soms. This mode of growing them is far easier than going to the trouble of staking and tying, which cannot be done without the expenditure of much time, and even then there is always a want of ease and stiffness about the plants that they never have with the netting. To get these Petuoias strong and fit for turning out in May, seeds cannot well be sown too soon, and this should be done in heat, where we or them to entire the result of the strong than the control of the strong than the st where, to get them to germinate freely, it is necessary to cover the surface of the pan or pot containing them with a pane of glass, which keeps the soil uniform as to moisture, and saves watering and its attendant risks of getting over-wet, and thus rotting the seeds. As soon as these are no through the soil. its attendant risks of getting over-wet, and thus rotting the seeds. As soon as these are up through the soil, the pans should be placed on a light shelf in a warm house to prevent drawing, and when the plants become large enough to handle it is important that they be at once pricked off, and after a time potted singly so as to be ready for planting. Besides the magnifiscent single kindsof Petunia grandiflora, double varieties may be raised in the same way, as seeds are supplied from fertilised flowers, and plants obtained from them are charming for pots to furnish greenhouses or conservatories, where they make a grand show. To have them bloom freely without being drawn they must be grown in light sunny pits or houses, where they ear grown in light sunny pits or houses, where they can have plenty of air, under which treatment the shoots come short jointed and strong. After May it is a good plan to plunge the plants outdoors, and to draw from them there when wanted for use. J. S.

Saxifraga Burseriana major, so faithfully illustrated at p. 141, is one of the most beautiful of Saxifrages. It has just gone out of flower on our rockers when the flowers, even in such dull, drizzly weather as we have lately had, lasting two weeks in beautiful. The single form of the common Snowdrop is, I think, if one may venture to make comparisons, the most beautiful of all in its simple beauty, if we except Mr. Elwes' variety, Galanthus Elwesi. The foliage of this species is so distinct, and the flowers, which are larger than those of the common Snowdrop, droop so elegantly; it is also the earliest to flower. G. plicatus, G. Imperati, and G. Redoutei, are all well advanced to flower, though more of the blooms are quite open. The early flowering Snowflake (Leuccjum vernum) is also in flower in the borders, while a plant of Lithospermum prostratum has ventured to put forth a few of its deep blue flowers over a ledge put forth a few of its deep blue flowers over a ledge of rock. Pansies and Primroses are plentifully in flower. J. Douglas.

What is the Result of Premature Growth in Potato Seed or Sets? — For farm or garden there is no other vegetable of equal importance, nor one in which so many are interested. A discussion as to how a crop was secured of first-rate quality and perfectly free from disease last year is only second in interest as to how the same thing is to be secured in 1884. I propose to make a few observations on the interest as to now the same thing is to be secured in 1884. I propose to make a few observations on the first point, and then to ask the attention of your readers to the second, especially in its bearing on the above query. Our Potato crop was divided between the farm, large vegetable garden, and as small experimental vegetable garden, intended principally for comparative purposes. Sown in the end of February, with a good warm loam, stable manner, and ashes, and southern aspect, the old Ashleaf Kidoey was fit for use when of the size of small hens' eggs, without any protection, on June 8 following. Of thirty varieties, in quality it is the best and the earliest—Myatt's I am referring to, but I am not aware of the distinction between this and those sold as Veitch's, Rivers', &c., Ashleaf Kidney. The next to ripen was Carter's Eight Weeks, the earliest of all the round varieties, and with curiously marbled foliage. Neither is anything like so prolific as Carter's First Crop. A gardening friend tried to persuade me that this was a selection from the old Ashleaf Kidney, but the quality, productiveness, and time of Carter's First Crop. A gardening friend tried to persuade me that this was a selection from the old Ashleaf Kidney, but the quality, productiveness, and time of ripening are all different, and, except the last, in favour of First Crop. Cosmopolitan did not ripen as soon as I expected, and when better known I am not sure if Mr. Dean will not be satisfied to class it as a pro-lific second early. I did not purpose going into details as to varieties at present further than to say that Paterson's Victoria and Schoolmaster are here rather subject to blight, even more so than old Fortyfold, as second earlies I give the palm to Beauty of Hebron. I feel inclined to bracket with it White Elephant, but it is decidedly a general or late crop variety, sown at the same time. Both are very beavy croppers, of tolerably good quality and almost free from blight. But for the general farm and, I may add, garden crop—whether you take productiveness, freedom from disease, but especially quality — commend me to the Champion (Scotch). Some few years ago I wrote of his variety in those terms in a contemporary, and a correspondent poked fun at the "mere Irishman" who spoke so strongly of a Potato "with a stone in the heart of it." Since then I hope his opinions are changed—mine are not; and last year I ordered 5,30 worth of fresh seed, for change, from Forfarshire, and have found the following results in addition. The crop was heavy, new lea land, and of the several tons produce, sorted under my supervision, I am perfectly satisfied there is not up to the present I stone rotten, while the quality simply leaves nothing to be desired. Mr. Taylor has long since stated this variety is preferred at the table of the Marquis of Bath, and in a recent issue of a contemporary Mr. Gilbert, of Burghley, steps aside to give the Champion a preference. Later in the season, to my mind, they must give way in quality to the Magnum Bonum. So much for past experience, which will have an interest just now, and perhaps induce others more competent to state theirs; but if we are to have equal success this year the above query is of vital importance. I have Potatos in pits, in houses, on dry shelves, &c., and in every instance they are exhausting themselves at a rapid rate by growing. Those in the houses, that have already been turned three times, to-day I find with stalks half a dozen inches long. I have reason to know that this is general over Ireland, and you may be able to speak for England. The mild winter and moist weather supply the explanation, but the material point is how this will affect the future growth—whether the central bud can any further be depended on—and whether, if not, in case Potatos intended for seed have much grown, it would be safer not to cut the set? I need not specifically draw attention to the vast importance to millions of this matter. W. T.

ORCHID CULTIVATION FOR AMATEURS.—V.

I HAVE said that our methods of ventilating planthouses are generally of too crude a kind, and for epiphytal Orchids or "air plants," more especially, we ought to have the most perfect system of ventila tion possible. I have thought sometimes of the funnels or tube-ven'ilators used on board ship, by means of which vitiated air is drawn up from the cabins below; also of a tube or a narrow strip of perforated zinc fixed all along the ridge of the house, which would allow of the heated air passing slowly away. But apart altogether from the ordinary ingress and egress of air I am greatly in favour of houses which are unequally heated, whether at the sides or each end does not so much matter, as in all houses or compartments so heated there is always an internal circulation, the warmest air continually flowing towards the coolest part of the house. Orchid-houses are en suite, and particularly when built in a straight line and so joined end to end, there should, I think, be perforated ventilators over the doors, so that a current of air may pass from one compartment to the other. In this way, no matter whether the outer ventilators are open or not, there will always be a circulation of air inside the houses, and this is of course a great benefit to the plants.

Not very long ago a gentleman complained to me that his "cool Orchids" did not thrive well. "Oh l well, perhaps you keep them too warm?" "No, the thermometer is olten as low as 40° first thing in morning." "And are the plants covered with dew at the same time, or are the leaves and the floors quite dry?" I asked. He could not say, "but, would I go and see the plants for myself?" I did so, and found out that although his Odontoglossums and Masdevallias were cool enough, they were grown in an atmosphere too dry for them, and especially so at night. Even when syringed at night the leaves were dry by morning. The house was overheated, and to lower the temperature air was freely admitted from without. It took some time and trouble to find out exactly how things were, but at last we succeeded, and by placing valves in the pipes as they entered the cool-house we checked the heat, much less air was admitted from outside (I ought to have said the house -a lean-to-stood in a very exposed or windy position), and then ventilators were broken through the back wall into a warm plant-stove, and covered with perforated zinc slides. The result exceeded our expectations. But very little fire-heat is now used for the cool-house, as a good deal of heated air comes into it from the stove; and the greatest gain of all is this moisture-laden air, which condenses as it disperses itself into the cool atmosphere; and the result is, that first thing in the morning every leaf is covered with dew just as occurs in Nature on the mountains of the tropics.

An old collector of Odontoglots and Masdevallias long ago told me that the warm moisture from the plains or from the sea comes up every night, and condenses in the cool atmosphere of Bogota, so that every morning a white mist hangs over everything until it is dispersed by the sunshine. Early in the morning, as he told me, every leaf and blade of grass and moss was wet, not merely moist, but drenched by these heavy nightly dews. It is so on Table Mountain at the Cape, where the Disa grows wild. As a simple matter of lact, this state of things is found to exist on the warm mouotains of the world nearly everywhere, and the absence of the conditions resulting from this state of things may account in some measure for our failures in the culture of many mountains plants from the tropics and temperate regions alike.

No doubt we have many plants which fail to grow satisfactorily in our cool greenhouses, simply because this nightly mist or dew bath is absent from them. I believe this in the main is the reason why Nepenthes Rajah puzzles nearly all our best cultivators, at any rate I can vouch for the fact, that at the altitude of from 5000-10,000 feet (that is, in the Nepenthes on Kina Balu, North Borneo, this plant, together with its congeners, enjoys several hours of rain nearly every afternoon, and there are always very heavy dews which fall at night. No doubt the same is true on the Andes and on the Himalayas, indeed on all the mountains of the world. I believe the above plan of partially heating, and nearly entirely ventilating a cool house from a much warmer one will give us the most perfect of all atmospheres in which to grow mountain Orchids. This principle was long ago adopted by Messrs, Backhouse at York, their cool Filmy Fern-cave being (at least it was) in communication with a heated structure, so as to insure a nightly, if not a daily, dew-bath for the delicate

This question brings me to another contested point in Orchid culture, namely, the syringing of Orchids. Some Orchids enjoy syringing overhead, indeed some of the thin-leaved Dendrobiums of the D. Falconeri and D. Devonianum type can rarely be well grown without coostant syringing, so also of Cyptiediums, Ceologynes and Pleiones, Disas, and most "cool Orchids" of the Odontoglossum and Masdevallia type. In moist houses I know that the latter can be grown—well grown—without syringing, but in dry ones not so successfully. I should never syringe Cattleyas or Lelias, in fact, no very hard-leaved pseudobulbous Orchids of any kind. Vandas, Aerides, Saccolabiums, and even Phalænopsis and Annestochilus, are greatly refreshed by a light "skiff" with a fine rosed syringe after a blazing hot summer's day, especially if grown in large or in dry and airy with a fine rosed syringe after a blazing hot summer's day, especially if grown in large or in dry and airy houses. In such houses syringing is a necessity, if the lower leaves of Vandas, Aerides, Angræcums, &c., are to be retained. In a state of Nature all Orchids are more or less drenched with rains during their annual season of growth, and it is worth notice that the bulk of tropical rainfall is at night; after the very hottest of days there are sure to be nightly showers. If pleoty of air be left on, nightly syringings after hot days during summer would greatly benefit all Orchids, if we except Cattleyas and Ledias, It is, as we have said, of especial service to those thin-leaved kinds which have no pseudobulbs. At the same time amateurs must be extremely cautions in syringing their plants. The syringe is like a rife, or a good horse—most useful to those who understand their usage best; and so in good hands the syrings becomes a garden implement of the greatest service. F. W. B.

NOTES ON VEGETABLES.

NEVER before at this season of the year do I remember to have seen green vegetables so abundant and good; as not only are Brussels Sprouts and all Kales full of growth, but what should have been spring Cabbage are fast turning in, and Broccoli, such as Veitch's Winter, Backhouse's, Snow's, and Osborne's, are now fit for use, and all other kinds are looking as well as at any time during the autumn. As we can hardly expect to escape frost altogether, it will be necessary to be on the alert now, as in their present tender state such things as the last named will soon suffer, especially those with heads showing, plants of which should be laid in, moderately close, in some sheltered spot where they can be readily protected by scattering some long loose straw over them, the shelter of which will not only ward off frost, but preserve them against cutting winds, the effects of which are often fatal to vegetation during the mouths of February and March, when the sap is sometimes dried quite out of the leaves. With the later sorts of Broccoli it is as well to run the risk of losing some by letting them stand, for were they laid in now the check would be so great that the heads would be small, as the plants would have no time to root, and frost and drying wind passing over them in that unprepared condition would be sure to tell severely upon them. Much value has hitherto been attached to the London Colewort, but with us Wheeler's Imperial Cabbage is far superior; as, sown and planted about the same it hearts in with the first named, and is larger closer, and much more delicately flavoured. Besides being so serviceable during the autumn and winter, this splendid little Cabbage is the best I know or planting to cut first in the spring, for which pur-pose it stands in high esteem in the West of England. where it was raised many years ago by Mr. Wheeler, of Warminster, whose name it so worthily bears, and those who have not grown it will do well to make its acquaintance by obtaining and sowing a packet of seed. If this is done in gentle heat the heads will come in useful in May, and though small, they will be found delicious when cooked. Another vegetable we have found most serviceable is Gilbert's Chou de Burghley, which resembles a tall Sugar-loaf Cabbage, and which will, in my opinion, take the place of the old Savoy, which few will eat if they can get anything less strong and better. Chou de Burghley has all the merits of a Savoy by turning in during the autumn and winter, and none of its drawbacks; for, instead of being rank, Chou de Burghley is mild and delicious Of its capability of withstanding frost I in flavour. can say nothing, but if thoroughly hardy its reputation will then become entirely established. Unfortunately Couve Tronchuda has all its goodness taken out of it after being frozen, else it would be the best of all the Brassicas for this late season, as it most certainly is when Cauliflowers are over, when if it has been well and freely grown it is, after being cooked, as tender as marrow, and seems quite to melt in the mouth. to Cauliflowers, they are, like the farmer's Wheat during mild seasons, "proud," which proudness will result in their "bolting;" as, judging from present appearances of most plants, they are sure to button and be useless for cutting. This being so, it will be advisable to sow seed of some early sort at once, as plants raised now, and nursed on by pricking them out on a gently fermenting dung bed, will nearly catch up to any that stand through the winter; and they are often more satisfactory, as they afford close white beads that have no tendency to run or discolour. The Early London used to be considered the best for first cutting, but there are several now that are superior to that well known old variety, one that are superior to that went known one variety, one of the most desirable being Veitch's Extra Early Forciog, which, though small, is very compact both in the flower and habit, and so dwarf and upright that the plants may be grown much closer than any other kind. To form a succession, I should advise a sowing of both these Cauliflowers to be made together, and if the seed be placed in hoxes in heat it will soon be up, and the plants ready for pricking off in a frame, as mentioned above. At the same time it is quite worth while raising a few of Veitch's Giant, the merits of which as a summer Cauliflower are only known to the few, but when sown early, and got up strong, it stands dry hot weather better than any other I know. I found this out by sowing in the autumn, thinking to grow some for seed, and they came most acceptable in August, when we had no others to cut. 7. S.

NEW KINDS OF POTATOS .- The list of new kinds of Potatos given at p. 109 includes those only which took honours from the Royal Horticultural Society, but from the committee of the International Potato Show such fine kinds as Prince Munster, The Dean, Recorder, Lord Mayor, Edgcote Purple, have all received Certificates of Merit, and are therefore worthy of mention, being placed in commerce for the first time this winter. No doubt there are more kinds being offered for the first time just now than can be fully mentioned, but it is just possible that some highly meritorious kinds may be overlooked. It is most certain, as all who have had experience of the kinds put into commerce recently will admit, that few but what are first-rate are now sent out. I refer, of course, to English-raised kinds only, as few persons seem to care about new American sorts; indeed, the demand for them is comparatively nil-that is, at least, my experience. Of these I find only the most infinitesimal difference in quality as compared with such old kinds as Early Rose and Snowslake. But the other day I read a very eulogistic notice of Adirondack, but the best that can be said of its quality is, that it is hard and flavourless; yet I think this kind obtained a Firstclass Certificate from the Fruit Committee, Snow-

drop Kidney, spoken of at p. 108 as resembling Snowflake, certainly did present such characteristics at Chiswick last summer, but the stock of it I have from Mr. Perkins in quantity shows it to much more closely resemble a handsome sample of the old Dawes' Matchless Kidney than Snowflake, and its table quality is excellent. I think it will take a high place as a show kidney, and with Recorder, Wood-stock Kidney, Cosmopolitan, and Welford Park Seedling, help to displace inferior kinds. In a year or two there will he no kinds of indifferent-looking quality seen on our exhibition tables. A. D.

BRUSSELS SPROUTS .- Apart from the flavour of these vegetables, which is liked by most persons, there seems to be growing up in certain quarters a preference for them when they exceed the old recognised normal size, and not only so, but there is a kind of propagandism carried on by the believers in the big Sprouts to the detriment and decline in the quantity grown of the little ones. Gardeners are too gregarious in their ways of thought, and are always very apt to follow the lead of some man who has made a name in his profession by exhibiting with success at horticultural shows. Judges, again, are often impressed by mere bigness when that is accompanied with some preconceived notions as regards symmetry, and the awards made by judges of kitchen garden produce have doubtless helped to form the ideas prevalent about big Sprouts. Assuming that the flavour remains identical in all the kinds grown, we gain nothing whatever when the Sprouts are large, for if fewer are required to make a dish, the plants bear a smaller number than do those of the best imported sort, so that the balance of requirements versus quantity remains where it was before the introduction of the Aighurth, the Rosehery, and others. Most people will prefer the appearance of the little green nodules of the one to the less shapely, seemingly under-sized, small Cabbage-look of the other. And here we must allow the cook, to whom the matter really pertains, to give an opinion, and she will say that all vegetables of the Cabbage tribe must have the water-strongly flavoured we know it to he-drained or pressed from them. Now the water will not run sufficiently quick from the big Sprouts, so they are pressed to make them free of the water, and of course to the detriment of the form of the Sprout. With the hard small Sprouts there is much less lodgment for the water, and so draining them in a colander is all that is required. We cannot make Brussels Sprouts hardier, for they defy now all the severities of the usual English winter, and the improvement most desirable would be a longer stalk, with the rosettes set as thickly as they now are found on the best selected strains.

ROYAL HORTICULTURAL SOCIETY.

THE following is the report of the Council for 1883, to be presented to the Fellows at the annual meeting on Tuesday next :-

The Council congratulate the Fellows on the financial position of the Society, the revenue of the year having been sufficient to satisfy the debtor balance carried forward from the preceding one, and to give a considerable surplus after paying or providing for the payment of

every liability to December 31 last.

The Council regret that some of their Fellows should have felt aggrieved by the partial curtailment of their enjoyment of the gardens, which was necessitated by the holding of the Fisheries' Exhibition; but apart from the fact that this curtailment was unavoidable, the Council have the gratification of believing that the great majority of Fellows found ample compensation for any loss they suffered in this respect, in the large privileges which they enjoyed in connection with that Exhibition.

The Council have the pleasure of being able to announce that they have succeeded in arranging with the Executive Council of the International Health Exhibition that Fellows shall have in respect of this Exhibition the same privileges, except as to the opening ceremony, and six evenings which may be reserved, as they

enjoyed during the Fisheries Exhibition. The Council take this opportunity of recognising the spirit of friendly consideration for the interests of the Society which has been shown by the executive of each of these Exhibitions, and the liberality of the Council of the International Health Exhibition, which enables them to present to each former Debenture Holder of the Society a ticket, giving all a Fellow's privileges of admission, but not transferable, in addition to the privileges granted to him last year.

In the early summer an experiment was made in the form of two evening meetings, which the Linnean Society very kindly allowed to be held in their rooms at Burling-

On both occasions a lage number of valuable plants On both occasions a lage number of valuable plants were arranged in the library, including Orchids, sent by Sir Trevor Lawrence, Mr. Lee, Messrs, Veitch, and others; Rhododendrons by Mr. Mangles; herbacous and other plants by Miss Jekyll, Mr. Loder, Mr. G. Maw, Mr. T. Ware, Messrs. Barr, and others, as well as speciments from the Royal Gardens, Kew, and the Society's gardens at Chiswick. The company assembled in the library some time before the reading of the papers. in the library some time before the reading of the papers commenced, and showed very great interest in the examination of this collection of flowers. On both occasions the chair was taken by the President, Lord Aberdare, strongly supported by members of Council.

At the first meeting, on May 8, after some appropriate introductory remarks by the Chairman, Dr. M. Foster, F.R.S., gave an account of the Onocyclus groups of Irises, dwelling on the characters of their construction, their botanical affinities, their geographical distribution, and the proper method of culture. His remarks were illustrated by means of large diagrams, and with freshly cut blooms of Iris iberica, one of the best known of the group. A discussion followed in which Sir J. Hooker, Mr. H. J. Elwes, and Mr. J. G. Bakertook part. Mr. E.G. Loder then read a paper on hardy Cacti, giving an account of their affinities and distribution, and describing the method of culture which in his hands has proved so successful. Dr. Hogg followed with an account of some Australian Applies, recently imported, exhibiting specimens, and distributing them freely among the audience. The meeting was brought to a close by Dr. Foster briefly describing and exhibiting on behalf of Herr Max Leichtlin, several new plants recently flowered at Baden Baden.

At the following meeting, June 12, the reading of papers began by "Notes on Conilers," by Dr. Masters, F.R.S., in which the author drew attention to the mode of growth and to other physiological features of certain Pines and Firs. Mr. W. Goldring followed with a paper on "Cypripediums," admirably illustrated by a very large number of choice Cypripediums in bloom, kindly sent by various gentlemen. The author passed in review by various gentlemen. some of the leading types of the genus, as well as the striking hybrids recently produced, and an animated dis-cussion followed. Mr. G. Maw then gave an account of the genus Crocus (concerning which he, as is well known, is the highest authority), dwelling particularly on the light which a knowledge of the geographical distribution and babits of the various species and varieties may be made to throw upon the culture most likely to be

The experiment of these meetings may certainly be considered most encouraging. The audience was not only large, well filling the Linnean Society's meetingroom, but included, besides the gentlemen incidentally mentioned above, many distinguished horticulturists, and mentioned above, many distinguished.

Several Fellows of the Linnean Society. Great interest was shown both in the papers read and in the discussions which followed, while the opportunity afforded for examining and conversing about so many beautiful or rare plants helped to make the evenings very enjoyable, and repeated expressions were heard of the desire that more of such meetings might be held.

The gardens at Chiswick have been maintained in a high state of efficiency, the practical work of the Society being carried on as usual. Fellows and their friends visited these gardens in larger numbers than during past

The trials by the Fruit and Floral Committees com-The thats by the Fruit and Floral Committees com-prised respectively Peas (of which 154 samples were tried), Potatos in great variety, Lettuces, Tomatos grown in pots and in the open ground, and Celeries among vege-tables; and among flowers and plants, Pelargoniums, Verbenas, Sweet Peas, Begonias, single Dahlias, Tydæas, Gloxinias, and others.

It is proposed that trials shall be made during the

present year by the Fruit Committee of new varieties of Potatos and Peas, and of the entire class of Cauliflower and Broccoli, which is in great confusion; and by the Floral Committee of new Pelargoniums, Begonias of the Rex or bandsome foliaged type, Ferns of the Adiantum or Maidenhair class, and Chrysanthemums. Fellows of the Society and other cultivators of any of these plants, &c., are invited to contribute for this purpose. Facilities were afforded to the committees of the Pelar-

gonium Society and the International Potato Society for the trials of new varieties of the objects submitted to these bodies respectively for cultivation.

The success attending the novel experiment of the Apple Congress at Chiswick surpassed the most sanguine anticipations of the Council—such a display of different varieties, of which the Society's garden contri-buted 260, having never before been seen. About 10,000 persons visited the exhibition, which enabled the Fruit Committee to obtain much valuable information in connection with the fruit exhibited. A report embodying this information is being prepared for pub-

It is contemplated, should the season prove favour-

It is contemplated, should the reason prove favourable, to hold similar shows of other fruits.

The number of plants required for distribution to Fellows continues to increase. During the past year 19,470 plants in pots have been sent out, with 30,000 packets of seeds, and about 5000 cuttings of Vines and other fruit trees; the number of Fellows availing themselves of this privilege being 997. The cost of repairs during the past season shows some increase, the Great Vinery having had to be repaired and several plant pits renewed.

There were among the Fellows during the year 155 new elections, 147 resignations, and fifty-seven deaths, twenty-three of these deaths having been those of life Fellows.

Fellows. AUDIT,—The auditors' report that they have great pleasure in stating that the accounts are perfectly correct and satisfactory in every respect, the books being now kept in a clear and lucid manner, and reflect great credit on the officials of the Society. They offer their congratulations on the prosperous state of the affairs of the Society, the number of Fellows being nearly maintained when a serious falling off might have been auticipated in consequence of the great disturbance which took place in its affairs last year.

The Society for the first time for several years commences the current year with a surplus in hand after discharging all liabilities up to the end of 1883, and the auditors express a hope that it is now entering on a new era of prosperity. Jan. 30.

The Poultry Yard.

POULTRY EXPERIENCES .- My notes as to the product of my few hens in the matter of eggs during the past year, and published in these pages a few weeks having attracted considerable attention, I now ask permission to record the product in eggs of the same number of hens, viz., nineteen, for the month of January just past. I am quite aware that my hens show no egg-producing capacities of a phenomenal kind as far as the average season is concerned; their good features are found in their continuous winter laying, in giving us an abundant supply of good eggs during that time of the year when eggs are invariably scarce. That winter-laying characteristic is not due to any accidental circumstances, but, as I believe, entirely to the fact that the kind of which I have, about two-thirds in number are white Leghorns-a breed that well merits to be placed in the front rank of layers at any time, but specially of winter layers. Again we find throughout the whole of January not a single day without eggs, and the entire product was 169 as against 145 in January last year; but something is perhaps due to the remarkable mildness of the past month. Should any readers be disposed to hold that the abundant egg-producing is chiefly due to the mildness of the winter, I would again point out that in all directions I hear complaints from other poultry keepers, that they, with even more fowls, get few or no eggs whatever; indeed the prices paid for eggs-2d. and 3d. each-tell of comparative scarcity. One town poultry keeper complains, that with a fair run and ample feeding of grain in variety, yet his hens do but give him at the rate of ninety eggs per hen per year, whilst mine for last year gave about 120. Prohably having regard to the diverse conditions under which town and country fowls exist, his average is very fair; still I think much is due to breed. Hens that are rarely broody, and are neither coarse nor fleshy, are usually heavy layers. It is breeds that display these features which poultry keepers should have if they want eggs. Of course, with such qualities there must be also an easy adaptability to food and run, and fair hardiness of constitution. All these things I think the Leg-horns show in a marked degree. Their productive-ness and good-sized eggs, of high quality too, are

It would be interesting to learn whether other poultry keepers in a small way can with such fancy kinds as Laogshans or Minorcas, or even with Spanish or Hamburghs, show better winter returns. It may be well worthy the consideration of poultry societies to ascertain how far their shows are tending to promote the production of eggs in this country, as well as handsome breeds. Big birds and fine feathers are not the requirements in poultry, and most persons will agree that if good eggs and plenty are produced, and specially so in the winter, the colour or breed of fowls is of little consequence. We have recently had fowls is of little consequence. a high authority advising the larger production of poultry and eggs, and the advice is good. Novices, however, will ask what are the best breeds for our purpose, and in the hope of aiding them in their enquiries I have penned these homely experiences.

Chanticleer.

Jan 3t.—Dull raioy day and night.
Feb. r.—Fine morning. Heavy raio from t P.M. to 2.45 P.M.

2.—Fine day and night.

3.—Fice bright morning. Suo shining till noon.
Oversat afterwards. The maximum temperature of this day took place at midnight.

4.—Fice day and night; overcast.

5.—Dull day and night;

6.—Dull day; overcast. Fine night; clear sky.

LONDON: Almospheric Pressure.—During the week ending February 2, the reading of the barometer at the level of the sea increased from 28.71 inches at the the jevel of the sea increased from 28.71 inches at the beginning of the week to 29.91 inches by midnight on the 28th, decreased to 29.77 inches by 9. A.M. and increased to 29.85 inches by midnight on the 29th, increased to 30.03 inches by midnight on the same day, decreased to 29.39 inches by midnight on February 1, and was 30.33 inches by the end of the meable. week.

The mean reading of the barometer for the week

at the level of the sea was 29.70 inches, being 0.18 inch lower than last week, and 0.25 inch below the average of the week.

average of the week.

Temperature. — The highest temperature in the shade in the week was 54°.5, on January 30; the highest reached on the 27th was 41°.5. The mean of seven high day temperatures was 48°.6.

The lowest temperature was 32°.5, on January 28; on the 30th he lowest temperature was 45°.1. The mean of the seven low eight temperatures was 38°.5.

The greatest range of temperature in one day was 1°.1, on the 29th; the smallest was 6°.8, on ebruary 1. The mean of the seven daily ranges February 1. was 10°.1.

The mean temperatures were-on January 27th, 37.2; on the 28th, 38.8; on the 29th, 47.7; on the 30th, 49.5; on the 31th, 47.9; on February 1, 45.9; and on the 24, 38.8; and these were all above their averages (excepting January 27, which was 0.9 below) by 0.6, 9.4, 11.1, 9.4, 7.3, and

0°.1 respectively.

The mean temperature was 43°.7, being 1° lower than last week, and 5°.3 above the average of the weck

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 84°.5, on January 29. The mean of the

sun was 54.5, on January 29. The mean of the seven readings was 73.2. The lowest reading of a thermometer with its bulb placed on grass was 26, on January 28. The mean of the seven readings was 32.1.

Rain.—Rain fell on four days, to the amount of 0.72 inch.

ENGLAND : Temperature .- During the week ending February 2 the highest temperatures were 56°.2 at Cambridge, 55° at Truto, 54°.5 at Blackheath; the highest at Sunderland and Preston was 50°, and at Brighton and Bradford 51.° The general mean was 53°

was 53°.

The lowest temperatures in the week were 28°.8 at Wolverhampton, 30° at Leeds, 30°.1 at Bolton; the lowest at Freston was 35°, at Plymouth 34°.8, and at Turro 34°. The general mean was 32°.1.

The greatest ranges were 24°.2 at Cambridge and Wolverhampton, 24° at Leeds; the smallest ranges were 15° at Preston, 18° at Brighton, and 18°.9 at Plymouth. The general mean was 20°.9.

The mean of the seven high day temperatures was highest at Truro, 51°.4, at Plymouth 50°.7, at Cambridge 10°.7, at C

bridge 49°.r.; and was lowest at Bolton and Sunderland, 44°.2, and at Hull 45°.2. The general mean was 47°.2.

The mean of the seven low night temperatures was highest at Turto, 41°.3, at Plymouth 46°.1, at Brighton 38°.7; and was lowest at Wolverhampton, 33°.7, at Bolton 34°.4, and at Sunderland 34°.5. The general mean was 37°.

The mean daily range of temperature was greatest at Wolverhampton and Nottingham, 12°.9, at Sheffield 10°.8; and was least at Preston, 7°.7, at Brighton and Liverpool 9°.1. The general mean was 10°.2.

The mean temperature was highest at Truro, 46°.1, at Plymouth 45°.6, at Blackheath 43°.7; and was lowest at Bolton, 30°. at Sunderland 30°.1, and at Wolverhampton and Hull 39°.8. The general mean was 41°.8. was 41°.8.

Rain.—The largest fall was 2.80 inches at Bradford, 2.49 inches at Leeds, 2.23 inches at Brad-ford, 2.49 inches at Leeds, 2.23 inches at Bristol; the smallest fall was 0.49 inch at Cambridge, 0.72 inch at Blackheath, and 1.01 inch at Wolverhampton. The general mean fall was 1.58 inch. Rain fell on six or seven days in the week at nearly every station.

SCOTLAND: Temperature.- During the week end-

SCOTLAND: Timperature.—During the week ending February 2, the highest temperature was 48°.7, at Edinburgh; at Dundee the highest was 42°.1. The general mean was 45°. The lowest temperature in the week was 27°, at Perth; at Glasgow the lowest temperature was 30°. The general mean was 28°.5. The mean temperature was highest at Glasgow, 30°.8.; and lowest at Perth, 35°. The general mean was 36°.7. Kain.—The largest fall was 2.76 inches, at at Glasgow; 2.75 inches at Paisley; and the smallest fall was 0.56 inch, at Perth, and 0.75 inch at Dundee. The general mean fall was 1.60 inch.

[JAMES GLAISHER, F.R.S.

Enquiries.

"He that questioneth much shall learn much."-BACON.

TREES BLOWN DOWN.—Cau any one tell me how long timber trees of Larch, Scotch Fir, and Spruce Fir, blown down, but having some hold of the ground, will lie without suffering in value? H. IV. M.

Answers to Correspondents.

APPLES IMPORTED: G. C. Eaton. The number of bushels imported in 1882 was 2,386,805, but we have no means of knowing how many came from America, or how many from the Contineat.

Books: D. M'V. Greenhouse Management for Amateurs (Bazaar Office, 170, Strand, W.C.).—IV. W. Bentham's British Flora (Reeve & Co.).

CAMELLIA SPORT: R. Sawford. Your sport from Jenny Lind is a very fine variety, but it bears such a strong resemblance to a pale flower of an old variety called Saccoi nova that we should hesitate to say it is distinct.

CEANOTHUS: A Reader. Gloire de Versailles is a seed-ling variety of C. azureus, and is of a darker shade of

CELERY WHITE PLUME (see p. 155): Messrs. Waite-Nash, Huggins & Co., 79, Southwark Street, S.E., inform us that they have imported seeds of this variety from New York.

CHRYSANTHEMUMS: S. Cairnbeul, We cannot name the variety; and without knowing something of your method of cultivation, it would not be advisable to recommend it for late flowering.—G. 3. W. Very good in quality for so late in the season. We do not recognise it.

CINERARIAS: A. F. Skinner. A fair average sample; by no means first-class.

CROCUS IMPERATI: E. T. It was named C. Imperati by Prof. Tenore in honour of an old Italian botanist— Imperato.

CYPRIPEDIUM INSIGNE: D. Inglis. We have seen similar leafy sheaths on single-flowered stems, but not on a double one before. The variety is a very nice

EUCHARIS DISEASE: Nemo. The disease on Eucharis is noticed in our number for July 28, 1883, and attributed there to a fungus. Your specimens seem in a better condition than those before received, and shall be fully examined shortly. M. Y. D.

FOLIAGE FOR BOUQUETS: Florist. We think you would do best by growing a bed of secuted-leaved Pelargoniums. If we understand your question rightly, there are no annuals that will stand fresh long enough after being cut to answer your purpose.

HELLEBORUS: Cor. The species were described in our columns by Mr. Baker in 1877, vol. vii., pp. 432, 464; the garden varieties (other than those of niger) by Mr. Moore in 1879, p. 431.

NAMES OF FRUIT: Camjee. Apple: Warner's King.
—Skinner & Son. Most closely resembles Striped Beefing.

NAMES OF PLANTS: W. Baxter. Tropæolum brachy-

ceras.—W. Z. 3. Sparmannia africana. We have no means of identifying garden varieties of Camellias.—Y. Smith. Seedling warteries, apparently, which we cannot identify.—K. P. 1, Send a better specimen; 2, Euonymus fimbriatus; 3, Euonymus sp.; 4, not recognised; 5, Iasninum heterophyllum?—IV. P. 6-5. A variety of Odontoglosum Wilckeaum.—H. M. H. A good and well known form of Ceoloxyne cristata.—H. Y. Ros. Ceologyne flaccidia. The Fern is probably Adiantum cubense, but we are not yet quite satisfied with this identification.—IV. IV. Nephrodium molle, and Cypripedium venustum, a good variety. variety.

NITRATE OF SODA: W. & 7. B. We should certainly not use it as a substitute for ordinary liquid manure to apply to soft-wooded plants. Its proper use is as a dressing to Grass or other green crops.

ODONTOGLOSSUM ROSSI MAJUS: G. P. No. 1 nearly approaches Rossi majus rubescens; 2 is very like a variety in Mr. Lee's collection under the name of Rossi majus pallens; 3 is an ordinary form of Rossi majus.

ORCHID SEEDS: X. They are of no commercial value, for the simple reason that they may be simply seeds in appearance, having no germinating power. There is nothing more deceptive.

ROSES FOR EXHIBITION: O. B. The Rose Garden, by William Paul (Kent & Co.); A Book About Roses, by the Rev. Canon Hole (Blackwood). If you want one cheaper than these, Roses and their Culture, by W. D. Prior (Routledge).

Prior (Routledge).

SEASIDE SHRUBS, Robt. Ellis. The following will grow well in your locality, if they can only be slightly protected from the prevailing sea winds: — Arbutus Unedo, Philiprea angustiolia, Ceanothus, any variety; Daphne Laureola, D. Mezereum, Garrya elliptica, species of Fuchsia, Levessteria formosa, Buddleia globosa, Pyrus japonica in variety, Rhamuus frangula, Myrltes in variety, Rose, Escallonia in variety, Goes single and double, Embothrium coccineum, Tamarisk germanica, Weigela of sorts, Camellias, especially the single varieties. Do not plant any large-leaved plants; either deciduous or evergreen, for nobvious planted should sheltering hedge that should first be planted should sheltering hedge that should first be planted should sheltering hedge that should first be planted should should shelter has followed the sheltering hedge that should first be planted should should shelter has compared to the shelter has got established the other plants can be put in.

PARING TREES: Old Subscriber. If the trees are young there is little doubt but that it will kill most of them, if not all, and seriously cripple the remainder, Aged trees, with old rough bark, do not suffer so much. A mixture of cowdung and soot, put on with a brush, would have answered your purpose, and would not have injured the trees.

TUFA STONE: 'J. Wallace. This can be obtained from Messrs. Joseph Ellis & Sons, East Street, Leicester.

Messrs. Joseph Ellis & Sons, Last Street, Leicuster.

VEGETABLES: J. E. Watton. Cauliflowers — Early
London, Walcheren, and Veitch's Autumn Giant, if
you cau afford to give it the room it requires. Lettuces
— Cabbage, Paris Market, Tom Thumb, All the Year
Round, Cos sorts, White Paris, Brown Bath (black
seeded). Turnips—Snowball, Early Munich, American
Strapleaf, Chirk Castle Black Stone. Peas—First of
All, Advancer, McLean's Best of All, G. F. Wilson,
Veitch's Perfection, Ne-plus-Ultra. Cabbage—Little
Pixie. Nonnareli. Wheeler's Imperial. Cocoa Nut. Pixie, Nonpareil, Wheeler's Imperial, Cocoa Nut.

VEGETATION ON A WALL: S. Mary Ormerod. It is the spawn of some fungus, such as is common in such situations, but which in its present state it is impos-sible to identify. Probably a Polyporus.

INTELLIGENT READERS, PLEASE NOTE: — Letters re-lating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the Publisher, and NOT to the Editor.

FOREIGN SUBSCRIBERS sending Post-Office Orders are requested to send them to the Publisher of this journal, 44, Wellington Street, Covent Garden, and to make them payable to William Richards, at the Post Office, Drury Lane, London, W.C.

SEEDS

SEEDS.

London: Feb. 6.—The business passing in farm seeds is at present moderate. Of home-grown red Clover seed the supply continues good, but choice samples prove exceptional. The American and Continental markets keep steady, but, meantime, the English demand is quiet. The stocks, however, all round now held in London are, for the time of year, unusually light. There is no change in either Aiske, white, or Trefoil. Imported Italian meets with rather more inquiry. Very little attention is given to perennial Ryegrasses. Spring Tares are scarce. Canary seed is exceedingly time. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

HAY.

Tuesday's Whitechapel Market report states that supplies were large, especially of Clover, prices being as follows:—Prime Clover, 95s. to 107s.; inferior, 60s. to 75s.; prime second cut, 90s. to 105s.; best meadow hay, 80s. to 80s.; inferior, 40s. to 65s.; and straw, 28s. to 37s. per load.—On Thursday there was a large supply offering. The trade was dull, at about Tuesday's rates.—Cumberland Market quotations:—Superior meadow hay, 82s. to 92s.; inferior, 60s. to 72s.; superior Clover, 10ss. to 12s.; inferior, 70s. to 88s.; and straw, 34s. to 38s. per load.

POTATOS.

The Borough and Spitalfields Markets reports state that there were good supplies on offer, but the trade was quiet, as follows:—Magnum Bonums, 80s. to 90s.; Regents, 70s. to 90s.; Champions, 60s. to 70s.; and Victorias, 70s. to 90s. per ton. — The imports into London last week consisted of 28 bags from Hambug, 81 bags from Boulogne, and 100 sacks from Bordeaux.

COALS.

The following are the prices current at market during the week:—Walls End—Hetton, 16s.; Hetton Lyons, 14s. 6d.; I cambion, 15s. 6d.; Wear, 14s. 6d.; Hulam, 15s.; East Hartlepool, 15s. 3d.; South Hartlepool, 14s. 9d.; Thornley, 15s. 3d.

NOVELTIES.

LOBELIA Prima Donna.

Awarded First-class Certificate Royal Horticultural Society. No modern introduction to the world of Flora has received a heatter welcome than was accorded to this charming novelty when it was placed before the Committee of the Royal Horticultural Society. In abbit it is very compact and dwart, whilst the rich velvety crimson-maroon flowers—equal in size to those of Lobelit speciosa—are thirdly studded over the cottierplant, with an effect that is at once most unique and benutuful. Price, in sealed packets, 2s. 6d. and 5s., post-free.

NEMOPHILA atomaria atrocorrulea. — Awarded First-class Certificate, Royal Hotticultural Society. After years of actious care and selection we have succeeded in fixing the beautiful rich purplish-blue in this charming novelty. The colour of the flower is a deep ultramarine, pure white centre, with a zone of black-purple.

Price, in sealed packets, 1s. 6d., 2s. 6d., and 3s. 6d., post-free.

SWEET PEA Adonis.

The bright rosy-carmine blossoms of this distinct novelty contrast most pleasingly with the pure white, scarlet and other decided colours already in cultivation. Price, in sealed packets, 1s. 6d. and 2s. 6d., post-free

PRIMULAS.

CARTERS' HOLBORN GROUP.

Awarded Fronze Banksian Medal Royal Herricultan Medal Royal Herriculfrom Herricular Herricular Herricular
competences of habit, and substance and size of flower.
The better to distinguish our new straios from the
ordinary ones in general cultivation we have formed
then into a section designated "The Holbon," and
the group will hereafter be identified with that appellation.

NO IRON, ZINC, OR PUTTY USED.

No Special Contract Required for its Adoption.

SUITABLE FOR ALMOST UNIVERSAL APPLICATION.

N.B.—The Lead Strips, which are the special feature of this System, require no Skilled Labour to fix; breakages can be repaired by any one; and ALL OUTSIDE PAINTING IS DISPENSED WITH.

SOLE MANUFACTURERS OF THE PATENT LEAD STRIPS,

GROVER & CO. (Limited), Engineers, &c., Britannia Works, Wharf Road, City Road, N.

Write for Prospectus, Illustrations. and Testimonials.

BALSAMS.—Saved only from very select double flowers.

BALSAMS.—"Hender & Sons' strain appears to possess all the good qualities of the best type of double flowers. They are of good size, well filled out, and of good substance. The motive durings and outled reds, the scarlets and pure whites, 1830 every way first-class."—Gardanier's Chronick, July 21, 1830 every way first-class.

are in every way mraceass.

108 Messex, Hender & Sons' Balsans were much admired, the flowers of which resembled Camelluss in their size and form."—
Report of Royal Western Hortenthural Show, August, 1881,
Gardeners' Magasine.

Eight varieties, separate, 22. 6d,
HENDER AND SONS, Nursery, Plymouth.

CHRYSANTHEMUMS.

THE extraordinary exertions made by us to execute all orders has given us sufficient stock to fill a roo feet house with fine young thrifty Planes just ready for a form of the state of th

SEMI-DOUBLE DAHLIAS.

As beautiful and as far away from others as our Single Varieties are, yet for cut flowers and decorative purposes the above are certainly the most useful.

We have a large and foe stock of ANIEL, pure white, 6d. each, 5s, per dozeo, GLARE OF THE GARDEN, crimson, 1s. each, GLARE OF THE GARDEN, crimson, 1s. each, JUAREZII, selected to the Whole Eamily of Dahlias sent post-free, Catalogues of the whole family of Dahlias sent post-free.

THE HOME FOR FLOWERS, SWANLEY, KENT.

FLOWER SEEDS.

THE productions from our seeds have won so many Medals, prizes, and Certificates in various parts of Europe, that it is perfectly unnecessary for us to say a word beyond this simple amouncement, for the world not only knows that we have the best, but grow and save our own. All are cordially invited to see our flower-growing and seed-saviog during the season.

HOLLOWAY'S PILLS and OINTMENT. TOLLOWAYS PILLS and OINTMENT.

—Glad tidings—Some constitutions have a tendency to rheumatism, and are throughout the year borne down hy its reprotracted tortures. Let used sufferers battle the affected parts with warm brine, and afterwards ruh in this soothing Ouatment, and afterwards ruh in this soothing Ouatment, and assisted by Holloway's Fills, the surest way of overcoming their disease. More need not be said than to request a few days trial of this safe and soothing treatment, by which the disease will ultimatedly be completely swept away. Pains that would make a giant shudder are asstated without difficulty by Holloway's early and the safe of the safe

NEW AND CHOICE POTATO,

12s. per Bushel of 56 lb. 4s. per Peck.

"SNOWDROP." 12s. per Bushel of 56 lb. 4s. per Peck.

(JOHN PERKINS & SON, Northampton.)

Awarded a First-class Certificate by the Royal Horticultural Society, Aug. 24, 1883.

`HIS New Early White Kidney is a Novelty of Sterling Merit. It is fit for use within a few days of the earliest Kidney. The tubers are perfectly formed, eyes very shallow, skin clean, and it is beautifully white and mealy when cooked.

It is a most abundant cropper (as many as forty handsome tubers, weighing 12 lb. in the aggregate, have been dug from one root), and, unlike most New Potatos, it improves year by year. It is perfectly distinct from any other, and is, without doubt, the finest Second Early Potato in cultivation.

TESTIMONIALS.

From Mr. THOMAS LAXTON, Seed Grower, Girtford, Bedford.

From Mr. THOMAS LAXTON, Seed Grower, Girtford, Bedford.

"I Snowdrop' Potato as tried at Girtford this season against most of the newer varieties as well as the old standard sorts, has proved itself a very first-class Potato. I had frequeotly, during the past two seasons, upportunities of seeing it exhibited at Northampton and in the neighbourhood, and I noted it then as the handsomest Potato I had ever seen. I am pleased to add that usize, productiveneess, and quality, for an early variety, it has no superior. We have had our full share of the Potato disease, but at lifting time I could detect no signs oft in "Snowdrop." I have sime examined the stock and it is still free, whilst many others of the never varieties are suffering very much. I found it, too, quite distinct from "Snowdrake," and it must not be confounded with that variety."

From Mr. EDMUND COLE Gardener to Hie Excellency Earl Spencer, K.G.,

"Your new early Kidney Potato" Sanwdrop 'proved with me ooe of the best. For cropping, appearance, cooking, freedom from disease, and other good qualities, it cannot be surpassed. When better known it will no doubt become a great favourite both with gardeners and market gardeners."

From Mr. RICHARD THOMAS, Gardener to The Right Hon. the late Lord Overstone, Overstone Park, Northampton.

"I have grown your new Potato 'Snowdrop' for two seasons. It is excellent in every respect—early, large, and handsome, a great cropper, of good quality, very white (as its name denotes), and has been entirely free from disease. 'Snowdrop' was in my prize collection of Vegetables at the last Northampton Horticultural Show."

From Mr. J. HARLOCK, Gardener to The Right Hon. the Lord Lilford, Lilford Hall, Oundle.

"After growing your Potato 'Snowdrop' for two seasons, I think it the best Potato for quantity and quality I have ever grown. I recommend it to all my friends."

From Mr. J. WITNEY, Gardener to George Farrer, Esq., Brayfield House,
"I have grown your 'Soowdrop' Potato for three seasons on heavy and light soil, and find it
one of the best Potatos extant, and the best quality Potato I have yet grown—and I have fifty of
the leading sorts of the day. With respect to the statement I have seen in print as 'to it's long
like 'Snowflake', I entirely disagree. It is a different shape, being oval, while 'Snowflake' is
flattish and generally larger at the heel, 'Snowdrop' being uniform the whole length of the tube.
It is also much earlier fit for use, the skin a different colour, and the haulm more robust—though
not tall. Altogether I think it the best gentleman's Potato yet sent out."

From Mr. EDWARD WILSON, Gardener to The Right Hon. the Earl of Lindeay, Uffington House, Stamford.
"Your' Snowdrop' Kidney Potato with me is excellent both for quality and crop. I planted 6½ lb. in the ordinary way, and the produce was 23 stone 9 lb. of excellent tubers."

Prom Mr. J. GREGORY, Gardener to The Viscountess Clifden, Holdenby House,
"I have grown your Potato' Snowdrop' since 1881, and am very much pleased with it. It
is early, large cropper, good even shape, very white and of fine quality. This year I have again
lifted a very fine crop of good sound tubers. It is very much liked in this neighbourhood."

From Mr. J. JENNINGS, Gardener to Leopold de Rothschild, Esq., Ascott, Leighton-Buzzard.

"The 'Snowdrop' Potato I had from you last February is the best second Potato I ever grew. It is very handsome, prolific, and of good quality."

From Mr. H. WALLER, Gardener to F. E. Walker, Esq., Wooton Basset, Wilts.

"The new Potato 'Snowlerpo' is the finest Potato I have yet seen for exhibition. It has a very shallow eye, and is a handsome Potato. I had 168 lb. from a gallon, and some of them 9 inches long."

From Mr. JOHN ROWE, Gardener to Major Orred, Lavant Houee, Chichester,
"I think 'Snowdrop' Potato one of the best second early Potatos that can be grown. In
1882 I planted ra lb io the ordioary way, and the produce was 554 lb. Had I given them more
room I have no doubt I should have had a much larger produce."

From Mr. WILLIAM CARDEN, Gardener to Miss Watson, Langton Hall, Tunbridge Wells.

"I think your 'Snowdrop' Potato is one that cannot be spoken too highly of, both as regards cropping and resisting the disease. It is an excellent Table Potato."

From Rev. WILLIAM LAW, Marston Truesell Rectory, Market Harhoro', "11 mg lad to inform you that having grow o 'Snowdrop' Potato for two seasons, it has asswered my fullest expectations. It is of his flavour, white and meally when boiled, and so far unaffected by the disease. I scarcely know whether to term it one of the latest of the earlier as field of various sorts by its robust growth and compact habit. It has only to be known to be appreciated and extensively grown. I have sent a simple to a Clergyman in Wales, and be also pronounces if inter-rate."

AERIDES ROHANEANA.

M ESSRS. PROTHEROE AND MORRIS are favoured with instructions IVI from Mr. F. Sander to SELL the above by AUCTION, at their Central Sale Rooms, 67 and 68, Cheapside, E.C., on FRIDAY NEXT, February 22, at half-past 12 o'Clock precisely.

Professor Reichenbach says: - "This is a grand new Aërides. It ranks near the rare A. Reichenbach-

ianum, but its very long inflorescence is much denser."

The individual flowers are 11/2 inch in diameter, and fifty or more borne on the spikes. It combines the good quality of easy, free, and vigorous growth with beauty of colouring and size of flowers, and a great diversity of colour in the varieties. The lip is sulphur colour to deep orange, the sepals and petals purple, crimson, violet, white, often tipped rosy-violet and purple-violet. The importation came home five weeks ago, and the plants may be looked upon as perfectly safe. They are simply in superb order, with fine roots and sound healthy leaves. The entire importation will be offered, and among them is a mass of immense proportions. (See Drawings.)

On view Morning of Sale. Catalogues had at the Rooms, and 8, New Broad Street, E.C.

HURST & SON'S NOVELTIES for 1884.

PEA-DUKE OF ALBANY (Abbott's).

This splendid new Pea has proved to be the finest yet introduced, either for exhibition or for table, and undustled as a main crop wriokled variety. It is very productive, bearing a profusion of extra large, well-filled pods, borne in pairs, which, being dark green in colour, are very handsome, and contain from nine to twelve fine Peas each. The flavour and quality are also excellent. It grows about 5 feet high, is of a vigorous and branching habit, and should, therefore, be sown thinly. In Sealed Haif-Pint Packets, 2s. each.

WILTSHIRE GIANT SCARLET RUNNER.

A vigorous grower and heavy cropper. The pods are of a large size, very fleshy, deep green in colour, and of excellent quality. The best variety for exhibition.

Per Quart, 2s. 6d.; Per Pint, 1s. 6d

SWEET PEA-PRINCESS BEATRICE.

Awarded a First-class Certificate by the Royal Horticultural Society as New Carmine Rose, August 14, 1883.

Sioce the introduction of the Inviacible Scarlet nothing has been offered as a novelty in Sweet Peas equal in merit to this charming variety. The colour of the flower is a rich and beautiful carmine-rose, slightly shaded with lighter and darker tints, entirely distinct from any other kind. They are of remarkable subnease, similar in this respect to Violet Queen, but the plant has a much more robust and free-blooming habit than the latter—It is perfectly constant, and the perfune is remarkably sweet, more so than in any other sort.

It will undoubtedly become one of the leading varieties of this useful and popular annual, and can be recommended as one of the very best of hardy flowers for cutting purposes.

Fer Packet, 1s. 6d.

MYOSOTIS SYLVATICA COMPACTA AUREA.

The merit of the Old Cliveden Blue Forget-me-Not, particularly as a spring bedding plant, is so universally recognised, that this new golden-leaved variety cannot fail to become a popular favourite. It is similar in habit and colour of foliage to the Golden Pyrethrum; the flowers are of the same clear bright blue as its prototype, and their contrast to the golden-yellow of the foliage is one of its chief merits. As its name implies, it is of peculiarly dwarf compact habit, and as a spring bedder it is destined to occupy a most conspicuous place.

NEW MELON for 1884. ST. BLAISE.

This splendid green-fleshed Melon was raised by Mr. W. Carmichael, who was for many years Head Gardener to H. R. H. the Prace of Wales. The fruit are handsomely and evenly netted, and of large star, weighing a to 6 pounds each. The flavour and delicate aroma. This variety will be found most valuable during the shooting season, owing to its lateness in ripening, when all other sorts in the house are vere, often carrying its large, handsome, and fine flavoured fruit through to the end of November. Scock very limited.

Price 5s, per packet, to be obtained only of

DANIELS BROS., SEEDEMEN TO H.R.H. the PRINCE OF WALES, NORWICH.

W EARLY RHUBARB, Charles Kershaw's "Paragon." NEW EARLY

This is unquestionably the finest variety of Rhubarb ever offered; in mild seasons it is ready to pull in February. The crowns and stalks are produced in such profusion that more than twice the weight can be pulled from this than from any other sort. The columy is a splendid red, flavour excellent, and it has this qualification over all others, IT NEVER SECO.

PRICE-Per Plant, 1s. 6d.; per Dozen, 15s. Price to the Trade on application.

For Testimonials and all other information, see back page of Gardeners' Chronicle for October 13. May be had of all the principal Nurserymen and Seed Merchants, or direct from

Special Cheap Price LIST of NEW and other PLANTS

CUTBUSH'S "MILLTRACK" MUSHROOM SPAWN.

This Spawn has been celebrated for many years, and can be only obtained here, as it is manufactured under a peculiar process known exclusively to ourselves, and wherever once used no Gardener will willingly take to any other kind. One chief feature in its superiority is the extraordizary length of time it continues to produce Mushrooms; many instances have occurred where beds have continued in full bearing for eight or nine months. The Mushrooms are also of a rich fleshy kind, so packages with printed cultural directions euclosed, with our signature attached.

Parton (see Parton 1) and proceedings of the printed cultural directions euclosed, with our parton (see Parton 1) and the printed cultural directions euclosed.

Price (exclusive of packing), 6s. per bushel, or 6d. per cake; free by Parcels Post. 1s. per cake.

per cake; Ires by Parcels Post, 1s. per cake.
None genuine unless in scaled packages, and printed cultural
directions enclosed with our signature attached.
Testimonials are constantly being received.
The Gardens, Sandringham.—" I have tried all other Mushroom Spawn advertised, but toope to be compared with yours,
which I have used for the last twenty years without once failing
a quick and good crop."—CHARLES PENNY, Gardener to
H. R. H. the Prince of Wales.

THE BEST LATE BROCCOLI

LATE QUEEN.

This is, without exception, the latest Broc-This is, without exception, the latest Broc-coli known, and as it fills up the gap which previously existed between the late Broccolis and Cauliflowers, it is invaluable. Sutton's Late Queen is perfectly distinct from all other Broccolis, very dwarf and compact in growth, is rarely affected by frost, and produces splendid heads up to the end of June. At our Experimental Grounds it was the only one out of sixty-five which successfully resisted the intense frosts of 1880-81. The heads are well protected, of medium size, hardsome and of creamy white colour. handsome, and of creamy white colour.

PRICE,

1s. 6d. and 2s. 6d, per packet, post-free.

SUTTON'S LATE, QUEEN BROCCOLI.—"Of the six varieties of Broccoli I have grown bere this season, in exactly the same soil and situation, I find no equal to the above. In this variety we not only have one good quality, so for at least a mooth later, sphendid white compact heads of the very best quality. The habit of the plants is all that can be desired, being as dwarf as it is possible. Many of our other kinds of Broccoli have been killed outright this Chronicle, May 19, 1838. Chronicle, May 19, 1883.

"Your Late Queen Broccoli came remarkably fine; a great number were more than a foot across, very white and close. One measured 19 inches in diameter, of beautiful form and colour."—P. Capon, Esq., Brighton.

form and colout. — CAVON, ESQ. Progaton.

"Your Late Queen Broccoll is splendid. I cut one which measured a feet 6 inches in circumference, most compact, not opened in the least degree, Several others are over 2 feet in circumference. It cannot be surpassed as a late warety, and is deserving of universal cultivation."—E. M. S. PARKER, Esq., Chew Magna.

S. PARKER, Esq., Chew Magna.

"SUTTON'S LATE QUEEN BROCCOLI.—In July last you published a sbort account which I sent you respecting the good qualities of this forecoli. This year it respecting the good qualities of this forecoli order that you may test it.—Thos. Oldman, Friera Watch, Finchley. [An excellent Broccoli, quite free from that bitter taste which Covent Garden Broccoli often has.—Eb.]"—Garden, Mny 20, 1882.

OSIERS.

WHEN, as at present, large numbers of those engaged in the cultivation of the land are at their wits' end to decide what can be grown that will give a fair return for the necessary expenditure, it is well not to overlook what may be termed things that appear of small or secondary importance, as compared with the staple crops that our soil and climate are particularly adapted to produce, and which consequently must ever hold the leading place in the consideration of those whom it first concerns. First concerns, we repeat, for to those who look at all below the surface it must be evident that the community collectively is concerns, and that seriously, when, as it has been recently stated on good authority, farms in Suffolk have been let at 5s. per acre. With such a state of matters, the cultivation of Osiers is a subject not unworthy of the attention of the many who have land that is suitable for this kind of crop, or that could easily be made so. Yet, common as the Osier Willows are, so little is known about them by most people engaged in rural pursuits that the prevailing notion anent them is that a swamp, the edge of a stream, or a water-logged piece of ground is alone suitable for growing them.

Neither is their value as a crop any better understood. Yet, so far as the latter very important part of the question is concerned, we may state that it would be difficult to point to anything that will return so much per acre as a well managed crop of these Willows grown on land that suits them; added to which a plantation, when properly managed, quickly comes into bearing, and lasts many years without renewal. The amount of both top and root growth natural to them requires a good deal of moisture to support it; a cool moist subsoil is what they like, where in dry weather the water present below the surface is constantly rising upwards, so as to be available for their thirsty roots.

Land that is subject for any length of time annually to be covered with water, even if ever so little in depth, is by no means so well adapted for Osiers as such as above described, if only on account of the difficulty existing under these conditions of getting on early in spring with whatever hoeing is required to destroy weeds, which must not be permitted to exist if anything like the best results are looked for. This especially relates to Couchgrass, to the presence of which half the failures in Osier growing are due; neither is this to be wondered at, if a little consideration be given to the impoverishing effects of this worst of land exhausters. It often happens that in determining to make a plantation of Osiers the land has been found unsuited to everything else, and is over-run with Couch, the necessity for extirpating which previous to planting is not recognised; hence the crop becomes half smothered from the first, and never has a chance. In place of this the ground should be completely cleared from this and other perennial weeds before planting.

As to annual weeds, after the first year, beyond a good hoeing or two in spring, at a time when the land and weather are dry

enough to kill the weeds, the crop each season, when it gets fairly into growth will take care of itself by smothering weeds of this character. To insure average crops the soil should be of fair quality and depth, as the weight of produce to be looked for annually is heavy, and consequently requires proportionate sustenance. Extra heavy crops can be grown where a brook or small run of water is at hand that can be turned to account so as to irrigate the land when required, especially in the summer time; but the best results of all are obtainable where sewage can be had. There is no crop that can be put in the land that is naturally better adapted for growing with sewage. As is well known to those who have had to do with this kind of liquid in the usual condition it has to be dealt with, it is so much diluted that to afford sufficient manurial elements to the crops It is applied to, more has to be run on the land than the crops will bear; but with Osiers no difficulty of this kind occurs, for if there is enough fall for the water to get away as it passes through the soil it will do no harm, even if applied to the land at short intervals up to saturation point.

On land so light and dry that otherwise it would be unsuited to the purpose, Osiers may be successfully grown; on light peaty soil, where sewage can be used, they do splendidly. One of the most successful instances in the cultivation of this crop with which I am acquainted is on land of this description, not many years ago reclaimed from its primitive condition. It had been badly farmed, and was in a very foul state; but before planting it was well cleaned from Couch, yet it was as full of seeds of most of the worst annual weeds as bad management could make it. There is just enough natural fall in the land to admit of the water passing slowly away; it was ploughed up in beds about 4 yards wide, with moderately deep alleys between the work was done so as to lay the beds tolerably high in the middle, down which a channel was made to convey the water, which, when running on, is dammed at intervals in the usual manner so as to cause it to flow right and left, when, after percolating through the soil it ultimately finds its way to the alleys between the beds and is thus conveyed away. The land was harrowed before planting, the cuttings, made of the thickest portion of strong two-year-old growth, 18 inches long, were put in early in winter, inserting them half their length, quite upright, 15 inches apart in the rows, and the same distance between the rows. The crop the first summer was three or four to a stool, averaging 6 to 7 feet in height, the second season they were in full bearing, the growth was almost as full as a Reed bed, and 8 to 10 feet in height. They are hand-hoed once or twice each spring to get rid of any weeds that appear until the crop gets fairly into growth, when no living plant could exist under them.

On loamy soils where sewage is not available the plants should stand 18 or 20 inches apart each way, or the land will get exhausted, not having anything to compensate for the heavy yearly drain which a crop of this description subjects it to. On such land, at this distance apart, horse-hoeing in the spring is the best and cheapest, but the work should be done with care, not going so deep as to injure the roots. In this way less hand-work is required, only the spaces between the plants in the rows where the implement does not reach requiring the hand-hoe.

It will do no harm to repeat that clean cultivation is the sheet-anchor to be relled on; suitable soil, with or without sewage, even when well prepared at first, will avail little if the work is not well followed up each spring; the cost of this and cutting the crop is not a serious item, as a matter of course varying according to the

character of the land. A plantation of Osiers will last in a profitable state ten or twelve

Of the two species of Osier Willow, Salix rubra, the red Osier, and S. viminalis, the twiggy Osier, the last in most cases is preferable and yields the most remunerative crop.

A matter of importance connected with the subject is, that if the best results are looked for, the work of preparation and planting needs to be done by experienced hands, for, simple as the operations here detailed may seem, those not fully acquainted with them oftener than not fall short in something that turns out to interfere with favourable returns. For instance, if the cuttings are inserted in a slanting position, when the crop comes to be cut the stools are liable to be half wrenched out of the ground. T. B.

AËRIDES ROHANIANUM, n. sp.

THIS is a grand Aërides. It ranks near to the rare Aërides Reichenbachii, Lindl., but its very long in-florescence is much denser, and the horns in the spur are quite peculiar, and unlike anything that has been seen hefore. I have a representation hefore me-an inflorescence with a leaf. I have not seen such a long leaf, but my dried spindles of inflorescences fully match those in the sketch. Then there is a sketch of a few flowers in water colours. The sepals are said to be white or rose, or rose-mauve, always with a white border. The lacinize of the lip are white. There are two purple lines running over the middle. There are also purple blotches. The central lacinia is nearly rhomboid, bilobed at the apex, with some small crenulations, unlike the teeth in Aërides Reichenbachii. The side lacinize are cuneate and retrorse. The spur is bent forwards, sulphur or orange coloured, with numerous small purple spots. I rely chiefly on the fine characters in the spur. There are two horns, those on the anterior side being nearly hammerlike, dilated and retuse at the apex. Under those horns, just in the middle, a keel runs down. I never before saw such curious bodies in any Aërides among the hundreds and hundreds of flowers I have had under my eyes. The horns of Aërides virens and Reichenbachi are acute. No doubt the species comes from Eastern Asia (ask Mr. Sander, who has been lucky enough to introduce it). It will prove a very desirable addition to our collections. I have three dried inflorescences, a dead plant, with the remnants of four long racemes, fresh leaves.

This grand novelty is most respectfully dedicated to His Royal Highness Prince Camille de Rohan, Prince de Guémenée-Rochfort and Montauban, Knight of the Golden Flecce, the possessor of one of the finest gardens and parks of the world, at Sichrow, in Bohemia, and a most enthusiastic lover and connotineur and collector of plants. H. G. Rohb, f.

Oncidium endocharis, n. sp. "

A curious slender racemo of five flowers, smaller than those of Oncidium brachyandrum. Sepals and petals cuneate oblong acute, the petals a little broader, lateral sepals under the lip. Lip ligulate, expanding at the top, into a rhombic emarginate blade, with two larger lamellæ, and three teeth at the base, which are alternating and superposed to the lamellæ, all of a very bright orange. Column with rhomboid wings and large angles to the tabula infrastigmatica, i.e., the base of column under the stigmatic hollow. It appeared with Messrs. H. Low & Co., and I am told it has the pseudobulbs of Oncidium cheirophorum. Its origin is unknown.

It comes nearest to Oncidium hyphæmatleum, but it is far more tiny, and very distinct in its self-coloured lip, as in the column. H. G. Rehb. f.

CLEMATIS JACKMANNI:

M. LAVALLÉE, the President of the Central Horticultural Society of France, and an enthusiastic cultivator and student of hardy trees and shrubs, of which he has a very fine collection at Segree, has just published a splendid monograph of the large-flowered Clematis, in which we find the following account of the plant known as C. Jackmanoi in gardens. As this account differs very materially from that given by Mr. Jackman, the raiser of the plant in question, we have thought it right to add his original statement:—

Clematis hakonensis made its appearance in our gardens about 1860; the first plant cultivated at Segrez was bought at Angers, and was planted there in 1861. I received two other plants in the following year under the names of C. viticella violacea and C. patens rubra. Some time after the species came into fashion, and its varieties received the names, soon widely circulated, of Jackmanni, rubella, purpurea, hybrida, &c.

Horticultural literature welcomed the newcomer with deserved favour; unfortunately, as its history remained unknown, it was stated to have proceeded from cross-breeding hetween C. lanuginosa, C. Hendersoni, and C. viticella var. atrorubens.* It is not necessary to show how unlikely this triple descent is. When a hybrid plant is successfully raised, that is to say, a product the female parent of which belongs to a different species to that which constitutes the male parent, a plant is produced which is generally sterile, or at least only exceptionally fertile, and then very inconstant. It is, therefore, necessary to multiply such plants artificially either by cuttings or by grafts. As to seeds, if some possess the power to grow, the new individuals do not for the most part remain intermediate, but return to one of their parents, or at least show a tendency to revert to the characteristics of their ancestors. C. hakonensis does not do this—far from it; its seeds are always numerous, germinate easily, or reproduce the species almost without variation. If the newcomers present any modifications it is only in the size or colour of the sepals.

This proof, quite experimental, is, therefore, quite unanswerable; but let us for a moment admit the very unlikely hypothesis of the constant fertility of a hybrid which would then behave like a true species: our Clematis is stated to have proceeded from cross-breeding of C. lanuginosa and C. viticella or C. eriostemon (C. Hendersoni). The last of these species must first of all be eliminated, as it belongs to quite a different section; it is not climbing, produces cylindrical tubular flowers, and differs so greatly in all its characters that it is useless to entertain even for a moment the supposition that it could have had a share in the formation of the flower with spreading segments we are considering, and it will be sufficient to remember the researches of M. Naudin to be convinced of the impossibility of such an association.

As to the two other species, C. lanuginosa and C. viticella, considered as the progenitors of C. hakonensis, we must enquire how their characteristics are reproduced in the newcomer. C. hakonensis resembles C. lanuginosa in the shape and size of its flowers, Its hairy leaf-stalks and peduncles, while the violet or ruddy-violet colour, often more or less blue, of the sepals, is sufficiently like that of C. viticella; but that is the limit to the analogy of these Clematis, and the especial characteristics of our plant are reproduced in neither of these two species, which cannot be considered as intermediate. C. hakonensis attains far larger dimensions than the species to which its descent is attributed, the height of which seemed limited. The segments of the leaves differ in shape, size, and texture; the stamens are erect, and surpass the carpels in size; finally, the reniform achenes, each furnished with a long, persistent, generally erect style, remain characteristic of the new species. It seems useless to pursue this comparative examinanation further, whence it results that, with the exception of the shape and colour of the flowers there is nothing in common between C. hakonensis and the species to which its origin was attributed. If it were possible to retain any doubts as to the specific entity of C. hakonensis, and to still consider it as a hybrid product, this may be removed by studying also the habits of the plant, which differ greatly from those of the species considered as its ancestors. The latter are, in fact, natives of cold or tem-

Oncidium endocharis, H. G. Rohb, f. — (Iotegrilabia.)
"Pseudobubis Oncidii cheirophori; "ratemoţeuui paucifloro; sepalis cuneato-oblongis acutis] tepalis suberqualibus paulo latioribus; labello a basi ligulato antice rhamboideo dilaato caraginato, lamellis in basi rhombeis geminis, denticulo utrique apposito, uno minori interposito; colluma slis ascendentibus rhombeis; fabula utrique appulata. H. G. Rehb, A.

[&]quot; Moore and Jackman, Clematis, p. 9.

perate countries, remarkable for a very intense summer heat, and are only met with in dry, warm places; C. lanuginosa, in fact, grows in the North of China,* and C. viticella in Central Europe.† two plants have so long a period of growth that the first frosts of our countries often find them in full C. hakonensis, on the contrary, easily accomplishes in the course of an ordinary season the several severa have to do with a species belonging to the flora of a country in which the variations of temperature are limited, that it has a climate more or less maritime, or at least rather damp, and in which the heat of summer is never excessive? Thus, I had good reason lor supposing C. hakonensis to he a native of the same country as C. patens, which has, in fact, the same habit, and with which, as we have said, it has probably been confounded. "Les Clematis à Grandes Fleurs," par Alphonse Lavallie, 1884, p. 12.—The following is Mr. Jackman's account of the origin of the plant as given in our columns in 1864:—"I feel hound, for the credit of our firm, to at once commence by explaining the origin, sowing, flowering, and working of those varieties, stating and confining myself unrereservedly to facts as they occurred. Batch of seedlings, No. 1: in the summer of t858, when C. lanuginosa and C. viticella, Hendersoni, and atrorubens were in flower, the idea occurred to me that if I could succeed in hybridising the latter varieties with the former, I should get something distinct in colour and shape of flower. I did so, and the seed ripened was gathered and sown in November. 1858. . . . The seeds did not vegetate in the year 1859, but they came up in 1860, and the young plants were potted off in the spring of 1861, . . . and they flowered for the first time in the summer of 1862, when we selected from among them some of the most rare and distinct varieties." G. Jackman, Jun., Gard. Chron., Aug. 13, 1864, p. 773. It may be added that Hendersoni is supposed to be a hybrid form between C. viticella and C. integrifolia, and that C. atro-ruhens is supposed to be a form of C. viticella. The figure given by M. Lavallée of C. hakonensis is undoubtedly such as to suggest C. Jackmanni before it had been improved by cultivation. It seems quite possible that C. hakonensis may have been unconsciously introduced by Fortune.

BODNANT HALL.

THIS recently built mansion, the country residence of Henry Davis Pochin, Esq., J.P., is situated in one of the most pleasant districts of North Wales (see pp. 209, 213), and commands interesting views of a vast extent of country. It is within easy distance of Llandudno Junction, on the line of railway between Chester and Holyhead. The gardens have been laid out, greenhouses, vineries, and forcing-houses built quite recently; but as the estate comprises some 2000 acres, and as the owner is an enthusiast in gardening, with an accurate knowledge of trees, shrubs, and all hardy plants, it is quite likely that the present extent of pleasure grounds will be enlarged considerably. There are many natural advantages, and these have been made the most of. The ground is undulating in its character, and an ex-cellent trout stream flows through it. The banks of the stream are very precipitous in places, and in others the ground slopes gradually, rising to a considerable height. Advantage has been taken of these natural conditions to form a very pleasant walk on either side of the stream, while trees, shrubs, and hardy flowers have been planted wherever it was thought they would add to the beauty or interest of the grounds.

It would take up too much space to give a full account of all that has been done at Bodnant since it came into the hands of Mr. Pochin; but a few details, a mere outline as it were, may be useful and interesting. Attached to the mansion is a handsome conservatory with a fernery. The latter is quite unique; the internal arrangements are of artificial rock, and mirrors have been placed in suitable positions, apparently increasing the extent of the fernery to a wondrous degree, at the same time great care has been taken to provide for the root-growth of the Ferns and other plants. Foliage Begonias and Panieum variegatum have been used to give variety. The Begonias are exceedingly

It is no great distance from here to the kitchen and fruit garden, and the Peach-house first claims attention. Although the fruit had been gathered at the time of my visit last autumn, the excellent condition of the trees hore witness to the fact that the fruit was of more than ordinary quality. From the Peach-house a door leads into a spanroofed greenhouse, well adapted for the culture of plants; and here they are grown extensively for cutting from. The following flowering Begonias are found very useful to supply cut flowers:-B. parviflora, white; B. manicata, pale rose; B. fuchsioides, rich deep red. A door next opens from here into the early vinery, in which Black Hamburgh Grapes are grown of splendid quality. But the fruit in this house is greatly surpassed by that in the Muscat-house; the Vines are all Muscat of Alexandria, and were bearing a full crop, and many bunches weighed from 5 lb. to 6 lb., while colour, flavour, and size of berry were all that can be desired. I was told the bunches were larger last year; some of them weighed 7 lb. The next house is for late Grapes, and is planted with Lady Downe's and Alicante alternately. One rod is Gros Colmar. Bunches of Alicante weighed from 5 lb. to 6 lb. This house is 40 feet long, the other two 30 feet each. The stove is at the end of this vinery, and I was glad to see some of the old useful flowering stove plants, such as Pentas carnea, Justicia speciosa, &c. Behind this range of houses are the sheds, kitchen and fruit

I have already alluded to the excellent quality of the Apples grown on espaliers, but the Peach wall which divides the garden from the park also shows what can be done when the trees are well cared for and planted in the first place in a well prepared border. It is 9 feet high and 65 yards in length, and planted with the following varieties, viz., Early Beatrice, Early Louise—the first a week earlier, but the Early Louise is the best; Alexandra, Noblesse, Bellegarde, and Princess of Wales; Nectarines, Pine-apple, Elruge and Violette Haive. I did not notice Lord Napier, but this is the earliest and best Nectarine, to come in first.

The range of houses parts the fruit and kitchen garden from the dressed grounds, and the first object of interest is a long and wide Laburnum arcade; the trees are arched overhead, and when in flower must form a striking feature. A large bed is filled with Pæonia moutan edged with hardy Heaths, the latter nearly always in flower. Here also was a great mass of Tritoma Uvaria, with flower-heads 18 inches long by 12 inches round on stout stems 6 feet long; and in the immediate vicinity many fine specimens of Coniferæ
--Retinospora pisifera, and Cupressus nutkaensis. Abies Lowiana is a striking tree, whatever view be taken of its hotanical status; Biota elegantissima Juniperus chinensis aurea, a very beautiful and distinct variety of the species; the young growths were of a bright golden colour, and had a beautiful effect amongst the others. Juniperus japonica aurea is also a very desirable plant, the recently formed branches being very distinct and striking, Retinospora ohtusa aurea gracilis was also noted as a desirable coniferous tree; Cupressus Lawsoniana lutea, planted in the form of isolated specimens in a small geometrical flower garden, exhibited this fine form of the species in good condition. These are merely a few of the most interesting of the Conifera in front of the mansion. Amongst them there are many fine flowering plants and shrubs. Here, for instance, are heds of Tropæolum speciosum, T. polyphyllum, and T. Barlowi, growing and flowering profusely; the last-named is not so well known as it ought to be. It has rich crimson-scarlet flowers, while the leaves are of a distinct bronzy shade over the green. Masses of Leycesteria formosa have an excellent effect from the contrast of the white flowers and the purple bracts.

A bed of Gaultheria Shallon is also very pretty. Osmanthus and Pernettyas form a large and distinct group on the margin of the dressed grounds; there are several varieties of the Pernettyas, and the following Osmanthus are the best, viz., O. ilicifolius. aureus, and variegatus. Garrya elliptica has also formed a great mass; while in another position the Escallonias have an excellent effect, the best being E. macrantha and Philippsiana,

There were also beds, or rather clumps, in suitable positions of Kalmia latifolia and various species of Andromeda, such as A. formosa, A. floribunda, and a species that succeeds A. floribunda in its flowering, A. calyculata. Hardy Azaleas and Viburmum suspensum planted in the same bed have an excellent effect,

We have to pass from the well-kept grounds to the wilder portion by what is termed the Miller's Walk, on the steep and undulating sides of which rock gardens have been formed, and planted with an extensive collection of Sedums, Saxifrages, &c. There were also masses of Heath amongst them the golden-leaved form of Erica vulgaris, with paler flowers than usuals This walk leads over the brook by a rustle bridge, and on the right-hand side of the path there is a large space of very damp ground, on which Leycesteria formosa grows with wondrous luxuriance. As we walk along the banks of the rippling stream interesting trees, shrubs, and flowers meet one at every step. Coniferous trees especially are well cared for, and take kindly to the soil and situation. The Douglas Fir, Abies Douglasil, grows more rapidly than any of the others, but it is not the most handsome tree. and A. Nordmanniana are very handsome, while the tree grown here under the names of A. lasiocarpa and A. Lowlana, was in splendid health. A. Veitchii (true) I marked as a very fine tree; while P. Alcoquiana, with its distinct foliage, glaucous on the under-sides, is the best of the Japanese Spruce Firs. [Probably this is P. ajanensis. Ed.] A. Pinsapo glauca is very distinct, and A. Parryana glauca (Picea pungens) is a new and handsome form of this hardy species. Cedrus atlantica (africana), and a form of it with glaucous foliage, grow very freely indeed; while C. Libani also forms a vigorous speci-The Retinosporas are all here, and all do well ; while the various forms of Cupressus Lawsoniana are equal to the task of forming a pinetum themselves.
A handsome specimen of C. Lawsoniana erecta viridis, 9 feet high, places this form in the front rank.

sliding, 9 feet high, places that form in the riorit rank. Skimmia japonica does better here than I ever saw it elsewhere; Mr. Pochin says it requires a moist bottom, partial shade, but not under the dip from trees. This plant with the oblata form, and many sub-shrubby species and varieties of St. John's Wort (Hypericum), are planted amongst the rocks. The various species and varieties of Rubus (Bramble) beat fruit freely, R. laciniatus is the best of them. The very distinct Artbrotaxis selaginoides does well in a sheltered position, and in good alluvial soil.

fruit freely, R. laciniatus is the best of them. The very distinct Arthrotaxis selaginoides does well in a sheltered position, and in good alluvial soil.

After walking a considerable distance up the stream we retrace our steps on the opposite side, and soon find ourselves in the vicinity of extensive works. Mr. Pochin is building a mortuary chapel on the sloping hillside, and to add to the romantic character of the scenery Mr. Fulham, of Broxbourne, has been called in. Enormous masses of rock have been formed and added to the sloping hillside, not only to partly support the walls of the building, but to form a winding and rugged walk, natural and yet picturesque. Mr. Pulham has finished his part of the work in his usual excellent style, and the gardener has not failed to plant suitable plants, trees, and shrubs where they would add to the natural effect of the whole. Agroup of hardy Heaths near the margin of the winding path is remarkably interesting. The individual specimens are wonderfully fine. The most conspicuous examples are E. codonodes, E. mediterranea, the varieties alba and rubra. E. scoparia, E. stricta, E. cinerca, and the following varieties of E. vulgaris, viz., aurea, "Alportii, and Searlii. Coming bath and rubra. E. scoparia, E. stricta, E. cinerca, and the following varieties of E. vulgaris, viz., aurea, "Alportii, and Searlii. Coming bath and rubra. E. scoparia, E. stricta, E. cinerca and a grand bank of golden Hollies, mostly being about 40 feet. There are also more coniferous trees and a grand bank of golden Hollies, mostly being about 40 feet. There are also more coniferous trees and a grand bank of golden Hollies, mostly sould be supposed to the string shrub, with bold foliage, suitable for covering walls, was amongst them, viz., Schizophragma bydrangeoides. Some of the Japanese Maples were doing when a consideration of the string shrub, with bold foliage, suitable for covering walls, was amongst them, viz., Schizophragma bydrangeoides. Some of the Japanese Maples were doing well against

esteemed.

I am deeply indehted to Mr. Pochin for so kindly showing me his beautiful place, in which he evidently takes no common interest, and it is only right to say that everything is very creditable to Mr. Sanderson, who is very careful, as all good gardeners ought to be, to follow out the instructions of his employer, 7. Deuglas, [For illustrations see pp, 209, 213.]

well adapted to cling to walls and rockwork. Many of the Ferns had grown into very handsome specimens, particularly Asplenium fabianum, Microlepia hirta cristata, Adiantum cardiochlænum, and A. concinnum latum, Dicksonias, Lygodium scandens, and a great variety of Lycopodiums.

