnut; leaves longer than broad, and not cordate at the base, from 4 in. to 10 in. long. Flower-scapes about 1 ft. high, bearing from four to ten small flowers, little more than 1 in. long. This was also discovered and introduced by Allan Cunningham. He found it growing in dense somewhat humid woods of Araucaria on the banks of the Brisbane River, near Moreton Bay. W. B. HEMSLEY.

THE FRUIT GARDEN.

REMEDY FOR THE CODLING MOTH GRUB.

The well-known German pomologist, Dr. Edward Lucas, has recently called attention to a simple method of guarding against the ravages of that tiresome insect-plague, the caterpillar of the Apple or Codling Moth (*Tortrix pomona*). It is dependent for its success on the fact that the moth most frequently deposits her eggs between the leaves of the calyx, whence the grub afterwards commences its attack on the heart or pulpy portion of the Apple, and finally escapes by a hole made in the circumference. Observing this, it occurred to Mr. Krausz, of Stuttgart, the discoverer of the remedy, to try the effect of cutting off the calyx, quite low down at its base, as soon as the Apple should have attained the size of a Hazel or Walnut. The prominent situation of the calyx at that

Grub of the Codling Moth (*Tortrix pomona*).

period of the fruit's growth greatly facilitates its removal, and in the case of some hundreds of Apples Mr. Krausz experimented on—several hundreds can be done in an hour—none appeared afterwards to be the least injuriously affected by the operation. In those instances in which the cutting slightly damaged the calyx-tube, the wound soon healed over and became covered with a yellowish-green, cork-like substance, the latter eventually closing the tube, and thus creating an impassable barrier for the insect. As regards the shape of the Apple, this is somewhat altered by the above treatment, so as to render the variety less easily distinguishable, but the slight diminution in length, resulting from its adoption, is more than compensated for by increased thickness, total absence of grub, and, consequently, generally finer appearance. For the purposes of comparison, a considerable portion of the fruit on each of the trees selected for experiment had been left in its natural state, and the Apples operated on were chosen quite at random, regardless of aspect or situation. Not even in the case of the Emperor Alexander, a sort particularly liable to rot on the tree, was there met with, however, amongst the calyxless Apples, a single unsound or grub-eaten specimen, and with reference to the fallen fruit under the different trees it was found to consist exclusively of such as had not been operated on. Naturally regarding his discovery as one of no slight importance to fruit-growers, Mr. Krausz sent a collection of

Apples (to show the difference in their growth and appearance), one half with, the other half without, calyces, to an exhibition recently held at Canustadt, in Würtemberg, and the remedy which he recommends is now likely to be thoroughly tested throughout the fruit-growing districts of Germany. T. S.

FIELD CULTURE OF HARDY FRUIT TREES.

(Continued from p. 456.)

SUMMER PRUNING.—To form the crown quickly, summer pruning should be resorted to. The following are a few instances in which it should be adopted:—When the graft, or the head of the tree, if it has not been grafted on the head or at the height of the crown, is vigorous, and promises to greatly exceed the height at which the branches ought to begin, the top of the shoot ought to be pinched during the summer, in order to make it branch out, and so obtain what only could be obtained in the following winter. Whatever may be the method adopted for growing the future branches of the crown, care must be taken during the summer to keep the tree pretty even—for instance, if the branch (c, fig. 40) grow too upright, a stout stick should be placed between it and the stem, so as to throw it outward, whilst if, on the contrary, it happens to grow too horizontally, it must be made to grow more upright, by means of a wire attached to the stem (as shown at b, fig. 40).

Fig. 40.

The fifth or sixth leaf which shows on the first shoot of the branches should be pinched off if the superfluous buds have not been destroyed at the winter pruning. We recommend the last plan to those who grow a large number of trees, as well as to those who are doubtful of being able to give as much attention as is necessary to the trees during the summer months.

SECOND YEAR.—The first woody branches are cut down to a length of about 1 ft. from their base on two opposite sides, so

as to obtain forked branches, as shown at *b* (fig. 41). The system of pruning as shown at *a a a* (fig. 42) should also be adopted. A false application of the rule, according to which strong branches ought to be pruned short, and weak ones long, is often made during the second years' pruning.

Fig. 41.

When a difference of vigour exists between the first year's branches (*a a a* fig. 42) they ought, nevertheless, to be pruned down to the given length of about 1 ft. The proper balance ought to be obtained by making a notch underneath the strongest branches, and a longitudinal incision, passing

Fig. 42.

through the rind only, along the entire length of the weak ones. We may also, as pointed out in the directions for the first year's treatment, be careful to train the weaker branches in a more upright direction. During the summer following the second pruning, the shoots of the second year's branches

(*b b b* fig. 42), bearing five or six leaves, must also be pinched off to make them woody.

THIRD YEAR.—All trees which have not the requisite number of woody branches, say six or eight, should be pruned so as to form additional forks. The woody branches of the crown should be so trained that they form a hollow cup, as shown in fig. 42. When the woody branches are in sufficient number, and there arises no necessity for making them fork, they are cut down to three-quarters of their length, as shown in fig. 42, without paying any attention to their future growth. The crowns thus formed are imitations of the natural growth of the tree, and should be only adopted in the case of the Apple, Cherry, and Plum, whose crowns are flat and cup-shaped. The Nut, Mulberry, and Chestnut naturally form a ball-shaped crown without the need of much pruning. Little need be done with the pruning-knife, except to cut the graft down to three or four buds, after which they may be allowed to grow in their own way. Pears and Bigarreau Cherries, which have a natural tendency to form a conical crown, are trained in a pyramidal manner. In order to form such crowns it is necessary to allow only a single shoot to grow in its own way during the summer without being pruned. It should be shortened to 12 in. or 15 in. at the winter pruning, which should take place about the beginning of the year, the cut being made just above on the opposite side of the graft. By this means we obtain four or five lateral shoots, and one perpendicular stem. The upper shoots are pinched down during the summer, so as not to injure the lower shoots, which ought to be the stronger of the two. For the first three years the lower branches should be allowed to increase in length without making them forked. Every year the weakest parts should be pruned, taking care that the lower branches are always left longer than the upper. All crowding of the branches forming the crown should be avoided. This defect is not perceived at first, but it soon manifests itself, and is only to be remedied by gashing the tree without mercy. Pyramidal crowns especially require to have their branches properly distanced, in order that they may receive their proper share of light and air. The pruning operations of the next two years are confined to shortening the lateral shoots which are growing too luxuriantly on the woody branches, and to taking care that the branches grow with equal vigour and in the right direction.

THINNING THE CROWNS.—For some time after the formation of the principal branches, in fact, for three or four years, the crown ought to be thinned out so that light and air have free access to it. The weakest shoots should be chosen for pruning away, and watery shoots should be ruthlessly topped, as well as all hanging shoots, or those which interfere with the evenness and symmetrical form of the crown. When two shoots cross, the weaker should be cut away, or at any rate the one which is placed in the least convenient position. If they are both left to grow, they will rub together with the slightest breath of wind, and both will be sacrificed. In the case of stone fruit trees, in which the cut wood does not heal so easily, only the small, weak, and sickly branchlets should be pruned away. The other branches, more especially those which show a tendency to grow in a vertical direction, should be slightly shortened at pruning time in order that they may furnish new wood. In fact, the operation of pruning should be so carried on that there is never any necessity for cutting away the old wood except where it is dead. In certain parts of the country there is a very mischievous system of pruning fruit only once in seven or eight years, and then on a large scale. This is the cause of the decay of many of our old kinds of fruit trees, especially Apples and stone fruit trees. Pruners who practice this kind of work, which is apparently but of little importance, should take the best advice on the subject that they can get, for pruning operations require a large amount of tact and skill. In any case they would be nearer the mark if they pruned away fewer branches than is their general habit, and if they thinned only the different parts of the crown with a little more moderation. If they follow out this advice they will find that they are no longer under the necessity of cutting away large branches, because they have ceased to bear at their base, or because they produce only a few feeble shoots. If it be necessary to prune somewhat severely, a winter following a prolific summer should be chosen for the operation. It is also preferable, when it can be done,

to thin out towards the end of the year just as the leaves are beginning to fall, because the shape of the branches and general growth of the tree are more apparent. Good pruners who are afraid of cutting away too much are apt to err on the other side, for a leafless tree rarely seems to have too many branches. Although it results from what we have already said, that orchard trees do not need the continual attention that garden trees require, it does not mean that it is not necessary to visit well established orchard trees at least once a year armed with the proper tools, even when it is not advisable to prune regularly. A large number of irregularities always want looking after, and preventive measures require to be taken against future defects. Dead and decaying branches want

Fig. 43.

Fig. 44.

Fig. 45.

cutting away, and Moss and caterpillars require destroying. The tools necessary for this purpose are the sécateur (fig. 43), the chisel or cleaner (fig. 44), the échenilloir (fig. 45), and the saw (fig. 46). The curved knife is but seldom used, except for small trees. It is best not to cut too deeply into the interior of the crown, and that only when there is absolute necessity for it. The inexperienced pruner should never be allowed to meddle with this part of the crown. Winter operations may be perfectly well performed with the échenilloir, which, when it is well made and properly sharpened, may be used for cutting branches of medium thickness. This instrument is quite indis-

Fig. 46.

pensable to the orchardist. Small twigs and shoots which ought to be cut away entirely, may also be cut from below. In this category we include adventitious watery shoots, which grow accidentally below the crown, and thus deprive the other parts of the tree of their food. According to the thickness of the branches to be cut, we use either the curved portion of the chisel, or else the flat part, using a mallet from below in the former case.

TREATMENT OF WATERY SHOOTS.—When a tree has attained an advanced age, and the sap circulates but feebly, widen the hardened bark. The decrepitude of the tree begins to show itself by the appearance of succulent shoots, which are rather the effect than the cause of approaching decay. These adven-

titious shoots first show themselves on the branches, which have been allowed to grow to a great length, or else on those which have been entirely abandoned. The whole of these watery shoots need not be pruned away. When the trees have, more or less, fallen into a state of decay, the branches are cut off a good deal farther back than the rottenness seems to extend, the fresh shoots on the living portion of the tree being properly pruned. A certain portion of the ordinary shoots should also be allowed to remain; as they will serve, in the future, to replace the old branches which have been cut away, as they spring exactly from those parts of the tree from which the decayed portions have been cut away. It requires, however, great skill on the part of the pruner to know how to make use of the young wood in order to replace the old. It is true that by this means we get a number of ugly stumpy branches, but they will not be long before they produce new ones, which will soon restore the beauty of the tree. The tree soon begins to wear a leafy appearance once more, and will produce abundantly throughout a long series of years, a result which we should not have obtained so speedily had we endeavoured to replace the old tree by a new one. By this system of severe pruning, we may greatly improve the appearance of trees which have grown deformed; those, for instance, whose pruning has been neglected during the first few years of their growth, and have mis-shaped crowns. This operation is required in a great number of orchards.