JENSEN ON THE POTATO DISEASE.*

I BEG to lay before the Scientific Committee some important observations upon the life-history, the means of its diffusion, and of the prevention of the ravages of the Potato disease, which Mr. Jensen has done me the honour of communicating in a series of letters during the last few months. I would only preface these remarks of Mr. Jensen's by saying that my object is mainly that the Committee may have early information of what has been done in this important field of research, which cannot fail to be highly interesting, not only from a scientific, but also from an economic standpoint. Although so much has already been done in elucidating this subject, yet there are many points upon which we are apt to accept what has become current belief without perhaps fully realising what this belief entails. example, we are too ready to say "heat and moisture" are the two conditions favourable to the spread of the disease, without having any definite idea as to what are the limits of this favourable temperature. Again, we speak of the spawn hybernating in the tubers, but I think few of us have any exact knowledge of how this hybernation takes place, or how long the mycelium can exist in a tuber and still retain its vitality. Judging from what we see of the disease in summer and autumn we are apt to think when once it has established itself in a tuber it will continue to invade it until it becomes a mere mass of putridity. But this is a very erroneous view, for Potatos are to be found all through the winter only partially diseased. We know from the observations of De Bary that a diseased tuber if cut across and placed in a damp atmosphere will produce conidia upon its cut surface as long as the mycelium in it is alive, although conidia-bearing hyphæ are but rarely protruded through conton-tearing nypnæ are out rarely protruoca tarouga, the unbroken cuticle. During the past month I cut several diseased tubers and placed them under a bell-glass inverted over a plate containing water, with a view of obtaining fresh conidia. My object, however, was not attained, for not a single tuber produced conidia, for the simple reason that the mycelium or spawn in them was dead. If the mycelium is already dead in the month of January, what must it be in the month of July, when the disease appears upon the foliage with such dire certainty? is the question which naturally presented itself to my mind. The observations of Mr. Jensen refer to this point as well as to the-

I. RAPIDITY WITH WHICH THE DISEASE SPREADS. -Fifty sound and fifty diseased tubers were planted at Neuilly on May 11, 1883, in close proximity to eight rows of healthy tubers planted on April 30. The fifty sound tubers produced fifty healthy plants. The fifty diseased tubers produced twenty-four plants only, of which eighteen were healthy, and six diseased. The plants appeared above-ground at the end of May, One of the diseased shoots was covered by a bell-glass, when it was found that it took six days for the disease to spread from the lowest to the third leaf. Some of the diseased tubers gave sound shoots, but nearly all the plants from them were very small. In many instances, where no plant appeared above-ground, it was found that shoots had been given off from the diseased tubers, but had not sufficient vigour to reach the surface before they died underground, having been killed by the fungus. When, however, these shoots were placed under a bell-glass they produced conidia. Often shoots given off from diseased tubers appear to be healthy for some time after they have appeared above-ground, but after a time they die, because the base of the shoot has been destroyed by the fungus under-ground. It is obvious, therefore, that a diseased tuber near the surface of the ground is more likely to produce conidia-bearing shoots which appear above-ground than one more deeply planted. Thus, of fifty diseased tubers planted 4 inches deep six gave diseased shoots which appeared above ground, while of fifty diseased tubers planted 8 inches deep only one gave a single dlscased shoot, which reached the surface of the ground. The rapidity with which the disease spreads atfer conidia have been produced above-ground upon the foliage and stem is comparatively slow at first, but, of course, becomes exceedingly rapid by geometrical progression afterwards. The following of the experiment just referred to show this very clearly :- Fifty sound and fifty diseased Potatos were

planted at Neuilly, as before stated, on May 11, 1883, in four rows, 5 inches apart; adjoining these had been planted on April 30, eight rows of healthy tubers, as shown in the following diagram:—

				- 6		•
25 Diseased tubers 25 Sound tubers 25 Diseased tubers 25 Sound tubers	k X X	:	•	*	* 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2	Planted May 11, 4 inches from row to row.
Eight rows of sound tubers.	1. · · · · · · · · · · · · · · · · · · ·					Planted April 30, in the ordinary way.

The first diseased shoot appeared on May 29, followed by five other diseased shoots—all, in fact, that were produced from the fifty diseased tubers. It was not until June 12 that the first conidia-bearing leaf was found. Eight days later (June 20) the first diseased leaf was found upon the next adjacent healthy plant (i.e., produced from a healthy tuber). Seven days later (June 27) thirteen diseased leaves were found upon these two plants. On June 28 another of the diseased plants had become a centre of infection, which extended to sixteen leaves. On July 2 the disease was still confined to these four experimental rows. It had only spread 3 feet from these two points above mentioned. The other eight rows (see diagram) had no disease upon any of their leaves.

July 3-A few diseased leaves scattered here and there over the whole twelve rows.

July 14—Disease so advanced as to be observable from a distance.

July 31—Only about 4 or 5 per cent. of leaves left. Up to July 23 no disease existed in the surrounding fields, but six days later (July 29) it was pretty general.

During the time this experiment was being carried on the weather was favourable to the spread of the disease.

Thus, it took from May 29 to July 2 for the disease to spread 1 yard—i.e., thirty-four days; but in twelve more it had become so general in these plants as to be observable from a distance; and in seventeen more the plants were practically destroyed. It should be remembered that the disease did not appear at all in the surrounding fields until July 23, and was not general in them until the 26th.

II. EARLY DISEASE A SMALL CROP: LATE DISEASE A LARGE CROP.—This may seem to be so obvious that it is not worth wasting further time about; but it is true, irrespective of the disease in the tubers themselves, and is brought about by the injury done to the foliage, and is not influenced altogether by the rainfall. It would naturally be thought that an early disease year must necessarily produce more diseased tubers, because they are exposed to the conidia while the skins are young and tender; but this is compensated for to some extent by their being placed relatively lower on the ground than is the case after they have attained their free growth. Thus, in 1877 the disease appeared very early in Denmark, and consequently a very small crop only was obtained, while in 1881 the disease did not appear till late, and a large crop was the result. The rainfall in these years during the months of June, July, and August was not very dissimilar:—

			18	77-	1881.		
June				40.7	mm.	32.1 mm,	
July				88.6	at	74-5 ••	
Augus	t			122.2	19	1124 ,,	
				251.5 Or about	mm. 10 inches.	219.0 mm. Or about 9 inches.	

We must consequently look for some other cause for the earlier appearance of the disease than the mere rainfall. This is to be found in the period at which the disease appeared in preceding years respectively, 1876 and 1880. When a tuber is attacked by the Peronospora early in the year the fungus grows in it with great vigour, and in a short space of time completely destroys it. Those Potatos, however, which are attacked later in the season do not fall a prey so rapidly to the parasite, and those which are attacked later still in the autumn, or in the winter, when the temperature is not too low in the graves for the production of the conidia, do not become thus totally annihilated by the "nycelium, but it remains in them

in a state of quiescence, or hibernation. In 1880 the disease appeared early, and, as a consequence, destroyed the Potatos it attacked-annihilated them, in fact-so that few only were left in which the mycelium could hihernate, therefore only few diseased sets were planted, and, as a consequence, the centres of infection were few and far between in 1881, therefore it was late before the disease seriously damaged the On the other hand, in 1876 the dis-Potato plants. ease was very late before it appeared in Denmark, hence after-sickness was very prevalent in the storepits, and, consequently, many more tubers were planted with living mycelium in them in 1877, so that the starting points were many, hence the general outbreak was early. This is shown even more strikingly by comparing 1873 and 1881. In 1872 the disease was late, and in 1873 it was very early, so that the crop was about half that obtained in 1881, yet the rainfall was less in 1873 than it was in 1881.

			1873.	1881.
June		 	33.0 mm.	32.1 mm.
July		 	72.8 ,,	74-5 11
August		 	81.9 ,,	112.4 11
			187.7 mm. Equal about 7½ in.	219.0 mm. Equal about 9 in.

The disease has, therefore, a tendency to alternate between late and early as regards the general outbreak. Thus in 1867 it was early; 1858, late; 1869, early; 1870, late; 1871, early; 1872, late; 1873, early; 1874, late. Of course this tendency in influenced undoubtedly to a considerable extent by the weather, for in a year in which it should be early it may be retarded by want of rain during June and July, but a late year can never be made very early however much rain there may be. The main cause of an early outbreak, or, more correctly speaking, an early general development of the disease, is the greater number of diseased sets planted that spring than is the case in a late year. C. Plowright.

(To be continued.)

COLONIAL NOTES.

SINGAPORE.—We have received the report on the Botanical and Zoological Gardens for 1882, detailing the work of the year, the most important of which was the relabelling of the plants in the garden, a matter that had, it is alleged, been very inefficiently attended to. The sons of H.R.H. the Prince of Wales, each planted a specimen Martinezia caryotifolia on the occasion of their visit to the garden.

Mr. Cantley has also issued, under date July, 1883, his report on the forests of the Straits Settlements, in which attention has been called to the scarcity of forest and forest produce in the Settlements from want of forethought and reckless felling. A description of the island of Singapore and its physical features is given, including some meteorological details, from which it appears that the highest temperature observed is 91°, the lowest 66°, the relative humidity of the atmosphere (counting saturation as 100°) varying only from 78° to 80°, the annual average being 79°.4. The rainfall averages 91.6 inches per annum, as much as 6.25 inches falling within twenty-four hours, and serving to flush out the drains. No forest rules at all exist in Singapore, and indeed, no timber seems to be now available, as all that is used for constructional purposes is imported from Johor and the neighbouring Dutch islands. Most of the fuel used is also derived from the same source.

MALACCA. — The meteorological phenomena are practically the same as those experienced in Singapore. There are still some 40,000 acres of forest land in the hands of the Government, but the forest conservancy is "as meagre as in Singapore."

PENANG is more hilly than the previously mentioned districts, and more subject to drought, though the annual rainfall is still cited at 107.7 inches, and the mean temperature at 88°, the mean minimum being no lower than 75°.

PROVINCE WELLESLEY, an island separated from Penang by a narrow strait, has a somewhat cooler climate, the temperature having been registered as low as 65° Fahr., though the mean is still 79° Fahr. Mr. Cantley makes suggestions as to the creation of forest reserves, the enactment of a proper system of

^{*} Paper read at the meeting of the Scientific Committee on February τz .

conservancy, and adds a list of the species still remaining in the districts visited by him. The list of timber trees given in one of the appendices is interesting, but unfortunately the number of species, enumerated only by their Malay names, is very large. A Forest Flora would, therefore, seem to be a desideratum.

Çhe Kosery.

A Rose House,—Out of the many glass-houses in the gardens of The Wilderness, Reading, none seem to be of more interest or useful than is a

through the ventilators, which reach from top to bottom of the roof. The heating power is obtained by connecting the pipes with the general system, and, as the area expused to the external air is so small, and the pipes are near the glass, the cost of heating is of the most infinitesimal kind. Specially valuable has the house proved for the storing of a large number of zonal Pelargoniums of many kinds that not only have been blooming finely all the winter, but were a beautiful sight for the time of year when we saw them the other day. The combination of Roses planted out and zonal Pelargoniums in pots for winter blooming is a happy idea, and, indeed, it is somewhat uncommon to find both these summer blooming plants in flower at the

needed, except where in the winter months the water comes near the surface. If the house was of considerable length it might be divided into compartments, with Roses or other climbers throughout, but with the sides filled with Ferns and mosses in one case, with Pelargoniums in another, with Chinese Primroses, Cinerarias, Cyclamens, &c., in another, and so on, thus giving variety in each compartment, and affording a pleasant promenade. The entire absence in such a house of all staging and ordinary fittings would render its enjoyment as a promenade all the greater.

ROSE MERVEILLE DE LYON.—The Florist, in the January number, gives a coloured figure of this beautiful variety, which was introduced by M. Pernet, of Lyons, in 1832-3. Its habit is like that of Baroness

Fig. 38.—Bodnant Hall, eglwysbach, north wales, the residence of H. D. Pocilin, Esq. (see P. 207.)

low span-roof structure that Mr, Lees had put up by a local carpenter from his own plan, and which is chiefly devoted to the growth of Roses. The house is at the base about 10 feet in width, and, there being no sides, the span-roof rises direct from the earth level. To give ample head room the soil has been excavated in the centre to a depth of 2 feet, and a neat pebbled path formed. On either side some stout woodwork, faced with Hazel, forms lower and upper beds; the latter, being some 18 inches wide, are planted with Roses, and the lower ones with various suitable plants, or, as we saw the other day, utilised as stages for numerous plants. The house is ventilated by means of long lights, something on the Paxton principle, so that ample air is admitted when needed. Roses do remarkably well here, as they are trained up the sloping roof on either side, and may be well watered, not only from within, but also

same time in the month of February; for several of the Roses were in good bloom. Tree Carnations being always somewhat lanky in growth also do admirably in this house, for, stood amongst other plants on the lower bed, the blooms come up near the glass, and are good and rich in colour. Lapagerias, both white and red, are doing well in this very temperate house, and so also are other fairly hardy climbers. Mr. Lees finds this simple and cheap house to be of the greatest possible service, and at all times, being some 50 feet in length, it forms an agreeable promenade, but specially so at this time of the year. There are few gardens where such a house might not be found of exceeding service, and it might be even longer, if required, though the width is, for all ordinary purposes, ample. Whilst simple in structure, by dispensing with glass sides, very much of the ordinary cost is saved. Of course, with a floor 2 feet below the surface, care must be taken that the house is well drained, but that precaution is not

Rothschild, and the flowers are nearly white, very large, moderately full, but nearly scentless.

ROSE COLONEL FELIX BRETON, Schwartz, Journal des Roses, January, 1884.—A Rose raised by M. Schwartz, of Lyons. It is a hybrid perpetual with the habit of Charles Lefevre, the flowers large, full, of good form, petals regularly imbricate, velvety crimson, with a violet tinge on the outer surface.

TEA ROSE JEAN PERNET (Fournal des Roses, December).—A seedling from Devoniensis, but with flowers of a clear pale yellow.

HAZEL NUTS, which form an important article of export from Trebizond, are stated in a recent report to be produced in Kerassond of a superior quality to those grown in any other parts of the vilayet. The values of the exports of nuts to Great Britain during the second part of the decade exceed by nearly £9000 those in the former years.

Prehid Notes and Hleanings.

ORCHIDS AT STAMFORD HILL .- The destructive effects of the fogs which prevailed at the end of the year on the advancing buds of Orchids is apparent in Mr. Bockett's collection, which contains a particularly fine lot of well-managed Phalænopsis, a genera that those acquainted with Orchids know to be amongst the first to suffer by these disagreeable atmospheric visitations. There are few Orchids in which the plants feel the weakening effects of bearing a crop of flowers so much as Phalænopsis, hence the loss of the huds has one redeeming feature. Many of the plants are now pushing new buds. Much of the sphagnum is moved from about their roots during the winter, so that there may be less moisture-holding material in contact with them-a precaution that is found to answer at a season when the drying influence of the sun and circulation of the air are at the lowest. The rare P. intermedia Portei was in flower. A row of Odontoglossum Roezlii on a shelf in the same house close to the glass show by their thriving robust condition that light and heat is what they want. The house containing the principal stock of Coelogyne cristata, comprising different forms, which almost fill the centre stage, will soon be a sheet of bloom; many of the plants are very large, and bristling with flower-spikes; they, however, exhibit a good deal of difference in the freeflowering disposition of the different forms. This fine old Orchid is one of the best for winter-blooming, and deserves to be grown in quantity by all who have a cool stove, as it does not like too much heat, and succeeds as well, if not better, amongst ordinary stove plants, where it receives more air than is usually given to Orchids. Nothing could possibly exemplify the better condition in which imported Orchids now reach this country than in time past than a lot of Cattleya Trianæ here, comprising about a hundred plants, which arrived last summer, and have done splendidly; many of the plants are flowering or coming on to flower, with the bulbs and old leaves as fresh and plump as if grown in this country. Mr. Ebbage attaches them to pieces of wood, and as soon as they begin to move hangs them up near the glass; this is a better and safer course with imported Cat tleyas and many other Orchids than putting them in pots. The points of the growing roots of Orchids-are as sensitive as the sight of the eye, and the least movement of the pots or the plants in them endangers the roots which the plants in their first efforts at growth make; when securely fastened to a bit of hard wood the roots attach themselves to it without danger of being chafed or moved about, There is equally less chance of the first roots, which are of such vital importance, being molested with insects when hung up in this way. After the first season's growth the plants, with the wood to which they have fixed themselves, can be put in pots. Amongst the large and beautifully grown lot of Odontoglossums there was an unusually fine variety just opening of O. Andersonianum with the brightest yellow ground in the flowers. The collection of Odontoglossums will shortly be a sight; the size, strength, and condition of the plants is such as to insure their flowering pro-The same holds good with the Masdevallias, the collection of which is extensive and io excellent condition. T. B.

THE NEW HALL HEY COLLECTION .- There were a few weeks ago many things of a most interesting character, either in flower or showing well for bloom, in the Orchid-houses at the gardens of G. W. Law-Schofield, Esq., New Hall Hey, Rawtenstall, Lan-It cannot be said that the Orchid-houses in this establishment, or, for the matter of that, the whole garden itself, is situated in the most advantageous position for the growth and culture of floral varieties. Doubtless years ago the whole neighbourhood could boast of clear skies and pleasant breezes, and if the air was sharp it was free from the coal dust and sooty deposits that are now carried along, and too often left on the roofs of the glasshouses, robbing them of much of the light that is so needful to the growth of all things under glass. In spite, however, of local surroundings, such as tall chimney-shafts, a busy railway station, and trains continually passing within 200 yards of the houses in which some of the plants are stood, the Orchids all through look well, are

healthy and vigorous; and if the flowering of them is the true lest of culture, then we must certainly con-gratulate Mr. Schofield, and his energetic gardener, Mr. T. Wise, on their success. Passing by the early and late vineries, conservatory, Peach-house, and Rose house, we pass into the square where, bit by bit, the present Orchid-houses have been erected. First, a range of low span-roofed houses in three compart-ments were put up, and in due time filled with plants; then two larger span-roofed houses were put up chiefly for Cattleyas; next a low pit was taken for Odontoglossums; and just recently another span-roofed house has been finished, where these latter can receive more light and air than could be obtained in receive more ign, and air man about to consider in the low range of pits. When I say that the floor of this last house is just about level with the roof of the sunk-pit, it will be seen at once that inequalities of surface sometimes have an influence on one's building operations; it will also be admitted that the position now chosen is likely to secure those two most important essentials to the successful culture of this class of plants—light and air. Say what we may about the building of Odontoglossum-houses on the north side of walls in the central and southern counties of Feedand in those localities it way he processory. of England, in those localities it may be necessary, and in some situations success can only thus be achieved; but the Irwell Valley is another district altogether, and there we must endeavour to remove every obstruction to light, and make the most of what we get, for in truth sometimes it is but little. Since the Odontoglossums have been removed to their new the Odontoglossums have been removed to their new quarters they have improved very much, and now are in the way to become strong and sturdy plants, producing, as many have already done, those stiff spikes and round plump buds we all so like to see, In this house I noticed a strong plant of Dendrobium infundibulum with many bulbs 18 inches to 2 feet in length growing as free as any D. nobile, and promising well for bloom. In the Cattleya-house are many fine specimens of such things as Ledia purpurata elegans. Cattleya cripta. Wesrie, also rata, elegans, Cattleya crispa, Warneri, Mossie, also excellent masses of Trianæ, some just opening their flowers. C. Percivaliana was blooming also. A mass of C. Gaskelliana was just breaking with twenty-seven leads, likely to be fine in a short time, Sanderiana and gigas varieties were strong pieces, deriana and gigas varieties were strong pieces, having made fine growths; at present, however, they are resting. The rare C. Schofieldiana, figured and described in the Orchid Album, is here in capital condition, and will soon be breaking. The rare Oncidium hæmatochilum, figured likewise in the same work, is looking well grown in a basket. Some excellent plants of Lælia autumnalis, albida, and anceps were flowering, the Barkeriana variety of the latter being very dark and fine. The chaste L. anceps Hilliana was also flowering. This is here pure white, with a yellow throat, and a light purple lip, with white margin—certainly a nice and pleasing variety, white margin—certainly a nice and pleasing variety, Several Oncidium Forbesii were in flower, so, too, was Sophronitis grandifora on a block, with fifteen of its showy scarlet blooms. Several D. Ainswere in excellent health; and the same may be said of many other of the Dendrobiums. The neat japonicum, with its pure white flowers, and sweetlycented withal, was very interesting. Another rare cendrobe in flower was Veitchianum (macrophyllum scented withal, was very interesting. Another rare Dendrobe in flower was Veitchianum (macrophyllum as it is now designated). This is a very distinct species, bearing erect spikes of flower, which are of a greenish-yellow; the lip, too, is of the same colour streaked with purple. The stem of the bloom and the back of the sepals are covered with numerous the country of the same that he are the spike a singular than the spike a spik the back of the sepals are covered with numerous fleshy hairs, which give the entire spike a singular and distinct appearance. D. crassinode and D. Wardianum have made strong bulbs, and soon will be clothed with their rich and showy blooms. Of D. moniliforme there is one of the finest plants to be seen anywhere; it has been in flower just a month, and has lost a little of its freshness, and though some blooms have been taken off, it is now a mass of flower. There are over thirty flowerine bulbs. mass of flower. There are over thirty flowering bulbs, some having twenty and twenty-two flowers on them. some having twenty and twenty-two flowers on them, The whole display of 400 blooms is quite a picture, and one that is calculated to give a thrill of pleasure to all true lovers of Orchids. The D, devonianums promise to be equally good. One plant has thirty-five flowering bulbs just showing the flower-buds; another has fifteen flowering bulbs, 2 to 4 feet long; whilst a strong plant, less in bulk, has seven new bulbs just over 4 feet in length, and stout in proportion. These in about two months' time will be worth going to see. Cymbidium Lowii was in good health, showing Cymbidium Lowii was in good health, showing flower. Saccolabium violaceum was flowering well This is a most desirable winter Orchid, retaining its This is a most destrable winter Orchid, retaining its flowers quite fresh for a long period: eight to ten weeks is not at all an unusual length. An imported V. Sanderiana has recently been added to the collection, and though at present it is not making any new roots, it has improved in colour, and looks hopeful and promising. Phalenopsis on cylinders are just starting away—several plants of P. Stuartiana were in flower. The many forms of Cypripediums were looking well, and Odontoglosum Roezlii and O. vexillarium in a warm division were growing freely, and already a few were showing flower. W. Swan,

The Fitchen Garden.

SEED SOWING, &c .- The Onion crop, as a rule, succeeds Celery, therefore no time should now be lost in taking up the latter and laying it in as deep as before in another border, alter which the ground should be well dug, and if necessary, manured. The ground should be trodden closely all over when sufficiently dry to prevent its adhering to the feet, raked and made level with a wooden rake, and then rolled with a light roller and again raked, this time and subsequently with an iron rake, the ground having first received a good surface-dressing of dry soot and wood-ashes, after which the drills can be drawn I inch deep and I foot apart, and the seed be sown thinly and evenly in the drills. The soil should then be closed in over the seed with the feet, and again trodden over each individual row and rolled, and finally raked over in the same direction as the drills, so that the bed when finished may present a fine, firm, and even surface. As to varieties, of which I gave a list at p. of the current volume, I would remark that the keeping varieties and those which are grown chiefly on account of their fine size and for autumn use, should be sown in proportion to their keeping qualities, and a few rows of the Queen or Early White Naples should be got in to succeed the autumn-sown ones. A few beds of the silver-skin variety, for picklers, should also be sown thickly broadcast on a poor, dry, and shallow soil, to prevent them growing too large. Carrots and Parsnips should also be sown as soon as the condition of the ground will permit of the work being done in the same manner as recommended for Onions, except that the rows should be further apart-that, is from 15 to 18 inches apart. It will be advisable to make two sowings of Parsnips (of which the Hollow Crown and Maltese are good varieties), one at the end of this month and the other about the end of April. Another sowing of Early Nantes Horn Carrot and Turnips (Early Purple-top Munich and Early Snowball) should be made adjoining those previously sown. A small sowing should also be made in a sunny horder of the following seeds, namely:—Wheeler's Imperial Cabbage (or any other good early variety), Early Ulm Savoy, Brussels Sprouts, Leek (Carenton or Musselburgh), Green and White Paris Cos Lettuce, and Grand Admiral Cabbage Lettuce, round-leaved Spinach (a row between the early Peas), and Early White and Scarlet Turnip-rooted Radishes the latter under a south wall between the trees. soon as the Cauliflower and Lettuce plants, which should now (excepting those intended for early use) be all planted out as recommended in a previous Calendar, the cold pits these occupied should be got ready for and planted with some of the early Kidneys, taking care that the young shoots are not broken off in the operation. In favourable weather plant out Shallots, Garlic, and Chives, in beds 4 feet wide, with an alley between each bed, in rows 9 inches apart and 6 inches in the row, which will give five rows in each bed. The surface of the beds should be even and firm, over which some woodashes should be strewn, and then be patted down with the back of the spade, and the Shallot bulbs planted by pressing them barely under the surface, and the Garlic and Chives 2 inches deep; the bottom of the alley (which should be neatly cut) should then be made level.

RHUBARB, SEAKALE, AND JERUSALEM ARTI-CHOKES .- Where large quantities of Rhubarb roots are taken up annually for forcing it will be necessary to make fresh plantations every year, by dividing the roots and planting the divisions with the buds a couple of inches under the surface in rich deeply trenched ground—the soil being rather light than otherwise-in order to maintain an adequate supply of good established roots for the purpose; thereforeadvantage should be taken of the present open weather to get this done, together with the overhauling and replanting of the herb borders, and any other operation that will be as well done now as a month later. In covering Rhubarb and Seakale crowns place a number of Rhuharh pots over some of the hest established plants of a good early variety, in the case of the latter, and, if necessary, cover them with stable litter, a little of which should also be shaken over the remaining crowns, to protect them from possible injury by frost. We cover rows of Seakale

with boxes 8 feet long, 9 inches deep, and of about the same width, which are made as follows:—Two boards, of the dimensions above given, and two end pieces—the latter an inch higher than the sides, to keep the lid in its place—are nailed together, and a board of the proper length and breadth placed upon the top as a lid. These boxes are then covered over, and the space hetween them filled with decayed leaves, so as to exclude light and air from the interior of the boxes. We thus are able to obtain Kale of the best description—short, thick, and crisp. Plant Jerusalem Artichokes in rows 2 feet asunder and 1 foot in the row, in good ground, having an open situation. A field is the best place for this crop.

FORCING DEPARTMENT.—Sow in pots any kinds of Capsicums, placing the pots in a warm frame near the glass, and pot them off singly into small pots as soon as they are large enough to handle, returning them to the frame when done. Celery plants, too, when large enough, should be pricked out in rich finely-sifted soil 4 or 5 inches apart in a frame near the glass or in pots and boxes. If the latter are more convenient and placed in a similar position, and then watered through a fine rose to settle the soil about the roots of the plants, the plants must be shaded from the mid-day sun for a few days until they have rooted, and sufficient air be admitted to the frame to prevent the plants making a weakly growth. As the plants increase in growth so also should the ventilation be increased, and subsequently the sashes should be titled up at eight preparatory to the plants being planted in the treaches in due time. Seed of the Trophy Tomato should be sown at the eod of the present month for outdoor culture, as also Marjoram and Basil. H. W. Ward, Longford Caule, Wills.

FRUITS UNDER GLASS.

PINES.-The winter season so far has been a most propitious one to the Pine grower; recourse to hard firing, which causes an unhealthy parched atmosphere, and fluctuations of hottom-heat, has not been requisite, so that it has not been an arduous task to preserve the plants in the best possible state. Young plants rooted last autumn should now be shifted into fruiting-pots of 12 inches in diameter efficiently drained. In potting place a layer of dry moss coated with soot over the drainage, and use the soil recommended in a former Calendar io a warm, rather dry, and moderately rough state; remove the bottom leaves from the plants, as well as the inert soil from the surface of the balls, place the plants sufficiently deep in the pots to insure their firmness, and as the best results are derived from firm potting give particular attention to this by well ramming the soil. As the work proceeds a second mao should receive and plunge the plants 2 feet apart each way if space admits, keeping the pots perfectly level, and closing the material tightly around them. Maintain a hottom-heat of 85° to 90°, and a night temperature of 65°, with corresponding warmth and humidity during the day; endeavour to secure a sturdy growth by carefully ventilating on every favourable opportunity, and, above all things, guard against over-watering the plants. Suckers of Smooth Cayenne and Charlotte Rothschild on the winter fruiters and old stools that are large enough should be potted into 6 or 7-inch pots, and, if allowed a brisk hottom-heat and a warm moist atmosphere, they will root freely, and soon become fit for their fruitingpots. The plants in the early house will he commencing to show their fruits; the temperature should, therefore, be increased, that for the night to 70°, with about 5° more in the day from artificial means; admit air on sunny days when it reaches 80°, and close early with a high temperature, which will cause the plants to raise their fruits well out of the foliage, at the same time damp with tepid rain-water hetween the plants and among their bottom leaves. While using moisture in moderation, see that it does not rest around the young fruits. Water regularly as required, employing Peruvian guano and sheep manure-liquid alternately, of moderate strength, and at a temperature of 85°. Voung fruits intended to ripen their fruits next winter should receive liberal treatment to induce strong growth. A second house may be started the end of this month, which, if composed of the varieties recommended in the issue of January 5, will give a lengthened succession of fruits,

VINES,—Where Vines are to be planted this spring the borders may now be prepared for them. Perfect drainage being one of the primary essentials to success, it should receive thorough consideration; and another matter of first importance is the compost, and for this nothing is better than tolerably heavy turfy soil stacked long enough for its verdure to have decayed. This should then be mixed with a fair sprinkling of charred wood, hones, and old mortar well reduced to a moderately fine state; these ingredients, however, are not absolutely necessary. Our horders have no hones in them, and are all either entirely inside or outside—the early and late Vines being confined to the former, the mid-season ones to the latter. In wet, cold districts, where a heavy soil (the best for Vines) is employed, I would especially recommend this practice, and that of planting for all purposes in side, providing sufficient water and labour are at command to meet all requirements. Internal horders may be advantageously made 3½ feet deep, but for outside ones shallow ones are certainly best. In forming them the piecemeal principle should always be adopted, the soil should be dry and coarse, and made firm by treading each layer from the bottom to the surface. The present is likewise a good time for making additions to incompleted borders of Vines that are now at rest. Late houses containing such kinds as the Alicante and Almwick Seedling, also the Lady Downe's house, should be closed towards the end of this month, in order to have their fruit well impened and wood matured early in the autumn. Another successional-house, comprising Hamburghs, Foster's Seedling, and others, should also be closed at the same time. Gentle fire-heat should be allowed where fermenting material is not used, the rods regularly damped over with chilled water several times daily, and where there are young ones bring them into a horizontal position, and in doing so see that the rows of huds are level with each other, as when one is over the other the uppermost buds break first and strongest, to the detriment of the others. Moisten internal borders, if dry, with tepid water; those that are outside should have been protected with thisk, fram coatings of leaves and covered with shutters in the autumn.

STRAUMERRIES.—The forcing of these should be still followed in a mild form, for however satisfactory other conditions are, the Strawberry in its early growth with undue haste is not followed by good results. With correct treatment the blossoms and leaves advance simultaneously and closely, and when not it may be concluded that excessive heat has been employed. Afford plants in all stages as much light as possible by keeping them near the glass, which should be kept clean; and for those in blossom such treatment as will ensure them being dry for some time in the middle of the day, so that successful impregnation may occur. When the blossoms fall, thin the fluits, reserving the best for the crop, and move the fluits, reserving the best for the crop, and move the fluits, reserving the best for the crop, and move the front ventilators, and increase it from the back sashes early on favourable days, and make the most of sunny weather by closing early and well syringing the plants. Arrange the plants on shelves without crowding, with their fruits supported, and fully exposed to the sun, and place a thin, porous turf under each pot; this is a satisfactory old practice, as the roots readily seize on the turves, and greatly support the plants. Attend closely to watering, using tepid liquid manure, made of sheep's dung and soot, in a mild state, alternately with that of guano. Put successional batches of plaots in quantities as required, into heat, using up the early varieties first. Furnificate on the first appearance of greenfly; kept independent of the sun more of the syringe, and look out for worms in the pots, applying lime-water to dislodge them. Thos. Coomber, Hendre Gardens, Monmouth.

Plants und thein Sultune.

REPOTTING STOVE PLANTS .- It will be necessary to proceed with this work now, without much longer delay, in all cases where an average stove temperature is maintained. In the event of the stove plants being kept at the lowest possible point in temperature, with due regard to safety, this indispensable operation of every spring can with advantage he deferred a few weeks longer, when, from the greater influence of the sun and the lengthening days, vegetation will be more active. No pains should be spared in the preparation of the soil suitable for the several sections of plants that are cultivated. Due regard to this important point will greatly facilitate future successful culture. All peat of a close, adhesive character should be discarded, the small quantity of fibre in such as this will rapidly decompose after a few waterings, leaving the mass of soil both sour and inert; in this the roots cannot be expected to thrive. Just when the plant is reasonably expected to be making progress in the new soil the vitality of this latter is all but exhausted. As with peat, so also with loam, of which, if any doubts

are entertained in regard to its suitability, it had better be laid aside for more common uses. We prefer loam of a friable character, not too light not too heavy, but with a good amount of fibre. The top spit of a good pasture that does not retain an excessive amount of moisture, will be found the best. As we cannot obtain just what we should like at all times, it is advisable to have a bag of charcoal at hand, which, with the assistance of some crocks broken up small, will greatly aid in keeping the soil open and sweet. The charcoal will absorb impuritise healthe being a most effective fetiliser.

open and sweet. The charactan will assorb impurities, hesides being a most effective feitiliser.

A good stock of leaf soil is a valuable axistance to the cultivator, when it can be obtained from such deciduous trees as the Oak and Beech. In the case of a miscellaneous collection of decomposed leaves from shrubberies, it is necessary to be somewhat cautious. When the leaf soil is not to be relied on, it will be a better plan to use a greater quantity of peat. Some spent Mushroom bed maoure, when tairly dry, will be suitable for mixing with the soil for Caladiums and other rapid growing plants—any plants in fact that are annually divested of the soil in which they have been grown will succeed better with the addition of such-like materials. The object being to extract as much plant food as possible during the one season, necessitates the mixtures of soil being made accordingly. Where convenience of storage under cover exists, it is much the best plan to keep a good stock of each requisite, so protected. The soil will handle better if a little on the dry side, besides being more congenial to fresh root-action. We prefer to do the greater part of the reporting of stove plants in the house, rather than removing them to the potting-shed at this season of the year. Should the same, however, join the stove it is not of so much importance; better still if the shed is heated with hot water, then all syringing and cleaning can be done herein without causing any obstruction in the house itself. This work should be expedited as much as possible when once taken in hand, therefore have a good number of flower-pots prepared with drainage that has been once taken in hand, therefore have a good number of flower-pots prepared with drainage that has been once taken in hand, therefore have a good number of flower-pots prepared with drainage that have been once taken in hand, therefore have a good number of flower-pots prepared with drainage that have been once taken in hand, therefore have a good number of flower-pots prepared wit

pared. Any modifications that are used to proceeds.

Firm potting is to be recommended in the majority of cases; the growth made at first may not be so rapid, but more permanent results will ensue as the season advances. Do not pot plants just for the sake of potting them airesh if they do not require it; better pass them over for a time. Any plant that has seen its best days had better be consigned to the rubbish-heap to make room for vigorous young stock. In the case of plants that are easily grown, it is a waste of time to nurse up old, decreptid specimens, Of course this does not refer to large stools of such as the Eucharis and Anthurium Scherzerianum, which can be broken up for stock when of great size. About a year ago we shook out some of the former that had been standing for some years in the same pots. They were divested of nearly all their soil, what few roots remained clinging to each bulb were preserved; and theo, after an assortment into different sizes had been made, we repotted all that were worth keeping, thereby gaining several pots to our stock. The bulbs having become excessively crowded had no further room to develope themselves, being packed one on top of the other; the shaking-out process was therefore the best thing to do. Each of this stock is now in full vigour again, having also yielded an abundant supply of flower-spikes. Those who have any Eucharist that have become unhealthy had better proceed in a somewhat similar manner. The addition of bottom-heat would be of service to encourage fresh root-growth when plants are not in good health. In poting Palms use soil chiefly composed of turfy loam, with a little peat mixed with it. In the case of large specimens a little bone-meal or half-linch bones is of great assistance. With specimen Crotons also the loam may predominate, but, on the other hand, the Marantas thrive best in a compost of nearly all peat; Loras and Dipladenias prefer peat alone. Whilst the potting operations are about, the woodwork and plants, and slightly raise the day

APPOINTMENTS FOR THE ENSUING WEEK.

Linean Society meets at 8 R.M. Papers to be read:—1, "West African Cyperace."

H. N. Ridde, 2, "Penetration of Ani-H. N. Ridde, 2, "Penetration of Ani-H. N. Ridde, 2, "Penetration of Ani-H. S. O. Ridde, "Carrain on Structure of Coral," S. O. Ridde, "Carrain in Structure of Coral," S. O. Ridde, "Carrain on Structure of Coral," S. O. Ridde, "S. O. Ridde, "S.

A SUBSTANTIAL balance in hand is such an unusual feature to be announced at the ANNUAL MEETING of the ROYAL HORTI-CULTURAL SOCIETY that it might be held to cover a multitude of defects. The explanation of the circumstances under which this result has been obtained is, however, not quite so satisfactory as could be wished. It arises almost entirely from the successful results of the Fisheries Exhibition last year—a result which was sufficiently surprising to those who remember the ill-success of the former annual exhibitions, and who look forward somewhat doubtfully as to the repetition of the experiment this year. While gratified at the fact that the Society not only starts free from debt, but with a substantial balance in hand, the Fellows may well look to the future with some apprehension. We do not much heed the interruption of some disappointed debenture - holder who asked a disagreeable question at the meeting, because it is by no means clear that the Society was even morally responsible to the debentureholders, and indeed the law courts have in substance decided that it was not. On the other hand it is certainly to the credit of the Society that they should have fought the battle of the debenture-holders and not only been mulcted in the sum of some nine hundred pounds for their pains, but actually deprived of all the property upon which the debentureholders could fairly rely for the satisfaction of their claims. Under the circumstances the President was quite justified in considering the debenture-holders as defunct, though that statement is a little inconsistent with the fact that the Society has succeeded in obtaining privileges for that body to which it appears they have no legal right whatever. Letting that matter pass, however, it can scarcely be said that the position of the Society is a satisfactory one : but now that, as we ventured to prognosticate last year, the Society has passed its lowest ebb and is at any rate in a better financial position than for many years past, we may trust that the Council will take heart of grace, and do their utmost to put the Society in a more satisfactory state. They hold their present cramped position at South Kensington on sufferance, and have not even a corner which they can call their own. It may be well for the present to make the best of circumstances as they are, particularly as they involve no payment for rent, but the Council will not be doing their duty if they do not look forward, and do their utmost in the direction hinted at by Lord ABERDARE of procuring a suitable habitation for the Society. A convenient office for business purposes, a meeting-place for the committees, a locality for the larger exhibitions (for which Kensington is perhaps the best available), a home for the library, and a readingroom for the Fellows, are all desiderata of the greatest urgency. The present arrangements, if possibly the best that can be attained under existing circumstances, are all so thoroughly bad and inefficient, that no effort should be left untried to ameliorate them when opportunity offers.

The evening meetings, upon which so much stress was laid in the report, furnished at least an indication that public support would not be wanting were a resolute attempt made to carry on the Society's proper work in a fitting local habitation. It is abundantly clear that the Society can still command the willing services of the best practical gardeners and the leading scientific men. The material is to hand; the defect appears to be in the spirit to turn the material to account. We regret to see at present no effort made to secure the support and co-operation of that vast body of horticulturists in the provinces who still look up to the parent Society, and who would assuredly respond to its call were it made in no uncertain manner. The proof of this was furnished by the unprecedented success of the Apple "Congress," and by the universal feeling of approbation of what is done at Chiswick.

Not one word was said in the report or at the meeting as to the suspension of the publications of the Society, and, indeed, it must be admitted that the want of interest taken by the Fellows when the Journal was issued with less or more regularity is not very encouraging. Still, we cannot but think that were the Fournal put upon a proper footing, the reputation of the Society would be greatly enhanced. reports of the trials at Chiswick, and the proceedings of the practical committees, have hitherto lost their value from the irregularity and tardiness of their publication. Again, the subjects brought before the Scientific Committee, from their number, variety, and importance, would alone suffice to keep a society afloat, but under the present arrangements they command the respect only of the limited few who are in position to judge of their value, and are to those who, from want of knowledge of what is really done, little more than subjects of jest-jest that is really unfounded we grant, but which is quite natural under the circum-

Among matters of first-rate importance which the Society has the means now to elucidate we may mention three-the report on the effects of the severe winters of 1879-1880, and 1880-1881; on the Apple Congress; and on the Jensenian method of protecting Potatos from disease. We might mention many others, but these three will suffice for our purpose. The report on the effects of the severe winters was obtained by inquiries made throughout the country, and a vast body of information was collected which, if properly digested, would be of incalculable service. In the meantime, not only is it lying dead, but those who were good enough to furnish the desired information are naturally irritated that their services should be held in so little esteem. Supposing that in future any similar inquisition should be desirable, what chance is there that gardeners and others would be found willing to contribute their experience? The report of the Apple Congress is, we believe, in the hands of Mr. BARRON, and no more competent could be found; but what encouragement is there to go on with such a laborious undertaking? Still, it is one of so much general interest that we cannot imagine the Council allowing it to suffer the fate of the report on the effects of the frost, Third on the list come the questions connected with the spread of the Potato disease, and the alleged methods of preventing its ravages. What more important and practical subject agitates the minds of cultivators at this moment? What subject is there that could be more fittingly tested than by means of the members of the Scientific Committee, and the practical tests that could be so readily carried out at Chis-

Verily, in the face of such matters as these, the award of unnumbered Certificates to new Pelargoniums, trifling varieties of Odontoglossum crispum, and the like, seem very petty

We are far from denying their value; but there is a sense of proportion which neither Fellows at large nor Council seem at present adequately to recognise. The Society is, it is said, in a transition state; let us hope that the transition will be towards the realisation, not of individual commercial advantages and personal fancies, however innocent and attractive, but of those larger national interests which the Society was established to promote.

- EXTRAORDINARY TITHES. -At a large meeting of Hop, fruit and market gardeners, held at the Bridge House, London Bridge, on Monday, Mr. BOLTON in the chair, it was unanimously resolved:— "That the Government be urgently solicited to redeem the promise made by Sir W. HARCOURT in the House of Commons last session, by bringing before Parliament a measure to abolish extraordinary tithes as soon as posssible."

M. RODIGAS. - The Government of Venezuela has conferred on our confrere the decoration of Chevalier of the Order of the Liberator. M. Rodi-GAS amply deserves every recognition for his industry and zealous devotion to horticulture and natural

— MR. M. SAUL is, we regret to hear, leaving Stourton Park, Knaresborough, where he has been Gardener for the long period of thirty-seven years.

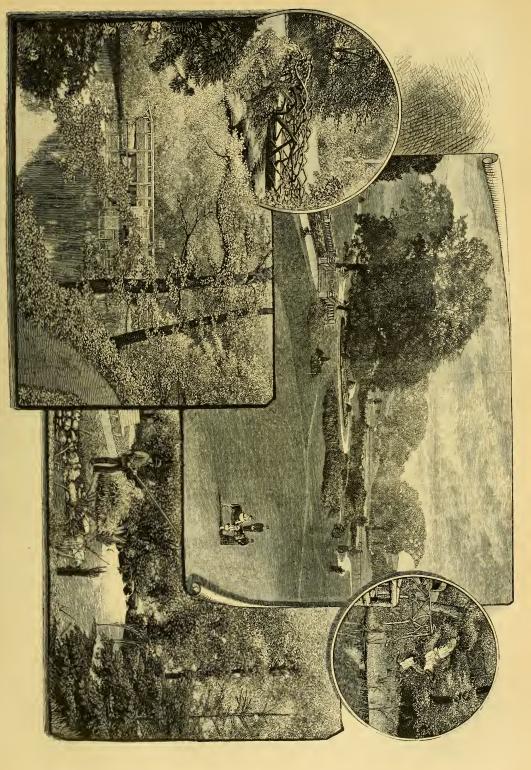

"THE FLORA OF BRITISH INDIA."—We are glad to be able to announce the publication of the eleventh part of this very useful and important publication. The present part includes the remainder of the Scrophulariaceæ and the Orobanchaceæ, by Sir JOSEPH HOOKER; the Lentibulariaceæ, Gesperaceæ, Bignoniaceæ, Pedaliaceæ, and Acanthaceæ, by Mr. C. B. CLARKE. It will thus be seen that the work is making substantial progress, and its utility is such that we trust every means may be taken to advance its completion. We are now within measurable distance of the Orchids, and we need not say how serviceable an authentic descriptive catalogue of those plants will be.

- Double Hellebore, -Mr. Koeppen, gardener to OTTO FORSTER, Esq., kindly forwards us a semi-double flower of Helleborus niger, which he found wild in the neighbourhood of Scheibbs, Lower Austria. The stamens are replaced by white petallike bodies, and there are various changes between stamens and nectaries which necessitate further examination.

THERMOMETERS .- The Council of the Royal Meteorological Society have arranged to hold at 25, Great George Street, S.W., on the evening of March 19 next, an exhibition of thermometers, and invite the co-operation of makers and others, that as large a collection as possible of such instruments may be exhibited. The committee will also be glad to show any new meteorological apparatus invented or first constructed since last March, as well as photographs and drawings possessing meteorological

- New Commercial Plants and Drugs. Mr. Christy, 155, Fenchurch Street, has published the seventh part of his periodical under the above title. Among the plants mentioned in this number are Cinchona Ledgeriana, Theobroma Cacao, Acacia arabica, Siam benzoin, Pepper, Nutmeg, Indiarubber, Menthol (Mentha arvensis var. piperascens), Liberian Coffee, Conocephalus niveus (the tough fibre of which is used in Ceylon for fishing lines), Boehmeria nivea (Rhea). The object of the publication is to diffuse information and stimulate inquiry as to plants useful in agriculture or commerce in all countries.

- ALLIUM OVIFLORUM .- This is a remarkable bulbless species, with very narrow, Leek-like leaves, surrounding a central angular scape, which hears at the summit an umbel of small, dark lilac, bell-shaped, nodding flowers, each rather less than half-an-inch in length. The stamens are filiform, longer than the perianth; the lobes of the ovary have two tooth-like projections at the upper edge. This species was in-troduced by Mr. ELWES from the Chumb range, between Tibet and Sikkim, and was described for the first time by Dr. REGEL in the Gartenflora, t. 1133.

- THEY ARE COMING !- Messrs. BARR & SON sent us last week the advance guard of the army of Narcissus, which they marshal before us every year. The first is a Daffodil with very pale segments and a light primrose-coloured crown of equal length; or it might be said that while the crown was sulphurcoloured the segments were the colour of flowers of sulphur! It is a very refined-looking flower, and the earliest of its race to bloom. It is, we are informed, not yet in commerce, and we hope before it gets into the catalogue Messrs. BARR will be good enough to relieve it of some, at least, of the four or five appellations under which they send it to us. the case of garden varieties like this an English name would be preferable. The other forerunner of spring is the beautiful Narcissus monophyllus, with its elegant white flowers, which have had merely the protection of a light to preserve them from being soiled by rain.

—— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 20th inst., at 7 F.M., the following papers will be read:—"The Great Storm of January 26, 1884." By WILLIAM MARKIOTT, F.R.Met.Soc. "The Height of the Neutral Plane of Pressure, and Depth of Monsoon Currents in Iodia." By Professor E. D. ARCHIBALD, M.A., F.R.Met.Soc. "On the Sunrises and Sunsets of November and December, 1883, and January, 1884." By the Hon. F. A. ROLLO RUSSELL, M.A., F.R.Met.Soc.

- THE OXFORD PROFESSORSHIP OF BOTANY .-Dr. BAYLEY BALFOUR was on Saturday last appointed Sherardian Professor of Botany. In 1879 Dr. BAL-FOUR was elected Crown Professor of Botany in the University of Glasgow, and is son of the Regius Professor of Medicine and Botany in the University of Edinburgh (whose death, only a day or so after the election of his son at Oxford, we regret to have to announce in another column). Dr. BAYLEY BALFOUR Doctor of Medicine and Gold Medallist of the University of Edinburgh; be took first-class honours in botany, and has had practical direction of the affairs of the Glasgow Botanic Gardens and Herbarium. Io 1874 Dr. Balfour was appointed by the Royal Society Botanist and Geologist to the Transit Expedition to Rodriguez, and in 1880 he made a scientific exploration of the island of Socotra. There were six candidates, and the electors were Sir John LUBBOCK, Professor BABINGTON, the President of Magdalen, Professor BARTHOLOMEW PRICE, Professor MOSELEY, the Bishop of WINCHESTER, and Sir JOSEPH HOOKER. The duty of the Professor is to lecture and give iostruction in botany. He will also have charge and supervision of the Botanical Gardens and of the botanical collections belonging to the University, and it will be part of his duty to make the gardens and collections accessible to and available for the instruction of students attending his lectures. A Fellowship in Magdalen College is attached to the Professorship. The Professor will be entitled to the emoluments derived from the benefaction of W. SHERRARD, Doctor of Civil Law, and assigned to the Professorship, and also to the emoluments appropriated to the Professorship by the statutes of College. The combined emoluments of the offices from these sources will be £500 a-year. The Professor will be subject to the statutes of the University in regard to the Professorship, and to the statutes of Magdalen College in regard to the Fellowsbip. The Professor will also receive £200 a-year out of the Common University Fund, provided that he conform to the particular regulations to which the Professors are subject. A residence is provided for the Professor in the garden, rent free.

—— UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this Society, which was established in 1865, took place at the Caledonian Hotel, Adelphi, on Monday evening last, Mr. RICHARD DEAN, of Ealing, in the chair, when there was a numerous attendance of members. The report of the committee and balance-sheet was most satisfactory, the Secretary stating that if it were necessary to bring the operations of the Society to a close, and every penny due to the members was paid, there would remain a sum of £150 over and above what was required, leaving the benefit fund, which amounts to over £1000, untouched. There is now invested in Consols the sum of £269 12s. 6d., in cluding stock to the value of £216 15s. 5d. purchased

during the past year. The Secretary stated that when he was first elected to this office in 1872 there were but sixty-six members connected with the Society, that in December, 1883, the number had risen to ninety-two, and there are now 150 members, a considerable accession having recently taken place owing to the publicity given to the operations of the Society. The Society has been working quietly for years past and certainly prospering; but it has not made itself sufficiently known. It is now proposed to remedy this by issuing a number of copies of the annual report and balance-sheet to gardeners eligible to become members. The Hon. Treasurer is Mr. James Hudson, The Gardens, Gunnersbury House, Acton; and the Hon. Secretary Mr. J. F. McElroy, The Gardens, Moray Lodge, Campden Hill, Kensington, of whom all necessary information can be obtained.

- BROMELIADS .- The zeal with which Bromeliads are cultivated on the Continent is exemplified by the publication of which we have now the first part before us—Allas zur Phylo-Iconografhie der Bromeliaceen des K. K. Hofburggartens, von Franz Antoine (Vienna: Gerold). It is a folio work, to be devoted to the illustration and description of the plants of this order grown in the Emperor's garden at Vienna. The author is Herr Antoine, whose competence in the matter has long been beyond dispute. The Imperial Court Garden contains one of the richest collections of these plants in existence, and during the last ten years Herr ANTOINE has been collecting drawings of all the species as they flowered. Only fifty copies are to be put into publication. The plants are lithographed of life-size from drawings by the author, the flowers and portions of the foliage being coloured, the remainder uncoloured. The plates will be accom-panied by a text in quarto size. The introduction comprises an account in the German language of the conformation, affinities, geographical distribution, principles of cultivation, and literature of the order Bromeliaceæ. The plants figured in the present part are Vriesia Wawranea, Antoine, a night-flowering species; V. conferta, of GAUDICHAUD; and V. paraibica, the two latter Brazilian species; V. psittacina var. decolor, of WAWRA. The publication is got up with the finish that previous Viennese botanical works have led us to expect, and its use in defining and fixing the nomenclature will be very great. A full description in German of each plant is given; but we trust that, for the benefit of other nationalities, Herr Director ANTOINE will presently add a synopsis of the species described in the Latin tongue, and thus increase the obligations under which botanists must be to him.

— THE FLORISTS' SOCIETIES.—At a committee meeting held at South Kensington on Tuesday it was decided that the annual exhibition of the National Auricula Society should be held on April 22, and that of the National Caroation and Picotee Society on July 22, under the anspieres of the Royal Horticultural Society, and in the large conservatory. At both exhibitions a Veitch Memorial Medal and \(\mathcal{L} \)5 will be awarded in competitions open to amateurs and gentlemen's gardeners:—1, For the best twelve dissimilar show Auriculas; and, 2, For the best twelve Carnations (selfs and fancies excluded), and six Picotees.

- DUTCH BULBS AND PHYLLOXERA .- Dr. WAKKER, at the instigation of the Dutch Minister of Commerce, has published a note, in which he shows that the Phylloxera cannot live on any other plant than the Vine; and (2) that it has never been found on bulbs, either in Haarlem or elsewhere. WAKKER does but confirm—with regard to bulbs—what is true for all other plants (except the Vine), that nothing in the history of the insect justifies the measures taken by the several Governments to prohibit the introduction of living plants, and that such measures can only cause great losses to the merchants, without offering in compensation the slighest protection against the invasion of Phylloxera. It may be safely said that where the conditions (climate, food, &c.) are favourable to the spread of the Phylloxera no power in the world can prevent its entrance. But all this has been dinned into the ears of the Governments concerned without the slightest effect for years pastthe Phylloxera itself spreading in defiance of the Convention, and for aught we know being rather amused than otherwise at the impotence of the measures taken against it! — KETELEERIA FORTUNEI.—We learn from the Revue Horticole that this interesting tree has produced fertile cones in the nursery of MM. ROVELLI at Pallanza. The tree is about twenty-five years old, and measures 14 metres in height by 2 metres in circumference; the spread of the branches is about 10 metres; the bark is spongy, like that of the Colk tree. MM. ROVELLI say of it that in none of its characters does it resemble the Silver Firs (Abies of the Continent), nor the Hemlock Spruces (Tsuga), nor the Douglas (Pseudo-Tsuga), except perhaps in the cones, which are somewhat like those of the Tsugas; but while the cones of the Tsugas are peadulous, those of the Keteleeria are erect. The tree has more of the appearance of a Torreya or of Podocarpus totara as to the foliage, but the habit is different, and much more slender.

- THE EXHIBITION AT NICE. - Mr. II. RENTON MEIN, of the firm of STUART & MEIN, of Kelso, writing from Nice on the 9th inst., says :-"At the exhibition now being held here there are exhibited in the department devoted to the productions of Nice the woods of Eucalyptus globulus, Cupressus mexicana, Laurus regina and Glypto-strobus pendulus, or Taxodium sinense pendulum. These are the trucks of the first specimeos of each of the above trees planted in France, all baving been introduced by Mr. C. HUBER, who had then (1857), and has now, nurseries in Nice. In February, 1857, Mr. HUBER received a packet of six grains of Eucalyptus globulus; four of these germinated, and three trees still exist. The Eucalyptus is now found everywhere in the south here, and the wood is very highly prized on account of its durability; it is, however, very hard, and thus difficult to cut and work. It is said the French Government endeavoured, eight years ago, to utilise it, but found it was necessary to soak it in water for two years before it was sufficiently soft for workmen's tools. The English department is not large, and the only seed house represented is that of SUTTON & SONS, Reading, who have a very tastefully arranged exhibit of wax models of vegetables and seeds in tins."

- CAMELLIAS .- Were it not for Messrs, WIL-LIAM PAUL & SON, of Waltham Cross, the visitors to the meetings of the Royal Horticultural Society would seldom look upon a good representative series of cut Camellias, such as that produced on the 12th inst. Looking over the collection of blooms, Mathottiana was undoubtedly the finest dark variety to be seen, and it is remarkable alike for its depth of colour and massiveness of petal. Marchioness of Exeter, crimson-rose; Corallina, bright deep crimson; Eximia, rich crimson, fine form; Fatima, pale crimson-rose, with white bars; Leeana superba, crimson, much banded with white; L'Incaspitata, pale rose, barred with white; Fimbriata, pure white, extra fine; Eugénie Massina, delicate rosy-pink, margined with white, charming, and very distinct; Imbricata, crimson; and Montironi, pure white, were the gems of the collection; but this list does not exhaust all the fine varieties contained in this interesting exhibit, which consisted of some forty or so distinct varieties.

— PINUS PINEA, GOLDEN-LEAVED VARIETY,—Messrs. DAMMANN & CO., of Portici, Naples, send us specimens of the Italian Stone Pine, some of the leaves of which are of a bright golden hue, Sometimes one leaf only of each pair, at other times both, are thus affected, and it is evident that the tree when seen in the bright sunlight must be very effective.

--- PRIMROSES, -- Of all the floral features that went to make up the show seen in the Conservatory at South Kensington on Tuesday last, few collections excelled in interest — though, perhaps, some in effect—the truly beautiful lot of Primroses sent up from Knap Hill by Mr. ANTHONY WATERER. Perhaps it is not quite exact to describe them as Primroses, because that term is generally applied to the Primula acaulis only, and not to the Primula veris, with which Bagshot plants are most associated. Some term them Polyanthus Primroses, others hybrid Primroses, but all familiar with the beautiful strains of fancy Polyanthuses now so plentiful know that these produce plants which, as a rule, send up true Primrose flowers first, and to those follow umbels of flowers borne on stout stems that continue the bloom late into the spring. Of this peculiar habit were the

majority of Mr. WATERER's plants — robust, free blooming, early, and very varied in colours and marking, many of the blooms of great size, and all singularly beautiful. It says much for the diversity of the flowers of identical hues. Pin-eyes and thrum-eyes were in nearly equal proportion, though of even the latter, lew, beautiful as they were, would fully satisfy the exactions of the strict florist. That, however, is of little moment. Here was the interesting fact, that this fine lot of beautiful flowers, all in 48-sized pots, had been liftled from the open ground but a few days previously, and had been placed under glass to enable the blooms to be shown clean and fresh. It is impossible that exact descriptions of the colours or markings can be fully given. They were varied and beautiful beyond compare, and prettily set up behind an edging of hardy Heaths of various colours.

- THE NEW ORLEANS EXHIBITION.—We learn from a REUTER telegram to the Daily News that arrangements have been completed for the embellishment of the Exhibition grounds, which embrace 247 acres. The plan includes the formation of four lakes and the construction of a railway connecting all parts of the grounds, special separate gardens for the rarest trees and plants from Mexico, Central America, and Florida, and reserved spaces for foreign countries and the States of America. construction of the Horticultural Hall has begun, This will be the largest conservatory ever erected, being 600 feet long, and 184 feet wide in the centre. A Special Commissioner has been appointed to confer with the principal horticulturists of Europe, with a view to securing the co-operation of various European societies, of many of which he is a member, and also to secure the interest of foreign Governments in the display of fruit and plants, which is expected to be the largest and most interesting international collection ever made. Special Commissioners are already engaged in Mexico, Central America, and Florida, where they are being actively assisted by the Govern-ment. The collective Mexican exhibit will be of a very extensive character. The Exhibition opens in December next.

— LATE CHRYSANTHEMURS.—We were not a tittle surprised at the end of last week, on entering the old greenhouse at Heckfield, to see a couple of strong plants of the yellow Japanese Chrysanthemum grandiflorum in good bloom, the flowers, if not large, at least young and fresh, and the plants covered with robust healthy leafage. This is, indeed, lengthening out the Chrysanthemum season of blooming, for as it now begins in August, we get a period of six months, such as the one named Ethel, Meg Merrilles, &c., are more accommodating for late blooming than others there can be no doubt, but care must be taken to keep the atmosphere of the house fairly dry, not ounduly force them. Further, the plants must be well established in their pots, and not have been fresh lifted from the ground, as with all such the season of bloom is short, if an abundant one.

THYESACANTHUS RUTILANS.—A number of specimens of this rich scarlet-flowered plant are blooming superbly in a warm house at The Wilderness, Reading, giving at this dull time of the year an appearance of unwonted brightness. Mr. Lers, in preference to crowding the plants in amongst many others, by which the long pendent spikes of flowers come into contact with the foliage and soon decay, has suspended them by means of stout wire from the rafters of the house, and thus elevated above the other things they looked remarkably effective and beautiful. This style of house decoration is one that may well be adopted with many things of similar habit of growth, care being taken that the pols are suspended evenly.

MYOSOTIS DISSITIFLORA ALBA. — This charming hardy novelty ought to become very popular as a market plant. We have seen some plants of it in the regulation 48's, which had been lifted in good clumps from the open ground, potted and put into a gentle warmth for three weeks, that were full of bloom of the purest hue, and the entire plants not more than 6 inches in height. It is naturally very hardy and very early, and keeps very true, although originating in a sport. It is a mistake to keep this Forget-menot and its blue congener in pots all the winter. The exceeding susceptibility to damp when in a frame or

greenhouse militates against early potting. It is best, therefore, to lift and pot as fast as required.

WINTER-BLOOMING PLANTS AT MAIDEN ERLEIGH .- In the houses at this place, where the requirements of the family render an abundance of cut flowers at this time of the year imperative, that valuable winter Orchid, Coelogyne cristata alba, is largely grown, the plants giving an abundance of flowers that are specially valuable for feminine decoration. The bulbs are strong and clean, and show excellent cultivation. That curious Acacia platyptera, which has tall erect growth not unlike that of the Stag's-horn Fern, and blooms like those of Acacia armata is represented by some tall plants that would attract by their novel appearance even if not in bloom. They grow freely and are easy of cultivation. Centropogon Lucianus is not a common plant, but Mr. TURTON grows it largely for its rich deep red-coloured flowers. These, not unlike those of the Salvia, are borne in racemes and thrown out on the upper side of the drooping blooming wood. It is a striking thing for bouse decoration under artificial light, and like the even richer flowered Thyrsacanthus rutilans, seems to bloom as freely in the winter as can be desired. Erica persoluta alba is represented by several stout dwarf bushy plants just bursting into abundant bloom. Of ordinary forcing kinds it is perhaps one of the most floriferous and bushy, and merits wide cultivation. Of exceeding value, too, in a greenhouse temperature, are a number of plants of Salvia gesneriflora, blooming superbly. Small spikes of these are charming in bouquets as button-holes and large ones in vases. The plants average 5 leet in height; were struck in spring, planted out in the open air and in the summer, and in the autumn lilted into 9-inch pots. By pushing on some early and keeping others cool it sible to have this Salvia in abundant bloom for three or four months. Its culture is of the easiest.

- THE PHYLLOXERA LAWS .- Since the meeting on the 6th inst, the following letter has been received from an eminent Belgian nurseryman. It is to be regretted that the letter did not arrive in time to be read at the meeting :- " I think that the English nurserymen, and the English Government as well, have much exaggerated the difficulties which the execution of the Berne Convention would raise, and that they are mistaken about the expenses the same would entail. The starting point of view being wrong, the conclusions are affected with the same disease. On the other hand, I confess that in a country where commercial liberty and free trade are the prime objects, there would be but little chance to see the Berne Convention, with its restrictions in commercial matters, adopted with sympathy, however small these restrictions might be. In Belgium we thought at first in the same way as you do; consequently, we are not in the least astonished at your opinions and ideas, We in Belgium simply consider it as a mere formality. In England you have also, without knowing it, partially submitted to its rules, seeing that you forward with the plants you send to the Continent a cer-But it should be borne in mind that your certificates are not drawn up in conformity with the stipulations of the Convention, and that it is only on sufferance that our Custom-house officers consider them as sufficient. Some day they may be refused, and then difficulties will commence. All that the Convention now requires of the adhering countries is that they should send consignments of plants with some precautions, and when it is proved that the plants originate from establishments where no Vines are grown, or from a place distant not less than 20 metres (30 yards) from any Vine, plants are allowed to enter into any country without inconvenience, The official experts scarcely cost anything to our Government. These officials are appointed in every horticultural centre, pay a visit once to every nursery in their district, and declare to the local authority, who is entitled to deliver certificates, that the nursery is or is not in the desired condition. This is what is meant by the "Déclaration de l'expert officiel." These officials are selected by the Government amongst State, county, or city officers, and they receive no particular payment for this supplementary work. When a nurseryman wishes to have his place visited and be declared in good condition for exportation business, he pays a trifle to the official to cover it is well understood that no expenses, and further formality is required after this visit to obtain certificates. It is not necessary that every package should be examined by an official; this is a mistake,

When your name is included in the list drawn up by the local authority as in right order, you are entitled to a certificate for every consignment, and that is all that is wanted. The official need not be a scientific man, as long as he is in a position to determine that an establishment contains no Vines, or is situated at 20 meters from any Vine, or separated from the same by an obstacle which he considers sufficient to prevent the roots of the plants coming into connection with those of the Vines (such as a ditch, a road, a wall, &c.). In France all the gardes champêtres (rural policemen) are "experts officiels." In England police inspectors or clerks of some Board might do the work. To export plants into the adhering countries it suffices to send with them a declaration of the sender and an attestation of the local authorities-in other words, a certificate such as you do now; only your certificate must be in proper form. the importation of plants you would have to claim the same formality—viz., the certificate—from the senders. A difficulty arises when plants arrive from non-adhering countries : then it is necessary to employ some more competent officials to examine the goods. It was precisely to avoid this difficulty that the wish was expressed at our international meeting last spring that every country should join the Convention. Here, again, the Government does not pay those special officials. It is the nurseryman who calls for special officials. It is the nurseryman who caus for his services who has to pay them, (We pay five francs.) When all countries have joined the Convention, all the difficulties will be reduced to the mere addi-tion of a supplementary paper to the documents already wanted for exporting."

— Indigofera Gerardiana.—This handsome and very free-flowering Himalayan shrub is known in gardens under a number of names. It was long ago figured in the Botanical Register under the name of I. Dosua dvol. xxviii., tab. 57), the true I. Dosua being a totally different species. Besides this name, which is still perpetuated in some nurseries, the species is to be met with as I. coronilizefolia and I. foribunda. I. Getardiana makes a beautiful wall plant, and produces a profusion of its racemes of purplish-red flowers during the summer months; it also succeeds well in the ordinary shrubbery border, and it is only in severe winters that it sustains any injury—as a rule it soon springs up again, even after being severely cut back by frost.

THE WEATHER.—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending Feb. 11, 1834, issued by the Meteories of the carlier part of the period was generally fair, but subsequently became very dull and squally, with rain, hail, or sleet showers. In the north-west and southeast some thunderstorms were experienced. The temperature has been about equal to the mean in the "Channel Islands," but above it elsewhere, the excess varying from t° to 3". The maxima were registered in most places on the 9th, and ranged from 50° in "Scotland, W.," to 55° in "Ireland, S.," The minima, which were recorded either on the 7th, 3th, or 17th, ranged between 27° in "Scotland, E.," 32° in "Ireland, N.," 32° in the westerly parts of England, and 38° in the "Channel Islands," The rainfall has been about equal to the mean in "England, S.," and "Ireland, N.," and rather more in "England, N.W.," and 7 in "Ireland, S.," but in all other districts the fall has been less than its normal value. Bright sunshine shows a slight increase generally, the percentages of possible duration varying from 6 in "England, N.W.," and 7 in Tengland, N.L.," to 23 in "Scotland, E.," and "Ireland, N.," and 25 in the Channel Islands. Depressions observed.—During the first few days of this period pressure over the greater part of our islands and France was comparatively uniform and the changes unimportant. As the week advanced, however, some large and deep depressions skirted our western and northern coasts, and travelled on in Scandinavia, causing the barometer in the United Kingdom to oscillate considerably. The wind, which had previously been light, or moderate, and generally W. or S.W., consequently backed to the S., and increased greatly in force of our coasts.

—— Gardening Appointments.—Mr. William Lawrence, from the Vale Royal Gardens, Cheshire, as Gardener to R. J. Pillings, Esq., Crimble Hall, Rochdale.—Mr. G. H. Richards, lately Gardener at Chetwynd Park, Newport, Salop, has succeeded Mr. Buchanan, as Gardener to Lady Stemens, Sherwood Park, Tuodridge Wells.—Mr. J. Hill, as Gardener to J. J. D. Paul, Esq., The Lawos, Eaton, Norwich.

INSECT ENEMIES.

SCALE INSECTS.—Dr. Riley, in his annual reports to the American Department of Agriculture, gives the result of numerous further experiments with paraffin oil emulsions for the destruction of the insects and their eggs. The following is a formula which has proved useful in practice :- Kerosene, 2 gallons = 67 per cent.; common soap or whale-oil soap, ½ lb. = 33 per cent.; water, 1 gallon. Dissolve the soap in boiling water, and add, while still boiling hot, the kerosene; churn or stir the mixture very thoroughly for five or ten minutes. The emulsion, when properly made, forms a thick cream, which adheres without oiliness to the surface of glass. When required for use, one part of the emulsion should be diluted with nine parts of cold water. The above formula gives 3 gallons of emulsion, and makes, when diluted, 30 gallons of wash. The proportion of kerosene may be increased, but cannot be diminished with advantage. In any case, a preliminary trial should be made, so as to secure the right strength. The emulsion should be used with a fine strength. Ine transfor with considerable force—the aim being to reach and thoroughly wet every portion of an infested tree. An ordinary garden syringe is declared to be practically useless, nothing less effective than a force-pump with a nozzle giving a finely atomised spray should be used attached to a length of flexible hose so as to allow of the introduction of the nozzle into the top of a tree. The orifice of the nozzle should be directed at right angles to the hose, the jet of spray may thus be directed upwards or downwards and brought into contact with all parts of the foliage from beneath as well as from the upper side. The cost (retail) of the emulsion is given at 45 cents. per gallon. The dilute wash costs (wholesale) 1½ cent per gallon.

THE CABBAGE WORMS .- Such was the destruction effected by the larvæ of the white Cabbage butterflies (Pieris) in the United States, in 1881, that large quantities of Cabhage were imported from Europe in 1881-82. Some of the insects were introduced from Eogland, others are indigenous. Dr. Riley makes them the subject of a report to the American Department of Agriculture, giving full particulars as to the natural history of the several insects. Preventive measures are of course the best, and this may be effected, on a small scale, by spreading a white net with meshes two-thirds of an inch in diameter, at a height of about I foot above the plants. The hutterflies alight on this net, but do not pass through it, and consequently lay no eggs on the leaves. Other preventive measures consist of hand-picking, allowing the access of poultry, or netting the flies. Among the more readily available remedies, hot water (130° F. = 55° C.) poured over the leaves will kill the insects without injuring the plant if proper care be used and a few experiments made beforehand. Pyrethrum powder, in the proportion of 200 grains to 2 gals. of cold water, kept stirred, may he syringed on to the plants with excellent effect. Kerosene emulsions are also recommended.

CYCLAMEN PERSICUM.

WHEN looking through Mr. H. B. Smith's fine collection of Cyclamen at his new Hanwell nursery a few days since we were struck with the pro-portions of some of the flowers. There were to be seen petals measuring 11 inch across, and some from 2 to 24 inches in length; and these were not on plants that had any special culture bestowed upon them, but were simply representatives of an ordinary large flowering strain, of which there were hundreds of specimens. The broadest and longest petals appeared to be found among the white varieties, those of the pink-flowered and pale rose flowers were very massive also. The richer coloured flowers have the smallest petals, but they are heiog gradually enlarged by the process of selection. Two varieties of the largeflowered section, both pure white, showed a remarkable distinctness of character. One named Baroness Burdett Coutts has very massive, smooth, flat, finelyrounded petals, broad and very striking-a truly superb variety; the other, Dame Blanche, has long, tall, somewhat spiral-shaped petals, narrower than those of the preceding variety. These are both very fine indeed, and they possess the strikingly marked foliage and freedom of flowering that are characteristic of Mr. Smith's selected strain.

Home Correspondence.

Pelargonium Dresden China.—My first sight of this singular Pelargonium was at the meeting of the Royal Horticultural Society on April 24 last, when it was named "Dresden China" (Turner, he gardening papers which noticed it at the time alluded to it as Mr. Turner's Dresden China, and also when shown subsequently at the May exhibition of the Royal Botanic Society. It was Certificated at the Crystal Palace show on May 19 as Turner's Dresden China. At the Pelargonium Society's Exhibition on July 25 it was staged as Dresden China (Turner), but it did not receive a Certificated from that body. In the list of flowers Certificated from that body. In the list of flowers Certificated from that body. In the list of flowers Certificated from that body. In the list of flowers Certificated from that body. In the list of flowers Certificated from that body. In the list of flowers Certificated from that body. In the list of flowers Certificated in 1883, which appears in the Gardeners' Year-Book for 1884, it is noticed as "Dresden China" (C. Turner, In never saw any raiser's name put to it other than that of Mr. Turner, and I naturally enough concluded that it was one of Mr. Turner's own productions. R. D.

Sisyrinchium grandiflorum.—This is one of the earliest and most beautiful of spring flowers. Its red-

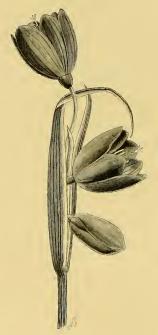

FIG. 40.-SISVRINCHIUM GRANDIFLORUM.

dish-purple bell-like flowers associate well with the larger Snowdrops. Botanically it is closely allied to the Crocuses, having but three stamens. Its grass-like foliage, too, is not unlike that of the Crocuses, but longer. Our illustration (fig. 40) is taken from unusually fine specimens sent to us from Messrs. Rodger, McClel-land & Co., of Newry, and show what good cultivation can do. Generally speaking the flower is not much more than half the size of the one now figured. The white variety is much less common, but is very chaste in appearance. The plant is a native of the United States,

The Eucharis Lily.—A gardening friend said to me a few days ago, "'llawe you seen Mr. Riall's Eucharis amazonica in bloom?" I had not, and be added, "'It is a sight worth going ten miles to see, I went to-day, and must agree with the observation just quoted. Let me try and give your readers an idea of it—there were several, but I am now referring to the largest. It was situated in the stove, and growing in an 18 or zo-inch pot, with a rich brown maiden loam for the major part of the compost, while the foliage was of that dark rich green that indicates rude health. Now, as to the blooms. I counted thirty-one flower-stems, and from five to seven perfect flowers to each, making a total of

upwards of 180, and most of the individual blooms from $3\frac{1}{2}$ to 4 inches in diameter, of the most peerless purity. IV. J. M., Clonnel.

Canker in Fruit Trees.—Mysterious at all times, and if Mr. H. Weir's assertion of insect agency should prove to be well founded, and an antidote invented, we should be well on the way towards stamping it out. Mr. C. J. Nicholson, a large fruit grower at Loughgall, near Armagh, and a most persevering and observant man besides, and who has suffered much loss from time to time through canker, tells me that he has quite got rid of it by never making holes when planting his trees. He simply spreads the roots out upon the surface, no matter how hard it may be, and places new soil over them. He also states that in the case of established trees he has got rid of it by double grafting. Some sorts are much more liable to canker than others, say, for instance, you have a large tree of some comparatively worthless variety. You head it down and graft it with another, which becomes cankered at once; whereas, if you place another kind between it and the stock, no canker ensues. A resumé of his experience would be most interesting and instructive to your readers, but the misguided man does not read the Gardeners' Chronicle! T. Smith.

Brussels Sprouts.—In the neighbourhood of Reading there is grown a strain of Brussels Sprouts known as the Reading Exhibition. The stems are very short, ranging in height, according to quality of soil and time of planting out, from 13 to 30 inches, and from top to bottom are thickly covered with large solid Sprouts. We saw grand samples of this kind the other day at Heckfield, the earlier plantings having been pretty well stripped, whilst the later ones gave stiff erect plants covered in the most perfect form with solid Sprouts. Actual size in these is, of course, even with this strain, much governed by cultivation, as in another garden in poorer soil the plants were estill as perfect in character, but the densely studded Sprouts were about half the size of those seen at Heckfield. For field culture, where the soil is never too deep or rich, this strain would be well suited, as there the Sprouts would prove just such as to satisfy the most exacting. X.

Lilacs Flowering Twice.—It is a well known fact that many deciduous shrubs and trees, if more or less denuded of their leaves, either by storms or otherwise, will often produce in the same season a second crop of leaves and flowers. A correspondent of the Revue Harticale, writing on Eastern gardening, calls attention in a recent number to the practical value of this secondary season of flowering with regard to the Lilac. The writer says:—"M. Davillon's observations, that the plants which flowered best were those which had most suffered from the storm—that is to say, those from which the leaves had been almost stripped—are perfectly correct. Here, and particularly at Smyrna, my native place, the experience is a very common one. From my childhood I amused myself by picking off the leaves of the Lilacs immediately after they had flowered in spring, in order to have them in flower in August; sometimes we only experimented on one half of a tree, in order to have them in flower in fact, our method of forcing Lilacs. If Lilac flowers are required in August and September, it is necessary, after the spring flowering, to keep the bushes without water for some days; the leaves are then removed, water is administered, and at the end of some weeks the plants are covered with bloom."

American Potatos,—We had thought that the days of dear Potatos had passed, and that reasonable prices were ruling, It is true we hear no more of 125, per pound, and never shall again; but our American friends are not without sufficient confidence in the value of their own raisings as still to ask a dollar the pound for a new variety that, under the name of Dakota Red, hears a remarkable resemblance to our large-tubered old acquaintance, Late Rose. In our own country, where Potato raising has of late made rapid strides, raisers start with 15, to 15, 6d, per pound, and are content with these simple prices that of course can be main-tained only one season, and then when the stocks are small. The new American is credited with being disease resisting, but so are many of our kinds more or less, and the past two years have shown them to be more than less, so that we have nothing to gain in spending our dollars; whilst, in the matter of cropping, our new kinds are equal, and in the important one of quality, we are beating all foreigners out of the field. We shall hardly hear much of the Dakota Red in this country at present, or probably at any time. Y.

Seedling Hepaticas.—On p. 175, at the end of an interesting note on growing Hepaticas in pots, I observe that "R. D." asks for information about their coming up from seed. Hepaticas are amongst those plants of which the seed will not germinate if

dried and stored, but which come up freely from the self-sown seed, if the conditions are favourable. After the flowering is over the crown of the plant should he sprinkled with fine peat soil, or some equivalent, until the base of the leaf-stalks is covered. Into this the seeds fall, and about the time that active growth commences in the parent plant in autumn they germinate, producing a pair of leaves simultaneously with the growth of the new leaves on the old plant. When the leaves are fully developed the seedlings may be removed. Some flower the next year. They generally follow the colour of their parent, though pink seedlings occasionally come from blue plants. Shades of colour vary a little. I have over tried crossing them. I find that seedlings of H, Barlowi come tolerably true to colour. "K. D." is quite right in saying that Hepaticas want a deep rich, very well drained sandy loam, and cannot stand being dried up in summer; but they are not always satisfied with these conditions. They do well wherever Christmas Roses do well. I should state that more seedlings come up amongst the leaves than outside them. C. Wolley Dod, Llanducho, Ftb. 11.

Iris reticulata cyanea—I. histrio.—The very interesting note on this plant given by Professor Foster in the Gardeners' Chronicle of January 26 last was read by me with much pleasure, and I return him my best those for it. I immediately requested Messrs. Haage & Schmidt to seed me a couple of flowers of their variety, and they had the kindness to do so; and now I must say I perfectly agree with Dr. Foster, that we have here doubtless a variation of Iris Krelagei. It is very probable that this is the same variety which seems to be found in a wild state at Tiffis, but it might be a garden seedling. Various cultivators have obtained seedlings both of the typical form of Iris reticulata and of Iris Krelagei, more or less varying in a darker or paler direction. So there

Fig. 41.-BULB OF IRIS RETICULATA.

have been obtained reddish or purple seedlings from I. reticulata typica, and more in the blue colours from I. Krelagei. If these varieties, which seem to be not very easy to grow, are true, multiplied, and offered to the trade, there may be expected fine collections of both forms. As for Iris histiro, this is quite a different thing, and this Iris, in my opinion, is as to delicate and elegant coloration superior to all the forms of the two other sorts. As Dr. Regel, without any doubt, has described this Iris as I, reticulata cyanea, this name ought not to be given to any other form; and Messrs. Haage & Schmidt's variety, therefore, would certainly be much better called I. Krelagei curulea. If more varieties, however, of these Irises are coming into the trade it will not do to designate them only by their colours, and ti will be preferable to give them vernacular names, as to other collections of florists' flowers. As to the earliness of the different sorts, the reports concerning them are variable. At present in my grounds Iris Krelagei is in bloom, and the I. (typical) reticulata will flower only some time later on. Others here say Iris Krelagei is alter than the type (Album Van Eoden, text of plate 30). As for beauty, very good growers give the preference to the varieties of the type, while others prefer the Krelagei form. There is also some difference in the form of the bulbs of the three sorts. Then these Irises, like other sorts of the Xiphium section, vary much in height, so that they become dwarfer, and sometimes by change of soil again taller. This, for example, may be observed especially with the varieties of Iris Xiphium. The reticulata group, too, have the same properties. For years I classified my very extensive collections of Iris Xiphium for bedding purposes into the everage height, and among the dwarf ones; although less frequently, single tall-

growing plants have to be taken away. Finally, as to the confusion in the names of Iris histrio and this Iris reticulate cyanea, it originates from the circumstance that the variety first offered by Messrs. Haage & Schmidt in their catalogue of 1881 was there noted as Iris reticulata cyanea (Iris histrio), in the lists of 1882 and 1883 the designation Iris histrio was not given; but I must express, by the way, that it was stated in 1881 to be the same plant, and this is

FIG. 42.-BULB OF IRIS KRELAGEL

the reason my attention was not formerly fixed upon it. Had the plant been obtained in 1881 as different from I, histrio I should doubtless have tried to get it, as I like to keep my Iris collection as complete as possible. J. H. Krelage, Haarlem, Feb. 5.

FORESTRY.