PRUNING LARGE TRANSPLANTED TREES.—It is customary, when large trees have been planted in permanent positions for several years, to prune them severely, under the pretext of equalising their branches and roots—reciprocity, as it is called. It is an erroneous notion to prune the roots and branches in the same proportion. There ought certainly to be a certain proportion between the two, but this ought to be obtained by thinning judiciously. When the crown requires severe pruning, the operation ought to be postponed for a full year after transplanting; that is to say, until the following spring. The tree suffers greatly in any case, and when the roots and branches are both severely cut about, as is the usual custom, it frequently fails to recover from the shock.

SUMMER PINCHING.—Trees growing in the open ground, like those in gardens, ought to be carefully looked after during the summer, more especially if it be desired to keep them in the very highest state of perfection. The operations necessary for this purpose consist in cutting away all useless shoots, and to pinch back those which are intended for branches, but which are growing too fast. When the tree is young, these operations may be performed from the ground, but when the branches are out of reach it is better to use a ladder.

Where there are many fruit trees, a double step ladder is necessary. Orchardists neglect a number of little operations by not using this useful adjunct to the orchard. The single ladder in unskilful hands will often cause more damage than will be repaid by the operations performed by its means. We understand, however, that small growers are afraid of the outlay necessary for procuring a good double step ladder, which is only used a few days in the year, and is generally in the way at other times. At fig. 42 we give an illustration of a set of steps which may be used either as a single or double step-ladder, the construction of which is neither more difficult or more expensive than that of the ordinary rung-ladder. If we wish to use it double it is folded in the middle, and if on the other hand we wish to use a single ladder, we lay it down on the ground and slide the two portions together. We have used this ladder for several years, and would advise all orchardists to provide themselves with one. As shown in the figure one part is narrower than the other, so that it fits exactly with the broader half. The top rung of the broader portion is an iron rod (f) which passes through the narrower half by means of a slit about 3 in. in length. At each end of the narrow half there is a notch which, when the ladder is stretched out to its full extent, clutches the last rung of the broader part. The instrument shown in fig. 47, which acts like an échenilloir, but with greater ease and precision, was invented by M. Aubert, a Paris cutler. It consists of a flat piece of steel which carries an immovable blade. This new tool, of which we give a cut (p. 476) which shows it in action, has not the defects of the old fashioned échenilloir when used for ordinary

summer operations on account of the long arm of the lever being absent. It is more solid than the so-called *supprime échelle*; which has never been a favourite amongst cultivators or orchardists, as it only acts on tender shoots. The instrument in question, however, easily slices in two a woody twig as thick as a lead pencil, leaving a clean wound, *A* is a sharp cutting blade, which is a fixture; *b* is a movable cutting blade, which is pulled downwards towards the operator by the cord (*d*) and slides in a groove, and on a rod flying back to its proper position by means of a spiral spring when the cord is released. By means of a clip (*e*) and a thumb screw (*r*) it may be rapidly attached to or detached from the handle (*g*) at pleasure. This mode of adjustment ought to be applied to all instruments of this nature, which are usually fixed to the handle, such as *échevilloirs*, fruit gatherers, &c., and must consequently remain perpetually attached to their long handles, which makes them very inconvenient for stowage, to say nothing of the impossibility of using handles of different lengths. All the arguments brought forward in favour of the old-fashioned *supprime échelle* are equally applicable in the case of the instrument invented by M. Aubert; in fact, it places the whole tree, so to speak, within our reach, and may be used for pruning superfluous shoots, pinching off buds, destroying caterpillars and their habitations, thinning out the fruit and gathering it when ripe, doing away entirely with the use of ladders, double or single.

(To be continued).

Fruit Stores and Frost.—When frost penetrates a fruit store, the flavour and keeping properties of fruit are destroyed; notwithstanding this, many fruit rooms are not built frost-proof. An ordinary iron stove or a hot-water pipe will, of course, keep out frost, but their incautious use often dries and heats the atmosphere too much, and does harm in that way. In small stores, one or two paraffine lamps lighted so as to burn during severe nights, will be both cheap and effectual; or, on sudden emergencies, candles might be made useful. I have known places in which stoves have been taken out and lamps substituted, with satisfactory results. Where gas is burned on the premises, that might be usefully employed.—H.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Top-dressing Vine Borders.—This is the best time for adding fresh soil to Vine borders. Secure a quantity of the best loam or soil obtainable. If in taves, cut it up into small pieces, add a quarter of its bulk of good manure; and, if ground bones cannot be had, add about the same quantity of wood ashes and charred refuse. Mix the whole up together twice over; then remove all the old surface from the border quite down to the roots. That done, the fresh material may be put on; apply a thin layer all over the surface first, and work it in with the hands amongst the roots; then the whole may be laid on. Unless the soil be very dry, it should not be trampled firm, but only gently pressed down. A substantial top-dressing of this kind is of far more permanent benefit than a layer of soft manure; and when properly done, it will last good for two or three years.—CAMBRIAN.

The Heaviest Bunch of Black Grapes that has ever been grown, or, we should say, that has ever been recorded, is now on view at 22, South Frederick Street, Dublin. The variety is Gros Guillaume, and the grower, Mr. Roberts, gardener to the Countess of Charleville, Charleville Forest, Tullamore, King's Co. Its weight is 23 lb. 5 oz.; its length, 24 in.; and width across the shoulders, 22½ in.; and in point of colour, bloom, size of berries, and general finish, it is described as all that could be desired. This bunch stands third on the list of heaviest bunches (irrespective of colour), being 2 lb. 15 oz. less in weight than the bunch of Raisin de Calabre, 28 lb. 4 oz., shown by Mr. Currer at Edinburgh in September, 1875, and 2 lb. 5 oz. less than the White Nice, 25 lb. 15 oz., shown by Mr. Dickson, of Arklton, at the same time and place.—“Gardeners' Chronicle.”

THE GEOGRAPHICAL DISTRIBUTION OF PLANTS.

Introductory Remarks.

IMPORTANCE OF THE STUDY.—A knowledge of the fundamental laws regulating and limiting the dispersion of plants over the surface of the earth is not merely of abstract interest; it is of great practical use, and is gradually increasing in importance as the natural sources of one valuable vegetable product after another become exhausted. To examine and discuss this subject in all its bearings would fill many thick volumes, and therefore it is necessary to confine our attention here mainly to those points which more immediately concern the cultivator. The principal aim of this brief sketch being to give prominence to useful facts connected with the present distribution of plants, a critical exposition of any particular theory does not fall within its scope, nevertheless it does not appear desirable to avoid all reference to anything and everything that cannot be supported by absolute proof. Indeed, it is almost impossible, in speaking of the agents known to be actively engaged at the present moment in altering the aspect of the vegetation of different countries and different regions, to exclude all speculations as to what these and other forces may have effected in bygone ages.

EVIDENCE OF FOSSILIZED PLANTS.—We have the irrefragable testimony of the rocks that vegetation of a very simple type of structure existed in very remote ages, in a very early stage of the consolidation of this planet, co-early with animal organisms of equally simple types. It is also beyond doubt that fossil plants and animals of a growing complexity of structure are found associated in successively more recent strata, until we reach the deposits of historic times, in which occur impressions of parts of plants identical with living forms. Comparatively so little of the globe now remains unexplored that it may be confidently asserted that an enormous number of distinct plant types, of the Coal Measures for instance, have become extinct, and are now replaced in the same countries by forms not only widely diverse in themselves, but likewise belonging for the greater part to totally different families. Another fact—many, and perhaps all, of the more ancient types known to us only in the fossil state had a very extensive geographical range.

CONTINUAL CHANGE THE ORDER OF NATURE.—How far these facts support the theory of evolution, or descent from one or several types, I shall not attempt to show, but they indicate at least that constant change is the order of nature. It may always be, and have been, gradual, and too slow for us to be able to appreciate; but it is none the less surely going on. Besides these changes in the character of the vegetation of the surface of the earth and the waters of the ocean, we know that the globe itself, both as to the land and water, has undergone great alterations. It will doubtless always be a matter of surmise how much, and what parts of the present seas, were dry land at any or different periods; but, on the other hand, there is no difficulty in finding traces of the sea or mighty rivers or lakes where now is dry land. According to geologists, since the deposition of the older strata of the Tertiary Epoch, the whole of the south-eastern portion of England, from Portsmouth to the Humber, has been covered by the sea; Wales has existed as an island, and Scotland and Ireland as clusters of small islands. Formerly the theory that the history of the world consisted of a number of distinct and separate epochs, each terminated by a universal catastrophe, was much in favour; but further research has brought evidence to light which indicates continuity and local changes; in some cases of a violent and sudden character, in others the reverse. This slight allusion to the vegetation of past ages is intended to lead up to a more correct estimation of the agents now active in modifying the physiognomy of nature.

AGENTS WHICH HAVE EFFECTED THE PRESENT DISTRIBUTION OF PLANTS.—The principal factor in determining and limiting the flora of a country is now, and probably always has been, climate. Therefore, when it is intended to attempt the introduction and cultivation of any particular plant into another country than its own, as, for example, the Cinchona in India, the first thing to be considered and studied is the climate of the native country of the subject and of the country where the experiment is to be made. Should the country of the two

Fig. 47.

places differ materially, there is little chance of success, and there is a great risk of total failure; and many such failures are on record, simply because the promoters of certain schemes of "acclimatisation," as they please to call it, have neglected or been ignorant of the fact that every plant, according to its constitution, requires a certain amount of heat to attain perfect development. It is true that some plants are much more elastic than others, and accommodate themselves to greater variations of climate. But man, as he has increased and spread over the world, has done much, as far as climate would permit, to alter the character of the aboriginal vegetation of most countries. The influence of man is of two kinds, active and passive; and he is to be distinguished from all strictly natural agents. Man's active influence is exercised in the introduction and cultivation of exotic plants; and among other ways in which he passively contributes to the changing of the flora of a country is the involuntary introduction of weeds. A fruitful source of destruction of the indigenous plants of several countries has been indirectly effected by man through the importation of hogs, goats, rabbits, and other animals. Among other agents which have assisted in widening the area of distribution of many plants are birds and various other herbivorous members of the animal kingdom, ocean currents, rivers, winds, violent gales, &c.; but all these agents are limited in their action by climate.