CONIFERS IN THE BELGIAN CAMPINE. — Travellers through Belgium from Antwerp towards Rotterdam will have noticed the sandy plains covered

Fig. 43.—IRIS RETICULATA.

in many places with young Conifers. It appears from a lecture of M. de Smet, reported in the Revue de PHorticulture Belge, that the sorts most grown are Pinus silvestris (Scotch Pine), Pious Pioaster, Picea excelsa (Spruce), Abies pecticata (Silver Fir), and A. Douglasii. The Scotch is the favourite, owing to its hardihood and accommodating habit. It is used in a small state for Hop-poles, telegraph poles, for charcoal-making, or for firewood. However poor the soil, the Scotch yields a revenue of from 2000 fr. to

3000 fr. per hectare (£40 to £60 per acre and upwards) when the trees are thirty years old. The Pinaster has lost the reputation it formerly possessed, the trees having been almost all killed in the winter of 1879-80; nevertheless it is recommended for culture on heaths that are broken up. Sown in a well-trenched soil the Pinaster grows rapidly. When eight to ten years old the trees yield faggots, and by their dense growth prevent the spread of the under-growth so difficult to extirpate. Land upon which the Pinaster has grown for ten years is as well pre-pared to receive a plantation of Scotch Fir as if it had been well manured for crops of Rye, Wheat, Potatos, &c. The Spruce does well on damp but not wet soils. At first it grows slowly, but after the sixth year its growth equals that of the Scotch Fir. It grows as well isolated as in groups. The Silver Fir is a valuable tree on good soil. It grows rapidly, and its wood is much esteemed. In Holland it is koown as Vuurnhout. Of the Douglas Fir a large quantity have been planted, and in a rich open soil grow at the rate of 75 centimetres a year. They were not hurt in the winter of 1879-80. In some parts of France this tree was not hurt by a temperature of -25° or -26° C. (-13° F.), though it was killed in Alsace and Champagne by a temperature of -28° C. (-18° F.). The trees should not be planted to closely together. When planted in avenues they produce a fine effect,

INTERNATIONAL FORESTRY EXHIBITION. — At the meeting of the Executive Committee, held on the 6th inst., a communication from the Secretary of

FIG. 44.—BULB OF IRIS RBTICULATA.

State for the Colonies was read with much satisfaction. In it, among other matters of importance in connection with the Exhibition, it was stated that the Government of Gambia would require at least 100 square feet of space for its exhibits, Governor Havelock taking an active interest in getting up a very complete collection of the forest products of the British Settlements in West Africa. It was also stated that among the contributions of some of the native chiefs of Iodia to the Exhibition now open at Calcutta, "the Maharajah of Travancore has on loan a beautiful collection of ivory carvings; one of these, representing a fair girl seated, is particularly spirited; and there is a fine ivory tankard of great size on a silver stand. The decorations on the latter are simple, thoroughly Eastern, and in excellent taste. It is understood that the whole collection of these articles is to be sent to the Forestry Exhibition in Edioburgh." The committee had before them a large number of applications from exhibitors for space, which were mostly approved.

A LARGE CORSICAN PINE.—Probably the largest Pious Laricio ever felled in Britain was yesterday sent to our sawmill to be cut into boarding. The cut end was 32 ioches in diameter, and at 9 feet it measured 6 feet 2 ioches io circumference. Eighteen feet in length of the cut end was free of branches, and as straight as an arrow, and contained exactly 30 cubic feet of timber. The wood appeared of excellent quality, resembling very closely the red deal of commerce, and contained a great quantity of resin. This tree was growing on almost pure gravel, and but for an accident would never have been removed from the position it so nobly filled.

A peculiarity of this Pine, which unfortunately was left out in my notes, is the narrow spread of branches in proportion to the tree's height—one of the most valuable qualities we are acquainted with in a forest tree. A. D. Webster.

EFFECTS OF THE LATE GALE.—Recently thinned plantations have suffered somewhat severely from the effects of the late storm, and many fine trees in the park have also been uprooted. One or two of our largest Austrians have unfortunately been heeled over, and in less number Cedar of Lebanon, Abies Douglasii and Pinus Laricio. Several hardwood, such as Oak, Ash, Beech, Spanish Chestnut, and Elm, have also been blown down, and branches broken and twisted in all directions. Vegetation has, however, received little or no check, indeed to-day I noticed several Thorns, young Sycamore, and Honeysuckle in almost full leaf. A. D. Webster, Penrhyn Castle, North Wales, Feb. 7.

THE PROPAGATOR.

THE PROPAGATION AND CULTURE OF ACHI-MENES: 1. From Cuttings .- A great number of plants should be set apart and grown for cutting purposes. When they have reached the height of 6 inches the plants should be cut down, leaving, however, one or two tiers of leaves. That portion of the plant which has been cut away must be divided into as many cuttings as possible, care being taken to leave an inch of the stem below the leaf on each cutting. It is not necessary to sever the cutting at a joint of the plant if the stem is buried in the soil up to its junction with the leaf. Well drained 48-sized pots will best receive the cuttings. They should be filled with soil composed of three-fourths peat and onefourth sand, which had previously been subbed through a 4-inch sieve and well mixed together. The soil should be pressed firmly into the pots, and a layer of sand a quarter of an inch in depth spread upon the surface. In order that the soil may be firmer, and thus better suited to receive the cuttings, it will be found advisable to well water the cutting-pots and allow the soil to settle. This will make the surface level. A dozen cuttings should be arranged around the outer edge of the pot and six in the centre. The holes made on putting the cuttings in should be filled up with dry sand. After they have been well watered, to make the surface level, and each sort properly labelled, they are ready to be placed in a cutting-frame,

2. Propagation from Leaves.—Only a few simple intentions are necessary as a guide to the propagation of the leaves. The "hard" or well-developed leaves of the plants should be severed with a sharp koife close to the main stem. They should be put into cutting-pots, arranged on a similar plan to those for the cuttings—eighteen leaf cuttings to form the outer row, and twelve in the centre. The leaf should be placed in an upright position in the pot, and the whole of the leaf-stalk should be beneath the soll. The surface of the soil, with the cuttings in, should be well watered to make it level, when the pots will be ready to be placed in the cutting-frame.

3. From Corms, or Bulbs.—A fruitful method of increasing Achimenes is from the corms, or bulbs. The largest and ripest bulbs should be selected and laid in an empty pan. After two or three days have elapsed the process of "scaling" must be commenced. This is done by rubbing the bulb gently in the palm of the hand until it is separated into many scale-like pieces; or, if this will not separate the particles, the bulbs should be rubbed between the finger and thumb. These scale-like particles should be sown like seeds in shallow pans upon the surface of the soil. The soil must be sandy, and should be gently sprinkled over the particles, havely covering them. They are now ready to be placed in the cutting-frame. As soon as the shoots which spring from the particles are 1,-inch in height they must be pricked off and placed in shallow pans, each t inch from the other. After they have been replaced in the cutting-frame for two or three days, they should be put upon a warm shelf until they are large and strong enough to be potted into separate pots.

4. From Secat.—Several well-drained shallow pans should be filled with soil composed of equal proportions of sand and peat, adding a small quantity of loam after the whole has been sifted through a fine sieve. The soil in the pots should be watered to make it firm and level. The seeds should be sprinkled on the surface of the soil, but care should be taken to see that they are not covered by it. The pans are now ready to be placed on a warm shelf. The shelf should be covered with river-sand an inch deep. Many young seedlings may be spoilt if they are not protected from the occasional drip of water from the root. In order to guard against this four thumb-pots should be placed on the shelf so as to form the correst of a square, and a plate of ordinary glass placed upon the top of them, the pan being placed between the thumb-pots and under the piece of glass. When the seeds spring up the seedlings should be pricked off and put into "thimble" pots, these little pots being sunk into an inch of river-sand, which should always be kept moist. In proportion as the seedlings increase in size and strength they must be potted and repotted into larger pots until they arrive at maturity.

The Culture of Achimenes. — The bulbs should be potted in 60-sized pots, four bulbs forming the outer circle and one in the centre. They should be gently pressed down and covered with the soil, which should consist of half peat, one-tibrid loam, and one-fourth sand, well mixed together, and the pots should be filled to an inch below the top. Having potted the bulbs they should be placed on a shelf close to the glass, and the greatest care must be taken not to allow them to become dry from the time the bulbs are potted to the time the plants droop and die down. When the bulbs send out shoots 2 or 3 inches in height they should each be potted into large 48-sized pots and removed to a front platform in the house. The Achimenes are naturally weakly-growing plants, and therefore they do not require a very high temperature; that ranging from 55° to 65° is most suitable, though plenty of moisture should be kept on the floor of the house and round about the pots. When the plants commence to flower they can be removed to the greenhouse or conservatory.

Hybrid Achiments.—Of late years few new hybrid varieties of excellence or celebrity have been produced, and therefore this department of Achimenes culture affords a good opening for gardeners. It will be found a good plan to select six good varieties—say, Grandiflora, Mauve Queen, Mauve Perfection, Loogi-flora alba, Ambroses Verschaffelt, and Williamsti—and to hybridise the dark flowers with the light ones, and vice verse. By this means you will obtain, as it were, a "double cross," and will certainly produce good varieties. Much may also be done by inter-crossing with true species, even though they may not be in themselves showy. Each flower that has been hybridised should have a piece of white worsted tied round its stem, attaching thereto the name of the variety with which it has been hybridised. These plants should be placed upon a warm airy shelf, or upon the front platform of the house. All the flowers and buds which have not been hybridised should be removed from the plant as fast as they appear. Thus all the strength will be concentrated in the hybridised seed-pods. The seed-pods of the Achimenes take a considerable time to ripen—indeed, not until the polant has withered. They should be gathered so soon as they are ripe, but the seeds should remain in the pods until the time arrives for sowing them, which is the first week in January.

In concluding our remarks upon this subject it

In concluding our remarks upon this subject it will, we think, be well to say a few words respecting the best and easiest method of wintering a large stock of Achimenes where the space is limited. The requisite number of 48-sized pots should be prepared, and some pieces of pot placed flat side downwards over the holes, and a piece of green moss rammed tightly into the pot, upon which a layer of sand an inch in depth should be spread. Having shaken out the bulbs, and freed them from soil, they should be placed in the pots on he sand, by which also they should be covered to a height of 1½ inch. Each pot should be rotered to a height of 1½ inch. Each pot should be rotered to a height of 1½ inch. Each pot should be ladeled. The pots should be placed on a shelf or front platform, and covered, in a temperature of over 50° to 55° Fahr. with three sheets of paper, in order to prevent the water which drips from the roof reaching the bulbs; or they may be placed in a cool dry shed or sectorom. By this plan a large stock can be wintered in an incredibly small space. So wintered the corms are ready for potting, after turning them into a fine sieve, and picking out the green moss and pieces of pot, thus leaving the corms separate, after having given the sieve a twist round to sift off the sand, Tr. O.

PIFTANTHUS NEPALENSIS. — Perhaps the safest place for this beautiful Himalayan shrub is against a wall, and it is well worth that protection. Except ln unusually severe winters the handsome dark glossy green trifoliolate leaves are retained uninjured; the rich yellow flowers, similar to, but much larger than those of the common Laburnum, open in May and June.

∯loqists' ∯lowers.

CYCLAMENS AT SOUTH KENSINGTON, - The meeting of the Royal Horticultural Society last Tuesday brought so many and fine collections of Cyclamens that a kind of Cyclamen festival resulted. Most of the leading growers were represented, foremost being a really splendid collection from Mr. H. B. Smith, of Ealing Dean, whose plants and flowers were noticeable for their fine culture and large size. Of the new varieties staged by Mr. Smith, one, named Dame Blanche, received a First-class Certificate of Merit. It must be regarded as the finest pure white Cyclamen yet seen, being characterised by great smoothness and solidity of petal, large in size, and charmingly displayed. It belongs to the giganteum section. Two other whites were also shown on this occasion-viz., Baroness Burdett Coutts and Mont Blanc, which, like the foregoing, were true white selfs, without a taint of colour, and both highly valuable. Rose Perfection is a very fine variety, remarkable for the size of its flowers, which are of a pleasing pale pinkish-rose, and having a crimson base. Crimson King, a rich coloured variety, was also shown in fine form, and there were other fine varieties also, but unnamed. Mr. J. Wiggins, gardener to W. Clay, Esq., Kingston-on-Thames, had a large collection, but many of the plants looked as if they had suffered from travelling. His new varieties comprised Una, pure white; Vesuvius, bright crimson; Albert Victor, white, with crimson base; Eastern Queen, white with purple base; and a very large specimen of a pure white variety named General Gordon, really a splendid plant, finely grown and bloomed. Then Mr. Clarke, of Twickenham, had an extensive collection, also of Twickenham, had an extensive collection, also including several new varieties, such as Cardinal, very deep crimson; Rose Queen, bright rose, with crimson base; and King of Roses, delicate blush, with pale purple base. Messrs. Veitch & Sons, E. S. Williams, and others also had collections, and it is long since we looked upon so many plants at one meeting of the Society.

PRIMULA SINENSIS AT SOUTH KENSINGTON. -A very large number of these were to be seen at the meeting of the Royal Horticultural Society on Tuesday, and, as in the case of the Cyclamen, several well known growers had collections. For thoroughly well-grown plants none could excel those shown by Messrs. Veitch & Sons. It is true the collection contained little of novelty, but the older types were seen to great advantage. Messrs. Carter & Co. staged a collection of comparatively new varieties, but they were not presented in good condition; and if the blue variety, Holborn Gem, had a little more of the brilliancy of colour depicted in catalogues it would perhaps be more valued. But it is no doubt capable of higher development, which will appear in course of time. The group from Messrs. H. Cannell & Sons, of Swanley, possessed the greatest amount of novelty, and to one of the Swanley novelties, named Emperor, a First-class Certificate of Merit was awarded. It is a very fine salmon-carmine coloured variety, intense in hue, and with a pip of great size and substance. Swanley Giant, very large, pale-purple; Mammoth, large lilac-purple; and the Queen, very large, pale blush, are all of great size; but, as too often happens in the case of very large flowers, the petals are apt to reflex on the edges, and they take on an inelegant appearance. The best deep coloured variety we saw was Swanley Red; a selected form of Chiswick Red; a variety that maintains its colours well, and which is also of good habit, displaying the flowers well above the foliage. But there was a marked absence of the pretty shaped varieties Messrs. Windebank & Kingsbury used to raise at Southampton years ago.

FERNS IN THE LARE COUNTRY.—We learn from the Mancheter City News that Mr. Hodgson, lecturing recently at Carlisle on the Flora of the English Lake District, entered a protest against the ruthless and indiscriminate way in which Ferns were being rooted up and exterminated. In the Keswick neighbourhood, once famous for its Royal Ferns, the Osmunda in its wild state was extinct. Other rare Ferns were undergoing the same fate. A Fern new to the district had recently been discovered, the precise location of which he would not make public.

Reports of Societies.

Royal Horticultural : Feb. 12.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker, K.C.S.I., in the chair. Present:—Messrs. Berkeley, Boscawen, Houston, Smee, Loder, Masters, Wilson, Boulger, Bennett, Pascoe, W. G. Smith, Murray, Mangles, Ridley, and Lowe.

Scedling Plants of Dodder .- Mr. W. G. Smith showed seedling plants of Cuscuta trifolii, raised from seed taken from siftings of imported Clover seeds. The seeds vary greatly in the length of time required

for germination—some springing up in four days, others requiring two months.

Mushroom Growing.—A paper on this subject, relating to the culture of Mushrooms in disused retaining to the culture or mustinous in Gussace, stone-quaries near Bath, was read by Mr. Bennett, and referred to Mr. Berkeley. The necessity for watering the beds with warm water after letting the bed get thoroughly dry was insisted on.

Electric Light and Palato Culture.—Mr. Boulger

Electric Light and Polital Country, and Bodget drew attention to the negative experiments of Mr. Cross with reference to the culture of Potatos under the electric light. When the light was employed exclusively no chlorophyll was produced. These negative experiments, however, are of less moment than those which show that chlorophyll can be produced the influence of the light.

duced under the influence of the light.

Crocus Imperati.—Mr. Loder showed the white form of this species, which led Dr. Lowe to remark that he had found the variety wild within 30 miles of Naples.

Crocus Balansæ,-Mr. Loder also showed flowers

of this rare Crocus, the outer segments of which are of a rich velvety-bronze colour.

Missa Ensete.—Mr. Loder also exhibited a small plant of this species in flower, although the seed had

only been sown during the last summer.

Snowdrops.—From the same gentleman came a series of specimens, representing most of the varieties

d species in cultivation,

Hyacinths Grown in the Dark,—Mr. Smee showed bulbs of Hyacinths which had been allowed to remain unheeded in a cellar since 1882; the plants were now growing at the expense of the bulbs, which had even

thrown off small secondary bulbs.

Stanhopeas and Frost.—The Hon. and Rev. J. T.
Boscawen alluded to the case of a Stanhopea which
he had turned out of a hothouse into an open shed, where it was subjected to 13° of frost without injury

even to the young growth.

Pear Branch.—From Lord John Manners came a branch of Pear tree growing on a wall, and presenting large oval patches of dead bark. The cause of death

large oval patches of dead bark. The cause of death was probably sun-burn, acting on wet bark. Thebrous Species of Solanton.—Sir Joseph Hooker showed drawings of S. Maglia and S. Jamesi, to species alluded to in Mr. Baker's recent paper. The Filtering Power of Sand.—Mr. Plowright sent a paper, with illustrative tubes, to show that and in tubes to which spore-laden water is added in drops does arrest the passage, not only of fine inor-ganic matter, such as red-lead and lamp-black, but also of fungus spores. The experiments corroborated Mr. Jensen's views, that a sandy soil does prevent the access of spores.

access of spores,

Root-Hairs,—A drawing was shown of the roothairs of Poa pratensis growing in water, and which
were coiled up spirally as if they were the subject of
greatory movements; similar phenomena had been
witnessed in the case of pollen tubes,

(The Outer Towney,—A fine specimen of this

The Oyster Fungus.—A fine specimen of this fungus, Trametes gibbosa, was exhibited by Mr. Sidney Ford, gr., Leonardslee, Horsham.

FLORAL CONMITTER.—Present:—Section A. John Fraser, Esq., in the chair; Messrs. G. F. Wilson, E. Hill, J. O'Brien, J. Dominy, H. Ballantine, J. Hudson, J. Woodbridge, H. Herbert, H. Williams, J. Moore, Dr. Masters, and the Rev. G. Henslow.—Section B. Shirley Hibberd, Esq., in the chair; Messrs. H. Bennett, W. Bealby, J. D. T. Llewelyn, I. Douglas, J. James, J. Child, G. Duffield, D. C. Latibury, H. Turner, W. B. Kellock, and H. Cannell. Quite a dazzling display was made to-day by several exhibitors with collections of Cyclamen, of which were fine examples of skilled uclture and careful which were fine examples of skilful culture and careful hybridisation. Mr. R. Clarke, Twickenham, was awarded a Silver Banksian Medal for a collection consisting of plants ranging from the purest white to red, and white and red flowers, some of them being red, and white and red flowers, some of them being of more than ordinary merit, viz., Cardinal, King of Persicums, Rose Queen, and Compactum. A Silverill Banksian Medal was awarded to Mr. Wiggins, cr. to W. Clay, Esq., Grove House, Kingston-on-Thames, for a finely-bloomed collection of Cyclamen persicum, possessing a most robust habit with excellent foliage, Mr. H. B., Smith, nurseryman, Hanwell, obtained a Silver Banksian Medal for a grand group of seedling

Cyclamens; and for one named Dame Blanche, a very fine white, a First-class Certificate was at the same time awarded. The only one exhibit of Hyacioths, fortyfive in number, was that of Mr. B. S. Williams, Victoria Nurseries, Holloway, which was awarded a Silver Eanksian Medal, the spikes being exceedingly good, as forced bulbs, the plants showing also careful good, as forced bulbs, the plants showing also careful management. Some of the best were those of well-known kinds, such as Lord Derby, Baronesse Van Thuyl, Grandeur à Merveille, Grand Lilas, Rubra Maxima, Lord Macaulay, Charles Dickens, Von Schiller, &c. Mr. Williams also contributed specimens of his fine strains of Cyclamens and Primulas. Mr. A. Waterer, nurseryman, Knap Hill, received a Silver Banksian Medal for a pretty collection of Polyanthuses, which showed a great diversity of colour, well developed blooms, and healthy foliage—a proof of how valuable these easily grown hardy plants are for winter decorative work and for cutting for table and other bouquets. An excellent collection of Camellia blooms was shown by Messrs. W. Paul & Son, Waltham Cross, and which most deservedly was awarded a Silver Banksian Medal. Messrs, W. Paul & Son, Waltham Cross, and which most deservedly was awarded a Silver Eanksian Meddl. A recognition of these beautiful flowers, which are apt to drop into the background at present, is of much value. There were about twenty-four varieties in all, amongst them being fine examples of Annette Franchetti, a pure rose, with a white stripe in the petal, and reflexed; Monteroni, a good reflexed white, the bold-looking rosy-scarlet incurved Marchioness of Exeter, a pretty bouquet reflexed flower in Eximia, scarlet; Princess Charlotte, a fine white; Ecany of Hornsey, a rose-coloured variety; Fatima, a good pink, having a white stripe; Fannie Sanchioli, a fine opaque-white, with a blotch of faintest rose on the centre petals; Lucrezia Gazzarini is another pale rose, with a white stripe in the middle of the petals; and with a white stripe in the middle of the petals; and Monteroni Vera, a very pretty white faintly suffused with rose colour. A First-class Certificate was awarded to a bunch of flowering shoots of the rare hardy tree Parottla persica, valuable in early spring for the colour displayed by the bunches of dark red inconspicuous flower-buds, but more especially for the magnificent coloration assumed by ally for the magnificent coloration assumed by the leaves in autumn. The pretty Saxifraga Burseriana was shown by Messrs. Carter & Co., Burseriana was shown by Messrs. Carter & Co., of Holborn, and for which they were awarded a First-class Certificate, Messrs. Veitch & Sons received First-class Certificates for Epacrises Diadem (deep rose) and The Premier (flesh-pink)—good examples of these somewhat neglected plaots. Mr. James, Farnham Royal, was a warded First-class Certificates for two distinct seedling Cinerarias, named Lottie Williams, dark maroon, with a violet ring round the grey disc; and Great Eastern, violet-rose, a flower 3 inches across. From R. P. Percival, Esq., Southport, came a cut bloom of the rare white variety of Cattleya Percivaliana; and Major Lendy, Sunbury, had a nice specimen of another variety of the same species named citrioa, in which the lines on the lip are orange-coloured, instead of yellow. Lalia lip are orange-coloured, instead of yellow. Lælia anceps Williamsiana, showo by Messrs. Sander & Co., is a lovely waxy-white flower, with beautiful markings is a lovely waxy-winte hower, with beautiful markings on the wings of the labellum. The same firm also had in Oncidium anthocrene a species much resembling O. fuscatum, the flowers being chocolate-brown, barred with yellow, and the lip white. Mr. H. M. Pollett showed a very pretty supposed hybrid Odontoglot named Pollettianum, the flowers of which are of a flesh tinted ground colour spotted with crimson, and which might be taken by some as an extra fine form of O. Ruckerianum. With this came one or two nice of O. Ruckerianum. forms of O. Rossi majus, including Mr. Day's original

plant of the variety erubescens.

Votes of thanks were given, amongst others, to Mr. A. Waterer, Knap Hill, for a finely-flowered plant of Andromeda (Pieris) japonica, a subject no one possessing an American garden should be with-out; to Messis, Veitch & Sons for Violet Comte de Brazza and Freesia refracta alba, the latter a useful decorative bulbous plant; to Mr. James, Farnham Royal, for a collection of Primula sinensis; to Mr. Royal, for a collection of Primula sinensis; to Mr. Walker, nurseryman, Thame, for a plant of Fuchsia procumbens, carrying a few fruits. Votes of thanks were further awarded to Mesrss. Cannell & Sons, Swanley, for Primula sinensis of new varieties, some of them having particularly vivid colours and regular outline; and also for a boxful of Cineraria blooms; to Mr. Hodges, gr. to Edwin Wright, Esq., Gravelly Hill, Birmingham, for cut blooms of Lælia albida, Calanthe vestita alba major, and Odontoglosum Alexandræ luteum. A plant of Vanda Cathcarti, carryiog eleven of its neculiarly barred blooms, came Calanthe vestita alba major, and Odontoglosum Alexandre luteum. A plant of Vanda Cathcarti, carrying eleven of its peculiarly barred blooms, came from the garden of G. Heriot, Esq., Choinuley Park, Highgate; and Mr. James O'Brien exhibited a pretty specimen of a Japanese Fern, several grotesquely trained examples of which were illustrated in our last volume at p. 461. The plant as shown was a good form of Davallia Mariesii, and is certainly not a form of D. hullata. as hay recently been groneously stated. of D. bullata, as has recently been erroneously stated.
Messrs, Stuart & Mein showed a plant of Spirae contusa, which is of some decorative value, but it was not improved in appearance by the way it had been trained.

The awards made were :-

FIRST-CLASS CERTIFICATES.

Section A.

To H. M. Pollett, Esq., for Odontoglossum Pollett-

ianum. To Messrs, F. Sander & Co., for Lælia anceps Wil-

To Messrs. F. Sander & Co., for Oncidium antho-To Messrs. James Veitch & Sons, for Epacris The

Premier.

CULTURAL COMMENDATIONS.

To Major Lendy, for Cattleya Percivaliana citrina. To Mr. Wiggins, for Cyclamen General Gordon. To Mr. R. Aldons, for Vanda Cathcarti.

FRUIT COMMITTEE .- Beyond collections of Apples FRUIT COMMITTEE.—Beyong concentros of appropriate there was no other varieties of fruit shown, and of these Messrs. Lane & Son, Great Berkhampstead, showed a fine selection, some of the varieties being apparently in prime condition. We noticed Forge, these Messrs, Lane & Son, Great Berkhampstead, showed a fine selection, some of the varieties being apparently in prime condition. We noticed Forge, Galloway, Watham Abbey Seedling, Annie Elizabeth, Queen Caroline, Lucombe's Seedling, Adams' Pearmain, Baumann's Red Winter Reinette, Dutch Mignonoe, Kirk's Fame, Selwood Reinette, Belle Boone, Prince Albert (this last looking quite the best in the collection), Bedfordshire Foundling, and Sturmer Pippin. Mr. G. Goldsmith, Hollanden, Tonbridge, showed almost as large a collection, in which we remarked good examples of Hall Door, Golden Knob, Winter Queening, Herefordshire Pearmain, Fearn's Pippin, Dumelow's Seedling, Golden Noble, Cox's Orange, Warner's King, Lincoln Pippin, Royal Russet, Lord Derby, Gloria Mundi, Hollandbury, and Reinete du Canada. Mr. Robert Doe, The Gardens, Rufford Abbey, Ollerton, a seedling, Apple; and various sorts came from Dr. Bull, Hereford; Mr. Divers, Maidstone; the Cranston Nursery Company, and from the Royal Horticultural Society's Gardens, Chiswick. A quantity of fine Schoolmaster Potatos were shown by Mr. Turner, Slough; some enormous Onions, by Mr. Walker, of Thame, of a kind named The Exhibition, seemingly a good variety for late use.

THE ANNUAL GENERAL MEETING was held the THE ANNUAL GENERAL MEETING was held the same day in the gallery attached to the large conservatory, at which but few Fellows attended. The President, Lord Aberdare, took the chair, the other members of the Council present being Sir Trevor Lawrence, Bart, M.P., William Lee, Esq., G. F. Wilson, Esq., E. G. Loder, Esq., Dr. Hogg, W. Haughton, Esq., Treasurer, and Major Mason, Esq., Secretary. The minutes of the last annual meeting having been read and confirmed. Dr. Masters W. Hanghton, Esci., Treasurer, and Major Mason, Esq., Secretary. The minutes of the last annual meeting having been read and confirmed, Dr. Masters and Mr. Charles Noble were appointed scrutineers of the ballot. The President called upon Mr. Haughton to explain the reason for altering the bye-law (No. 96) which unnecessarily compelled him to write his name on about a thousand blank subscription receipt forms every January, and which with proper safeguards could be just as well done by the clerks in the office, as the receipts were duly checked. The alteration was unanimously agreed to.

tion was unanimously agreed to.

The report having been taken as read, Lord Aberdare, in moving the adoption of the report and balance-sheet, said that the fact of the meeting being held where it was, was suggestive of the transitional held where it was, was suggestive of the tradistional position of the Society at that moment, and as a result of such uncertainty in their position he had to regret the fact that the number of resignations had increased, and that there was also a falling off in the number of persons seeking election. In 1882 124 Fellows resigned and 147 were elected, while last year the number of resignations was nearly 150, and the number elected was only 135. The connection of the Society with those gardens had in former years brought a great accession of members, and now that the connection was virtually terminated, inasmuch as it was now only a tenant on sufferance, it was natural that nection was virtually terminated, masmuch as it was now only a tenant on sufferance, it was natural that many Fellows should cease to care about member-stip, and that fewer candidates should seek admis-sion. His only surprise was that there had not been more resignations, but he was glad to know that the Society had not lost many of the Fellows who joined it solely on ancount of its horticultural status. As to the financial position of the Society he was glad to be able to say that for the first time in five years they had a balance in their favour, the general result of

the year's working being a balance to the good of £1864. The Council had availed themselves of their present flourishing position to wipe off all doubtful assets, and after making a clean sweep of all their liabilities they had still about \$800 in hand, and they assets, and after making a clean sweep of all their liabilities they had still about £800 in hand, and they looked forward to their financial position being still further enhanced during the present year. They had secured for the Fellows, from the authorities of the Health Exhibition, the same advantages as they had enjoyed last year, and against their loss of members they could well put their better financial position, and the increased interest which their present members took in the scientific character of the Society. Their present transitional position pointed out to them the necessity of making arrangements for obtaining a better lodging, and he was not without hope that at some future date the Society might attain to the digoity of those learned societies that were lodged at the public expense in Burlington House. There was one change in contemplation which he had to announce, though the final arrangements had not been completed, and that was that as they did not propose to hold a summer show themselves a proposition had been made to them that, in addition to the usual fortnightly meetings, monthly fruit and flower shows should be held in a building to be erected for that purpose in connection with the Society, but at the expense of the Health Exhibition authorities. He was sanguine that this proposal would be carried out in a liberal way, and houge the Fellows would derive

expense of the Health Exhibition authorities. He was sanguine that this proposal would be carried out in a liberal way, and hoped the Fellows would derive as much pleasure under this arrangement as they obtained through the large show.

Mr. Shirley Hibberd, who seconded the resolution, was gratified to know that the Society was in a sound financial position; but they should not forget that that was entirely due to their having got some of the mooce by an accident. As regards the management of the Society, he could not help stating that for some months past a feeling of distribut had arisen among practical men that the best interests of horticulture were not being developed by the Council; some months past a feeling of distrust had arisen among practical men that the best interests of horticulture were not being developed by the Council; their arrangements for the season were made so late that the growers of some things had no time to get them ready for the shows, and on that account the proposed monthly shows would not be so good as they might have heen. There was a danger, too, of the fortnightly meetings being starved out of existence, so little is the sum of money expended on them; but while the meetings suited the nurserymen as an advertising medium, something must be done to encourage the practical gardeners, or they would soon have nothing but trade groups, and the place would become but a branch of Covent Gardeo Market. On behalf of the International Potato Show Committee, he thanked the Council for the good service done to the committee by the facilities placed at their disposal at Chiswick, and paid a well deserved tribute to Mr. Barron and his staff for the most satisfactory manner in which the garden is maintained. Complaints having been made by one or two Fellows about the closing of some of the entrances, Lord Aberdare replied, and the motion was adopted without a dissentient.

without a dissentient.

The result of the ballot showed that the following The result of the ballot showed that the following elections had been carried unanimously:—Viscount Enfield, Professor Michael Foster, F.R.S., and F. Du Cane Godman, Esq., F.R.S., as members of the Council; Lord Aberdare as President; W. Haughton, Esq., as Treasurer; Major F. Mason as Serelary; and Messrs, John Lee, James F. West, and William Richards as Auditors.

A vote of thanks to the Chairman brought the meeting to a close.

meeting to a close.

Obituary.

PROFESSOR BALFOUR. — How many students in successive annual generations have taken their botanical nourishment from Balfour's Manual, or Class Book, it would be difficult to say, for though it might be easy for the registrar to give the numbers of those who attended the Professor's classes, first in Glasgow, then in Edinburgh, it would assuredly be a difficult, if not impossible, task to enumerate who indirectly claim Balfour as their teacher. Writing nearly ten years ago, we said of Balfour that he was a pre-eminently successful teacher-one whose zeal inspires, whose energy maintains, whose lucid style facilitates, the progress of his students. This was written not long before failing health induced the Professor to retire from the more active duties of his office. In our Edinburgh Supplement, which was published in September, 1875, we gave a full account of the Botanic Garden then under the directorship of Professor Balfour, and the Curatorship of Mr. MacNab. In that account we were naturally led to allude to the work done by the Professor-work which it was evident even then was in excess of his strength.

John Hutton Balfour, for long the most prominent

member of the medical faculty in the University of Edinburgh, was born in 1808, and in 1845 succeeded Dr. (afterwards Sir William) Hooker in the Chair of Botany in Glasgow. He was the friend and associate of Wight, of Falconer, of Dickson, of Greville, and a host of memorable men, most of whom have passed away before him, but who were knit together by the common bond of sympathy in the shape of a love for plants. Their excursions mid moor and mountain were fruitful, as a glance into many a berbarium testifies, and they formed the precursor of that series of herborising expeditions undertaken year by year by the Professor and his students with such zeal and with such advantage to the pupils. In 1845 the Chair of Botany in Edinburgh fell vacant, and Dr. Balfour was appointed to the office and to the Regius-keepership of the Royal Botanic Garden. The Professorship of Medicine was more nominal than real, so far as teaching was concerned; but, as Dean of the Medical Faculty, Balfour was brought into connection with his brother Professors and generation after generation of students. His powers of work and organisation and his sympathetic manner contributed largely to the advance that has been made in the progress of the University. seconded by Mr. MacNab and Mr. Sadler, both of whom predeceased him, Dr. Balfour brought the Edinburgh garden to a high standard of perfection, and especially of practical utility. New Palm-houses, museums, rockeries, all bear testimony to his zeal. The Edinburgh Botanic Society also profited largely by his example and constant aid. Some few years since, from failing health, Dr. Balfour resigned the active duties of the Professorship, being nominated Emeritus Professor. After some time his health improved, so that, to some extent, his death on Monday morning last, was unexpected.

Feb. 7.—Fine day and night; overcast.

8.—Dense log io morning; fine, dull afternoon and night. The maximum temperature of this day took plack at midnight.

9.—Look plack at midnight.

10.—Fine bright morning till 10.70 a.84.; showers of rain till 4.30 F.M. Fine clear night.

11.—Fine bright morning, deep blue sky; wet afternoon.
Fine clear night from 5 F.M.;

12.—Fine bright day and night.

13.—Fine bright day, deep blue sky. Rain at 10 F.M.; fine afterwards.

LONDON: Atmospheric Pressure.—During the week ending February 9, the reading of the barometer at the level of the sea increased from 30.33 inches at the beginning of the week to 30.49 inches by 9 A.M. on the 3d, decreased to 30.43 inches by midnight on the same day, increased to 30.45 inches by midnight on the 4th, and was 29.40 inches by the end of the

week.

The mean reading for the week at the level of the sea was 30.14 inches, being 0.44 inch higher than last week, and 0.20 inch above the average of the

Temperature. - The highest temperature in the shade in the week was 51°, on February 9; the highest reached on the 3d was 41°.2. The mean of the seven high day temperatures was 46°.5.

The lowest temperature was 29°, on the 3d; on

the 9th the lowest temperature was 42°.5. The mean of the seven low night temperatures was 37°.4.

The greatest range of temperature in one day was 12°.2, on the 3d; the smallest was 6°.3, on the 5th. The mean of the seven daily ranges was 9°.1.

The mean temperatures were — on the 3d, 36°; on the 6th, 45°.5; on the 6th, 45°.5; on the 6th, 41°.4; and they for the 5th, 41°.7; and these were all above their averages (excepting the 3d and 7th), which were 2°.8 and 0°.2 below) by 6°.4, 6°.5, 2°.3, 2°.6, and 8°.4 respectively.

The mean temperature was 42°.3, being 1°.4 lower than last week, and 3°.3 below the average of

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 70°.5, on the 7th. The mean of the seven

The lowest reading of a thermometer with its bulb placed on grass and fully exposed to the sky was 22°, on the 3d. The mean of the seven readings was 30°,2.

Rain fell on the 9th to the amount of 0.05 inch.

ENGLAND: Temperature,—During the week ending February 9 the highest temperatures were 53°,2 at Cambridge, 53° at Turo and Sunderland; the highest at Preston was 49°, at Bolton 49°,4, and at Bradford 49°,5. The general mean was 51°,2.
The lowest temperatures in the week were 24°,3 at Wolverhampton, 26° at Truro, 26°,4 at Nottiogham; the lowest at Liverpool was 35°,5, and at Bradford, Leeds, and Preston 30°. The general mean was 28°,5.

Leeds, and Preston 30°. The geoeral mean was 28°.5.

The greatest ranges were 27° at Truro, 26°.1 at Wolverhampton, 25°.2 at Cambridge; the smallest ranges were 17°.2 at Liverpool, 19° at Preston, and 19°.5 at Bradford. The general mean was 22°.7.

The mean of the seven high day temperatures was highest at Truro, 50°.7, at Sheffield 49°, at Liverpool 48°.7; and was lowest at Leicester, Bolton, and Bradford, 46°. The general mean was 47°.3.

The mean of the seven low night temperatures was highest at Sunderland, 40°.3, at Liverpool 40°.2, at Leeds 39°.4, and was lowest at Wolverhampton, 33°.5, at Truro 35°, and at Nottingham 35°.2. The general mean was 37°.3.

The mean daily range was greatest at Truro, 15°.7, at Wolverhampton 12°.6, at, Sheffield 11°.5; and was least at Bradford, 7°.1, at Treston 7°.5, and at Sunderland 7°.7. The general mean was 10°.

Sunderland 7°.7. The general mean was 10°. The mean temperature was highest at Liverpool, 44°, at Sunderland 43°.7, at Leeds 43°.2; and was lowest at Wolverhampton, 30°.4, at Bolton 40°.3, and at Nottingham 40°.5. The general mean was 42°. Rain.—The largest fail was 0.84 inch at Bolton, 0.63 inch at Truto, 0.55 inch at Sheffield; the smallest fail was 0.04 inch at Phymouth, and 0.05 inch at Bristol, Blackheath, and Cambridge. The general mean fail was 0.27 inch.

SCOTLAND: Temperature.—During the week ending February 9, the highest temperature was 53°.8, at Leith; at Greenock and Paisley the highest in the week was 49°.5. The general mean was 51°.6. The lowest temperature in the week was 24°, at Paisley; at Leith the lowest temperature was 31°.4. The agency mean was 22°.8.

The general mean was 27°.8.

The mean temperature was highest at Leith, 45°, and lowest at Perth, 41°.5. The general mean

45°; and rowes was age. 8.

Kain.—The largest fall was 2.03 inches, at Greenock;

Rain.—The largest fall was 0.11 inch, at Edinburgh and Aberdeen. The general mean fall was 0.60 inch.

Abies Nordmanniana: Duncke. The white substance on the branches is not a fungus, but the work of an insec atilized to the American blight of Apple the Apple of the Apple of

Asi Tennis Court: Old Suburiber. As described by a correspondent in our issue of March 5, 1881, the whole area of the court was excavated to about 8 inches in depth, and the bottom filled in with hard-burned ashes (clinkers), but any coarse hard material would be as good. This was rammed down, and then a layer of less coarse ashes put over it, fisishing off with a still finer stratum. This was pleasant to tread upon, being neither slippery nor hard, and only required nore frequent rolling than gravel. The "court" proper was marked off by strips of wood 1 inch thick

and 6 inches wide, let into the surface of the ashes, and level with it.

BOOK5: Mrs. Milward. Dr. Wallace's Notes on Lilies, published by the New Plant and Bulb Company, Colchester.

CYCLAMENS: $E.\ W.\ &\ S.\ A$ very poor sample as compared with what was shown at South Kensington on Tuesday.

AMP LAWS: F. W. S. Cynosurus cristitus would not be suitable. Either of the Poas, P. trivialis or pratensis, with or without a small admixture of Agrostis, would be preferable. If you make known your requirements to a respectable seed firm they will supply you with a mixture suited to your case. DAMP LAWN:

FLOWER SHOW MANAGEMENT: 7., Lak. 1. Certainly not. 2. You are an amateur. 3. The man should be allowed to show as a cottager.

GOOSEBERRIES: J. K. R. Aoy good free-bearing sort, like Monarch, will suit your purpose.

GRASS LAND: Correspondent. Apply nitrate of soda at the rate of 100 lb. per acre, about the end of March.

NAMES OF PLANTS: Camberwell Park. We cannot name the plant without leaves.—A. M. Acada deal-bata.—T. Griffiths. We do not recognise the variety.
—IV. Inglis. A very good form of Cattleya Triane.
—F. H. Guevina Avellana.—John Parnell. Lissanthe sapida.

sapida.

ORANGE AND CITRON TREES: Enquirer. Hard spring water, if it is aérated in some way before using, by exposing it in an over-ground open tank, would do your trees no harm. Deep planting is very iojurious. Get them up now, and do not cover the top of the ball with more than 2 inches of soil; remove a good portion of the bad soil, prune off diseased and decaying roots. Probe the balls with a thin pointed iron rod, so that water will reach every part. For soil use sandy fibry loam, not much decayed, one-eighth manure, and the same quantity of foely-broken wood charcoal, Ram this firmly round the ball, taking care to fill in all interstices properly, and finish off by leaving a shallow basin round the stems of the diameter of the ball. Water throroughly, but no oftener than is absoshallow basin round the stems of the diameter of the ball. Water thoroughly, but no oftener than is abso-lutely required. Prane in the heads symmetrically, and ply the syringe well night and morning after April till August, except when in bloom, and do not let them earry many fruits till health is restored. When they want top-dressing give them some bone-meal

PRIMULAS: C. G. Pretty, and good in colour, but too inneh like Chiswick Red to be considered distinct.

TAR: An Old Subscriber. It is only a question of de-gree, but the gas-tar is certainly much the most injurious.

VIOLETS: Iny-lea!. You do not say whether the Violets are grown in pots or in the open border; but in any case it is clear the soil does not suit them, and if they are in the open air the climate also may be unfavourable to them, for Violets will not do well everywhere. You ought to be able to obtain them from a cold frame, if the bed is made up of good sound loam and sand mixed with at least a third of leaf-mould.

SEEDS.

SEEDS.

LONDON: Feb. 13.—The seed market to-day was thinly attended, and no leature presented itself either of interest or importance. With regard to both red and white Clover seed there is this week no quotable variation; meantime, the demand is quiet, and buyers generally show an inclination to postpone their operations. In Trefoil and Alsike the tendency is downwards. Italian and perennial Rye grasses are also easier. Bird seeds are unchanged. According to the Board of Trade returns the imports last month into the United Kingdom of Clover and grass seeds were, 36,886 cwt., value £90.574; against 46,537 cwt., value £113,747, for January, 1883. John Sanu & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday the demand for Wbeat was very limited, but little business was transacted, and rates remained the same as on Monday se hnight, but were in a great measure nominal. Flour had a drooping tendency. There was not much doing in Barley, and the same as on the same as on Monday, but had been same as on Monday. Beans and Peas met as one same as on Monday, but had same as the same as on Monday. Beans and Peas moved off in retail at previous currencies. Maize was dull, with moderate arrivals. Barley was quiet and unchanged. Fair arrival of Oats and slow sale, at previous quotations.—Average prices of corn for the week eading February 9;—Wheat, 37. 3d.; sarley, 33. 4d.; Oats, 191. 6d.; For the corresponding period last year:—Wheat, 401. 8d.; Barley, 321. 3d.; Oats, 212. 3d.

HAY.

HAY.
Tuesday's Whitechapel Market report states that supplies were large, and trade very dull, especially for Clover, which was rather lower. Quotatioos:—Prime dol Clover, 955. to 1054.; inferior, 60. to 752.; prime second cut, 905. to 1055.; hay (first meadow), 80s. to 865.; inferior, 405. to 955.; and straw, 285. to 375. per load.—On Thursday there was a fair supply, but the trade was dull.—Cumberland Market quotations:—Superior meadow hay, 847. to 921.; inferior, 60s. to 721., superior Clover, 1001. to 1121.; iolerior, 60. to 845.; and straw, 345. to 385.

POTATOS

POTATOS.

The Borough and Spitalfields Markets reports state that there were moderate supplies and a quiet trade. Quotations:—Magnum Bonuens, 80s. to 100s.; Regents, 80s. to 90s.; Champions, 60s. to 70s.; Victorias, 80s. to 100s. per ton. — The imports into London last week consisted of 396 bags 1 case from Hamburg, 305 bags from Boulogne, 100 bags Bordeaux, 100 tons Landerneau, and 1 case from St. Nazaire,

COALS.

The following are the prices current at market during the week;—Walls Eod—Hettoo, 155.; Hetton Lyons, 135. 6d.; Lambton, 147. 6d.; Wear, 131. 6d.; Thornley, 145. 6d.; South Hetton, 157.; East Hardlepool, 145. 6d.; South Hardlepool, 136. 6d.; South Hardlepool, 136. 6d.

Government Stock.—Consols closed on Monday at roo½ to roo½ for delivery, and rot to ror½ for the account. The prices of Tuesday and Wednesday were roo½ to ror for delivery, and ror½ to ror½ for the account. Thursday's find Jupatations were, ror½ to ror¾ for delivery, and ror¼ for the account.

GRATEFUL-COMFORTING. EPPS'S COCOA.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocos, Mr. Fpgs bas provided our breakfast-tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enzough to resist every amound us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame," Civil Service Gazette.

Made simply with boiling water or milk. Sold only in Packets, labelled thus:—

WONDER." WORDSLEY

This valuable new Pea, now sent out for the first time, is the result of crosses between Advancer, Little Gem, and Prizetaker, and whilst possessing all the good qualities of the two former varieties, it has both the constitution and productiveness of the latter. It is a blue wrinkled marrow, growing 2½ feet high, of strong and vigorous habit, and we believe it to be the earliest Pea of the kind in cultivation, as it comes into use but a few days after Sangster's No. 1 and Kentish Invicta. The pods—produced in pairs at every joint—are of medium size, slightly curved, and each pod is literally packed with from 10 to 12 large Peas, which are exceedingly sweet, of beautiful colour, and the finest flavour.

Price 3s. 6d. per Pint. In Sealed Packets, Post-free.

WEBBS' VEGETABLES FOR **EXHIBITION** AND

WEBBS' Pride of Stourbridge Melon.

A magnificent new scarlet-fleshed variety, of delicious flavour, very free setter, and specially adapted for exhibition.

28, 6d. per packet.

WEBBS' STOURBRIDGE MARROW PEA.—This grand variety is unequalited for exhibition purposes or general use. It is second early, and grows about 4 feet high. 28. 6d. per pint.

WEBBS' ELECTRIC LIGHT PEA.—
The best main crop variety in cultivation; height 3½ feet. 3s. per quart.

KINVER GEM PEA, — This is undoubtedly the earliest round blue variety ever offered to the public; height 2½ feet. 18. 6d, per pint.

WEBBS' Perfection Broccoli.

From Mr. CHARLES WILLIAMS, Gr. to J. Pulley, Esq., M.P. "Your Perfection Broccoli is a grand variety. I have a fine lot growing alongside six niher kinds, 'Webbs' Perfection' sur-passes all."

6d. and 1s, per packet; 2s. per ounce.

WEBBS' KINVER MAMMOTH LONG-FOD BEAN.—This new Broad Bean is highly spoken of by every une. It grows about 3% feet high, and produces well-filled podsy, measuring 17 juches in length.

18. per pint. WEBBS EARLY PURPLE-TOP
TURNIP,—A distinct kind, of bandsome
shape and fine flavour. 6d, per packet.

ONION CRANSTON'S EXCELSIOR.

(Price per Packet, 1s. 6d.)

This grand new variety grows a very hand-some globe-shaped bulb, large and solid, with exceedingly small neck, and of a beautiful pale exceedingly small neck, and of a beautiful pale straw-coloured skin; it possesses mild flavour and excellent keeping qualities. It is perfectly hardy, and should be sown both for Spring and Winter crops; having been repeatedly tried against all the best sorts generally known in the trade, it has in every instance proved its superiority.

CRANSTON'S NURSERY & SEED CO. (LIMITED), HEREFORD.

CRANSTON'S "EXCELSIOR" ONION may be cured (at our own price) from any of following eminent Seed Merchants: any of the

IRELAND & THOMSON. 20, WATERLOO PLACE, EDINBURGH.

HURST & SON'S NOVELTIES for 1884.

PEA-DUKE OF ALBANY (Abbott's).

This splendid new Pea has proved to be the finest yet introduced, either for exhibition or for table, and unequalled as a main crop wriakled variety. It is very productive, bearing a profusion of extra large, well-filled pods, borne in pairs, which, being dark green in colour, are very bandsome, and contain from nine to twelve fine Peas each. The flavour and quality are also excellent. It grows about 5 feet high, is of a vigorous and branching habit, and should, therefore, be sown thinly. In Sealed Raif-pint Packets, 22. each.

WILTSHIRE GIANT SCARLET RUNNER.

A vigorous grower and heavy cropper. The pods are of a large size, very fleshy, deep green in colour, and of excellent quality. The best variety for exhibition.

Per Quart, 2s. 6d.; Per Pint, 1s. 6d.

SWEET PEA-PRINCESS BEATRICE.

Awarded a First-class Certificate by the Royal Horticultural Society as New Carmine Rose, August 14, 1883.

Since the introduction of the Invincible Scarlet nothing has been offered as a novelty in Sweet Pess equal in merit to this charming variety. The colour of the flower is a rich and beautiful carmine-rose, slightly shaded with lighter and darker tints, entirely distinct from any other kind. They are of remarkable substance, similar is this respect to Violet Queen, but the plant has a much more robust and free-blooming habit than the latter. It is perfectly constant, and the perfume is remarkably sweet, more so than in any other sort.

It will undoubtedly become one of the leading varieties of this useful and popular annual, and can be recommended as one of the very best of hardy flowers for cutting purposes.

Per Packet, 18, 6d.

MYOSOTIS SYLVATICA COMPACTA AUREA.

The merit of the Old Cliveden Blue Forget-me-Not, particularly as a spring bedding plant, is so universally regulated that this new golden-leaved variety cannot fail to become a popular favourite. It is similar in habit and colour of foliage to the Golden Pyrethrum; the flowers are of the same clear bright blue as its prototype, and their contrast to the golden-yellow of the foliage is one of its chief merits. As its name implies, it is of peculiarly dwarf compact habit, and as a spring bedder it is destined to occupy a most conspicuous place.

PRICE TO THE TRADE ON APPLICATION.

HURST & SON, 152, Houndsditch, LONDON, E.

CUTBUSH'S MILL-TRACK MUSHROOM DECENTION ONCE used as other will receive the superior of the superior of the Price Gr. per bushel, or 6d, per cake; None genuine unless in sealed pack-ages and printed cultural directions enclosed, with our signature Tutter.

WM. CUTBUSH AND SON (Limited), Highgate Nurseries, London, N.

WHEELER'S

OF EXTRA FINE QUALITY.

pouble GLOUCESTER.—This remarkable variety is one of the most productive Potatos ever introduced. It bears an enormous crop of good sized tubers, which are of excellent quality for the table. His entirely, free from disease. Its compact habit of growth, and its capability of bearing cutting well for seed (it is advisable that each piece should have at least two eyes), renders it a very economical and profitable variety. It is of excellent flavour and good colour. We feel sure it will become a popular variety for the garden, and, as it is so remarkably productive, that it will also become a Farmer's Favourite.

Price 4s. per peck; 14s. per bushel.

RECORDER (Dean) WHITE KIDNEY.—
First-class Certificate of Merit, International Potato
Committee, 1882. From Success and Woodstock
Kidney. A very fine, second early white Kidney;
tubers long, flat, smooth, and handsome, a great cropper and excellent quality. A first-rate garden Potato;
very distinct, and a rare acquisition. We hold the entire
stock of this valuable variety. It is excellent not only for
exhibition but of high-class quality for table use.

Price 1s. per pound ; half-peck, 6s. ; peck, 10s. 6d.

WHEELER'S GLOUCESTERSHIRE KIDNEY maintains its position as one of the earliest and best Potatos in cultivation.

Price 3s. per peck.

NOW is the TIME to PLANT CARNATIONS. TWO NEW VARIETIES.

MARY MORRIS.—One of the most valuable of moder introductions. Of a strong, vigrous habit, producing monstrous flowers, often 235 inches in diameter, of an attractive deep rose colour. Has been awarded a First-class Certificate.

CLOVE "GLOIRE DE NANCY." WHITE -Without question the finest White Clove ever intro-luced. It has a very robust habit, like the first into-luced in the second of the second profusion, commence sized flowers, which are pure white and delict-ously Clove-scented. Has been awarded a First-class Certificate.

Certificate.

CATALOGUE, containing fuller descriptions of the above, with a vast number of other choice Carnations, as well as every other section of HARDY FLORISTS' FLOWERS, is now eady and shall be sent free to all applicants.

WILLIAMS' Prize Strain of

LOXINIA,

Per packet, 1s. 6d. This produces immeose flowers, o he most brilliant and varied colours, ooth of the erect and drooping rarieties.

WILLIAMS' POLYANTHUS. GOLD LACED.

Per packet, 18.

Very Superior Strain. Has taken numerous First Prizes.

WILLIAMS'

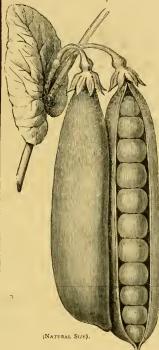

PRIMULA SINENSIS FIMBRIATA, unset packets, containing six erneties, containing six erneties, and and the fer packet, and and the fer packet, and and the fer packet, and and the fer packet fails to take its Prizes wherever exhibited. For ewe Fimulas and supperb strain of Primulas, see Illustrated Seed Catalogue.

Illustrated Seed Catalogue for 1884, Gratis and Post-free on application.

THE LATEST

INCULTIVATION.

Per pint, 1s. 9d; per quart, 3s.

"'Latest of All' Pea attains an average beight of 3 feet, is robust and very productive; the large closely-packed pods being produced from the bottom to the top of the haulm. That the Peas are of good colour and flavour it is hardly necessary to say, but it must be stated that the variety, owing to its robust constitution, is well able to resist the attacks of mildew, which usually does so much damage to the main-crop Peas in hot summers," — Geneticiers' Mogazine, January 20, 1831.

"Your 'Latest of All' Pea is an excellent variety. Grown alongside Veitch's Perfection, it proved of better constitution than that good old variety; very prolific, and of the best quality."—Mr. W. ICCULDEN, Gardener to the Right Hoo. the Earl of Cork and Orrety, Marston House.

CUT FLOWERS.

ROM the days of old, when Rome's champions and athletes were crowned with Laurel, down to the present, flowers for personal adornment have been more or less held in estimation by all civilised nations. In fact, the extent to which these gems of earth find favour might be taken side by side with an appreciation of the arts of sculpture or painting, as a measure whereby to gauge the degree of civilisation that a people has attained. If this be correct, it cannot be said that there is a retrograde movement at the present day, for if there is one thing more remarkable than another it is the immense increase in the demand for flowers that has taken place within the last decade or two of the century. Nor is this confined to those possessed of the greatest wealth, and who can afford to pay extravagant prices for costly rarities in flowers as in other things, although in their case the demand may be safely set down as having increased tenfold within the time named. In what is understood as middle-class society the use of flowers has alike grown, and it has reached a lower stratum, as may easily be seen by a glance at the market in any manufacturing town, where will be seen loads of posies made of Primroses, Daffodils, Wall-nowers, Dasties, Roses, Pelargoniums, and other welcome favourites, which are sold by thousands in these hives of labour; even the costermonger who supplies the residents in the back streets with Potatos and Cabbages has his bunches of common flowers in their season of plenty, for which he finds ready sale.

As a natural consequence, along with an increased liking and demand for flowers, there has been a marked improvement in their arrangement, whether in the decoration of a table, the filling a vase or a basket, the formation of a wreath, or of a bouquet or a button-hole. In all these cases the arrangement can now be effected by many in a way that admits of the work being associated with productions of art. It will be considered that this is not claiming too much when we see that groups of flowers are often subjects that painters of note take to delineate, for surely an arrangement of flowers that is faultless from an artistic and elegant point of view has some little pretensions to be classed with its representation. And it may be well here to hint that those who would excel in the arrangement of flowers will do well to study the simple elegance in the grouping and association of the colours on the canvas of acknowledged masters of the art in this particular branch of painting; in such there will be found no crowding, or formality in the groupingnothing to show that there was a superabundance of rich materials at command, such as is too often apparent in floral arrangements, by which all pretensions to elegance are destroyed. Neither will there be found that indescribable mixture of colours and shades so destructive of harmony; in place of these a few kinds, often not more than one or two, are introduced to the picture, loosely put together so that each flower has a space between it and its neighbour equal to or more than that which it fills. A table arranged in this way, or a vase or basket, in

which only a sufficient quantity of flowers of a few sorts and colours is used, with enough green foliage, is so much superior to the overdone affairs frequently met with that it would scarcely seem needful to urge it were it not that the opposite course is so often followed.

In table decoration better taste prevails than when the cumbrous high epergnes were in general use. Even the improved stands, made as light as possible, and which, when nicely filled with a few suitable flowers, Ferns and the like, had a chaste elegant appearance, have, with many, given place to low shallow appliances not many inches high, or to a moss bed hid over the cloth in which the flowers and greenery are placed. Here, again, may be seen the advantage of using only a few kinds of flowers; equally limited in their colours, and with a no larger quantity than may be needful to avoid meagre appearance. In this kind of decoration, as in all others where flowers are used, there is one important matter that should never be overlooked-that is, a due regard to proportion in the size of the flowers for the particular use they are to be put to, or that of the receptacle in which they are to be placed. Big Poppies, Pæonies, or Lilies, and full-sized Richardias, are admissible, when furnished with long stalks, in large vases proportionate in size to the flowers they contain; but otherwise they are incongruous in the extreme. As to the big, overgrown Sunflowers that one sometimes sees used in floral decorations, they simply afford an evidence of the lengths some people will go to in imitation of any absurd fashion, rather than think for themselves as to the fitness of things. The same principle as to suitability in size in the flowers used holds good in whatever way they are disposed. Flowers that are individually large and massive are wanting in the elegance present in those that are smaller; of the latter there should always be enough present to prevent the sem-blance of a formal even surface; to further guard against this the targest nuwers in each combination should be relieved by others protruding further than them, no two placed by each other being equal in height. If this course be not followed the production will not unlikely result in a display of formal informality, which is only a degree less objectionable than the

Following the same law of proportion, the largest blooms should always be placed at the bottom, or lowest in the arrangement, whether it is a vase, a wreath, a bouquet, or anything in which a combination of various sized flowers are used. Many a bouquet that otherwise would have been a creditable production is spoilt by having a big Camellia or something similar stuck right at the top. Stands of the March shape, or any of the numerous modifications of them now existent, should always have whatever large flowers are used for furnishing them placed in the base, and principally at the outer edge. Colour has also a good deal to do with apparent size; high or dark coloured flowers fill the eye more than white or light shades, conveying an idea of size. To put high coloured flowers in the upper part of stands of this description is a glaring mistake; the largest and darkest should be at the base, such as are medium in size and colour next above, with the lightest-coloured and smallest at the top. The same principle is applicable in the case of an ordinary vase, stand, or basket. The largest size and deepest colours should be used in the base or foreground of the arrangement, with the smaller more elegant forms and lighter shades at the top. Stiff, erect spikes, even if composed of individually small flowers, can rarely be used with such good effect as those that are flexuous and drooping.

The rule which applies to the use of only a fewflowers loo ely put together, as advised in the filling of vases, stands, &c., cannot be followed to the letter in making hand-bouquets, as if so

sparingly used in these, having to be carried about, they would directly have a flagged, straggling appearance that could not be tolerated; at the same time, any approach to crowding the material together should be avoided. Better to err in the opposite direction; each flower should have enough room to only slightly touch those next to it; no crushing together ought to be allowed. To avoid their getting packed too close, there is no recourse except mounting almost every flower on a separate piece of wire that will hold them in the required position. Here again the largest flowers should always be placed near the base, and the deep colours also kept well away from the top, in bouquets as well as in all other combinations of flowers of high or dark colours, such as the different shades of red and purple, or dark blue-a little goes a long way-and they should be very sparingly used, or in place of the required chaste elegant appearance a glaring monstrosity will be the inevitable result: far better have a bouquet too light coloured than too high. As to the Ferns and other green foliage indispensable in all flower combinations, these should never be used with a sparing hand. Fear of hiding the flowers by using enough green material spoils half the arrangements of the kind that are attempted. Not only should there be sufficient green garniture to form a base, but also spersed amongst the flowers. A mistaken idea, that rare productions must necessarily be better than such as are commoner, leads to the native grasses, many of which are unequalled for their elegance, not being used nearly so much as they deserve to be even in the season when they are in suitable condition. As to the size hand-bouquets are now made it is useless to speak, it is simply a question of elegance and adaptability on the one hand, and fashion on the other; and the latter so far prevails with many that the former essentials are not considered worth a thought.

What may be called ladies' button-hole flowers, or the sprays that are now so much worn, are fast following the fashion of the bouquets in their propertion of size, and it is hard to say where they will stop when double red Paconies and Sunflowers are worn in this way.

The competitions in the various arrangements of cut flowers now so generally introduced by horticultural societies, have no doubt done much in furthering a better taste in such matters. Yet it is evident in this, as in everything else where the touch of the artistic hand is required, that those who can excel must have a natural taste for the work, otherwise the beautiful combinations of form and colour so frequently forthcoming from the master hands in this kind of decoration would not stand out so markedly in advance of the general run of such productions.

GUMMING IN FRUIT TREES.

AN essay, by my friend Dr. Beijerinck,* on the contagion of the gum-disease in plants, which has lately been published by the Royal Academy of Sciences at Amsterdam, contains so many facts likely to be useful in the study of contagion that I venture to ask you to iosert a brief notice of its chief contents. The gum disease (gummosis, gumfux) is only too well known to all who grow Peaches, Apricots, Plums, Cherries, or other stone fruits. A similar disease produces gum-arable, gum-tragacanth, and probably many resins and gum-resins. It shows itself openly in the exudation of thick and sticky or hard and dry lumps of gum, which cling on branches of any of these trees where they have been cracked or wounded through the lark. To any students of medicine or pathology who live within range of such trees, Dr. Beijerinek's observations may suggest some interesting researches.

Dr. Beijerinck was induced to make experimental inoculations of the gum-disease by suspicions that, like some others observed in plants, it was due to bacteria. He ascertained that it is in a high degree contagious, and can easily be produced by inserting the gum under the edge of a wound through the bark of any of the trees above named. The observation that heated or long-boiled pieces of gum lose their contagious property made it most probable that a living organism was concerned in the contagions; and he then found that only those pieces of the gum conveyed contagion in which, whether with or without bacteria, there were spores of a relatively highly organised fungus, belonging to the class of ascomycetes; and that these spores, inserted by themselves under the batk, produced the sume nathelogical changes as did the pieces of gum

same pathological changes as did the pieces of gum. The fungus thus detected was examined by Professor Oudemans, who ascertained it to be a new species of Coryneum, and has named it Coryneum Beijerinckii. Its characters, which are minutely described, are chiefly that it has a cushion-like stroma, consisting of a bright brown parenchyma, on which numerous conidia stand on colourless, unicellular and very slender stems, about as long as themselves. The conidia are small, cask-shaped, about one-thirtieth of a millimetre in length, and usually divided by slightly constricting septa into four cells, of which the two terminal are longer than the two middle. From these cells germinal filaments may proceed, from which are developed either yeast-cells, or brown thick-walled and many-celled mycelia.

and many-cented mycera. The inoculation experiments are best made by means of incisions through the bark of young branches of healthy Peach trees or Cherry trees, and by slightly raising the cut edge of the bark and putting under it little bits of gum from a diseased tree of the same kind. In nearly every instance these wounds become the seats of acute gum-disease, while similar wounds in the same or other branches of the same tree, into which no gum is inserted, remain healthy, unless, by chance, gum be washed into them during rain. The inoculation fails only when the inserted pieces of gum contain no Coryneum.

By similar inoculations similar diseases can be produced in Plum, Almond, and Apricot trees, and with the gum of any one of these trees any other cao be infected; but of many other substances which Beijerinck tried, not one produced any similar disease.

The inoculation with the gum is commonly followed by the death of more or less of the adjacent structures; first of the bark, then of the wood. Small branches or leaf-stalks thus affected in winter, or in many places at the same time, may be completely killed; but in the more instructive experiments the first symptom of the gum-disease is the appearance of a beautiful red colour around the wound. It comes out in spots like those which often appear spontaneously on the green young branches of Peach trees that have gum-disease; and in these spots it is usual to find Coryreum-stromata, or mycelium-filaments. The colour is due to the formation of a red pigment in one or more of the layers of the cells of the bark.

But in its further progress the disease extends beyond the parts at which the Coryneum, or any structures derived from it, can be found; and this extension, Beijerinck believes, is due to the production of a fliid, of the nature of a ferment, produced by the Coryneum, and penetrating the adjacent structures. This, acting on the cell-walls, the starch-granules, and other coastituents of the cells, transforms them into gum, and even changes into gum the Coryneum itself, reminding the observer of the self-direction of a stomach.

In the cells of the cambium, the same fluid penetrating unites with the protoplam, and so alters it that the cells produced from it form, not good normal wood, but a morbid parenchymatous structure. The cells of this parenchyma, well known among the features of gum-disease, are cubical or polyhedral, thin-walled, and rich in protoplasm. This, in its turn, is transformed into gum, such as fills the gum-channels and other cavities found in wood, and sometimes regarded as gum-glands. And from this also the new ferment-fluid constantly produced, and tracking along the tissues of the branches, conveys the Coryneum infection beyond the places in which its mycelium can be found. Communicated by Sir James Paget, Bart., F.R.S.

GLADIOLUS QUARTINIANUS is a tropical African species, lately introduced to Kew. The flowers are pale yellow, flushed and streaked with scarlet. The innermost petal is larger than the others, and conceals the purple anthers in its hood-like tip. It is figured in $Bot.\ Ma_{S^*}$ (1884), t. 6739.

ORCHIDS AT MESSRS. VEITCH'S

NEARLY thirty-two years of carnest study and care, coupled with a continuous and lavish outlay in introducing new plants and raising new structures for their accommodation, have rendered the collection at the Royal Exotic Nursery, King's Road, Chelsea, the largest, richest, and best cultivated trade collection in the world. Of course the long career of Orchid growing before the Chelsea establishment was started, and that knowledge acquired in the infancy of the Orchid science in which the name of Veitch played such an important and lasting part, would lead us to expect no other result; nevertheless, in these days of spirited competition it is no small compliment to pay to the owners of any such gigantic establishment to say that they have always maintained the lead in whatever they have taken in hand, and more particularly in the It is a pleasant task to view the beauties gathered from all parts of the world and contained in their thirty Orchid-houses, for go when you will even the hottest houses are carefully regulated and ventilated, so that they are only just comfortable and never oppressive. This system was first studied by the Chelsea firm for the comfort of the visitors, but the plants seeming to like the cool and airy treatment so well, it soon became the standing rule never to keep any section of Orchids in so high a temperature as to feel uncomfortable even to the most delicate of mankiod. Thus it is comfortable to view the plants, but as our duty is to notice them, where are we to begin among the thousands of lovely things commanding attention? A most difficult task is before us, for it would be almost as easy to do justice to one of the large sections of the British Museum in a couple of columns as to say even a word each for the countless new and fine things which so many distant Orchid growers would like to hear about. No other course is before us than to touch only on those in bloom, and, careful as we may be, a great quantity of them will no doubt be missed.

Messrs. Veitch's method of arranging the Orchids in bloom is a good one. At the entrance of the Orchid department a long range of lean-to north houses receive the flowering plants from several of the smaller and more out-of-the-way houses, and thus provide a lovely show near at hand for the general plant lover who would not have time to go the round of all the houses; here be may feast his eyes and go away contented, but this is only the commencement of the real Orchid lover's pleasure, for every one of the large houses beyond contains the plants which flowered in it, and is a veritable show-house in itself at all seasons. Here on any day in the year are to be seen some or other of those famed plants whose reputation has spread over the whole of Europe wherever Orchid-growing has been commenced-and where has it not been commenced? The first long house viewed from the doorway seems like a walk between two banks of the beautiful Odontoglossum Alexandræ and O. Pescatorei, for on either hand, sloping from the roof, and falling over the staging, are countless huge spikes of those varieties in their endless variation, those of many of the O. Pescatorei being so much branched and so profusely flowered as to cause wonder how the plants could bear them. On entering, however, we find there are well-bloomed plants of many other species which help to show off the snow-white flowers of the two first-mentioned, and give variety to the general display.

Among them may be mentioned some good forms of O. Wilckeanum, O. luteo-purpureum hystrix, O. l. radiatum, a profusion of O. cirrosum, many O. Rossii majus, O. Cervantesii, O. nebulosum, O. triumphans, O. tripudians, O. Coradinei, O. Ed-wardii, some fine pots of the bright orange Ada aurantiaca, Sophronitis grandiflora, Oocidium vari-cosum, &c. Among the rare things in this house are a splendid large form of Odontoglossum blandum, with lange mauve-dotted labellum, and quite distinct enough to warrant its being distinguished by a special name : the rare and pretty O. prænitens; a very fine form of O. Hallii xanthoglossum, a prettily spotted variety of O, Chestertoni, and a neat hybrid Odontoglossum resembling some of the forms of O. Andersonianum, but having the shape and substance of O. Ruckerianum. The next house is a wonderful sight, many hundreds of blooms of Lycaste Skinneri being there mingled with fine pans of Cologyne cristata, both the ordinary, Chatsworth, and the Lemoniaga varieties; and to introduce colour, and to bring forward favourites,

some of those heautiful hybrid Cypripediums for which this firm is noted are interspersed here and there. The Lycastes are a study in themselves, such endless variety do they present, their tints varying from the palest flech colour through all shades up to the intense crimson-lipped forms, and although many scores of plants are in bloom no two flowers on different plants can be found alike. The great variability of this lovely Orchid offers a reasonable excuse for building a Lycaste-bouse, indeed Mr. Lee, of Leatherhead, and a few other growers have done While on the subject of Lycastes it will be well to say that Mr. Canham, Messrs. Veitch's Orchidgrower, whose twelve years' experience at such an establishment after many years of Mr. Pilcher's tuition renders him no mean authority, considering that the success of the Chelsea Lycastes is in a great measure due to their being kept all the year in the cool north house on the end of this range, and in which the stock looks very healthy, and showing well with bloom in spite of the quantity taken into the house previously mentioned.

The large airy Phalænopsis-house is also a north house on this range, and it is probable that its aspect, too, may have something to do with the great vigour of the plants contained in it, for during the years they have occupied this house not a single instance of or degeneration has occurred; and yet spot during that period many have started Phalænopsis growing with everything seemingly in their favour, and have lamentably failed. The failure may always be traced to the same causes—over-heat, want of sufficicent and permanent ventilation, too much sunlight, too much water when not making growth, and too much stuff about the roots. In Messrs. Veitch's house will be found a great quantity of P. Schilleriana in bloom, as well as good representatives of most of the other species or varieties, including a splendid form of P. leucorrhoda, and another resembling P. casta, P. Stuartiana, &c. In this house, too, the Cypripedium niveum grows very freely. Passing up the large span range in several divisions reveals flowers on all sides, not arranged without due consideration of effect or the interest to be derived from comparison; for instance, in the first division we found grouped together Dendrobium nobile, D. heterocarpum, and their offspring, the varieties of D. Ainsworthii and D. splendidissimum. In the comparison the last-named—a Veitchian production—has decidedly the best of it, splendidissimum. as the flowers seem more to resemble a Wardianum × than a nobile. Here, too, are D. crassinode album, 1). macrophyllum, nearly white variety; a quantity of D. Wardianum, D. Findlayanum, Calanthe Regnieri, Angræcum sesquipedale, Saccolabium gigaoteum (a very fine form), Cymbidium Lowianum, with five long arching spikes; Epidendrum Wallisii with twenty-eight spikes, several Vandas, &c.

The several Cattleya-houses are well stocked, many of the plants being imported direct. One house is filled with the C. Trianæs, which Messrs. Veitch imported only in March last, and yet the plants have pow turned their apartment into a show-house-the quality of the flowers seat up from the 500 sheaths and the intensity of their colours causing one to think less of the petted varieties of old. To follow on the Trianges hundreds of flower-sheaths of C. Mendelii appear, and after that the succession is well marked in the other species to warrant us in saying that there will be no scarcity of Cattleya blooms throughout the whole year. In a division of this range are many good varieties of Lælia anceps, some of them being white ones, and with them are two of the finest and most distinct forms of Oncidium unguiculatum ever seen. A peep into the private Orchid-house discovers Mr. Seden among his prolific family, many of them again pregnant with wonderful things, not to be revealed perhaps until many of us have passed away. Every year, however, brings to this firm rewards for its forethought in taking up and persevering in Orchid cross-fertilisation, and even now some povelties are exhibiting their first flowers. Scattered through these houses are blooms of many things rare and interesting, which it is gratifying to be allowed to inspect. The large new Cattleya-house (what Orchid establishment is now without its new large house?) is nearly finished; it is a perfect structure, 130 feet long and 22 feet wide, and seems to be well adapted in every detail for the culture of Cattleyas and Vandas.

In the nursery we found everything as clean and neat as usual, the famed collections of Nepenthes, Sarracenias, Droseras, &c., in beautiful trim, and the

house of Amaryllis, containing over 2000 bulbs, many of them producing two spikes each, superior to anything that has yet been seen of its kind. Lovers of Amaryllis would do well to inspect the houses at Messrs. Veitch's, and endeavour to learn their system of treatment for these bulbs, as it seems to have been well and successfully studied by them.

JENSEN ON THE POTATO DISEASE.

(Continued from p. 208.)

III. INFLUENCE OF TEMPERATURE UPON THE DISEASE. - In a previous communication to the Gardencrs' Chronicle (July 28, 1883) I gave a resumé of Mr. Jensen's investigations concerning the geographical distribution of the disease, in which he observed that the Peronospora could not exist in those countries where the mean temperature exceeded 77° Fahr. for any length of time during the Potato eason. The influence of temperature upon the Peronospora has been worked out by Mr. Jensen by means' of slices of Potato dipped in spore-charged water and placed in constant temperatures.

IV. CAN WE DO ANYTHING TO RETARD THE OUTBREAK OF THE DISEASE?-If it be true that an early outbreak means a small crop, naturally the question arises, Can we do anything to convert an early into a late outbreak of the disease? Certainly we cannot influence the weather; if we could there would be easy solution to many agricultural difficulties which now baffle us; but although we cannot lessen the rainfall we can reduce the number of starting points from which the disease commences. By subjecting our seed Potatos to such a degree of heat that shall be fatal to the Peronospora, but not sufficiently high to injure the Potatoe, as has been already shown. The spread of the disease is at first comparatively slow, and therefore much may be expected by thus disinfecting our seed Potatos. Of course individually we cannot retard the appearance of the general outbreak, although this could be accomplished by co-operation. Time might be gained, too, by adopting the well-known device of letting our seed Potatos sprout, after being disinfected, in suitable places, under cover before they were planted. Mr ensen considers, by adopting these two plans, something like from two to four weeks might be gained before our neighbours gave us sufficient conidia to produce the general outbreak. What two to four weeks' start of the disease in an early year means may be gathered from the subjoined table by König and Hammerbacher * obtained in 1857 at Munster, showing the total solid residue of young tubers :-

Seed Potatos,	9 16	grammes,	sown	April	32.

That it is possible to kill the fungus in tubers without injury to the germinating power of the Potato by the application of heat Mr. Jensen has shown, and that there is a margin of from 8° to 10° C. (from 15° to 20° Fahr.) to come and go upon. In the subjoined table the points are shown very clearly. The tubers experimented upon on September 1 and

J. König, Fr. Hammerbacher, and C. Brimmer, in Bieder-tami's Central Blatt, 1878, pp. 273, 274.
† Konig and Hammerbacher, loc. ct.

These tubers were exposed to a dry heat for four hours-to a temperature above 40° C. (104° Fahr.); after which none of them gave conidia, although their germinating power was unimpaired.

V. IS THE FOLIAGE MORE SUSCEPTIBLE TO DISEASE WHEN THE PLANTS HAVE ATTAINED A CERTAIN STAGE OF DEVELOPMENT?-It has been said that the foliage of young Potatos is not so susceptible to the disease as that of plants more mature. The following experiment was tried:—Six flowerpots, each containing one Potato planted at different dates, were placed in the first days of July, 1883, in a row about 10 inches apart near some Potatos affected with the disease. On July 27 the diseased leaves on each plant were counted, with the following result :-

	Plants appeared above ground.	
Nos. 1 aod 2	June 12	72
,, s and 6	Juae 30 July 8	51

Nos. 1 and 2 were nearest the diseased Potatos, from which they were distant about a yard, and had, as might be expected, rather more diseased leaves than those further distant; but the youngest of all, which had not been above-ground until nearly a week after the others were exposed to infection, had even more disease upon them than Nos. 3 and 4. It is a matter of common observation that the disease first makes its appearance upon the lower leaves of Potatos, and it has been thought this was because, being older, they were more susceptible than the upper. this is not the real cause is shown by the simple experiment of bending the stems down close to the ground, when it will be found that the upper leaves fall as easy a prey to the fungus as the others. true explanation is, that the nearer the ground the more moist and the more stagnant is the atmosphere surrounding the foliage, for next to heat nothing is so fatal to the conidia as dryness. Hence the upper leaves escape longer than the lower, because they are more exposed to the wind. As a rule the foliage of the late varieties is less susceptible to the disease than that of earlier sorts, but this is really of no advantage to the Potato grower, because, being less advanced when the disease does attack them, the injury done to the foliage has more deleterious influence upon the development of the tubers than is the case with the earlier varieties, which have attained a greater degree of maturity when the disease comes upon them.

When a very young leaf is attacked by the Peronospora, its tissues being more tender, the fungus penetrates more easily into them, so that, as a rule, we find the disease passes from the substance of the leaf into the petiole, which causes the leaf to wither and hang down often before the mycelium has had time to destroy it entirely, as is the case with the older leaves. In fact, like other parasitic fungi, the Peronospora attacks young plants more vigorously than old ones.

VI. THE SPREAD OF THE DISEASE IN NATURE. -As has been previously stated, the spreading of the disease is very slow at first, but extremely rapid when

once it has become fully established. This apparently sudden spread has been thought to be due to the sudden maturity of resting-spores. The suddenness, however, is apparent only, not real. In order to see how this spreading occurs, an experimental plot was examined about a fortnight after the disease first made its appearance in it. Every plant was examined, and the number of diseased leaves upon it counted. A map was then constructed showing each plant with the number of diseased leaves. By this it was distinctly shown that :- I, the disease developes in the direction of the wind; 2, it has a tendency to follow the rows; 3, it is developed from centres. C. B. Plowright.

(To be continued.)

TRITONIAS.

WERE it not for the consignments of Ixias, Sparaxis, Tritonias, Babianas, and other bulbs of a similar character that come to the London seed houses in spring from Guernsey, and which can be seen at one or other of the meetings of the Royal Horticultural Society, the dwellers in London would scarcely have an opportunity of seeing these charming South African bulbs. How they are admired when set up in such a state of perfection! But how many cultivate them? And yet they find a place in bulb catalogues, and there must be a demand for them.

The Guernsey growers make a list of the following varieties: - Amoena, orange, centre spotted with bright yellow, each spot encircled with crimson; Fulgens, bright orange-scarlet, very effective; Laura, deep salmon, a very pleasing colour, and regarded as a great acquisition; Longiflora, buff colour, long tube-shaped flowers; Longiflora rosea, of the same character as the foregoing, but rose-coloured; and Speciosa, brilliant orange-scarlet.

Some quarter of a century ago there lived a clever gardener who used to grow with considerable success a collection of Cape bulbs, and among them some of these charming early flowering Tritonias. to pot a few at intervals from August to the end of October, in order to ensure a succession of bloom, putting three or more bulbs in a pot, according to the size of the pots and the hulbs, they being well drained and filled nearly to the rims with the rougher parts of the compost used; then the bulbs were placed on this, and covered with some finer soil. The compost used was made up of pure turfy loam of a sandy nature, some peat, and silver-sand, and in the case of Sparaxis and Ixias a little more silver-sand was used; the only manure employed being some well-rotted cowdung. When potted they were placed in a cold frame, and covered over with ashes, as one would Hyacinths. This was in the days before cocoa-nut refuse was introduced, else that is the hest material that can be employed for the purpose. As soon as growth was apparent the covering was removed, and the growing plants brought nearer the glass, but protected by covering in frosty weather.

As the days lengthened, and genial weather happened, the sashes were removed, and every encouragement given to the plants to make a kindly growth, and warm showers were suffered to fall upon them. In this way charming pots of flowers were had that were of great decorative value in the greenhouse in April and May; the later sorts further on.