NUMBER OF SPECIES OF PLANTS.—Independently of the lower Cryptogams, the number of known distinct species of plants in

the whole world is estimated at from 100,000 to 120,000, according to the view taken as to what constitutes a species. Of course the number would be much larger if computed from the standpoint of a botanist like Mr. Jordan, who has divided the Whitlow Grass (*Erophila verna*) into seventy species, or from the stand-

point of a florist, who regards slight differences as sufficient to warrant him in giving distinctive names. For some further information respecting the definition of species and varieties we may refer to the article on classification. These 100,000 to 120,000 species are referred to from 10,000 to 12,000 genera. But these genera vary very much in the number of species they embrace. Some few, such as *Solanum* and *Erica*, include several hundred species, whilst other equally distinct genera, such as *Atropa*, *Deadly Nightshade*, and *Hippophaë* (*Sea Buckthorn*) are each limited to one species. The genera are grouped under 200 to 250 Natural Orders, some of which comprise a large number of genera and species, whilst others include very few or even only one genus. Thus the *Compositæ* (*Aster* family) includes, at a very moderate estimate, 750 genera and 10,000 species, and the *Leguminosæ* (*Pea* family), 400 genera and 6500 species. On the other hand, the *Ulmaceæ* (*Elm*

family) numbers only four genera and twenty species; and there are several Natural Orders that are not represented in our native flora, which are still more restricted.

ANOMALIES OF DISTRIBUTION.—Some of the Natural Orders have a relatively small geographical area, and others are

Sectional View, showing operations in Mushroom Cave at Montrouge at the time of gathering and of sending up and down the materials of beds. Drawn by A. De Bar in 1877.

represented in every country and region to which plants penetrate. Here again it is necessary to say that the lower Cryptogams, such as Sea-weeds, Mosses, and Funguses, are left out of the comparisons, as they are all through, except where specially mentioned. A familiar Order (the Bromeliaceæ, or Pine-apple family) is limited to tropical and temperate America, though several species have now become thoroughly naturalised in other countries. The Gramineæ (Grass family) is a striking example of a very natural group of plants, extending into nearly all climates and situations. Genera and species exhibit similar peculiarities in their distribution. The genus *Eucalyptus* (Gum trees of Australia) includes nearly 150 species, and is almost confined to the mainland of Australia, forming its largest and most valuable forests. Not a single species extends to New Zealand; and only three or four each, any of the islands north of Australia. In contrast to this the large, natural genus *Rubus* is found in the most distant and diverse countries—from the Arctic regions in the north, through all the continents southwards to New Zealand, Australia, South Africa, and South America; but in certain regions the species are much more numerous than in others. The genus *Fagus* (Beech trees) offers a remarkable instance of widely separated species. Altogether it comprises less than twenty species, which are divided between the temperate regions of the northern and southern hemispheres. In the north they belt the world, and in the south they are found in South America, New Zealand, Tasmania, and South Australia, forming considerable forests in some parts, especially New Zealand; and *F. Moorei* is a beautiful tree 150 ft. high, forming dense forests in the mountains of New South Wales. The great Water Lily (*Victoria Regia*) is confined in a wild state to some of the rivers of equatorial America, whilst an allied aquatic (*Brasenia peltata*) occurs in America, the East Indies, Australia, and tropical Africa. Many familiar genera are dispersed over nearly all tropical and sub-tropical countries. To this category belong *Abutilon*, *Acacia*, &c., whilst *Clematis*, *Ranunculus*, *Trichomanes*, &c., occur in nearly all temperate and sub-tropical regions, and *Ranunculus* extends to the coldest countries in which flowering plants have been found. Generally speaking, aquatic plants and Ferns have the widest areas of distribution. Aquatic plants are less exposed to the effects of atmospheric changes, and they are also subject to being carried to great distances by the element in which they grow. Our common Pond-weed (*Potamogeton natans*), to give an example, is almost ubiquitous, as is also the common Duckweed (*Lemna minor*); and *Trichomanes radicans* occurs in Europe, Africa, Asia, America, and Polynesian Islands. Similar curiosities of the distribution of plants might be multiplied indefinitely, but enough have been adduced to show that types are not necessarily characteristic of certain climates. *Rubus arcticus* is at home in the coldest regions, and *R. rosæfolius* is a native of the tropics, so that under cultivation these two closely-related plants would require totally different treatment. This brings us to the consideration of climate. For purposes of comparison, and as a starting point, the climate of Great Britain will serve as a basis, just as the indigenous and cultivated plants of this country will be employed for illustration in all cases where it is possible.

Climate in its Effects on Vegetation.

CONSTITUTION OF PLANTS.—Given a favourable soil, certain climatal conditions are necessary to enable plants to grow and reproduce themselves. The absence of a sufficient amount of heat and moisture, or the presence of too much, according to the constitution of a plant, will determine its fate. Practically speaking, plants do not alter as to the amount of heat and moisture they require, and years of cultivation effect nothing in the way of reducing or increasing the amount that will suffice. The foliage of the Scarlet Runner, Bean, and the Potato is destroyed by a slight frost now as in former days, and these plants are no more acclimatised, in the sense of being able to endure a greater degree of cold, than they were a year or two after their introduction. These are instances in which cold, that is, a temperature below the freezing point, influences successful cultivation. Should they escape frost there is normally sufficient heat in the climate

of London, for example, for them to attain perfection. Take the Grape Vine for another illustration. It bears our severest winters without injury, but it rarely matures its fruit, because the amount of heat is inadequate. Heat, it may be observed, as the word is employed here, signifies a temperature above the freezing point. Too little heat and too much cold act in an equally prejudicial manner; but they are very unequal opponents to grapple with in practical gardening. We cannot supply the missing amount of heat except, of course, under entirely artificial conditions, though we can avoid the too great cold, in the case of such plants as yield their crop the same season, by planting at a seasonable time. Plants in different stages or conditions of their development are less susceptible to cold, or are naturally protected from it.

SEEDS WILL BEAR GREAT EXTREMES OF TEMPERATURE.—In the dormant stage, in the seed, the plant will bear much greater extremes of temperature without injury than at any other phase of its existence; consequently, annuals that would be killed by a few degrees of cold when actively growing, escape annihilation through their immunity to cold in a certain condition. And, as in obedience to another law, their seeds do not germinate in a medium which is below a temperature, varying in amount for diverse plants, they avoid, to a great extent, exposing themselves to an unfavourable influence. Protected in this way, annuals are able to attain maturity and reproduce themselves in a climate of less heat than that of their native country. Herbaceous perennials, which annually die down to the ground, or shrubs like *Fuchsia macrostemon*, which may be treated as such, escape the full force of the cold, and flower and produce good seed in due season. But there is no compensating a deficiency of heat, and unless a plant suffering under this disadvantage is able to propagate itself asexually, it must die out if left to take its chance. Unusually late or severe frosts often blast our native plants, and the character of the vegetation of any country undergoing a gradual change of climate must in time become quite metamorphosed. Alternate changes of climate would account for the character of the vegetation of this and other countries, of which we have evidence in the fossil forms of plants; and also affords an easy and an acceptable explanation of the distribution of existing forms of the vegetable kingdom. This view is now generally accepted, and the evidence in support of it is almost irresistible; but it would occupy too much space to enter into details on this point. The gradual disappearance of one set of plants, enfeebled by unfavourable climatic changes, and overcome by the increased vigour and reproductive power of another set of plants, is a picture easily conceived. Thus, many of our common weeds, introduced into the Australian and New Zealand settlements, have developed an extraordinary degree of vigour, and spread with astonishing rapidity, taking complete possession of the soil, to the exclusion of the native plants. The common Water-ress was introduced into New Zealand, where it soon attained 8 ft. or 9 ft. in length, with stems as thick as one's wrist, choking the streams, and even impeding navigation in the rivers. Timothy Grass (*Phleum pratense*), introduced into California, there attains a height of 5 ft. or 6 ft., with a flower-spike nearly 1 ft. in length, and yields a crop of hay equal to 4 tons per acre. Gradually, however, it seems, introduced plants of this kind return to a more normal state, and are reduced to even terms with others of the same duration.

THE SAME SPECIES NOT CREATED IN DIFFERENT PARTS OF THE WORLD.—It is true that to accept this theory of change of climate in its full significance involves the acceptance of the corollary, that all forms have been dispersed from a single centre; that is to say, dissimilar forms have been created in different centres, but the same form was not created, or did not originate, in two or more diverse centres. Of course, this would not preclude the possibility of the same form, in distant habitats, developing different lines of variation, or the converse. The last sentence presents some apparent contradictions, which would require much explanation and illustration to elucidate. At the present time such British plants as *Sanicula europæa*, *Scabiosa succisa*, *Galium aparine*, *Limosella aquatica*, *Sibthorpia europæa*, *Luzula campestris*, and many others, independently of their distribution in Europe and Asia, &c., occur in the isolated mountains of tropical Africa. Although

in this situation they are widely distant from the nearest habitats of the same species, it is assumed that they owe their existence in all the localities where they abound, not to separate creations, but to climatal changes that have destroyed them in the intervening plains, and driven them, or permitted their extension to the mountain heights, where they find a suitable climate. It is almost superfluous to add that the distribution of heat depends upon altitude as well as latitude. In equatorial countries, where there are lofty mountains, it is possible, by ascending, to pass successively through belts of tropical, sub-tropical, temperate, and Alpine forms of vegetation in a few days at the outside. Each 1000 ft. of altitude is equal to a journey of something like 200 miles in latitude. The decrease of temperature for elevation, even within the tropics, will vary considerably, according to the situation, aspect, &c., of the mountains.

HOW PLANTS MAY HAVE MIGRATED.—Supposing in the course of time the earth's course with respect to the sun should be so changed that the climate in the latitude of these mountains of Africa would become a temperate or cold one, the tropical plants of the plains would disappear where the climate was getting colder, and the temperate plants of the mountains would descend to the plains and only extend and propagate in the direction of the most suitable climate. A gradual return of heat would bring about a restoration of the former conditions, or similar conditions. Such changes, it is believed, have actually occurred during the existence of the world. Whether this is a correct interpretation of the present distribution of plants is, however, from a practical point of view, a matter of secondary importance. What concerns us more nearly is the present distribution of plants and the actual climatal conditions. W. B. HEMSLEY.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. G. PRAGNELL.

November 19.—Tying in Raspberry canes to wire trellises. Getting the remainder of the Strawberries for forcing stacked up in ashes against north wall, so that they may be easily protected in severe weather. Turning over Mushroom-manure to sweeten. Commencing to clear out an old Vine border, wheeling the mould on to vegetable quarters. Used to sow at this date Sutton's Early Ringleader and Maclean's Little Gem Peas, but find it much better to sow them in pieces of turf, 1 ft. by 6 in., about the middle of January under shelter.

Nov. 20.—Looking over Calceolaria cuttings, and picking off all flower buds and leaves that are damping off. Getting early borders well manured and trenched from 2 ft. to 3 ft. deep. Planting Peach, Nectarine, and Apricot trees in holes previously prepared for them. Getting manure on to all vacant ground whilst the weather is favourable, and clearing out all useless and decayed vegetables.

Nov. 21.—Potting another batch of Lily of the Valley. Covering up Endive and Lettuces to blanch. Taking up the drainage of Vine border and relaying it. Getting home new maiden loam from the deer park for new Vine border. Clearing off flower borders and getting them forked up. Planting the following sorts of pyramid Pears in well-trenched ground—William's Bon Chrétien, Jargonelle, Gratioli of Jersey, Louise Bonne of Jersey, Dunmore, Beurré de Capiaumont, Broom Park, Marie Louise, Doyenné du Comice, Beurré Diel, Ne Plus Meuris, and Knight's Monarch.

Nov. 22.—Earthing up French Beans and putting sticks to them. Pruning and nailing Cherries on north walls. Getting up a few roots of Rhubarb and putting them in Mushroom-house for forcing. Getting all the boiler flues and chimneys cleaned out. Making new Vine border with loam from deer park, with $\frac{3}{4}$ in. bone, old mortar rubbish, and a little charcoal added.

Nov. 23.—Potting 100 pots of French Beans; also Cucumber plants. Taking up Asparagus for forcing, and filling a three-light frame. Mulching all newly-planted trees. Clearing up leaves in pleasure grounds, and getting all gravel rolled down firmly. Looking over Caniflowers, turning down leaves for protection where required. Looking over the Pines, and giving them a little water where required.

Nov. 24.—Potting up Mint; also a little Tarragon for forcing. Moving tender plants from cold pits to Vineries. Looking over fruit-room, and removing all fruits that are decaying. Looking over the Grapes in bottles, taking out any bad berries, and filling up the bottles where required. Clearing up the rubbish yard, and burning all refuse for ashes. Fruit in use for dessert—Pines, Grapes, Pears, Apples, Medlars, and Nuts.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Trees Suitable for Screens.—One of the first conditions that most people desire in a garden is privacy; whether the garden be that usually attached to a small villa residence, or of a more pretentious character, one of the first things ordinarily looked to is the planting of the boundary lines to, as far as possible, exclude the sight from outside except at such points as it is desirable to leave open to afford views from the interior of objects more or less in the distance, as local circumstances may determine. In the case of large places, this is easily managed where there is sufficient room to introduce a belt of deciduous and evergreen trees, which should be skilfully arranged so as to effect the object without making the intention more than can be avoided apparent; but with amateurs' gardens of an ordinary size, there is more difficulty in making an effectual screen without its occupying too much land. Erect-growing Poplars, from the limited space which they cover, and their rapidity of growth, are most frequently used, yet these are unsatisfactory, inasmuch as divisional lines of this sort should be as impervious to the eye during winter as they are in summer, a condition which cannot exist when deciduous subjects are used. Much better every way, both by their ability to thoroughly answer the purpose in view winter and summer alike, as well as thriving well in most soils and situations where not exposed to too smoky an atmosphere, are such things as *Pinus cembra*, *Pinus austriaca*, evergreen Oaks, and Hollies; these, by a judicious arrangement in not planting them in exactly straight lines, with a few dwarfier-growing subjects in front, such as *Rhododendron*, *Portugal Laurels*, and *Acubas*, will make an effectual screen in a short time if the plants be sufficiently attended to, and the soil fairly enriched. It is a prevalent, though very mistaken idea, that such plants as these do not like an enriched soil in which to grow; this, however, is anything but the case. Green, rank manures do not suit them, but a fair admixture of that which is well decomposed stimulates their growth amazingly. In the case of all plants required for screens, it should ever be borne in mind that they must always have enough space to keep the lower branches in a healthy, thriving state, otherwise they get naked below, which completely defeats the object in view. With trees so grown for such a purpose, a moderate use of the pruning knife is admissible, in order to prevent their unduly encroaching upon each other, and to encourage and direct growth where it is most required. Not only is the boundary line of a garden, composed of evergreen subjects like the above, much more effectual for the purpose intended, but it has the additional advantage of looking well at all seasons, and affords much more protection to everything requiring shelter during the winter and spring, at which time it is most needed, than can possibly be effected by trees and shrubs that cast their leaves.

Planting.—Now that the season has arrived for planting many things for both use and ornament, such as fruit trees, Roses, and other deciduous as well as evergreen shrubs and trees, I would especially caution amateurs against a very mischievous practice that is often recommended, and too often acted upon. It is this, when the natural soil is not of a character well suited to the trees that have to be grown in it, it is a common practice to dig holes to a considerable depth, and to fill these in with what is termed suitable soil; this often takes place where the ground is naturally of a clayey and retentive description; in such soils, holes like those just alluded to are made for fruit trees against walls, by the sides of walks, and in open quarters; standard Roses have similar stations prepared for them by the sides of walks, and in other situations where their presence is deemed desirable; under such conditions as the above, the soil used for planting in will naturally be considerably lighter in character, more open and porous than the surrounding earth, the inevitable result of which is that the holes so dug and filled in with this lighter material at once become receptacles into which the water of both the surface and the surrounding ground drains, reducing the newly-put in material to a state of saturation, in which the roots of the trees and shrubs so planted stand through the winter as in a cold bath; the extremities more or less broken in the operation of removal, at once absorb the superabundant moisture rotting back to a considerable extent, and entailing disappointment more or less. In all cases where planting is being done the whole of the ground if possible, should be dug, trenched, or, what is termed sometimes, bastard-trenched, that is, the upper surface, to a greater or less depth, according to the good or indifferent nature of the land, turned over, and that underneath stirred, but not brought to the top, fully as deep or a little deeper than the deepest holes which have to be made to admit the plants; by loosening the whole body of earth to such a depth, it will easily be seen that the water collectively has a chance of passing away, without obstruction, into the drains, which land of such a character will not do without. Where, as in planting Roses, in prepared stations such as above, when

the surrounding ground is often lawn, and digging in the way described would be out of the question, or in planting fruit trees or anything else, where the places the roots are to occupy are prepared in the way first named, in every case a drain of some description should be laid from the bottom of the hole so dug out, which will carry the water off into one of the ordinary drains in the place; if this simple but indispensable precaution were taken, a good deal of the disappointment that results from planting trees in exceptional situations would be avoided. It will be easily seen that where the land is naturally of a too light character for the growth of the subjects intended to be planted, and the stations are opened and filled with soil of a stronger and heavier description, the mischief above spoken of will not occur, as the open character of the ground admits of the superfluous water passing off.

Shrubberies, Lawns, Walks, &c.—As soon as the leaves are all fallen, attention should be given to making a general clearance so as to get everything into a tidy condition for the winter. In the case of leaves the most natural course undoubtedly, with a view to returning to the soil that which has been extracted from it, is to allow them to rot on the ground where they fall, as frequently advised by those who treat on the subject; but in gardens of small or moderate extent, where anything like a neat appearance is required, this is out of the question, as every gust of wind blows them out from under the shrubs and trees on to the walks and lawns; and in small gardens, where the soil is of an average description, the deciduous trees will generally grow even too fast without any manorial assistance, either in the shape of the leaves they have produced or otherwise; consequently, the best course to follow is to gather them up and bury them just at the extremities of the roots of evergreen shrubs, on which they will have a most beneficial effect; but, before this is done, enough should always be secured for laying up to rot to furnish leaf-mould for potting purposes, and also for mixing with stable manure for hotbed work in winter and spring. After the shrubberies are cleared, the lawns should be well swept and rolled, and in the case of any that have been recently made, where the Grass is generally disposed to grow luxuriantly, advantage should be taken of a few dry days to go over them again with the machine; this will be the more necessary after the present exceptionally fine autumn, which has kept the Grass growing longer than usual. On old lawns, on the contrary, where the Grass generally grows weak, and is liable to suffer through drought in summer, it is well not to mow more in autumn than is necessary for appearance sake, and in such cases never to cut the Grass too close, as the shorter it is cut the weaker it gets. Walks should be again gone over, and every bit of weed picked out; common Grasses, that spring up on the gravel, always give the most trouble on walks, and amateurs who have not had much experience in gardening often take very little notice of these, especially at this season, when they are small; but they should never be neglected, as being British plants of the hardiest kind, they will go on seeding at all times, except in the very depth of winter. Keep the walks well rolled, so as to present a clean, even, firm surface. When everything in a garden is neat and orderly it goes far to compensate for the lack of flowers. Those portions of the garden devoted to decorative purposes should again be looked over, to see where any additional bulbs can be planted with good effect. Few places are met with, large or small, where a sufficient number of the earliest of these flowering plants are grown, such as Snowdrops, Crocuses, Early Tulips, Aconites, Erythroniums, Daffodils, Narcissi, Hyacinths, and Crown Imperials. The advantage arising from these plants being grown in quantities enough to produce an effect, is that they make the garden interesting and cheerful in appearance from the first dawn of the lengthening days, and their absence can never be compensated for by any amount of summer-flowering subjects.

Kitchen Garden.—A slight hotbed should now be made up for growing Seakale, where this is wanted by the end of the year. If it is made of leaves alone all the better, as these are not liable to get too hot, in the way that stable manure frequently does; make it about 2 ft. 6 in. in thickness; it may be soiled at once, and the crows put in 6 in. apart. Any ordinary garden soil, or old potting material, will do, keeping it fairly moist but not too wet. A small garden frame will answer to place on the top, covering it with boards or shutters, so as to keep the inside quite dark, which is better than using the glazed lights, as it would be necessary to put over them mats or litter, which in a wet state naturally cause decay.