But this grower used to care for the bulbs after they

But this grower used to care for the bulbs after they had done flowering, which is perhaps what is not done in these days, when there is such a greater number of things to cultivate. When they had done blooming they were put aside in a cold frame and cared for, watering in dry weather, until the foliage decayed, then the bulbs were shaken out of the soil and put away for potting another year. The same was done with Juic Scenaric and Pabliance additional contents of the soil and put away for potting another year. then the bulbs were shaken out of the soil and put away for potting another year. The same was done with Ixias, Sparaxis, and Babianas, additions being made as new species and varieties were announced. The beautiful Freesia refracta alba, which Messrs, James Veitch & Sons showed in such fine condition with maniful of the Paris Hosticitus Springer of the Paris H

at the meeting of the Royal Horticultural Society on the 12th inst., was so charming that they should serve to call attention to the beauty of the Cape bulbs. Such a course of treatment as that followed in the case of the Tritonias would do for the Freesias, but they are of such early growth that it is necessary they be obtained as soon as possible, and potted as required from August to October, if not too far advanced. But it is almost useless to recommend border culture unless a garden be prepared specially for them. Then there is one cheereful. for them. Then there is some chance of success; but it planted in ordinary garden soil they will fail for lack of conditions essential to success. Pot culture is what is required—suitable soil and proper management—and then success may be looked for, and with it a revelation of beauty unknown to thousands of modern gardeners.

THE HEMLOCKS. - Every one remembers Longfellow's lines-"This is the forest primæval. The murmuring Pines

and the Hemlocks Bearded with moss and in garments green . . . ;"

but not every one knows that the beautiful Hemlock Spruce of our gardens, Tsuga canadensis, is the tree intended. The truth is, we rarely see it save in the bush form, and are apt to overlook the fact that it is a timber tree even, although here and there we meet with trees of this species, but which, to say the truth, are scarcely so elegant as when in a younger state, The illustration we give, through the courtesy of Professor Sargent (fig. 45), of a group of these trees in the Arnold Arboretum at Boston, will show that it is capable of forming straight boles. Its timber is only of second-rate quality, though useful for certain special uses, and the bark is largely used for tanning Tsuga is one of those tiresome genera that purposes. seem to have been made to plague the botanists. It is not a Spruce, nor a Silver, nor a true Pine, but it combines some of the characteristics of all. Even the solitary resin canal in the leaf, thought distinctive by anatomists, has its parallel in Picea Maximowiczii. Tsuga has representatives in North-east America (T. canadensis), in California (T. Mertensiana = Alhertiana), T. Hookeriana, T. Pattoniana, T. Williamsoni; in Japan (Tsuga Sieboldi and its variety nana); and in the Himalayas (T. Brunoniana, alias dumosa). Of these we may speak on another occasion.

ABIES (KETELEERIA) FORTUNEI. - Of this Messrs. Rovelli send us cones and sprays from a tree growing in their nursery at Pallanza, Italy, the home of numberless rare and interesting trees and shrubs. The trunk is covered with a thick layer of cork; the shoots, with their flat leaves, leaving a circular scar as they fall off, are like those of the Silver Fir (Abies). The cones grow erect, on short stalks, and have persistent scales, like those of a Spruce (Picea), thus justifying Mr. Bentham's assertion that Keteleeria Fortunei is a species of Ahies (Silver Fir), with the scales of the cone persistent. In any case the tree is one of unusual interest, so that we shall gladly avail ourselves of Messrs. Rovelli's courtesy by giving in due time a representation of the plant, and defer further comment for the present. Meantime planters may be glad to know that seeds and young plants can be had from the renowned Pallanza estab-

PSEUDO-LARIX KÆMPFERI. - A magnificent example of this species, the Golden Pine of China, is also growing in the nursery of the Brothers Rovelli, at Pallanza. It is more than 12 metres high (40 feet), and about 11 metres through the branches, and has a superb effect. The tree produces cones abundantly every other year, which enables MM. Rovelli to supply their clients with young plants by post or otherwise.

CARAGANA ARBORESCENS. - In common with many other shrubs thoroughly deserving of more extended cultivation, the arborescent Caragana, or Siberian Pea Tree, is comparatively rarely met with except in old-fashioned gardens, or in strictly hotan-ical establishments. Not without beauty by any means, and capable of withstanding great extremes of heat and cold, as well as being almost impartial both as regards soil and situation, this species might have been expected to become quite a common denizen of British gardens soon after its introduction to this country. It is a native of Siberia, and in the cold dry North is largely used as a hedge-plant. Mr. Gibbs, in his Hasty Notes on Trees and Shrubs of Northern Europe and Asia, writes as follows respecting the species now under notice :- "On the Finland Road, that suburb which is the resort of the townspeople of St. Petersburg during their short cool summers, the Caragana is the common hedge-plant. It and the red-berried Elder are the commonest shrubs. In the tea-gardens of the Petrovskoe Park, near Moscow, where the Russians meet to enjoy their tea around their hissing samovars, the dividing screens are formed of Caragana. At Moscow and Kazan it and the Siberian Thorn are the common hedge-plants."

ORCHID CULTIVATION FOR AMATEURS.—VI.

HEAT, ventilation, and moisture are three great factors in Orchid culture, and all, to a great extent, amenable to modification at our hands; but with light this is not so. True, we can limit its influence by shading, but what we want is a shading which, while intercepting the heat-rays does not rob us of the actual light also, for it is impossible in our climate for Orchids to have too much light. The old idea of growing Orchids in heavily shaded glass-roofed tunnels is exploded for ever, and with it the old "bake and shrivel" system of "resting" also. Now-a-days good Orchid growers grow their plants in lighter bouses, and only break or diffuse the sun's rays, instead of totally obscuring them, as was formerly the rule. Then more air is given, and cooler night temperatures are found advantageous, and not only are more Orchid growers and amateurs successful than

so far as they rob us of the light in dull or cloudy weather (at which time all shading is unnecessary of course) as well as duriog bright, hot days when it is really needful. Light span-roofed Orchidhouses are the best for reasons which we shall Of course, splendid Orchids have been grown in lean-to structures; indeed, some of the best "cool" Odontoglots I ever saw were grown in a little low lean-to house with a north-western aspect. Now, as to staging in reference to light, which is an important point. Orchids, like all other plants, have an inclination to grow towards the light; and when the light comes all from one side, a tendency to unequal or onesidedness is fostered.

Again, when a lean-to bouse has a path down
the centre, and a stage on either side, there is danger of the plants being staged rightly (i.e., to face the light in one part), while others are liable to be staged wrongly, i.e., so placed as to face the spectator, and with the backs of their leaves to the light. In the case of some of the thin-leaved that this idiosyncrasy is due to the incidence of light being suitable in one place while it is not so in another.

In the case of cool Orchids, as we have before pointed out, a high maximum temperature during the hottest of summer days is more harmful than a low minimum; in a word, many Odontoglots, Masdevallias, and Oncidiums suffer as much from summer heat as Phalænopsis and Saccolabiums would do from too cold a temperature. If the house has a northern aspect ample ventilation and abundance of moisture on floors and stages alike will do much to lower the temperature, and this may be further done by raising the shading material 6 or 8 inches above the roof itself, so that a space is left for a current of air to pass up between the canvas and the glass. In warm localities, or on extremely hot days, the canvas might be kept wet and cool by either syringe or hose-pipe, but this would scarcely ever be necessary in the case of a house having a northern aspect,

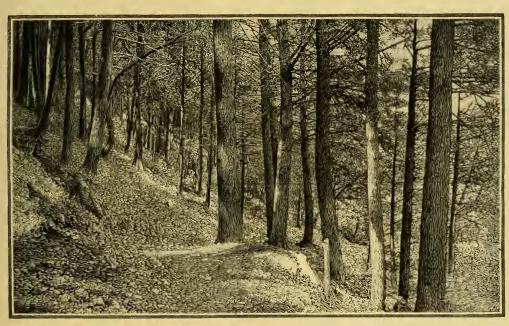

FIG. 45.-HEMLOCK SPRUCES NEAR BOSTON, U.S. (SEE P. 240.)

formerly, but it is worth noting that this modern plan of culture has nearly entirely banished that "big bogey" of the olden time, namely, "spot." If "spot." appears in an Orchid-house to-day, the modern grower does not look upon it as a zymotic disease, but at once looks to some error in his own treatment as the cause of its appearance.

Now as to shading: whenever it is used it should be movable, easy to roll up and down by ropes and pulleys on a light pole. Coarse bempen or woollen threads woven net-wise, the meshes one-third or even half an inch square, are generally sufficient to break the sun's rays, if elevated from 4 to 6 inches above the glass. So arranged, each thread casts a shadow, and the result is, the breaking up or diffusion of the sunshine, rather than an actual obstruction of the light itself. In other words, a far larger proportion of heat rays are obstructed than of light rays, a result much to be desired during the hottest of summer days. Especially is this to be wished for in the case of cool Orchids, for reasons before pointed out. All kinds of fixed or permanent shading material, whether tinted glass, whitewash, "summercloud," or tiffany, tacked to the rafters are wrong Orchids this is a matter of but small import, since their leaves soon turn to the light, as do those of a Fuchsia or Pelargonium, no matter how staged. But in the case of hard-leaved plants, such as Cattlevas, Lælias, Angræcums, Vandas, &c., they often suffer irreparable injury by being staged with the backs of their leaves to the light. This question of staging all Orchids so that their young growths can grow towards the light is very important, and the neglect of this rule entails a great waste of growth force or energy. In a word, Orchids, of all plants, must be staged that the light falls on to the upper surfaces of the leaves, and they should never be staged merely for the sake of effect from other motives, as is so frequently the case. We often hear gardeners say that an Orchid is very "touchy;" it will only grow in one particular place in the house, and if removed elsewhere does not do so well. No doubt the heat of some houses is a little too much for individual plants, and such will then naturally succeed best at the coolest end of the house, or in a position near a door or ventilator where there is a flow of cool air from outside.

In a great many cases, however, I am convinced

ST. HELENA.

MR. D. MORRIS, the Director of Public Gardens and Plantations io Jamaica, has written a Report upon the Present Position and Prospects of the Agricultural Resources of the Island of St. Helena, which has just been printed by the Colonial Office, and which contains much matter of interest, as our readers may infer from the short account we are now able to give.

St. Helena has an historical interest to every Englishman, in consequence of its being the island home of the exided Napoleon I. after the battle of Waterloo. Mr. Morris, in his introductory notes, briefly refers to this fact, and points out that the island was discovered on May 21, 1502, by the Portuguese; it was held by the Dutch until 1651, when the East India Company took it, and it was transferred to the Crown in 1833. The area of the island is about 45 square miles, 10¢ miles long, and 8½ miles broad. "Of the 28,800 acres of which the island consists, the greater portion suitable for cultivation is in private hands. The Crown lands, with the exception of Longtown Farm and a few other places, are barren wastes on the outskirts of the

island, incapable of cultivation." The special characteristics of the island are, Mr. Morris says, observable both in the geological nature of the soil as well as in the plants which affect them.

The coast zone, which at the present day is dry and barren, was at one time covered with luxuriant vegetation, "and with trees drooping over the tremendous precipices that overhang the sea." The barren coast zone is described as at present extending about 1 mile to 1½ mile around the island. Deep wide valleys, and rocky, almost inaccessible ridges run from the central ridge towards the sea, breaking up the coast zone into numerous almost detached prominences and ledges. It is absolutely devoid of vegetation, except Prickly Pear, a few plants of Mesembryanthemum, and the rare indigenous Pelargonium, Pharnaceum, and Trip-On the Bam there are straggling bushes of the Scrub Wood (Aster glutinosus, Roxb.), which is probably the most abundant of the indigenous plants of the rocky coast. In this zone the plants are so scattered and so buried in crevices and hollows that they are scarcely seen from the sea, and do little to relieve the parched and barren appearance of the island.

The middle zone extends from the boundary of the coast zone to about three-quarters of a mile inland; its surface is not so rocky, and the slopes are more covered with grass. Here Australian, Cape, and American shrubs and trees have established themselves into thickets of considerable size. The slopes are often covered with Furze, with an occasional plant of the indigenous gum woods, and in the damp bollows some of the larger Ferns. "The English Brooms," Mr. Morris says, "together with Brambles, Willows, and Poplars, Scotch Pines, and Gorse bushes, Cape of Good Hope bushes, Australian trees, and American weeds, have driven out most of the indigenous plants from this belt. The tendency of these introduced plants is to encroach more and more upon the higher lands where the indigenous flora still re-As regards the larger trees, such as Pines and Willows (Acacias), they appear to be spreading downwards in the direction of the valleys, following, no doubt, the distribution of their seeds by the action of the trade winds."

The central zone is described as being not more than about 3 miles long, and 2 miles wide; in some places the rocks are very precipitous, while in others the land is undulating, with grassy slopes, meadows, hay-fields, a few farms and gardens, and well-wooded glens of Oak and Acacia. On the extreme crest of the central ridge, extending from High Peak to Rock Rose, there is still left a portion of the indigenous forest with Cabbage trees (figured in Gardeners' Chronitde, 1880, vol. xii., p. 401) and Ferns, the wild Olive (Nesiota elliptica), Angelica, Lobelia, and the delicate campanulate Wahlenbergia. Here the soil is for the most part rich, though not very deep, and the climate is particularly cool.

Mr. Morris suggests that Aloes, Furcræas, and plants of a similar character, together with some hardy trees should be established in warm and sheltered valleys as a pioneering vegetation to spread over these wastes to gradually reclaim them. About Sooo acres are in pasture and hay-land, and the tendency is to allow this to increase. The country houses, which in the East India Company's time were inhabited by prosperous merchaots and officials, and surrounded by well kept gardens and orchards, are fast falling into decay and becoming ruinous. The cultivated areas around them are simply converted into grazing lands, and a few cattle and sheep are the only indications of life for miles around.

About 400 acres are under cultivation with indigenous and introduced trees, and nearly 300 acres with root-crops, forage, orchards, and gardens. The census of 1881 showed the population of St. Helena, exclusive of the garrison and shipping, was about 4500, and of this number more than half live in Jimestown.

After giving the rainfall, temperature, and other meteorological conditions of the island, Mr. Morris thus refers to the future:—"Speaking from my point of view, and after a careful consideration of the soil, climate, and general resources of the island, I am led to take a hopeful view of those resources, provided they are developed in such a manner as to place the island in fair competition with other countries. I look entirely to the soil for the elements necessary to bring prosperity to St. Isleina. But the people require to be shown what these resources are; they need to be taught how to use those resources aright, and they require to be encouraged and assisted while so

engaged. I should recommend, in the first instance, that an intelligent and competent gardener be sent to the island to take up the entire question of the revival of agricultural pursuits, and that if the local Government is unable to support such an officer and a small staff that a grant be made for the purpose by the home Government."

Mr. Morris further recommends the formation of a small establishment, with nurseries, &c., at Plantation House, for a gardener and a small practical staff, who should introduce and raise for distribution plants not already in the island.

We have quoted thus freely from this interesting report to show its nature and character; the remainder treats of economic plants under their separate heads, and is of equal, if not of greater importance, to that to which we have specially referred.

Floqists' Flowers.

CYCLAMENS AT WHITTON .- The hamlet of Whitton is situate midway between the well known West Middlesex towns of Hounslow and Twickenham, and Mr. Walker grows his heautiful Cyclamens almost within the shadow of that fine pile of buildings once famous as the residence of Sir Godfrey Kneller, but which is now a Government musical institution for the training of army bandmasters. Popular as the Cyclamen has become as a market plant, we have but few first-class growers, and of these Mr. H. B. Smith, of Hanwell, and Mr. R. Clarke, of Twickenham, are two of the foremost; Mr. Walker, of Whitton, who does not exhibit his plants at South Kensington, is in no way inferior as a cultivator. From Whitton go out 7000 or 8000 plants yearly; the season of sale, and of course of bloom, beginning early in November and ending late in April, so that nearly half the year, and that the winter half, too, is at Cyclamen establishments the busiest period.

If, however, some growers turn cut a few thousand more plants yearly, at least that cannot alter the matter of culture and quality, and in these two im-portant features Whitton is not a whit behind other We noticed in looking through the Cyclamen houses that even where what appeared to have been old vineries were utilised for the plants, stages were all brought up near the glass. One long low house must have presented a wondrous spectacle when full, as it contained then 2300 plants all in 48's, but after more than three months' sale the quantity is greatly diminished. Very great pains are taken by Mr. Walker to fertilise high-class flowers each season. Seed for own sowing only is saved and the plants to produce this after due fertilisation are placed in a separate house where if any of that pollen which is so abundant in the Cyclamen gets liberated at least it shall be from from no inferior kind. with care self-fertilisation is improbable, whilst artificial fertilisation is of the greatest importance.

Market Cyclamens are divided as a rule into persicums, that is, white or tinted flowers, having a dark coloured base, pure whites and reds. Of these sections Mr. Walker has many superb examples, specially selected for seed production. One splendid persicum had a habit of expanding its reflex petals, so that the flowers were of unusual breadth; that is, as in this case, allied to first class quality, a very desirable feature. Another with remarkably fine flowers of pure white had an intense deep crimson base of unusual depth. This fertilised in the right direction might lead to an equally bicoloured strain of exceeding beauty. A very striking kind of an inter-mediate form had blooms pure white with a pale mauve base that was both novel and beautiful. flowers were of first-class form, and most profusely borne. Pure whites were of first-rate form and quality, and though abundant not so largely pre-dominant as in some strains, for Mr. Walker is peculiarly rich in colour.

A charming flaked kind was fertilised with other flowers, having similar markings, as Mr. Walker thinks the securing of a defined flaked strain is not an impossibility, and we see no reason to disagree; whether flake markings would become popular remains to be seen, but if not acceptable in the market where decided colours are most in request, at least they would be appreciated by the amateur growers. Whilst at Whitton there are many varied and beautiful shades in the red section, there are none quite so deep in colour as perhaps is Mr. Clarke's Cardinal and King of

Crimsons, but then these very deep hued flowers are never large, and many burn or fade at the edges. Mr. Walker aims to secure size, allied to fine form, and rich glowing yet constant hues. His darkest flowers are rather rich rosy-crimsons than deep crimsons, and some of the paler reds are singularly beautiful and distinct. One plant, having flowers of a magenta, hue, yet heavily shaded with violet or purple, was most noticeable amongst myriads of others; so also was a pleasing rosy-lilac flowered one, not less distinct amother, having flowers of a rosy-flesh bue, and of fine form, was not less attractive; indeed, each of these would be valuable acquisitions to any private collections.

It is to be deplored that no encouragement in the form of prizes worth contesting is offered to growers for specimen plants of Cyclamens in variety. A dozen in 24-sized pots, and quite distinct, if icabuling such charming sorts as we have described, would make a beautiful class. As it is, growers, rather than risk the chance of getting many of their most distinctive forms cross-fertilised in the transit, keep them at home as seed producers. Myriads of plants are turned out fit for market in some twelve or fourteen months from the date of sowing; but show specimens should be some two or three years old, to enable the corms to fully exhibit what under good culture is from them possible. We have elsewhere alluded to some Cyclamen oddities at Whitton.

A house quite full of forced white Narcissi was very attractive, the bulbs, after they have ripened, being planted out for a couple of years at least, to recuperate. After the Cyclamens follow Strawberry plants in pots, and only Sir Charles Napier, which does so well at Whitton, is grown. The plants are stored on their sides in banks for the winter, but now are being run into frames, and soon a batch will go into the houses.

FLOWERS IN SEASON.

FROM Messrs. Veitch, at Combe Wood, come flowers of the following hardy shrubs:-

RHODODENDRON EARLY GEM.—One of the very best of its class, being free flowering and with large funnel-shaped, reddish-lilac flowers. It is figured in Gard. Chron. at p. 335, vol. ix., 1878,

R. PARVIFOLIUM is a dwarf form, with very slender, wiry branches, clothed, like the under-surface of the leaves, with brownish scales. The leaves are about three-quarters of an inch broad, narrow, oblong-obtuse; the flowers small, less than half an inch long, tubular, funnel-shaped, like-purple, and clustered in compact heads. It is a native of the Baical Mountains, and was figured in 1877 in the Gartenfora, t. 994. We do not remember to have seen it previously, but can now commend it for its very deeply coloured flowers, very different in tint to the figure above cited.

ANDROMEDA OR PIERIS JAPONICA, with its long drooping racemes of conic I, white flowers, is sure to be admired whenever seen. We gave an illustration of it at p. 797, vol. xvii., 1882.

CYDONIA JAPONICA NIVALIS is a white-flowered variety of our old friend Pyrus japonica.

Lastly, in AZARA MICROPHYLLA we have an evergreen Cotoneaster-like shub of the greatest merit for us neat habit and deep green foliage. The flowers are very minute, and but for their yellow colour would be inconspicuous. The winters of 1859—80, and 1880—81 played such havoc with the Azaras at Kew that we were agreeably surprised to see this specimen. It was figured in Gard. Chron. at p. S1, vol. 1., 1874.

RITODODENDRON DAHURICUM,—In some of the Rhododendron clumps at Kew, the purple blossoms of this species have been conspicuous for some time. Although rather small, and borne at the tips of almost or quite leafless slender twigs, the bright and decided colour of the flowers render R. dahuricum one of the most striking of all early-flowering shrubs. Both in size of the flowers and in the profusion in which they are produced, the hybrid R. præcox is a more desirable plant, but the flowering season of this latter is not so prolonged as is that of the one of its parents to which it, perhaps, approaches nearest, the one whose name heads this note.

Anemones, — Mr. Burbidge sends us a boxful of Anemones, little and big, rich and varied in colour, from Dublin. The seeds from which these were grown were sown no later ago than February, 1883,

Orchid Potes and Cleanings.

CATTLEYA TRIANÆ, POPAYAN VARIETIES .- The splendid form of the dark-flowered section of Cattleya from this district which Messrs. Shuttleworth, Carder & Co. had at Stevens' Room on Wednesday, February 20, served to demonstrate their excellence. The flowers were nearly 7 inches across, petals 21 inches wide. Sepals and petals pale rose, the petals having each a heavy violet blotch at the tips, the lower and expanded half of the labellum intense violet-crimson, throat pure white with orange rays extending upwards, outside of the tube of the labellum rosy-purple. Altogether it is a beautiful thing, and being the first to flower out of this firm's importation it speaks well for it. The strain of Cattleya from this district is now becoming well known for its excellence, many fine things, some of them lovely massive white varieties, having already flowered out of Chesterton's and Lehmann's gatherings on the Popayan ground, which were sold in the beginning of

PILUMNA NOBILIS.—A species with a single evergreen broad leaf issuing from the top of the pseudo-bulb; the flowers are disposed in a loose raceme, which comes from the base of the bulb. Each flower measures about 2 inches in greatest diameter; the segments are very narrow, undulate, milk-white; the lip is much larger, cuneate, and convolute at the base, the disc pandurate, emarginate, pure white, with a golden blotch on the throat. It is a native of Columbia, and is figured in the Orchid Album, t. 128 (1884). It requires coal treatment, with moderate moisture during growth, and prefers rough peat to grow in, with good drainage.

TRICHOCENTRUM PORPHYRIO.—A species with wedge-shaped oblong acute leaves, one-flowered peduncles; sepals and petals cuncate oblong acute, yellow flushed with brown; lip cuncate at the base, pandurate, emarginate, flushed with purple, with a central yellow blotch, from which proceed five lines leading to the short spur. It differs from T. purpurcum more particularly in the column. Figured in *Hustration Horticole*, t. 508.

LYCASTE COSTATA, Lindl,—A species with large ivory-white flowers, borne singly on the end of a flower-stalk proceeding from the base of a two-leaved pseudobulb. The lip is much shorter than the other flower-segments, with two short, rounded, ascending labes and a terminal tongue-shaped anterior lobe, much larger than the others, irregularly cut at the margin, and with a thick transverse crest in the centre. Columbia. Cartenflora, 1884, t. 1141.

LYCASTE SKINNERI.—It is supposed that the ancestors of existing Orchids had regular flowers and six stamens, and that in course of time the flower has become irregular, and the number of stamens reduced to one (two in Cypripedium), such irregularity of form, and such reduction in the number of stamens being connected with the efficient fertilisation of the flower by insects. We need not here repeat the varied evidence by which this conclusion has been arrived at; it must suffice to say that we have before us a flower of Lycaste Skinneri from Mr. King, gr. to J. Gwynne, Esq., Henton Grange, Edgewate, which, to some extent, bears out the theory beforementioned. It has, in fact, two lips, and a narrow petal-like band springing from the front of the column. The second lip is evidently within the first, and is doubtless the representative of one of the missing stamens, while the petal-like wing to the column may citter represent another stamen or one of the styles.

SOPHRONITIS ROBEA.—This is a distinct and very pretty addition to this well-known genus. In character it is very like the typical form of S. grandi-flora, having a plump round bulb, and a thick fleshy leaf, bearing a large well-formed flower of a rich rose colour; the labellum is small, the wings enfold the column, and are heavily marked with orange and scarlet at the base. The variety seems to be somewhat unknown, which is to be regretted, as it forms a desirable addition to the limited genus of Sophronitis. The variety has appeared annually with Mr. Peacock, of Hammersmith, and at the present time some finely flowered examples enliven the collection. W. Gost-flug. [Is not this the short-hulbed, rose-coloured form of S. grandiflora? Ed.]

The Flower Handen.

THE continuance of wet, stormy weather, with occasional downpours of hail, has tended greatly to deface the beautiful effect presented in the spring garden a month ago. Everything now exhibits a washed-out appearance, which can only be rectified by dry, sunny weather. As soon as the soil gets dry enough it will be advisable to loosen the surface of the beds, where this can be done without injuring the plants. All dead leaves and subbish should also be removed, and where the plants have become loose they should be made firm in the soil, either by pressure with the hands or feet; and where necessary a slight top-dressing of sandy loam should be given between the plants, to make the surface even. Where the walks are of gravel it will be necessary to resurface them, when sufficiently dry, with fresh gravel, as they have, in consequence of so much rain, become extremely wet, disagreeable to the eye, and unpleasant to walk on. This will not only give the garden a bright appearance, but if well rolled they will require but little attention during the rest of the season to keep them in good condition. If the paths between the beds are composed of grass they should be swept when dry, the edges sheared and well rolled, to produce a neat and trim appearance, and so increase and improve the general effect of the garden. Should the beds be surrounded by Box, Thrift, or other similar edgings, these should now be examined, and where necessary replanted. The whole should be clipped into neat form and size in proportion to the beds they surround. In replanting Box edgings great care should be taken to make the soil sufficiently firm before planting, and also to thoroughly ram the Bux in the operation. This not only prevents its growing too rapidly afterwards, but it cannot be so easily disarranged by the roller and other causes. It is much better to perform this work now than to defer it till later in the season, when more important work will demand attention, and by duing a small quantity only at a time the beauty of the garden need in no way be marred.

Frequent and careful attention will now be required in tyiog up and protecting the bulbs from frosts and severe storms as they push through the soil. Every attention thus given will be doubly repaid by their increased beauty. Clematis, Roses, Honeysuckle, and other climbers, will also require the same care, especially the former, as their young shoots grow to rapidly, and are so tender and brittle at this season as to require almost daily attention. Roses growing on warm walls, as they are unusually forward this year, may now be pruned, but extreme care should still be exercised, espe-cially with respect to the Teas and Noisettes, not to cut back too hard, lest severe frosts should set in and destroy them. Where it can be conveniently done it will prove advantageous, and most pro-bably preserve the early and best blooms and fuliage from injury, if a light woollen net be suspended a few inches from them when frosts or cold drying winds For this purpose an open-meshed woollen net is greatly superior to a close-meshed cotton or canvas one. The former, while it acts even more efficiently as a protective against frost, will also partially break the force of the wind without offering such resistance as to be blown forcibly against the trees, to their injury. Roses, either as dwarfs or standards, will be better left unpruned for a short time longer, for the reasons already adduced. I have for some years adopted this late pruning practice, and have every reason to be satisfied that it is the most safe and advantageous. Since the Tea and Noisette Roses planted in exposed positions have suffered so severely it has been found necessary to take them up annually in November, and lay them in by the heels behind a sheltered wall, where they can be easily protected during severe frosts, and transplanted to their summer quarters each spring. As they are this season already growing rapidly this operation must be performed at once; in doing which a mild dull day should be chosen, and the work should be done as quickly as possible, so as to expose the roots to the air no longer than is necessary. As each one is planted a slight watering should be given immediately, so as to settle the soil closely round the roots. Four or five stakes should then be driven into the ground a few

inches from each plant and tied together at the top over the plant; round these stakes a garden mat should be wrapped after the plant has been syringed overhead. By continuing these coverings for two or three days, removing them at night, when mild, also during dull or wet days, and by repeating the process of syringing overhead if bright sunny weather occurs, and keeping them closely covered during the day exhaustion will be prevented and scarcely a leaf will be lost. A warm open situation should be chosen where the plants will be fully exposed to the sun, and in order to secure early ripened wood, which is most essential in following this practice, and an abundance of fibrous roots, a somewhat poor sandy loam mixed with a good proportion of old mortar rubbish, plaster, and charcoal, is preferable to a rich unctuous loam. In planting this compost it should be trodden or rammed thoroughly firm round the roots, for which purpose it should be in a comparatively dry state. It can of course be enriched with liquid ananure during the growing period, but caution should be exercised not to continue its application too late in the season, else too exuberant growth will be produced, it will fail to ripen, and the object in view will be defeated.

THE PROPAGATION of the summer bedding plants should now be carried on with all possible speed, so as to get the plants well established by planting time, Dahlias, Salvias, and Begonias should now be potted, and where an increased number is required they should be plunged in a brisk bottom-heat, and as the young shoots appear cuttings may be taken to any extent; and if potted, and also plunged in the propagating pit, they will quickly take root.

Seeds should now be sown of all the best kinds of subtropical plants for the summer decoration of the lawn and garden; for this purpose the most suitable are such as possess grand foliage, as also those of graceful habit. If these are placed in a brisk temperature they will quickly germinate; they should then be potted off singly, and be kept growing without a check. If planted either in masses or as separate specimens in sheltered nooks in rich moist soil, they not only have a very imposing appearance, but produce great variety both in outline and colour, T. S. C.

The Handy Fruit Garden.

WHERE there are vacancies on the fruit walls not a day should be lost in filling them up with suitable trees. Temporary trees can also be planted by their side, which may comprise cordon Fears on south-east and west aspects, and Gooseberries or Currants on the north wall. The pruning and training of Peach trees may now be proceeded with, laying in the shoots at full length, if the wood is thoroughly ripe and there is no risk from overcrowding, but if it must be shortened see that it is cut back to a wood-bud, because if this is overlooked the shoot will die back as far as the next wood-bud. The Peach and Nectarine being nearly always trained on the fan system, the principal thing to observe in forming a tree is to keep the cectre shoots pruned back till the side branches, are produced in sufficient numbers; the sap naturally has a tendency to ascend to the vertical branches, hence the necessity of giving them the least encouragement at first. If the walls are covered with wire for the purpose of training the trees, observe the instruction given in a previous Calendar. When walls are old and the bricks have become disfigured with nailing they are best covered all over with Portland ement, which will prevent insects harbouring in them, and the walls will have a clean appearance. See that material of some kind is got in readiness for covering the trees while in blossom, the best being glass copings, from which cutains can be suspended. Common netting doubled is sometimes employed, and offectimes Sprace branches, but whatever is used it must not be allowed to blow about in windy weather and injure the blossom s. A board some 12 inches broad fastened just under the coping helps to keep the blossom day, and has, therefore, a beneficial influence on the fruit setting. In damp localities the orchard trees will offentimes become coverd with lichen, to get iid of which on a damp day scrape it off with sone blunt instrument. Then with a mixture of equal parts of soot and lime made into a liquid, wash or syringe the stems

APPOINTMENTS FOR THE ENSUING WEEK.

Sale of Arardy Plants and Bulbs, at Stevens' Rooms.

THE investigation of the inner life of the ROOTS-their structure, what they do, and how they do it-though obviously points of the very highest importance to cultivatorsdemands special qualifications and special means, neither of which are at the disposal of the ordinary gardener. It is unfortunate that it should be so, but it is our duty to make the best of the conditions under which we are obliged to work rather than lament over the impracticable. The observation of the development and growth of roots, so far as they can be seen by the naked eye, is a matter quite within our range, and we cannot too strongly urge upon young gardeners and others the necessity of carefully examining and noting the nature of the root-growth in all plants that come under

At first, perhaps, they will find that little interest is to be got out of isolated observations, but when they begin to compare the root-growth of one plant with that of another they will very soon become possessed by that most valuable of human faculties, the desire to know the reason why. Their interest will get excited, and will increase as their observations accumulate, while practical inferobservations actimized, while practical inter-ences will begin to suggest themselves, which latter must be rigidly tested before they are made articles of faith. One hint we may be allowed to give, and that is, as the problem is a very intricate one, that they attack it not all at once, but in detail. To sit down before a great leash of roots, and endeavour to disentangle them physically and mentally-to trace what, if any, connection there is between them and the branches or leaves, and so forth - is a disheartening

By investigating seedling plants, or watching how, when, or where, and under what circumstances, the roots are produced, there is a better chance of arriving speedily at some useful result. The student in this, as in most other problems of a similar nature, must act as the arithmetician does in working out a complicated sum-reduce his materials to the lowest possible denomination. This is what the microscopists and the chemists do in their laboratories-they endeavour to isolate each constituent, detach it from its associates, and study it in its isolated state. By treating each constituent in a similar manner they find out what is peculiar to each, and are very soon led on to see how they act and react on each other when in combination. As we have said, what the microscopist can do minutely, the ordinary observer can do roughly. To give an illustration. One particular branch of a tree we will assume dies, or becomes unhealthy, the rest remaining sound. This happens constantly with the Moor Park Apricot. Why that one branch? Is it that the roots corresponding to that branch are diseased, or placed under unfavourable conditions?

The reply to the question, it will be seen, turns upon the question whether or no there is any such connection between certain branches and certain roots. In the full-grown plant the inosculation and intercommunication that goes on between the several parts are so great and so complex, that the question can hardly be satisfactorily answered; but if the

problem were attacked before all that complexity arose, we might get a definite reply. M. CLOS,* in a treatise now before us, has gone into this question of root developto an extent beyond any of his predecessors, and botanists who have hitherto paid little attention to the subject will be surprised to find the degree of variation there is in the mode of production of what are called adventitious roots in different plants, and the constancy which prevails in individuals of the same species. M. CLOS groups these roots accordingly as they spring from the nodes, beneath them, above them, around them, or at a distance from them, and he indicates very numerous variations in different natural orders -details into the consideration of which we cannot now follow him, but which clearly are of great practical interest to the propagator. We may, however, reverting to the question above raised as to the connection between the branches and the roots, mention that M. CLOS has been studying plants of Myosurus minimus, a weed of the simplest structure, consisting of a root, a tuft of leaves from which uprises a single flower-stalk or several. If there is only one, then there are no adventitious roots; but if more than one, then the number of roots is equal to that of the flower-stalks, as if there were one such root to each flower-stalk. It must be remembered here that M. CLos is speaking, not of the original roots derived immediately from the seedling plant, but of the adventitious roots developed subsequently. M. CLOS' paper is written from a purely botanical point of view. but it is very suggestive of the store of most important practical information which lies ready for utilisation by those who will take the trouble to do so.

—— DAFFODILS.—No, we do not propose to quote Wordsdorm nor Jean Ingelow, nor even that well-worn assertion of SHARESPEARE's, which always does duty on such occasions. We will take for a change the opinion of that clever and altogether delightful rascal, Autolycus, who was, at any rate, a keen observer, though, poor man! he knew nothing of phenology—

"When Daffodils begin to peer, Why then comes in the sweet o' the year."

So may it be! The Daffodils are "peering," and, much as we admire them in the border or frame and on Mr, BARR's Cloth of Gold tables at South Ken sington, there is Bohemianism enough left in us to prefer to come upon a flush of wild Daffodils in a spinney, as shown in Mr. FITCH's sketch (fig. 46). We cannot doubt that the flower is fertilised by insects-but by what insects? At any rate there can be no doubt that the curvature of the flower-stem, so as to bring the flower into nearly a horizontal position, and the deep tubular crown, are devices which have been gradually evolved to meet the hest interests of the flower. Originally the flower was-nay, it is-vertical; it becomes horizontal, as we suppose, by compromise between the original upward thrust and the weight of the flower, which would tend to pull it down. Add to this a tendency in the immediate support of the flower to grow fastest and strongest on the upper side, and the curvature is amply accounted for.

— CHATSWORTH.—We have authority for stating that Mr. OVEN THOMAS, who was for several years Gardener to Sir Robert Peet, at Drayton Manor, and latterly Gardener at Impney Hall, Droitwich, has been appointed to succeed the late Mr. Speed at Chatsworth Gardens.

— HORTICULTURAL CLUE,—The annual dinner of the Club took place on February 12, and was numerously attended. The chair was taken by Mr. John Lee, Chairman of the Committee, and amongst those present were—Dr. Hogg, the Rev. F. H. Gall, Rev. T. Flintoff, Messrs, J. D. T. Llewellyn, Shitley Hibberd, Harry J. Veitch, George Deal, J. F. Strange, C. R. Whetstone, Herbert J. Adams, J. S. Cousens, C. T. Druery, H. W. Slottentoff, &c. It

was announced that the Club had during the past year subscribed ten guineas to the Gardeners' Royal Benevolent Iostitution, and that the following gentlemen had been elected members of the Committee in lieu of four who had retired according to rule:—Messrs. Shirley Hibberd, Harty Turner, Charles T. Druery, and the Rev. Theodore Flintoff. A report was agreed upon, and will shortly be issued.

— A LITTLE BIT OF HISTORY.— In a recent number of the Illustration Horticole we find the following historical memoranda, taken from a Flemish almanac of the year 1816:—

Double white Camellia, first flowered at Ghent in 1809. Azalea calendulacea, introduced from North America

in 1806.
Botanic Garden of Ghent, planted in 1797.

Pæonia alba, introduced from Siberia in 1791.

Hydrangea, the first Hortensia introduced from China

Rheum palmatum, introduced from Tartary in 1765.
Rhododendron ponticum, introduced from Gibraltar

BODNANT HALL. — We are requested to supply an omission in the notice of this place given at p. 207, by stating that the conservatory and range of fruit and plant houses, illustrated at p. 209, were designed and built by Messrs. Messenger & Co., of Loughborough.

— RED-BERRIED IVV.—Some time since we mentioned the occurrence of a red-berried Ivy in France. M. Andre, in the current number of the Revne Horticole, now gives a coloured figure and a description of the plant, which may be had from MM. Besson, of Nice, who were the first to bring ituader notice; or from M. Palllet, Chatenay, near Sceaux. As figured, the berries are of the colour of those of the Mountain Ash—orange-red. Mr. HIBBERD inclines to the view that it is of Indian origin, and the true Ivy of the poets.

- HAS THE CLIMATE CHANGED ?- Some of our readers will remember the controversy which took place some years ago on this subject, and those that are concerned in it will be interested to read the following passage from Lord MONCRIEFF's address to the Royal Society of Edinburgh, as printed in Nature: "Now that we have an observatory on Ben Nevis, our successors at the end of the next century will know accurately the conditions of climate under which the hundred years have been spent. There are, however, some details scattered over the Transactions, which are sufficiently interesting, although, whether they show any material alteration in our seasons may be, doubtful. The only cheering fact which they disclose is that the first set of returns is decidedly the most discouraging, and certainly does not support the idea that the mean temperature in the olden time was higher than it is now. There are two sets of returns printed in the first volume of the Transactions-one kept at Branxholm from 1773 to 1783, communicated by the Duke of BUCCLEUCH, who was the first President of the Society; and the second by Mr. MACGOWAN, kept at Hawkhill, near Edinburgh, from 1770 to 1776. In the first the mean temperature of the ten years is 44°, in the second 45°—not a very genial retrospect. Thiogs must have been somewhat discouraging for the farmers in 1782, for a paper is noticed in the second volume of the Transactions, by Dr. ROEBUCK, of Sheffield, who was the manager of the Carton Iron Works, recommending farmers not to cut their coro in October, although there was ice three-quarters of an inch thick at Borrowstounness, because corn would fill at a temperature of 43°. Things looked brighter from 1794 to 1799, for which years we have results furnished by PLAYFAIR. For the first three years-1794, 1795, and 1796-the mean temperature was 48°; and that although 1795 was one of the most severe winters on record, the thermometer having stood several degrees below zero, and a continuous frost having lasted for fifty-three days. The mean temperature of 1794, however, was 50°. The account of the great frost of 1795, which is given in the Transactions, is well worth referring to. In the next three years the mean temperature was 48°, the next time years the mean temperature was 40, that of 1798 being 49°.28. Of this year (1798) PLAYFAIR says that the climate of this part of the island hardly admits of a finer season. No tables were furnished to the Society, in continua-

^{*} Des racines caulincures. Par M. D. Clos. Mem. Acad. Sc. Toulouse, t. v., 1883, p. 222.

tion of those of Professor PLAYFAIR, until 1830, when, fortunately, Dr. BANNES, of Carlisle, communicated to the Society a series of meteorological tables kept at Carlisle for the first twenty-four years of the century. The results seem mainly to concur with those of Professor PLAYFAIR; the mean temperature for the twenty-four years being 47°.4547, being 3° bigher than the average of the ten years from 1773 to 1783 at Branxholm, and 2° higher than the mean temperature of the seven years, from 1770 to 1776, at Hawkhill. The highest temperature I have noted in these returns is that of May, 1807, when the thermometer stood at 85° at Carlisle, and the next, that on August 5, 1770, when the thermometer at

with regard to their applications. In response to a request made by His Royal Highness the Prince of WALES, President of the Exhibition, the eight Water Companies of London have resolved to exhibit, in a pavilion which is being errected for them, their appliances for the supply, filtration, &c., of water, together with diagrams showing the various processes and localities; and a powerful sub-committee, under the active chairmanship of Colonel Sir Francis BOLTON, has been formed to carry out this branch of the Exhibition. The Water Companies have also determined to put up in the grounds a large fountain, which will be illuminated at night by electricity. This fountain of light will, it is anticipated, materialy

of note. The habit of the plant was all that could be desired, and exceedingly floriferous. The flowers, borne on stout stalks, were of a pleasing rosy-pink hue, and whilst all had a most unusual number of petals, some had quite six times the customary quantity, so that these blooms were so double as almost to resemble the flowers of a double Tropæolum. Whilst outside of the florists' section yet the kind, beyond its novelty, was of a very ornamental or decorative nature, and, having its fertile organs intact, might be made the parent of a most interesting strain. As pulled flowers—and thousands of bunches of these are anoually sent into the market—the double kind would have considerable value, and no doubt

Hawkhill was 81°. The two years of the century in which the mean temperature was the highest were 1811 and 1822, in both of which years it was 49°."

—— INTERNATIONAL HEALTH EXHIBITION.— Freparations for the holding of this Exhibition are proceeding rapidly. The Board of Trade have certified that the Exhibition is an International Exhibition, and exhibitors thereat will accordingly participate in the privileges accorded by the Patents, Designs, and Trade Marks Act of 1883. The Lords of the Treasury have also consented to the buildings being considered as a bonded warehouse during the continuance of the Exhibition. The allotment of space, which has been largely applied for, is being rapidly proceeded with, and applicants will soon be informed of the decision of the Executive Council add to the beauty of the illumination of the gardens. To China has been allotted the space which it occupied last year at the Fisheries' Exhibition, and a Chinese Tea-garden, restaurant, and shop will not be the least interesting objects in the Exhibition. India is to be adjacent to China, and stremuous exertions are being made to secure the united action of many of the principal Tea planters in India, so as to insure a good and representative show of the Indian Teagrowing industry.

— DOUBLE CYCLAMENS,—There is such grace and beauty in a well-formed Cyclamen bloom that we cannot accept with pleasure any departure from the correct form. Yet we saw the other day in one of Mr. WALKER'S houses at Whitton a double-flowered kind that possessed some features of interest worthy

would prove very enduring. The plant has, we learn, passed into the hands of a well-known amateur florist, who will, no doubt, turn it to useful account. In the same house was another curiosity in Cyclamen flowers in the shape of a single one with petals of unusual length, and in each of which Nature had given an extra twist, so that the blooms bore no inconsiderable resemblance to those of some of the Parrot Tulips. In all well-shaped Cyclamen blooms it is found that the petals make, after all, but a quarter turn in their revolution. That seems to be the correct thing. The plant in question produced flowers, the petals of which, because of their great length, had made exactly half a turn, and it is just possible, were its peculiarities persevered with, that an entire turn might presently he produced. these curiosities have no market value.

- THE PHYLLOXERA CERTIFICATE. -- Although it has been considered advisable for the present not to urge upon our Government the propriety of joining the Convention of Berne, yet there can be no doubt as to the desirability of securing, as far as may be, uniformity in the certificates required by the Customs authorities of the several countries. To this end we transcribe from the Revue Horticole the form of certificate used in France, and which runs as follows :--

I. DECLARATION OF THE SENDER,

I, the undersigned A. B., nurseryman, of Nurseries [or amateur, of , as the case may be], declare-

1. That the plants contained in the packages marked , addressed to C. D., Cattleyaburg, by Bonn, via Harwich, Rotterdam, Cologne, or elsewhere, come from my establishment exclusively.

2. That they contain no Vines.
3. That the plants are packed specify whether with or without earth around their roots .

Signed, A. B., ot

11. ATTESTATION OF THE COMPETENT AUTHORITY. testifies, on the report of the The Mayor of

inspector (expert delegue)-1. That the package of plants above referred to comes trom an establishment (terrain) separated from any Vine by a distance of 20 metres (70 yards) at least, or by an obstruction to the passage of the roots judged sufficient

by the competent authority.

2. That no Vine exists in the establishment (terrain).

3. That Vines are not stored in the establishment.

- NOTES FROM CLAPTON .- Cape of Good Hope and Australian plants still obtain a place in Messrs. Low's nursery, and if the species are much reduced in numbers from their original abundance there are some things met with here that will soon be considered to be novelties by our younger men. Acacias come in for a large share of space, and among them we saw specimens of A. cultriformis, with triangular short leaves; A. cordata, looking, as far as regards foliage, like a small edition of the first; A. granditolia, A. Drummondi, A. platyptera, a curious species, with narrow Scolopendrium-like leaves. The Genistas, that are found to be such a useful class for early work, are much enhanced in usefulness by G. elegaos, a freegrowing large-spiked variety-a great improvement on better known kinds. A useful plant, not difficult to manage, is Hibbertia Reidi, with Diosma-like foliage and numerous shining yellow saucer-shaped flowers that cover the plant in spring and early summer, making it a very effective greenhouse subject. Boronias, such as B. megastigma, B. anemoniæfolia, B. serrulata, and several others indeterminable when not in bloom. Coleonema rubrum, Thibaudia acuminata, with bright tubular flowers of scarlet and gold; Leschenaultias of various kinds, as well as Chorozema Chandleri were coming into bloom. Witsenia corymbosa, a pretty blue flowering greenhouse species, and Leucopogon Cunninghami, together with several varieties of Eriostemon, little plants quite gay with white stars, the sorts being E. laurifolia, E. buxifolia, and E. myoporoides. The increasing volume of smoke that pervades this suburb has made the culture of the Heath almost an impossibility, so that Mr. Low has seen the necessity of taking up ground at Enfield, where hardwooded plants are now being grown. There were very healthy specimens in bloom of Erica regerminans, E. me'anthera, E. candidissima, E. ventricosa, to have grown which in Clapton would have taxed the utmost ingenuity of the able staff, and then they would not have succeeded.

- JAM .- The public mind has been much exercised as to the ruling prices of that now almost necessary of life-fruit preserve or jam-since Mr. GLAD-STONE drew popular attention to the subject. doubt the Premier took a somewhat pessimist view of the subject, but we must remember that persons in his position in life do not as a rule purchase from those who cater for the poorer classes, and that his figures may rather have been taken from the tariffs of high-class traders than from those of universal providers. But some of the Premier's critics have gone conversely low in their estimate of jam prices, and have put them as low as $3\frac{1}{2}d$. and 4d. per pound. Certainly such are the retail prices of mixed preserves, from which may Heaven deliver us, and also of the inferior marmalades, but these articles include in their composition a vast deal that may not be absolutely injurious, but which yet is the reverse of genuine,

The best test is found in the retail prices of such jams as are sold in pots by first-class houses, because that may be taken to represent bond fide fruit products; and of these, exclusive of pots, first-class preserves can be purchased at 5d. and 6d. per pound, and such price is undoubtedly cheap when we regard the enormous expense incidental to the cultivation of fruit, rent, rates, taxes, planting, years of waiting for crops, uncertain scasons, cultivation, manuring, gathering, and marketing, and fically manufacturing into preserve, we may well ask how it is possible for genuine fruit preserves to be sold to the public by the retail tradesman at less cost. Cheap if wholesome preserves are of course public boons, but it would be a misfortune were the market to be so swamped with them that their manufacture and the cultivation of the fruit was no longer profitable. These may seem to be farfetched objections; but it must be remembered that even now, when we get a big fruit crop, growers' piices are of the lowest, whilst a scarce season brings universal loss.

- FLAKED CHINESE PRIMROSES. - At the bottom of a note on Chinese Primroses at p. 216 last week, reference is made to pretty "shaped" varieties formerly seen at Southampton. "Shaped" was a misprint for "striped," as the context showed. Striped or flaked flowers of this beautiful winter blooming section of Primulas are certainly not now nearly so abundant as they were ten years since, but their impress has been left in some of the enduring double forms, though even these are so far erratic or sportive that they sometimes become pure white. The striped single forms seem to owe their present scarcity to two reasons; first, they have ever been unreliable and sportive, not easily fixed as self-colours are; and second, they lack effectiveness when compared with good self-coloured sorts. Perhaps the introduction of deep rich hues into our selfs has had much to do with the declension of the striped kinds, because the popular taste has run after showy effective colours. Whites always look well, but in the winter months the rich reds and purples at all times, and especially under artificial light, lend an element of warmth and brilliancy before which all striped as well as delicatehued flowers must pale their ineffectual fires.

It is a pity that this prominent taste for glow and colour should outweigh other considerations, for no doubt the flaked purple and carmines, the pale blues, delicate pinks, and lavenders are all truly The trade does not much care for these tints, hut private growers should have much regard for them. A few intense reds or purples in a collection are delightful, but masses of these hues only become monotonous. Truly, with Chinese Primroses, as with many other flowers, variety is charming.

- ANEMONE FULGENS. - Of the great beauty of this, the most brilliant of all early spring-flowering plants, it is hardly necessary to speak. No little dis appointment has been caused in some quarters, however, by its tendency to develope flowers in which the stamens and petals have become sepaloid, and thus large clumps, instead of showing glowing masses of vivid colour, exhibit a number of green flowers, undistinguishable a short distance off from the foliage itself. From a gardening point of view, a very much superior plant is the one which is found in some catalogues under the name of Anemone Regina; in this the numerous stamens and pissils are changed into narrow petals. Even this latter, however, is not so handsome or so effective as the ordinary singleflowered type.

- LANDMARKS OF HORTICULTURE -One of these was undoubtedly Ealing Park, in the days when Mrs. LAWRENCE had her wonderful collection of plants, and the dite of fashionable Society crowded to her garden parties. A visitor to London who had an interest in horticulture went to Ealing Park as a part of his duty, and as a pilgrim does to a holy shrine. But what a change now. A broad carriage road runs right across the park and pleasure grounds, east to west-from Ealing Lane to Windmill Lane, passing along at the south end of the famous avenue of Cedrus Deodara. The cutting away of the soil to form the roadway loosened the roots of one of the specimens, and during the gale of a few days ago it toppled over like a ninepin. Unfortunately this avenue does not appear to be included in the private grounds now left to the residence, and to all appearance a margin of houses will presently spring up all along where stood Mrs. LAWRENCE'S plant-

houses, as also the gardener's house, vineries, &c., in Mr. J. S. BUDGETT's time. If this be so, many a fine tree will have to be felled to clear the ground for the builder. The Cedar avenue is already open to the incursions of children, and much damage is being done to the specimeos. The magnificent Cedar of Lebanon (probably one of the finest in the country) which stood at the south-east corner of the pleasure grounds, appears well nigh dead, and will soon be felled. Nearly a thousand houses are to be erected on the park, and already some villas are near completion. But it will be years before memories of Ealing Park become utterly though the circle of contemporary horticulturists narrows as each year passes away.

- GREVILLEA SULPHUREA is one of the few proteaceous plants which can lay claim to be fairly hardy in this country, and, therefore, apart from its merits as a subject for cool conservatory decoration is doubly interesting. A good-sized specimen has flourished for many years against an outside wall of one of the houses in the Coombe Wood Nurseries of Messrs. VEITCH, and when in flower it looks strikingly different from anything else which grows in the open air and withstands the cold of winter in this country. Some well-grown bushy examples at Kew are now blooming, and the sulphur-yellow flowers form a pleasing contrast to the dark green Gorse-like foliage.

- SAXIFRAGA LIGULATA. - This is an excellent plant for flowering in pots at this season of the year. It is a very early flowering form, and if grown in pots, and stood out-of-doors all the summer, and brought into a cold house in December, it will be in flower in the early part of February. And it appears to vary in colour a little. There is one variety in which the flowers are slightly blush—almost white, with a coloured base; this is very pretty indeed, and a fine plant bearing six or eight panicles of bloom is a very attractive sight. Another has pale rose-coloured flowers, and is quite distinct from the foregoing. There may be other varieties, but these are well adapted for culture in pots, as they are very free. is a species that flowers very early and freely in the open air, and the consequence is that, owing to the bad weather which prevails at the time of flowering, their beauty is lost. By cultivating the plants in pots this danger is averted, the flowers are finer for the protection afforded, and they last much longer in a state of perfection.

- THE ALATAU MOUNTAINS .- The following account of these Central Asiatic mountains, whence we may derive numerous interesting alpine and other plants, is taken from a recent number of the Daily News:-"The northern chain of this range presented to our view an uninterrupted mountain mass rising to an average height of S600 feet, and in its central portion to the limits of perpetual snow. Tal Cheku, the highest peak, has an vation about equal to that of Mont Blanc, and the snow line is visible for more than 30 miles, besides which we could see many heights with snowy patches, fully entitling the range to its name, Alatau, or the Spotted Mountain. Before the settlers came not only the slopes, but also the lower spurs, of these mountains were covered with forests. Now grass alone grows on the summits, and the clear, bright, emerald green of this mingles with the dark green of the few Fir trees that remain on the hill-tops. The spectacle presented by the lower spurs in spring must be very beautiful, especially in the Almatinka valley when its Apple trees are white with blossom, mingling with the delicate pink of the Apricot bloom. The traveller may ascend this chain by five high passes, three of which are higher than the highest in Europe, but only to discover heyond him ridge after ridge, chain after chain, of the enormous Thian Shan, the largest mountain system on the northern slopes of The entire length of the Thian Shan is about 1660 miles, and its highest peaks everywhere exceed the limit of perpetual snow. Members of the Alpine Club who are beginning to think that Switzerland is nearly played out, will perhaps he interested to know that this mountain mass in Central Asia is estimated as being twenty-five times larger than the Swiss Alps, covering an area that is as large as France and Spain, and forming a protuberance upon the earth's surface considerably larger than the aggregate of all the mountains of Europe. It has plenty of peaks from 16,000 to 18,000 feet high,

and one of them, of which I was said to have been These alpine within sight, exceeds 21,000 feet. mountaineers may be further interested to know that the glaciers of the Thian Shan are computed at not less than 8000; that there are numerous snow bridges, some of them the mile in length and 100 feet in thickness; and, finally, that any one wishing to make a little summer tour from Vierny to Kashgar, the distance merely from London to Durham, will be under the pleasant necessity in so doing of crossing not one but eight parallel ridges, most of them rising to the limit of snow. In the cattle market I inquired the price of sundry animals. For camels they asked from £5 to £6 each, and for horses from 30s, to £10 Sheep were valued at from 7s, to 10s.; a foureach. year-old cow at 24s., and a goat at 5s. 6d. Beef I heard cost from 1d. to 1\flat{d}, per pound, and veal from 4d. to 5d. Chickens fetched 5d. each, and ducks 1s. 3d per pair. More tempting to me, however, were the luscious Water Melons (some of them weighing 36 lb.), at less than id. each. Grapes, also, have been introduced by the Russians, and small but excellent Nectarines, the latter for a halfpenny each, of which, as I sat over my writing at night, I ate so many as to alarm, though needlessly, the medical instincts of my companion, Mr. SEVIER."

BRUSSELS SPROUTS .- We have received an excellent specimen of a variety of this vegetable from Messrs. BARR & Son, Covent Garden, measuring 2 feet 9 inches in height, exclusive of the root, and 61 inches in circumference at the bottom of the stemdimensions that mark a giant form of growth. The sprouts correspond to these large figures, the fuller grown ones almost equalling small Cabbages; but then it must be stated that as none whatever had been gathered from the stalk, these have grown much beyond the size that may be called usable. The variety or strain is that of Mr. MAY, gardener, Northam House, Barnet,

- ERICA STRICTA .- When in flower this beautiful Heath is one of the most attractive of ornamental Although introduced to this country just before the commencement of the present century, it is not so well known as it ought to be. Under favour-able conditions it attains a height of 6 feet. At Sir JOHN CAMPBELL ORDE'S, at Kilmorey, on the west coast of Scotland, the species is thoroughly established and seeds freely, many bushes being fully 6 feet high. It is a native of South-Western Europe; under cultivation in this country it thrives well in peaty soil except in exposed situations. The habit of the plant is erect, and the flowers, which are produced in great profusion, are a fine purplish-red colour.

- CALAMANDER WOOD-or, as it is sometimes called, Coromandel Wood-which is so much valued for small ornamental articles on account of its beautiful figure, is, as is well known, the produce of Diospyros quesita, THW., a large tree of Ceylon. Considering the value of this wood, both in Ceylon and also for exportation to Europe, it is not satisfactory to learn, on the authority of Dr. TRIMEN, that the tree has become extremely scarce. GAMBLE, in his Manual of Indian Timbers, also describes it as the most valuable ornamental wood in Ceylon, which is much in demand, but now scarce.

- PULTENÆA SUBUMBELLATA.-Considering the amount of flower produced, and the compara-tively little attention necessary to grow them, it is matter of wonder that this Pea-flowering plant should not be more universally grown. The same might be said of many other hard-wooded New Holland plants, but the present one has this further recommendation, that is of low, bushy, and erect habit, and flowering at this season would be useful not only in a collection of greenhouse plants, but for the cut-flower basket. The flowers themselves are brownish-orange and yellow. The plant is figured in the Botanical Magacine, t. 3254, and may be seen now, in a flowering state, in the Winter Garden, Kew.

- PARAGUAY TEA .- Yerba, or Paraguay Tea seems to be coming to the fore as a beverage in this country, if we may judge from the way it is being advertised by a firm in one of the large Midland Counties, who style themselves importers of this Tea. The following appears in the Church Times: - " No more bad tea! Drink Verba (trade mark), as adopted by the most fashionable circles in Paris. Descriptive

catalogue post-free. Verba, the finest quality of the samous Brazilian tea (Maté), is very nutritious, and has all the stimulating property of India or China tea, but no tannin, consequently never produces indigestion, and can be safely taken with meat. A light, thin, refreshing drink like tea, with fine fragrance and flavour, yet as nourishing as cocoa. Millions of pounds are used annually in Brazil. Price 2s. per pound." It will be interesting to see whether the leaves of Ilex paraguayensis will ever become an acknowledged beverage in this country. Readers of the Gardeners' Chronicle will remember the persistent attempts of Mr. FORSYTH to introduce the use of the leaves of the common Holly for this purpose.

BATH AND WEST OF ENGLAND SHOW .-At this show, which is to be opened at Maidstone on Whit Monday, prizes will be given for Orchids and for fruits and vegetables. A Cup of the value of \$10 10s., or its equivalent in cash, will be given for the best collection of Orchids; a Cup, or £5 5s., for the best specimen Orchid. Two Cups, of the value of £5 each, will be given for collections of fruit and of vegetables respectively. In view of the fact that Maidstone is the centre of a great fruit-growing district, these prizes, albeit that the season is too early to secure adequate representation, either of fruits or vegetables, ought to do good service, and we trust the Society will see its way to take steps to bring under the notice of its members, by demonstrations and exhibitions if possible, of the best varieties to grow for particular purposes, and the best methods of pruning. Such practical teaching would be even more useful than the exhibition itself.

— MR. JOHN LOADER, who for the last seven years has been Gardener to R. W. BANKES, Esq., Kingston Lacy, Wimborne, Dorset, has commenced business as a Market Gardener and Fruit Grower, at the Ivy Nursery, Reddings, near Cheltenham,

HARPENDEN HORTICULTURAL SOCIETY .-The sixth annual show of this Society has been fixed for Thursday, August 28.

- THE WEATHER.-General remarks on the temperature, rainfall, and duration of hright sunshine, for agricultural and sanitary purposes, during the weck ending February 18, issued by the Metcoro-logical Office, London:— The weather has been generally fair and comparatively dry in the southeastern, eastern, and north-eastern parts of the kingdom, but dull elsewhere, with a good deal of kingdom, but due tescwhere, with a good deat of raip. Temperature has been about equal to the mean in "England, N.W.," but from 1° to 3° above it in all other districts. Readings were high during the first lew days of the period, but subsequently became rather low; thus, while on the 13th or 14th the maxima were as high as 56° in "England, E.," 57° in "England, S.," and 58° in "Ireland, N.;" on the 10th they were below 40° in many parts of Eng-land and Ireland, and at some stations did not exceed land and Ireland, and at some stations did not exceed age or 37°. The minima, which were registered on the 16:h, 17th, or 18th, varied from 30° in the "Midland Counties" and "England, S.," to 34° in "Scotland, W.," and 42° in the "Channel Islands." The rainfall has been less than the mean in all the "Wheat-producing Districts," but considerably more in the "Grazing Districts." considerably more in the "Grazing Districts," Bright subshine shows an increase in duration generally, the percentages varying from 8 in "Scotland, E.," to 28 in "England, S.," and 34 in "Scotland, K.," and "England, E." Depressions observed.—During the early part of this period pressure continued highest over France and North Germany, while depressions travelled in a northerly direction outside our western coasts. The wind was consequently south-west, and at our more western outside our western coasts. The wind was con-sequently south-west, and at our more western and northern stations blew with the force of a strong breeze to a fresh gale. As the week advanced, however, the highest pressure was gradually transferred to Denmark and Scandinavia, while over France and our south-western coasts the barometer fell briskly. With this change in the distribution of pressure, strong south-south-easterly gales were experienced in Scotland, moderate to fresh south-easterly gales over the greater part of England south-easterly gales over the greater part of England and Ireland, and moderate to strong easterly breezes over the Channel and south of England.

- GARDENING APPOINTMENTS,-Mr. B. PER-GARDENING APPOINTMENTS.—Mr. B. PERRYMAN, Foreman in the houses, under Mr. KETLEWELL, at Balrath Bury, Kells, Co. Meath, as
Gardener to Mrs. Webb, Quadretrown Park, Mallow,
Co. Cork,—Mr. W. Dowden, late Gardener at St.
Peters, Isle of Thanet, as Gardener to the Dowager
Marchioness of Downshire, Wakehurst Place, Hayward's Heath, Sussex.

NEPENTHES MASTERSIANUS×.

OF all the Nepenthes grown by Messrs. Veitch in their wonderful treasure-house of these plants, this is the richest in colour, almost the largest in size, while it is also a free grower, and not slack in producing pitchers. On this account we give an illustration (fig. 48) of a full-grown pitcher, and a sketch (fig. 47), showing the habit of the plant, to supplement the meagre illustration given on a former occasion, when the plant had not assumed its full proportions. Its parentage is stated to be N. sanguinea × N. Khasyana.

Home Gorrespondence.

Clematis Jackmanni : its Origin,-I read with amazement in last week's issue of the Gardeners Chronicle M. Lavallée's theory as to the origin of Clematis Jackmanni and other hybrids sent out by our firm; though, as this account differs very materially from the facts, it will not be necessary to travel far to substantiate the true origin of the plants. Lavallée asserts that Clematis Jackmanni is nothing more nor less than a species called Clematis hakon ensis, and he then describes its characteristics thus: -"Its seeds are always numerous, germinate easily, or reproduce the species almost without variation. If the newcomers present any modification it is only in the size or colour of the sepals." But previous to this he states the peculiarities of hybrids, thus:— "When a hybrid plant is successfully raised, that is to say, a product the female parent of which belongs different species to that which constitutes the male parent, a plant is produced which is generally sterile, or at least only exceptionally fertile, and then very inconstant. It is, therefore, necessary to mul-tiply such plants artificially either by cuttings or by grafts," &c. Now, had I been asked to describe the peculiarities of the hybrid Clematis Jackmanni and peculianties of the hybrid Clemans Jackmann and its allied varieties, I could not have found words more to the point than those quoted in this latter extract, and which go to prove—were proof required—that my plants are true hybrids. Therefore, the only conclusion at which I can arrive is that M. Lavallée is at present totally unacquainted with the true Clematis Jackmanni, rubella, and the other seedlings of the same parentage, distributed by our firm in this country. Again, I take exception to the hypothesis that Clematis Hendersoni could not have been one of the parents of C. Jackmanni, for, as a matter of fact, we had about a dozen hybrids in the batch of seedlings that were non-climbers; these had dark purple cylindrical tubular flowers, and mostly differed from their male parent in increased size; but they were of no commercial value in comparison to those sent out. As you appended my original statement in your last week's issue, it is not necessary to go over the ground again, but in passing I would mention that I fertilised the flowers with my own hand. I could, after twenty years, produce confirmatory evidence, were it needed—amongst others, that of my then propagator, Thomas May, now a pensioner of the Gardeners' Benevolent Institution, who sowed the seeds, and reared the seedlings, and would corroborate what I stated in

my letter of 1864. George Jackman, Woking Nursery.— I have read with astonishment your version— I have not seen the original—of M. Lavallée's observations regarding this plant, in which he says that Clematis Jackmanni, which we know is an English hybrid, is not so, but is the C. hakonensis of Franchet and Savatier, published twenty years later (1879), which has been imported and claimed as an English raised novelty. Now what do the plants themselves say in reply? C. hakonensis has "folia ternata," which is a characteristic of the patens group, while in C. Jackmanni the leaves are "pinnate" or "pinnatisect" with five or more leaflets, and, therefore, quite different. I need add no more, though another note of F. and S.—sepals "vix pollicaria"—would be a caricature rather than a character of our English plant. My object—having known all the facts as they transpired—is to bear my testimony to the undoubted good faith and veracity of my friend Mr. Jackman. As regards your own note, that M. Lavallée's figure of C. hakonensis suggests "Jackmanni before it had been improved by cultivation," I can bear witness that Jackmanni has not been improved by cultivation, but that at its flowering it was

at least as fine as it ever appeared since, except as regards the size of the plant. Thomas Moore, Botanic Garden, Chelsea,

Protecting Fruit Trees, — The time will soon be here when protection for the majority of our wall fruit trees will no longer be a matter for contemplation but of actual fact, and the present time may be considered opportune for a few remarks thereon. For some few years now the successful culture of some of the more tender kinds of fruit on open walls has been looked upon by not a few cultivators as being altogether a hopeless task and quite a thing of the past, owing, as they aver, to altered circumstances and to different climatal conditions from those formerly existing, the latter fact necessitating the work of partially or wholly covering walls with glass. This view of the matter will not in many cases bear an investigation without proving itself to be in some degree altogether a fallacy; happy is the man, how-

for years with proper care and attention in regard to keeping it clean and dry. The most convenient method of employing it is in the way of rollers and blinds, to be worked from a rail and brackets fixed under the coping; and to prevent injury to the blossoms upright posts should be placed about 5 feet apart, being joined to the top rail and resting in sockets at the bottom of the wall and about 18 inches therefrom, ordinary sash-cord being used for winding them up and down as occasion requires. Canvas and other materials of a like nature may be used in the same way. Other and more primitive ways of affording protection are to be found in fish netting, Spruce branches, bast, and straw mats. The latter, although thoroughly effective and proof against several degrees of frost, are in a certain sense objectionable, chiefly on account of their non-durability, which extends on an average to about two seasons, or three at the outside, and also on account of the littery appearance they give to a fruit border from loose and falling straw. No fruit wall can be said to have been properly constructed which has not a good broad coping of from 12 to 15 inches either of tiles or stone; where

Fig. 47.-Nepenthes mastersianus x: To show habit and foliage,

ever, holding such views who can make them prevail in a practical form, and thereby obtain what to him is certainly a boon—viz., a glass-protected wall for his Peaches and Nectarines. There is no disputing the fact that a higher class of fruit is produced under such artificial conditions than is to be obtained without them; nevertheless it may, I think, be said that with proper care and attention as good fruit can be obtained on from open walls as in days long gone by. Occasionally we may have a season when it becomes impossible to ripen outdoor Peaches; happily, however, such seasons are exceptional, and, speaking in a broad sense, it cannot be said that we are worse off in regard to weather to what past generations were. What has just been stated must not be taken as implying that a glass-protected wall is a useless expenditure of money; on the contrary, I hold that every shilling laid out for such a purpose is money well invested, and in time will repay its owner fourfold. Of other protecting materials there are now many, some of which have stood the test of time and may be confidently recommended as answering fully the purpose lor which they are intended. Frigi Domo probably stands unrivalled, and although its first cost is somewhat expensive as compared with other materials used for the same purpose, it is cheap in the end, lasting as it does

this defect exists it should be remedied by portable wooden ones, made in convenient lengths, so as to be easily fixed in position or removed at will. For Apricots, Plums, and Pears growing on walls Spruce bracches tied on somewhat sparingly will be found ample protection to secure a "set" in most cases. The same material, as well as netting of a double thickness, may be used for pyramidal and horizontal trained cordon trees growing along the garden walks. A little trouble taken in this respect will invariably in the worst of seasons secure a fair crop of fruit and fully repay all pains and outlay thereby entailed. Reverting for a moment to the matter of wall-protected trees, it is very essential to bear in mind one important point, viz., that the trees should nos be deprived of a single hour's daylight more than is absolutely necessary; lengthened spells of darkness not unfrequently occur on the Sundays, owing to a little dilatoriness in the morning, and eageness to have done with the work in the afternoon. As a matter of course, it will sometimes occur that the thermometer will be down to freezing-point to as late as 10 or 11 o'clock in the morning, and occaionally there may be a day when storms of sleet and a frosty air prevail throughout; under such conditions the blinds are much better down, neverthe-

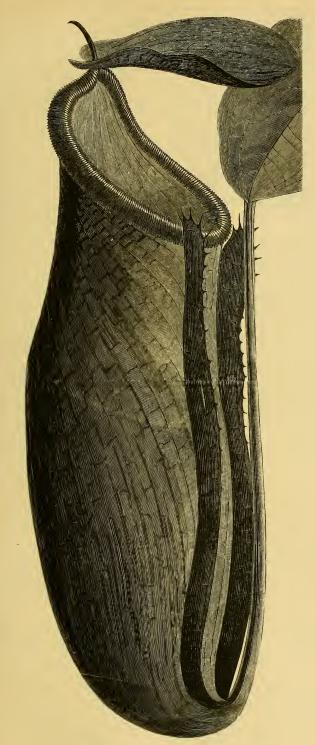

FIG. 48,-NEPENTHES MASTERSIANUS X: DEEP CRIMSON, (SEE P. 248.)

less the fact still remains, that too little light has a very weakening effect on the blossoms, and a very great tendency to defeat the object in view. 7. H.

Lilium candidum.— Reference to this plant, regarding its value for pot culture, has been previously made in your columns, and perhaps there will be nothing lost by a repetition, as it is invaluable for early forcing, and one of those popular subjects most frequently met with in our berbaceous borders. Last year about this time we dug up a few clumps, and put them into 12-inch pots; they were put into a gentle heat for the first two or three weeks, alterwards into a higher temperature, and produced their first lot of flowers towards the end of April. After these were cut the plants—or perhaps in strictness I ought to say bulbs—were transferred to the borders again without disturbing their root unnecessarily at the end of October. We were rewarded by a second batch of flowers from the same clumps, which in our case proved equally as valuable as the first. In taking them up now the roots should be lifted carefully, allowing the clumps to be as near the size of the pots they are intended to be forced in as possible, and when they are matured they should have the benefit of weak liquid manure. H. J. H.

Hepaticas.—I am grateful to the Rev. C. Wolley Dod for his valuable information respecting this charming flower. A large plant of the single blue that came into bloom quite early, now appears to be forming seed-pods. As soon as the weather is milder I will plunge the pot up to the rim in an open border, and sprinkle some peat about the flower-stalks as suggested, in the hope that seed-lings may come from it. In addition to the single blue, thave now in flower a Continental variety I got under the name of coerulea levigata, paler than the single blue, of a delicate lavender-blue—a very pleasing shade indeed, and of good size. It is quite distinct in shade from angulosa, which is also in bloom. Then there are Barlowi and the single purple, both deep shades of blue, and quite distinct—the purple the deepest of the two. The double blue appears to be later, and is only just coming into flower. I have some fine plants in pots, and they will flower freely presently. The single white is a perfect gem among Hepaticas, it is so pure and sweetly pretty. A vigorous young plant is now in nice bloom, and it is truly charming among the blue-flowered varieties. This, like the single blue, will cast its seed, and produce seedlings. I remember seeing, a few years ago, in Mr. Perry's nursery at Banbury, some self-sown white seedlings that had grown and flowered about the parent plant, but they appeared to be in every case inferior to it. Plants of the double red are in full beauty; it is every free indeed, and charming in colour. What few plants of the single red I have have not flowered this season, for some reason. Can Mr. Wolley Dod, or any one else, say how many distinct varieties of single red Hepaticas there are? During the summer my Hepaticas stand in a bed of coccan-tut refuse on a north aspect, and fully exposed to all weathers. This position seems to suit them well; there is a cool and moist bottom, and the roots find their way down into it. They are not allowed to become dry. The greatest turble is with the worms; they

the plants from the pots and remove the worms. R. D.

— It may prove of some interest or use to those who, like myself, find a difficulty with Hepaticas, to know that a light covering during the winter of withered Ferns seems to help them on a good deal. Some sort of protection would seem but natural, since in their wild state they grow under Pine trees, or on the sheltered side of steep banks. With us the white Hepatica does well, making rather large robust plants; but the blue and the pink, both double and single, go ofi. The plants certainly seem happier, however, since we have tried the Fern covering. It is a little bit of gardening that I take pleasure in doing myself, laying the Ferns with as light a touch as possible, so that the flowers may rise through them. It is possible that something else might answer better—such as Beech twigs with the brown leaves still hanging on them. A little garden in Cornwall has been described where Hepaticas bloom in beautiful masses of blue underneath Roses trained on a trellis 2 feet above them. The leafless Rose hranches would here give the slight protection needed in winter, while later on the summer leaves would shade off the sun. From "A Buckinghamshire Garden,' Feb. 16.

Storing Potatos. — When I came here, some three years and a half ago, the place had only just been built, the garden was only a field that had not been cultivated for four or five years, and there were no store-rooms; but two years ago we had some rooms built, with two cellars dug out of the solid

chalk. A workmen's room, Onion room, and seed room over the latter were provided, the seed room being fitted up like a fruit room, with the battens on the shelves placed an inch astunder to allow the air to pass from top to bottom, and the windows face the east, the door the west—an arrangement which I find answers very well. Our Potatos at the present time, although the winter has been so mild, are only speared about half an inch, and the shoots are almost as thick as one's little finger; and I think Potatos never do better than when planted in that condition. They come up healthy and strong, and out of 60 tons stored these last two seasons I have not had more than to cwt. diseased, and those have been early sorts, chiefly Ashleaf Kiddeys. The cellars are fitted up with bins to hold 3 tons of Potatos each, and are made with 14 inch deals, which run in grooves, both sides and front right up to the ceiling, with a trapdoor at the bottom for getting them out. Last winter, although the door and windows were kept open every day, the tubers exhausted themselves so much that was used I had some ventilating shafts sunk on the east side, one to each bin, with iron gratings, which in case of frost had only to be covered with tiles to stop the draught. In addition to this I had all the loards of the bins brored with inch holes diagoually, and about 18 inches apart, so as to always have a current of air passing right through the bins; and the result has been so satisfactory that the tubers are now quite dormant. The sorts stored are Magoum Bonum and Red-skinned Plourball, which seem to do best in this chalky soil. I have sent a few for your inspection, which I think will fully bear out my remarks. [Certainly. Ed.] C. F. Prangell, Kensington and Chelas Scholes, Bontlead, Survey.

Sisytinchium grandiflorum. — On inquiry amongst gardening friends I find that this bulb is rather earpicious in its requirements. Books of cultural directions recommend peat for it, but with me it dies out in two years in peat, but is now flowering grandly in two or three places in light very well drained sandy loam. Mr. Barr tells me that at Tooting, on raticed beds of equal parts of loam, leaf-mould, and sand, it increases "like Chickweed." On the dmarty loam of Devonshire, so good for most bulbs, it pines away. The general name Sisyrinchium has puzzled those who give the meaning of names in botanical dictionaries, who generally connect it with a pig's snout. It is one of those classical names which were utilised by the herbalists of the sixteenth and seventeenth centuries, probably without taking much trouble to inquire what plant was originally enough the bulbs, and the sixteenth and seventeenth centuries, probably without taking much trouble to inquire what plant was originally much to Old World, it is clear that Theophrastus and Fliny did not denote by the word the same plant as Linneas did. In such cases the connection between the name and the nature of a plant is less important. An editor of Pliny, at the beginning of last century, first suggested, not very happily, that the name and hen nature of a plant is less important. An editor of Pliny, at the beginning of last century, first suggested, not very happily, that the name and and a coating of wool, from which flannel clothes in Theophrastus, I find, after a long huat, a very short notice of the bulb, and the passage is evidently imperfect, as it makes no sense as it stands. The author had just been speaking of eriophorous or wool-bearing bulbs, which between the fleshy edible tunics had a coating of wool,

Potato Planting.—The present time seems the lest for a little discussion as to the best method of the many now in vogue of planting seed Potatos. Some are anxious about the strength of the tubers being wasted in the growth they make in the seed rooms, cellars, or wherever they may have been packed away, while some advise rubbing the growths oil, and some let them take their chance. Now it seems to me that the present beautiful weather should be made use of io getting them planted and done with. It has been my practice for the last five years possible in the autumn. As a rule this takes place during September or October, and as Potatos follow Peas and Beans I know of no better plan than to get these cleared off as early as possible after the crops are gathered, and to get the ground ridged up and put in order for the winter. I have to-day (February 18) planted several bushels of Ashleaf Kidneys between

ridges thrown up last October, and the ground works like ashes. We first draw a drill along the bottom of the furrow, lay the Potatos in, and cover them with a handful of burut refuse, then run a rake along the sides of the ridges, which brings down sufficient soil to cover the sets deep enough to be out of the reach of frost, and to leave the greater portion of each ridge to serve as protection from cold winds, and also for covering the young Potato plants as fast as they come through during the first few weeks till danger from frost is over. After the last covering of soil, the Potatos get very little attention; but if we get much rain to beat the surface down hard the soil between the rows is forked, or a hoe is run through them once or twice as is needed, and they do not require carthing-up, as by planting as I have described they get sufficient from the ridges. No doubt many others could give some valuable hints ou this important matter. It seems to me to be altogether wrong to leave Potatos growing in the sheds until they are grown together like a mat, or to set men to rub off the growths, to expect a good return for your labour; and when the old practice of dibbing in is carried on I do not see how the sets are to be got in without being more or less injured. Now that I have given my opinions, may I hope that some more able pen than mine will take the matter up? There is one more point: I would strougly advise those of your readers who have not made use of burnt refuse as a dressing for Potatos to do so this season.

Strangled Hyacinths.—Taking the Hyacinth as a whole, it does not lend itself so readily to forcing as amany winter-made-flowing plants, indeed there are few, very few kinds that can be forced with any degree of certainty before Christmas and be had in anything like presentable condition. To attempt forcing either blues, end as to whites it is a question of experience among the varieties as to what kinds artificial heat may be applied to without injuring the prospects of the plant. Apart from the early Romao Hyacinth, none can equal, nuch less surpass, the double white kind known as La Tour d'Auvergne for early forcing. I have this winter forced a considerable quantity of this variety, and not in a temperature generally recognised as forcing, viz., 70° or 75°, but on a bottom-heat which sends the thermometer (which was placed among the plants for test) to 112°; the bulbs of these, which were only an ordinary sample, were potted the second week in October, and were introduced into heat in batches as soon as they were deemed fit, the temperature ranging from 50° to 55°, and kept dark, and finally they were placed on the bottom-heat referred to above; the result lar exceeded any previous experience with it, though I remember on one occasion, some eight years since, having got a few of this same variety in flower very early. These were placed upon a hot-water circulating tank, which was supplied direct from the boiler, and situate immediately over it, the plants belog about 6 inches from the water. The individual pips of this variety have a distinct tapering outline, and with the aid of a little cotton-hool use. The majority of the failures in early forcing. I am strongly of opinion that the double white kind cited above may be had inflower from the first week in December, provided the bulbs are potted in good time—say the first or surfangled "forms (see p. 181) one so often sees in the none office, while those that energed from it bore the serve element of the first were experimented with under similar conditions,

Blending Petroleum with Water,—Petroleum can be blended with water, evenly held in solution, by freezing Gishurst Compound and the oil separately; and then uniting the two at a freezing temperature; the lower the more rapid will the oil dissolve the compound, and remain with it till required for use, when boiling water has merely to be added to make what I know, from experience, to be a really effective, and probably the best insecticide known for general purposes. The Woodward, Ardgillan Castle, Balvirgan.

Luculia gratissima, — I can quite understand how delighted Mr. Inglis was to look upon and inhale the perfume of this grand old plant. I had the pleasure of seeing a fine plant at Syston IIall, Grantham, on the 21st ult., with, I dare say, close upon a hundred fine trusses; it was a splendid sight. The old plant, to my knowledge, has occupied the same trellis on the back wall of the five conservatory for upwards of twenty-four years, and looks likely to keep its post for years to come. ? Bauser, The Rookery.

CLIMATE AND VEGETATION.