Flower Culture in Algeria.—In a land like Algeria, where every bit of turf becomes a parterre after the rains of December and January, we naturally look for sweet smells rivaling the fragrance of field and meadows, nor are we disappointed. Vast tracts in the Metidja, consisting of thousands of acres, have been turned

into flower-gardens, and the harvest they yield, being less exposed to risk than any other, is exceedingly productive. The marketable value of flowers used in distilleries, laboratories, &c., may be gathered from the following prices given per quintal (owt.): Borage fetches 300 francs; Mallows, 300 francs; Verbena, 400 francs; the little pink Centaury, 60 to 80 francs, &c. The most esteemed of Algerian perfumes are made from the Orange tree, Tabersee, Jasmine, Verbena, and other well-known flowers rarely seen to perfection under colder northern skies. No traveller should omit to visit these flower farms, gorgeous tracts of unimagined brilliance flecking the brown plain, oases of colour between the monotonous mellow sky and the transparent blue of the sea and mountains. A few years ago this feature, as well as many another now characteristic of Algerian scenery, was wanting. The highly-cultivated farms, Vineyards, and orchards, the bran-new villages that have sprung up in every direction, and above all the plantations of Eucalyptus globulus or Anetralian Blue Gum, are changing the whole face of the country. —“Fraser's Magazine.”

Ivy on High Windows.—In cities where there may be little opportunity of planting the Ivy in the street, it is easily grown as a box plant. The window framed in Ivy, as shown imperfectly in the accompanying sketch, was a very high one (four stories), and the

effect was very good indeed. A deep, strong box, filled with very rich soil (in which the manure is well rotted before being used) suits these window Ivies best.

Epiphyllums at Chatsworth.—We hear that these precious winter-flowering plants are in great beauty at Chatsworth, where Mr. Speed has wisely got many of the varieties well grown—large plants, and plants in baskets. This last is an excellent way, as it permits of the under parts of the drooping flowers being well seen.

Violets by Post.—Mr. Groom has sent us, from Henham Hall, a tin box full of Violets and other flowers, to show how well they travel by post packed amongst a few of their own leaves, and when they reached us they were as fresh and fragrant as Violets just gathered. As regards the boxes, their size and form were fully described at p. 388; any tinsmith can make them. They are 6 in. long, 2½ in. wide, and 2 in. deep. Such boxes, for a few stamps, will carry several dozens of Violets.

Zonal Pelargoniums in the Greenhouse in Autumn.—The various newer forms of Zonal Pelargoniums are now very attractively in bloom at Chiswick. The various shades of rose, salmon, and the eyed kinds are among the most attractive, and there is one beautiful white kind—Evening Star. The beauty of these plants must astonish those only familiar with the older kinds. They make the greenhouse gay as a flower garden in November. Grown in this way we see some of the charms of the Zonal Geranium. Making telegraph lines of it through the land was the way to rob it of its beauty.

TREES AND SHRUBS.

THE TULIP TREE.

(LIRIODENDRON TULIPIFERUM.)

THIS highly-ornamental deciduous tree belongs to the same Natural Order as the Magnolia. It is indigenous in North America, chiefly in the Western States, where it attains large dimensions, particularly so in deep alluvial soils on the banks of rivers, where, it is said, there are specimens from 120 ft. to 130 ft. high, with stems girthing at 5 ft. above the ground from 18 ft. to 22 ft. It was introduced into this country as far back as 1688, but it appears from Evelyn's 1776 edition of "Silva," that many years after it was cultivated in England it was considered to be not hardy enough to stand out in the open ground during winter. Evelyn says: "The first tree of this kind which flowered here was in the gardens of the late Earl of Peterborough, at Parson's Green, near Fulham, where it was planted in a wilderness among other trees; before this was planted in the open air, the few plants which were then in English gardens were kept in pots, and housed in winter, supposing they were too tender to live out of doors; but this tree, soon after it was placed in the open ground, convinced cultivators of their mistake by the great progress which it made, while those which were kept in pots and tubs increased slowly in growth; so that afterward there were many others planted in the open ground, and these are now large in size, especially those which were planted in moist soil." Since the above was written, this tree has been pretty generally planted, though perhaps in limited numbers, throughout the country, mostly in parks and pleasure-grounds, on account of the ornamental aspect which it presents amongst other trees, especially when sufficient room is allowed it in which to develop its branches, and where it is fully exposed to the sun. In such situations it produces its conspicuous cup-shaped, or rather Tulip-like flowers, in abundance, on the ends of the shoots; the colours of the flowers are orange, yellow, and red, and when contrasted with the smooth, highly-polished green foliage, they produce a striking effect—

—Through the verdant maze

The Tulip tree

Its golden chalice oft triumphantly displays.

The flowers, which are slightly scented, are generally fully open about the latter end of June or the beginning of July; its large saddle-shaped leaves, which are lucid green above and pale green underneath, hang on the tree until late in the year, when, during a dry autumn, they die off a deep rich yellow. The ramification of the branches, too, of the Tulip tree is very distinct from that of most other trees, the outline being of an unusually graceful character. The habit of the tree is upright, but the limbs are inclined to make many bends and elbows, and the branchlets, particularly those on the lower branches, are pendent. In short, taking the Tulip tree as a whole, it is one of the most stately and ornamental trees which we possess.

As a timber tree it is not likely to be held in much esteem in a commercial point of view. Its wood is white, clean-grained, soft, and easy to work, but it is not durable when exposed to alternate moisture and dryness; it is also rather brittle or "short-grained," and deficient in toughness and strength of fibre; this latter fault is very evident in growing trees, the limbs of which are liable to be broken off by rough winds; on this account young-growing Tulip trees should receive timely foreshortening as regards any straggling branches, or those that are gaining too much strength in proportion to the rest of the tree. The Tulip tree is specially adapted for planting in smoky towns, and for adorning parks and squares, on account of its large, distinct, fresh green leaves, that hang on so late in autumn, as well as the rich appearance which they exhibit when changed to deep yellow before they fall. There are many large and fine specimens of this tree growing in different parts of the country. Perhaps, therefore, some of the readers of THE GARDEN who possess, or know of, examples of remarkable dimensions will kindly record them in your columns; such information could not fail to be interesting to all lovers of trees. There are several large and majestic Tulip trees growing at Longleat; the two largest containing respec-

tively 160 ft. and 210 ft. of timber, and girthing 10 ft. and 10 ft. 10 in. at 5 ft. above the base; of these trees the former has a fine, round, solid butt, 15 ft. long, where it divides into three straight, upright stems, each quite a timber tree in itself, and the ends of the branches droop gracefully, a habit peculiar to this tree, which adds much to its beauty; it is close upon 100 ft. high. The last-named specimen is about 85 ft. high, and its butt is 10 ft. long, up to where it diverges into five main upright branches, and forms a fine, ample head of foliage, which just now (October 26) is a beautiful golden colour. The appearance of these trees in their brilliant yellow autumn clothing is a sight not to be easily erased from the memory. At Zeal's House, Wilts, about 5 miles from here, there is growing on the lawn in the flower-garden a Tulip tree even larger and finer than those which I have mentioned. It is the best specimen with which I am acquainted, and I should think there is scarcely its match for size of butt, and beauty of form and outline, in this country. The butt is 6 ft. long up to where it divides into several huge, handsome limbs; the smallest part of the butt girths 13 ft. 4 in.; the diameter of the spread of the branches is about 70 ft., and the height of the tree is fully 60 ft. When I saw it recently, its wide, oblong head of broken and irregular outline was a mass of healthy, fresh green foliage, the branchlets on the lower limbs hanging vertically, and almost sweeping the turf.

As a proof how hardy the Tulip tree is, I may mention that the situation where this specimen is standing is very exposed, being on an elevated, open piece of ground at the foot of Mere Downs, a breezy part of the country, and quite destitute of shelter as far as the eye can reach from the site occupied by this splendid tree. The soil in which it is growing is thin and light, with a green-sand subsoil. The Longleat Tulip trees are growing in a strong loamy soil, on an Oxford clay subsoil. These two instances of the Tulip tree flourishing equally well in strong and light soils is good evidence in its favour as regards more general planting where ornamental effect is the primary object required.

GEORGE BERRY.

Longleat.

EUROPEAN TIMBER.

THE real area capable of producing valuable wood in Austro-Hungary amounts to something above 9,270,000 hectares (about 19,000,000 English acres). This area is decreasing, though in some provinces it does so in a small proportion and gradually. On an average 31 per cent. of the surface of the country has remained under the cultivation of trees, and in some of the provinces more than 50 per cent. of the whole surface is devoted to forests. Provided, however, that care be taken to replenish all the area of the forest in different gradations from the youngest to the oldest trees, it may be stated without exaggeration that an annual increase of 32,000,000 "test cubic metres" (the official and usual measure) may be reckoned upon. This does not include the wood that may be made use of in the intervals of clearing, nor of the quantity of wood kept as stock. The means for transporting timber are so insufficiently developed in Eastern Galicia, the Bukowina, and, owing to their inaccessibility, the upper regions of the Alps, that the forests in these places have remained in all their pristine grandeur and luxuriance, and are still unavailable. The country produces Pine, Larch, Fir, Beech, Oak, Elm, Willow, and Poplar; and the export trade averages about 67,400,000 cubic metres decennially. The forests of Hesse Darmstadt and Baden cover about 594,975 English acres, leaving only 162,145 acres for agrarian purposes. There are besides about 9797 acres of wood belonging to Hesse in Prussian and Bavarian territories, which swell the total area of land covered by woods to 604,772 acres—in other words, four-fifths of the Grand Duchy are wooded. In Baden, the forest-covered land occupies an area of 1,268,956 English acres, which is equivalent to one-third of the whole Grand Duchy. There is no appreciable decrease here, as every thirty years the land which has once belonged to the cultivation of trees must return to its original employment. The forests contain some of the finest timber in Europe, and consist of Pines, Oaks, Firs, &c. The various provinces of Prussia produce timber as follows:—

Province of Prussia.—Pine, Larch, Beech, Oak, Norway Maple, Sycamore, Elm, Alder, Birch, Sallow, Linden, Ash, and Aspen. Pine wood comprises three-fourths of the total extent of forest in this province.

Province of Posen.—Pine, Oak, Birch, Beech, Alder, Elm, Maple, Aspen, and Hornbeam.

Province of Pomerania.—Pine, Oak, Birch, Beech, Alder, Larch Elm, Maple, Hornbeam, Aspen, Linden, and Hazel.

Province of Silesia.—Pine, Pitch Fir, Oak, Alder, Birch, and Beech.