THE FLORA OF THE COUNTRY BORDERING THE RIO GRANDE, IN CHIHUAHUA AND TEXAS. - The country bordering the Rio Grande, iu Chihuahua and Texas is nearly destitute of trees-a feature which marks the aridity of the climate; yet, in certain localities, as on the bottom lands of the Rio Grande and Rio Concho, a vigorous and somewhat varied forest growth was found at the advent of the whites. No better illustration of the relation between the kind of vegetation and the water supply in a country can be found than that afforded by the luxuriant growth of trees of several kinds along the Cibola Chinati Mountains, Texas; while on all sides this oasis is surrounded by an apparently boundless grasscovered prairie, where the rainfall is inadequate for trees. On the mountain summits, south of the Rio Grande, is a sparse growth of Piñon (Pinus edulis) and evergreen Oak (Quercus Emoryi). The lowlands in certain localities, over thousands of acres, are thickly set with Mesquite (Prosopis glandulosa), here a strong spreading shrub, never a tree, but with roots disproportionately large, composed of very dense tissue, and furnishing a large amount of excellent fuel. Along the arroyos Cotton-wood may occasionally be either the narrow or the broad-leaved form (Populus mouilifera or P. angustifolia), and more commonly the Hackberry (Celtis occidentalis), and the Nopal, the little Black Walnut (Juglaus rupestris), the Mexican Buckeye (Ungnadia speciosa), and the Guayacan (Guaiacum Coulteri). The drier portions, especially the gravel terraces bordering the Rio Grande, are frequently covered with the Creosote plant (Larrea mexicana) and Fouquiera spleodens. The latter forms a cluster of fifteen or twenty canes, 10 or 12 feet high, springing from the same root, and bristling with spines an iuch or more in length, of which the bases are in contact. Usually it is without leaves, and seems as though dead; but for a brief interval in the rainy season it is covered with small, crowded, obovate leaves, and from the summits of each stem springs one or more spikes of brilliant crimson flowers.

Among the shrubs which form the "chaparral," or thickets, the Holacantha is the most conspicuous, and Salazaria the most interesting. The former, as its name implies, is a mass of thorns, which are often as large and strong as those of the Honey-locust. The branches and spines are covered with a green epidermis, which performs the functions of leaves, and in the spring these bear bunches of yellow flowers similar to those of Berberis. The Salazaria is a Labiate allied to Scutellaria, and the seed is inclosed in a balloon-like capsule, similar to that of the Balloon Vine (Cardiospermum), also found here, and having the same function, namely, dissemination by the wind. Two species of Acacia and one of Berberis (B. trifoliata), all spiny, help to make the chaparral as nearly impenetrable as the thickets of Cactus further west. We are here fairly within the confines of the Cactus country, but not in its heart. Many species, differing much in babit, are constantly in sight - the Nopal, an Opuntia, being the most common, one species growing in a mass 10 feet or more in height, with each leaf-like subdivision of the stem a foot in diameter. Though covered with spines this plant is largely eaten by cattle, and nothing is more common than to see a patch of it trampled down, half-eaten, and the flattened stems notched by semicircular bites. One species or variety of Opuutia, growing abundantly in Chihuahua, is of a deep purple colour, which makes it conspicuous and often orna-mental.

The most striking feature in the botany of this region is formed by the Century-plaot and its allies, other species of Agave, Habranthus, and Dasylirion, and the Yuccas. In many places these are the only plants attaining any large size, and are very numerous, scattered over the plains and slopes of the mountains; the plants not crowded, but separated by intervals of a few feet, which are occupied with a luxuriant growth of Gramma grass. The Yuccas belong to four species, or three species and two varieties—Yucca augustifolia and Y. baccata. Of these, two rise to the height of 5 to 15 feet, with trunks from 6 to 12 inches in diameter, the crowded radiating leaves crowing the summit in a round or oval mass, 6 feet or more in diameter, the old leaves hanging perpendicularly, and forming a peculiar thatch around the trunk and extending to the ground.

The Century-plant is in Chihuahua represented by

a variety with shorter and broader leaves than that commonly cultivated. From the centre of the tuft the flower-stalk rises from 10 to 25 feet in height, composed of woody tissue and standing some years after bearing flowers. These persistent flower-stalks, crowning the ridges and visible for miles, give a peculiar aspect to the scenery. The Century-plants are, however, nowhere as numerous as the species of Dasylirion, with which they are associated, and which do not die with the effort of florescence. Further south the Agave supplies from its sweet juice the material from which an intoxicating drink is pro-In this region, however, an alcoholic beverage is obtained from the Sotol (Dasylirion texanum), which, from its abundance and the use made of it, deserves a prominent place among the economical plants of the country. Hundreds of thousands of acres are covered with this Sotol, and it would seem that it might be much more largely utilised than it is for the manufacture of alcohol. The leaves are flat, and garnished on either side with strong recurved hooks. The colour is yellow-green, and the leaves are very numerous. From the centre rises, at a certain stage of growth, a woody flower-stalk, 10 feet high, and at the base as large as one's arm. The trunk rises but a few inches above the ground, and is completely concealed. The top of this trunk, com-posed of the closely imbricated leaf-bases, which are broad, yellow, shining, succulent, and sweet, with a pulpy mass at the centre containing much saccharine matter, raw, or better roasted, is palatable and outritious; so much so, that in the country where it grows it is said the Indians never really suffer for want of food, as this affords them an abundant if not varied

In the preparation of Sotol whiskey-a liquid called "mescal," as is also that made further west from other plants-the portion of the plant which has been described is trimmed so as to resemble a head of Cabbage, then roasted and fermented, the product of the vinous fermentation being distilled in the ordinary For roasting the Sotol a pit is dug, some nasonry. In this a fire is built, and whee it has been hurned down the pit is filled with several hundred Sotol heads. When roasted they are chopped in pieces and fermented in vats.

Another interesting plant, the companion of the Sotol, is the "Lechuguilla" (Agave heteracantha), of which the leaves furnish a strong fibre, universally employed for ropes, sacks, &c., in Northern Mexico. This grows on the mountain slopes, generally at an elevation of about 4000 to 5000 feet, is common in all Northern Chihuahua, and especially abundant on the Chinati Mountains in Texas. Dr. Newberry, before the New York Academy of Sciences.

COLONIAL NOTES.

FARMERS' PROSPECTS IN CANADA.-Your observations on the subject of the future of your farmers' occupations are undoubtedly judicious, and borne out by the general experience of the cultivators of land in this country; and first, with regard to vegetables, it has been found, as you remark, that any attempt to exceed the regular supply has turned out unprofitably. With regard to small fruit, the only way to ensure a profitable demand for a quantity would be to can it, and for this purpose too much cannot be grown; and in all situations planting forest trees might be undertaken with a good prospect of success, as the denudation of our forests has been going on to such a fearful extent that numbers have to go away an immense distance from their homes, and at large expense to obtain a supply of timber far inferior to what they used to obtain cheaply in their own neighbourhoods. In this district, and in all other parts at all contiguous to our large towns. Twenty years ago the woods were full of fine large l'ines, Oaks, and Elms, but now they are nearly all gone, and the lumberers have departed to work in inferior timber at places far distant. It may also be remarked that in many of the Pine districts the quantity of available timber has been very much restricted by the bush fires, which the last few years have ranged over hundreds of thousands of acres, and destroyed a considerable proportion of it. In some districts of Muskoka and elsewhere, moreover, the Pine has been, all of it, turning out defective, and hence the poor lumber you complain of. With the prospective colonisation of our great North-west Territory, Wheat may be expected to be grown to any extent that the expenses of its transportation will allow; and should Hudson's Bay be found open enough to afford an outlet to Europe, there will be scarcely any limit to the production of this cereal. At present the cost of transit and the value at the railway station leave no margin of profit for cultivation for export. A Constant Realer, Minesing, Ontario, Canada, Feb. 5.

Reports of Societies.

Manchester Horticultural Mutual Improvement Society: Feb. 7.—At this meeting, over which Mr. Bruce Findlay presided, Mr. W. Nield read a paper on "The Apple," which was unquestionably the best and most useful of all bardy futus. Though it possesses many good qualities, the Apple had not received from those ho till the soil anything like the amount of attention to which it was justly entitled. According to the agricultural returns for 1883 there were in England 185.782 acres of land planted with fruit trees. If 35,782 acres, a liberal estimate, were deducted for land planted with Pears, Plums, Cherries, and Filberts, there remained 150,000 acres devoted exclusively to the cultivation of Apple trees. About seventy standard Apple trees can be grown on an acre, so that the total number of trees would be 10,500,000. There are probably as many Apple trees grown in hedgerows and farm orchards, not returned as such, and market gardens, as are grown on all the land specially devoted to their cultivation. This would bring up the total number of Apple trees to 21,000,000, or nearly one for every individual in England. If one-half is deducted 10,500,000 trees still remain, and, assuming each tree to bear 2 bushels per annum, the yearly crop would amount to 21,000,000 bushels, the market value which of at 4s, per bushel amounts to £4,200,000. Supposing the trees to be grown in 150,000 acres, the annual value of the crop would be £28 per acre, which, with good cultivation and a better selection of sorts, might easily be doubled. In fact he did not know of with good cultivation and a better selection of sorts, might easily be doubled. In fact he did not know of any purpose to which the land could be put which would brigg in so large a return for the capital employed, if farmers and market gardeners only knew how to go about it. If epointed out that demand for raw fruit is increasing in a greater ratio than the population. We have now from 3000 to 5000 different names for Apples, though he very much doubted if we have anything like that number of varieties in cultivation. The greatest may be a supplied to the control of the state of the control of the

A LARGE APPLE TREE. - Probably the largest Apple tree in the world is to be seen on the farm of Delos Hotchkiss, in Marion, Conn., U.S.A., the exact measurements of which are as follows :-

Circumference of trunk near the ground ... 15 feet 3 inches, ... 3 feet 15 inches, ... 3 feet 3 inches, ... 16 n. 2 n. 16 n. 1

A peculiarity of this tree is that it is what is termed "an alternate bearer," five limbs bearing one year and four the next. The usual yield from the five limbs is about 85 bushels, although in a single instance it reached 1 to bushels; and the four limbs vary from 35 to 40 bushels. The fruit is said to be excellent for winter use, though on this point I can only speak from hearsay. The age of this venerable Apple tree is estimated at about 175 to 180 years. Curiously enough the patriotic old tree marked the centennial year by bearing fruit on all its branches, the first time it has been known to do so in its life, and it has continued to do so down to the present time. Some of the limbs are now dying, others are broken down, signs of decay appear in many places, and it is thought that this noble specimen of Pyrus malus will soon be numbered among the things of the past. Rev. C. H. Hovey, in "Scientific American."

Obituary.

HENRY MILLS, late head gardener to G. L. Basset, Esq., Tebidy Park, Cornwall, died on Wednesday, February 13, aged seventy-seven years. He entered the above gardens at the age of twelve years, and worked himself up to the head position, which he held for several years. He served in the gardens, in one capacity and another, sixty years. He had for some years received an allowance from his employer.

The Menther.

STATE OF THE WEATHER AT BLACKHEATH, LONDON FOR THE WEEK ENDING WEDNESDAY, FEBRUARY 29, 1884.

Feb. 14.—Fine day, sun shioing at times. Light rain frequently from 6 r.M. till mideight.

— 15.—Fine cold day, occasional sunshine. Fine clear cold oight.

— 16.—Fine day and oight, cold wied.

— 17.—Fine day and oight.

18.—Very fape bright day. Fine night, cloudless till

19.—Rain falling from early morning till 10.30 A.M., dull afternoon. Thin rain from 3 F.M. to midnight.
 20.—Fine bright day, windy afternoon. Fine night, dark and cloudy.

LONDON: Atmospheric Pressure.—During the week ending February 16, the reading of the barometer at the level of the sea increased from 29.40 inches at the beginning of the week to 30.03 inches by 9 A.M. on the 12th, decreased to 29.94 inches by midnight on the same day, increased to 30.18 inches by 3 F.M. on the 14th, decreased to 30.18 inches by 9 A.M., and increased to 30.18 inches by midnight on the 15th,

and was 30.02 inches by the end of the week.

The reading of the barometer for the week at the level of the sea was 29.06 inches, being 0.18 inch lower than last week, and 0.02 inch above the average

of the week.

Temperature, — The highest temperature in the shade in the week was 56°.5, on the 13th; the highest reached on the 16th was 42°.2. The mean of the seven high day temperatures was 49°.3.

The lowest temperature was 31°, on the 16th; on the 14th the lowest temperature was 45°.5. The mean of the seven low night temperatures was 37°.5.

The greatest range of temperature in one day was 45°, on the 13th; the smallest was 6°.5, on the 14th. The mean of the seven daily ranges was 11°.8.

The mean of the seven daily ranges was 11°.8.

The mean of the seven daily ranges was 11°.8.

The mean of the seven daily ranges was 11°.8.

The mean of the seven daily ranges was 11°.8.

14th. The mean of the seven daily ranges was 11°.8. The mean temperatures were—on the 10th, 42°.6; on the 11th, 49°.8; on the 12th, 49°.8; on the 13th, 49°.8; on the 13th, 48°.3; on the 13th, 39°; and of the 16th, 36°.5; and these were all above their averages (excepting the 16th, which was 2°.2 below) by 3°.6, 1°, 4°, 9, 10°, 9, 9°.5; and 6°.3 respectively. The mean temperature was 42°.9, being 0°.6 higher than last week, and 4° above the average of the week.

the week.

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 97°.5, on the 13th. The mean of the seven readings was 85°.4.

The lowest reading of a thermometer with its bulb placed on grass and fully exposed to the sky was 24°, on the 16th. The mean of the seven readings was

Rain fell on four days, to the amount of 0.34 inch.

ENGLAND : Temperature .- During the week ending ENGLAND: Temperature,—John gitte week enting February 16 the highest temperatures were 56°,5 at Blackheath, 56° at Cambridge, 55° at Truro; the highest at Bolton was 49°,4, at 1 Preston 51°, and at Wolverhampton 51°.8. The general mean was

The lowest temperatures were 29°.5 at Wolverhampton, 31° at Blackheath, 31°.1 at Bolton; the lowest at Plymouth was 38°.9, at Leeds, 35°, and at Liverpool 34°.3. The general mean was 33°. The greatest ranges were 25°.5 at Blackheath, 24° at Cambridge, 22°.2 at Wolverhampton; the smallest ranges were 41°.5 at Plymouth, 17°.5 at Preston, and 17°.6 at Liverpool. The general mean was 20°.3.

and 17 to a 20°, 3.

The mean of the seven high day temperatures was highest at Plymouth, 51°, at Truro 50°,6, at Sheffield 49°,6; and was lowest at Bolton, 43°,8, at Liverpool 20°,6; and was 48°,6. The general mean was 48°,

49°.6; and was lowest at Bolton, 42°.8; at Liverpool 46°.2, and at Hull 46°.6. The general mean was 48°. The mean of the seven low night temperatures was highest at Plymouth, 41°.1, at Turo and Brighton 40°; and was lowest at Wolverhampton, 34°, at Bolton and Hull 36°.4, The general mean was 37°.8.

The mean daily range of temperature was greatest at Wolverhampton, 13°.3, at Nottingham 12°.4, at Sheffield 12°.3; and was least at Bolton, 7°.4, at Liverpool 8°, and at Brighton 8°.6. The general mean was 10°.2.

The nean temperature was highest at Elymouth.

mean was 10°.2.

The niean temperature was highest at Plymouth, 45°.6, at Truro 44°.9, at Brighton 43°.9; and was lowest at Bolton, 39°.7, at Wolverhampton 40°.2, and at Hull 41°.1. The general mean was 42°.5. Kain.—The largest fall was 1.69 inch at Truro, 0.68 inch at Preston, 0.61 inch at Bristol; the smallest fall was 0.05 inch at Leicester, and 0.09 inch at Cambridge and Nottingham. The general mean fall was 0.09 inch fall was 0.40 inch.

SCOTLAND: Temperature.—During the week ending February 16, the highest temperature was 56°, at Glasgow; at Dundee the highest was 49°.3. The general mean was 51°.2.

general mean was \$1.2.

The lowest temperature in the week was \$1°, at Perth; at Glasgow and Paisley the lowest temperature was 35°. The general mean was 33°.1.

The mean temperature was highest at Glasgow, 43°.2; and lowest at Dundee, 39°.7. The general mean was 41°.

Mean was 41°,5.

Rain.—The largest fall was 1,39 inch, at Glasgow,
Greenock, and Paisley; and the smallest fall was 0.24

The general mean fall was 0.83 inch. JAMES GLAISHER, F.R.S.

Answers to Correspondents.

ADVERTISEMENTS: H. W. The subject does not call for any interference on our part.

AZALEA AMGENA SPORT: D. D. Your sport, bright rosy-cerise, is very pretty, and certainly well worth propagating.

BEES: C. M. A debateable question. See the answer given to a similar inquiry in our number for January 19, p. 80.

Books: J. H. U. Kemp's How to Lay Out a Garden (Bradbury, Agnew, & Co.).

CEREALS, THE WILD FORM OF: Enquirer. Nothing definite is known on the subject. M. Fabre's observations have not been confirmed. The latest information is given in De Candolle's Origine des Plantes Cultivest. We do not know where seed so Ægiogo can be obtained. An enquiry of some of the seedsmen in Marseilles or Genoa, or of Messrs. Vilmorin, of Paris, might be successful.

Erratum. — At p. 217, col. c, fig. 44, for "Iris reticulata" read "Iris histrio."

IMPORTED LILIUMS: J. F. J. C. In the South they do best pluoged in cocoa-fibre refuse in the open air, but in your wetter climate it would be better to protect them from rain. Any cool place will do.

LILIES OF THE VALLEY: IV. L. If you use such excessive atmospheric heat against your better judgment it is no wonder that you have met with failure. It is never difficult to get good results from strong healthy crowns if you will avoid parboiling them.

NAMES OF FRUITS: H. O. Apple: Cellini. — Thos. Taylor. Pear: Broom Park. — Jas. Lloyd. Your Apple we cannot recognise. It is most likely a local variety.

NAMES OF PLANTS: A. Y. Z. The Paper-white Narciss (N. tazetta var. papyracea); 2, yes, it will grow in the open air. — Camjee. Cymbidium sinense.—Cambrian. Odontoglossum Coradinei var. —A. IV. The flowers are 100 much withered for identification.—Buckland. 1, Euphorbia charasias; 2, Abies Nordmanniana; 3, Rhododendron ponticum var.; 4, Quercus llev, 5, Prims Laricio; 6, Quercus llev var.; 7, Rubus leucodermis.

NOTICE TO QUIT: F. C. G. has not stated his question sufficiently plainly, and had better consult a solicitor.

ORANGES IN AUSTRALASIA: Orange, See P. I. Simmonds' Tropical Agriculture, published by Spon; also in vol. ii. (1882—1883) of The Tropical Agriculturist, compiled by A. M. and J. Ferguson, Colombo, Ceylon, and published by Trübner & Co., you will find much general information on Orange culture. culture,

TUBEROSES: Florist. The earlier you start with these the more patience you must have. The best practice is to pot into soil that is in a fairly moist state, one in

a pot, plunge into a bed of fermenting material of enduring warmth, of about 80° Fahr, eovering the surface of pots and bulbs with a layer of moss or eacoa fibre, to keep in the moisture and to do away, as far as possible, with watering till the bulbs start. Keep them near the glass, and do not let the air temperature in the pit or hotbed exceed 60° by night, with a 10° rise by day; air when necessary, to rid the pit of excess of moisture, and give more and more water as the pots fill with roots. They will not all begin to grow at one time, and must therefore be treated according to their wants. When fairly on the move remove frem bottom-heat, and place in a more airly position, where the temperature is about 60° to 55° by night, and see that they do not get drawn by shade, or from being at a distance from the root.

TULIPS: T. & T. We can only suppose that there has been some mismanagement, but you give us no information on the subject.

** All communications intended for publication should be addressed to the "Editor," and not to the Publisher or to any member of the staff personally. The Editor would also be obliged by such communications being written on one side only of the paper and sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

FOREIGN SUBSCRIBERS sending Post-Office Orders are requested to send them to the Publisher of this journal, 41, Wellington Street, Covent Garden, and to make them payable to William Richards, at the Post Office, Druy Lane, London, W.C.

INTELLIGENT READERS, PLEASE NOTE: — Letters re-lating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the Publisher, and NOT to the Editor,

Markets.

COVENT GARDEN, February 21.

Its subjoined reports are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list weekly, and are responsible for the quotations. It must be remembered that these quotations are averages for the week preceding the date of our report. The prices fluctuate, not only from day to day, but often several times in one day, and therefore the prices quoted as averages for the past week must not be taken as indicating the price at any particular date, still less can they be taken as rudies to the orice in the coming week. E.o.1 as guides to the price in the coming week. Eo.].

TRADE has been more lively this week, with a general improvement in all classes of goods. James Webber, Wholesale Apple Market.

- Flowers continue to arrive from France in large quantities, prices of which vary so much that it is hardly possible to quote figures.

SEEDS.

LONDON: Feb. 20.—No fresh feature presented itself on the seed market to-day. Red Clover seed shows no quotable change. Of foreign seed the available supplies in London are unusually small. White Clover is reported in London are unusually small. White Clover is reported from Hamburg as exceedingly firm. Somewhat easier rates are accepted for Alsike and Trefoil. Extremely low prices are asked for imported Italian Rye-grass. Spring Tares realise former currencies. Haricot Beass continue very reasonable. The trade for blue boiling Peas is slow. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

CORN.

On Monday at Mark Lane a moderate business was concluded in English and foreign Wheat at steady rates, as compared with Monday se'nnight. Flour was quiet, with liberal arrivals. Earley was fully steady, grinding sorts being il aoything the turn against the buyers. In Deans and Peas a fair trade was done at previous rates. Oats ruled firm, and generally 3d. dearer. Maize was not quotably altered in value.—Wednesday's Wheat trade was quiet, but steady rates were current. Flour was quiet and unaltered; Harley steady in value, with a moderate inquiry. Beans and Peas sold at Monday's rates, and Oats further advanced 3d., the common qualities of Russian being more especially im. Maize was slow at previous rates.—Average prices of corn for the week ending February 16:—Wheat, 37i. 3d.; Barley, 31; 11d.; Oats, 19i. 10d. For the corresponding period last year:—Wheat, 411; Barley, 33s. 1d.; Oats, 211, 9d. 215, 9d.

CATTLE.

CATTLE.

At the Metropolitan Market on Monday the supplies of stock were much about the same as on Monday se'noight. Danish cattle sold at 4s. 6d. to 5s. 2ar., Swedish, 3s. 8d. to 4s. The sheep trade was not quotably altered from that of the previous Thursday, except, perhaps, the sale was not quite so dragging. Calves sold without change in value. Quotations:—Beasts, 3s. 8d. to 5s. 4d., and 5s. 6d., to 5s. 10d.; calves, 5s. to 6s. 10d.—Thursday's trade was quite and featureless. Supplies were short, but were sufficient for the very small demand, and values of both beasts and sheep remained about the same as on Monday.

POTATOS.

The Borough and Spitalfields Markets reports state that good supplies have been on offer, but trade dull at the following quotations:—Magnum Bonums, 70. to 90.; Regents, 60. to 80.; Champions, 90. to 70.; Victorias, 70. to 80. per ton.—The imports into London last week consisted of 128 bags from Boulogne, 111 bartels 86 boxes from Bermuda, 100 sacks Bordeaux, 200 sacks St. Nazaire, and 105 tons from Brest.

COALS.

The following are the prices current at market during the week:—Walls End—Hettoo, 15s. 6d.; Hetton Lyons, 15s.; Lambton, 16s.; Wear, 15s.; East Hardepool, 15s. 9d.; Thoroley, 15s. 9d.; Tees, 16s. 6d.

Government Stock .- Consols closed on Monday at 101g to 101g for delivery, and 101g to 101g for the account. Tuesday's prices were, for delivery, 102g to 101g, and 101g to 101g for the account. The final quotations of Wednesday and Thursday were 101g to 101g for delivery, and 101g to 101g for the account.

BURMESE ORCHIDS.

HEATH AND SON beg to announce the arrival of a magnificent lot of the above, per s.s. Martaban, consisting of SACCOLABIUM GUTTATUM, S. BLUMEI MAJUS, many of the flower-spikes 18 inches long, with 150 to 200 flower-seats—foliage 2 inches in diameter, in masses of four to twelve growths; S. CURVIFOLIUM, masses up to thirty growths; DENDROBIUM FORMOSUM GIGANTEUM, from the same district as the magnificent varieties flowered by us, and for which we were awarded a Silver Medal, October, 1882; D. JAMESIANUM, splendid pieces, with 2-feet growths, and set with flower-buds; D. FYTCHIANUM.

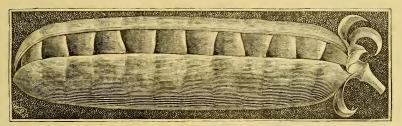

The whole will be Arranged and on View on Monday next, 25th inst.

HOT-WATER BOILERS, PIPES, and CONNECTIONS, and all Castings for Horticultural Purposes.

Illustrated CATALOGUE, 14th edition, price 1s.

Price List on application Free.

Hot-water and Hot-air Apparatus erected Complete, or the Materials supplied.

KEITH'S PATENT HOT-WATER BOILERS.

Can be heightened or lowered, or made to suit any require-ments. They stand complete in themselves, and require no building work, being wholly water-jackted and thus entirely free from risk by fire. They can be had all sizes, to heat from, say, a few feet up to 8000 feet of 4-sinch pire each; are now in all part of the world, and are unrealled as heigh to best, most powerful, and most economical Hot-water Bollers in use.

most powerful, and most economical Hol-water Boulers in use.

Specimen Extracts from Testimonials:

From W. Morgan Robbins, Esq. Architect, Ilfracombe,

September 9, 1850.

"I am delighted with your Boiler; it answers admirably, and
the directors are satisfied that it is one of the best £25 worth
ever put in the hotel."

From Q.C. CHALMERS, Gardens of James Mudie, Esq.,

Broughty Ferry, September 15, 1880.

"Your Boiler beats all my expectations: at present one fire
serves for twelve hours, and keeps up a good, steady heat."

From ISAG HOLDEN, ESD. Oakworth Houser, Keinher, YorkFrom ISAG HOLDEN, ESD. Oakworth Houser, Keinher, York-

From Isaac Holden, Esq. Oakworth House, Keighley, York-shire, June 19, 1881.
"Your Boilers are the best we have tried." (Note: One of these Boilers heats nearly 80co feet of 4-inch pipe.)

From WM. FRASER, Kippen Gardens, Dunning, Perthshire, December 6, 1881. "I consider your Boiler most efficient; as for economy, it is the acme of perfection."

the acme of perfection."

From Rev. JAMES CAROWALL, Military Academy, Highlands, From Rev. JAMES CAROWALL, Military Academy, Highlands, "Ency, December 31, 1881.

"Nothing could be better than the Boiler you seat me; it burns all sorts of rubbish, and gives an excellent heat."

From ARTHUR BOOTY, Eaq., Rese Fillad Nurseries, High Harrogate, March 22, 1882.

'Your Boiler has exceeded all my expectations; it will pay for itself as a fuel saver in a short time. It heats seed feet of 41nch pige."

BREAKFAST.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a carrell application of the fine properties of well-selected Cocoa, Mr. Ryps approvided our breakfast-tables with a delicately flavoured heverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of suttle maddles are floating around us ready to attack wherever there is a weak punt. We may escape many a fatal slath by keeping ounselves well fortified with pure blood and a properly sourished frame." Civil Service Gazette.

Made simply with boiling water or milk. Sold only in Packets, labelled thus:-JAMES EPPS & CO., Homeopathic Chemists, London, England.

Knap Hill Nursery, Woking Station, Surrey.

WHEELER'S

OF EXTRA FINE QUALITY.

DOUBLE GLOUCESTER.—This remarkable variety is one of the most productive Potatos ever introduced. It bears an enormous crop of good sized tubers, which are of excellent quality for the table. It is entirely when are of excellent quality for the table. It is entirely free from disease. Its compact habit of growth, and its capability of bearing cutting well for seed (it is advisable that each piece should have at least two eyes), renders it a very economical and profitable variety. It is of excellent flavour and good colour. We feel sure it will become a popular variety for the garden, and, as it is so remarkably productive, that it will also become a Farmer's Favourite.

Price 4s. per peck; 14s, per bushel.

RECORDER (Dean) WHITE KIDNEY.—
First-class Certificate of Merit, International Potato Committee, 1982. From Success and Woodstock Kidney. A very fine, second early white Kidney; tubers long, flat, smooth, and handsome, a great cropper and excellent quality. A first-rate garden Potato; very distinct, and a rare acquisition. We hold the entire stock of this valuable variety. It is excellent not only for exhibition but of high-class quality for table use.

Price 1s. per pound; half-peck, 6s.; peck, 10s. 6d.

WHEELER'S GLOUCESTERSHIRE KIDNEY maintains its position as one of the earliest and best Potatos in cultivation.

Price 3s. per peck.

WHITE CLOVE CARNATION.

"THE GOVERNOR."

Per Pair, 3s.

The usual Discount to the Trade.

A limited number only left to dispose of.

CROSS AND STEER, SALISBURY.

NOW is the TIME to PLANT CARNATIONS.

TWO NEW VARIETIES.

MARY MORRIS.—One of the most valuable of modern introductions. Of a strong, vigorous habit, producing menstrous flowers, o'ten 3½ inches in diameter, of an attractive deep rose colour. Has been awarded a First-class Continent.

WHITE CLOVE. GLOIRE DE NANCY.

WHITE CLOVE "GLOIRE DE NANCY."

—Without question the finest White Clove ever introduced. It has a very robust habit, like that of the old Cimson Clove, and produces, in the greatest profusion, immense sized flowers, which are pure white and deliciously Clove-scented. Has been awarded a First-Cartalocoust Cortificate.

CATALOGUE, containing fuller descriptions of the above, with a vast number of other choice Carnations, as well as every other section of HARDY FLOKISTS FLOWERS, is now eady and shall be sent free to all applicants.

SPECIAL OFFER.

CRANSTON'S NURSERY

AND SEED CO. (Limited)
Hold a large stock of superbly grown Plants
of the following, and will be pleased to send
Samples and Prices on application:—

RHODODENDRON PONTICUM, 1 to 1½ foot, 1½ to 2 feet, busby.

RHODODENDRON PONTICUM, 1 to 175 1004, 1/2 to 2 feet, buthly.

"choicest named, in 30 to 60 varieties, magnificent plants, grown in sandy loam soil.

LAUREL, Common, 1/2 to 2 feet, 20 10 feet, 2/2 to 3 feet.

"COLCHICA, 10 1/2 front, 1/4 to 2 feet, 2 to 3 feet.

"PORTUGAL, 10 1/4 foot, 1/4 to 2 feet, 2 to 3/2 feet.

"ROTUNDIPOLIA, 11 to 1/4 foot, 1/4 to 2 feet.

"ROTUNDIPOLIA, 11 1/4 foot, 1/4 to 2 feet.

LAURUSTINUS, 3/4 to 1 foot, 1 to 1/4 foot, 1/4 to 2 feet. CATALOGUES of Roses, Fruit Trees, Coniferæ, Shrubs, &c., free on application.

CAUTION

SEASON 1884.

In again calling the attention of Market Growers, Gardeners, and Amateurs to Clay's Fertiliser, we feel a pride in stating that it has increased in popularity year by year, until it has attained the position of being considered an absolute necessity for the production of Fruit, Flowers, and Vegetables of the highest excellence.

Unfortunately, this success has induced some unprincipled persons to adulterate the Manure, causing great disappointment to users and serious annoyance to ourselves. We have therefore decided, after the 1st of January, 1884, to send out all Manure (except 1s. packets) in Sealed Bags; and we trust buyers will, for their own protection, insist on having it in our bags with our Trade Mark and Seal attached, for which alone we shall be responsible.

SEEDS OF SUPERB

FLOWERS.

NEW PRIMULAS

	Per packet.
Purity	25. 6d.
Rosy Morn	2s. 6d.
Scarlet Emperor	., 2s. 6d.
Exqusite (mixed)	2s. 6d.
The finest strains in	cultivation.

WEBBS' Superb Cineraria.

From Mr. W. Dell, Gr. to the
Earl of Dartmouth.
"The Cinerarias were really
splendid, some of the flowers
measured 2 inches across—of
the richest colours.

1s. 6d. and 2s. 6d. per packet.

WEBBS' Perfection Cyclamen.

From Mr. Wm. Richards,
Holly Cottage.
"Out of the packet of Cyclamen seeds (thirty in number)
you sent me last year I have
raised twenty-five bealthy young
plants."

1s. 6d. and 2s. 6d. per packet.

WEBBS' Superb Calceolaria

From Mr. HATHAWAY, Gr. to Capt. J. Beavan.

"The Calcenlaria seed was a magnificent strain in almost every shade of colour." vs. 6d, and 2s. 6d, per packet.

WEBBS' Excelsior Gloxinia.

LACEISIU UIUMIIIA.
From the Head Garbener to
the Marquis of Ripon.
Webbs Excelsior Gloxinia
is a remarkably fine strain.
Every plant bas been good,
with a splendid variety of beautiful flowers.

15. 6d. and 2s. 6d. per packet.

WEBBS' SHOW PANSY.

From Mr. WALTER CHILD, Gr.
to the Earl of Coventry.
"The flowers of Webbs' Show
Pansy are quite unique in colour;
the strain is very good.'
15, 6d, and 25, 6d, per packet.

WEBBS' TUBEROUS ROOTED BEGONIA.

A. D. COCHRANE, Esq., writes : "Begonia seed from your special strain is worth 1000 gs. 1s. 6d. and 2s. 6d. per packet.

ATEST OF ALI

Per pint, 1s. 9d; per quart, 3s.

"'Latest of All' Pea attains an average height of 3 feet, is robust and very productive; the large closely-packed pods being produced from the bottom to the top of the baulm. That the Peas are of good calour and flavour it is hardly necessary to say, but it must be stated that the variety owing to its robust constitution, is well able to resist the attacks of mildew, which usually does so much damage to the main-crop Peas to hot summers."—Gordener's Margazine, Yanuary 2n, 183;

"Your 'Latest of All' Pea is an excellent variety. Grown alongside Veitch's Perfection, it proved of better constitution than that good old variety; very prinlic, and of the best quality."—Mr. W. IGCULDEN, Gardener to the Right Hon, the Earl of Cark and Ortery, Martin House.

THE QUEEN'S SEEDSMEN, READING.

Gardeners' Thronicle.

SATURDAY, MARCH 1, 1884.

GLASGOW BOTANIC GARDEN.

OTWITHSTANDING the boasted position which "cannie" Scotchmen claim for Glasgow as being the "second city in the empire," both its great commercial sisters in wealth and enterprise, Manchester and Liverpool, if they have not more interesting or better appointed botanical gardens, are far more successful, financially speaking. Man-chester, of course, fifteen years ago was in very deep water until the spirited enterprise of Mr. Bruce Findlay, with a strong will and indomitable perseverance, pulled his company out of the quagmire. By a series of Whitsuntide exhibitions which have become world-famous, the shillings of the multitude in these busy hives of industry in the Lancashire and Yorkshire districts, flowed in to, we have no doubt, a grateful Chancellor of the Exchequer; and now Manchester is reckoned, and no doubt it is, the most successful unsubsidised botanical garden in the kingdom. The garden at Liverpool is taken in hand by the municipality, and consequently wants for nothing in the way of good keeping. Of course all municipalities are apt to be niggardly, because they have to face their tax-paying constituents and give an account of their stewardship, but be that as it may the curator and his staff are certain to be supported in a very different way from a private company that cannot even pay the interest of their debt. The Glasgow garden happens, as will be seen from the last published balance-sheet, to owe the Corpora-tion £40,000, and it is quite obvious that it is only a question of time when it will pass under municipal rule : and the sooner the better, too, every lover of horticulture will say. The £40,000 has been spent to some purpose; for, 1st, the grand Winter Garden, known formerly as the Kibble Conservatory (see pp. 271, 279), has been acquired; and 2d-even more important still-a set of houses 320 feet long, with a short range at either end at right angles, of 105 feet, each varied in width to suit the subjects set down as a sort of permanent tenants, has been built of Teak-wood by Messrs. James Boyd & Sons, and thoroughly equipped in every respect internally for varied plant life (see p. 275); and it is to these houses that I wish to direct your readers' attention.

Beginning at the tail-end of nur subject first, these Teak houses, quite recently finished, do not present externally much of an ornate character. There is nothing at first sight that would indicate an expenditure of £10,000 about them, but when the sightseer gets in and about them his opinions are sure to change. Everything done is so good and substantial, the Caithness pavemented passages, the Welsh slate tables, the piping, ventilation, and general fittings at once indicate that the designer of the range insisted upon generally useful structures, combined with extreme durability. None of the houses are too lofty for their inmates, and but for the great mistake of making the Victoria Lily-house or tank from 6 to 10 feet too small in diameter, which is an unfortunate oversight-better have had no Victoria-house at all-the range would, horticulturally speaking, be as nearly faultless as possible.

In the centre of the range is the Palm-house, 85 feet deep, with a frontage of 55 feet, and 42 feet 6 inches in height. Around the interior are

shelves for smaller Palms, and in the body of the house a couple of beds filled with soil in which the large Palms are planted out. The roof of this house was purposely kept low, as Palms after attaining a certain altitude cannot be well seen unless by the formation of a series of galleries; and by filling up the top of the house with their leaves, they also shade the smaller plants around them, and thereby pre-judice their healthy growth. The height of the house erected here is quite sufficient for exhibiting typical moderately-sized specimens. With efficient heating apparatus one special feature in the construction of the house may be noticed, viz., the introduction of a small heating pipe round the lantern of the roof, This great improvement it has been found stops to a very large extent the drip from the roof, which in houses of old construction seriously damaged the The boiler-house for the whole range is underneath the Palm-house-a most advantageous arrangement-which caused some trouble in construction, as a ventilation drain had to be driven from it under the Ewing range to the bank of the Kelvin. The latter range forms a nucleus for supplying the new range, and for nursing onwards bedding plants and similar plants.

The principal subjects in the Palm-house comprise Borassus flabellilormis, with its beautiful shining green leaves, making a capital fellow to the well known umbrageous Latania borbonica; so also does the round-leaved Livistonia (L. rotundifolia), fronted with great plants of Fourcroya cubensis and argentea. In the nooks and corners are noble plants of the prominent Zamia horrida, and several handsome tufts with woody crowns of various Macrozamias, These, along with towering plants of Seaforthia elegans and Livistonia sinensis, with no end of smaller Palms round the side tables, make an interesting tropical-house. There are two central beds, each 15 feet in width, and the path between grated, to allow the heat to ascend from the stack of pipes underneath, with a solid-looking stone kerb to form the borders. The side tables are of Welsh slate, and in order to husband moisture for atmospheric purposes, a layer of cocoa-fibre rests on the tables, into which the pots of Palms, &c., are plunged.

The house on the east side of this is the succulent-house -possibly, next to Kew, the best appointed house for species and varieties in the kingdom. Most of the plants are in capital health, and Mr. Bullen has them arranged according to groups, which is important for the student and for the general sightseer. In the centre bed are very prominent plants of Agave Salmiana, and many others, among which was the rarer Mexican variety with short, elegant, swordshaped leaves of fine glaucous surface, and quite a host of ornamental Agaves, among which we noted applanata, univittata, Ixtli, ixtlioides (very distinct), attenuata glauca (with broad, concave leaves of the most captivating green), macrantha, Lindeni (very beautiful, from having an irregular prominent silver margin adorned with short stumpy spines). margined with Beaucarneas, Yuccas, Dasylirions, Opuntias, Fourcroyas, and many others of the grosser growing succulents, render this house one of the most important in the range. By the way, not the least prominent of this centre group was a grand specimen of Aloe platylepis, with four highly ornamental Tritoma uvaria-like spikes, towering above its fellows. On the side benches the groups were specifically distinct, first coming Euphorbias, then Opuntias, Fourcroyas, Mesembryanthemums, Echinocactus, of which Leopoldi, with its fierce-looking spines, stood out distinct; and then Phyllocactus in numerous sortsnone, however, at this season more stylish looking than P. anguligera with flowers studded along both edges of leaves like heads, then Crassulas, Sedums, Cn-Myledons, Echeverias, Agaves, Rhipsalis, Beaucarneas, Pilocereus, Echinopsis, Yuccas, Gasterias, Cereus, and among them C. Tweedei is the most ornate, standing up like a column of stone; Haworthias, Mammillarias, and Alnes, of which there is a fine assortment. This in time will prove to be both an interesting and instructive houseful.

On the west side is the economic-house, of similar dimensions in every way. Chief among the lot in the centre is Heritera littoralis, with a stem as straight as a gun-barrel, carrying very large ovate leaves with very prominent venation; then the wild Banyan tree (Ficus indica), the Anchovy Pear, the Cinnamon as well as the Ginger and Chocolate plants; the Indian Fig tree (Ficus eburnea), with handsome obovate leaves and singularly prominent white

venation; the Coffea liberica, much larger and stouter than the common C. arabica; the Clusia grandifolia, with stiff leaves, and as concave as a saucer, and many other medicinal and useful plants, such as Tea, sugar, quinine, Guava, Mango, &c., all in good order, having plenty of space for extending themselves.

Adjoining this is the stove fernery, full of fine fresh foliage. In it were Drynaria morbillosa, Asplenium Gardnerianum, a fine pot Fern, and Asplenium scandens, with lots of Maidenhairs in their many forms; the handsome Nephrolepis davalloides, a grand mass of Microlepis hirta cristata, and some climbing Lygodiums. Suspended from the roof were several tropical Orchids, which always revel in the plethora of moisture arising from such a lot of greenery. Saccolabium giganteum and several Moth Orchids (Phalænopsis) were evidently enjoying life in this climate.

Next to this again is a high-temperatured house, with several specimens of Eucharis, Crinum, the large-leaved Acalypha, the pretty rose-painted Phyllanthus (P. rosea picta), a handsome and useful plant for botanic gardens. The many forms which these exotic plants take on is interesting to observe, and it is chiefly in such gardens as I write about that the public can see such things. Here the Aralia umbraculifera shows up its foliage, crowded in whorls, and the leaves ovate and plain-so different to many of its compeers; and then again the Columbian Maranta sanguinea at once arrests attention from its leaves throwing, as if it were on second consideration, great footstalks 2 of 3 feet long, which are surmounted with tufts of smaller leaves, and all nicely coloured. Crotons in variety, Pandanads, and Dragon's-blood plants give colour and variety to the group.

At right angles to this is an intermediate-house, in which Orchids live among other plants, but are not in quantity such as many people would desire to see. Still, there are many nice Dendrobes, some capital Moth Orchids—the spotted and barred-leaved Schilleriana being in excellent style, and so are several Cattleyas, Roezl's Odontoglot in fine flower and clear and vigorous. Among the grosser growing lot are masses of Eucharis in fine flower, the lasciculated Hæmanthus with its highly ornate spotted stem, some of the newer Crotons, the exceedingly grotesque-looking Philodendron crinipes, with the centre lobe of the leaf saddle-shaped and having two ear-like reniform wings at the base, &c.

The circular house, which forms the extremity of the range in the east, is the Victoria-house, which is fitted up in every way to suit water plants but not to give space for the Victoria leaves which in summer not only extend over the wall of the tank but get on to the path. This along with Nympheas and other water plants fully occupied the spatula-like-formed tank; on the side stages are Orchids, Bromeliads, and some other ornamental plants. It may be stated that, not-withstanding the cramping of the Victoria, it had thirteen flowers expanded last season.

The houses east of the succulent-house are chiefly filled with New Holland plants and Azaleas, of which there is a large and well managed lot. These, with the denser growing Himalayan Rhododendrons, occupy the large house in the east wing in which the visitor generally enters.

At right angles are the cool Orchid-house and the greenhouse fernery. The stock of Orchids is only limited, and it seems a pity that Mr. Bullen, who always has been a keen Orchidophilist, should not have more of them to cultivate. As it is, there are among the Odontoglossums, crispum, Pescatorei, nebulosum, a graad lot of Oncidium varicosum growing and flowering magnificently, suspended in baskets and otherwise in this cool house, in which also were lots of Ladies' Slippers, the finely fringed Dendrobium fimbriatum in mass of bloom, as also Cologyne cristata, and the sweet-scented Trichopilia and many others. Among the Ferns are Pellea ornithopus, the handsome Gymnogramma triangularis and Pteris straminea, Lastrea tenericaulis, with prominent pinnatifid frondae; the singular Goniopteris refracta, with fronds opposite, and leaves entire; Alsophila Williamsii, Balantium Culcita, Nephrolepis umbrosa, &c.

In addition to this range are four span-ronfed houses detached for propagating and other purposes, each about 40 × 12 feet. The whole range is heated by two of Bullen's 8-feet Glasgow boilers, to which are attached about 2 miles of 4-inch piping, and they

seem to do their duty well, and could do more, we understand, if required.

Not to speak of the Ewing range, nor of the most interesting shaded house for filmy Ferns and mosses, we proceed to take some notice of what is known as the Kibble Conservatory (see p. 271), which was also built by the Messrs. Boyd, and by them remodelled about three years ago. As you enter there is a spacious pentagonal corridor, with a span-roofed house at either side, that is, at right angles, of 40 × 22 feet. On the one side is a nice collection of Heaths, with the front stages covered with plants in bloom, such as Primulas, Cinerarias, &c. In the corresponding house are New Holland plants with Epacris in flower, and lots of Acacias; while in addition to the climbers of ordinary cast in the corridor is Lonicera fragrantissima, with gnodlooking ovate leaves set opposite each other on wirylooking stems—a very good plant for a full house. The Kibble proper is circular, with a border of 10 feet wide, then a path 14 feet wide, then a bed 16 feet in width, then a path, and then the centre. The coolness of the climate has given an immense impetus to the growth of the Tree Ferns since they were planted some two or three years ago. Among them are quantities of Cibotium Schiedei, Dicksonia antarctica, some of them with 10 feet stems; the grand distinct Cyathea dealbata, Alsophila prænitens, Moore's Todea barbara, as dark green as a Scotch Leek; Dicksonia Smithii and D. regalis in extra fine cut frondage, the Chinese Cibotium Barometz; these, along with some smaller fry, fill up the centre, which is about 40 feet diameter.

On the border surrounding, warded off by the path, are some grand specimens of Cibotium princeps, with great chaffy rachis and beautifully formed opposite leaves, the pinnate fronds turning up and forming a splendid outline for the eye to rest upon. Then the spiendia outline for the eye to less span-sikkim Rhododendrons towering up, some of them towards the lofty roof, studded with buds in such quantities as will make a display in spring worthy of going a day's journey to see. This is the place for such gigantic species as Nuttallii, Jenkinsii, Dalhousianum, and such leggy fellows as ordinary growers cannot provide accommodation for. Among them are several Acacias, the New Zealand Flax, a noble plant of Astrapæa Wallichii covered with bloom, hosts of Camellias, the Eucalyptus globulus, Araucaria Bidwillii and A. excelsa, together with several Palms of the Kentia race. Unquestionably this is one of the finest promenades, covered with glass, where plants have been collected to show their growth, proportions, and beauty, that I have ever had the privilege to see. In times past, as a quasi singing salnon, and a meeting-place for entertainments of various sorts, it turned out practically a failure; as a great plant-house, capable of showing what Nature in that way can produce, it promises to he an abundant success. The grounds have been remodelled, and the garden seems to be well appointed in every way. A. [For illustrations see pp. 271, 275, 279; figs. 49, 50, 51.]

New Handen Plants.

PHALENOPSIS VEITCHIANA BRACHYODON, n. var.

A very interesting surprise, and no doubt an exceedingly rare and nice thing. The sepals and petals are pure white, the lateral sepals with brown spots at the inner and superior part of the base. There is also a slight tinge of the lightest sulphur on those organs. The side laciniæ of the lip are purple at the top, white at the base, stem with numerous brown small spots. Anterior laciniæ of a dark purple, verging to brown, and some spots of the same colour on the light whitishochre ground and margins. The apex of the lip is retuse, and nearly bidentate. The great stoutness of these teeth suggested the name. Callus normal. Column fine amethyst. Messrs. II. Low & Co. kindly sent me the flowers with the following remarks:-The plant on arrival was set aside and marked owing to its peculiar appearance. The leaves in appearance something resembled those of Phalænopsis leucorrhoda lightly mottled on the upper surface, and with a light purple tinge underneath. Imported leaf 6 inches long by 2½ wide. Roots round. The plant has a very sturdy

habit. Flower-spike like a very strong P. rosea, 15 inches high, standing very crect. Flowers well thrown out from the spike. Below the first flower there are three eyes (dormant branches!) which would seem to indicate that the plant when established will branch. H. G. Rehb. f.

DENDROBIUM VEXABILE, n. sp. (?), hyb. nat.

I am sorry to say this is an old and very unwelcome acquaintance of mine. I was, in April, 1878, with my excellent friend Mr. H. Low, and amidst a multitude of Dendrobium luteolum appeared a plant which made me think of Dendrobium Ruckeri. It had, however, light sulphur-ochre-coloured flowers, partly white; the side lacinize of the lip with oumerous aarrow lines, the anterior lacinize very wavy, sulphurtransverse, rhomboid, with a small fleshy mid-lacinize, nearly obliterate, and a fleshy mid-line, covered with short hairs. I believe Mr. Sander compared the growth to that of Dendrobium Falconeri. There are no mauve stripes, but purple ones on the side lacinize. I never had any other news about this, but if it was not an accidental monster it may reappear some day. H. G. Rehb. f.

VANDA TERES (Lindl.) AUROREA, nov. var.

A lovely variety. Its sepals and petals are white. Petals with an exceedingly light hue of rose, perhaps a sign of fading, as I was informed lately by Mr. W. Lee, who sent a grand Cattleya in the way of Wagneri. Lip lightest ochre-coloured in the throat, rose on the lobes, with two rows of small purple dots.

unsightly, and shortlived. Even to the present day examples of the results of the ordeal by fire on Cattleyas are not wanting, although, thanks to the knowledge of the subject spread from such extensive establishments as Mr. Lee's, the cases are rare. Now and then, however, we see small collections which were begun with enthusiasm advertised for sale, and a glance at the plants when staged in the auction rooms invariably tells the same story—they have been oddled into that state of misery which renders them not worth keeping and hardly worth selling. On the other hand, such is the hold which Orchid growing obtains on him who once takes it up that it is seldom we see the collection commenced in earnest, and by one who has made up his mind to take hirts from his neighbour's experiences, come to the hammer

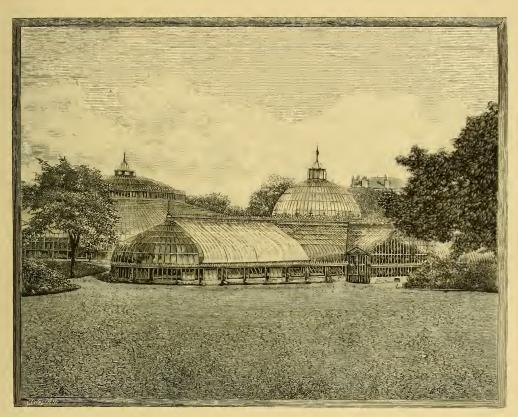

FIG. 49.—THE KIBBLE CONSERVATORY IN THE GLASGOW BOTANIC GARDEN. (SEE P. 270.)

coloured, with an orange blotch at each side of the tuft of hairs. The stem was not like that of Dendrohium Ruckeri, but more like that of Dendrohium luteolum, reddish, thicker, with a strong tendency to constriction at the joints. The late Professor Schrader, of Göttingen, used to prescribe thus: "Write a label, lay it aside, and do not think any more of it." I followed Schrader, hoping Mr. H. Low might forget this specimen among his many fine plants. Alas! Mr. H. Low forgets onthing, and after six years he sends me a specimen, with a demand for a name. After all, there is more satisfaction in naming it than there is in the case of certain Cattleyas, which are gifts of the goddess Eris, notwithstanding their beaute de diable.

I must add that in February, 1880, Mr. Sander sent another thing, of nearly the same stamp. The mentum was very short and twisted, with the lip Column light rose-purple. It came into flower with Sir William Marriott, Bart., the owner of Vanda Parishii Mariottianæ, grown by Mr. T. Denny. I had it from Messrs. H. Low & Co. H. G. Rehb. f.

MR. LEE'S CATTLEYAS.

THOSE who remember the poor condition of the cold-house Odontoglossums of twenty years ago will readily be able to understand in its fullest sense the lamentable state into which the Cattleyas were fast drifting before Mr. Lee and a few other enterprising and clever gentlemen took them in hand some years ago. It is true that in a few of the principal collections some or other, but rarely all of them, were to be found in fair condition, but in nine out of every ten of the smaller collections the plants were miserable,

in its infancy. It is to such persons that Mr. Lee's extensive and well-kept Orchid collection is of inestimable service in its educational capacity, and it is to such that he always accords a gracious reception.

After all the successful culture of Orchids is simple enough provided the beginner starts with a full determination to study his plants, and, above all, to see to the sanitary arrangements of his houses, and to the providing of a careful and well balanced top and bottom ventilation to be open night and day. It appears that in the matter of glazing Orchid-houses our glaziers have become a trifle too clever, their perfectly fitting joints having the opposite to the desired effect. In this matter Mr. Lee has had important results from seeing that each lap is left open enough to admit of the passage of a thin sixpence, and this plan is to be carried out on the new large Phalæoppishouse, which is about to be commenced. The spacious

Cattleya-house (fig. 43, p. 30S, vol. xix.), 100 feet long, 21 feet 6 inches wide, 12 feet 6 inches to ridge, has now had a trial of a year, and certainly never was the good influence of a cleverly planned structure more pointedly asserted than in its case, the growths made by the plants during that time being, in many cases, superior in size to those made in their native habitats, and what is of more importance equal to the imported bulbs in the firmness of their healthy tissues. The result has been an extraordinary show of flowers during this mouth, which has attracted visitors from all parts.

About 500 immense flowers of Cattleyas are to be seen in this house at a glance, chiefly Trianæs, but such Trianæs are not often to be seen. In addition to the many fine plants in bloom among the freshimported pieces are some of the finest plants of the best named varieties in existence, prominent among them being that most gigantic and lovely form, C. T Osmanii. The fine rosy-petalled flower has an expansion of 8 inches, and a broad labellum, crimson margined with rose on the lower half, and stained with orange in the upper portion. Near it is the original specimen of C. T. Dodgsoni, and here and there along the house are nicely-bloomed plants of C. Backhousiana. There is no need to approach this lovely variety closely to discover its merits, for it is visible the whole length of the house, its intense maroon-tinted crimson labellum being much more telling than others which, on close inspection, seem brighter. C. T. Normani is here represented by a large plant well bloomed. It is a variety of the first merit, having much the appearance of C. T. Backhousiana, even to the feather in the petal. Many other noted forms are here, and among them one of the best-shaped and whitest C. T. albas ever seen.

Some of the above-mentioned have cost, I believe, one and two hundred guineas apiece; but let not the uneducated in Orchid lore hold up their hands in horror at the outlay. The day has arrived when the rare works of Nature take rank with the rare works of Art, and surely it is as excusable to give a couple of hundred guineas for one of these grand and variable Cattleyas because it is beautiful, excellent, and never likely to be imported again in exactly the same form, as it is to give ten thousand guineas for a picture for reasons of a like nature. Experience, too, teaches us that the values of well cultivated plants rise instead of fall; no more pointed proof of this fact could be given than the case of the true old autumn flowering labiata; even as near to our time as 1876 Rollisson and others supplied it at about 5 guioeas each, and better plants than those which have fetched 50 guineas during the last two or three years. Arranged among the Cattleyas are a couple of plants of the true Coelogyne cristata alba with several spikes each, some good Lælia harpophylla well bloomed, plants of Brassavola glauca, and Epidendrum Wallisii, and a fine specimen of the rare orange-yellow Lælia flammea, a hybrid of Messrs. Veitch's between L. cinnabarina and L. Pilcheri it gives a new and telling colour among Orchids. The whole of this house and its entrance lobby with its rare Cypripediums, Odontoglossum Roezlii, Pitcher plants, &c., present such a sight as even many Orchid growers have never seen equalled. The Phalænopsis-house, which is to be superseded by a new model structure, is full of bloom of P. Schiller-riana, with some few P. grandiflora, P. amabilis, P. intermedia and its variety Brymeriana, P. Stuartiana, &c. Along the whole of the side of this house on a shelf near the glass are arranged a quantity of plants of the beautiful white Angræcum citratum, their long spikes of bloom (some of them 2 feet 6 inches in length) hanging gracefully over, and mingling well with the Phalænopsis. This Orchid is not so variable as many, but we observe the fine large round-flowered plant which we noted last year holds its own and is probably the best ever seen of its kind.

In this house, too, the rare Vanda Parishii Marriottiana is producing its large wax-like mauve flowers. The cool houses are well supplied with flowers in which of course the varieties of Odontoglossum Alexandræ and Piscatorei predominate, but good masses of O. pulchellum majus, O. Rossii majus, O. blandum, O. facetum, O. lyroglossum, O. prionopetalon, O. mulus, O. Andersonianum, some fine varieties of O. triumphans, and many others are promineot, while in each of the houses the glowing orange and scarlet of the Levlia harpophylla and Sophronitis grandifora, give a cheering effect at this season. In every house flowers abound, the Dendrobes giving quantities of different varieties of D.

nobile, the curled looking D. n. Tollianum not being the least beautiful; D. Wardianum, D. heterocarpum, D. Ainsworthii ×, D. Findlayanum, D. primulitum, D. Lowii, D. Jamesianum, the beautiful D. luteolum chlorocentrum, with flowers over 2 inches across; and a grand form of D. finbriatum, which was originally in Mr. Day's collection. It beats all in its section for the brightness of its orange tints and size of flowers.

The Lycaste-house is as showy as the other departments, many dark and several of the pure white forms being there arranged with fine plants of the lovely white Cymbidium eburneum, large masses of C. Lowianum (one with three spikes of about a score blooms each), Zygopetalum crinitum roseum, and well bloomed pans of the pretty little white-flowered Odontoglossum Oerstedii. This last does very well grown like Sophronitis in a cold house. The Masdevallias are just beginning their main flowering in the long lean-to house, which only contains part of them, with M. tovareosis, M. Veitchiana, M. Lindeni, and several varieties of M. ignea, of which the roundflowered M. i. Stobarteana and the high-coloured M. i. Massangeana are perhaps the best. In the chimæra lobby a fine plant of M. Roezlii (the black chimæra), some M. bullata × M. erythrochæte are n bloom; and among the curious things are Schomburgkia undulata, Angræcum pellucidum, A. arcuatum, and Saccolabium bellioum. Many fine forms of Authurium Scherzerianum lend the show of their scarlet spathes, and the vigour of all the plants seems to say that Mr. Woolford has not much trouble with the sick list.

The Henbageous Honden.

VARIETIES OF NARCISSUS PSEUDO-NARCISSUS "MAJOR."-Few tribes of plants have caused more perplexity to botanists than the Narcisseæ. Salisbury, Haworth, Herbert, who laboured almost simultaneously in the Daffodil field about fifty years ago, each elaborated an arrangement of his own, without any very satisfactory results, except that botanists, both native and foreign, were glad to acquiesce in any plausible system of classification which disposed of so troublesome a class. In fact Haworth—who described not only every variety he had himself seen, but added to his list and classified all that had been described by others-seemed for a time to have left nothing for successors to do. He divided the Narcisseæ into sixteen genera, containing 146 species, and that at a time when none of the new hybrids had yet been introduced. As an example of his minute subdivision it may be mentioned that he made ten species of N. corbularia, the Hoop-petticoat Daffodil. also made the variety N. abscissus (the Clipt-trunk Daffodil) into a separate genus with five species, none of which he had himself seen, but he inserted them, as he tells us, "with a view to excite inquiry after them." Between these two genera comes in Haworth's arrangement, the genus Ajax, in which he has twenty-four species, including all the rest of the Trumpet Daffodils then known either in Nature or cultivation, and probably several which were never known at all,

In 1869, nearly forty years after the publication of Haworth's monograph, Mr. J. G. Baker, of the Royal Herbarium, Kew, proposed in the Gardeners' nicle a far more simple and easy arrangement of the Narcisseæ, including them all in the one genus, Narcissus, and dividing them for convenience into three classes, according to the length of the crown. He arranges the whole genus into twenty-one species. The Trumpet Daffodils, which, exclusive of Corbularia, form two genera and twenty-nine species in Haworth, are all included in the single species N. Pseudo-Narcissus. It is satisfactory to find that in the Genera Plantarum of Bentham and Hooker Mr. Baker's classification is approved and sanctioned; and as that book is likely to be an occumenical authority for many years, we need not be alarmed at the number of new Daffodils which are appearing year by year, every one of which has quite as much claim to specific distinction as many of those enumerated by Haworth.

I propose to speak briefly of a few of the better known and older forms of the larger Trumpet Daffodils, confining myself to-day to those which are not smaller in size than the typical N. Pseudo-Narcissus. Of the white-flowered Trumpets, and the varieties of minor and minimus, of which I have collected several, I shall perhaps ask leave to write at some future time. I shall take it as favour if any one will contradict and correct anything I say in the following notes, which I write as much "with a view to excite inquiry" into the history of these interesting flowers as because I have anything new to tell about them.

Parkinson's account of the first appearance of the large Double Daffodil of gardens is too well known to repeat. Opinions as to what the flower was before it became double have often been given. Those who assert that they can produce it by cultivation out of the common single wild Daffodil have never proved their words, though for many years they have been challenged to do so. I continue to receive so many promises about this that I am not altogether without hope that the feat may be performed, though there are two things that will require explanation:-1. Why does the wild Daffodil in Devonshire produce double flowers quite distinct from those of the large garden Daffodil? 2. Why did the wild Daffodil, which was well known to Parkinson both in its single and its double form, never turn into the large garden variety before his time? The nearest single I have ever seen, both in form and colour, to the common garden double Daffodil, was sent to me two years ago by Mr. Peter Barr, to whom it came from the banks of the Arno, in Tuscany. The same geotleman who sent it to Mr. Barr sent me in that year many bulbs which be hoped would prove to be this single variety. They grow, he says, in great abundance in the meadows between Florence and Pisa, single and double flowers being mixed together. He is unable to keep them single in his garden in Italy, as they soon become double. I regret to say that all that have yet flowered of these in my garden have been double, and cannot be distinguished from the common kind.

It is possible that these Daffodils may have been introduced double from England to Italy, and have degenerated to single, and that they again revert to double when planted in a garden; but why does this reverting to single never happen in England in any of the ten thousand fields and orchards in which the great double Daffodil is naturalised?

I mention next a form not so vigorous in growth as the large double Daffodil, but flowering freely, and increasing rapidly. It has the outer or perianth segments of the flower sulphur-coloured, and the crown clear yellow; and when grown side by side with the common wild Daffodil is twice its size. It does not occur in Hawoth's enumeration, nor do I know its history, but I found it by chance in a cottage garden in Buckinghamshire.

Another variety, which Mr. Barr identifies with

Another variety, which Mr. Barr identifies with Ajax spurius, is exactly like the last in all but colour, which is uniform golden-yellow. Both varieties are early and free flowering, seldom producing barren leaves. Both force well, and are about the best of the major forms. N. spurius is the Trumpet major of many Dutch catalogues. It is naturalised in at least one place in Iteland—in county Cork—where it grows in company with typical N. Pseudo-Narcissus, but flowering about a fortnight earlier—about the middle of February.

The Tenby Daffodil is another major form now becoming a favourite in English gardens on account of its earliness, the hardiness of its flower in enduring rough weather and frost, and its rich golden colour, but the shape of its flower is not nearly as elegant as in the two varieties described before it. instance of Haworth's mistakes, he calls the Tenby Daffodil "lobularis," but identifies the figure in Bandout locations the light in Rot. Mag., No. 1381, which undoubtedly represents it, with obvallaris, a name which Mr. Barr has adopted for it. The Tenby Daffodil is naturalised in one or two parts of Ireland, and on the banks of Windermere, where it is mixed with the common wild Daffodil. It produces seed more freely in my garden than any other Daffodil. It was unknown in Holland till Mr. Barr introduced it. The self-coloured varieties imported annually from Holland, where they probably originated in cultivation, bearing the names of major and maximus, differ slightly on different bulb farms. They are, however, for the most part tolerably distinct from one another. With me maximus is by far the best of the two, and preserves its character, though it increases slowly, and does not flower freely.

The varieties bought as major, though they increase in quantity, produce very few flowers, and those generally deformed, having the crown disfigured by deep irregular gashes. I will not dispute that these are the "great Spanish Daffodils" of Parkinson, though I seek in vain for evidence that either of them is, or ever has been, found wild in Spain; yet all authors follow Parkinson in ascribing them to that country. N. major is included in local botanical catalogues of the South of France, but when I ask to have it sent I get a rather large pale form of N. Pseudo-Narcissus. Much the same may be said about bicolor. I believe that the bicolor figured Bot. Mag, No. 1187-the only old coloured plate of the variety which I can find—is of garden origin. When I send to the neighbourhood of the Pyrences for N. bicolor I get something intermediate between our wild Daflodil and N. muticus, or the Clipt-trunk Daflodil of the Pyrenees. These Clipt-trunks often occur amongst our own wild Daflodils, when a slug has nibbled the nose off a bud just piercing the ground, but in this case a corresponding mutilation of the tip of the outer segments of the flower shows the cause of it. The fine garden form called lorifolius is distinct the shape of the flower; but I have some wild hulbs from a field in Dorsetshire exactly corresponding to it except in size. It is interesting to mark ing to H except in size. It is interesting to mark this divergence from the type. I mention one other large form, named princeps, long cultivated in Hol-land, but not mentioned by Haworth. As imported by Mr. Barr I find it first-rate for forcing, producing flowers the first year nearly as large as those of Emperor; but when planted out in my garden the flowers degenerate to the size of the common wild species, and are very sparingly produced.

In conclusion, I repeat that the only large forms of N. Pseudo-Narcissus besides the garden double Daffodil which I know to be naturalised in the kingdom are Tenby and spurius. Nor can I hear of any being wild in the South of Europe, if we except the N.

Telamonius in the Vale of the Arno.

I find to-day two single-flowered Italian Daffodils in flower. I mentioned above that Mr. Bars sent me a flower two years ago as single Telamonius. I had passed these flowers several times as spurius, but I find them quite distinct, the Italian flower being somewhat more robust, and having the outer segments striped with green. The bulb-leaves, however, are less broad than those of double-flowered Daffodils which came from the same locality, and I hesitate before pronouncing the two plants quite similar. C. Wolley Dod, Edge Hall, Maipas, Feb. 25.

DORONICUMS .- I think I could make some of the most blase of gardeners open their eyes just now did they look into a cool greenhouse here, in the soil bed of which I planted some time since all my stock of Doronicums thickly. I have two kinds, and am not quite sure which is which, but a few plants have stout glossy round leaves, whilst all the rest have leaves much like those of a Cineraria hybrida. austriacum, the other caucasicum, but which is which I do not know. There is comparatively no difference in the flowers, and all the plants are blooming most profusely and beautifully, and being under glass the flowers are singularly pure and fresh. Those who go into ecstacies over yellow Marguerites or Cornflowers would be elevated into a seventh heaven of joy could they have a handful of Doronicum flowers-they are so delicately lined, so elegant and refined. The blooms average 3 inches across, and each has some sixty or seventy narrow petals or florets. The eye is relatively small, as its average dimensions are seven-eighths of an inch only. about Orchids, where in all that family of costly flowers can be found any thing that can compare in wondrous beauty with a Doronicum bloom? I hope lady readers will universally enquire for these flowers, and thus encourage the culture of one of the earliest and most charming of hardy plants. Quercus.

ANEMONES.—The season has been a most generous one to the garden Anemones, for they have been blooming beautifully all the winter. Why do not we see a big bed of these in all large gardens, not necessarily in the flower garden, but in the reserve garden, where a constant supply of flowers would be found? My bed is of second season plants, but a second one from seed sown last June, the seedlings being dibbled out when strong enough, are just pushing up flowers, and there will be a grand show in a few weeks. The blooms of course do not come to their full dimensions just yet, but if gathered when half-expanded, and put into water, they will open splendidly, and make a truly grand posy. I have kept flowers fresh and

bright for a fortnight. Seed is so cheap and strains so good there is no reason why gardeners should not have a few hundreds of plants raised every year.

PULMONARIAS.—How beautiful is the large red-flowered kind, saccharata grandiflora, blooming just now. It is one of the very earliest of herbaceous plants, and is really a lovely thing. Bees favour the flowers greatly. The plant is of the hardiest, and when the bloom is gone and the leaves come up they are found to rival those of Dieffenbachias in marbled markings and beauty. This is a fine plant wherewith to margin subtropical beds, or, infleed, big beds of any sort. As a hardy foliage plant it has scarcely a rival for the purposes indicated. Quercus.

GOLDEN VALERIAN.—A patch of this rich-hued foliage hardy plant is now a striking object in my garden. It nearly resembles a yellow Centaurea ragasina, but is much more easily grown; in fact, unless touched to be divided, it simply wants to be let alone. After the flower-stems spring the plant has no merit, but in the early spring its golden-hued leafage is beautiful, and makes a charming feature. Quercus.

ORCHIDS AT UPPER HOLLOWAY.

AT Mr. B. S. Williams' Victoria and Paradise Nurseries it is quite a pleasure to find so many fine named varieties of Cattleya Triame in bloom after the great number of poor and middling varieties we have seen about of fate flowering among the more recent importations. After all, the fine and distinct varieties are rare even in these days of large importations, and it therefore amounts to this, that those who wish for quality and yet expect variety in the flowers of their C. Triame must either buy a named and described collection of acknowledged good sorts, or adopt the slower method of bringing fine and distinct forms in bloom as they present themselves. The beauty of the varieties Dodgsoni, Itilii, Russelliama, &c., is well known, and Mr. Williams now has in bloom many which are well worthy to class with them, and of which a short description will be serviceable to many.

Cattleya Triame formosa is a massive variety, with

Cattleya Triance formosa is a massive variety, with pale blush sepals and petals, and a rather long labellum, with the lower portion magenta-crimson, and the upper part veined ioside with orange, and

feathered on the outside with rosy-lilac.

C. T. Williamsii.—A well-formed flower, and, viewed from all points, one of the finest of named Triancs. Its sepals and petals are light rose, lip bright dark magenta, the colour merging into dark maroon as it extends up the throat, the outside portion of the labellum veined with purple. The whole plant also is distinct, many of its parts being stained with dark red, and the joint of the leaf and the flower-sheaths are of a rich crimson-brown.

C. T. Rougieri.—This is a vaunted Continental variety. It in some respects bears a resemblance to C. T. Williamsii, but seen side by side with it the

variety Rougieri is a long way behind.

C. T. splendidissima has very much the form and many of the other characteristics of C. T. Dodgsoni. The sepals and petals are white, the latter being 2½ inches in width, and having an expansion of 7 inches. The labellum is dark rose, and it has a much wavier edge than that of Dodgsoni. C. T. rosea gives a very pleasing variety; its welf-formed flowers are entirely of a delicate pale rose, the only departure being a slightly darker blotch on the labellum. It is distinct from those varieties found in gardens under the name C. Warscewiczii delicata. C. T. Regina is a very lovely plant, with flowers of the most exquisite form, and of the most pleasing tints. The sepals and petals are pearly white; the lower half of the labellum is bright mauve, broadly bordered with a white frill, and having in the throat a bright light yellow tinge. It will always be a great favourite.

Cattleya T. Thomsoni has a light rose well-formed flower, but the great peculiarity which renders it distinct from any other is the extraordinary manner in which the sides of the labellum which usually cover the column are thrown back, thus exposing that organ fully to view, and imparting a novel character to the flower. C. T. tyrianthina of Backhouse is a neathooking kind, and very floriferous, with flowers of

medium size, petals bright rose, lip majenta-mauve with orange throat.

C. T. marginata was imported by Mr. Williams, and the singular circumstance is, that the whole of the plants in the importation were exactly alike. The flowers of this variety are very large, but rather narrow petalled, light rose with a darker blotch, and some yellow in the labellum, and a broad white margin round it, which makes the flower very attractive.

C. T. Backhousiana.—This variety is very distinct; out of the thousands of recently imported plants not one has appeared exactly like it, the deep maroon-crimson of the lip running far up the throat, and the purple feather in each of the petals rendering its identity easy and certain. C. T. alba.—It will not be fair to omit this chaste old favourite, which, when true, is as valuable now as it was ten years ago; a fine form of it is now in flower at Mr. Williams', with the whole of the flowers as nearly snow-white as it is possible to get in a Cattleya, the only colour being a very faint tinge of yellow and pink in the throat. A striking feature in the collection here is the large quantity of the best named varieties of Vanda tricolor and V. suavis; they are already furnished with a few flowers, and examination discloses the just pushing spikes, which will give a supply of bloom to extend over the whole summer.

Fresh imported plants do not find much favour here; the space is, therefore, occupied by established plants, many of them with a good character. Among the fine things in bloom are Odontoglossum luteopurpureum hystrix, a very fine thing, as showy as a good O. Wilckeanum; Calanthe nivalis, a variety with snow-white flowers, and without any colour in the lip; C. Turneri, C. Regnieri, Galeandra Devoniana, with its terminal bunch of large flowers, with Gloxinia-like labellum; many Lælia harpo-phylla, Dendrobium Boxalli, D. Findlayanum, quantities of D. Wardianum, D. nobile, D. Ainsworthii, and other Dendrobes. The cold-houses are gay with Odontoglossums of many sorts, among them being prominent O. Chestertoni (true), some good O. Iallii, O. triumphans, and O. Pescatorei; one fine branched spike of over fifty flowers of the last-named presenting a lovely object, which would need no accessory as a plant for table decoration. In the intermediate-houses Miltonia cuneata, with its large white lip, many Cypripediums, Phalænopsis, Oncidiums, &c., are in be found in bloom; and that difficult plant to manage, Epidendrum bicornutum, is growing very strong, and sending up several spikes in a warm, moist, sheltered house: lew white Orchids are prettier, or have beaten more growers than this

One cannot fail to notice the healthy appearance of all Mr. Williams' stock, and the absence of insect pests and all traces of them.

JENSEN ON THE POTATO DISEASE.

(Concluded from p. 240.)

VII. HIBERNATION OF THE DISEASE.—In order to see whether diseased tubers left in the ground from the previous year may be expected to give diseased shoots in spring, the following experiment was tried:—Eighty tubers were infected on December 15, 1852, by dipping them in spore-charged water after their skins had been broken by being pricked with a fork. On December 28—

	Temperature during the time, about	Gave conidia on March 26, 1883.
Sixteen were buried 2 inches deep in a garden	41° F.	t
Sixteen were buried 4 inches deep in a garden	41* F.	2
Sixteen were buried 8 inches deep in a garden	41° F.	2
Sixteen were placed in a cellar	45° F	0
Sixteen were placed in an ordinary living-room	57° F.	o

They were examined on March 26. Those in the living-room were as hard as horn, and gave no condida. Most of those in the cellar were in a similar condition, none gave condidi. Of the forty-eight placed in the ground, twenty-five had rotted so completely that they could not be found. One tuber, 2 inches deep, gave condid; two tubers, 4 inches deep, gave condid in great profusion; two tubers, 8 inches deep, gave condid in great profusion.

Another experiment was made by keeping a large number of Potatos (180 lb.) in a box in a cellar in Copenhagen. They were placed there in October, 1881. About Christmas they were picked over, and the diseased ones, which were many, removed, yet about 20 per cent, were found diseased on May 10. Of these thirty tubers were cut open and placed under bell glasses, of which nine gave conidia on the 13th, and fourteen more on May 15. The temperature of the cellar would be ordinarily about 40° or 41° Fahr., but every fortnight it was used for some domestic purpose, when it was heated by a stove. Now we know that the disease does not spread at a temperature of 41° Fahr., so that unless this artificial heating had taken place no fresh tubers would have become diseased, and the large proportion of tubers which gave conidia in May seems to point to the fact that the mycelium had not hibernated from Christmas to May, but had originated at some more recent date.

VIII. OTHER ORGANISMS CAUSING DECAY IN THE POTATO.—The so-called "wet rot" has been known in Europe long before the Potato disease appeared. Its occurrence is favoured, but not caused, by the presence of the Peronospora. It is especially apt to occur upon the Potatos which are kept during the winter in graves, and is caused by a Bacterium.

Another Bacterium causes the sap of the Potato plant to turn black or brownish black. This species is also associated with the Peronospora, and is more common in the foliage and stem (causing the black patches so characteristic of the disease) than in the tubers, although it is sometimes found in them. Mr. Jensen has produced the Peronospora upon the leaves of Potato plants unaccompanied by this Bacterium; in these instances the spots were of a light colour.

Much of the above information has not as yet been published by Mr. Jensen-such, for example, as the temperature table, the hibernation experiments, &c. It will, therefore, be the more interesting to the committee.

REMARKS .- Mr. Jensen's assertion that the period at which the general outbreak of the Potato disease takes place tends to alternate in successive years certainly took me by surprise, for I was always under the impression it occurred in England generally about the second week in July, subject to the amount of raintall. Before accepting his dictum upon this point I was anxious to find, if possible, whether or no it was supported by any evidence obtainable in Great I have, therefore, summarised the valuable reports which for the past seven years have been given in the Gardeners' Chronicle. These appear to have been made during the last week in July and the first two or three days in August. The 900 reports for the years 1877—1883 were classified into four groups: - (1) those which reported the disease absent; (2) those which reported it just commencing or doubtfully present; (3) those which spoke of its presence in more or less distinct terms; (4) those which spoke of it being exceptionally virulent. The result may be stated in a tabular form, as under :-

in other words, these were late years; while 1878, 1880, and 1882 were early years. In order, however, to see whether this was really the case, the following table has been constructed, showing the percentage these various figures bear to the total number of reports :-

			Year.	Absent.	Slightly.	Distinctly,	Severely.
Late			1877	50 4	16.5	28.8	4.3
Early			1878	41. I	12.4	31.0	15.5
Late			1879	43-7	11.5	31.6	13 2
Early			1880	30. 7	6.9	56.5	5.9
Late			1881	8n 3	13.9	5-8	
Early			1882	8,8	17.5	55 a .	18.7
Late	••	••	1883	68. 2	14.1	17 7	

From the above it is obvious that the number of reports in which the disease was absent alternates very markedly, with one exception (1879), and it is also clear that 1877 was a late year, 1878 was earlier; and while there is very little difference between 1878 and 1879, yet 1880, 1881, 1882, and 1883 were most distinctly early and late alternately. It is not always the case that facts fit so well to a theory as these do. The year 1879, however, should have been late, whereas if it was not early there was certainly very little difference between it and the preceding year.

Let us now see what the rainfall in the months of May, June, and July for these seven years was. the reports are from Great Britain and Ireland, it is necessary that we should have the mean rainfall for each month of these countries. I have had some little difficulty in obtaining this, but at last the Rev. Henry Ffolkes, of Hillington, kindly obtained it for me from Mr. Symons, F.R.S.

verage Rainfall for the Months of May, June, and July, for the past Seven Years, for Great Britain and Ireland:—

		May.	Juoc.	July.	Total.
1877	 	In, 2.88	In. 2.82	In. 4 °3	In. 9 73
1878	 	4.24	3.27	1.48	8.99
1879	 	2 63	4.72	4.66	12.03
188o	 	1 47	3 01	5 13	9.6r
1881	 	2.30	3.49	3.31	910
1882	 	2.38	4.21	5.09	11,68
1883	 	2.23	2.87	3.67	8 77

From the above table it is obvious that the great rainfall of 1879 (12.03 inches) almost extinguished the alternating tendency, and in point of fact made what otherwise would have been a late year into a medium. The next highest rainfall was in 1882 (11.68 inches); this would have been an early year, but the rain made it very early, reducing the absent reports to 8.8 per cent., against 80.3 per cent. of the preceding year (1881).

Mr. Jensen says the disease appeared early in Denmark in 1877. Certainly this was not the case in

of them speak of it being "earlier than usual," four others of it being "very early," and from Somersetshire it was reported at the end of May and beginning of June; from Essex, Sussex, and Wilts, on June 25. In Clare it appeared on June 4, whereas, in previous years, its advent had been noted as being ten days later.

1879 has already been shown to have been a late year, made a medium by the excessive rainfall in May, June, and July. Yet from Westmoreland and Clare it was reported "later" than usual; from Cheshire, Suffolk, and Wilts it was not reported till the middle of July; and in Galway the tops were said to be "as green as Leeks. This time last year (1878) there was not a green leaf to be seen."

In 1880 it was reported from Suffolk as early as June 30, and from Wilts in the first week of July.

In 1881 no less than 80 per cent. of the reports made between July 30 and August 2 speak of the absence of the disease.

In 1882, on the other hand, the disease appears very early, for in only 8.8 per cent. of the reports do we find it absent (made for July 29 to August 2). In Lapark it was noted as being earlier, for Middlesex as "unusually early," from Wilts "very early," from Cornwall one report says a "month," and another "five weeks earlier than usual."

In 1883 the disease was late. One reporter from Hants says, "Considerably later than usual;" 68 per cent. of the reports were free from it during the last week of July; therefore I think it may be taken as proved by the Gardeners' Chronicle reports that the Potato disease has a tendency, subject to the rainfall of May, June, and July, to alternate between a late and an early date in its outbreak.

In conclusion, I would only add that the perusal of the reports for any year will convince the reader that the general outbreak does not occur, as is not in-frequently imagined, suddenly. Reports from one district will speak of it as absent, and the next from the same country, as present perhaps severely. Very many reports, too, speak of it in such terms as having "appeared about here in many places, but it has not attacked us yet." Charles B. Plowright, King's Lynn, Feb. 8.

PROTECTING ROSE CUTTINGS FROM HARSH WINDS .- I always propagate each successive October some Roses I am anxious to increase from cuttingsgenerally the newer kinds, or varieties that do particularly well in our soil or situation; but more especially for comparison with the same or other kinds with myself or others on stocks. There is still another reason almost equally potential—passing over the saving effected—that is, the interest and zest experienced in watching them rooting, and the innate satisfaction you experience when you find you have succeeded. I am now referring to the simple process

TABLE OF THE REPORTS UPON THE POTATO CROP FOR THE SEVEN YEARS, 1877-1883, GIVEN IN THE GARDENERS' CHRONICLE,

The reports were made up during the last few days of July and first two or three days of August in each year. The first column under each year shows the number of reports which speak of the disease being absent at the time the report was written. The next columns, 1, 2, and 3 show relatively the degree with which the disease existed—1, slightly; 2, distinctly; 3, severely Of course there three late reports were or less arbitrary.