Province of Brandenburg.—Pine, Oak, Beech, Birch, Ash, Elm, and Maple.

Province of Saxony.—Alder, Birch, Oak, Elm, Maple, Beech, Hornbeam, Hazel, Yew, Pine, and Pitch Fir.

Province of Westphalia.—Alder, Beech, Oak, Elm, Maple, Birch, Pine, Ash, and Larch.

Rhine Province.—Beech, Oak, Pine, Larch, Hornbeam, White Alder, and Pitch Fir.

Hohenzollern.—Fir, Pine, Oak, Aspen, Birch, Alder, Sallow, and Beech.

Schleswig-Holstein.—Beech, Oak, Hornbeam, Maple, Poplar, Hazel, Pine, and Larch.

Province of Hanover.—Beech, Oak, Pine, Fir, Larch, Maple, Ash, Elm, Hornbeam, Birch, Alder, and Yew.

Province of Hesse-Nassau.—Beech, Fir, Oak, Maple, Elm, Birch, Aspen, Sallow, Hazel, Hornbeam, Alder, Larch, and Yew.

Respecting the recently-annexed provinces of Alsace-Lorraine, we have no available statistics. Exclusive of these, the forest land covers 23 per cent. of the whole area of the kingdom; 70 per cent. of the total annual produce of the entire country is hardwood, of which one-fifth is timber and 30 per cent. firewood stumps, roots, and brushwood. Probably in no country is greater care taken of forests than in Germany. Strict precautions are taken to prevent anywhere a greater area being cleared than is annually replanted. Most large forests are mapped out according to their size and the age and quality of the trees; a section being annually felled and an equal area replanted. The timber trees of Saxony are similar to those of Prussia, and the whole forest area covers about 1,163,000 English acres. There is a general tendency to diminution arising from the forest land being constantly thrown into cultivation by small proprietors, and about one-third of the forests and woodlands belong to the State. Competent authorities give 1,000,000 cubic ft. as the quantity cut in all Saxony every year, and the amount is not considered to be excessive. Wurtemberg may be generally divided into five distinct natural timber-producing districts, following the geological and climatic conditions of the kingdom. They consist of—(1) the Pinewood districts of the Sakt Circle; (2) the hardwood district of the Unterland; (3) the Pinewood district of the Black Forest; (4) the hardwood district of the Swabian Al; (5) the Pinewood district of Upper Swabia. In the Pinewood districts the Spruce and the Silver Fir largely predominate, although Scotch Fir is to be found, chiefly on southern slopes, mostly in conjunction with Spruce, and sometimes separately. In the hardwood districts the Beech, interspersed more or less with Oak, furnishes the bulk of the growth. Of other trees there are the small Beech, Ash, Maple, Elm, Birch, Alder, Lime, and various kinds of Willows. Wurtemberg has a superficial area of 4,819,675 English acres, of which 30.6 per cent. are forest lands. The area of timber-producing lands is rather on the increase than diminishing, and between 1861 to 1873 there was an increase of about 10,000 acres. As might be supposed, the State exercises a vigilant control over the forests, and neglects no opportunity of increasing its forest property by the purchase of contiguous lands, so that any general diminution arising from clearances elsewhere is more than counterbalanced.

As nearly as can be ascertained, the extent of timber-producing forests and lands in Sweden (exclusive of Lapland, which has never been surveyed) is 3190½ geographical square miles, or about 30,000,000 acres, being 42.8 per cent. of the whole area of the country. It can hardly be said that the actual area of timber-producing forests is diminishing to any great extent, since comparatively small quantities of forest land are being brought under cultivation. The same cannot, however, be said of its productive power, which is rapidly getting smaller. The Red Pine or Scotch Fir, and the White or Spruce Fir, form the staple of the forests—the greater portion of which are situated in the northern and central provinces. They also produce Oak, Beech, Birch, Aspen, Elm, and Lime. The timber and deals exported to this country are of Red and White Pine. Birch only attains a small size, and is chiefly used for firewood. Aspen is used for making matches, which industry is one of the most flourishing in the country. Sweden exports her timber to almost every country in the world; perhaps China and Japan are the only exceptions. Great Britain consumes the most, and then come France, Germany, Holland, Denmark, and Belgium. Very stringent forest laws are now enforced, the good effects of which cannot be seen before the lapse of some years, but there can be no doubt of their ultimately effecting a marked improvement in the yield of the forests.

The total area of forest-producing land in Norway is computed at 66,000 square kilometres, but in this survey considerable so-called timber-producing lands consist of comparatively unproductive rocks, swamps, and moors. The Pine and Fir, even more than in Sweden, constitute the riches of the Norwegian forests. The Scotch Fir is found up to the most northern latitudes, and grows there up to a height of 3400 ft. above the sea-level. The Spruce Fir ceases near the Arctic Circle. The forests are principally situated in the east of Norway, near Christiana, Hamar, Trondhjem, and Christiansand. Those of Bergen have long since been exhausted. In the western districts of the country forests can hardly be said to exist. As in Sweden, strict forest laws are now in force, but the mischief done by indiscriminate felling will take a long time to repair. In Messrs. Churchill and Sims' circular of the 5th June, they remark—"So few deals now come from Norway that there can be no longer said to be a trade in them." Battens and prepared floor boards from the principal export, and wood, 9 in. wide or upwards, cannot be supplied as formerly.

The forests of Russia are, in several respects, an important feature of the country, as a physical characteristic, in a commercial point of view, and supplying fuel in a country only recently found to possess coal. Forest economy is now being more attended to, and young Russians are constantly sent to study forestry in the German and French colleges devoted to that science. The brushwood, covering a vast extent of forest land, consists almost entirely of the Hazel, Dwarf Birch, Alder, Willow, and Juniper. There are many conjectures as to the result to the timber trade, should unhappily any misunderstanding arise between England and Russia. Prices of Russian deals have already advanced; but in all probability, any further serious rise would only drive builders to use cheaper wood, which, with the contracted building operations such a calamity as war might bring about, would make us more independent of Russian supplies than some are willing to admit.—"Building News."

PLANTING TREES ON MOUNDS.

In comparison with other methods of tree planting, this is remarkable for the manner in which it has succeeded in soil where young trees do not strike root readily when first transplanted. As a rule, trees with spreading roots are preferable for this kind of planting,

Tree-planting on mounds.

the tap roots being cut off before planting. The soil of which these mounds consist must be of the best quality, and prepared, the autumn before it is required, as follows:—By means of a strong hoe, the turf is taken off a piece of ground and placed on the side; the soil is then thoroughly worked and thrown into a mound, all roots or other injurious matter being removed. A part of the turf which was taken off is shaken to pieces, and placed on the first layer of soil; over this is laid another layer of good earth, and so on until the mound reaches a height of 8½ ft. A small excavation is then made at the top of the mound, in which all the refuse is burnt, and the ashes are mixed with the soil. This affords sufficient mould to furnish 500 or 600 mounds. When prepared in this way, the composition requires no further manipulation before being formed into the round and pointed mounds on which the trees are placed. When these are planted, the mounds are covered over with two layers of turf, the upper part or grassy sides facing each other.—"Journal of the Farm."

[These mounds, as shown in the annexed woodcut, seem to me to present an unsightly, and, at the same time, an unnatural appearance. The method is altogether unnecessary as far as success in planting is concerned, although it may with advantage be carried out on a modified scale on naturally wet, stiff, clay soils; on dry, light soils, mounds are wholly unnecessary, particularly such abrupt, high mounds as those represented in the woodcut, which would be detrimental rather than otherwise by encouraging the evaporation of moisture from the roots, which, probably, during an extremely dry, burning summer, would suffer so much from drought that the trees would be found to die outright. There is no better plan for

planting ornamental trees and shrubs than turning the soil and sub-soil to a depth of at least from 18 in. to 24 in., and a yard or two more in diameter than is required for the roots when planting, turning out stones, roots, on very bad subsoil, and replacing them by fresh soil or turf, well chopped up and stirred in with the original soil. On stiff clay lands inclined to be wet, the trees should be planted on the surface, covering the roots with fresh soil so as to form a slightly raised mound over the roots, and outside or beyond the latter, not less than a yard or so. The method of surface-dressing trees every few years with turf, leaf-mould, or other enriching material and gradually forming easy mounds, is preferable to the system indicated by the annexed woodcuts.—G. B.]

PINUS BOURSIERI.

(SYN. P. CONTORTA).

THIS dwarf-growing, hardy tree seldom attains a height of more than 20 ft., even in favourable situations. Its leaves, which are stout, are from 1½ in. to 2 in. long, and mostly in twos. The branches are much twisted, and long in proportion to the height of the tree; indeed, in habit the latter is very irregular, assuming more of the scrub than the tree form, and of no value in the shape of timber. It was discovered by M. Boursier on the north-west coast of North America. It some-

Pinus Boursieri.

what resembles *Pinus Banksiana*, but is scarcely so bushy in habit, and its leaves are a shade lighter in colour. It is shown off to best advantage when planted on a rough bank, or it would be in character if associated with natural rocky sites in pleasure grounds. As an isolated specimen on a lawn it presents a mean scrubby appearance, and is scarcely worthy of a place even in a Pinetum except as a curiosity. G. B.

Escallonia macrantha in Nottinghamshire.—This is one of the best evergreen shrubs which we have for planting against terrace walls having a south or west aspect. It grows freely in loam mixed with a little sand. When in good health, the foliage is of a bright and cheerful tint of green; and now, when in flower, it is very effective and useful for cutting purposes. E. Ingrami is another good variety; both are quite hardy here, having stood unprotected for six years.—A. H., *Thoresby*.

THE KITCHEN GARDEN.

MUSHROOMS IN WINTER AND SPRING.

ALTHOUGH Mushrooms form valuable additions to our list of kitchen garden productions at all seasons, they are exceptionally welcome from October to May. I doubt, however, if there be not more failures in their culture than in that of any other esculent grown—and these chiefly from kindness rather than from lack of attention. The routine which we adopt with general success is very simple and varies little from that generally followed, viz.:—Sufficient fresh stable manure is shaken out from the longest litter to make one good large bed. It is carted into a heap, and about one load of fresh turfy soil is added to four of manure; this is turned over two or three times, at intervals of a couple of days, to prevent violent heating, and if very dry and likely to become mouldy, sufficient water is added to ensure a general sweet temperature throughout the heap. When fit for making into a bed it should be about 85° or 90°, and neither wet nor dry, but moist. We make up our beds in dark sheds or cellars, where a close, warm atmosphere, not easily affected by external temperature, is maintained at an average of 60°. Fire heat should be applied with caution, as it is too drying, and when fresh successional beds are in course of formation, the genial warmth given off by them is far more congenial than fire heat. We make the beds from 15 in. to 18 in. deep, and tread them firmly in order that the heat may be gentle and lasting; after a few days the spawn is inserted in pieces about the size of a hen's egg, 1 ft. apart, just covering it with the manure. Upon the quality of the spawn success depends; if good and fresh, there will be abundance of Mushrooms; if bad, there will be few or none, however well the bed may be made or treated; therefore the spawn should be obtained from a trustworthy source. Use it fresh, or store it in some perfectly dry, airy position until it is required. The beds should be earthed with good fresh loam, beaten down as solid as a spade can make it, and in a month or six weeks the Mushrooms will begin to make their appearance. In gathering, they should be pulled or twisted at the base, so as not to disturb the successional crop. When the beds appear to be dry, a good soaking of weak liquid manure, at the same temperature as that of the house, will assist the development of later crops; but as soon as the produce is not sufficient to be worth gathering, the most economical plan is to remove the old bed and make a fresh one in its place. J. GROOM.

Henham.

THE TWO BEST POTATOES.

HAVING to grow about 2½ acres of Potatoes to keep up a good supply, I have always been anxious to prove the qualities of any new and good sort which has been from time to time sent out. Last year I grew upwards of forty sorts, and in November, 1871, I exhibited a collection at South Kensington of upwards of fifty kinds. This year I have grown as a main crop only four sorts, namely, Lapstone, Fortyfold, Regents, and Paterson's Victoria. The disease set in fully a month earlier than usual this year, and by the middle of July the leaves of the Lapstones were all black and dead; the other three sorts, although close by, suffered much less, the foliage of these being still green, although much spotted, when lifted in the second week in August. The Lapstones, which are generally of first-rate excellence, are this year scarcely second-rate in quality; the Fortyfolds are good, as are also the Regents, the former being the whiter of the two. We peel, steam, and dry off both sorts, and then they are too mealy to be taken up by a fork. The Victoria is not first-rate, but being a late sort, it may be better in spring. Brownell's Beauty, which did so well with us last year in the field, is this year a comparative failure, owing to its weakly growth. The ground was prepared for it by being thrown up into 3 ft. ridges, steel forks being employed for the purpose, and then it was well worked down just before planting time with drags, roller, and Colman's cultivator, thus being got into a fine tilth. The Potatoes were ploughed in 6 in. deep and 3 ft. apart. Just before they were up, on a fine day, a pair of light harrows were drawn over the surface, and killed all small weeds then coming up. About July 20, Grey Stone Turnips were sown between the drills, which were not earthed up, and now there is a fine piece of Turnips to be fed off by sheep, preparatory for Potato culture next year. Although we had many diseased, I have a better

store of Potatoes this year than last, as the crop was much heavier. What I wish to show is that after having for many years tried most of the sorts in cultivation, I have come to the conclusion that there are no two better kinds for general purposes and good quality than the Fortyfold and York Regent. The Red Skin Flourball I grow in 1871, but have never grown it since, as I did not consider it good enough for table, and the American Rose is never satisfactory with me; I am told that its quality is best when grown on poor dry soil.

Killerton, Exeter

JOHN GARLAND.

Precautions against Slugs, Snails, and Worms.—When putting out young plants in showery weather, some sifted ashes scattered over the surface of the beds will make travelling most uncomfortable for any soft-skinned vermin. Lime and soot are also distasteful to them, but the first shower not only neutralises their effect, but they have a tendency to clog up the pores, so to speak, of the surface-soil; sifted ashes, on the contrary, keep the surface loose and friable, and attract and absorb what little warmth there is in the sun's rays at this season. A very light sprinkling is sufficient, and the effect is permanent. Some object to the use of ashes, but for heavy soils their application in the way just described is very beneficial, and, what is more, they can be obtained in most places for almost nothing.—E. H.

The Late Pea Season.—Carter's First Crop was the earliest Pea here this season, coming in about eight days before William the First. Carter's Improved Sangster's No. 1 has been with me this year an excellent early variety and a good cropper. A new early Pea, marked Carter's No. 100, has been sent to me for trial by that firm, and has proved to be one of the best varieties which I have ever grown; it only grows about 3 ft. high, and becomes covered with pods of a good size, and the Peas are excellent as regards flavour. Another dwarf new early Pea, sent to me by the Messrs. Suttons', has likewise proved a desirable kind for growing in pots or for early market purposes. Carter's Early Premier Gem has proved likewise to be one of the very best for forcing in pots, and than this and Multum in Parvo a better selection could not be grown for that purpose. Of the main crop varieties of Peas, or second earlies, the Hundredfold, or Cook's Favourite, has shown itself to be a great bearer, and to those not liking the sugary flavour of some Peas this variety will suit them. Advancer is still one of the best, both as regards fine flavour and productiveness; Fillbasket is another blue Pea, with very large and well-filled pods, and valuable for exhibition purposes. Of the general, or late varieties of Peas, the following selection, which I have grown this year, will be found to be a good one:—Turner's Dr. McLean is a wonderful bearer, an improved Veitch's Perfection, which is saying a great deal for it as regards productiveness; Veitch's Perfection is, however, still one of the best late Peas for keeping up the supply till the frost cuts them down; G. F. Wilson is after the same type, but a week earlier in coming into use than Perfection; Carter's Commander-in-Chief is a wrinkled marrow with curved pods, containing Peas of exquisite flavour. Very few varieties of late Peas can excel Ne Plus Ultra, either for productiveness or flavour, and, next to Omega, it is one of the latest bearing varieties. A new variety of late Pea has been sent me by Messrs. Carter, under the name of Culverwell's Telegraph, and it is certainly one of the largest podders with which I am acquainted, and they are of a fine shape for exhibition purposes; it grows from 4 ft. to 5 ft. in height, is a great bearer, and the Peas are excellent in flavour.—W. TILLERY, Welbeck.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

James's Intermediate Carrot.—I have just taken up, from a piece of ground measuring 4 poles 22 yards, 24 cwt of Carrots, which, as regards quantity and quality, are all that one can desire; many of them are 15 in. in circumference.—RICHARD NISBET, *Aswarby Park, Folkingham.*

St. John's-day Cabbage.—It is suggested (see p. 453) that somebody will probably take up and re-christen the valuable Cabbage known in catalogues as St. John's-day Dwarf; but allow me to say that we have already got names enough; what we want are distinct forms to represent the names. Besides, who would change the present name of this valuable little Cabbage—indeed, the most valuable of all for spring sowing, and the least valuable for autumn sowing? St. John's-day Dwarf Cabbage and Winningstadt are the two most valuable Cabbages which we have for spring sowing, but somehow or other they have never become favourites with English cultivators.—P. B.

—I know of no Cabbage to equal the St. John's-day in flavour and richness. I have grown it many years, having received it when first distributed by the Royal Horticultural Society, and I hope never to be without it. If planted 1 ft. apart, each way, it forms good heads, and is more productive than some of the larger kinds.—W. DIVEAS, *Werton, Maidstone.*

STANDS OF GROWING PLANTS.

JUST now, when one cannot always obtain as large a supply of cut flowers as may be necessary for the decoration of sitting-rooms, pretty arrangements can be made by means of flowering and fine-foliaged plants, grouped in baskets or stands. This style of floral decoration has an advantage over that of cut flowers, as of course I need hardly say the growing plants remain much longer in a fresh condition. The baskets in which the plants are arranged may be of any shape, according to the taste of the decorator; for standing on a small drawing-room table a long-shaped basket, with a handle across, looks very well; then, again, some can be obtained almost in the form of a March vase, except that the upper tazza is supported on a tripod in place of a straight stem. Some pretty plant stands on a larger scale can be obtained almost in the style of a small circular basket work-table; indeed, I have seen an old work-table of this description utilized before now, as I shall explain further on. In all baskets in which growing plants are arranged, there should be loose linings or cases of zinc. I know it is a common custom to line the receptacles only with Moss, but this I do not approve of, as the wicker-work soon becomes decayed with the damp, and also the soil and wet comes through when the plants are watered. Many baskets for this purpose are painted white, with a good deal of gilding about them; to the white paint I do not object, as it does not interfere with the tints of the plants, and it also preserves the wicker-work; but I do not admire the gilt. When the white becomes soiled it may receive a coat of black, or dark brown varnish. As I have just stated, there should always be moveable zinc trays in the baskets, and then, when the plants require to be watered, the tray-case can be lifted out on to a window-ledge, or some similar place, and left there till the moisture has drained through the holes, of which there should always be some, in the bottom of the tray. Over the bottom should be laid a layer of finely-broken crocks; the plants should then be turned out of their pots and set in the tray, the spaces between them being filled in with Moss, such as grows in woods or on old banks, or such as may be obtained for a penny a bundle at any nursery; the greenest should be placed at the top and neatly arranged, so as to look as if it were growing. The basket work-table, which I have mentioned as being converted into a flower-stand, was done as follows:—A zinc tray, such as I have described, was fitted to the size of the top, and to hide the sides of the pan a piece of flexible rustic edging was employed, such as one often sees used along the edges of conservatory stages to hide the pots, and which can be bought by the yard or foot, according to what length may be required. As to the different varieties of plants for arranging as I have described, these, of course, must depend on what the decorator has at command; but I should recommend that they be well hardened off before being used, as if brought out of a stove or warm greenhouse direct into the dry atmosphere of a sitting-room, they are sure to flag. Plants with succulent leaves can be made to retain their freshness much longer than they otherwise would do by being sponged over two or three times a week, and Ferns should be lightly sprinkled with water. I have seen pretty little baskets filled with hardy Ferns, and a spray of small-leaved Ivy twined round the handle has a most pleasing effect. Such an arrangement as this will look healthy for months, and is well adapted for dark rooms in towns, where other plants would only retain their freshness for a very short time.

ANNIE HASSARD.

The Redwood (*Sequoia sempervirens*) as Underwood.—Mr. Berry (see p. 437) has done good service in bringing this tree so prominently into notice. I have long thought that it would do well in Ireland, where the climate is so favourable to its growth, and it is a matter to be regretted that so little of it is planted in that country. This *Sequoia*, *Pinus insignis*, and *Cypripedium macrocarpa* all assume a robust character in Ireland, and, where seen there, are for estrees of great beauty. Allow me to supplement Mr. Berry's remarks by recommending the Redwood for planting as underwood where it would not succeed as a tree. There is no other evergreen that is so fertile as regards suckers when planted as a bush; the shoots, too, are very tough, and could be turned to profitable account in various ways.—CHARLES McDONALD, *Garden House, Stokesley, Kent.*

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

A JAPANESE GARDEN.