Of course circle curse such groups are more or less architects.

From this it will be seen at a glance that the greatest number of reports of the disease being absent -that is, of not having made its appearance at the time the reports were made-for sooner or later we may take it for granted it did attack the Potato crop-are the years 1877, 1879, 1881, and 1883;

Great Britain if the reporters can be trusted, and if gardeners do not know the Potato disease when they see it I do not know who does. Here it was a late

On the other hand, 1878 was an early year; so much was this the case, that of the 129 reports sent in four

-within the reach of the humblest-of putting in the cutting in the open air. So far I have not lost I per cent., and as the leaf-buds have expanded they seem started on their career. Not so yet. Perhaps not 5 per cent., are rooted. The fierce March winds have hitherto been the funeral dirge of a large portion

of those I tried. I am putting moss and fine hay between them as protection against it, as they must not be wholly covered. W. J. Murphy, Clonmel.

PRUNING MARÉCHAL NIEL ROSE.—Looking over or rather up at the fine growths made by Maréchal Niel Rose trees under glass last year, I can but note how, differing from Vine rods as a rule, these Rose rods, S or more feet in length of fine robust growth, have broken at every bud, with the exception of perhaps three or four at the most at the base; of course every shoot will carry a bloom, and the exhaustion from so doing is so great that if the long rod he left to carry bloom another year, the product will not be one-half so good as that of this year. Do we not cripple our Maréchal Niel Roses by reltaining from hard pruning,

FORESTRY.

FOREST WORK FOR MARCH.—The bitter parching blasts of March tell most detrimentally on newly planted trees and shrubs, and clearly proclaim that the work of transplanting should be suspended for the present, and until such time as more genial warm weather sets in. Should it be necessary, or rather unavoidable, to plant during the present month proper precaution must in all cases be taken to expose the roots as short a time as possible to the drying influence of the air. A covering of any material such as damp straw, or even old mats, is readily obtained, and should always be used in transferring plants from

rocking with the wind. Should any be found they must at once be tramped up and placed in an erect position, or, better still, with a slight inclination to the point from which the prevailing winds of the district usually blow. Stones should never be placed in the holes formed by the plants when rocking about, as it is not only injurious to them, but next to useless for the purpose intended. Considering the strain and consequent damage to the roots of trees when rocking with the wind, it well repays us to use every effort to avert it, either by a timely staking or firm trampling of the soil around the collar of the plants.

March is usually a busy month in the home nursery, for between the refilling of vacant plots and meeting the planters' demands those employed in this

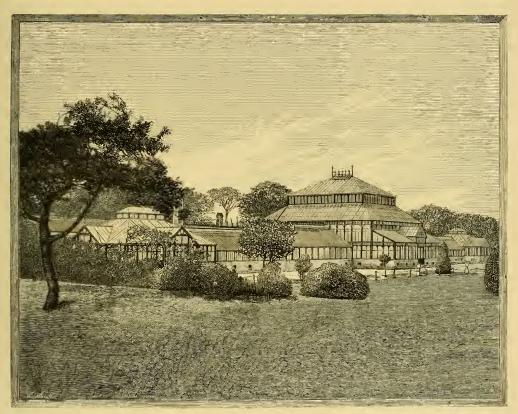

FIG. 50.—THE NEW RANGE OF PLANT HOUSES IN THE GLASGOW BOTANIC GARDEN. (SEE P. 269.)

because strong growth seems to be the very life of the plant, and the only wood that will give good flowers? I propose as soon as the flowers from the present shoots are all cut, to shorten back all these long growths to one or two dormant buds, in the expectation that other fine rods will go up, and produce next year a grand lot of blooms. Perhaps it is a wise provision of Nature that these best buds should remain dormant, that they may be made to develope in proper course by hard pruning. That old plants of Maréchal Niel are wondrously recuperative I have seen ample evidence, and an old one with a very large stem cut back to within 2 feet of the soil is, now pushing buds out of hard wood and rind that bid fair to make spleodid growths during the summer. That growth is unusually early this year there can be no doubt. Flower-buds are showing, although the house is a cool one; and with a prospect of an early Rose harvest early hard pruning should be all the more favourable to strong new rods. A. D.

the home nursery to the plantation. It is also well only to lift sufficient plants for immediate requirements, and not to keep, as is usually the case, quantities laid in ready for use. Watering is highly beneficial to March transplants, but can only be resorted to in the case of evergreens, being impracticable in general forest planting, at least where such is carried out on an extensive scale. In the latter case puddling the roots previous to planting is of the utmost benefit, and may be practised with the most satisfactory results. In all cases, however, where possible, it is best to defer the transplanting of trees and shrubs until next month unless we are favoured with unusually mild weather during the present. After the late succession of storms with which we have been visited, it is particularly necessary during dry weather to go round newly formed plantations and thoroughly examine the plants, to see that none are

branch of forest work are kept pretty busily engaged. The roots of young nursery stock should be well puddled and covered during their transit, and kept out of the ground as short a time as possible. Cut out all double or competitive shoots, as well as strong side branches, from plants while being removed from one situation to another. When lining-out, give young plants ample room, which will not only induce robust growth but the formation of strong fibrous roots as well. Overcrowding is highly injurious and should be avoided.

The thinning of mixed plantations should be completed by the end of the month, as considerable risk is incurred by felling after the buds begin to burst. Pine and Fir plantations may be left to the last. Thinning should be regulated by situation and exposure, as well as by the previous treatment of the trees; almost as much damage being done by a too

sudden and reckless clearance as by overcrowding Where woods have been neglected the thinning must be gradually performed, and proportionate to the age and size of the trees. Remove, as early as possible, timber from the woodlands, particularly from those portions where the stools are intended for reproduction. Bind faggots, and during dry weather have them stacked or carted to the drying shed for use as required. Layering for game coverts may now he proceeded with, and the pruning and dressing of ever-greens completed as early as possible. No time should be lost in pruning off such branches as have become broken or twisted by the violence of the late storms, and the greatest care should be taken to guard against the lodgment of water in any of the mounds. Great damage has been done to trees and shrubs by the terrific storm which passed over this district on Wednesday night and Thursday morning, the 20th and 21st ult. All the plantations on this estate suffered severely, and in the park many fine specimen trees have been levelled with the ground. For the past six weeks we have had a succession of storms, but that of the 20th and 21st was certainly the most severe, and has occasioned an amount of work that will take some months to accom-

Open drains, and the outlets of covered ones, will require attention, as they are in many cases apt to get choked with an accumulation of fallen branches and leaves. The excessive rainfall of the past month necessitates strict attention being paid to drainage of all kinds. Have all fences put in thorough repair, and look well to tree-guards, rabbit-proof netting, and erections of various kinds for preventing the attacks of game.

Finish the repairing of roads, drives, and walks, and examine woodland rides, as rabbits are apt to undermine these with their burrows, thus rendering them highly dangerous for the removal of timber. See that wire fences are not too tight during frosty weather, a slight slackening of the wires will prevent overstraining and breakage. A. D. Webster, Fenrhyn Castle, North Wales.

Che Erboreinm.

CERASUS PSEUDO CERASUS, THE FALSE CHERRY.—This is earlier in bloom than any allied tree in the Cambridge Botanic Garden. It is desirable on account of its earliness, and because of its moderate size. The flowers are pale pink in colour, and possess a pleasing perfume. Cuttings are easily rooted. It was tried by Mr. Knight as a fruit tree, but there has been no evidence here of its being useful as such. The fruit is small, of pale red colour, and is said to be of pleasant sub-acid flavour. It has been found to force better than any other kind.

TILIA PETIOLARIS, D.C. — In British gardens a tree is often found under the names of Tilia americana pendula, T. alba pendula, platyphylia pendula, or argentea pendula. It is distinctly one of the handsomest of its class, is quite hardy, and ripens seed. Sir Joseph Hooker has investigated the history of this line tree, generally supposed to be of Northest American origin. This, however, turns out to be an error, and the tree is now referred to a species which is probably native of the Crimea. T. petiolaris is like a pendulous variety of the white Lime, but has longer leaf-stalks; smooth, not crumpled leaves, and a five-lobed warted seed-vessel (not ellipsoid five-angled and smooth). A figure is given in the Bot, Mag. (1884), t. 6737.

TALAUMA CANDOLLEI.—Like some of the Magnolias the flowers of this plant give off a grateful aroma as they expand, and were it not for their fugacious nature the various members of the genus would undoubtedly become popular subjects for the stove or warm conservatory for this property alone. The large pale yellow spoon-shaped petals are of great consistency, and overlap each other in the manner of a rosebud, while the nearly white sepals are more spreading. The only valid distinction between this and a Magnolia is that the matured fruits become fused together, and fall away in irregular masses, whereas in the latter they are persistent. Several plants of T. Candollei have flowered in the Palmhous: at Kew, and there is a figure of the species in the Balanical Register, 1709.

Prehid Notes and Cleanings.

PHAIUS TUBERCULOSUS, Bl. - Mr. A. Sillem, Laurie Park, Sydenbam, S.E., kindly informs me of his flowering now five inflorescences of this in the finest development, and one of those, a six-flowered one, is on my table, thanks to this gentleman. The flowers are much superior to the first developed ones. There would also appear to be a great difference in colour. The flowers at hand are nearly red over all the side lobes of lip, and there are but very small ochre dots, while those seen first were ochre with small red spots. The mauve colour of the anterior lobe of the lip is very intense, and the three orange long calli in the disc of that lobe are very bright; and so is the mauve-purple base of column. As it is, the species is very ornamental, very desirable, and we may expect its always lasting rare, since it is one of the shyest travellers to be found. H. G. Rohb. f.

EFFECTS OF CUTTING AWAY THE BACK BULBS OF ORCHIDS .- An apparent attempt to show that some new discovery connected with the cultivation of some particular kind of plant or other has been made, however opposed the practice may be to common sense and experience, is not always, when made public, so harmless as might be supposed, as for instance the mischievous practice of cutting off the back bulbs of Orchids, the advantage of which was held forth in a contemporary a year or two since, and by which, in a case that came to our knowledge, an owner of a fine lot of Dendrobes was unluckily led to improve, as he hoped, their health and appearance by removing the old bulbs before blooming time; for would not the plants look much nicer with nothing but the flowering growths then pushing their buds? Besides, according to the doctrine, all the strength of the roots would be concentrated in the leading bulbs; so a clean sweep was made of the whole of the back growth, with the result that might have been anticipated, for the advancing flowers turned yellow and withered away. But this was not the worst mischiel, for some of the plants died outright, whilst others were reduced to the condition of imported stock that had been half killed in transit.

OLCHIDS AT MR. DORMAN'S, SYDENHAM.

The fine collection of Orchids here is particularly rich in coul and intermediate temperature plants, such as Odontoglossums and Cattleyas; of the latter the Triances alone are a treat to see, combining as they do the various forms and colours, from those that are all but white to the splendid high coloured C. Trianæ Backhouseana, with its inteosely deep-shaded lip and crimson-feathered petals. There are many fine forms of other species, such as C. Mendelii, C. speciosissima, C. Mossiæ, C. Warneri, and C. Skinneri, including the rare C. Skinneri alba, that will later on make a telling display. Of Lælias of the L. purpurata and L. elegans section there are a grand lot of fine specimens, which forecast by their big plump bulbs and numerous flower-sheaths what the bloom will be later on. Quantities of Lycaste Skinneri were in flower, amongst them being the scarce and beautiful L. Skinneri alba. Here also in bloom were several forms of the light-coloured Lælia anceps, each differing from the others. With these was a fine lot of well-grown Auguloas, comprising A. Clowesii, A. Ruckeri, A. uniflora, and others. Cologynes of the cristata section, including C. cristata Lemoniana, were flowering well so as to nearly hide the leaves and bulbs, carrying as many as seven flowers on a spike. In the adjoining house in the same range are grown the warmest species, in which are numbers of Phalænopsis with stout, healthy foliage. One plant of P. violacea has leaves 4 inches across; of P. Stuartiana, one of the best forms we have seen was in flower, with the spots larger and better defined than usual. Odontoglossum Pescatorei and O. vexillarium are grown together, and have a house to them-Both species are in splendid condition, especially the last-named, which from their size and number must be a sight worth seeing when in bloom. One specimen we understand bore 114 flowers last season, and has now some fourteen leads. sweet-scented Dendrobium, D. japonicum, was flowering nicely. There is an extensive stock of Odonto-glossum crispum filling a large span-roofed house,

many of them consisting of the finest selected forms, large plants with strong plump bulbs that, when fully in bloom, must be a feature in themselves. The unique plant of O. crispum aureum magnificum, shown and certificated last year, is coming on with two immensely strong spikes, two others having been removed to avoid distressing the plant; in habit it is quite distinct, the leaves are large, 2 inches wide, the bulbs are of immense size and of the deepest brown colour, almost black, the spikes are stout, dense, and erect; the colour of the flowers is yellow, with markings in the way of O. Ruckerianum and O. Ander-sonianum. In the house principally occupied by Masdevallias are located the cream of this deservedly favourite genus; they are in good condition, a fine plant of the singular and beautiful M. Shuttleworthii was in bloom, the individual flowers 91 inches from tip The house almost wholly devoted to Dendrobiums will be a sheet of bloom shortly. Amongst a host of the leading kinds, D. Ainsworthii x, D. heterocarpum, D. crassinode, and D. Wardianum will soon be loaded with flowers; the plants are strong, some of the bulbs of D. Wardianum are 4 feet long. extensive collection throughout bears evidence of the care and attention bestowed on it.

"SELECT ORCHIDACEOUS PLANTS,"—Mr. Robert Warner has, we bear, been awarded a Silver Medal for his Select Orchidaceous Plants at the Calcutta Exhibition.

FRUITS UNDER GLASS.

VINES .- The heavy falls of cold rain and sleet which we have recently experienced, will have had an injurious effect upon early Vines that have their roots in unprotected borders, for these must of necessity have become saturated, and their temperature brought to a very low point, thereby keeping roots in a state unfitted to properly carry on their functions. Early Vines subjected to these adverse conditions suffer in a degree which those growing in protected borders are not exposed to; I would, therefore, again impress upon those who purpose planting not to overlook the considerable utility of well made inside borders. Houses in which the fruit is thioned should have a 'night temperature of 65°, with a little air on on those that are closely glazed. We contrive this by having pipes fixed in the front wall, one end covered with perforated zinc, and the other abutting on the warm pipes. As soon as the thermometer commences to rise from solar heat admit a little air by the back ventilators, and allow it gradually to reach 85°, giving additional air at intervals cautiously so as to avoid cold draughts; close before the sun loses its power, at the same time damping the borders and all other surfaces, During dull weather raise the day temperature only 10° above that recommended for the night, and preserve a moderately moist atmosphere. Continue to disbud and stop sublaterals. Sponge foliage that is attacked with thrips or red-spider; by the way I have never seen satisfactory results accrue from the use of sulphur placed upon heated pipes, which has been frequently advised to destroy the latter; but the practice of sponging the foliage, although not unattended with mischief if carelessly done, is remedial if promptly undertaken and persevered with. Any seedless berries that were overlooked at the time of thinning should be cut out as soon as seen, and the shoulders of the larger bunches carefully suspended. Persevere with the work in successional-houses, keeping late Hamburghs still open and as cool as

PEACHES AND NECTABINES.—Trees that have set too many fruits should be thinned as soon as it can be seen which will swell freely, remembering that a good surplus should be left until the critical period of stuning is over. If possible obtain an even crop with those that have taken the lead upon the upper surfaces of the strongest wood, and as far as practicable do not over-crop the weakest. Follow up the disbudding and heeling-down of young shoots as they become fit, likewise mulch the borders with cow and horse manure, and see that they are sufficiently watered when that is required; those that are shallow and well drained requiring particular attention, while trees whose roots have filled their borders will be much assisted by occasional soakings of weak liquid-manure. Those that have extended over a considerable space of trellis produce finer fruits and more

satisfactory crops than do those that are restricted, therefore where an inferior variety exists between two valuable ones it is well to cut it away by degrees, allowing the others to fill its space. On mild nights maintain a maximum temperature of 58°, and still admit the circulation of air by the front ventilators. Syringe and ventilate early on clear days, and allow the warmth to increase gradually with more air given until it reaches 75° to 80°; syringe thoroughly at closing time, but avoid directing the water so as to tear the young leaves. Pay unremitting attention to the requirements of the second house, and close a third if an unbroken supply of fruit is required during the season. In fertilising the blossoms carefully attend to those that are deficient of pollen, and where ants abound exterminate them : these diligent pests in their search for honey sometimes cause wholesale destruction by removing stamens. Be careful that there is no lack of moisture in the borders, for a check to the trees when in blossom from this cause will prevent a good set of fruit. Retard the latesthouse by keeping it open until the blossoms begin to expand, and keep trees that have been recently planted, also those that have had their roots lifted, mulched with short manure.

MELONS. - Short days and a deficiency of sunlight are unfavourable to these plants. As the roots of the early plants reach the outside of the ridges or hillocks add more warmed soil, firmly pressed down. Train the main shoots and stop them when they have reached 3 to 4 feet up the trellis, carefully thin and tie-out laterals and nip out their points at one or two joints beyond the female blossoms. Impregnate as many of the latter on one day as can be found open, selecting, as they commence to swell, the most perfect fruits for the crop. It is usually difficult to induce other fruits set on a plant upon which one or more are swelling, hence the advisability of securing several blossoms together. Cease syringing while the plants are in blossom, and after the crop is insured mulch with short manure, and water regularly and copiously with tepld diluted manure-water, preventing either from coming into contact with the stems. Keep plants in pots in a steady bottom-heat, and see that these are also top-dressed and well nourished with liquid manure. In preparing fermenting material for heds employ three-fourths of leaves with one of stable litter. Well mix these together, and throw the bulk in a heap, which turn occasionally until the rank steam has escaped, when the beds can be formed. Plant successional plants in their fruiting quarters as they become fit, bearing in mind that a few planted at frequent intervals yield a more satisfactory supply of fruits than do large batches planted at longer intervals. Two highly-flavoured valuable varieties for general crops are William Tillery and Blenheim Orange, the former green and the other scarlet-flesh, Thos. Coomber, Hendre Garden, Monmouth.

Che Pitchen Garden.

SEED SOWING .- Small sowings may now be made in a warm situation of the following seeds :- Early London, Dean's Snowball, and Veitch's Autumn Giant Cauliflowers; Snow's Winter White Broccoli, Drumhead and Early Ulm Savoys, Brussels Sprouts, Cottager's and Scotch Kales, and a box of Curled Parsley (in heat) for transplanting later on, Make another sowing of Broad Beans and Peas, and draw a little soil up to those sown early in January, and stake the latter forthwith. This done lay on five or six inches thick of rotten dung on either side the rows of Peas, which will serve a threefold purpose, viz., that of protecting the young haulms from cutting winds during the present month, maintaining the roots in a more equable condition than would otherwise be the case, and conserving the water given them during the summer months. Old Cabbage stumps should be removed fortwith, and the ground be made ready for Potatos, of which a small planting of the Early Kidneys may be made at once in drills, 5 inches deep, 2 feet asunder, and 10 or 12 inches apart in the row. It will be advisable to defer planting the main garden crop of Potatos a fortnight longer, with a view to their escaping the dangers of late frosts. If the ground has been liberally manured for the preceding crop, and is moderately rich, it will not be necessary to manure it for the Potato crop; in fact the latter, under the circumstances, will be hetter in quality and quantity without it. Onion, Parsnip, and Carrot seeds should be sown as recommended in last Calendar, as soon as the condition of the ground will admit of the work being done. Early plantings of Cauliflowers should, if not already done, have the Spruce boughs with which the plants have been protected removed and be earthed up. Seed-beds and seedlings just coming through the surface of the bed will require to be protected with a piece of netting from the ravages of birds.

PREFARING GROUND FOR ASPARAGUS.—Where new plantations of Asparagus are contemplated the ground should be got ready for planting next month; it should be deeply trenched, and a liberal supply of well-rotted manure be incorporated with it as the trenching proceeds. There should be a uniform depth of 3 feet of soil at least, and if it be of a sandy alluvial nature it will in every respect be suitable, providing the drainage is good, for the growth of Asparagus. Existing beds should at once have the short dung that was laid on them last autumn covered with a few inches of soil from the alleys, which should then be lined off afriesh. This soil after a few days exposure to the weather will be sufficiently dry to rake over, and, where leaf-mould is plentiful, a few inches thick might then be put on the beds. This in my opinion adds considerably to the crispness of the produce and improves its colour.

FORCING DEPARTMENT .- French Beans growing in early vineries and Peach-houses will require extra attention in the application of water both to the roots and overhead, otherwise red-spider will be sure to attack the plants, and spread to the parmanent occupants of the house. Sufficient batches of seed should be planted at frequent intervals to maintain the supply. Top-dress succession crops when about inches above the rim of the pots with warmed soil, similar to that in which the plants are growing, and pinch out the points of the shoots to make them Young plants of Brussels Sprouts, Cauliflowers, Lettuce, Leeks, &c., should be pricked out in a frame on gentle bottom-heat as soon as large enough, preparatory to being planted in the open later on. Sow Moore's Cream and Muir's Prolific later on. Sow Moore's Cream and Muir's Frontie Hybrid Vegetable Marrows, and Stockbridge Ridge Cucumber seed singly in 3-inch pots. A sowing should also be made of red and white Celery, of the varieties most approved of, Turner's Incomparable White and Leicester Red being excellent soits. See that the supplies of Asparagus, Seakale, and Rhubarb are equal to the demand, and that pits and frames in which Potatos, Carrots, and Radishes are growing have sufficient air admitted to them to prevent the plants making a weakly growth; the former, howe latter and the condition of the weather, which latter being favourable the sashes should be taken off crops of Potatos, &c., early in the morning, and replaced late in the afternoon. H. W. Ward, Longford Castle Gardens, Wilts.

Plants and thein Sultune.

FERNS .- Whilst the potting of the stove plants is being carried on many seedling Ferns will probably have been saved from the pots of those plants in which they have germinated accidentally. Where many cut Fern fronds or small plants are required for decorative purposes these seedlings should be looked after; they will invariably make more robust plants than when increased solely by division, Davallias excepted. The strongest of these young plants should be potted singly into thumbs or small 60's, from which they can be shifted as they become well established. The smaller plants should be pricked off into seed-pans or around the edges of small pots. A good stock of young growing stuff of Adiantum cuneatum, A. concinnum, A. formosum, and A. gracillimum, with Pteris argyrea, P. cretica, P. serrulata, and P. tremula, would at all times be of essential service for decorative purposes in small pots. To these also should be added several of the Aspleniums, as A. bulbiferum, A. Belangeri, A. flaccidum, which can be raised from spores or increased from the numbers of young plants that are to be found on most well developed fronds. Some few seedlings, too, of the

golden and silver forms of Gymnogrammas will be found useful, and when well looked after will quickly overtake the old plants. The Davallas are readily propagated by division of the rhizomes, the small growing forms being invaluable for cutting purposes. D. bullata, D. Mariesii, D. dissecta, and D. elegans are of the best, and will well repay a little extra attention given them. Lygodium scandeos should be grown by those who have much demand for dinner-table decorations, being the best of all climbing Ferns for cut purposes. When required for such, each frond should have a good length of string, to which it can be trained and readily removed when needed. The following Ferns are all useful for filling vases and rustic baskets for indoor decorations, most of them having great persistency under adverse circumstances, viz., Asplenium bulbiferum, Cyttomium falcatum, Davallia cannaticosis, Lastrea Sieboldi, Nephrolepis tuberosa, and N. exaltata, Niphobolus lingua, and Platycerium alcicorne. Todea superba, with ordinary attention, will thrive for a great length of time in a case or under a bell-glass. The use of such Ferns as we have just named would be much preferable to drawing the supplies from more delicate kinds that easily suffer.

All the stock of Ferns should be gone through

closely for repotting, as may be necessary. We disposed to think that Adiantum cuneatum will disposed to limit that random with the best grown in nearly or quite half loam, when required to supply cut fronds. These will not, as a rule, be so large in the pinnæ as if they were taken from plants growing in a mixture containing a great quantity of peat, but will be all the better calculated remain fresh for a greater length of time. that may now be making a fresh start should have all the light possible for some months to come, to develope a sturdy growth; a temperate-house will be found the best, without an excess of or stope a stury growth; a temperate-house will be found the best, without an excess of moisture. Under such conditions the fronds will be harder and better calculated to retain their freshees when cut. Most Ferns that are of vigorous growth will succeed in a mixture of peat and loam. Leaf-mould would be beneficial to the smaller-rowing section when it is of coal to the smallergrowing species when it is of good quality, instead of quite so much loam. There are, of course, some exceptions, such, lor instance, as the Gymnogrammas, which succeed best in all peat, and are potted as hard as a New Holland plant; the Cheilanthes and the Nothochleenas thrive best under the same treatment. Nothochleoas thrive best under the same treatment. A few pieces of charcoal mixed with the peat suits these delicately-rooted Ferns. All the true Gleichenias grow most freely in peat, with an abundance of drainage as a safeguard against the extra amount of water they require. G. flabellata of the Mertensia group succeeds best with an excess of loam over that of peat, developing much finer fronds than when in the latter compost alone. Keep an eye on such as Leucostegia immersa. This handsome deciduous Fern will soon he nutting ma firsh lot of fronds. This and similar immersa. In the state of the declared from a source be putting up a fresh lot of fronds. This and similar kinds should be reported before any growth is far advanced. Any Tree Ferns that give indications of putting up a crop of fresh fronds will be benefited by having some sphagnum moss bound around the stem, if the same should not already have been done. if the same should not already have been done. Where it has been practised in previous seasons a fresb supply will be necessary close up to the crown, where fresh roots are likely to be emitted. The moss is a great encouragement to the perfecting of finer fronds, and is also a conserver of moisture to feed the roots that are put forth up the stem. We would not advise this treatment with stems that are already of extra circumference, but others would in most cases be improved in annearance. Whilst the notmost cases be improved in appearance. Whilst the potmost cases be improved in appearance. Whils the potting operations are being carried out, keep a close
watch after insect pests—of which brown scale and
the are the most troublesome. Those fronds that
are the worst affected should be removed before any
fresh ones come in contact with them, and the others
carefully sponged where possible. If such as the
Maidenhairs are troubled with scale, severe thinning of the fronds will be requisite to lessen the numbers.

FORCING DEPARTMENT.—All kinds of plants that are grown for forcing purposes will now be found to come along far quucker than a month back. See therefore that the supply does not get io excess of the demand to any great extent. All the hardier plants that have been forwarded in heat should be moved to a trifle cooler house to expand their flowers, or else have the temperature of the forcing pit slightly reduced. The flowers may not be so fine, but this will hardly be perceived, the advantage being in greater substance and a prolonged flowering season; when in full flower a slight shading will be uccessary in bright sunshine, and close attention to the watering. Any cut bloom that is required should be cut early in the morning, avoiding doing so in the later hours, when the sun is on the plants, as much as possible. Do not expose those plants that are past their best to sudden changes of temperature, and if only a slight protection can be given it will certainly repay the trouble, either in forwarding the plants for another season or keeping them in better condition for being planted-out. Tannes Hudson, Gunnersbury House Gardens, Acton, W.

SATURDAY, Mar. 8 Index of Hardy Plants and Bulbs, at Stevens' Rooms.

Mar. 3 Sale of Lilium auratum Bulbs, at Stevens'

H AVING regard to the enormous increase of our metropolitan population, it is not to be wondered at if those whose vocation it is to furnish this vast gathering of people with vegetables, fruits, and other garden products, are found constantly pushing their gardens farther and farther out into the country, and are absorbing as fast as they can all suitable ground that comes in their way. When we regard the sad stories told of the state of agriculture, of farms going to ruin for lack of tenants, and thousands of acres of fertile land left lying waste for lack of cultivation, it is not possible to help comparing with it what seems to be the prosperous condition of MARKET-GAR-DENING around our metropolis and large towns. Those familiar with the market trade see growers in every direction grasping, not only every field that offers within easy distance of their homesteads with avidity, but even engaging land in remote districts to grow for the season Potatos, Peas, and similar crops. That this expansion indicates prosperity there can be no doubt.

Market-gardening in the hands of mere farmers (a class, by-the-bye, for which the well trained market-grower shows scant respect) or of amateurs too often results in failure and loss. On the other hand, well trained men make it pay, and not only so, but all around them is greatly benefited. The land is better cultivated and made far more productive, far more labour is employed, and it is well paid. The wages of the working class employed in metropolitan market gardens, when helped by what their wives and elder members of their families earn during the summer months, suffice to make the mouths of the poor farm labourer to water, for whilst the regular pay is 3s. per day, summer over-time often adds 6s. or 7s. more per week; and the wife, with day-work as a rule, and piece-work in the best flower, fruit, and vegetable-gathering season, often earns as much more, so that of real poverty amongst the market-gardening population little is known except what is created by their own foolish habits. Then, too, rent is higher, and higher rates are paid, so that when to these things are added the blessings to society resulting from increased production of the best edible material. it becomes evident that wherever market-gardening is practised it is a great boon to the locality.

The bona fide market-gardeners seem to hold their purely agricultural brother cultivators of the soil just a little in contempt. The latter are too limited in their range of thought and action, and in the scope of their cropping and general work. We have actually heard market-gardeners charge the farmer with lacking energy in times of trouble and pressure, and as preferring to sit down and growl lustily over the badness of the times and seasons than to set to work and evolve what good may be got out of ill. Market-gardeners have their losses, their troubles, their competitions with foreigners, and heavy ones, too; they have their bad seasons and oft disasters to their crops from wet or frost, but still they bear up, and not only live, but thrive. As

to the bugbear of foreign competition we admire the manly spirit shown by one large grower who said but the other day that, though it seemed to hit them hard at first or at times, yet it did them good in the end. It spurred them on to better cultivation, to the growth of more varied crops, and, not least, it helped to create so strong a penchant in the public taste for all kinds of garden products, that when the foreign supply ran short-and it did sometimes-the home growers reaped the benefit by greatly enhanced prices. But though this may seem to lead to the suggestion that farmers should take to market-gardening, there is much force even in this case in the old adage Ne sutor ultra crepidam, for nothing is easier than for the farmer accustomed as he is chiefly to exceedingly routine methods of culture and cropping to get out of his depth.

Our market-gardening friend said that he owed as much of his success in his trade to his regular frequenting of Covent Garden Market for thirty years, as he did to any thing. It is said to be a school of instruction, where men learn, not merely how to sell profitably, but also what to sell, to follow the public taste, and thus at home to keep pace with its requirements. Farmers are at a disadvantage as far as knowledge of this kind is concerned, and they, unless men of unusual energy and intelligence, are too apt to find that in market gardening there is no royal road to success. No man is born a gar-dener, he must learn his vocation, from his youth upward, and when he becomes a tradesman, cultivating perhaps 100 to 200 acres of highly-rented soil, he finds that besides being a good gardener he must be a good business

We do not write thus to check any one's honest aspirations, but it is well all should un derstand that success in market-gardening will be only commensurate with capacity.

- WALL TREES,-Almost universally there is a wondrous wealth of bloom upon Apricot trees this season, and it is rapidly expanding, so that the next few weeks will be critical ones for the future of our earliest and most enjoyable of wall fruits. We may, perchance, find the season to continue soft and favourable, and if so a grand crop of Apricots will be assured. March is, however, a treacherous month. It too often steals a "march" upon unwary gardeners, and ruins the prospects of their wall fruits. It will be as well, let the weather be as promising as it may, to be ready with some protection, for frosts come like thieves in the night. Peach and Nectarine trees are full of promise of bloom also, and generally all wall trees indicate a great floral show. If cold cutting east winds and keen dry frosts prevail, protection will be worth any trouble; but it will be but fair to the season to give it its due, should its mildness render a fruit crop easy and assured.

- AMARYLLIS AT HILLINGDON PLACE .- For several years past Mr. HENRY LITTLE has been a foremost cultivator of these, and he exhibits at the spring meetings at the Royal Botanic Society and at South Kensington. He has now a very fine collection occupying one of FOSTER & PEARSON'S frames, raised a few feet above the ground, and with one hot-water pipe all round level with the rims of the pots so as to give a gentle stimulus. The pots in which the Amaryllis are growing are plunged in a bed of cocoa-fibre up to the rims, and are now throwing up strong flowering-stems. They are not forced, but allowed to come on gently, and air is given on all suitable occasions. A more promising lot of plants can scarcely be imagined. But they do not include the whole of the collection, for in an intermediate-house there is an overflow both of Amaryllis and Orchids. Mr. LITTLE's tenure of Hillingdon Place being a little uncertain, he has to erect glass structures with some caution, or else more glass is needed to accommodate the many treasures gathered together at Hillingdon Place.

- A TEXAN PLAGUE-PLANT.-According to gentlemen who have recently come to this country from Texas, a plant of which they have brought specimens to Kew is fast becoming the terror of graziers. Unfortunately the said specimens were not in flower, but as far as can be judged from the long

silky pinnate leaves and the general aspect of the plant, it may be Astragalus Bigelowii; of course without flowers it is impossible to venture a positive opinion in such a case. The plant, whatever it is, is spreading rapidly from the south in a northerly direction. Great patches from half an acre to an acre in extent occur frequently, and, to render matters worse, cattle are very fond of it. As soon as they begin to feed on it, however, they lose flesh very rapidly, their eyesight is affected, and they soon die. A friend of the gentleman who furnished these details lost nine horses recently through their having fed on this plant, about which it would be desirable to have more information.

- COSTUS IGNEUS .- Under this name Mr. N. E. BROWN describes, in the Illustration Horticole (1884), tab. 511, a Zingiberaceous plant from Bahia, with erect stems, bearing at their extremities tufts of broadly oblong acute glabrous leaves, from amid which proceed the flattish oblong flowers, each about 2 inches in diameter, and consisting of two unequal flat roundish orange lobes.

- FRUIT AND FLORAL COMMITTEES. - We learn that the Syndical Chamber of Belgian Nurserymen has decided to institute monthly Floral and Fruit Committees, like those which have been found so useful at South Kensington.

CULTURE OF ALPINE PLANTS .- Our corre spondent, M. CORREVON, of Geneva, has been appointed Director of the "Jardin d'Acclimatation pour les Plantes Alpines," a garden established under the auspices of the Swiss Association for the protection of plants, and designed to promote the legitimate culture of these plants. By discouraging extermination by ruthless and ignorant collectors, and by securing an adequate supply by appropriate methods of collection, and specially by propagation by seed, the Director hopes to be able to gratify the taste for these plants without incurring the risk of destroying them. The establishment for the sale of seeds and the experimental garden will be in the immediate vicinity of the city, at the Plainpalais. M. CORREVON takes charge on April 1 next, and from what we have seen of his practical skill as a propagator, and from his clear insight into the requirements of this class of plants, as illustrated in his articles in these pages, the undertaking should prosper.

--- THE LATE MR. HENRY PARKER .- The will (dated February 16, 1883) of Mr. HENRY PARKER, late of the Centre Row, Covent Garden Market, who died on December 29 last, was proved on the 19th ult. by HENRY WILLIAM BRIDGMAN and JAMES WEBBER, the executors, the value of the personal estate amounting to upwards of £29,000. testator bequeaths £2000 each to the British and Foreign Bible Society, the Church Missionary Society, and the Religious Tract Society; £1000 each to the Church Pastoral Aid Society, Charing Cross Hospital, King's College Hospital, Brompton Hospital for Consumption and Diseases of the Chest, and the Brompton Hospital for Cancer; £500 each to the Young Men's Christian Association and the Covent Garden Lifeboat Fund; £1000 to the rector and churchwardens of the parish of St. Paul's, Covent Garden, the dividends to be distributed annually at Christmas in sums of not less than 5s. and not more than £1 among the thoroughly deserving poor of the said parish; and considerable legacies to his niece, nephews, executors, old friends, and old servants. The residue of his property he gives to his old and faithful servant THOMAS DAY.

- RHODODENDRONS AT MESSRS, R. B. LAIRD & Sons' WINTER GARDEN, EDINBURGH .- A visitor to this establishment during the winter or spring will invariably find some of these gorgeous plants in flower. A splendid plant of R. Falconeri, or rather a seedling raised from it, named Lady Balfour of Burleigh, is now in bloom; the plant is a large standard with the head entirely covered with immense trusses of remarkable size and beauty: also to be observed are fine plants of R. Nobleanum, of which the firm appear to have some very bril-liantly coloured examples. These are unsurpassed for forcing as winter decorative plants. There are also masses of R. præcox, very delicately tinted, looking charming amidst the Hyacinths, Tulips, Azaleas, &c., with which the stages of the Winter Garden are filled. There are also fine trusses of Rhododendron argenteum from their Pink Hill Nurseries, as well as those of jasminishorum, Taylori, Duchess of Edinburgh, and others.

—— NOTES ON ACACIAS,—When the Chrysanthemurins are over we do not possess any kinds of pure yellow flowers that add so much to the gay appearance of the cooservatory as the various kinds of Acacias. Classed usually as New Holland plants, they have suffered, but in a less degree, the neglect that has overtaken that interesting section, and it is possible that they, and some of the more heautiful of the other, may become again as much sought after as are now the more easily grown and ephemeral greenhouse herbs and anouals. If we have nothing equalling the brilliancy of a Telopea, a

racemes; A. Riceana, a sort with foliage similato the first, but without that peculiar mealiness on the
underside, and whose flowers are scentless. This is
a rapid and slender grower, and well suited for a
pillar or the roof of a conservatory. A grandiflora
has larger golden balls than either of the other two,
and undivided, Willow-like leaves; it is also somewhat later in opening, and is therefore good for succeeding those. A. Drummondii is one of the most
floriferous, a neat grower, but not naturally so, as we
see it usually grown and shown, and, in fact, looks
less beautiful when so tied-in and pinched and trained
into primness. A curiously leaved sort, called A.
platyptera, is worthy of more cultivation, as it is one
of the very earliest bloomers and is quite distinct in
appearance. The culture of the Acacia is not at all

dry state of the soil, that must be thoroughly soaked when it becomes too dry, and a night temperature from 40° to 45°, suits them admirably.

— GENTIANA WALUJEWI, Gartenflora, 1884, tab. 1140.—This is a tall-growing, herbaceous, perenial, with narrow, elliptic, glabrous leaves, and whitish tubular flowers, each about 1½ inch long, and aggregated in terminal clusters. The species is new, and was discovered by ALBERT REGEL in the mountains of Eastern Turkestan.

— PROPAGATING COMBRETUM PURPUREUM.

—It is possible that this gorgeous stove plant, which is so easily grown in an ordinary stove, has fallen Malmost out of general cultivation through the

FIG. 51.-VIEW IN THE KIBBLE CONSERVATORY, GLASGOW BOTANIC GARDEN. (SEE P. 269.)

Callistemon, a Metrosideros, or a Grevillea among greenhouse plants, excepting zonal Pelargoniums, we have no yellows in winter and spring exceeding the brightness of the Acacias. The Calccolaria cannot be had in bloom at that time. Azalea mollis, if it is yellow, is also mixed with pink, or some other red tint, which therefore detracts from its purity of hue. We have almost lost Azalea sinensis, and fortunately the ever-present Pelargoniums, Primulas, and Cineraira, cannot be made yellow, and so reliance is placed on the Geoistas to furnish the missing colour; but Geoistas are all alike, speaking generally, although G. speciosa is a great improvement on G. racemosa floribunda, and G. Atleeanus differs from all three; but the differences are at the best only minute, and oot noted by the laity at all. The Acacias that furnish early flowers are A. dealbata, a pretty leaved sort with deliciously aromatic-scented flowers in short

difficult to any one equal to growing an Azalea or a Camellia; two-thirds peat, one-third good sound loam, with a considerable admixture of clean silversand, a small portion of charcoal or burnt earth, may be mixed with the soil for these and most other species of New Holland plants. Over-potting and over-draining are two points not to be overlooked in Acacia growing, for frequent shiftings will make unwieldy plants that will not reward the grower with a good flower harvest; that is best attained by smallish pots and feeding during the most active period of growth with liquid-manure; and giving too many crocks means giving a great deal of water in spring and summer, and running the risk at the same time of causing the plants to suffer sometimes from the want of it. A few large concave pieces regularly disposed in one layer, with rough lumps or stiftings over these, will be found the best. In winter a moderately

difficulty experienced by gardeners in rooting cuttings of it. Every man likes to have a reserve plant or two of all his best plants, but if any particular one should prove itself not ameoable to his methods of increase, he would rather not be the possessor of it, as, in case of loss, he would not have the excuse that it was not of so much moment, he having duplicates in his stock. If an old plant he shaken out, and pieces of the root be cut from the stock 3 or 4 inches in length and as thick as a crow or a goose quill, and have short shoots of last year's wood grafted on them, precisely as is done with root-grafted Roses, he has a ready and almost certain method of increasing his stock. The root-pieces, after being attached, may be slightly clayed, and potted in sandy peat, in pots no larger than are required to hold them convenienty. These must be then placed in a close propagating case, furnished with bottom-heat, plung-

ing the pots up to the rim. Close attention must be given to airing and watering, and so soon as growth begins the plant must be moved from thence into a less close box for a tew more days, and afterwards into the stove pit, giving a shift as soon as the pot is filled with roots.

— RASPBERRY BAUMFORTH'S SEEDLING.—
Planters of Raspberries should not omit to obtain
this excellent sort, and when once they have given
it a fair trial they will plant it in quantity. It has
the character of being an excellent bearer, in good
seasons bringing a fair second crop of fruit to maturity.
The plant is vigorons, carries stont dark green foliage,
and large broad-pipped dark crimson fruit. It is
much valued on the strong loamy soils of Bucks.

- ANTS IN TRINIDAD .- British gardeners, who often complain, and not without reason, of the damage done by ants, may congratulate themselves to a certain extent after hearing what Mr. PRESTOE, in his recent Report on the Botanic Gardens, Trinidad, has to say concerning the ravages of these objectionable insects in the West Indies. "As locusts in North Africa, and rabbits in Australia," says Mr. PRESTOE, "are a national calamity for their destructiveness to herbage and corn crops, so are the parasol ants in this island for destructiveness to trees and shrubs of all kinds, particularly exotic ones." The labour of combating these ubiquitous pests is very heavy in Trinidad, as they occur in colonies of large area, and are composed of thousands of nests, extending over 1000 or 2000 square feet, The destruction of a colony some 50 feet over, employs four or five men ten to twelve days, according to the depth and nature of the strata. Where the use of boiling soap-water is impracticable sulphurous fumes are blown into each chamber, as it is opened by means of a machine with fan and tube. Care has to be observed to keep the ground clear of insects, otherwise the feet and legs of the workmen would be severely bitten. Mr. PRESTOE thinks that it is unlikely that the island will ever be free from these pests; for, though all within range may be destroyed, there is a continuous supply from without, impregnated females being brought in myriads to the shores on the Orinoco current. These are to be seen occasionally in the Gulf, floating in patches several inches thick, I to 2 feet wide, and many feet long. So far the habits and economy of these West Indian ants are only imperfectly understood, the best account of them known to Mr. PRESTOE occurs in BELT'S Naturalist in Nicaragua, a work which has been frequently mentioned in these columns. Mr. PRESTOE agrees with Mr. BELT, that the ants in question feed on "a kind of fungus, for growing which they obtain the leaves of certain trees or plants, when suitably dry, and apply them to the fungus mass for its sustenance Even in the neighbourhood of a and extension." small colony "no plant is secure from attack, and its leaves may disappear in a single night; for, the workers being in infinite number, could clear a large tree in a single night, each making but one journey.

ARDISIA JAPONICA is an interesting dwarf shrub with scented white flowers and scarlet berries about the size of those of the widely cultivated and deservedly popular Chinese A. crenata. Unlike this last-named species, however, A. japonica will flourish in a cool conservatory, and probably, if fairly tried, might succeed in the open air in many places in Britain. As a decorative berry-bearing plant for winter effects it can be successfully grown where its more tropical relative could not exist for lack of the increasing heat. A form with prettily variegated foliage is cultivated at Kew, and makes a pleasing pot-plant on the shelves in the large Temperate-house.

—— CAMELLIA M. RAYMOND LEMOINTER,— One of the P.cony-flowered race, with whitish petals, diminishing in size from without inwards, whitish, striped and veined with rose. When the flowers first expand the white predominates, but as the flowers get older the rosy tint suffuses the whole petals. It has been raised at Lille from C. speciosa, and is figured in the Illustration Horticols, t. 509 (1884).

— PERIFLOCA GRECA.—As a covering for a sunny wall or trellis this South European Asclepiad is thoroughly well adapted. It is remarkable for the rich velvety appearance of the conspicuous hairy brownish flowers; the folioge, too, is decidedly

graceful, and the plant is a vigorous and rapid grower, perfectly hardy in this country. The following paragraph, written by an evident admirer of this strange yet handseme plant, perhaps does no more than justice to it:—"One of the loveliest climbers that ever gave a leafy covering and a profuse floral serven to wall or trellis. Why it is not in every garden it is difficult to understand. We hear frequent complaints of how few wall-coverings we have; yet this, one of the hardiest and most floriferous of any, has been utterly neglected." The milky juice, in common with that of a good many members of the same natural order, is poisonous, and in the East is said to be used for the purpose of poisoning wolves.

—— IRIS FIMBRIATA.—It is close upon a century since this species was added to our collections, yet it is far less frequently met with than its merits deserve. Being a native of China it requires greenhouse treatment in wioter to flower it in perfection. The flowers are of a delicate pale lavender colour, with the bright yellow spot and radiating lines on the falls so frequent in this genus. The margins of all the segments, together with the stigmas, are beautifully fringed, giving the flowers an exquisitely attractive appearance, rivaling or even surpassing many Orchids, to which, moreover, the Iris is no distant relation. A large plant, with branching many-flowered stems, has been flowering for some time in house No. 5 at Kew, In gardening books it is generally recorded under the name of 1. chinensis, and there is a figure of it in the Botanical Magazine, t. 373.

— IRIS RETICULATA.— This kind is so lovely that it is well worth flowering in pots for the pleasure of its ornament in the greenhouse. Though it will probably not bear forcing, it comes in a little earlier if a few strong bulbs are potted and placed in a cold frame. With this treatment the colour is in no way deteriorated, and small pots with several flowers open at once are most effective. This has been tried in the Cambridge Botanic Garden, and the varieties would no doubt succeed equally well.

— ALLIUM NEAFOLITANUM.— Of the white-flowered kinds, this is probably the best, not only because of its superior beauty, but on account of the slight presence only of that unpleasant odour which many pretty allies of the Onion have the misfortune to possess. For this reason the flowers may be gathered with propriety for indoor enjoyment, and the pure white starry blooms meet with much admiration. It has been found pretty and good for pot culture at Cambridge.

-- MARKING GARDEN LABELS .-- In spite of the various ingenious adaptations of wood and metal, we do not seem to have got anything better, cheaper, and easier dealt with at short notice than zinc labels with an iron stem, such as were figured in the Gardeners' Chronicle, and those made of strips of lead to be stamped with letters or figures. Writing may be assumed to be not indelible. Let the makers of ink that is reputed to last as long as the metal say what they please, it does become obliterated, or at least to such a degree that the reading of the words, &c., becomes a work of difficulty. That being so, the next best method is that of stamping the letters or figures into the label by means of steel dies, which work is best done when the letters are arranged on the limbs of a pair of shears or pincers, eight or nine letters on each. Sometimes the whole alphabet is arranged on one pair, but then the letters furthest from the fulcrum can have but little force exerted on them, and the impression is therefore faint; but by having one-third of the alphabet on each, the jaws are not made needlessly long. The figures can be treated in similar fashion. As we know from experience loose dies are constantly getting mislaid, but pincers, being larger objects would be less likely to be missing when wanted. Under each die on the opposite limb a little boss or anvil is placed, upon which the label is held in making the impression, and the handles of the instrument being made of considerable length and strength, a great amount of pressure can be obtained, and which can be so regulated by the operator as will fit it for use on either lead or zinc,

—— EUPATORIUM ROSEUM,—This robust plant is a fine thing when seen planted in clumps or masses, and especially near water, which situation appears quite its proper habitat, as it will then grow from 5 to 6 feet high, and form an enormous Cauliflower-like head of dull rosy flowers. The flowering season is from August to September, when the flower-stalks begin to assume a shabby appearance, and may be finally cut down to the ground in October. It is well suited for parts of the pleasure grounds remote from the dwelling, and for the wild garden. It is propagated by division.

— FREESIA REFRACTA ALBA.—This flower, so useful for all kinds of bouquet purposes, where something white is desirable, is beginning to find its way into the florists' shops. The flowers are so neat, and so readily mounted, besides being produced in good quantity by the bulbs, that it is no wonder that its special merits have been noted by the growers for market. It is, as yet, in no way abundant, but a beginning has been made and the increasing of stock will go on apace.

— MARACOUJA.—Under this name we recognise our old acquaintance. Passiflora edulis, the fruit of this well known stove creeper being recently on sale in Covent Garden. The colour can hardly be called a pleasing one, it being black, with a grey bloom on it, but the perfume is delightful. The true Muraculas are species of Taesonia.

— Messrs, John Warner & Sons, of the Crescent Foundry, Cripplegate, who sent a large and valuable collection of their special manufactures, such as windmilla, steam pumps, water-wheels, garden engines, &c., to the Calcutta Exhibition, have, we hear, been awarded no fewer than three gold and ten silver medals,

— MR. GEORGE WILLIAMS is, we hear, leaving the service of the Earl of MEATH, Kilruddery Castle, Co. Wicklow, to commence busioess, at an early date, as a market-gardener, in the neighbourhood of Macclesfield, Cheshire.

— THE WEATHER,—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending February 25, issued by the Meteorological Office, London:—The weather, with the exception of a few bright intervals, has been generally cloudy or dull, with frequent falls of rain. Thunder and lightning occurred in the west during the night of the 19th. The temperature has been about equal to the mean in "England, N.W.," and "Ireland, S.," but has continued from 1° to 3° above it elsewhere. The maxima were registered in most places on the 20th, and varied from 45° in "Scotland, N.," to 54° in most of the English districts and in "Ireland, S.," The minima, which were recorded on the 19th in most parts of Great Britain, on various dates in Ireland, and on the 24th in the north of Scotland, ranged from 25° in the "Midland Counties," to 35° in "Eogland, S.W.," and 28° in the "Channel Islands," The rainfall has been a little less than the mean in "Scotland, E.," "England, N.E.," and 18 the "Channel Islands," and about equal to it in "England, E.," but more in all other districts, the excess in Ireland being considerable, Bright sunshine shows an increase in duration in nearly all districts, the sexess in Ireland being considerable, Bright sunshine shows an increase in duration in nearly all districts, the sexess in Ireland being considerable, Bright sunshine shows an increase in duration in nearly all districts, the percentages of possible duration varying from 17 in "England, S.W.," to 35 in "Scotland, E.," and 38' in the Channel Islands, Depressions observed:—At the commencement of the period the barometer was highest over Scandinavia and the south-east of France, and lowest to the westward of our islands, In the former region the high-pressure area soon gave way, but in the latter it increased somewhat, and extended westwards. During the first few days a series of large depressions travelled northwards, outside our western and norther oass, causing strong sou

— GARDENING APPOINTMENTS. — Mr. A. GREGORY, late Foreman at Kilruddery Castle, Co. Wicklow, as Gardener to Mrs. Ergown, Oakland, Rathgar, Co. Dublin. — Mr. Chas. Fowell, late Foreman at the Duke of Graffon's, Euston Hall, as Gardener to Edward A. Ball, Esq., Roll's Park, Chigwell, Essex.

THE PROPAGATOR.

THE PROPAGATION AND CULTURE OF N.EGE-LIAS.—The following are the different methods of increasing Nægelias (corm-forming Gesneras):—1, from cuttings; 2, from leaves; 3, from corms; and 4, from seed. It is, perhaps, advisable at the outset to point out the necessity for the early propagation of those plants the cuttings of which form bulbs. If the plants are propagated early in the season, the young bulbs formed by the cuttings will have reached a stage of development by the winter that will sustain and support them under the many trying circumstances which that season brings in its train. But should this operation be delayed till late in the summer, the young bulbs, being undeveloped and weak, and therefore unable to resist the searching tests of winter, die almost to a bulb.

I. FROM CUTTINGS. -A large number of plants should be set aside for propagation and well tended till they are 6 or 8 inches in height. They must now be cut down to the first leaf above the pot, and made into cuttings. Commencing at the top of the plant, the first cutting should be made, which should four or more leaves attached to it; the next and following cuttings should be made so as to leave an inch and a-half of the stem below the leaves. The main stem of the latter kind of cuttings should be divided down the centre, thus making, as it were, two cuttings of one, and having on each piece a leaf and an eye. They are now ready to be placed into long thumbpots. The soil used should be composed of half yellow loam, one-third peat, and one-quarter sand, which should be sifted, or, better still, rubbed through a quarter of an inch sieve and well mixed together.

In potting the Nægelia cuttings, those having a single leaf attached to the stem must be tied to a small stick, to support them in an upright position.

Having watered the cuttings they should be placed in a cutting frame over a brisk bottom-heat. greatest care must now be exercised to see that the glasses" are taken from off the frame, for one hour in the night and in the morning, and under no circumstances must they be allowed to become dry. Also to protect them from the bright rays of the sun, sheets of newspaper should be placed over the "glasses" as a shade. As soon as the cuttings are rooted they should be removed from the frame and potted into large 60-sized pots, and repotted as necessity dictates.

2. FROM LEAVES .- The leaves selected for propagation must be well matured or "hard leaves they should be severed with a sharp knife and close to the leaf. On the under side of the leaf, the midrih and principal veins branching therefrom should be notched, the former in three or four places and the latter in one or two. The notches, however, must not be made so deep as to cut through the rib or vein. Some well drained pans should now be filled with soil, similar to that mentioned above. The soil, however, should be an inch higher in the centre and made to slope gradually downwards to the rim of the pan. The leaves must be spread upon and pegged loosely to the surface of the soil-the under part being next the soil. Having well watered the leaf cuttings with a fine-rose pot they must be placed in the cutting frame over a brisk bottom-heat.

So soon as the young plants have made their appearance, and grown to the height of half an inch, they must be pricked off, and placed each in a thimble-pot. Those in thimble-pots must be placed upon an open hottom-heat, i.e., without the protection of the case. As they grow larger in size and strength they must be potted into small 60's, and replaced upon the open bottom-heat, and repotted

until they attain the requisite size.

3. NÆGELIAS FROM CORMS .- A sufficient number well-drained pans should be filled with the scil previously mentioned, ready to receive the scale-like particles of the corms. A selection of well-ripened corms should be made, and commencing at the large end of each one, the scale-like particles of which it is composed should be separated one by one. These particles must be sown like seeds on the surface of the soil, with which they should be partly covered. pans must now be placed in the cutting-frame, and it s not until they have been in the frame for three or four days that they must be watered with a fine-rose

pot. When these particles have sprung up, and grown half an inch high, they must be potted, each into a thimble-pot, and replaced upon bottom heat until they are strong enough to be potted into small 60's. They must be repotted into larger pots as the plants increase in size and strength.

4. FROM SEED.-When large quantities of one, or, indeed, many sorts are required (without the necessity of being true to name), the better means is to obtain them from seed. They should be sown early in January, and in pans arranged like those for the corm-particles. A piece of glass must be placed over each pan to protect the seeds from the constant dripping of water from the roof—the whole of the pans should be placed upon a warm shelf. When the seedlings have grown a quarter of an inch in height they must be pricked off and potted into thimble-pots and replaced upon a brisk bottom-heat. As the plants grow larger and stronger so they must be potted into larger pots and replaced upon the bottom-

HYBRID NÆGELIAS.—Seeing that the seed plays so important a part in the multiplication of Nægelias, it will be well to say a few words upon hybridisation. If a strain on one particular variety is required the plants of that variety should be separated, and each plant fertilised with its own pollen, and care taken to prevent any other reaching the pistil.

Only the largest flowers of the plants should be fertilised, and the remainder removed in order that the whole of the strength and nourishment may be concentrated in the former. But should new varieties be our object a selection should he made of two or more distinct ones, such as Mrs. Fox Strangways, zebrina splendens, and each one may be crossed with the other, while observing the same directions as mentioned above. The plants must be fertilised three days in succession, and it is a fact well worthy to be remembered that the best time for effecting this operation is between the hours of 12 and 3. plants so fertilised must be removed and placed in a warm airy house and on a front platform or shelf, where they will be safe from the destructive effect of the syringe. Here they may be allowed to remain until the seed is tipe.

THE CULTURE OF NÆGELIAS.-The old corms, or bulbs, should be potted in small 60-pots, in soil composed of half yellow loam, one-third leaf-mould, and a quarter river sand, and they must be started into growth early in April. The pots must be placed on a bottom-heat, and when the bulbs have thrown up shoots and grown to a height of 4 or 5 inches, they must be potted each in a 48 sized pot, or if it is more convenient, three can be placed in a 32-pot, in such positions as to form the angles of a triangle. They must be replaced on bottom-heat, where they must remain until they begin to show signs of flowering, At this period they may be removed to a platform in an airy, warm house, till they bloom, but so soon as the flowers begin to open they should be removed to the conservatory or greenhouse. Negelias are very useful for indoor decoration. The following will be found to be good and distinct :- N. cinnabarina, exoniensis, fulgida, bicolor, Hon. Mrs. Fox Strangways, Leopard, Mont Blanc, refulgens, zebrina splendens, T. O,

A PLEA FOR BRITISH FERNS.

As a student for some years past of our native British Ferns, it becomes more and more a matter of surprise to me that they should receive so little attention, and that the culture, especially of the numberless beautiful departures from the normal types, should be limited to so very few persons that, to the hest of my belief, the collections worthy of the name around London might be told upon the fingers. This lack of general interest is sufficiently evidenced by the fact that, comparatively speaking, hardly any of the nurserymen in the country either keep a stock or know anything worth mentioning about them, the result being that at the horticultural and floral shows these lovely plants are all but utterly ignored, though exotic Ferns of considerably less attractiveness are exhibited in profusion. Here, however, it may be argued that the lack of demand justifies their absence, though I doubt the logic; we will, therefore, go outside this aspect of the case and look to our national botanical collection at Kew for a decent display of this most interesting branch of our native flora; but

here again we are doomed to disappointment, for although a few specimens may be found scattered about amongst the exotics in the Temperate-house, and a few others are discoverable in the rockeries, yet every Fern lover who has seen it will agree with me in stigmatising the collection as unworthy of the nation, the comparatively few forms exhibited being, so far as culture is concerned, nearly all of the shabbiest possible description compatible with existence, while hosts of the most beautiful and striking varieties are altogether unrepresented, and even the normal forms betray by their position and treatment an absence of that knowledge and careful supervision which we are certainly entitled to expect in such a place as Kew.

That in our national collection of plants our native Ferns should be thus treated is a matter of regret to all who know their capabilities, especially when one calls to mind their facility of culture on the one hand, and on the other the wonderful delicacy, beauty, and singularity of such forms as

-and hundreds of others which space precludes me from naming, all of which are as hardy as the normal types from which they sprang, and, notwithstanding their superior beauty, would be as easy of culture in thousands of gloomy nooks in our crowded cities where now nothing green gladdens the cye because flowers will not grow, and the people are ignorant of the very existence of these plumy gems and worthy substitutes.

Last summer, in the Zoological Gardens at Clifton, I had the pleasure of inspecting a magnificent collection of some hundreds of the best varieties of our native Ferns ranged for a long distance by the side of the public path in representative groups of each These were duly protected from the wind by shrubberies, and presented at once a most delightscene and a splendid field for study of the curious and the beautiful in their many extraordinary

departures from the normal forms.
Here, however, in London, I know of no such public collection, though I believe Colonel Jones, to whom Clifton is indebted for the plants there dis-played, offered a similar collection to Kew; but why, I ask, should we not have a fair representative gathering of the most marked forms, well grown and shown to advantage, so that the public at large might learn the capacity for varied beauty with which Nature has endowed the Ferns of our native country, of which at present the majority of people only know the existence by seeing a few uninviting dried or bedraggled specimens in the hands of street hawkers, or bundled up like rubbish heaps in the corner of some nurseryman's shop, whose windows, it may be, are monopolised by exotic Ferns, many of less beauty, and nearly all of more difficult culture? In our parks there are scores of shady nooks and corners all ready to hand where our British Ferns, even the most delicate varieties, would be at home, and where a splendid collection might be located and kept up with a title of the expense and labour lavished upon row after row of formal carpet-hedding designs which, to my mind, in most cases mar rather than adorn the prospect, owing to their utter artificiality and lack of harmony

with their surroundings.

That our national collection of Ferns should be a That our national collection of Ferns should be a complete one is, I am fully aware, quite out of the question, new varieties continually being raised under culture or found wild, so that the known forms number many thousands (Mr. G. B. Wollaston, for instance, has some 3000 or more); still I venture to think that adequate room and proper accommodation should be afforded for the most marked and typical variations and especially for sports found in a wild state, since these undoubtedly should rank among our native plants, whatever objections botanists may urge against what they are sometimes pleased to call "mere garden varieties." C. T. Druery.

NOTES FROM SWANLEY.

As might be expected, nothing could look better than did Messrs, Cannell's houseful of Cinerarias, the richness of the colours, the size of the blooms, and the universal regularity of their markings being quite remarkable. Many are true seedlings, and others the produce hy offsets of the pick of former certificated hybrids, and the plants having been assorted and arranged in hatches, the effect of a houseful, seen from one end, was unrivalled. Of course, the sorts March Past and Victory were in considerable quantities. Of scarlet Pelargoniums there was not so much to be seen, as regards numbers, in bloom, the flowers being kept constantly cut for safe purposes, and the plants undergoing mutilation for the purposes of propagation. Remarkable for hrightness were Mitis, a single-flowered scarlet; Miss Hamilton, and Kate Farmer. An extra good sort for the winter is Mr. Bruuning, and another, very fine in its way, is the double zonal, Jules, which should he avoided for that purpose as it is found to be rather shy at that season. A fine hybrid nosegay that was flowering grandly is Jean Hill, a plant carrying extra large trusses of deep pink flowers in great numbers; these are elevated above the foliage in true nosegay style: this and Dr. Octon should make capital summer bedding kinds.

With an admiring look at a glowing scarlet with enormous pips, named Kate Greenaway, we will take our departure hence and view the choice collection of Cyclamens which is being assiduously collected and raised here. The stock fills two long houses—one holding the young plants which are intended for blooming next season, and the other the blooming plants. Although we miss the fine masses ot colour and the well bloomed plants, such as Messrs, Veitch & Sons, Mr. Wiggins, and others exhibited at the last meeting of the Royal Horticultural Society, still it is evident we have but to await the results of another season to see the energetic and indefatigable proprietor of the Home for Flowers well up to the front rank as a Cyclamen grower. The stock contains all the usual forms and markings prevailing in the C. persicum giganteum breed, and is marked by the presence also of a few pleasingly blotched varieties that are sure to be admired if they are faithfully reproduced in the future stock of plants.

The flower of the place is undoubtedly the Primula sioensis, and these are now at their best, and will so continue until the prevalence of bright weather dulis their colours. Admirable as are the older forms of pure double white for effective decorative worth, the palm must go to the coloured strains of single flowered varieties and to Gilbert's double hybrids. There were several long houses filled with these, chiefly one-year-old plants, although in one house were some masses of flower seen on two-year-old plants, standing pyramids of bloom 2 feet high. We noticed a very fine white single sort, named The Queeo, prettily fringed and yellow eyed; Marquis of Lorne, an equally good red (this sort and a good flesh-pink named rightly Delicata had the admired dark bronzy-green Fern leaves; indeed, many of the race possess this desideratum); Swanley Purple, White, and Red are excellent colours and very profuse.

The old double white variety is much improved on, as is visible in a dense or opaque white form of the flower, possessing an additional advantage in the heavily fringed margin. Of the coloured double flowers Mr. Gilbert's varieties were to be seen in very nicely grown examples, the best being Mrs. Laxton, white; Marchiocess of Exeter, Mrs. Crabb, the very large white Princess of Wales, and Earl Beaconsfield. One of Hillier's varieties, called Anne Hillier, a flesh coloured sort of a pleasing shade, was deserving of mention.

Amongst the innumerable plants to be found here the visitor is sure to alight on something old that is again to be taken in hand and reproduced for our pleasure, and amongst these may be mentioned the varieties of Polyanthus, of which Mr. Cannell hoasts he has all those known in English gardens, and if we may judge of the correctness of this statement by the quantity of ground covered with labelled kinds it is very possibly correct. Anything new in winter-hlooming Begonias is always welcomed, and doubly so when it is a very free-flowering, compact-growing plant like B. Carrieri. There are many pink and scarlet winter-flowering Begonias, but a good white was unknown. B. Dregei is poor beside it.

Home Gorrespondence.

Azara microphylla.—I am much surprised that in your notice of the somewhat inconspicuous blossom of the above-named graceful and ornamental hardy shrub you make no mention whatever of the delicious perfume which they exhale, which almost exactly resembles that of Vanille and which I consider a great additional recommendation. My large specimen is now covered with its small golden flowers undereeath almost every spray and branchlet, and quite perfumes the air all around it for some distance from the shrub. With me this shrub has never been the least injured even by the severest winters we have had from 1879 to 1881. W. E. Gumbleton.

Prolification in Sciadopitys.—We have previously alluded to the peculiarities presented by some native-grown cones of Sciadopitys(see p. 112, vol. xvii.,

FIG 52.- PROLIFEROUS LEAF OF SCIADOPITYS.

FIG. 53.-PROLIFEROUS CONE OF SCIADOPITYS.

1882), and now take the opportunity kindly afforded us by M. Carrière of representing a small cone grown in France, and affected in the same manner as that described by us previously (fig. 53). We also take the opportunity of figuring one leaf, if leaf it is to be called, which not only divides, but bears a bud and whorl of leaves in the fork (fig. 52). This is copied from a larger illustration by M. Carrière in the Revue Horticole.

Protecting Plants from Frost 200 Years Ago.—Eaclosed are some extracts of letters from Sir Hans Sloane to Mr. Jno. Ray on the above subject, written 200 years ago; they are taken from some MSS. which came into the hands of Nr. J. D. Enys. Mr. Enys thought that many of your readers, as well as myself, would be interested to know the beginning of heating greenhouses, out of which the various systems have grown, and has kindly handed them to me to send to you. Henry Mills, Enys, Penrhyn, Cornwall.

"London, Nov. 15, 1684.—Mr. Watts, having a new contrivance (att least in this countrey), viz., he makes under the floor of his greenhouse a great fire-place, with

grate, ash-hole, &c.; and conveight the warmth through the whole house, by the help of tunnell, see that be hopes, by the help of weather-glasses within, to bring or keep the air at what degree of warmth be pleases, letting in upon occasion the outward air by the windows. He thinks to make, by this means, ane artificial spring, sumer, winter, &c., of which I something doubt but in that matter experience must be the only judge."

"London, Dec. 20, 1684.—Yesterday I was att Chelsey garden to see how the plants were preserved there this cold weather. I found that in the day time they putt no fire into their furnaces, and that in the night they not only put in some fire but cover the windowes where they stand pitcht-canvasse, taking this of and opening them as much as the air or wind permitt."

"London, March 7, 1685.—I was the other day att Chelsey, and find that the artificys used by Mr. Watt have been very effectuall for the preservation of his plants; insomuch that this severe enough winter has scarce killed any off his fine plants."

Ribled any off his fine plants."

[To the above interesting communication we add the following from Dr. Semple's revised edition (1878) of Field's Memoirs of the Botanic Garden at Chelsea:—

"In the month of January of this year [1680] Mr. John Watts, a member of the Society, and one whose name has been mentioned as a contributor to the recetion of the wall, was appointed to have the care and management of the garden at £50 per anound, besides the allowance of one or two labourers; and in the following year a greenhouse, or stove, was erected in the garden at an estimated expense of £138. It was situated in the lower part of the ground, not far distant from the river," and was doubtless the house in which Watts carried out his experiments in geothermal heating. Both Evelyn and Ray mention this, and the latter speaks of a Tea-shrub as cultivated there. The Romans, teste Martial, had forcing-houses of glass (specularia), but in this country it was not till the reigo of Charles II, that such structures were erected. Ed.]

Choisya ternata,—We have the pleasure to enclose a few blooms of Choisya ternata. We find that this most fragrant plant flowers at once if placed in a temperature of 55° to 60°. The flowers sent were brought on in an intermediate-house, and then taken into an ordinary cool-house. We took the plants from the cold frames the first week of February, so that it has opened very quickly. The flowers are from plants grown here, plunged out in the summer. We find it sets buds as freely as an Azalea. We have had a nice stock of this plant for the past five years, and deem it worthy of very extended culture, and it could, we think, be had in bloom from Christmas to May without difficulty. We notice the wood when cut has a very pungent balsamic odour. Robert P. Ker & Sons, Liverpool.

cut has a very pungent balsamic odour. Robert P. Ker & Sons, Liverpool.

Early Potato Planting,—There is a weak point about Mr. Merritt's plan of planting Potatos early as described last week. It is, that should, as is so often the case, a heavy hailstorm come, the hulk of which would fall into the furrow on in which the tubers are planted, the soil would not only be heavily saturated with moisture, but it would be made excessively cold, and if followed by a sharp frost at night the thinly-covered tubers could hardly escape serious injury. Or course, the season may prove so kind as to present no dangers to early-planted Potatos, but, agaio, it may be quite the reverse. Those who are troubled with a sticky soil would, apart from frost, find the furrows saturated with water, that it would bake, and become excessively hard and tenacious. Of course, in sandy or porous soils no such harm may result, but those who know little of clay soils are hardly qualified to expatiate upon the merits of any system of culture in which they are concerned. I have often planted Potatosin furrows after winter ridging, but invariably have first dug the furrows deeply with a fork, then drawn a shallow drill with a hoe, and, having laid in the tubers, have forked the loose soil from the ridges or 5 inches. In this way the sets are protected by a ridge of soil, and are not exposed to daoger from flooding or late frosts. Just before the tops push through arake run roughly over the ridges leaves an even surface, through which the shoots come with ease and regularity. Well-prepared sets planted thus towards the end of March are safer, and seldom less early in cropping, than are those planted in February. Only a very careless grower would permit his seed stock to get into the matted state described by Mr. Merritt. As to his recommendation of huntr refuse and vegetable ash as dressing for Potatos that I cordially endorse. It consists largely of phosphates and potash, and these are among the most valuable elements in any Potato manuer. A. D.

and these are among the most valuable elements to any Potato manure. A. D.

Mr. Merritt's remarks (at page 250) on this subject are worthy of attention by practitioners who are situate on light soils, but they are scarcely suitable for those living on the stiffer soils of the country, which are certainly the commoner. He speaks probably having in view the well cultivated and almost artificial soils of vegetable gardens of long standing, and where furrow planting has its advantages, or

where, at least, the evils are counterbalanced by them. In heavy land the furrows are the wettest spots, collecting as they do nearly all that falls on the two sides of the ridges, and in consequence the land is coldest there, and ungenial to Potatos or any other vegetable. The warmest and driest place would be on the ridge itself. For my part, I much prefer planting on ground that has been dug as early as he states and laid up roughly. This land will be in fine condition in early spring for this or any other crop, and will not have wet places alternating with dry ones, as ridged ground always has. Having planted in a variety of methods, I am constrained to give the preference to planting on the flat, and not in drills or by dibbling, but by simply pulling out a quite shallow basin of 3 or 4, inches in depth with the end of a broad hoe. This must be done by the side of a line, so as to have regular work, and the set should be covered by another haud following, who collects the dry soil from the surface around the shallow basin thus made. You thus get a shallow planted set dry son from the surface around the standow basine thus made. You thus get a shallow planted set covered with dry soil, and so far frost-resisting, and practically standing in the natural position for a Potato, on the surface of the ground. The act of covering it over forms a small mound, which is added to the first the material districts. Potato, on the surface of the ground. The act of covering it over torms a small monal, which is added to at each further moulding up, thereby aiding to drain all excessive moisture away from the plant. Mr. Jensen's experiments and trails with Potatos seem to have settled the fact that the disease propagates itself fastest on plants surrounded by a moist, warm air, just such as exists between closely planted Potatos. Many growers recommend to to 12 inches between the sets, and 2 feet between the rows for early sorts and medium growers. I think this is much too close, for if the disease should appear everything in proper order to assist its widest development in the event of warm and showery weather setting in. Detailing my own experience will be of more advantage than advising any certain method. I had been only partially converted to thin planting of the Potato although I had long before given up thick seeding, as regarded all other crops, but observing the extraordinary field crops lifted by some Croatian farmers from out of widely planted mounds (I think these were 4 feet apart), I resolved to give it a trial in vastly better land, and not at 4 but at 2½ feet apart each way. The sort was a good prolific one, of excellent table qualities, named Prinz Friedrich Carl, not unlike a Regent in appearance. These were set in the way indicated above, and the crop grew so enormously both at root and top, that some difficulty was found in getting earth to mould-up with, and I repented not having put the sets at the farmers' distances apart. Other sorts planted in rows much thicker together produced an inferior crop of very much smaller Potatos from an anderior crop of very much smaller Potatos from an angeus abace of land, and were affected with the displanted in rows much thicker together produced an inferior crop of very much smaller Potatos from an equal space of land, and were affected with the disease to a very great extent, while the wider planted ones, although late in ripening, almost escaped the attack of Peroosspora. After that 1 always planted wide, according to the growth of the haulm, and so effected a saving in sets; the crop was freer from disease owing to the complete airiness around each mound, and perhaps because the spores fell in the spaces between the mounds where there were no roots to infert. M

Lilium giganteum.—An example of the most successful cultivation of this plant with which I am acquainted occurs at Brynmeirig, near the Penrhyn state quarry. Last season there were over half-a-dozeo plants of this majestic Lily in flower, several of which attained a height of about 10 feet. They are planted in the recesses along the outskirts of a Rhododendron that he be able to the afforded being evidently conin the recesses along the outskirts of a Rhododendron bed, the shelter thus afforded being evidently conducive to the most luxuriant growth. The soil is good stiff loam, resting at no great depth on shaley rock, and though the position is well sheltered on all sides by tall trees, still the aspect must be considered as east. The surface of the soil, from having been undisturbed for years, has become quite hard, indeed so much so, that I have often been surprised at the healthy, strong nature of the plants, more especially on considering the care and attention that are usually lavished on this king of Lilies. The Rhododendrons are from 4 to 5 feet high, and their dark green surface is certainly a most appropriate contrast to the light shining green of the Lily. A. D. Webster.

to infect. M.

Hepaticas.—I have grown these for years, but so far I have not been fortunate enough to have found a seedling growing either on or around the plants. Perhaps it is owing to their flowering here during an unfavourable time to the settling of their seed that we do not find young plants, or seeds, if formed, do not mature. Perhaps any one growing the single varieties under glass, as in a cold frame, might be more successful in this direction. Some writers were quite enthusiastic about these plants, but one can hardly understand this state of feeling in connection with such modest wee things as Hepaticas are. But it must in justice be said that this was during the hardy plant "revival" of a few years ago, when many things were said and written that will not bear the

reflection of to-day. Having grown the plants during a long period, and noted the practice of others as well, I am convinced there is nothing like letting the plants alone when once established in good soil. By good soil I mean that which is naturally fertile, has been well cultivated, especially deeply trenched and abundantly manured. If you have this you may grow almost any herbaceous plant if good soil is supple, mented by warm shelter from buildings and treesther Frimula tribe will thrive under such conditions it the craze of perpetually lifting and dividing is not indulged except at very long intervals. To keep the Hepatica in health, when there is some likelihood of the soil having become poor, nothing is better than slight coverings of decayed leaf-mould or old Mushroom beds; this should be fixely screeced and given at any time during autumn or winter. M. at any time during autumn or winter. M.

Slugs and Dry-rot, — The following curious passage occurs in Dr. J. G. Jeffrey's British Conchology, vol. i, p. 130, under Limax:—"They (slugs) are, however, sometimes useful in eating that kind of fungus which causes dry-rot, and another kind which infests cellars and makes choice port wine what is termed 'corked." This is curious, if correct. One would hardly think the latter fungus confined its attack to "choice" port. W. G. S.

New Inventions.—We have received from the Collapsible Packing Case and Parcels Post Box Company, Byfleet, Weybridge, a sample of a tin box made

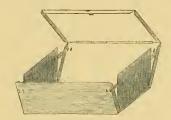

FIG. 54 .- COLLAPSIBLE PARCELS POST BOX

by them, and intended for the use of horticulturists in sending things through the post. The one advan-tage that we can see in a box that collapses is that great numbers of them can be sent in the collapsed

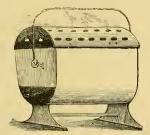

FIG. 55 .- ELCOME'S IMPROVED FUMIGATOR.

state in a small cubical space; we have also noticed that such boxes arrive with plants and blooms in them, and which, owing to the box having collapsed at the wrong time, were reduced to the consistency of jelly. This would seem to indicate that post officials jelly. This would seem to indicate that post officials are not sufficiently careful with things collapsible, or that the boxes, which are of tin, require some slight strengthening of their parts. We give an illustration (fig. 54), which is one-fifth the size of the original. Fumigator.—Mr. Elcome, 4. Chestnut Villas, Woodland Road, Upper Norwood, sends us one of his improved fumigators for horticultural purposes (see fig. 55). It is strongly made of stout sheet-iron, has a cover perforated with holes, to allow the smoke readily to escape, and a stout bow handle wherewith to carry it. The fumigator can also be used to burn charcoal or coke if necessary, and is not expensive. Practical men who have used it speak highly of its merits, not the least of which is the short time it takes to fill a large house.

Potato Disease.— I have forwarded to you a sample of Veitch's Improved Ashleaf Kidney Potato, and should be glad of some information as to the cause of the disease. I have grown about 2 acres of different varieties of Potatos for the last ten years;

the soil is sandy, and I have sown 6 cwt. of guano per acre in the drills before planting the Potatos, in addition to a very little farmyard manure. The produce was very satisfactory up to the last two seasons. The Kidney varieties are affected more than the round, and they all appear sound at lifting time, in fact it does not show itself until after Christmas. About one fourth of the Kidneys are affected. T. S., Chertsey. [The Potatos sent by "T. S." have been destroyed by the well-known Potato fungus, Peronospora infestaos. The case is a very bad one, showing large livid patches and cracks outside the tubers, the interior being full of brown corroded and putrescent material. The case is also an instructive one, as the material. The case is also an instructive one, as the tubers were grown in sandy soil, and showed no traces of disease at the time of lifting; the putrescence commencing from the inside towards the outside of the tubers after Christmas. "T. S." does not say whether the foliage of the plants was diseased in the autumn, but no doubt it was. There is no help forthcoming in such a case—the Polatos are dead and rotten. Now we venture to say that "T. S." case is not an exception, but a good example of the rule that in a very large number of cases the disease starts from the interior of the Polato tuber, and finds its way to the outside, often after storing and during the winter and spring months. At the time of lifting its by no means uncommon, on cutting open an apparently sound Potato, to find a small disease patch in the middle. Therefore published results of the apparently sound condition of Polato tubers at the time of lifting go for very little; we want to know the condition of the tubers in the following spring. Such of the readers of the Gardeners' Chronicle as have read the correspondence on the sand filtration of spores will have observed that Mr. Plowright and Mr. Jensen object to my experiments with dry sand. When the experiments were repeated with wet sand another correspondent, "A. D.," p. 58, wrote that, "Really, the result (i.e., non-filtration) was just what might have been expected." If this is not blowing hot and cold, I don't know what is. "A. D." concludes his letter with the following poetical remark, "Tis true, many Potato tubers show disease in the flesh, but not in the skin, but how it got here there is no evidence to show," for if it is certain it did not get there through the skin and rootlets it must have desecnded by the seen in the flesh, but not in the skin, but how it got here there is no evidence to show," We think, seen in the flesh, but not in the skin, but how it got here there is no evidence to show," We think, seen in the flesh, but not in the skin, but how it got here there is n material. The case is also an instructive one, as the tubers were grown in sandy soil, and showed no traces of disease at the time of lifting: the putrescence

Planting in Rubble.—I have just been examining a rather long belt of common Laurel that was planted five years ago, to shut out from view a rather unsightly railway embankment. The outer portion of this embankment was entirely composed of rubble, such as stones, fragments of rock, and slate refuse, and well do I remember the difficulty we had in procuring sufficient soil to cover the roots of the plants. The pits were opened of a large size, the plants inserted, and a spadeful or two of soil scraped up from wherever it could best be procured for placing next the roots, after which the rubble was filled in, and the simple process of planting completed. The results are almost incredible, for the plants have not only grown of a large size, but appear in such vigorous health, that one cannot doubt but they have got a congenial home and suitable composition in which to grow. The above is written for the sole object of pointing out that evergreens (at least Laurels) will not only live but thrive amongst rubble in its various forms; and as in many cases the planting of such unsightly heaps is of the greatest importance, it is well to know that this can be performed with a great amount of success. A. D. Webster. Planting in Rubble.-I have just been examin-

FRUIT NOTES.

PEAR CHARLES FRÉDERIX.-One of Van Mons seedlings. A medium-sized fruit, of regular pyriform shape, with a short stalk and yellow rind, flushed with russet, and with numerous small brownish specks; flesh white, melting, aromatic. S Bulletin d'Arboriculture, February. Season, October.

APPLE HEREFORDSHIRE BEEFING .- A mediumsized Apple of depressed globular shape, deeply unbilicate at hoth ends, with a short stalk and a large eye. The rind is of a rich crimson, streaked and spotted with yellow. The flesh white, acid. It is a cooking Apple for midwinter use. The tree is

vigorous and productive. Mr. Barron, from whose regards and productive. Air, Barron, from whose account in the February number of the Florist and Fomologist we cite this account, says, "The Apple dries well in the oven, like the Norfolk Beefing," and that "it dries up when bruised instead of rotting as most apples do." It is figured at tab, 604 of the periodical paned. periodical named.

ALPINE PLANTS.