SO MUCH curiosity now-a-days is excited when the mere name of Japan is mentioned, that perhaps a few notes from one who has lately been there may be interesting. For my own part, while greatly charmed with Japan and its people, thinking the country most beautiful, and the people most artistic, I cannot give much praise to their gardening. A Japanese garden is invariably extremely small—in fact, the court-yard of the house, the ground plan of a Japanese house resembling very nearly that of a Pompeian villa. It is artistic as a whole, but flowers play only a subordinate part in it; often they are only in pots, or, rather, china vases. There is invariably a pool of water at one end, or in the centre, edged with rock-work, so as to prevent any hard line, and this is of the most fantastic shape, with Japanese Ferns, such as *Lastrea erythrosora*, and various *Davallias* planted in conspicuous places on rocky islands or peninsulas. On one side, the rockwork will certainly rise steeply, and it will be planted with rose, red, and white Azaleas. Many of these were in full bloom when I was there, but in no case was the quality of the flower remarkable, judged by a European standard; but what is remarkable is the skill displayed in pruning out all vigorous growth, so as to keep the bushes small, and to send all the strength into flowering wood, and the extremely prolonged season of flowering. In early June, there were many varieties only just showing colour in the bud, while next might be a bush that had finished flowering three weeks before, and many were in full beauty. Our European varieties so greatly exceed the Japanese Azaleas in size and beauty of bloom, that the only step we can take now seems to me in the direction of prolonging the season of their bloom. Sometimes they are trained into fantastic shapes, but this is not very usual. In the most open and sunny part there is a *Cycas revoluta*, with many trunks, some branched, and 8 ft. or 10 ft. high; and in some more shady corner, overhanging the water, which reflects the blue of the sky, is a *Chamærops Fortunei*, heavily laden with its yellow panicles of bloom; this is almost invariable in its position, and near it will be some Japanese Maple, pruned yearly, as the Japanese can, so as never to out-grow its neighbour. Its colour is exquisite, and varies, according to the variety, from deep red, through all shades of rose, to primrose-yellow and apple-green. The beauty of the colour of these Maples has often been mentioned; but it must be understood that, in order to have a long continuance of colour, the bushes must be kept constantly growing, for the fully-grown leaves soon get dull, and do not resume their beauty till autumn has laid his fiery finger on them. The Japanese *Podocarpus* is also a necessary inmate of a typical garden. This assumes a most ancient aspect under the skilled hand of the cultivator, or is pruned so closely as to resemble an *Araucaria* in effect. The season for pruning all shrubs and Conifers in Japan is just as growth is first pushing, so that Nature may heal the wounds at once. Bushes of *Olea fragrans* are also indispensable, and they generally suffer much torture at the hands of the pruner. If one side be not enclosed, there will be a hedge of *Camellias*, which is headed back from time to time, and which grows with a vigour rarely seen in England. If there be any flowers that do not come under the heading of shrubs, they are usually in china pots or flat pans, and consist of *Chrysanthemums* not more than 1 ft. high, and yet in flower at this season (June), brown tasselled or yellow Japanese varieties being those amenable to the treatment to which they must have been subjected. Lilies, such as *L. longiflorum*, *umbellatum*, and *cordifolium* (which latter I do not think worth growing where there is room for its "double," *giganteum*), and varieties of *Dianthus chinensis* were also in pots at the edge of the verandah, running round the house and enclosing the garden. Add to all this a rustic flight of steps leading to the top of the

rockwork, where, if there be room, will be a stone-carved lantern, with paper sides, formerly used to burn pastilles or gold and silver paper for Buddha; a Pine tree, most cleverly trained over a trellis so as to give a sunny shade, and a few *Aralia* bushes and lilac Azaleas that may have intruded themselves, and you have a Japanese garden. The skill of a Japanese gardener consists in keeping everything in its place, allowing nothing to be smothered, nothing to get "leggy"; but when you seek for cultivated flowers, or artificial garden varieties, you will be disappointed. Nature has given them so many beautiful flowering plants and shrubs that they are content to take what she gives; but should she originate a variety, they will then dig it up and take care of it.

E. H. W.

PROFITABLE GARDENING.

A STAPLE topic for speeches at horticultural dinners and similar gatherings is the capability of the country to produce sufficient fruits and vegetables to meet the demand for such productions. It is easy to quote statistics, to show that so many thousands of pounds are annually paid to foreigners for garden produce, and to assert that we ought to save that outlay by growing more fruits and vegetable at home; but sufficient account is not taken of the cost of land, labour, manure, and of other difficulties under which cultivators in this country labour, but especially of the uncertain climate under which the cultivation of fruits and vegetables has to be conducted. It may perhaps by-and-by be shown that during the present year many tons of hardy fruits have been imported; would the economists will, therefore, at once rush to the conclusion that more fruit trees—Apples, Pears, Plums, and Cherries, for instance—ought to be planted; but no deduction could be more absurd. For two seasons, but especially during the present one, we have had only the most meagre crops of fruit, owing to the severity of the spring months, when the trees were in bloom. Thousands of acres of fruit trees had scarcely a fruit upon them, and this defect no amount of planting could remove. If all the fruit orchards of this country had produced good crops of the fruits just named, there would have been a glut in the market, and much valuable fruit would, for lack of a profitable sale, have been spoiled. Fruit culture in this country will only henceforth be embarked in as a speculation, and, therefore, if for two or three years in succession—through no fault of the cultivator, but rather in spite of him—his orchards fail to produce fair crops, what encouragement is found for the investment of capital in such a doubtful direction? In regard to the importation of vegetables, it should be remembered that this has arisen through free trade; by the removal of obstructive duties, the foreigner has been enabled to compete favourably with home growers. Are we any the worse for this competition and for the enormous importations which are now made to this country? Looked at from a narrow point of view, it might be assumed that the sending of so many thousand pounds in money out of the country for vegetable products is a loss to us; but that need not be the result. What does the foreigner take in return? How much of the money thus paid to him is reinvested in the purchase of our manufactured goods? In all that relates to the produce of the soil, the seller only parts with his productions in order that he may become a purchaser of something else which he needs. Another point worthy the attention of those who so strongly advocate a wider cultivation of vegetables is, the undoubted fact that much of what is imported is sent to us at a time when similar vegetables are not in season in this country. Early Peas, Beans, Potatoes, and many other things are imported here long before such vegetables are ready for market with us, and then it is assumed that we have, in paying the cost of them, been expending money that we should have kept at home. Thanks to foreign growers, our season for obtaining vegetables and fruits is now largely extended; in fact, such is the demand for foreign produce amongst the higher classes at home, that our central markets are now seldom without imported vegetables, most of which could only be grown here at such a cost as to place them out of the reach of all but the most wealthy. How often have our home growers to say that foreign importations are keeping down the

market; of course they are, and for the obvious reason that the cost of production abroad is much cheaper than with us. We have heard of fabulous sums being paid per acre for market garden land in the Channel Islands, but £20 per acre there is probably, after all, cheaper than from £8 to £10 in Middlesex, where the growing period of the year is limited to a few months, whilst in the Channel Islands it is almost perpetual summer. Vegetable culture, to be profitable, can only be carried on within easy reach of a good market and a plentiful supply of manure; but land in any thickly-populated locality is dear, and not easily obtained. Rates, too, are very high, and these, with taxes and tithes, fall heavily upon the tenant of market garden land, for, singular to say, the more a tenant or owner improves the productive power of his land, the more heavily the local assessors make him pay to the local rates. Labour is, with such cultivators, also a formidable expense; good help can only be obtained at great cost; and when to all these drawbacks are added the immense difficulties under which cultivators labour through the vicissitudes of climate, it will be seen that fruit and vegetable culture is with us by no means all swimming with the stream. Economists may be assured that as fast as it is found that an extended cultivation of fruits and vegetables will pay, so fast, and only so, will more capital be invested in market gardening.

NOTES FROM KEW.

MICROCACHRYS TETRAGONA, in the Winter Garden, presents many points of interest, not only to the skilled botanist, but also to the far greater class who admire a pretty plant simply because it is pretty, and do not trouble themselves much about its rarity, nor yet about any structural peculiarity which it may present. This remarkable Conifer comes from Tasmania, and is, perhaps, as rare in cultivation as it is in its native country, where it is confined to a few peaks of the Western Range, and to Mount Lapeyrouse. The Kew plant is a female one about 2 ft. high, its brilliantly-coloured cones being extremely handsome. These cones are produced in great abundance, and make so good an effect that we feel sure that the species would be a great favourite for the winter decoration of the cool conservatory. The scales of the cones are pulpy, semi-transparent, and of a very bright colour (characters not exhibited by any other Conifer known to science). *Protea mellifera* and *Banksia Cunninghamii*—two widely dissimilar members of that very extensive and most variable of Natural Orders, *Proteaceæ*—are also in flower.

In the pleasure grounds, in a long bed near the Winter Garden, is a bush, about 9 ft. high, of the Groundsel Tree of the United States (*Baccharis halimifolia*). Although the flower-heads themselves are small, there are many of them, and the involucre bracts, tinged with red, combine with the lightness of the panicles to render them pleasing enough for a place in the table bouquet. Besides the merit of flowering in the open air at such a dull season of the year, the shrub has very pretty foliage, and will interest those who, judging from the British flora alone, have always regarded the Natural Order *Compositæ* as made up entirely of herbaceous annuals and perennials. *Dahlia imperialis*, a coloured plate of which appeared in *THE GARDEN* for Oct. 13, is in flower in the Palm House. *Cassia Tora*, a dwarf species, and *C. viminea*, a much taller one, are somewhat conspicuous on account of their bright yellow flowers; a decoction of the leaves of the former is used in India as a specific for ringworm. A pretty little bushy *Convolvulacean* plant, *Evolvulus arbuscula*, is covered with its charming blue flowers. All the species of this genus bear very handsome flowers, and, for the most part, are easy of cultivation. The Brazilian *Claviija macrophylla* has bare, rod-like stems crowned with fine heads of large coriaceous leaves, from below which, on the old wood, spring a considerable number of racemes of orange-yellow flowers.