THE RANUNCULUS OF THE ALPS .- The genus Ranunculus furnishes to lovers of alpine plants and cultivators of rock plants a certain number of very interesting species, which are mostly free-flowering and easy to grow. The plants may be divided, from the cultivator's point of view, into two sets; the first contains the species found in turly soils, pasturages, and on more or less fertile land. These are characterised by the name "terrestrial." The other set, much less numerous, comprises the rockgrowing species, which require special treatment, and

which are more difficult to grow.

In the first category, which is much the most important for us, there is a series of white or rosecoloured flowered plants which grow in the higher regions; and there is a second group, the flowers of which are yellow, and which grow in the rocky and sub-alpine zones. The yellow flowered species are very easy to cultivate, and flower in our gardens, le the cultivation of species living in the higher regions requires more care. For our present purpose the plants may be thus grouped :- Ist, alpine and sub-alpine species (yellow-flowered Ranunculi); 2d, meadow species (white-flowered).

R. Thora, L. This is found in the Alps, the Jura, the Apennines, and the Carpathians. It possesses this peculiarity, that it bears on the centre of its stalk a circlet of orbicular leaves, which surround the stem like a collar. It flowers in May and June.

R. hybridus, from the eastern Alps. This species is considered by Koch as being merely a variety of R. Thora, L. The foliage is deeply cut, oblique, and smaller than that of the preceding species.

R. pygmæus, Wahl., a native of the eastern Alps, Norway, and of Lapland. This is an exceedingly small species, absolutely dwarf, and resembling Potentilla minima. It has never been in my possession, so that I cannot give any directions for its cultivation. Probably it is not difficult to manage, and would be content with the same treatment as its yellow flowered companions.

R. Villarsii, DC., a native of the Alps, of Savoy, and Dauphiny. It is a very beautiful species, with large brilliant yellow coloured flowers and pubescent foliage. It thrives in peat and drought, and prefers a rich but stony soil. It flowers in May and June.

R. montanus. Willd., is found wild in the Alps and Pyrenees. This is one of the most beautiful of our alpine Ranunculi. Its large brilliant flower enlivens the dry and calcareous slopes of the pasturages during a great part of the summer. It remains in bloom for a long time under cultivation.

R. lanuginosus, L., is common in all the mountains of Europe. It is a good-sized plant, with a whitish woolly foliage and bright yellow flowers. May and June. This last species has the objectionable property of spreading too much, and grows to a large size when planted in the rockery.

The different Ranunculi that I have just enumerated grow very well in ordinary soil. They like exposure to the sun, and a fertile soil, if possible, and are easily reproduced by means of seed. The seeds must be sown immediately after they are gathered; some species are two years germinating.

The white-flowered species, which are found in meadows, and grow in a deep rich soil, are the following :-

following:—

R. raticfolius, L. This grows in the snowy regions of the Grisons and Valais Alps. It is found on Mont Cenis, and in the eastern Alps. Its elegant foliage reminds one of that of the Rue. The flowers are white, rather large, spotted with orange at the base. It blooms in June and July, in the ground.

R. pyreneus, L., occurs in the meadows in certain parts of the Alps and Pyreness. This species has this peculiarity, that the stem is erect, with entire linear leaves, and the corolla of the flower is very

this peculiarity, that the stem is erect, with entire linear leaves, and the corolla of the flower is very caducous, and falls on the least blow. Flowers small, expanding in June under cultivation.

R. Seguieri, Vill. This grows on the Alps of Tyrol and Carinthia. This free-flowering species, the corolla of which is snowy-white, contrasting admirably with the bright green of the foliage, expands its flowers in June and July.

R. alfestris, L., grows throughout the Alpine chain and in the Carpathians. It is one of the most graceful of alpine plants; its corolla is of a crystalline-white, with a sheaf of bright yellow stamens in the centre. It flowers under cultivation in spring, and

centre. It flowers under currents and again in the autumn. It prefers a calcareous soil. R. Traunfelheri, Hoppe, a native of the eastern Alps, is a rare and prefty plant of low stature; its leaves are a dark shining green colour, deeply cut and digitate. It prefers a calcareous sandy soil, and flowers under cultivation in May and June.

R. amplexicallis, L., from the southern Alps, is one of the prettiest Ranuncull. The flower is fine, large, with broad petals. It is a rare plant, and one I formerly cultivated with success, but which I lost

through excessive damp.

R. crenatus, Waldst. and Kit., a native of the southern Alps of Austria and the mountains of Hungary. It bears a certain resemblance to R. alpestris, from which species it differs in its rounded foliage, which is cretated at the margin. It flowers in June

and July.

E. bilobus, Bertol., from southern Tyrol. This is a smaller plant than the preceding species, from which it differs also in the foliage, and in the two-lobed

petals of the flower.

Among the white-flowered Ranunculi there are also the two following species, natives of wooded mountainous regions—R. aconitifolius, L., and R. platanifolius, L. Their branching habit renders them untamous regions—A. acominolins, L., and K. piatani-folius, L. Their branching habit renders them un-suitable for cultivation on the rockery, where they grow too lavariantly, and where they become trouble-some. They may be cultivated successfully on a wild bank in the corner of a garden. They are easily re-produced by seeds without trouble.

As to the rock-growing species, there are but two in our Alps; these are R. parnassifolius, L., and R. glacialis, L. The first of these species is only met with in the crumbling rocks of the Alps or Pyrences, with in the crumbling rocks of the Alps or Pyrenees, while the second is peculiar to the icy summits of our own granitic and slatey Alps. Both are accustomed to a moist soil and a moisture-laden atmosphere. I have succeeded in making them flower without trouble by giving them a well-drained soil from which the water on accuracy and with the water on accuracy and with the water or accuracy and with the water of the property and which is a single property and the propert the water can escape easily, and which is mixed with stones and sand. A little leaf-mould or peat is suffistones and sand. A little leat-mould or peat is sufficient, but they require plenty of water, and as much light as possible when they begin to grow. What kills them is stagnant moisture. They must have plenty of air, light, and moisture. They flower very irregularly under cultivation. R, parnassifolius is easy to bloom, but R, glacialis is more difficult—it rarely retains the presendant of the state water. rarely retains the rosc-colour of the outer surface of tately retains the rose-colour of the outer surface of the petals which so particularly distinguishes it in the Alps. It thrives especially on a soil mixed with slatey and schistose dibris. Henry Correvon, Botanic Garden, Geneva.

ORIGIN OF DOMESTICATED VEGETABLES.

THERE are two methods of studying the origin of our domesticated plants, the one historical, the other through investigation into the causes of varia-The first method has the disadvantage that events of this character but rarely find explicit record; the second, that we as yet have a deficiency of proper We are hence obliged, if we would attain truthful conclusions, to combine the two methods, and through painstaking consulting of scattered mention, the guarded interpretation of hints to be gained from tradition and vernacular names, and the recognition of changes due to the acts of man, to follow the protean changes from course to course, until we either attain the limit of our knowledge or indication of the original species.

We may in the furtherance of this course recognise certain truths which we must consider axiomatic; that variation is an indication of changed environment, and that departure in the plant from the natural motive towards a motive more subservient to man's wants is evidence of man's interference; that as through man's agency plants become removed from natural conditions, and have qualities dependent upon domesticated conditions impressed upon them, so when neglected by man these acquired qualities disappear in a large measure, and the plant changes, not reverts, to conditions which enable it to satisfy the requirements of Nature; that change of form, added to the plant through man's selection, if beneficial to the plant, when left to Nature will be maintained in the plant escape or garden wilding; that a large number of varieties is an indication of antiquity of culture, especially if such varieties are of different types.

Applying these thoughts to a case in illustration. we should at once infer a greater antiquity of origin for the Turnip than for the Ruta-baga; for the Carrot than for the Parsnip; and where the varieties and types are very many, as in Maize, Wheat, Beans, &c., we should infer very great antiquity of culture. So seedless fruits indicate man's ancient interference, and should only be expected to occur in regions which are, or have been, occupied by man.

If a highway leads from Jericho to Jerusalem, it is certainly proper to infer that the same road leads from Jerusalem to Jericho. If variations of a certain kind are produced only by man's interference, if the fact be well established, it is certainly proper to infer that if variations of this kind are found they indicate a former cultivation. We can even go further, and say that if the agency of man induces numerous variations favourable to a man's wants in a species, then that the presence of numerous variations in a species, of a kind favourable to man, indicate a previous agency of man. Thus, the peculiar distribution of the Vitis californica ln rows, near Fort Whipple in Arizona, is considered conclusive evidence that the ancient Pueblo Indians were in the habit of cultivating it; evidence of a dissimilar character, but very nearly as conclusive, for the ancient cultivation of the Vitis Labrusca is seen in the variability of this species, which is strikingly in the direction of the improvement of the fruit in individuals, as is known to the many farmers in New England who have transplanted improved kinds to their door-yards, and is a matter of common repute, as well as evidenced in the various named varieties, as the Concord, which have originated from its seed. If we plant the seed of the Apple, as we note the varying quality of the seedlings, no two being alike, we can infer from this circumstance that the Apple is a domesticated fruit, and of human origin; if we likewise plant the seeds of the American Crab, we may properly infer that it is a wild or natural species from the power its seeds possess of coming true to name. This method of research, if supplemented by a historical record, offers much promise to the investigator.

When we consider the number of species of vegetables that America has furnished to civilisation, their number of variations, their high degree of improvement, and their constancy to type, we may infer, prima facie, that a civilisation capable of producing these results has existed in the past. We need but mention the Maize, the Bean, the Pumpkin and Squash, the Tomato, Peppers, the Potato, the Cassava, Chocolate, &c.

It is not improbable that many of our so-called natural species, to which our domesticated varieties are referred, are themselves but escapes from a cultivated state. I do not know whether the wild Parsuip of America has a close resemblance to the wild Parsnip of Europe or not. We cannot readily suppose that the wild Parsnip was really brought to America, for it appears more reasonable to believe that it is an escape from cultivation; as the Salsify certainly is about Geneva. In default of any mention, we certainly should be justified by common consent in referring our cultivated Parsnip for origin to our wild Parsnip, and yet how erroneous this would be. The same remark applies to the Carrot. Should we not, therefore, be slow to refer the cultivated Parsnip to the wild Parsnip of European fields, or the cultivated Carrots to the wild Carrots? Avena fatua is supposed to be the parent form of the cultivated Oat, but why not more reasonable to suppose it to be an escape, modified only from the cultivated Oat in order to meet the conditions necessitated by its struggle under Nature's conditions?

The history of the Indians, after the discovery, shows that they were greedy for new sources of food supply, and the facts connected with their habits of living all show that they exercised a care over vegetable productions. Thus the Melon and the Peach received distribution over wide areas in advance of a European discovery; the Onion was even mentioned by Cortez as found in Mexico; the Maize, the Bean, and the Squash, in varieties, all plants of tropical origin, and which could not maintain themselves without care, were staple crops throughout northern America, even to Lake Coulonge on the Ottawa river, and beyond the St. Lawrence, where the crops required seeding, protection and preservation of seed over the winter months. The Suoflower was grown for its seed by the Hurons, as seems also to have been the Jerusalem Artichoke for its roots. Bartram notes seeing in the South a plantation of Hickory Nut cultivated by the Indians. The Prunus americana seems to have been planted by the New England natives, and this seems also to have been the case with Prunus Chicasa in the South-west, although I find no distinct mention of the fact. Numerous other illustrations occur in my notes of a cultivation or domestication of plants throughout America, and a care and curious concern about forms and colours which must have caused selection to have been exercised; at any rate, when we have so-called wild species of the same varieties, the variability of these wild species in the portion which finds use is notice-

Indeed, the careful student must recognise that the American Indians were an agricultural people wherever natural conditions and tribal strength would admit, and that they were efficient agents, not only in the geographical distribution of certain plants, but also in the producing of varieties. Circumstances, as in European nations in times past, made the tribes usually hunters and agriculturists, often agricultural solely, and again devoted wholly to the chase, and living on wild productions,

The history of the origin of our American vegetables must come from a close study of the history of a people, as well as from a study into the causes and effects of variations. These two methods in time may admit of certain generalisations, and it seems safe to assume that the results of such a study will not be in accordance with accepted notions. The physiological method will bring a certainty so far as it accomplishes a conclusion, which the method of systematic botany does not supply. Until we can separate escapes from natural species—that is, until we can determine species apart from changes impressed upon plants by man-it seems unsafe to refer our cultivated plants to localities wherein occur wildings of like species. Far preferable the argument from historical mention of the habits and movements or migrations of peoples. It seems probable that variability or trueness to seed may become the test as to the sufficiency of a conclusion in favour of or against an assigned species. This fact is an interesting one for the scholarly botanist, for it only needs the reading of De Candolle's work to realise the uncertainty at present existing. E. Lewis Sturtevant, M.D., in "Botanical Gazette."

THE APPLE.

WHETHER the Apples which grew in the gardens of Alcinous, King of Corcyra (Corfu), before the Christian era (and whose orchards were said to be so fruitful as to give rise to the proverb " Poma Alcinoo date," were similar in texture and flavour to those varieties we now cultivate, or whether they were the harsh and uppalatable Crab in its original state, we have no exact information; nor does it perhaps much matter now; still, it would be extremely interesting to know the exact date when, as well as the name of the identical person who first commenced the commendable operation of transforming that small green ball of acid pulp into the highly coloured and delectable fruit which we now call the Apple. This question, however, is hidden with the past, as is also the exact date when the Apple io its improved form was introduced into this country. I say introduced, because I fear that the laudable act mentioned above cannot possibly be ascribed either to Divitiacus, the first known ruler of Britain, Hengist, nor Egbert, nor any of their Celtic or Saxon subjects, as it appears the clever Romans are in this case—as in nearly every other good thing for which we have to be thankfulcredited with this excellent act also. However true or untrue this may be, we have good reason to believe that these renowned warriors were amongst the earliest cultivators of this fruit; at any rate, the ancient naturalist, Pliny, who perished in the first known eruption of Vesuvius, A.D. 79, knew, or should have known, something about Apples, as there were, from his account, a score or more varieties cultivated in that country in his day.

The great advance in its culture, however, in this country, as in most things else, unless history is incorrect, took place when in 1066 William of Normandy first trod British soil, for soon after this period the different varieties of Apple began to engage the fond attentions of our ancestors, and so diligently, devotedly, and continuously have these attentions been paid by their descendants to this delicious fruit, that there are, it is said, about 4000 varieties in existence at the present time - rather a numerous progeny, all of which may be safely classed as good, bad, or indifferent in quality. Since the secret of changing its character was first discovered,

the great difficulty has been, I should imagine, not in obtaining numerous varieties, because the Apple is extremely prodigal in this respect, but rather in acquiring those of increased size and superior flavour, and even as they now exist, if this grand total were divided by forty, we should still have enough varieties and to spare. At any rate, the late Chiswick least in honour of Pomona pointed significantly in this direction, as did also the interesting and valuable which afterwards appeared in the Gardeners' Chronicle. It is not at all improbable that these Roman as well as Norman warriors soon found that there were some situations as well as some soils, even in this comparatively fertife island, where this tree refused to grow and fruit satisfactorily. No doubt their task of finding out the most favourable position and soil was a much more lengthy and difficult one to them than it would now be to us, aided and guided as we are by modern science; still their keen sense and wise judgment appears to have enabled them to choose the very same districts which we still find to be the most fruitful; but even in those days the results do not appear to have long continued altogether satisfactory, as we learn that even in that fertile county we now call the Garden of England the quality of the Apples did not equal that of the more southern clime from which they had been brought, hence great quantities of fruit were annually imported from the Continent.

Very praiseworthy efforts were made from time to time by enthusiastic cultivators to remedy this unfavourable state of things by various means, one of which was to import new trees from the Continent, which act plainly shows that even in the days of old the wearing-out theory had its disciples. "Richard Harris, fruiterer to Henry VIII., having observed that the fruit trees brought over by the Normans had lost their native excellence by length of time, and being under the impression that neither the soil nor climate were at fault, determined to obtain a fresh supply of trees, which he was enabled to accomplish at great labour and cost." These trees consisted of Apples and Cherries, the Golden Reinette and Pippin Apples, and the sweet, or, as it is now called, the Kentish Cherry. These were planted on 100 acres of carefully selected rich land called the Brennet, in Kent, and no doubt their produce, under the fostering care of worthy Richard Harris, contributed in no small degree to the gratification of the delicate palate of the monarch. Herefordshire and Worcestershire appear ever to have contested with Kent the honours of being foremost in Apple culture. This was first occasioned most probably by the Romans having settled principally in those districts. and afterwards by the strenuous efforts of influential individuals at various times in introducing and disseminating improved varieties from the Continent: but undoubtedly the chief cause was due to the general fertility of these counties and their suitableness to the healthy growth of this tree. Other counties have during the last half century vied with these in this special culture, and some improvement has been effected both in the selection of the varieties, as well as in the methods of cultivation; but still it is only too plainly apparent to any one who pays a visit to the Apple orchards in our rural districts that they are yet capable of still greater improvement, without which they must and will fail to give that profitable result which they are capable of giving under good cultivation. T. S. C.
(To be continued.)

GLADIOLI.

However great the outcry against these magnificent harvest-time flowers, there is still a large demand for them, and I believe they will be planted quite as, if not more, extensively during the ensuing season as at any previous one; and judging from the appearance of the corms, of which I have seen a large quantity, I think it does not require much prophetic acuteness to predict a good display next autumn, all other things being equal. The Continental crops are especially fine all round, the English grown corms are not so large, but very sound; and it is surprising what good spikes are produced by even moderate-sized, roughly sound corms; but I certainly prefer those grown on the Continent, as far as I have been able to judge. Some seasons I have planted them side by side, and especially last year I fancied there was a decided superiority in the size of the spikes of foreign to English grown bulbs; perhaps the home-grown

bulbs were not up to the usual standard which I planted, and, speaking candidly, I hope such was actually the case, for I much dislike puffing up Continental-grown stuff as superior to home-grown, unless the thing is patent to everybody.

The magnificent display which Messrs. Kelway, of Langport, are enabled to make every year both at home and at exhibitions certainly favours the idea that they may be cultivated most successfully over an extended period, even with our very precarious seasons. Many growers of repute complain of heavy losses, year after year, until what was once a complete collection gradually wastes to almost nil; and they assure us no stone has been left unturned in order to encourage what they considered their hobby. Certain is it, the Gladiolus is the subject of many ills, the most formidable of which seems to be the disease from which all collections suffer more or less. All interested in this noble flower should do their utmost to eradicate it by destroying all plants, however choice, directly the least sign of disease appears in the beds; pull them up in toto and burn them, and thus so far put an end to it.

Now is the time we gardeners are about to purchase a fresh stock; very frequently they are ordered with the garden seeds, but he is the wisest man who orders them with the other bulbs in autumn, giving instructions for them to be delivered as early as they are ripe. Not only is it probable that better, indeed best, bulbs will be received, but he will also be able to store them through the winter according to his own idea, and the storiog is an item of material importance, as they should be kept in such condition that they will either commence to grow or shrivel, nor must they be subject to frost. I have found pots of dry sand excellent media for storing them, and occasionally turn them out, say once a week, to prevent a temperature as possible. From the present time onwards they will make use of any stimulant which excites growth, but this must be checked, for it is not safe to plant them out, even first batch, till the first week in March, a second lot being planted at the end of the same month, while the final batch may be planted about the second or third week in April, by which a lengthened supply of flowers will be enjoyed. In order to secure a very early supply of flowers the bulbs should be started in pots, and ultimately planted out in a sheltered corner, or grown on in larger pots; such plants will be found most serviceable for the decoration of the conservatory. Some grown last season by myself in this way were much appreciated, and did excellent service.

Whenever practicable I think they should be grown in specially prepared beds, by which means you are more likely to secure good corms for another season. Certainly, as previously intimated, they have a most charming appearance in the mixed border, or among shrubs; but for this purpose the cheaper kinds may be selected, such as the dazzling old brenchleyensis, than which none is better adopted for the purpose; John Bull, Rebecca, James Carter, Ida, Impératrice, &c., as they will answer the purpose equally well as the more expensive kinds. Even the positions assigned them should, previous to planting, be well prepared, by being deeply dug and liberally manured, and the plants watered well if very dry weather is experienced. But where anything like a good collection is grown, it is much preferable to arrange them all in one bed, and this should be selected at once and well trenched, or and this should be selected at nace and well trenched, or turned up deeply and roughly, and when the time for planting comes, manure right well with rotten well-bodied manure, arranging the same directly under, not necessarily in contact with, the corms; and if the soil is stiff and damp sprinkle some sharp sand upon them and cover with about 6 inches of soil. A good distance for planting is about 18 inches between the rows, and with the corms 9 inches apart; there will then be plenty of room for staking and watering, as well as fertilising the flowers if seed be desired, when such operations are necessary. You can cover the surface of the bed with Migaonette without prejudicial effect upon the Gladioli—a crop which will be extremely useful. As I have previously intimated, it is necessary to give them good waterings if very dry weather is experienced, and especially as the flower-spike is emerging from the leaves. At this time they spike is emerging from the leaves. At this time they are greatly assisted by one or two supplies of manure-water—say once a week, if needful—the result will well repay the outlay. Do not neglect to stake so soon as the wind has control over them, or they may quickly be sanpped off, causing great vexation; besides, they present a much more tidy appearance when staked. With these remarks I close, and hope the growers of these noble flowers will derive more pleasure from them in 1884 than at any previous season. Daf.

COLONIAL NOTES.

BOTANIC GARDEN, MELEOURNE.—Mr. Gullfoyle has issued a catalogue of the plants under cultivation in the Melbourne Botanic Garden, prefaced with a general account of the garden, and illustrated with lithographs. The area of the garden is about 33 acres, the total area, with the Government House grounds adjoining, being 300 acres. The garden dates only from 1847, and for seventeen years it was under the energetic management of Baron von Mueller. For the last ten years it has been under the direction of Mr. Gulfoyle. Great attention is paid to the introduction and diffusion of useful plants, and the laboratory affords a means of testing their utility in different ways.

The catalogue is rather ambitious, but should have been revised by some one familiar with botanical literature and nomenclature. Authorities are cited both for the genera and the species, but there is no guarantee that any one of the plants in the garden is really the plant meant by the authority cited. At first sight we were puzzled by the authority " Hortoindicating that the name to which that word is affixed is of garden origin. Had this been written in the usual manner, "Hort.," no such difficulty would have arisen. As it would obviouly be impossible for any one to verify all the names, it would seem better to have issued an unpretending catalogue of garden names, without any reference to authors, except in those cases where the compiler, or competent assistants, by personal investigations, had been able to check the names. The lists of Arads, Bromeliads, &c., published in the Kew Reports are cases in point (pity 'tis they are so few): they are not mere lists, but carefully drawn up catalogues, in which each name has been hotanically verified. Such a list. accompanied by a rigidly exact system of labelling, affords the most precious assistance to the student. In the present case we think the insertion to a larger extent than has been done, of reputed synonyms, would have been more useful than that of authorities. on the first page we find this entry, "Abutilon vexillarum (sic), E. Mon. (?), Vexillary Lantern Flower. Hardy evergreen shrub." We feel pretty sure that Professor Edward Morren, who described the plant in the Belgique Horticole, spelt it vexillarium, and we believe we are correct in saying that the name in question should be superseded by the earlier name of A. megapotamicum of A. St. Hilaire. Moreover. the abbreviation used is not that commonly employed to denote Professor Morren's responsibility. Again, why take up room with such a nonsensical appel-lation as "Vexillary Lantern Flower"? Surely no one ever uses such an appellation in tralia, and no one does so, to our knowledge, in Europe. Christy (?) is given as the authority for Pious Heldreichii—we suppose Dr. Christ, the author of a memoir on the European Pioes, is intended; while for Bougard we ought certainly to write Bongard; for Griesbeck (see Pious peuke), Grisebach; for Filingi, Tilingi; for Garrya McLadeniana, G. Macfadyena; for Cotoneaster Simmondsii, Hortorum, C. Simonsi, Baker. The Golden or Corstorphine Plane is surely not a variety of Acer tataricum. Lindley is not the authority to cite for Aphelandra Roezliana var. auraotiaca; Passiflora macrocarpa has been fully described, first in these columns and then elsewhere, and figured, and hence is entitled to some other citation than " Hortorum" after it; and the same may be said of Passiflora sanguinolenta, We are at a loss to know what the "carpus" of a Thuis can be. The confusion of genders, which is so common in most catalogues, is well illustrated in the present one, where we find Abutilon floribunda, Alnus japonicus, Passiflora Herbertianum, while under Pentstemon we find thirteen species with the neuter termination um, one with the feminine a, and four with the masculine us. P. cohosa might count as a feminine termination were it not for the fact that it should, for reasons known to botanists, if not to gardeners, have been written P. Cobæa. Passiflora Kermesina, on the other hand, would have been better written with a small "k," or would have been still more correctly called P. Raddeana. Some of the Selaginellas, as S. Willdenovii, cæsia, denticulata, are mixed up without any indication with Lycopodium. In dealing with such a vast multitude of names misprints are of course to a large extent unavoidable, but they would probably have been not only absolutely but relatively fewer in number had the plan of the catalogue been more restricted, so as to

have allowed a greater concentration of attention upon this matter.

But it is a very ungracious task to criticise an index of this kind, which, whatever its defects may be, is sure to be useful. If we have alluded to some of the blemishes which have attracted our attention, it has been with the object of illustrating our opinion, that too much has been attempted in it, and with the view of securing a more correct edition on another occasion. So much gratitude is due to catalogue-makers and index-compilers that every allowance should be made for their shortcomings; and journalists, whose sins come home to them every week, should be among the last to throw stones. The list of native Australian plants in cultivation, such as the Eucalypts, the Acacias, the Hakeas, the Grevilleas, Proteas, &c., is very interesting.

∯loqists' ∯lowers.

THE CARNATION AND PICOTEE. -It is usual with a large class of cultivators of these plants to delay making any addition to their stock until the spring. During March and April, even as late as May, the trade will be sending out quantities of these choice flowers to their customers. It ought to be well known that October is the best month to make additions to the stock of plants. They can be sent with the roots securely wrapped up in damp moss, packed in small compass; whereas if the order is delayed nutil now it is necessary to send them in pots. are now busy repotting our whole collection, and while doing so it occurred to me that a few notes on some of the newer varieties might be useful to intend-ing purchasers. Those who still have a lingering fondness for the "good old varieties," as they are pleased to term them, will be left behind in the race if they depend exclusively upon them, and ignore the additions made to our collections during the last halfdozen years. Besides, the constitution of the "good old varieties" is not so robust and vigorous as that of the new ones. Mr. Dodwell, who is well able to give an opinion on this subject, informs me that the average life of a Carnation is fifteen years, although some few, possessing great vigour of constitution, have lived for more than fifty years.

I have just been turning over the pages of Hogg on The Carnation, 1839 edition, and I find 400 varieties enumerated and described, but I do not think even one of those 400 varieties is to be found in any trade catalogues, or even in any private collections, nowsufficient proof that the Carnation has a greater tendency to wear out than some other varieties of florists' flowers, the Auricula, for instance. In a list of 106 varieties of Auriculas I find eighteen that are at present in cultivation; some of them are in our own collection, and they are quite as vigorous as the seedlings of last year. Probably the cultural requirements of the Carnation are not sufficiently understood. We have learned a good deal during the last forty-five years from our own failures and the failures of others, and I fancy the Carnation is better grown now than it used to be. In Hogg's time the composts used were too rich, and it was no great wonder if a large number of the plants died. We use one barrow-load of decayed manure to four or five of loam, and find this compost sufficiently rich, Hogg's recipe is five barrow-loads of loam to eight or nine of horse-dung; and this, be it remembered, was considered not at all a rich compost. Other growers at that time used, in addition to the manure, sugar-bakers' scum, soap-

boilers' waste, night-soil, pigeons'-dung, blood, &c.

The wild progenitors of the Carnation and Picotee
find stifficient nourishment in the dibris of old castles
and rocks to keep them in health for many years, and
it is too much of a change to tear them from their
ancestral walls and transplant their roots into such a
mess as the old forsits recommended. The plants were
likely to do better planted out in the open ground.

Beginning, as usual, with the scarlet bizarre Carations, we do not find any new additions for this
year; indeed, it will be difficult to improve upon
such sorts as Mr. Dodwell has raised during the last
few years, viz., Arthur Medhust, Edward Adams,
Fred, George, Master Stanley, Philip Thomas, and
Robert Lord. These should be grown in the most
select collections. In crimson bizarres E. S. Dodwell
and Master Fred are not well known as yet. They

were sent out by Mr. Hewitt, of Chesterfield, and are both richly coloured and well marked flowers. William Skirviog, raised by Mr. Richard Gorton, of Eccles, and now being sent out by Mr. Turner, is distinct and very fine. It is classed with the pink and purple bizarres. Samuel Barlow (Dodwell) is a true crimson bizarre; it is now being sent out by the raiser. It has rich crimson and deep purple flakes on a white ground. Mr. Dodwell is also sending out a very distinct pink and purple variety named Mrs. Anstiss. It will be a great addition to this hitherto weak class. Mrs. Barlow, one of Mr. Dodwell's seedlings, has not yet been brought to the front, but it will yet be seen in the highest position; it will also have to be classed with the pink and purple varieties. Sarah Payne, for many years undisputed queen in this class, must now fall into the third or fourth rank.

In purple flakes James Douglas, raised and sent out by Mr. Simonite, of Rough Bank, Sheffield, stands highest in the regard of the florists; whether Mr. Dodwell's new variety, Squire Whitbourn, will push it from its pedestal remains to be seen. It is a very fine variety, of good form, and a rich purple flake.

Henry Cannell (Dodwell), scarlet flake, is certainly a great addition to this class; whether it will displace the celebrated variety, Sportsman, remains to be seen; it is certainly second to it, and has a better formed guard-petal. Figaro and Matador, raised by Dr. Abercrombie, of Cheltenham, and now being sent out by Mr. Turner, are quite distinct from Mr. Dodwell's variety. They are both well formed flowers; and, as shown by Mr. Turner, are good additions to this class, which contains but few vigorous growing varieties.

The rose flakes are to be greatly enriched this season by the addition of Mr. Gorton's well known and beautiful varieties, Tim Bobbin and Rob Roy. They are being sent out by Mr. Turner. I have grown them both for two seasons, and can truly say that they are the best formed and most beautifully marked flowers in this class. Distinct in every way from these two is Mr. Dodwell's pale rose flake, Dorothy; it is distinct from any other in this class, but it will not take with all florists, owing to its pale delicate rose colour, which does not suit the fancy of exhibitors. It will be a charming garden flower. would also strongly recommend Titania, which Mr. Dodwell insists on terming a rose fleck. It was raised three or four years ago by Mr. Dodwell, and is a very beautiful garden variety, being of very vigorous growth. It is flaked with very delicate rose on a pure white ground.

A few notes on the Picotee must be continued in another number. J. Douglas.

AMARYLLIS,-The usual practice with this plant is to repot the bulbs annually, separating the offsets from the parent bulbs and repotting them in small pots. If the offsets have no roots, and are not readily removed, it is better to let them remain on for another year. It is a great pleasure when a new variety forms offsets freely, as in that case we can very speedily get up a good stock. On the other hand, it is discouraging to grow a choice variety year after year and fail to obtain a single offset. I have grown a bulb of a good variety for ten years. It is larger, and flowers stronger than it did a decade ago. but has not made any increase. Some choice varieties will give as many as six offsets from a bulb. Considerable caution is required in watering them at this time of the year; they do not form roots very rapidly, and if the pots are plunged in a moist bottom-heat they absorb a deal of moisture. I do not give them any water for a full month after they have been repotted; indeed, if the bulbs and pots are large they will not require water for two months. When the leaves have made considerable growth, and the potting soil is dry, they may be watered. A bed of spent tan, with a portion of fresh added to it, will give a bottom-heat of 80° to 85°, and this, with a minimum temperature of about 55°, will suit the Amaryllis admirably. We used to grow them very well when there was no house at all, except the shelves in an early vinery. The bulbs were potted about the first week in January, and started that month. In early vineries a bed of leaves and manure is a good help to starting the Vines; and over this Amaryllis and other bulbs can be plunged.

CAMELLIAS. — These are now very valuable as an aid to keeping the conservatory and greenhouse gay with showy flowers. It ought to be well known that

this plant does not bear forcing into flower in heat. The result of a close, warm, and moist atmosphere would be to cause the half-expanded buds to drop off. The only way to force the Camellia is to put the plants into a warm house as soon as the blooming period is over. This will produce an early growth, and a corresponding early formation of flower-buds. I generally repot any that require it as soon as they have done flowering, and the Camellia is not so par-ticular about the kind of potting-soil as some people think. It will do well in peat, or in peat with turfy loam added, or even in loam entirely. Turfy loam answers very well until the turf is quite decayed, when it forms a rather compact mass not sufficiently pervious to the water. I prefer for potting turfy peat two parts and one part of good loam, with some crushed bones added to it, and if necessary some sharp sand and pounded charcoal. The leaves, like those of Orange trees, get dirty, and it is sometimes necessary to wash them with soft-soap and a sponge. Some people do not give their plants sufficient water in the late autumn and winter months. Over-dryness at the roots is another cause of the buds drapping very frequently. The plants stand out-of-doors during the moist autumn months, where they are almost nightly wet with dew, and frequently wet with the rains. By this time the flower-buds are all set. The plants are taken into the house, where the leaves are never wet; the atmosphere is dry; and in addition to this but little water is applied to the roots. What wonder, then, if flawer-buds drop off? The sudden change would cause this if nothing else did.

CHRYSANTHEMUMS. - Any cuttings that did not form roots in the cold frame, or on the greenhouse stage, should be put into a bothed, where they will speedily form roots. They seem to do best put in singly in thumb-pots, the kind known as Long Toms; but they very speedily fill these with roots, and should be potted into 60's or small 48's as soon as they are well rooted. There is generally considerable pressure of work at this time of the year, and these plants are apt to be neglected, but it is a great mistake to neglect them now. No good results will be ohtained unless they are grown on freely, and repotted when they require it. Plants intended to form specimens, either of the pompon or large-flowered varieties, will do best on a shelf near the glass in a heated house. The principal thing is to keep them on growing, using good rich potting soil. For this purpose we mix up some rich compost about the end of the year. It is composed of good loam four parts, one part short decayed stable-manure, one part leafmould, and an 8-inch potful of crushed hones to each barrow-load. It is very desirable to mix up the potting stuff a few months before using it, because in that case the manure is so much more thoroughly incorporated with the soil. When the young plants have grown about 6 or 8 inches the points should be pinched out. This will cause a number of sidegrowths to start, and as these grow out sufficiently they should be tied down.

FUCHSIAS. - These elegant but homely plants should now be attended to. They are starting into growth even where they have not been placed in a warm house. As soon as cuttings can be obtained a few of them should be propagated in a hotbed. There are few more useful plants than these for furnishing the greenhouse and conservatory during the late summer and autumn months. The old plants, if there is room for them, may also be grown on. Tall pyramidal plants have a fine effect in the centre of the greenhouse stage. J. Douglas.

Keports of Hocieties.

Notts Horticultural and Botanical: Feb. 20. The monthly meeting, over which Mr. C. E. Pearson Notts Horticultural and Botanical: Feb. 20.
—The monthly meeting, over which Mr. C. E. Pearson presided, was held at the Mechanics' institute, Nortingham, Mr. Meadows, Rock House, Basford, exhibited a very fine mass of Odontoglossum Rossii majus, grown upon a piece of Tree Fern (Cyathad calabata). It bore seventy-six flower-spikes, averaging three flowers on a spike, and had been grown perfectly cool. A Certificate of Merit was awarded. The same exhibitor also showed a plant of Dendrobium marmoratum in a 4-inch Orchid basket, with four good growths, about to inches in length, each carrying twelve flowers, the colour of the flowers by gaslight being of a deep purple tinge. Mr. Thacker, Minerva House, St. Ann's Road, brought a choice collection of cut illowers, including Phalenopsis

Schilleriana, Cattleya Triance, Cypripedium barbatum, C. barbatum nigrum, Odontoglossum Pescatorci, O. Alexandre, Ceologyne cristata; also fine blooms of Anthurium Andreanum, A. Scherzerianum var. pygmæum, ex. Mr. Walker, Hardwick House, showed Hyacinths and Paper-white Narciss in good condition. From Mr. Jenkins, of Radcliffe, came some splendid sprays of Clematis indivisa tobata; and Mr. Edrington, Wandstorpe Grange, bad a collection of Azaleas, Primulas, and Cinerarias. Mr. J. H. Walker read an interesting paper on "Mushrooms and Mushroom Growing," upon which a long discussion followed. Votes of thanks to the lecturer and to the chairman brought the proceedings of the evening to a close. T. E.

- Feb. 21.—Raio in early morning: fine bright afternoon.

 Dark sky at night.

 22.—Fine bright morning, raio at 1 P. M.; dull afternoon.

 Heavy rain from 3.30 P.M.

 23.—Fine bright morning; dull afternoon and night;
 drizzling raio.

 24.—Fine day and night.

 25.—Doint M.; hail falling at 3.15 P.M. Fine c'ear night.

 26.—Fog in morning; fine afternoon. Cold night, fog.

 27.—Fog in morning; overcast afternoon and night.

LONDON: Almospheric Pressure.—During the week ending February 23, the reading of the barometer at the level of the sea decreased from 30.02 inches to 29.93 inches by 3 F.M. on the 17th, increased to 29.93 inches by midnight on the same day, decreased to 29.84 inches by midnight on the 18th, decreased to 29.85 inches by midnight on the 18th, decreased to 29.57 inches by 3 F.M. on the 19th, increased to 29.58 inches by 3 F.M. on the 20th, decreased to 29.57 inches by midnight on the 22th, increased to 29.57 inches by midnight on the 22th, increased to 29.58 to 3 F.M. on the 37th and was 29.48 inches by the end of the week.

The mean reading of the barometer for the week. LONDON: Atmospheric Pressure .- During the week

The mean reading of the barometer for the week at the level of the sea was 29.76inches, being 0.20 inch lower than last week, and 0.23 inch above the average

of the week.

Temperature, — The highest temperature in the shade in the week was 52°, on the 20th; the highest reached on the 18th was 44°.7. The mean of the seven high day temperatures was 48°.9.

The lowest temperature was 31°, on the 18th; an the 20th the lowest temperature was 43°.9. The mean of the seven low night temperatures was 37°.8. of the week.

The greatest range of temperature in one day was 14°.7, on the 19th; the smallest was 8°.1, on the 20th. The mean of the seven daily ranges was 11°.1.

20th. The mean of the seven daily ranges was 11°.1. The mean temperatures were—on the 17th, 38°.9; on the 18th, 36°.8; on the 19th, 42°.9; on the 20th, 48°.1; on the 21st, 46°.3; on the 22d, 45°.5; and on the 23d, 44°.1; and these were all above their averages (excepting the 18th, which was 2° below) by 0°.2, 4°.1, 6°.2, 7°.3, 6°.4, and 4°.9 respectively. The mean temperature was 43°.2, being 0°.3 higher than last week, and 4°.3 ahove the average of the week.

the week.

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 97°.5, on the 20th. The mean of the seven readings was 84°.2.

The lowest reading of a thermometer with its bulb

placed on grass was 23°.5, on the 18th. of the seven readings was 31°.1.

Rain fell on five days, to the amount of 0.74 inch.

England: Temperature.—During the week ending February 23 the highest temperatures were 54°.5 at Cambridge, 53° at Truro, 52°.9 at Nottingham; the

highest at Bolton was 49°, 3, at Preston 49°, 5, and at Liverpool 49°, 6. The general mean was 41°, 3.

The lowest temperatures were 29° at Cambridge and Hull, 29°, 7 at Sheffield; the lowest at Trurn was 38°, at Plymouth 37°, and at Brighton 36°, 6.

The general mean was 32°, 7.

The greatest ranges were 25°, 5 at Cambridge, 23° at Hull, 22°, 2 at Nottingham; the smallest ranges were 14°, 4 at Plymouth, 14°, 5 at Liverpool, and 15° at Truro and Bristol. The general mean was 18°, 6.

The mean of the seven high day temperatures was highest at Truro, 52°, at Cambridge 50°, 1, at Plymouth, 49°, 6; and was lowest at Bradford, 43°, 8 at Preston 44°, 4, and at Bolton 44°, 9. The general mean was 47°, 1.

The mean of the seven low night temperatures

The mean of the seven low night temperatures was highest at Plymouth, 42°.1, at Truro 41°.7, at Brighton 40°.1; and was lowest at Wolverhampton, 33°.5, at Hull 34°.2 and at Bolton 34°.4. The

ton, 32°, 5, at Hull 34°.2 and at Bolton 34°.4. The general mean was 37°.

The mean daily range of temperature was highest at Cambridge, 13°.5, at Hull 12°.4, at Sheffield 12°; and was least at Flymouth and Preston, 7°.5, and at Brighton 7°.8. The general mean was 10°.1.

The mean temperature was highest at Truro, 46°.3, at Plymouth 45°.4, at Brighton 43°.5; and was lowest at Wolverhampton, 38°.7, at Bolton 39°.2, and at Bradford 39°.3. The general mean was 41°.6.

Rain.—The largest fall was 2.44 inches at Plymouth, 1,33 inch at Truro, 1.19 inch at Bolton; the smallest fall was 0.16 inch at Leeds, 0.22 inch at Hull, and 0.24 inch at Bradford. The general mean mail was 0.6 inch at Ill was 0.6 inch at Leeds, 0.22 inch at Hull, and 0.24 inch at Bradford.

fall was 0.76 inch. Rain fell on every day in the week at Truro, Plymouth, and Bolton.

SCOTLAND: Temperature. - During the week ending February 23, the highest temperature was 52 Glasgow; at Dundee the highest was 46°.7.

Glasgow; at Dundee the highest was 40.7. Ine general mean was 49°.2.

The lowest temperature in the week was 30°.9, at Edinburgh; at Leith the lowest temperature was 33°.5.

The general mean was 32°.4.

The mean temperature was highest at Glasgow and Aherdeen, 41°.1; and lowest at Greenock, 38°.4.

The general mean was 39°.8.

Rain.—The largest fall was 3.27 inches, at Greenock; and the smallest was 0.26 inch, at Leith.

The general mean fall was 1.35 inch.

JAMES GLAISHER, F.R.S.

Answers to Correspondents.

ARUM: Subscriber. It is very doubtful if the plant will throw up another double spathe, but you might mark it, and note its behaviour next season.

BEETLE: E. V. B. The beedle is no doubt an Aphodius, species of which are abundant in the droppings of domestic animals in spring. The spring-like weather has raised them earlier than usual. It will do no harm if nuwtitingly introduced into the house.

BOOKS: F. H. Mr. B. S. Williams' Choice Stove and Greenhouse Plants, published by the author; and Hardy Florist' Flowers, by James Douglas, Great Gearies, Ilfard.—F. H. F. Bentham's British Flora (Lovell Reeve & Co., Henrietta Street, Covent Garden, W.C.). Price about one guinea.

FUCHSIA: R. M. Your specimen is an illustration of the fundamental identity of sepals and leaves. In former volumes we bave figured much more striking illustrations of the same kind.

Indiatations of the same kind.

Indian Numeration: A. The figures are quite correct, the Indian mode of numeration differing from ours thus:—Units, tens, hundreds, bousands, tens of thousands, lakhs, tens of lakhs, krors. One lakh = too,coo; one kerr= to,coo,coo; one seer= 2 lb, avoirdupcis; one maund= 40 seers; one rupee of 16 annas= 2s. (about).

NAMES oF FRUITS: H. R., Tulue Hill. Of those sent Dutch Mignonne, Claygate Pearmain, and Sturmer Pippin are true and correctly named. The Apple labelled Northern Spy is Harvey's Wiltshire Defiance. Reinette du Canada is so much decayed that we cannot be quite sure of it; very doubtful.

Reinette du Canada is so much decayed that we cannot be quite sure of it; very doubtful.

NAMES OF PLANTS: A. B. 1, Imantophyllum miniatum, We cannot name the Azaleas.—R. P. B. Dendrabium finibriatum, if evergreen.—IV. M. G. 2, Narcissus nanus; 1, 3, and 4, Dutch varieties of N. polyanthus.—R. McK. Acacia dealbata.—H. J. R. Cattleya Triance, a fairly good variety. The Dendrabes are apparently forms of D. lituiflorum, of which species Freemanni is a variety, and a much better one than either of the flowers sent.—T. Cornelius. Gomezarcispt.—K. T. 1, a Rondeletia, which we are unable to identify—what is its bistory? 2, Adiantum—send again with fruit; 3, Begonia, which we cannot name—is it not a hybrid? 4, Acacia Ricesana.

PEARS, PRONING: H. R., Tulk Hill.—The fruit-spurs stand too thickly on the branches. Cut some clean away, so that the remaining ones are at 8 inches apart. Reduce the number of wood-buds also in each spur by euting the shoots or secondary spurs clean out at their bases—so far for the winter work. In summer you can prevent great quantities of twigg growing to any size b keeping them pout allow one or two shoots on each spur to grow at fall length till the

second week in August. Then these full-length growths can be cut back to 6 inches, more or less, according as the habit of the sort is either long or short jointed: this will usually cause the formation of buds at their base, in which furit-buds will be in the greater number. If the spurs should be very old cut them all away, leaving the branches quite smooth; in the next summer great quantities of shoots will appear, from which you can select your new spurs, removing what are not wanted in the month of June early. In your soil, which is heavy and wet, trees will require shallow planting on impervious bottoms of rammed asbes, or chalk, and should stand rather on mounds than on the level. Your fruit was of fair size, but was either picked too soon, or failed to ripen thoroughly. With regard level. Your fruit was of fair size, but was either picked too soon, or failed to ripen thoroughly. With regard to the time when the effects of root-pruning, &c., become noticeable, results are mostly to be looked for in the second season after; although diminished luxuriance will be seen the first season, it being then that fruit buds are formed that carry fruit in the second year. Pigou rouge is, perhaps, like many other foreign kinds, not so good here as abroad.

toreign kinds, not so good neer as abroad.

PHYLLONERA CERTIFICATE: Phyllosetra. There are no printed forms to be obtained, so far as we know. Copy out the form published in our last, and attest it before the mayor of the nearest town. An ordinary magistrate will not do. Consult also the nearest French coosal as to what port your plants should be sent to, as it is only through certain ports that plants can now be forwarded.

can now be forwarded.

SCOTCH First: C. T. The peculiar growth, or "sport,"
you send is like that from which the Clan Brassilian
and other similar dwarf varieties take their origin.
We do not think that in this particular case the
appearance is due either to insect or to fungus. The
'bexenbesen' is due to a fungus growth of quite a
different character. We have seen in Switzerland
forms like that you send, both as branch sports and as
seedling plants on the ground.

SEEDS.

SEEDS.

LONDON: Fib. 27.—There is now a steady demand for field seeds, under which the moderate stocks held are getting into narrow compass. Cable quotations for American Red Clover seed come somewhat higher, whilst Continental offers are by no means pressing. Choice home-grown seed comes forward less freely. For fine white a further advance must be noted: superfine samples are exceedingly scarce. Alsike and Trefoil are both dull of sale. Spring Tares move off freely at unchanged rates, In bird seeds there is no quotable change. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

At Mark Lane on Monday good white English Wheats ruled very firm; some descriptions of foreign red Wheat tended to harden in value, whilst quotations otherwise were study. By the word of the sale, but former rates steady, though tended to harden in value, whilst quotations otherwise were study. By the word of the sale, but former rates steady, though transactions were on a small scale, Beans and Peas showed unaltered value. Lentils tended against the buyer. Maize fully supported Fridny's rates, and on the week round corn was 3d. to 6d. dearer. Oats realised a further advance of 3d., making the rise 6d. to 9d. for the week.—Wednesday's trade, at steady rates. Flour met a dull sale, without quotable alteration in value. Barley was steady, Beans and Peas unchanged, and Oats were again higher.—Average prices of corn for the week ending February 22:—Wheat, 36d. 11d.; Burley, 31s. 10d.; Oats, 31s. 5d.; For the corresponding period last year:—Wheat, 41s. 9d.; Barley, 33s. 5d.; Oats, 21s. 7d.

CATTLE.

At the Metropolitan Market on Monday rather a better tendency was noticeable in the beast market at the opening, but it did not result in any quotable advance. Danish ranged from 45. 65. to 55. 44. Sheep met a dull sale at the recent decline. Lambs were dearer, at 85. to 85. 44. Frime calves were very scarce, and inferior not in request. Figs met a duil demand.—Quotations:—Beasts, 35. 84. to 54., and 55. 45. to 55. 104.; tolsves, 45. 84. to 65. 104.; sheep, 55. to 55. 85., and save no fresh feature in the trade. Fresh supplies were short but sufficient. Both beasts and sheep moved off at the prices quoted above. The demand for calves was steady.

Tuesday's Whitechapel market report states that trade was very quiet and prices as follows:—Prime old Clover, 95. to 10.5x; inferor, 6o. to 75.: Prime second cut, 90. to 10.5x; inset meadow bay, 80. to 85s; inferior, 6o. to 75.: Prime second cut, 90. to 65c; and straw, 28. to 37s, per load, 700. To 65c; and straw, 28. to 37s, per load, 700. Thursday there was a moderate supply. Prime qualities were in better demand, and prices remained about the same. — Cumberland Market quotations:—Superior Clover, 105s. to 112s.; inferior, 7os. to 84s.; and straw, 32s. to 38s. per load.

POTATOS.

The Borough and Spitalfields Markets reports state that moderate supplies were on offer, and met a quiet demand as follows:—Magnum Bonums, 80, 10 90,; 10 80;; [Champions, 70, 10 90; [Victorias, 60; to 70, per ton.—The imports into London last week consisted of 1103 bags from Hamburg, 100 Shanghai, and 90 bags 100 sacks and 69 packages from Poulogne.

COALS.

COALS.

The following are the prices current at market during the week:—East Wylam, 15x.; Ravensworth West Hartley, 14; 9d.; Bebside West Hartley, 14; 9d.; Walls End-Hetton, 16x. 6d.; Hetton Lyons, 15x.; Lambton, 16x.; Wear, 15x.; Hulam, 15x. 3d.; East Hartlepool, 15x. 9d.; South Hartlepool, 15x. 9d.; Thornley, 15x. 9d.; Tees, 16x. 9d.

Government Stock.—Consols closed on Monday at 101½ to 102 for both delivery and the account. Tuesday's final prices were, 101½ to 101½ for both the account and delivery. Business left off on Wednesday at 101½ to 101½ for the account. Prices on Thursday closed ½ higher for both account and delivery.

CANNELL & SONS' CRAND NEW PRIMULAS.

PRINCESS OF WALES, Delicata, and Lilacina. It is a well known and admitted fact, not only by the thousands who have seen our several houses (too feet each) devoted to their control of the property of the pr

The Gardeners' Chronicle, January 13, 1883.
"Primula 'Princess of Wales' (Cannell & Sons) is an excellent free bloomer that pleases everyboy; it cannot be too highly recommended as a decorative variety."

DELICATA (Fern-leaf).—The most charming and Invely nik or deep coloured Maiden's Blush ever offered, is one of our cedlings of 1830, and is pronounced by all a splendid acquisition. Seeds, 22. 6d. per packet. First-class Certificate.

LILACINA.—Another of our grand hybrids. When seed growing, with its bold strong heads of bloom, it attracts everyone; although it has not been awarded a Certificate, it is the best and the most distinct of that pleasing colour ever seet out. hest and the most distinct Seeds, 2s. 6d. per packet.

SWANLEY RED.—First-class Certificate.—Colour nearly equal to a Scarlet Geranium; caused quite a sensation, and sold better in the market than any other variety, 2s. 6d. per

SWANLEY PURPLE. — First-class Certificate.—A most brilliant colour. 25. 6d. per packet. SWANLEY WHITE.—First-class Certificate.—The purest and much the best white. 2s. 6d. per packet.

THE QUEEN.—First-class Certificate.—Very much the largest and finest white, slightly tinged pink. 25. 6d. per packet.

MARCHIONESS OF LORNE. — Similar, 2nd in some spects equal. 2s, 6d, per packet.

MARQUIS OF LORNE .- The best carmine. 25, 6d. per

NEW INSECT MANURE,

from China, Russia, and Japan.

INTRODUCTION.

INTRODUCTION.

A friend of the proprietor's, which travelling through certain parts of China, Russia, and Japan, was struck whith the luxuriant and fir riferous growth of the plants and flowers there. He naturally put it down to the climate and soil, but was surprised to find that it was mostly due to the natives using the dead of sikly for a masure. A rangements were at once mode for the collection and importation of a large quantity, which has been done. It is now prepared in a proper state for the English plant growers to use.

Results of Analysis of the New Insect Manure.

VINES AND VINE CULTURE.

By ARCHIBALD F. BARRON,

rintendent of the Royal Horticultural Society's Gardens. Opinions of the Horticultural Press :-

The Journal of Horticulture says:—
"It is the most complete, and it will be accepted as the standard work on the Vine."

The Gardener's Chronicle says:—
"It is emineatly practical and useful."

"It is emmoetly practical and useful."

The Garden says:—
"It is undoubtedly the most exhaustive volume upoo Vinces and Vinc culture ever published."

The Gardeners' Magazine says:—
"It will certaioly take, and probably keep a leading place in the class of literature to which it helongs."

The Educate of Pomological says:—
"The Power of Pomological says:—"

place in the class of literature to which it helongs."

The Finit and Pomologist says:— There is to solve to be found in our language so of Grapes."

The worker to be found in our language so of Grapes."

The Midland Counties Herald says:—

"The whole subject is dealt with exhaustively and authoritatively in plain, expressive, and singularly concise language."

Foundation of the County of th

The Irish Farmers' Gazette calls it —
"The most complete work of its kind that has ever been issued from the British Press."

NOW is the TIME to PLANT CARNATIONS.

TWO NEW VARIETIES.

MARY MORRIS.—One of the most valuable of modern introductions. Of a strong, vigorous habit, producing monstrous flowers, often 3½ inches in diameter, of an attractive deep rose colour. Has been awarded a First-class Certificate.

First-class Certificate.

WHITE CLOVE "GLOIRE DE NANCY."

—Without question the finest White Clave ever introduced. It has a very robust habit, like that of the did Crimson Clove, and produces, in the greatest profusion immense sized flowers, which are pure white and deliciously Clove-scented. Has been awarded a First-class CAT criment, containing fuller descriptions of the above, with a vest number of other choice Carnations, as well as every other section of HARDY FLORISTS FLOWERS, is now ready and shall be sent free to all applicants.

SPRING CATALOGUE

KITCHEN GARDEN and FLOWER SEEDS, GLADIOLI, IMPLEMENTS, &c., for 1884.

Is now Ready, and may be had, post-free, on application.

PEA, "NEW," PERRY'S "EXCEL-LENCY."

A splendid distinct main crop Winkled Marrow Pea, great ment. Is of a robust constitution, and habit very branching, roowing about 6 feet high, with pods of a medicative cach containing eight or nine large Peas of a deficious flavour. Very productive. In sealed I pint packets, each 3s.

POTATO, "NEW," OOLE'S FAVOURITE.
This variety is distinct from any other yet sent out, a remarkably heavy cropper and good keeper, showing no signs when
ever of disease, and for exhibition purposes stands unequalled.
Is a Kidney, and classed amongst the second early varieties.

Price for Pound, 11.

PERRY'S IMPROVED BANBURY ONION.

Acknowledged to be superior to any other type of White Spanish Onion. Possessing a fine shape, bright yellow skin, and mild flavour, and has been awarded numerous First Prizes in competition with all the popular kinds in cultivation. Per packet, 1s.

COLLECTIONS of VEGETABLE SEEDS.

These Collections contain only Seeds of recognised merit, proportioned to suit large or small gardens, all equally choice in quality. For detailed list of contents, see Catalogue.

arters! NEW FLOWE

CARTERS' CALCEOLARIA, Golden Princess.

Awarded First-class Certificate, Royal Horticultural Society-The finest Vellow Calceolaria in cultivation. "The blooms exhibited measured 3 inches in breadth."— Gardeners' Chronicle.

Price, in sealed packets, 2s. 6d., 3s. 6d. and 5s., post-free.

CARTERS' LOBELIA, Prima Donna.

" A CRIMSON-MAROON LOBELIA."

"A CRIMSON-MAROON LOEELIA."

Awarded First-class Certificate, Koyal Horticultural Society,
July 10, 1883.

No modern introduction to to the world of Flora has received
a heartier welcome than was accorded to this charming
nevelty when placed before the Committee of the Royal
as well as other Horticulturists who have seen Lobelia
Prima Donna, have pronounced it to be a gern. In thabit it
is very compact and dwarf, whilst the rich velvety crimason-maroon flowers— equal in size to those of Lobelia
price, in section of the property of the control of the control
are effect that is at once most usique and beautiful.

Price, in sealed packets, 21, 66, and 45, per purcket. Price, in sealed packets, 2s. 6d. and 5s. per packet.

CARTERS' NEMOPHILA

atomaria atro-cœrulea.

Awarded First-class Certificate, Royal Horticultural Society, After years of anxious care and selection we have succeed in fixing the beautiful rich pupish-blue in this charming novelty. The colour of the flower is a deep ultramarine, pure white centre, with a zone of black-purple. Price, in sealed packets, 11.6d., 22.6d. and 32.6d., post-free.

CARTERS' New SWEET PEA. Adonis.

The bright rosy-carmine blossoms of this distinct novelty contrast most pleasingly with the pure white, scarlet and other decided colours already in cultivation.

Price, in sealed packets, 1s. 6d. and 2s. 6d., post-free.

CARTERS' NEW PRIMULAS. THE HOLBORN GROUP.

Awarded Bronze Banksian Medal Royal Horticultural Soc. Awarded Bronze Banksian Medal Royal Horticultural Sce.
We have lately raised a section of Primulas—unique alike
for the novelly of colouring, compactness of habit, and substance and size of flower. The better to distinguish our
stance and size of flower. The better to distinguish our
we have formed then into a section designated "The
Holborn," and the group will breafter be dentified with
that appellation.

At the R. H. S. Meeting, Jan. 14, 1879, SUTTON & SONS received a SPECIAL AWARD of the SILVER BANKSIAN MEDAL for their magnificent display of PRIMULAS.

THE QUEEN'S SEEDSMEN READING, BERKS.

Gardeners' Chronicle.

SATURDAY, MARCH 8, 1884.

THE SEAWEED HARVEST IN JERSEY.

THE whole of the island of Jersey is encircled by a continuous chain of granitic rock, more or less exposed at low-water, and more or less distant from the shore. rocks, the bugbear of the local navigator, rendering, as they do, his harbours so difficult to approach and so unsafe to move in, are to the local agriculturist "ports and happy havens," so to speak, for upon them grow perpetually and luxuriantly the seaweeds with which year after year he fertilises his lands, and which, under the old Norman-French name of vraic, he so generally and freely uses.

Etymologists trace the root of the word to the Arabic word warak, meaning the leaf of a tree; from warak they derive the old Latin nouns varescum, or variscum, signifying shipwreck; to either of these bases they go for the French word varech, which stands in that tongue for seaweeds, or for wrecking at sea; vraic is but another and more modern spelling for varech, and, therefore, implies, say these experts, "leaves torn from the rocks and cast upon the shores," as it also denotes ships subject to the same calamities. The argument is ingenious if nothing more. Need it be said that our own once common word wrack, for wreck, and the still used one wrack, for marine algae, have the same parentage as vraic?

This vraic, then, consists chiefly of plants of the genera Fucus and Laminaria, with a few others sparsely mixed with them. The Fucaceae are composed of F. vesiculosus, F. serratus, and F. nodosus. The Laminariæ are L. digitata and L. saccharina, and the other much less abundant kinds are certain sorts of Sphacelariæ and Ulva. The Fuci grow upon the rocks, from which at certain seasons and under certain restrictions, which we shall presently hint at, they are cut, forming what is technically called vraic scié; the Laminariæ, with, more over, some Fuci and other algæ, are drifted on shore from outlying reefs in the Channel, or even from the Atlantic Ocean, and for this reason go by the name of vraic venant or venu. Upon this flotsam and jetsam we shall also touch. Rich in many of the salts of potassium and sodium are most of these seaweeds; the Laminaria saccharina has been found to contain in every hundred parts of its soluble ash no less than 60 per cent. of various compounds of these bases, and the Fucus vesiculosus has yielded 51.49 of similar ones from an equal quantity of its ash. Free sulphuric acid iodine, calcium, and potassium also exist minutely in almost all of them, and in the simply dried weeds the percentage of organic matter is from 70 to 83 per cent. But we may add, that it has been found by a local experimentalist that at different seasons of the year the quantities of organic and inorganic matter materially differ, and that certainly in the Fuci used in Jersey for manure the summer cuttings are more abundant in mineral fertilisers than are those of the spring.

Now, as it so happens, the soil of Jersey, and indeed of the Channel Islands generally, is singularly deficient in lime and other earthy salts, and this want was recognised even in

those bygone times when agricultural chemistry was in its infancy. Then by a sort of happy-go-lucky "find" the worthy islander discovered that the seaweeds springing up so thickly about him, and thrown upon his beach by stormy winds, were the very things he needed to supply the default in his land. So he set to work to cut and to gather, and what he did centuries ago he continues to do in the present day. Quaint Mr. Falle, chaplain to William III., and the historian par excellence of Jersey (1694), alluding to this want of "chalk-lime and marle in the island, says, "but Nature has supplied us with what fully answers the end in husdandry, It is a weed, but a weed more valuable than the choicest plant cultivated in our gardens, and the vast and amazing chain of rocks that environs our island is the grand garden of the vraic." Nearly 200 years have slipped away since this divine said his say; the "chalk-lime and marle," to repeat his words, are still non inventi in the ground, and the vraic is still its staple fertiliser; but its fertilising properties are now added to by phosphoric and ammoniacal composts; and where the Jersey farmer wants lime he will not trust to his Fuci or his Laminariæ to get it from.

The vraic venu consists mainly of the Laminariæ. Storm-waves have torn them forcibly from their beds, and brought them shorewards, where they become any one's legitimate property and right of capture at any time or at any season. So, after the godsend of a heavy gale, the fishers for vraic venu, armed with large wooden rakes, are many and eager. But with the vraic scie-the cut weeds-it is quite another matter. This must be cut with a sickle from the gardens of the wrack, as Mr. Falle words it, cut under certain legal permissions, emanating twice a year-in spring and in summer-from the Royal Court, and then only for a definite number of tides, cut between certain hours, and cut under certain agricultural conditions. All these are too numerous to detail, but woe betide the delinquent, or the poacher upon the vraic preserves, for fines, never under five pounds, and mounting to as many as fifty, await him. Until, therefore, Pabandon du Varech, as the law styles it, is announced publicly and legally, touch it, we repeat, who dare! And even when the permitted harvest is going on, there are many salutary restrictions as to precedence, proprietary, seignorial and parochial rights to be religiously complied with before the general oi-polloi swoop, and disposal can be made. This cutting and gathering is a very picturesque scene, and is worth a word of outline. At low spring-tide the reapers may be seen by scores, a mile or two from the scaboard, cutting and shearing where the crops are heaviest. Carts having been dragged through sand and slush soil, over low reefs, by pools, and other impediments, to these busy spots, and loaded-loaded to the utmost of horse-powerreturn in long strings of Indian file to the shore, thence to different farms, the water streaming from the dripping algae. This waic will sell for 10s. and more per load of over 1 ton, whereas the drift vraic may be bought at from 2s. upwards, according to the distance it is carted from the shore.

The vrate sett of the spring cutting now going on is generally applied wet as it is to all grass and pasture lands, and left untouched to decompose and soak in. It seems in this condition to render the grass crisp, tender, and highly palatable to cattle. The weeds of the summer cuttings in July and August become available for roots of sorts and again for berbage.

The drift wrack—vraic venant, gathered just now and a little while back—is ploughed deeply into the fields for Potato crops and general gardening purposes; later in the season, say after April and until August, it will be collected, every scrap of it, by cottagers

along the shores, dried, stacked, burnt as fuel, and the ash sold to the farmers as a top-dressing for corn lands.

It will take from 10 to 12 tons of vraic to fertilise as richly as the Jerseyman does fertilise an acre of his ever-being-nu ised ground, but besides vraic some small proportions of artificial manures will be required to produce the heavy crops he habitually calls upon his land to bring forth.

It is said that, excepting the Faroe Islands, seaweeds are more extensively used in Jersey than in any other part of the world for agricultural purposes. H. L. C.

DENDROBIUM SIGNATUM, n. sp.*

This is a good deal like Dendrobium Bensoniæ. The old stem is rather compressed and furrowed, yellowish. Inflorescence at present one-flowered. Chin very blunt-angled. Sepals ligulate acute. Petals broader acute, both reflexed, lightest ochre-white to white (no doubt white when opening). Lip shouldered at the base, being nearly square and narrow, and suddenly enlarged; in the middle is a triangular abrupt body, blunt at the sides. sulphur coloured, with a light longitudinal line at the base, in the situation where in some species velvet is to be seen. The disc is adorned by a broad transverse radiating brown blotch, and on each side of the basilar part there are four similar brown lines, going out nearly at right angles, and running, of course, nearly parallel. The column has two small apiculi at the top, and angles at the side of the stigmatic hollow; it is light green with some mauve longitudinal lines under the stigmatic hollow. The circumference of the lip may best be compared to that of Dendrobium nobile. For this neat novelty I have to thank Mr. W. Bull, who has introduced it from Siam. H. G. Rehb. f.

ODONTOGLOSSUM WILCKEANUM SULPHUREUM,

A grand new variety, of the finest sulphur colour, with a few red blotches and lines on the lip and column, and one or two red blotches on the lateral sepals. The sepals and petals are much elongated, and the whole flower is one of the most striking I ever saw in an Odontoglossum. There was sent at I to same time a remarkably glorious specimen of O. Wilckeanum albens. I received these fine things from Mr. Ch. Vulysteke, Loochristi, Ghent. H. C. Rebb. f.

Dendrobium superbum (Rehb. f.) var. Burkei, n. var.

An unusually fine white-flowered variety with two light blush rose cheeks on the base of the disc of the yellowish-white lip, and some purple on the column. It has the usual Rhubarb perfume. It was kindly sent by Messrs. James Veitch & Sons, and is dedicated to its discoverer, Mr. Burke.

It is well known that the Dendrobium macrophyllum and macranthum of gardeos (Sir William Hooker and Dr. Lindley) belong to this, but that Achille Richards' homonyme species are of prior date. H. G. Rehb. f.

DATE PALMS,—As an instance of the time Date Palms require to develope into fruit-bearing trees, says Mt. Prestoe in his report on the Trinidad Botanic Garden, "I might mention the flowering and fruiting of specimens planted out by me in 1869 from tubs in which they had grown—having been small plants in Bamboo pots in 1864—about twenty years. Their stems are now 12 feet high, having magnificent heads, large bunches of fruit having been produced last year."

OUTDOOR CAMELLIAS.

A CORRESPONDENT writes from a southern county: "The Primroses and Camellias outdoors are blooming beautifully." We have Primroses in abundance. especially the garden hybrid, or various coloured kinds, within easy distance of the metropolis; but of outdoor Camellias few indeed. Really it is exceedingly difficult to induce gardeners, or even their employers, to believe in the hardiness of the Camellia, for, treated ever since its introduction from Japan as a greenhouse plant, it is still in the majority of cases regarded as tender and needing house protection. Some few, very few, however, have boldly planted Camellias as though they were hardy shrubs, and have been for their boldness amply rewarded. Others less daring have planted against walls. At Chiswick the Camellia does well against a north wall, but in other localities we have seen grand trees against south walls, not so much that the plants needed the warmer aspect as that in such positions the summer wood is more fully matured, and free blooming is promoted.

Some of the best examples of outdoor Camellias in the kingdom are found in Mrs. Crabbe's beautiful garden at Glen Eyre, Southampton, respecting which much has been said from time to time. There not only do they thrive splendidly on walls, getting no protection, but some form noble shrubs, standing out in masses and singly, and literally growing as freely as do the Rhododendrons. Timorous persons hesitating to plant out Camellias should visit Glen Eyre, and they would see the shrubs there, not merely in warm positions, but in cold ones also, and the pleasuregardens, chiefly look east, so that they are at times swept by fierce cold winds. Still the Camellias with the lady of Glen Eyre, or with her estimable gardener, Mr. Stewart, would soon dispel many illusions respecting Camellias, indeed Mrs. Crabbe insists that they are even hardier than the common Laurel-that, unlike that shrub, the summer growth of Camellias is not made till the frosts are past, whilst the ripened wood of the previous year is far too hard to be injured by cold. 'Tis true heavy rains, sleet storms, rough winds, and white frosts may, to some extent, damage the blooms, but then, what outdoor flowers are there that will not suffer also from the same causes?

Appley, in the Isle of Wight, is no doubt a peculiarly favoured spot, through having a north-eastern aspect, and open to the sea. There Camellias thrive finely in beds, and are now in bloom. It will of course be said, that so much success is due to the position, and it may be true, but still, how much of it is due to boldness? The admirable way in which other shrubs grew doubtless led to the planting-out of the Camellias, but really there are myriads of gardens in the kingdom perhaps even better favoured for soil, and quite as well for position as either Appley or Glen Eyre, where Camellias will thrive equally well if planted out. That the plants like a black peaty soil there can be no doubt, and it cannot be too deeply worked, and, if needs be, made. The chief thing in outdoor culture is patience, for the absence of it is the rock on which many would-be cultivators become shipwrecked. The Camellia is at all times a slow grower, but is specially long in attaching itself to the soil; no doubt this arises from the fact that in most cases the plants put out are those which have been for several years in pots, the roots of which are cribbed, cramped, and distorted out of all natural form, and in a most unfit condition for planting out. No doubt we want Camellia nurseries where the plants are grown from the first in beds where in winter, whilst in the earlier stage of growth, they may be protected if necessary, but yet left when wanted with clusters of roots free and full of fibre.

It is almost certain that where Rhododendrons and other American plants do well Camellias would do well also. As a rule they do not seem to appreciate hot positions, because burning sunshinesometimes produces scald. At Glen Eyre the splendid trees on the south walls have high trees just in front of them, breaking the force of the sun in the summer months. Of course, when out in beds and borders the free play of air around them materially protects from excessive heat. Established Camellias outdoors are in the spring marvellously floriferous, large plants producing blooms of beautiful quality literally by bushels. X. [Camellias may flower freely enough in some of our southern and western counties, but near London at any rate we cannot from personal observation recommend outdoor cultivation of these shrubs. ED

ORCHIDS AT BIRKDALE, SOUTHPORT.

NONE who have watched the rise and progress of Mr. R. P. Percival's collection at Clevelands will hesitate to accord to that gentleman high honours for the important part he has played in assisting to simplify and popularise Orchid culture. Commenced but a few years ago with the intention of growing only really good and showy things, and mainly from fresh imported plants, the original scheme has in most cases been adhered to, and with what good result the clean and sturdy condition of the plants offers the best of evidence. The desirable end has been secured by Mr. Percival in a manner which it would be well for all commenciog Orchid culture to imitate, viz., by studying the reputed knotty points in the culture of each section before taking them in hand, by considering well the climatic and other influences to which they are subject in their native habitats, and by seeking information from all who are likely to be able to give it. In this last matter, while ever ready to give others the benefit of his experience, no member of the Scotland Yard brigade could be more persistent than Mr. Percival. Not always, however, does he act on the information given—ill would it sometimes fare with his pets if he did; but whenever any of those startling and improbable theories which we often hear is brought before him it is received, as it should be, with the proverbial grain of salt, and it is only credited for what it is worth when weighed with the general evidence on the same point; and in all his deliberations and the carrying out of his plans he has an able and enthusiastic assistant in Mr. George Beddoes.

True to its season each section of Orchids furnishes its floral picture, each in its turn being the frontispiece to the lesser illustrations, but these are at all times so numerous that were the main display absent enough would be found to admire. At present the show of Cattleya Trianæ is the pièce de résistance. The principal Cattleya-house is in three divisions, and the first of these (25 feet by 20 feet) is filled with C. Trianze in bloom, the effect of the hundreds of varied and gorgeous flowers being of a character impossible to describe and difficult to imagine. The whole of the plants have been imported within the last three years, and so well have they answered the cool and airy treatment which Mr. Percival gives them that it seems impossible that they should ever be able to surpass the condition in which they now are, and yet their owner is confident of annual improvement, although many of the bulbs already measure 10 inches in length, and as at Birkdale they are never content unless the mature growths have burst their sheaths, they are of course stout in proportion. There is not a bad variety in the whole house, and there are not two plants which were not originally derived from one specimen, all bearing flowers exactly alike. The intense bright crimsonlipped kinds predominate, but giving a charming relief to the eye are pure white, pale lilac, and light rose forms, not one of which but would be selected by some one or other as the best in the house, so much do tastes differ where colours and form are concerned.

Some of the plants bear from twelve to twenty flowers each, in a few instances four flowers being on Without a stick or tie each of these grand one spike. plants with its flowers naturally arranged is a beautiful thing to contemplate. Who can wonder at such plants being so popular? A sight of one houseful in bloom to refute the charge that Orchid growing is a mere craze. C. T. Backhousiana with twelve blooms asserts itself in true north country style, its colour is so telling that it is one of the first to catch the eye; a little plant, too, of the Popayan Trianæ, having an elongated and much filled labellum of an intense blood-red, bids fair to grow into a very fine and distinct thing. For the general run of the plants in bloom suffice it to say that they are beyond all praise, and for the general effect some idea may be formed by saying that there are over 650 fully expanded blooms. A fine specimen of C. Percivaliana with three dozen flowers open exhibits it in its proper light. The second divisionis filled with C. Mendelii, C. Mossiæ, &c., noticeable being the Burton Constable C. Skinneri with forty-eight flower-sheaths; and a grand lot of C. aurea, which although only purchased from Messrs, Shuttleworth in June produced a profusion of flowers in November, thirty of them being open at the same time. The third division is filled chiefly with C. Mossiæ, C. labiata

var., and C. Mendelii, and all in the same good trim, and bristling with flower-sheaths as firm as cardboard. One C. Mossiæ in an 8-inch pot has twenty-two flower-spikes, and a C. Mendelii in 16inch pot has tweoty-four. The rest are equally well furnished, and will be sure to give a fine display of blooms.

A word about Mr. Percival's treatment of Cattleys Free admission of air by day, and a diminished allowance at night, regulated according to the weather all the year round; a copious supply of water in the growing season, and a carefully restricted supply (the plants are not allowed to get quite dry) when at rest, and the most open net-like shading, and that to be used only when the sun is out-are his main points, and from a want of a proper knowledge of these points most of the failures of less fortugate growers proceed.

The Lælia-house in the new block promises as good results as the Cattleyas now give. It contains large masses of L. purpurata (one of them having twentytwo flower-sheaths), L. elegans varieties, Cattleya labiata Warneri, C. Leopoldi, C. amethystoglossa, &c. These are treated in much the same way as the Cattleyas in the other range, but still more sunlight is let in on them in summer. In this new block one of the houses is gay with Coelogyne cristata, chiefly of the Chatsworth and Lemoniana varieties, one plant of the latter having nine spikes, and eight flowers on a spike; many Lælia harpophylla, one having nine flowers on a spike; Odontoglossum pulchellum majus, twelve spikes; Cymbidium eburneum, twenty-five spikes; and Coelogyne ocellata maxima, eighteen spikes.

The cool-house leading to the new block exhibits the Odontoglossums, &c., quite up to the excellence of the Cattleyas and Lælias; it is showy with the ever-present O. Alexandræ varieties and O. Pescatorei, with which are mixed other interesting things, such as O. baphicanthum, O. hebraicum, and brighter tints are added by the scarlet Sophronitis, and a fine plant of Ada aurantiaca with fourteen spikes. In this cold house are wintered the varieties of Lælia pumila, which are so successfully grown here; they are as smooth, plump, and clean as one could wish to see them. In summer they are kept in a light, airy house, and are plentifully supplied with water when growing - indeed, they are now kept

The other cold houses all contain some flowers, among which the brilliant tints of the Masdevallias are beginning to give their help, and in one of the divisions there is a great show of O. Rossii majus, one of the plants in an 8-inch basket having twenty-one flowers, and a fine form of Oocidium macranthum. The Odontoglossum vexillarium-house contains large plants of that species, equal in vigour to any in cultivation; many of the growths are 13 foot in height, and, like all the other Orchids at Birkdale, perfectly clean and free from insects of all kinds. Th nopsis are in good order, the leaves large, fleshy, and firm, and the flowers profusely given. Just now the pretty P. Schilleriana supplies the greater part of the flowering plants, but P. Stuartiana and others are also in bloom, and a robust plant of Epidendrum bicornutum has strong spikes. In a quiet corner of the adjoining warm Cypripedium-house a good batch of very healthy Odontoglossum Roezlii are always sending up flowers. The secret of growing this plant is to find out a place where it will do well, and afterwards to let it remain there.

A new house has been arranged for the Vandas, and the Dendrobes now occupy their old quarters in company with the Aerides and Saccolabium. A profusion of bloom is supplied by many specimens of D. Wardianum, D. crassinode, D. Ainsworthii, D. A. roseum, The Phaius tuberculosus, although evidently not yet quite conquered, is sending up flowers, and a fine plant of what appears to be a good form of Phaius Blumei has many spikes of showy flowers. The conservatory is used for resting Dendrobes, each batch as they require removal from the warm house is placed in it. At present it has most of the evergreen Dendrobes, D. densissorum, D. thyrsistorum, D. Paxtoni, D. clavatum, &c., and some fine plants of D. Falconeri, D. Dalhousianum (one with growths nearly 5 feet long), D. nobile, &c. The fine trim in which Mr. Percival's Orchids are, and the pleasure which he evidently gets out of them, should induce others to imitate him by earnestly taking them in hand, and making a pleasure of the study of their habits and requirements.

HYBRID AMARYLLIS.

I COMMENCED crossing the Amaryllis in 1875, but having to leave Lucknow this work was continued by Mr. Ridley. In January, 1882, he kindly sent me some bulbs, descendants of my original hybrids. With these bulbs I hope now to make a fresh start, and branch off, if possible, into new colours and

In the course of my experiments in 1882-1883 I elicited some facts which may not be uninteresting to the students of scientific horticulture.

Ten Amaryllis flowers, in different plants, were tried by self-fertilisation, but all failed.

In 1882 one named Fiesole refused to cross, either with its pistil or with its pollen, and so did several others; while, on the contrary, two others, named Carina and Graziosa, took almost any kind of pollen. The former had seventeen blooms on three scapes in one pot, and almost all set seed; so that from this plant alone I have now upwards of 500 seedlings.

In 1882 I crossed promiscuously to obtain a number of plants to work upon, and only kept a record of the name of the female parent.

In 1883 I crossed more carefully, and ticketed every flower with the name of the pollen-bearing plant. Fiesole, again, had nine of its pistils tried with the pollen of eight different kinds, and all, as before, failed. Its pollen also failed to fertilise five different kinds of pistils.

From these experiments it appears that the following provisional conclusions may be drawn, viz., that the Amaryllis is incapable of self-fertilisation; that, crossed in and in, which I shall call high breeding, they have a tendency to produce mules, which will, as a rule, not cross among themselves, but may cross with their original ancestors, or perhaps with common kinds, with which they have no blood ties.

Mr. Ridley, in a letter written the year before last, informed me that the highly-bred ones in Lucknow did not seed. He attributed this to the rough crossing of the native gardeoers. He added that the common kinds, which were intermixed with the others, produced seed without being artificially tertilised. take it that the pistils of the common ones were so sensitive, that the pollen of the others carried by the wind, or insects, readily fertilised them.

Mr. Barron, in his book on the Vine, if I remember rightly, stated that he found highly-bred Vines crossed with wild or common kiods gave more vigorous and better results, than when crossed with other highlybred varieties.

In my experiments I found that some highly-bred Amarylis were all but barren, when tried with other highly-bred kinds; but crossed readily with a common kind. In 1882 I had three bulbs of a common pale orange expanded Amaryllis; they had no merit, either orange expanded Amarylis; they had no merit, etner of colour or form. I was going to put them aside, as worthless; one day, however, I thought, by way of experiment, I would try them with the pollen of the highly-bred kinds, and, to my astonishment, every pistil was fertilised and produced a full capsule. The following was the result. pistil was fertilised and pro-following was the result :-

Orange Expanded-No. 1.

- × Dilfarèb, 53 seeds—28 germinated, 8 perished. × Radha, 52 seeds—16 germinated, 3 perished. × Fiesole, 38 seed—56 germinated, 1 perished.

Orange Expanded-No. 2.

- × Bonavia, 54 seeds—38 germinated, 5 perished. × Diifaich, 70 seeds—43 germinated, 8 perished. × Radba, 3t seeds—18 germinated, 3 perished.

Orange Expanded - No. 3.

× Ditfareb, 42 seeds—2 germinated and lived. × Fiesole, 19 seeds—3 germinated and lived.

It will be seen that even Fiesole, so refractory when tried in every way during two seasons, fertilised this common kind, and although only pine seeds ninated, for Fiesole this is a wonder.

Of course there are exceptions to every rule, and Carina and Graziosa, although highly bred, may be such. While, on the one hand, there may be utter barrenness of pistil and pollen, there may be, on the other, complete sensitiveness to foreign pollen, as in Carina. No doubt there may be also intermediate

I should say, if one wishes to propagate by seed some fine character of a highly-bred Amaryllis, he is more likely to obtain *viable* seed by crossing it with one of the original wild ones, or with one but slightly one of the original wild ones, or will one but signify removed therefrom, using the latter as seed-bearers. Of course, where one has already found, by experiment, that a highly-bred individual is prolific, the case is different, and the knowledge thus obtained is very useful. E. Bonavia, M.D., Etawah,

(To be continued.)

308

THE PICOTEE, -This is a more modern production than the Carnation, and although they are doubtless derived from a common parentage, they are quite distinct in their markings. At the time Hogg's book was published the Carnation was divided into scarlet flake, pink-flake, purple-flake, scarlet-bizarre, crimson-bizarre, and purple-bizarre. The Picotee, he says, "is distinguished by its spots," but except the yellow ground varieties, he does not give the names of any. Edged Picotees were known and grown at that time, and it was stated by a contemporary writer with Hogg that the qualities aimed at were the same as in the Carnation, except the colour; "those flowers which are free from blotch or stripe down the petal, below the coloured edging, are greatly to be preferred to those which are marked and pouncy." The pure white ground colour was also greatly desired. Within my own knowledge the improvements in the Picotee has been very great. New varieties have not been sent out very freely, but those that have been distributed are well ahead of the older varieties. red-edged section come first, and I find Mr. Turner ren-eigen section come may, and a final final rentries is sending out a heavy red-edged variety, named Monarch, raised by the Rev. C. Fellowes; it has, says Mr. Turner, "a heavy red edge, good large smooth petals, and the white quite pure; large and fine." This I have not seen, but if it is as good as Princess of Wales, by the same raiser, it will soon find its way into every collection. Princess of Wales, John Smith (Bower), Brunette (Kirtland), and J. B. Bryant (Ingram), are the best in this class. Of the light red edges Simonite's Mrs. Gorton must stand first on the list; it is a better flower than Violet Douglas, by the same raiser: these two and Thomas William (Flowdy) are the best, Emily (Addis), and Mrs. Bower (Bower) are also superior flowers in this class. Of the heavy purple-edged type, Muriel, raised by Mr. Hewitt, of Chesterfield, and sent out by him in 1882, must certainly be placed before Mrs. A. Chan-cellor for quality, but I find it a weak grower, which Mrs. Chancellor is not. Mr. Dodwell has raised and sent out Purple Prince this season; it lacks the sent out Purple Prince this season; it has the refinement of the two first-named, but it is a large showy flower, and may exactly suit those who decry pot culture, and trust to the border only for their entire display. We cannot yet omit Zebriua (Lord) from the best six. Lizzie Tomes omit Zebrina (Lord) from the best six. Lizzie Tomes (Dodwell), recently sent out, grows strongly with me, is distinct, and of fine quality. Mrs. Summers, raised by Mr. Simonite, must also take its place in the best six; it has a very distinct broad edge, with pure white ground. With the newer light purple edges I am rather disappointed, and for the last two years Her Majesty (Addis) has been the best. It is a full-sized flower, with broad well-formed petals, having a fine wire-edge of a distinct colour. Nymph (Lord), Jessie (Turner), Baroness B. Coutts (Payne), Mary (Simonite), and Mr. Tutton (Payne), the last an old flower, not so much known as it ought to be. I have twice seen it first-class with Mr. Turner.

In the heavy rose and scarlet-edged section, Esther

twice seen it inst-class with Mr. Turner.

In the heavy rose and scarlet-edged section, Esther
Minnie, raised and being sent out by Mr. Dodwell,
has a broad margin of rosy-pink, with a clear white
ground. When it first flowered with me I thought it has a broad margin of rosy-pink, with a clear white ground. When it first flowered with me I thought it the finest of all the heavy rose edges. Ada Hannah, if not rather weakly in constitution, will probably be a good addition to this class. I flowered it last year, and fancy it may yet hold a good position; it is another of Mr. Dodwell's seedlings, and was sent out by him last autumn. Mrs. Payne as yet heads the list, but it is not really a heavy edge, being what is termed medium. Mr. Turner's new variety, Constance Heron, did not turn out quite as well as I expected last year, but it has been so fine with Mr. Turner that we must look for it to hold the highest place in the section to which it belongs. It is of the Dhadiah or Rosy Queen type. Mrs. Webb, heavy-edged scarlet, is a very large flower, shown remarkably well in Mr. Turner's stands last year. It has a good white ground, with a heavy scarlet edge, and is one of the best flowers for the back row in a stand. stand.

Light rose-edged flowers are not sufficiently plenti-

Light rose-edged flowers are not sufficiently Plenti-ful. For exhibition I depend upon Mrs. Alleroft (Turner), Estelle (Feilowes), and Ethel (Feilowes). There are two new ones being sent out this year— L'Elégante (Dodwell), a seedling from Ann Lord, with all its properties except colour. Dorothy (Feilowes), being sent out by Mr. Turner, is said to be of good quality. I have no personal knowledge of either of them, but new additions are so necessary that growers will be glad to try them. J. Douglas.

The Arboretum.

PICEA OMORIKA (THE SERVIAN SPRUCE) .- In our volume for 1877, April 14, and again May 19, p. 620, we called attention to the remarkable Spruce Fir discovered in the mountains of Servia, Bosnia, and Montenegro by Dr. Pancic (misspelt Paucie in our first article). Omorika is the Servian name for the tree, and Dr. Pancic, after consulting with the late Professors A. Braun and Karl Koch, published it as distinct. It forms a tree of the first magnitude, with short braoches, forming a pyramidal crown, and yields a valuable timber. The information we published was chiefly derived from articles by Dr. Bolle and Professor Reichenbach, and in our second article, above

Section of leaf much magnified; bud × 3; seed :: 2; leaves front and back × 2.

quoted, we copied the full description given by Dr. Pancic. It is, therefore, unnecessary to repeat what is there said, and there is the less necessity for so doing, as, thanks to the mediation of Mr. George Nicholson, we are now able to lay before the reader illustrations of this new Conifer, which will tell their story better than the descriptions. Further, those who are interested in the matter will soon be able to gratify their curiosity, as we believe Messrs. Freebel,

FIG. 57.-PICEA ORIENTALIS. Leaves × 2; leaf-section highly magnified.

of Zurich, have succeeded in raising a stock of it. We may, however, add a few details as to the leafwe may, however, add a few details as to the feaf-structure not before made public, and for the oppor-tunity of doing which we are again indebted to material furnished by Mr. Nicholson. The shoots have the "pegged" character common to Spruces, and are, moreover, covered with short stiff hair. The buds are ovoid cooic, dull brown in colour, and invested by ovate-lanceolate scales. The leaves in the specimens before us are flattish, straight or laterally curved, between half and threequarters of an inch in length, linear oblong obtuse face, and slightly flattened near the point; the ventral lace, and signify nattened near the point; in eventual surface is marked by a prominent midrib, on either side of which are lines of stomata. There is no indication of any twisting of the leaf, hence the stomata are really on the upper surface of the blades, as in some Junipers and other plants. A transverse section when

examined under the microscope (fig. 56) shows a layer of hypoderm cells beneath the epidermis, and in vesting the ground tissue of the leaf, which consists of spheroidal cells with undulating boundary walls and with a very slight tendency to form palisade cells on the lower sade, that furthest removed from the stomata. Close beneath the hypoderm, on the lower surface, are two resin canals, one on each side midway between the centre and the margins; each is surrounded by strengthening cells. The central bundle of fibrovascular tissue is surrounded by a well-marked bundle-bath and her, the william phone and the phoem sheath, and has the xylem above and the phloem beneath in the usual manner.

[MARCH 8, 1884.

beneath in the usual manner.

Ficea orientalis, which has been compared with it, has shorter leaves, more acutely pointed and more four-sided in section (fig. 57). The cells, also, which surround the central bundle-sheath are in P. orientalis not globular, but obloog, and radiate from the central bundle on all sides. Their walls are undulated. Hence, then, the superficial appearance, no less than the internal structure of the leaves, is quite distinct in the two species; a comparative examination of which, therefore, confirms Dr. Piancle's view, that he had to do with a previously undescribed species, and not with a form of P. orientalis. Moreover, the cones of P. orientalis are longer and the scales broader than in P. Omorika. As to its value as an ornamental tree or as a timber tree in this country, we can, of course, Omonika. As to its value as an ornamental tree or as a timber tree in this country, we can, of course, at present say nothing, but as a newcomer of very great interest, and one which comes with a good character from its native bome, we doubt not that many will be inclined to give it a welcome. M. T. M.

CRATÆGUS PINNATIFIDA. - Amongst the large number of Thorns cultivated at Kew this species is, as far as growth is concerned, by far the most forward. At present the tender green of the young shoots and At present the tender green of the young shoots and unfolding leaves render it very conspicuous in that part of the Arboretum where the Crategus collection grows. Shoots more than an ioch loog in the last week of February speak a good deal for the precocity of the species, as well as for the bitherto phenomenal mildness of the winter. A tree of Crategus oxyacantha var, præcox (the famous Glastonbury Thoro) beladed et the date above mentioned as if oxive a few cantha var. precox (the famous Glastonbury Thorn) looked at the date above mentioned as if only a few sunshiny days were needed to open its numerous clusters of large well-developed flower-buds. As regards the foliage, however, this tree seemed considerably behind the species named at the commencent of this note. C. pinnatified is a native of North China, Amurland, and the coasts of Mandeburia. Seeds were collected and sent to the St. Petersburg Gardens by Maximowicz and Maack some score or more years ago, and the species is now tolerably widely distributed in cultivation. Two distinct forms appear to occur in a wild state—one a very spiny tree, the other with stem and branches destitute of thorns; to this latter belongs the specimen in the Thorn collection at Kew. A figure of the species, the only one hitberto published, appeared in the Gartenfora for 1862.

DOUBLE STOCKS.

THE question might be asked, Do the fine strains of double German Stocks show signs of deterioration, in so far as the production of fine, full double flowers is concerned? From a pretty general knowledge of the value of some of the Continental Stocks it may be stated, with much truth, that there is little or deterioration in the case of firms who make a leading speciality of these things; indeed, one might fairly incline to the opinion that certain strains show decided marks of improvement. When examining an extensive trial of Stocks of all types and sections last summer, drawn from not one merely but from several Continental houses, it did appear as a charac-teristic of the different types that the flowers were large, full, and finely coloured, and that the percentage of double flowers was a highly satisfactory one. In the case of the autumnal Stocks, which a few years ago had a preponderating percentage of singles, the balance is now reversed, and the double varieties are in the ascendant. The saving of seed with a view to bring about this desirable result is carefully attended to on the Continent. In the case of double Stocks both stamens and pistil are changed into petals; seed cannot, therefore, be had from full flowers in these sorts, and the only resource is to save seed from those single flowers in which a tendency to fulness has commenced by having a petal or two more than usual. There are a great many amateur culti-vators of flowers who think that the seed which produces double Stocks is taken from double flowers instead of from single blossoms. Old cultivators of Stocks had curious notions as to assisting the production of double flowers. It was considered that they

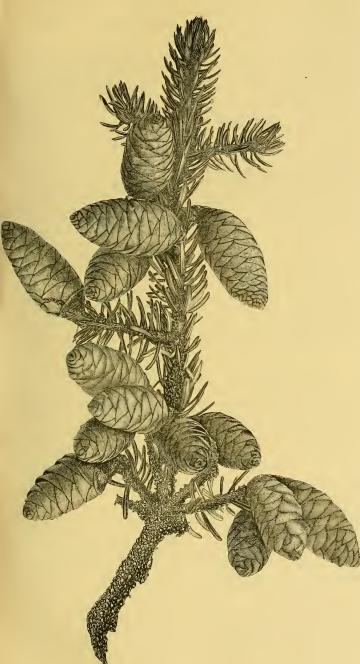

Fig. 58.—Picea omorika, the servian spruce: natural size: from a photograph. (see p. 308.)

would be more liable to be double if the plants are checked first by a deficiency of nourishment, whether of water or manure, and afterwards excited to luxuance by a plentiful supply, and the greater the change the greater the likelihood of success. Oldseed was looked upon as favourable also, and instances are recorded

of old neglected seed, which had been reckoned very inferior when it was fresh and new, coming almost every plant double when a little had been left over and sown when old. So it is held as an opinion that the seed for raising double flowers of almost any sort can hardly be too old, if it will grow

at [all; and]\"[the]\" weak plants, first started and then luxuriated, will be found most successful. The seed should be sown in heat, and the weak plants most cared for. After flowers have once been produced double or full, the habit of coming double will be retained, if kept so by rich cultivation. In looking through old gardening books one meets with similar notions as to producing double flowers in Stocks. Probably many of these fail to meet the test of experience. One thing is quite certain, that a great deal is being done in the way of selection, and this work is rendered all the more careful and necessary by reason of the keen competition which takes place among the leading Continental houses who have a reputation for Stocks.

The Herbaceous Borden.

DAFFODILS.-Mr. Wolley Dod's interesting essay opens the Daffodil campaign in your columns, and is as welcome as the cuckoo, which will also soon be here, if the spring is really upon us. I am always amused with our valued friend's hunt after doubles and their origin, but in this paper he carries his theory farther than usual, 11e refers to the meadows between Florence and Pisa, where singles and doubles grow together. It is possible, he says, that these Daffodils may have been introduced double from England to Italy! It is certainly possible, but it is improbable. Now, my opinion is that doubles come as seedlings, and may happen any year from any single plant, just as we have recently heard of doubles in Bouvardias, Cyclamens, and Lapagerias. In such a simple flower as a Daffodil the doubles from the same kind would always be similar, wherever they arose. If princeps produced doubles as seedlings they would always have the bicolor mixture in the "monstrous" admixture of crown and perianth segments multiplied; and if obvallaris happened produce a double it would be a self deep yellow, like the Tenby Daffodil, throughout. Messrs. Collins & Gabriel sent out a double Tenby Daffodil last year as a novelty, and I watched for its first bloom with no little interest, but when it arrived it was no Tenby double at all-light primrose and deep yellow segments filled the flower up, clearly indicating a bicolor parentage. There does not appear to be any double Teoby yet, so we can watch for its advent now that thousands are in cultivation, and perhaps the question will be cleared up thereby. It is possible that a double Daffodilis a species having the power of perpetuating its quality by seeds. [?] A double-flowered plant is stronger than a single one, and the double Daffodils are the earliest to bloom and the most vigorous, so that in the struggle for existence a double, if it produced seed, would soon drive out its single cousins, and the whole crop would in time become double. This appears to have been the case with the double white Narcissus in some parts of France, and probably the above is the explanation.

But Daffodils also produce varieties by sports. We had a large bed of N. Horsfeldil last year, all made up of the small bulbs gathered in replanting our Horsfeldil clumps. One of these produced a flower almost white, but still Horsfeldil in shape and peculiarities. This promises to be a new variety by a sport.

The mild season has favoured the growth of N. capax, which promises to be unusually floriferous this season. In our clumps of a dozen bulbs each there are fully three-fourths showing bloom. N. corbularia alba [N. Bulbocodium var. monophylla] is beautifully in flower, and in fact all the rarer Narcissi are showing buds.

N. nanus was earliest, and is everywhere in full bloom; the true N. minor was only a few days later, but it is not so vigorous a plant as N. nanus, than which there is no more useful Daffodil. Mixed with the blue of Scilla sibirica it makes a lovely edgiog to a long border. We have a few stray flowers of obvallaris, princeps, and Telemonius plenus, so we are much later than the South, as I had a large bunch of Daffodils sent from Cornwall tee days ago, Wm. Brockbank, Brockhurst, Didsbury, March 1.

ALFINE RANUNCULI.—Mons. Correvou's interesting note on the Ranunculus of the Alps suggests a few queries, which I hope be will be able to answer. Two of the varieties he named are well known in our English gardens in their double forms, but not at all in their single forms. R. aconitifolius, for example, he speaks of as being unsuitable for the rockery, but in its double form there is no better rockery plant. It is a very interesting plant, and a most popular one. I should like to know if its single form is also good, as to my mind a single white Ranunculus, if its port were as stately, and its habit were as good as that of the "Fair Maids of France," would be welcome in our gardens. Does the double form in the wild state? It was in England appear in the days of Gerard and Parkinson, and is a plant which many country florists make a specialité of, so ready is its sale in our flower markets. At the same time it is not by any means an easy plant to grow. M. Correvon also names R. lanuginosus, the double form of which used also to be a common plant in old-fashioned gardens, but which is now rare. Will he say also if this occurs in its double form, and if it does it would be worth while to compare the genuine plant with that now bearing its name in our English gardens, the identity of which I greatly doubt. R. gracilis never lives over the second year with me. I have had it both from Switzerland and Norway and with like results. R. amplexicaulis is also a very difficult plant to retain. IV. Brockbank, Brockhurst, Didsbury.

FORGET-ME-NOTS .- Some day I hope to obtain in reality that old illusion, a red Forget-me-Not. How di-appointing it has been in all the many years since we have known that charming kind, Myosotis dissitiflora, to note spring after spring plants here and there, and especially old or somewhat weakly ones, giving for a week or two flowers of a lovely rosy hue, that seemed as though they would leave their impress of colour stamped upon all that would come after. Not so, alas ! for presently the natural coerulean tint would come, and then the rose departed for good. Why this particular Forget-me-Not should in its early blooming stage thus show so much red colour is a What is there in the composition of the natural blueness of the flowers that makes red its ground? Is blue after all evolved out of red, with a little violet shading thrown in, or is the Myosotis blue diverse from all others? Certainly with the earlyblooming dissitisfora we seldom get the true blue tint until the sun rides high in the sky, and light is fairly abundant. We have got a beautiful pure white from that variety, why may we not hope for a red one? There is no limit to Nature's sportive fancies where flowers are concerned, and therefore the Forget-me-Not in red, white, and blue, our national colours, can hardly be beyond the range of the possible. The very rich tints sometimes seen in the early red flowers indicate that a red Myosotis would make a striking pot plant, just as the white one is found to be, under glass, exceedingly pure and pleasing. blue never is good at the first, but after it has about half bloomed then it becomes of good colour. Persistent saving of seed from sports that give unusually red flowers might in time give a permanent variety. It is worth trying for because in our early spring flowers we have few of a tint so striking and so desirable. Quercus.

SCILLAS,—I have a few patches of Siberian Squille giving up their rich and welcome blue flowers with the Snowdrops and Crocuses, but, unlike either of these hardy bulbs, the squills do not seem to increase. I think I have about as many roots as there were half a dozen years since, I should very much like to know what is the general experience not only of these common Scillas, but also of the pretty biflora k nd', and also of that newer form (Chionodoxa) so pretentiously styled the Glory of the Snow, Quercus,

PRIMEOSES.—What can be more charming than a big patch of that pretty, early, hardy single Primrose Lilacina? How very early and wondrously it blooms, and how well it thrives. Unfortunately, it is a sparse seeder, but perhaps that arises from constant propagation. Seedling Primroses of all colours seed freely in average seasons. Quereus.

HEPATICAS.—As my experience of Hepaticas somewhat differs from that of your correspondent "M.," p. 283, and as they are favourite plants of mine 1 send you this note. They seed freely with us. [10es the seedling plant present any peculiarity of growth, such as happens in some of its allies? En.] Some years ago, on the advice of a good authority (Mr. Frank Miles), I got a collection of varieties from Van der Swaelmen, of Ghent. This consisted of a number of shades of colour. I collected seed from them, and sowed it in one of our hurdle beds at Wisley, and

moved the young plants to a shady loam mound. They have bloomed this year beautifully, with large flowers of more than usually bright colours. Last week, as the parent plants seemed to be in a rather too low and damp a situation, I took them up to plant in the loam mound. Round most of the plants there were a number of young seedlings. Some of the larger flowers of Hepaticas are more than "modest wee things," especially II. angulosa, of which I believe there are two varieties, one not much larger than ordinary Hepaticas, the other with flowers larger than a halfcrown, and such a showy flower! As to dividing, some time back I bought a great clump of double pink in Covent Garden market, and planted it. As it never flourished I this year took it up, and found hard wiry roots. I broke it up into twenty-three plants, and might have further subdivided it. I have no doubt of their making good plants by next year. George F. Wilson, Heatherbank, Weybridge.

—— I have been very successful for the last five years in growing the double red Hepatica in a garden where previously it had never done well. My plan has been to keep the plants well watered during the summer, and in the autumn to bank up the earth well round the plants, so that the roots should not be exposed, as Hepaticas seem to have a tendeocy to raise themselves out of the earth. I have never moved the plants during the five years. They blossom most freely. E. Swann, Oxford, March 4.

LEUCOJUM VERNUM VAR. CARPATICUM. — Last week I saw a bed of L. vernum—probably containing two or three thousand bulbs—at Messrs. James Dickson & Sons, Newton Nurseries, Chester, and very nearly all of those in flower were twin-flowered and yellow-spotted—the characteristics, I gather, of the above variety. I send you this note because a contemporary describes it as being rare and nearly lost to cultivation, consequently many of the readers of the Gardeners' Chronicle may be glad to know where good bulbs can be secured. It is difficult to say where this batch originally came from, as they must have been in the above nurseries for many years. K.

The Rosery.

Rose Pruning .- Since writing my note concerning Maréchal Niel Rose published last week, I have more closely examined the rods, and find that here and there, but always quite on the under-sides, a few buds have remained dormant. This shows how much more actively the light [or, query, heat? Light, per se, retards growth. ED.] must act upon the buds nearest to it, or else that the rush of sap up the rods is much greater on the upper than on the lower side. I gather, too, from the fact that the base buds nearly all remain dormant, that this flow of sap gathers in strength as it ascends, hence the shoots at the top of the rods are the strongest. It is worthy of note, that of this same Rose the growth on a stout plant rooted inside is not a whit more forward than it is on those with roots outside. What the result would be were the plants forced early I cannot say, but I incline to the belief that the difference would be trifling. No doubt the greater range and freedom of the outside roots more than compensates for the slight additional warmth those within find. We see Roses everywhere cutdoors full of growth, and growers hardly know what to do with them. There seems to be a fear that this early growth will lead to exhaustion of the plants, and that the bloom will later on suffer. That does not at all follow. Probably few will care to prune till the end of the month, and then with roots forced into exceeding activity by the premature growth we now see, the now dormant buds should start with unusual force and vigour, and I have no doubt such will be most growers' experience. To strip off all or even a few of the early shoots, might lead to the undue excitement of the dormant buds too early. Better let them remain as they are till all is safe, then prune hard, and the plant recuperation will be all that can be wished for. A.D.

ROSE SOUVENIR DU ROSIERISTE RANBAUX (Tournal des Roses, February, 1884).—A Tea Rose raised by the late P. Rambaux from Goubault. It is described as of vigorous habit, flowering twice, leaves shining above, leaflets lanceolate, paler beneath, flowers erect, cup-shaped, petals straw-yellow, with the margins flushed with rose; sweet-scented,

Prchid Notes and Hleanings.

PRUNING DENDROBIUMS .- The practice of pruning away the bulbs of Dendrobiums which already flowered must have received its death-blow from the experience published in your last number. Many Orchid growers were prepared to hear of failure, and also of the practice being given up as a bad one, but few, I think, expected to hear such a sudden collapse as stated. The bulbs of Denbrobiums are useful to the plants so long as any vitality remains in them, and it is taxing a plant unduly to cut them away while they can contribute in any degree to the support of the young growths or flowering bulbs, All deciduous Dendrobiums depend on these back bulbs for much of the support the flowers require, and from these bulbs also the young breaks draw the greater part of their nourishment during their early growth. If this is not the case, and these bulbs are taking to themselves nourishment which would otherwise go direct from the root to the young growth or flowering bulb, how are we to account for the shrivelled state in which these bulbs are seen after the flowering period, and the continuance of this shrivelling until the young growth begins to root from the base? I have frequently seen four and fiveyear-old bulbs on plants of Dendrobium Wardianum so much shrivelled during this period that I became anxious for the life of the plant, and but for the strong and vigorous growth of the young break should have believed it dying. These plants were by no means in had health or deficient of root, neither was the compost in a sour or exhausted state. In due time these young growths made roots for themselves, and then began a rapid plumping of the old bulbs. After watching plants go through this process year after year, it is certainly hard to believe that old bulbs are not only useless but detrimental to the plant. Nature herself teaches us to leave them, and Orchid growers must follow Nature as closely as it is possible if they wish for satisfactory results. I have met with several cases of pruning Dendrobiums, but cannot call to mind a single instance of improvement; on the contrary, there are several where the plants are by no means what they once were. The last instance I saw, several plants of D. nobile had got so weak that they could not flower this year, and the knife at once got rid of these useless and unsightly bulbs. Their prospect of flowering next season is not a rosy one, as it will take all the strength of the remaining bulbs, assisted by the roots of those cut away, to make any growth at all this season. Unsightliness is the hook by which unwary Orchid lovers are caught, and they are only too ready to catch at any new theory which promises to rid their plants of this fault. A weak, badly flowered Dendrobium is surely more ugly than a well flowered plant, even if a few old bare bulbs are to be seen. IV. B. B.

THE ORCHID MARKET.—At Messrs, Protheroe & Morris' sale last week specimens of Cattleya Warsce-wiczii delicata realised £9 9s. and £15 15s. each; Lælta anceps Dawsoni, £15 15s.; Odontoglossum mirandum, £5 10s.; Ceologyne Lemoniana, £9 10s. 6d.; Cattleya Triane vars., from £4 10s. to £9 9s.; Phalænopsis Stuartiana, £6 6s.; and Lycaste Skinneri alba, £9 19s. 6d. to £11 0s. 6d. About £10 per flowering bulb seems to be an average price for this plant just now.

WARSCEWICZELIA WENDLANDI DISCOLOR, — Leaves sheathing, narrow, lanceolate, Flowers solitary, 4—5 inches across, segments lanceolate, green, lip ovate cordate, apex reflexed, disc purple, edged with a broad frilled edge. The species is a native of Costa Rica. The specimen figured was grown by Mr. Smee.—Orchid Album, t. 126. The cool end of the East India-house is stated to suit the requirements of these plants.

CATTLEYA MOSSIÆ HARDYANA.—A very remarkable Cattleya, figured in the last number of the Orchid Album, t. 125 (1854). Its segments are lilae in colour, curiously mottled and barred with magenta-purple, with a golden blotch in the throat, the disc striped and with a narrow irregular zone of white edged with a wavy line of violet. This curious variety was introduced from La Guayra, and is said to be constant. The specimen figured was taken from the unique specimen in the collection of G. Hardy, Esq., Timperley, Cheshire.

The Flower Handen.

SHRUBBERIES.-The most important work at this period of the year, and that which requires the most careful attention and skill, is perhaps in the shrubbery; not in transplanting, as this work is always so much better and more successfully performed in the late summer and early autumn months, but where circumstances render it necessary now it should be performed during mild weather only, and with the greatest care, otherwise the failures from the effects of spring frosts, and the equally destructive cold witherng winds acting upon the tender and partially exhausted tissues, will be very great. It is more particularly the thinning, pruning, staking, and cleaning that now demand attention, for upon these annual operations well and properly performed at this season depend to a great extent the charm and beauty of the pleasure-grounds. To endeavour to give instructions how to thin and prune skilfully is perhaps of all things one of the most difficult, simply because they are operations that can be properly learned only by practice and experience. Many there are who think they understand them, but few indeed there be who are really successful practitioners. Nature is un-doubtedly the cleverest and most truthful teacher, and he who studies her ways and follows her examples the most accurately will perhaps commit the fewest mistakes; there are times, however, when circumstances demand an entire deviation from her laws, and then it is that the operator's abilities are laxed to the utmost degree, and from such instances do we too frequently see the most inconsistent, unsightly, and absurd effects. The thinning and pruniog of forest trees, especially if they have been judiciously planted, does not involve, at least in the management of shrubberies, the same amount of care, skill, and periodical attention as do the lesser trees and shrubs. These are very frequently, when first planted, jumbled together in such a dense and indiscriminate manner, chiefly with the object of producing an immediate blind or protection, and with scarcely a thought as to their eventual size and form when developed, and quite irrespective of the general effect they will ultimately produce in shape, colour, and size while in contact with each other, and when compared with surrounding objects. These shrubs are too frequently per-mitted to grow together unthinned and unpruned till every plant or group of shrubs becomes overgrown, interlaced, deformed, and deprived of its natural grace and beauty; then it is that the services of the judicious and skilful pruner are most valuable. To be able to produce a natural and a pleasing picture out of such a tangled and intermingled mass of materials requires the eye of an artist, the knowledge of the naturalist, the experience of the gardener, and the skill of the practised pruner all combined and centred in one individual

Where shrubberies have been so neglected it is quite impossible that they can ever be made so perfect as if well and skilfully thinned from the first, still much may be done to improve their condition, and this is best effected by judicious and entire separation into suitable and proportionate masses, groups, or single specimens, rather than continue to allow them to grow together, irrespective of their varied shapes and habits, into one unmeaning mass. This method of breaking up into detached groups or specimens will not only save many weak and slender subjects from complete destruction, but many beautiful specimens hitherto obscured from view may be freely exposed, and their natural grace developed by This method the admission of light, air, and space. also admits of each plant or group being pruned according to its peculiar natural growth, and thus, while a greater charm is created by varied outlines, the general character of the mass need not necessarily be changed unless it is desirable. The actual opera tion of thinning and pruning consists in the timely and skilful removal of all dead and decaying branches, as well as those malformed shoots sometimes produced by various causes, and which, if allowed to grow, would interfere with the natural beauty of the tree or shrub. It is also requisite to prevent shrubs and trees unnecessarily crowding each other, or from over-growing walks, buildings, or other objects; and more especially does it consist in training them into such shapes as will best suit and contri-bute to the object we may have in view without

resorting to unnatural forms and unsightly mutilation. To saw off a limb in such a manner as to expose the wound to the full influence of the weather, to hack off a branch with a dull and unsuitable tool, to prune off a shoot so to expose the cuts to view, should always be carefully avoided. In sawing off a limb the cut should always, when practicable, incline downurds towards the tree, so that no wet can

possibly lodge upon it.

In branch pruning the cut should always he clean and sloping downwards, and in pruning off young shoots so as to reduce the size of the shrub, inslead of shearing off every young shoot, exposing every cut and mutilated leaf to view, and thus giving the appear-ance of a clipped hedge, the longer shoots only should be removed, close to an inner branch; by this means the size of the plant will be reduced without the cuts shape: for this purpose the best tool is a strong knife with a pair of nippers for the removal of the larger with a pair of nippers for the removal of the larger shoots. Great care should also be paid to the proper staking and tying of trees and shrubs, especially when oewly planted; serious mischief often results from the neglect of this simple operation, especially in elevated and exposed positions. Having completed the pruning and tying the shrubbery should be thoroughly cleaned from all weeds and rubbish, as nothing tends to mar the beauty and prevent the well-doing of the plants so much as an accumulation of rubbish around their base and stems. The ground underneath them should then be loosened or pricked over with a steel way injuring the roots, as the object should be, not so much to fork up the ground as to break and loosen the hardened surface, and so freely admit air and rain to the roots, by which means the shrubs will be greatly benefited. T. S. C.

The Bardy Fruit Garden.

THE time of the year, the state of the blossoms on the Apricot and Peach, and the cold and sometimes frosty mornings, show clearly that protection of some sort must at once be held in readiness. In addition to the protectors which we have already mentioned we would add worsted netting as being better than common netting and Frigi Domo—a fairly good non-conducting material made of hair and wool. This latter must either be fastened on rollers or house as cuttains, so as to enable one to withdraw it in the daytime. Presuming that all planting and pruning daytime. Presuming that all planting and pruning operations in the orchard are now finished the small fruit bushes will need watching, because oftentimes at this season of the year finches, tits, and sparrows play sad havoc with the young and tender buds, thereby reducing the quantity of fruit, and injuring the bushes; red worsted entwined amongst the branches will oftentimes frighten them away, but branches will oftentimes frighten them away, but failing which a gun shot off several times a day is certain to do so. This is the month for grafting, of which there are various methods, but that which is called whip grafting is to be preferred for ordinary kinds of fruit trees. But this is a thing which must not be done in a hap-hazard fashion. First begin by choosing those kinds which are known to do well in the district, and consider also in what month it is desirable to have the fruit ripe, as there is no difficulty in having, for inclusive Petris for six successive months. aiso in what month it is desirable to have the fruit ripe, as there is no difficulty in having, for instance, Pears for six successive months, and Apples for ten months. In choosing the stone set them from near the top of the tree, where the shoots are firm and thoroughly ripened, as these will make far better growth than any taken from the under branches. under branches.

The present is a suitable time to go over the

Strawberry plantations, and where gaps are found to exist they may still be made good. A piece of ground should now be got ready for a new plantation; and seeing that it may profitably stand for three years, the land wants to be well prepared beforehand by trenching it, adding at the same time plenty of manure. Plants which have been forced may be planted out in Plants which have been forced may be planted out in rows 3 feet apart in April and onwards from time to time as the crop is gathered; or runners from the bed which have been pricked out for that purpose do well. Nurserymen now advertise them for sale in 60-sized pots, and from these half a crop can be gathered the same year. We still grow on a south border Black's Seedling, generally known as Black Prince, for the first crop, and for the later and main crops, President, Sir J. Paxton, Vicomtesse Hericardte Thury, President Delacour, James Veitch, Sir Charles Napier, Mr. Radchiffe—the last belongs to the British Queen class, and is much hardier; and on a north Napier, Mr. Radchiffe—the last belongs to the British Queen class, and is much hardier; and on a north border Trollope's Victoria, Loxford Hall, Helena Gloede, and Frogmore Late Pine. That pretty white kind, and now seldom seen, called Bicton Pine, is very desirable, but perhaps the best-flavoured Strawberry in cultivation is Hammonia. This, when better known, will be much sought after. The Strawberry delights in a stiff loam, and should never

be dug amongst. If the ground gets weedy, it may be very lightly pointed over, but it is better not, and if the land is light, mulching cannot take place too soon after planting, and strawy litter, either from the stables or farmyard, laid on now will wash quite clean before June, when the crop ripens, and the large and abundant crop will show the advantage of

Leave the pruning of Fig trees till later on, for if cut now, and severe frost should follow, they are very apt to be injured. J. Rust, Eridge Castle, Sussex.

The Orchard House.

THOSE who started their early orchard-house in December have had a good chance to get the trees safely through the blooming period in February. It was easy enough all through that month to keep up the temperature without using much artificial heat. Peaches and Nectarines set their blossoms best when there is a current of air through the house, and it is also desirable to admit air at the highest part of the also desirable to admit an at the blowed to blossom at their ordinary season in April there is not much difficulty in setting the fruit. There is a difficulty in setting the fruit. blossom at their ordinary season in April there is not much difficulty in setting the fruit. There is a difficulty to do this in February, but only free setting sorts should be grown, and the best varieties of Peaches, such as Hale's Early, Early York, Royal George, Early Grosse Mignonne, Bellegarde, and Noblesse, set freely. Free setting Nectarines are Lord Napier, Stanwick, Efuge, Pine Apple, Violette Haitive, and Victoria.

The trees in the unbeated orchard-house output to

The trees in the unheated orchard-house ought to be retarded as much as possible. This is done by keeping the ventilators wide open night and day, except during severe frosts. I do not let the trees want for water at any time during the winter months. Some persons do not water them at all; in that case it will be necessary to saturate the balls well with water now, and one or even two applications is not enough to thoroughly wet the balls, which in most cases are a dense mass of fibrous roots. The trees ought now to be placed in the positions where they are to remain for the season. It will not yet be too late to prune any trees that may require this attention; indeed, the inexperienced cultivator had better leave the pruning until the early days of March, as it is easy enough then to tell which shoots ought to be removed and which should be left. Leaf and blossom

removed and which should be lett. Leaf and blossom buds can also then be easily distinguished.

It is not generally known that the blossoms of Peach and Nectarine trees set better in the orchard-house than almost any other kind of fruit. Apricots, Plums, Cherries, and Pears require a much drier atmosphere. When I first began to grow pot-trees in the orchard-house I used to place the Peaches and Nectarines in the best position—that is pearest to the Nectarines in the best position—that is, nearest to the light; but this was soon found to be a mistake. Apricots, Cherries, and Pears should have a house to themselves; and a light, cheap structure, not too closely glazed, would be better than one made in the best style. The trees in this house would not require much syringing. J. Douglas.

The Orangery.

DURING last season I had practical proof of the importance of a high temperature to bring up the flavour of the fruit during the ripening period. I have always advised a temperature of 65° as the minimum, but circumstances did not admit of our trees being cover in a higher temperature, then about 50°. mum, but circumstances and not again, about 55°, being grown in a higher temperature than about 55°, although we kept up the temperature in the day by sun-heat. I found a passage to-day in one of the useful little manuals published by Mr. Rivers, of useful fifter maturals purished by Mr. Kvets, of the paramount necessity of a high temperature during the period of the ripening of the fruit. He says:—
"In Grenada, West Indies, the Oranges commence to ripen towards the end of October, in a temperature to ripen towards the end of October, in a temperature varying from 70° to 80°, or thereabouts. Their flavour there, freshly gathered from the trees, is so delicious that they are far superior to those we receive from St. Michael's and other places, all of which are gathered before they are ripe." The Tangierine variety ought now to be in blossom, if the blossoming period is not already over. I alluded to the setting of the blossoms at p. 179. As soon as the fruit is set the trees may be pushed on in a temperature of 6°, but this is not quite necessary in the early stages. set the trees may be passed on in a temperature of 65°, but this is not quite necessary in the early stages. No harm will accrue to them if the temperature is lower. Mr. Rivers recommends plunging the pots, or placing them on a heated surface. Probably this would further aid in the rapid development of the would further aid in the rapid development of the fruit. It is a point of some consequence to have it in early. The Tangierine is succeeded later on by the Maltese Blood and St. Michael varieties. The trees should be surface-dressed or reported before they start into growth. I find some powdered bones a good addition to the usual dressing. J. Douglas, Great Gearies, Ilford.

APPOINTMENTS FOR THE ENSUING WEEK.

APPOINTMENTS FOR THE ENSUING WEEK.

MDNDAY, Mar 10 Sale of Homercown Lilles, Gladioli, &c., at Stevens Rooms.

Royal Horricultural Society: Fruit and Floral Committees, at 11 A.M.; Scientific Programmers, at 12 A.M.; Scientific Programmers, and Floral Committees, at 11 A.M.; Scientific Programmers, and Floral F

A YELLOW coloration of the leaves is too sure a sign of want of vigour in a plant, and is often rightly enough attributed to some mismanagement upon the part of the gardener; but, although this truth is generally recognised, it is not so well known to what precise causes the sickly condition is due. Some recent experiments of M. A. LECLERC, performed, as it would appear, with all the attention to details, and all the care requisite to eliminate possible sources of complication and error, tend to throw considerable light upon the matter; and, although M. LECLERC'S conclusions are based to a large extent upon plants grown in the open field by the farmer, yet it is clear that, if well founded, they must apply equally well, and indeed in many respects more definitely, to plants grown under the more neatly-defined conditions under which a gardener places his plants. M. LECLERC's experiments in the first instance were purely laboratory experiments, undertaken with a view of ascertaining the amount of watery vapour exhaled by plants, and the conditions under which that process takes place, but he was after-wards led to apply the conclusions at which he had arrived in the laboratory, where conflicting elements were eliminated, to the rougher test of the field, where all sorts of complications less under control of the cultivator arise.

Experiments showing the vast amount of fluid lost in the form of vapour or otherwise, have long been familiar to physiologists in this country from the time of HALES to that of LAWES and GILBERT, not to mention experimenters of other nations. We need not revert to these, nor to the confirmatory experiments of M. LECLERC. It may suffice to give some of the main conclusions arrived at by the last-named observer as detailed in a recent number of the Annales des Sciences Naturelles. As the results of his delicate and precise experiments M. LECLERC shows that light by itself has no influence on transpiration, and that, as might have been expected, it ceases when the atmosphere is saturated with moist vapour. At first sight it would seem as if a plant exposed to the light must necessarily evaporate more fluid from its surface than one not so exposed, and that is so; but the effect is not due to the light only, but partly to the heat-rays which act conjointly with the light, and by heating the tissues cause them to give up their vapour, and partly to the chemical action which goes on in the leaves during the process of assimilating the carbon from the carbonic acid gas, and the consequent elimination of oxygenfunctions which, as is well known, are exercised by all the green parts of plants when exposed to solar or electric light.

Turning to matters of more direct practical importance, M. LECLERC proceeds to speak of the yellow appearance so familiar to Wheat growers in certain states of the atmosphere. In his numerous experiemnts on evaporation M. LECLERC always found that plants grown for a certain time in a saturated atmosphere, or one which was near saturation point, soon became yellow. This yellowing was evidently caused by the atmosphere being overcharged with moisture. Previously he had considered that effect as the consequence of excess of water in the soil; but on examining into the validity of these two opinions, so radically different, and by the aid of easily repeated experiments, he arrived at the conclusion that the cause of the yellowing was intimately connected with transpiration, and consequently was dependent on the state of the atmosphere.

By means of an experiment, which we need not describe in detail, but the object of which was to expose the foliage alternately to dry and saturated atmospheres, the other con-ditions being uniform, and the roots in all cases plunged in water, it was found that the plants whose foliage was exposed to a saturated atmosphere became yellow. yellow plants were then placed in a dry atmosphere, and the green ones in a saturated atmosphere, thus reversing the previous experiment. The result was that the yellow leaves became green, and the green ones yellow. A repetition of the experiments in both directions produced the same results. Thus atmospheric conditions alone sufficed to bring about these changes, the roots remaining in all cases under the same conditions. These results were tested in various ways, but the same conclusions were always arrived at-viz., that the yellow state of the leaves was the result of diminished transpiration, due to the more or less complete saturation of the atmosphere with moisture.

In other cases an unhealthy condition is brought about, not by diminished, but by excessive transpiration. For instance, if a plant be grown under an almost constantly clouded sky, the atmosphere and soil alike charged with moisture, and then these conditions be suddenly altered, so that the leaves become exposed to a burning sun, then evaporation becomes excessive and the leaves wither. By removing a certain number of the leaves, and thus reducing the amount of evaporation, the ill effects were checked. By observing what happened under given conditions, and by noting the result of reversing and alternating those conditions, it was shown conclusively that the unhealthy conditions were due in the one case to defective, in the other to excessive, transpiration. The gardener has the advantage over the farmer in this particular, that he can to a large extent regulate matters and prevent either extreme. For this nothing more than careful observation and tact, born of experience, are required.

- CLERODENDRON TRICHOTOMUM. - For the opportunity of illustrating this beautiful hardy shrub we are indebted to Messrs. VEITCH, who sent us specimens for the purpose last autumo. The plant is a native of Japan, where it is recorded as being found on the outskirts of woods. In habit and general appearance it is like C. Bungei, but is destitute of the sagreeable odour characteristic of that plant, on which account it is perhaps preferable. M. LAVALLÉE, in his Enumération of the shrubs and trees cultivated at Segrez, mentions a glaucous variety which we have not seen. C. trichotomum is an old species, described by THUNBERG in his Flora Japonica, and taken up by all subsequent authors. In cultivation, however, it is still scarce, though introduced as long ago as the beginning of the century. (See fig. 59.)

- RHODODENDRON GRANDE .- A plant of Rhododendron grande belonging to Mr. MANGLES is now in bloom at Messrs. VEITCH's Chelsea establishment. The species is rare, but the peculiarity of the plant in question is its small and portable size, which has facilitated its transfer to London. As a rule, these plants bloom only when large, but in this case the specimen is about 4 feet high, and has two large trusses of blossom. It passed the whole of last winter (1882-1883) in the open air under a north wall without any protection.

- ROYAL HORTICULTURAL SOCIETY .- We are informed that, in addition to the fortnightly meetings, arrangements have been made with the Council of the International Health Exhibition to hold monthly exhibitions of fruit and vegetables in the conservatory on the following dates, when prizes amounting in the aggregate to £1000 will be offered for competition:—May 27, June 24, July 22, August 12 (cottagers' show), August 26, September 23, October 14, October 28. The schedules are now being prepared, and may be had on application.

- GARDENERS' ROYAL BENEVOLENT INSTI-TUTION.—We understand that at a meeting of the committee, held on Monday evening last, JAMES McIntosh, Esq., Duneevan, Oatlands Park, was elected a Vice-President in the place of the late R. HANBURY, Esq., and Mr. A. F. BARRON, of Chiswick, and Mr. JOHN LAING, of Forest Hill, were elected members of the committee in the places o Mr. JACOB ROSE, resigned, and Mr. B. MALLER, deceased. July 2 was the date fixed for holding the forty-first annual festival, at the "Albion," Aldersgate Street. It was also decided that a simultaneous collection in aid of the Pension Augmentation Fund should be made again this year, and a sub-committee, with Mr. JOHN LEE as chairman, was appointed to carry it out.

- A GOOD INVESTMENT .- At the last meeting of the committee of the Gardeners' Royal Benevolent Institution the death was reported of Mrs. Susan GREEN, of Fairford, aged eighty-four years, one of the oldest pensioners on the list. Her husband, who had subscribed something under £20, enjoyed a pension from the Institution for ten years, and on his death, in 1861, his widow was placed on the list, in accordance with the rules. Thus for less than £20 subscribed husband and wife together received in return no less a sum than £430; and in the face of facts like these there are still men in our midst who have not a good word for the Institution.

- MANCHESTER ROYAL BOTANICAL SOCIETY. -That " nothing succeeds like success " holds good in its relation to horticultural exhibitions as in most other things. When a society has once earned the approbation of the public by the displays it provides, the public testify their approval by continued attendance. Nowhere is this better exemplified than in the career of the Manchester Botanical Society, whose Whit-week gatherings have fostered a taste for flower shows through the surrounding neighbourhood, so that the Society is now each year able to hold a number of exhibitions alike remarkable for their excellence and the attendance they command. The schedule for the annual Whit-week exhibition, May 30 to June 6, is now being distributed, and is of a similarly comprehensive description to the many that have preceded it. The popularity of these Old Trafford gatherings is in no slight measure owing to their comprising the different plants and flowers in season shown in such numbers and condition as to give the display a thoroughly representative character. We have no doubt the forthcoming show will be in every way worthy of the long series of successes that have gone before it.

- PARKINSON'S "PARADISUS."-A good many people, we suspect, have experienced difficulty in construing "Paradisi in Sole Paradisus terrestris." The editor of Aunt Judy's Magazine, and the venerable Rev. H. T. ELLACOMBE, are confessedly among the number, but they have been the means of eliciting from correspondents of Notes and Queries the explanation that the title is a wretched pun. "Paradisus" is a park; "Paradisi" is, of course, the genitive of this; "in sole" is in (the) sun (son). Hence the title would run, "The Terrestrial Paradise of Park-in-son." Such punning titles were not uncommon in PARKINson's time.

- FORSYTHIA FORTUNEL .- This fine winterflowering deciduous shrub is now in fine bloom on the wall at Chiswick. It reminds one of Jasminum nudiflorum, but with longer, larger blossoms, and of a deeper yellow colour. It is a great improvement on F. viridissima, and should find a place in all collections of winter-flowering shrubs. The east wall at Chiswick appears to suit it exactly.

- CANKER .- While the discussion upon this subject is going on, it may be worth while to recall the observations of R. GOETHE in the *Monatschrift des Deutscher Garten* for 1880, in which he shows that

FIG. 59.—CLERODENDRON TRICHOTOMUM. (SEE P. 312.)

the disease is due to the growth of a fungus (Nectria ditissima) in the cells of the bark, as previously detected in a similar case in the Copper Beech. GOETHE succeeded in cultivating the parasite both from conidia (bud-sp-res) and asco-spores. The same fungus produces canker on various kinds of Pear trees, and the spores of the Nectria from the Apple were found by experiment to produce canker in the Beech and Sycamore, and conversely. The best remedy is to cut out the diseased tissue, and anoint carefully with warm

coal-tar. The fungus, according to HARTIG, enters through wounds caused by hail or by the puncture of an iosect, Agrilus viridis, so that it would seem that all the factors that have been invoked may have some part in the production of the disease, and that the discrepancies be thus harmonised.

— THE CAUSE OF DISTORTION IN APPLES.—
Mr. BUNYARD brought to the Fruit Committee of
the Royal Horticultural Society on February 12 some

strangely distorted Russet Apples. Of course several suggestions were made as to the cause, and one more especially, that the condition was due to the attack of some insect in a very early state of growth; but as such suggestions were oot founded on definite observation, they did not lead to any certainty. One of these Apples was kindly given to the writer of these observations, and after close microscopical examination it was observed that the Apples themselves show old cracks, in which the exposed tissue has

been overgrown with a compact, cork-like matter developed from the superficial cells, more or less transversely fissured; but besides these old cracks, there are what may be called wheals rising above th general surface, and of a green tint, contrasting with the russet skin. When these are examined with a low power, on the sides remains of the fissured corky tissue are observed, and on turning to the old cracks a very thin green line hetween the lips of the cracks is seen, which suggests that the wheals may be the result of the growth of the tissues of which this line is composed; and this is singularly confirmed by the fact that after three weeks in a warm room, exposed occasionally to sunbeams, the green line has extended, and, in fact, a new wheal has been formed, which is absolutely of the same nature as those first apparent.

THE

-- Snowdrops.-These have been, and still are, a charming feature at Chiswick. On a sloping bank of rockwork Mr. BARRON had planted up some varieties raised by Mr. MELVILLE, of Dunrobin, a very early blooming variety of Galanthus nivalis præcox being in full flower fully ten days before any other variety, even the common Snowdrop. Two others of Mr. MELVILLE'S follow : one, flowering, is now at its best, another is only just coming into bloom. While it would perhaps be difficult to class these as separate, they do certainly supply a kind of continuity in flowering. The large lateflowering form, named Melvillei, is also just expanding; its flowers are both fine and bold. The foregoing are all single-flowered, and they are really of great value for rock gardens and other places where they can remain undisturbed, being first of all planted in soil that affords them good nutriment.

- PLUNGING POTS IN COLD FRAMES IN WINTER .- Mr. BARRON has carried out this practice on a somewhat extended scale at Chiswick during the winter. All the plants in pots in the long range of pits where choice hardy subjects are propagated are plunged up to the rims of the pots in cinder ashes, and it imparts a very neat and orderly appearance; it suits the plants, and, as Mr. BARRON observed, the cost in broken pots from frost balances the cost of the extra labour required in plunging. Looking along this frame one sees the pretty and distinct yellowflowered Primula floribunda blooming merrily, and has been in good form for six weeks past. There are also some charming little specimens of what one does not often see-the pretty manve-coloured alpine Soldanella, with its pleasing-fringed flowers. unique for pot culture, and Mr. BARRON appears to have treated it very successfully. Cheiranthus mutabilis is also a striking subject, a small tree-like plant being in full bloom. The little yellow-flowered Dondia epipactis is there also, and it is in good condition on the rockwork, where such a small unobtrusive little plant can be seen to the best advantage.

- DISEASE IN EUCHARIS. - Since Mr. MAR-SHALL's communication of specimens of a formidable disease in Eucharis, which we promised to submit to further examination, we have received the formation from another quarter, where the disease affected the bulbs of every age, quite destroying the smaller ones, and more or less damaging all, but notwithstanding the collection is now perfectly healthy, and only a single speck could be found after diligent search, but, on the contrary, it seems transferred to different varieties On examination no spores were found, of Amaryllis. but numerous dark red perithecia, from which an extremely delicate mycelium or spawn branched in every direction, accompanied by abundant raphides, either scattered or in compact bundles. The disease did not seem to penetrate very deeply into the bulbs, though the tissue was stained with the brick-red endochrome for some distance. In Mr. MARSHALL's specimens there was a very curious condition, whether a form of the originally noticed disease or not is uncertain. Both in the leaves and roots, and the base of the bulbs, little cracks appeared, which are filled up with an altered condition of the tissues, of a beautiful red, the component cells of which formed an apparently pulverulent but rugged stratum, which at first looked like the spores of some Uredo, but absolutely without any trace of Fungi. The disease having vanished almost entirely in one case, gives hope that it may not be so formidable as was at first imagined. We have had more than one instance in which diseased bulbs which have been forwarded to us have

quite recovered when planted afresh, a fact which seems to imply that atmospheric conditions have in the first place encouraged the growth of fungi. M. J. B.

- Wheeling Bridges and Scrapers .- In many gardens these simple appliances are conspicuous by their absence; paths are often coated with the earth and manure the men carry on their boots, which, of course, drops off as soon as the path is reached, and thus expensive gravel soon becomes infested with innumerable small weeds, that cost a good deal of time and money to destroy. Now, if it were made the common practice to put up scrapers at each corner of kitchen garden quarters, this un-sightliness and expense would in a great measure be avoided. Worn out scythe blades, or strong hoop-iron cut into lengths of 15 inches, should be inserted at each end into hardwood stumps, of convenient size and strength, which should be tarred and charred at the lower end. These items are easily made, and cost little more than the labour of making. Bridges made of hard-wood sufficiently light to be easily handled supply also efficient means to keep Box edging in a tidy condition where wheeling has to be performed. Men are generally so little inclined to give themselves any trouble over the matter of breaking down the Box edging, that where these things are introduced a good deal of strictness must be used before they will make use of them in all weathers. The bridge is that point at which they ought to stop to clean the wheel if necessary before coming off into the path, so that there should be no excuse for bringing soil off the quarters either. A handy labourer can make these simple bridges, which are simply two-arched pieces of Elm or Oak cut so as to clear the edging, when half the bridge lies on the walk, the two pieces being joined together by nailing small spars across, so as to form the floor of the structure, the total length being about 3 feet, and the width I foot, and weight about 20 lb., as it is not requisite to nail the spars close together. Four of these would be found sufficient for a large garden.

- THE ISLEWORTH NURSERIES. - At the Isleworth Nurseries Ligustrum lucidum is made use of to make shelter-hedges between breaks of Euonymus japonica aurea. It is a fine thing, and in mild winters like the present almost an evergreen, but, like the golden Euonymus, which it is employed to shelter from cutting wiods, it has the failing of not heing hardy enough to withstand more than 12° of frost without suffering. L. sinense is to be found used as an edging plant to roads, for which purpose it is allowed to reach the height of 11 foot. It then forms a neat little hedge, and grows into an entangled miniature fence, which at first sight is suggestive of Ficus repens. Muhlenbeckia complexa was doing well as a clump at the foot of a wall. This uncommon plant would make a pretty thing for a low wall that would at the same time protect it and serve as a support. It is interesting as a greenhouse plant in haskets, or for covering small objects in wire, the tangled black wiry shoots and leaves bearing a resemblance to the pinnæ of an Adiantum. Garrya elliptica fœmina was full of catkins on the same wall, and near by was G. Fremonti, a much rarer and hardier species, of which there is a figure in our volume for 1881, April 2, p. 431. In foliage effect alone this latter is decidedly less ornate than the G. elliptica feem. The quantities of the different garden varieties of Euonymus, such as aureo-variegatus, albo-variegatus, aureo-pictus, as aureo-variegatus, alibo-variegatus, aureo-pictus, radicans-variegatus, which are propagated chiefly by grafting, would astonish those who are not acquainted with London requirements in this way. chiefly made of the above-named sorts are the filling of window-hoxes and pots, and winter bedding, in the whole range of hardy plants there being nothing that can approach them for clean bright tints. In arrangements of winter beds consisting of Ivies, Cupressus, Mahonia, Skimmia, Erica, and the like, these Euonymuses light up the sombre tints of greens wonderfully well; so that there is small reason to wonder what is the destination of the 100,000 plants turned out annually from this nursery alone. Other plants that are grown in great numbers are Conifers in considerable variety, and which grow well at this distance from London smoke; Roses and Clematises of many sorts, these latter being produced from cut-Out-of-doors such is the effect of the mild weather that Clematis Lady Dorothy Neville had very prominent flower-buds, although the plant was

quite away from any wall or other sheltering object; and Daphne indica rubra was full of flower against a south wall in the open, where it has stood now for the fourth year without covering. The collection of Camellias here is a good one, and the plants stocky, large leaved, and robust, The collection of Camellias here is a good the result of the practice of planting-out while one, two, and three years old. This is done in various cool structures, having little, if any, heating apparatus; and in these the plants make growths far in excess of that which is possible in pots. In the houses, beyond the general assortment of stove and greenhouse plants usually found, a good collection of greenhouse Heaths is still maintained, of which we noticed symmetrical plants of trade size of aristata major, aristata superba, the fine free E. Savillea, Cavendishii, Exquisite, æmula, Hartnelli, Shannoniana, Massoni major, tubæformis, inflata, Victoria Regina, and other good sorts, as well as others of the more ordinary type. The fine Statice floribunda, certificated May 23, 1882, by the Royal Horticultural Society, was growing very satisfactorily in a cool house. A few Pimeleas were seen, but the remnant only of kinds that once were very popular show and ordinary greenhouse plants. Acacia Drummondi is apparently a plant much in request, great numbers of it being

- TOBACCO GROWING, -In the House of Commons, recently, Lord JOHN MANNERS asked the Chancellor of the Exchequer if he had prepared a scheme for allowing the agriculturists of the United Kingdom to grow Tobacco for sale. The Chancellor of the EXCHEQUER said that, in accordance with the promise he gave the noble lord during last session, he had carefully inquired into this subject during the recess. For a certain number of years, beginning 1779 and ending 1830, Tobacco was allowed to be grown in Ireland, and at the end of that period a committee of the House sat, and a Bill was passed putting an end to the permission to grow it. At that time the free trade rules which are now understood to he the basis of our legislation were not so well understood, and Tobacco grown in Ireland was not subjected to duty. Of course, if now permission were restored, that Tobacco would have to payan Exciseduty and a countervailing Customs duty; and the Chancellor was quite satisfied that, inasmuch as the old experiment when there was no duty practically failed-not much Tohacco having been grown-nothing would be gained if permission were now granted. With an Excise duty it would fail altogether, except in the case of those who might hope to escape the duty. He therefore had, after the fullest consideration, come to the conclusion that it would not be possible to allow the growth of Tobacco in this country. - Lord J. MANNERS gave notice that he would call attention to the subject on an early day.

— Begonia Manicata,—This very free-flower ing old winter-blooming species is now to be seen in good form at Chiswick. Its freedom of bloom can be estimated from the fact that plants in 32-sized pots had thrown up sixteen spikes of flowers, these being small but plentiful, white tinted with pink. It is something in the way of B. carolina, which has flowers of the same character, but larger, while it is also decidedly coarser in growth. B. manicata is an excellent decorative plant in winter.

- FORCING PINKS,-These are now so much grown for their flowers in early spring, that it will not be out of place to utter a word of caution to cultivators in regard to the management of these plants. A lew days since we saw some placts of Pinks that had been put into a strong heat, with the inevitable result that the foliage had become drawn and attenuated; and if any flowers are produced they will be small and unsatisfactory. The fact is, that forcing Pinks in pots require a cool and airy treatment during autumn and winter, shutting up the house or pit close only when necessity requires it. If it is necessary to apply heat it should be of a gentle character, and the plants should be as near the glass as possible. A good head of flower is only possible with a robust, clean, healthy growth: and an airy position and plenty of light conduces to this. And it may be further stated, that if a little manure-water be given about twice a week, plants and flowers both will be greatly helped thereby.

— THE USE OF CHARCOAL as a medium in which to pack seeds to be sent to this country from abroad is very common indeed; in fact, a consider-

able number of scientific correspondents seem to pin their faith to charcoal, as a packing agent, to a remarkable extent. As far as our experience goes, its use is, however, decidedly objectionable, as, apart from its dirtiness, it absorbs the moisture from the seeds, and in many cases so thoroughly, that all germinating power is lost by the time the package arrives at its destination. All short-lived seeds seem to travel best in damp clay or moist earth. Packed firmly in damp clay, SIEBOLD succeeded in introducing Tea seeds from the Chinese Tea countries to Java, and also the seeds of a large number of Oaks, Camellias, and other Japanese plants, from their native country to Holland. Seeds of Tea, Coffee, and a host of other plants, which utterly fail to retain their germinative faculty during a lengthened sea voyage when packed either without any packing medium, or forwarded in charcoal, grow readily when treated in the manner adopted by SIEBOLD. We are glad to see Mr. PRESTOE condemning the use of charcoal in his last report on the Trinidad Botanic

- SEXES OF NUTMEG TREES, - Any method by which the sex of seedling plants of the Nutmeg may be determined with any approach to accuracy is a matter of no little moment to many who are interested in tropical agriculture. As the males, in excess of those required for purposes of fertilisation, are useless, much labour and time may be saved by following Mr. PRESTOE's directions. In the last published Report on the Trinidad Garden Mr. PRESTOE says :-"The planting out of successional Nutmeg trees has enabled me to determine the sexes in seedling plants under a foot high by character presented in the leaf form and venation, and with sufficient accuracy for all practical purposes; as also the proportion of male trees and female as usually raised from seeds." order to distinguish the male and female seedlings the form of the leaf and the direction of the veins must be observed, the female leaf being the most perfectly elliptical, with the straighter primary veins; the male leaf is broader towards the point than at the middle-that is, of obovate shape, and furnished with a point much longer than that of the female; the veins are curved-in towards the point much more roundly than in the female. Mr. PRESTOE has proved by experiments conducted by himself-and the young trees now fruiting fully bear out the statement-that by carefully following the tests above given, the results will be correct eight or nine times out of ten.

- AFRICAN WOODS .- It is not too much to expect that one of the results of the forthcoming Forestry Exhibition at Edinbugh may be the development of the timber resources of some of our colonies. The subject is one of very wide interest, and there is room at the present time for an extension, not only in quantity but also in variety of our timber and ornamental wood supplies. Many apparently excellent woods are brought home by different travellers from time to time from various parts of the African continent, but their botanical sources are, for the most part, unknown, and they never come into actual use. The principal African wood indeed of acknowledged value at the present time, is the so-called African Oak or Teak (Oldfieldia africana), which is so useful for piles for wharves, &c.
This, however, is an example of a durable wood, useful for structural purposes, but not of an ornamental character. An example of a West African wood, Loth durable and ornamental, has recently been presented to the Kew Museum by Captain MOLONY, C.M.G.; it is furnished by Chlorophora excelsa, BTH. and Ilook. f., a tree belonging to the Moreæ section of Urticaceæ, growing at Upper Guinea, where it is known under the names of Roko, or Iroko, wood. Notwithstanding its ornamental character, which, when polished, ex-hibits a combination of Satin and wavy Maple woods, it is noted for its great strength and durability for building purposes, as it resists the attacks of white ants-a great recommendation to any wood required for use in tropical countries.

— Mr. Bethell.—We hear that, through Sir RICHARD WALLACE having disposed of Sudborne Itall, Mr. Bethell will be open to another engagement at the end of the present month. Each department of this very extensive and well-managed garden alike bears unmistakable evidence of Mr. Bethell's skill and care. We trust he may soon meet with

another situation where there will be scope for his abilities.

WORK GALA.—The present season marks the entry of this important Society on the second quarter of a century of its existence. The extent and excellence of the shows, coupled with the never-failing attendance of the vast crowds who look upon the gathering in the Bootham Field as an established institution that must be attended, augur well for the future of the Society. The continuance of liberal prizes offered in the respective classes in each department of the schedule, combined with well considered and equally well carried out arrangements for the convenience of exhibitors, never fail to meet with a response from the leading growers, whilst the public, who in this part of the kingdom alike appreciate flowers and music, know that they will not be disappointed. We trust the Society has a future before it equal to the past. This year's exhibition takes place on June 18, 19, and 20.

THE SURVEYORS' INSTITUTION. — At the meeting to be held on Monday next a paper will be read by Mr. A. J. BURROWS (Fellow), entitled "The Construction and Maiotenance of Country Roads," The chair to be taken at 8 o'clock.

—— EALING, ACTON, AND HANWELL HORTI-CULTURAL SOCIETY.—The annual summer exhibition of this Society will take place on Wednesday, July 9, and the usual Chrysanthemum exhibition on Wednesday, November 5.

HEADING CHRYSANTHEMUM SOCIETY.— This is now a distinct organisation from the Reading Horticultural Society, and an exhibition will take place in the Town Hall, Reading, on Friday, November 11

THE WEATHER -General remarks on the THE WEATHER.—Leneral remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending March 3, issued by the Meteorological Office, London: — The weather has been generally cloudy or dull in all parts of the kingdom. Some hail or snow has fallen in the north and northeast, and rather heavy rain in Ireland and the south-west of England. Over the greater part of England the weather was dry till the close of the period, when the weather was dy in the close of the period, when the unsettled, rainy conditions previously noticed in the west had extended eastwards. The temperature, excepting at the Irish and some of the south-westero English stations, has been lower than during any English stations, has been lower than ouring any week since that ending December 10; in most parts of England it has been 4° or 5° below the mean, and the "Channel Islands" it has been 1° or above it, while in "Ireland, N.," in thas equalled its normal value. The maxima, which were generally instantially of the property of the prope registered either on February 23 or March 3, ranged from 44° in "Scotland, W.," to 54° in "Ireland, S." The minima, which were recorded on different days in the various districts, ranged from 24 to 26 and most parts of England, to 34 in "Ireland, S.," and 42 in the "Channel Islands." Rainfall has been a tle less than the mean in Scotland and the north of England, but more elsewhere. Bright sunshine has been less prevalent than during last week, the percentages of possible duration varying from 7 in "Ireland, N.," and 11 in "England, N. E., "to 28 in "Scoland, N." Depressions observed,—Soon after "Scoland, N." Depressions observed.—Soon after the commencement of this period pressure began to decrease over France and the south-west of our islands, and to increase in Scandinavia. Over the former region the barometer became comparatively low, while in the latter an area of high pressure was found. No depres-sions appeared in our immediate neighbourhood until the last day of the period, when some disturbances were shown in the north-west. The wind, which at the opening of the week was light and variable, subseshifted to the eastward in the south and southeast, to south-east in the west, and to south-south-east cas, to south-east at the west, and to south-south-east or south in the north, and in some places blew freshly or strongly; at the end of the period (owing to the disturbances in the north-west) westerly breezes had set in over our island, and southerly winds over the whole of Core blisting. of Great Britain.

—— GARDENING APPOINTMENTS.—Mr. JAMES CARDINER, lately Gardener at Esstead, Lanarkshire, N.B., as Gardener to Mrs. Dalton, Sleningford Park, Yorkshire.—Mr. William Maxwell, tately Gardener at Quarry Hill, Reigate, Surrey, as Gardener to Mrs. CHAMBERS, Clough House, Rotherham.—Mr. THOMAS BATHGATE, lately Gardener at Alderstone, Haddington, as Gardener to J. R. HAIG. Esq., of Blainfill, Parkgate, Withham, Sussex.—Mr. J. SYLVESTER, Gardeoer to T. ISHERWOOD, ESQ., Heywood, Manchester, as Gardener to E. ASHWOOTH, Esq., Staghills, Waterfoot, Bury.

ORCHID CULTIVATION FOR AMATEURS.—VII.

To any one who has seen epiphytal Orchids growing in the wild state and clinging to the stems and branches of trees far overhead, it is very wonderful to note the success obtained in our gardens where we treat the bulk of true epiphytes as if they were terrestrial or sub-terrestrial species. (See an article of mine on "Orchids at Home" in these columns, May 10, 1879, p. 587). If we wanted any direct proof that Orchids are as amenable to culture, as accommodating in their habits as Ferns, Aroids, or Bromeliads, we may find it in the success which modern Orchid growers attain. And they are right, for in our climate the atmospheric condition of our houses can but very rarely be maintained in a state suitable to plants grown as epiphytes pure and simple. There are two dangers in the potting of these plants, however, which amateurs must take care to avoid, viz., pots too large, and the absence of sufficient drainage. Epiphytes pure and simple, such as Dendrobes and Phalænopsis, require very little compost, and the smaller the pots are the better. Mr. Dominy did Orchid growers a great service when he brought the now popular shallow Orchid-pan (for suspension from the roof) into notice, and these paos have given ample proof that Orchids do not require the enormous bulk of compost formerly thought indispensable. As to the compost for Orchids itself four things are necessary :- Good brown fibrous peat, fresh sphagnum moss, picked and partially dried, crocks, and clean charcoal. Now and then a little fibrous loam will be required for strong-growing plants, such as Cymbidiums, Cypripediums, Calanthes, Phaius, and Pleiones. Even the delicate little Apactochilus grow best in clean loam-fibre and sphagnum moss. difficulty is to obtain good peat, and whenever a sound sample of the right sort ("sods as tough and as fibrous as door-mats" was the description given to me by a famous old Orchid grower when he sent me as a boy to the peat-stack for a supply) is found you can scarcely do wrong by obtaining too much of such a "good thing." All sorts of dark coloured greasy kinds of peat are useless, indeed actually injurious to Orchid roots, since it soon washes down uoder the watering pot into black mud. Washing is after all a really good test for peat. Bad samples you can wash all away like so much soap, but of a good tough fibrous sample only the sand and small earthy particles in the interstices of the fibre will be dislodged by washing. The same is true to a certain extent of the best of loam, it should possess a large proportion of fibre, which no washing can remove. This especially should be the case with the loam used

Sphagnum moss is a grand aid to success in Orchid culture, and especially so when of good quality. The best I have ever seen is found near Stirling, indeed it seems stronger and tougher in the North than elsewhere. Of late years it has been extensively employed, indeed as a fact it is interesting to notice that Orchids generally, and especially the cooler growing of mountain Orchids, were never grown successfully until the use of sphagnum or bog moss because general, just as some other Orchids, as Catasetum, Cycnoches, Gongora, &c., have never been well grown since the old "bark stowes" heated by flues went out of use. But I must remember that the history of Orchid culture is not quite what present-day amateurs desire, so I must get on to the potting and watering.

POTTING. — The potting of Orchids is really a very simple matter, and my golden rule is never to pot a plant until after it has commenced to grow, and then as soon as ever I see indications of the new roots appearing from the new growths I repot the plant, and so the new roots find new, fresh, and sweet composts quite ready for them. The amateur having learned, I hope, by this time, that there is no "royal road" to Orchid culture, will also now see clearly that there is no special season for reporting his plants. He must watch them like babies, and be ready to feed them when their new growths and new roots cry out for more room. For small plants shallow suspension pans are best; but all large growing things, such as Cattleyas, Lælias, Lycastes, &c., must be grown in Some use perforated pots, others rough glazed ones for the sake of cleanliness, and others common garden pots of the usual pattern, and in all three cases the results are pretty much the same. The

main point is to ensure plenty of drainage. This is a point amateurs are apt to overlook, but the fact is, the more water a plant requires the more drainage should be given, otherwise the compost soon becomes stagnant and sour. My own plan is to place large convex crocks over the bottom of the pot, taking care to enlarge the drainage hole, which potters always make much too small. Then a deep layer of small crocks is added-a layer of very small ones being placed along the top, and on these a layer of hypnum, or wood moss, which acts as a filter to prevent the earthy matter in the compost from washing downwards into the crocks. Over this the roots of the plants surrounded by the compost, which, as a general rule, will be composed of two parts of brown fibrous peat, one part of sphagnum, and one part of charcoal nodules and small crocks mixed together. The compost should be firmly pressed around the roots. If the compost is loosely packed two evils result from it.

Firstly, the plant is not firm but shaky, in which case no Orchid will grow well; and, secondly, loose compost retains too much water, and so is not only wetter but colder than if tightly packed. As I have before said in these papers, "it is not the quantity of water poured on the compost but the quantity retained by it" which influences the plant for good or ill, and my own experience is that "that Orchid is the healthiest which wants watering most often," and in order to ensure this state of things the compost must be firm and well drained, so that however much water is given only a certain quantity-namely, that absorbed and retained by capillary attraction-can remain. This is such an important point in the potting of Orchids that I must illustrate it for the amateurs most concerned. Now, as to firm versus loose composts for Orchids. Take a large bath sponge as big as your head and dip it, loose and open as it naturally is, in water. Of course it holds and retains a pint or more of water. Now squeeze it dry and ram it rettly tight into a configuration to the hold foliation. pretty tight into a coffee-cup or into a half-pint measure. Now dip it in water. Ot course it is too tightly pressed to hold much water; the measure itself can only hold half the quantity the sponge itself held before, but now it holds less in proportion to the fibres in the sponge. Now the measure is the flower-pot, and your peat and moss compost is the sponge, and the tighter you press it into the pot the less stagnant moisture it can contain. I find in practice that for such hard-leaved, pseudobulbous Orchids as are Cattleyas and Lælias you can scarcely pot them in too little compost, and that, further, that little can scarcely be compressed too firmly. This is true, also, when sphagnum and charcoal or crocks are used for pure epiphytes, such as Phalænopsis, Aërides, Vandas, Saccolabiums, and Angræcums, which do not take readily to a peaty compost. Some growers likewise grow cool Orchids, such as Masdevallias and Odontoglots, quite successfully in a compost of sphagaum moss and charcoal, or crocks only. But, as I have said before, if the atmospheric conditions of your house or houses are right and genial the question as to compost is not so important. It is, however, highly important that the compost, whether of peat and sphagnum, or of sphagnum and charcoal nodules, or of fibrous loam and crocks, it is highly necessary, I say, that it should be placed on a well-drained base, and one had better have too little of even the sweetest and best of composts rather than too much. As I before remarked, Matthews' shallow Orchid pans, now so popular, bave proved this much to be true, but in teaching reiteration is perhaps pardonable. F. W. B.

EUROPEAN PLANTS IN THE TROPICS,—In spite of the wealth of floral beauty which lies ready to the hand of the gardener in tropical countries the resources of temperate climates are largely drawn upon for the decoration of the flower garden in strictly tropical climates. In his report on the Tribidad Botanic Gardens Mr. Prestoe says that for some years more attention has been paid to the importation of such English spring and summer flowering plants as Gladioli, Dahlias, Phloxes, &c., with results that have much improved the display and resources of the flower garden. It has been found that though these plants are so little tropical, and bear tropical conditions so indifferently that they either revert to the original species type, as in the case of the Dahlia, or in two or three years die out—they grow and flower for a single season in a manner that is little inferior to the productions in Europe.

Home Correspondence.

Rhododendron Early Gem.—I do not see much notice taken of this really beautiful variety. There is a group of half a dozen plants of it in flower in our garden, and whether examined closely or viewed at a distance, they do not fail to please. The flowers began to open early in February, and gave us a mass of colour all through the month. It is quite a distinct plant from the numerous varieties of R. ponticum, but they are not to be thought of for a long time yet, and must not be compared with Eurly Gem. No garden should be without this choice little shrub. J. Dougdas. (See fig., p. 335, vol. ix., 1878.)

Apple, The Golden Spire, —Having seen the Golden Spire Apple noticed in your paper two or three weeks ago, I thought I would send you a small sample to show that, in addition to its other valuable qualities, that of late keeping is another (fig. 60). It is generally looked upon here as an early mid-season Apple, but when it will keep sound till the middle of February it may fairly rank as a late keeper; for Apples here generally begin to lessen in value when Rhubarb begins to be plentiful, as it now is to be bought at 2d, per bunch; in another week of the present weather Early Albert will be gathered out-of-doors without protection. I believe the Golden Spire Apple will be one of the best market-garden Apples known. It is a most prolific bearer; in fact,

Fig. 60.—APPLE, THE GOLDEN SPIRE: COLOUR, GOLDEN-VELLOW.

in a good season it sets too many. It can be used from the time it is large enough to pare; it then bakes splendidly, and it is excellent from then up to the present time; and it is well flavoured: all of which are excellent qualities. Market gardeners generally go in for what will produce the most, regardless of quality, but in the Golden Spire quantity and quality are combined. There is scarcely a tree to be bought of it about here, so great has been the run on it. Farmers are planting it greatly. I think from the appearance of it there must be some blood of the Keswick Codlin in it. Rev. Charles H. Wood, Preston, Lanuashire.

Zinc Labels.—Six or seven years since Mr. J. Allen, of Shepton Mallet, sent here some specimens of Primula Sieboldi named and numbered on zinc labels. Those having the names written on have been in use ever since, being above half the year outdoors, yet even now they are still clear and distinct, and seem as though they could be used for several years yet. I do not know whether Mr. Allen in writing employed any special ink preparation, but I am inclined to think that the ink used was of the common black kind. I should think just one coat of pale varnish would render the writing indelible, and the labels are practically imperishable. The zinc label in question is some 5 inches in length and three quarters of an inch broad, and a most useful size to mark pot plants. A. D.

Orchis Robertiana.—Have any readers a knowledge of this plant? I bought a dozen roots of an Orchid under this name; most of them have grown, and one is now in flower. The character of the plant resembles Orchis foliosa. It is 18 inches high, the

flowers thickly placed on a stout spike. The sepals and petals are greenish dashed with purple, spotted internally with reddish-purple. The labellum is divided at the margin ioto five or six brownish lobes; centre pale purple, marked with a deeper purple. The flowers are an inch and 1½ inch in length. If this species is quite hardy it is a good addition to an interesting class of plants. J. Douglas.

Grape Vine Sport.—It will be in the recollection of many readers of the Gardeners' Chronicle that a very uncommon case of a Vine sporting occurred at Culford, near Eury St. Edmunds. In this case a scion of the Golden Champion Vine had been worked on the Trebbiano, with the result that the sap of the Golden Champion had been commingled in some way with that of the Trebbiano say to cause a growth of the former to be produced below the point of union. Many good Grape growers doubted the correctness of the observation of Mr. Grieve, the gardener at Culford, at the time, and a long discussion took place on it in the Gardeners' Chronicle for 1876, vol. vi., pp. 82, 113, 145, 175, 212, 239, 595. Some of the gentlemen who tnuk part in that discussion may be glad to know that a similar case is to be seen within lour or five miles of London, in the market growing establishment of Mr. Sweet, Wilmot Road, Leyton. In this case the stock is a Black Hamburgh, and on it Mr. Sweet inarched a Gros Colmar. The union of the stock with the scion is plainly visible; and about a foot or more lower down the stem a strong shoot of Gross Colmar has grown out. It showed Gross Colmar bar grown out. It showed Gross Colmar burches last summer, but Mr. Sweet removed them. The wood is still there, and any Grape grower can easily tell that it is Gross Colmar growth, and will be very strong Gross Colmar growth, and will be allowed to produce fruit next season. 7. Douglas.

Resting-spores of Peronospora parasitica, Corda.—In the Gardeners' Chronicle for Nov. 17, 1883, I illustrated the resting-spores of the putrefactive fungus of Cabbages named Peronospora parasitica, and showed that these bodies, found by me in Turnips which had been destroyed by the Peronospora, agreed with the so-called Autotrogus of Montagne, as found in decayed Turnip by Mr. C. E. Broome in 1849, and the oospores of De Bary of 1863. I have lately been able to examine the immature resting-spores of the same fungus now found by the Rev. J. E. Vize in Cabbage stumps at Forden, Welshpool. The Peronospora had been on Mr. Vize's Cabbages for some time, and it is indeed upon them now, but the condidal form is only on the leaves. The resting-spores occur in the decaying stems, whose heads have been removed for kitchen use, and whose stumps are rotting in the ground. The oospores occur amongst the moist interior fibres, and the resting-spores occur in sundance in these yellow patches, yet this yellow oospore-producing state of the disease is exceptional. The oospores are at first smooth, and become chinulate with age, as in the Potato oospores, and in many other fungus-spores, W. G. Smith.

Myosotis dissitiflora alba.—Vou have done good service at p. 215 in bringing this plant before the public as a market plant, as it only requires to be better known to become a favourite with all. Seeds can now be obtained at a cheap rate, and it should become more popular for spring beds and early cut flowers. Being the raiser of this novelty, allow me to say that it does not require any heat whatever; a cold frame or pit, and the plants placed near the glass, with air on day and night, to allow the moisture to pass off, is all that is necessary. It can easily be grown in the same way as Violets, by planting out in the natural soil in a cold frame with plenty of air. I prefer a larger pot, and take up some strong seedlings early in the autumn, and leave them in a sheltered place outside as long as possible. I have grown it extensively for four years past, and it has not been out of bloom summer or winter except during frost. It seeds very freely, and propagates so fast naturally that we are often boeing it up amongst other crops in the garden. W. Dizers, Weirron, March 4.

Solomon's Seal.—What a common plant to write about! some people may say. So it is; but it is the custom now with the gardening papers to write gushingly about the commonest flowers. For instance, Jasminum undiflorum flowered well this season at its usual time, and it furnished a number of paragraphs forthwith; so with the Snowdrops, Daisies, &c., and it is well that we should be reminded of the use and beauty of common flowers. Solomon's Seal is now in flower in our greenhouse. The roots may be litted from the open ground, potted, and be put in heat at once. It is so easily forced, and the tall stems, arched at the top purposely to display the small delicate but pretty flowers, are so fresh and spring-like, they ought to be grown freely in every garden. Single

crowns may be potted in small pots, and great clumps in 15-inch pots have a fine effect. They start best with a little bottom-heat. J. Douglas.

Fuit Trees in South Wilts.—To write thus early regarding our fruit prospects for the current year will doubtless to many seem somewhat premature and to savour more of prophecy than of anything else. The outlook, however, at the present time with all outdoor fruit trees is one of the brightest and most encouraging one could wish for; Apricots are already fast expanding their blossoms and promise soon to present a very picturesque appearance, every shoot and spur being thickly studded with bloom-buds, so much so, in fact, that we have decided on thinning them out with no unsparing hand, by rubbing off the weakest and most backward. Peaches and Nectarines also are fast opening their flowers, and there will be more than sufficient of them to satisfy our wants, even supposing that only half of them "set." Plums are bristling with buds, and promise to be on a par with Apricots; this, of course, was to be expected

after the Champion. My experience for the past four years of this admirable Potato (against which I had previously written through ignorance of the proper time to use it) is, that before March it should not, in almost all cases, he used for general consumption—that is, when the Champion (Scotch) becomes of inferior quality take up the Magnum Bonum. This guides me in the planting on our farm, which commences within the present week. Reading Hero is said to have the good qualities of both combined. Next year I shall he able to speak definitely. IV. J. Murphy, Chonnel.

Tree Protection on Open Walls.—Many gardeners seem to think that trees on open walls require some kind of protecting while in bloom. If the walls have copings, say 12 inches wide, and are not very high, say 10 or 12 feet, and the copings are so arranged as to throw off wet quiekly, my opinion is that fruit trees will require nothing more to set a crop of fruit, previding that the trees have been well managed during the summer. A great deal depends on the summer

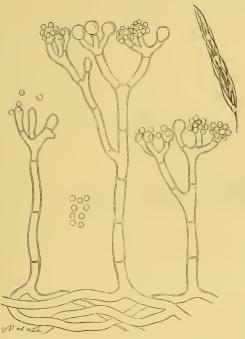

Fig. 61.-ACMOSPORIUM TRICEPHALUM, N. SP.: MAGN.

after the almost total failure of last year's crop. The Apple and Pear blossom will probably be less abundant than last year; still, it cannot be said that the present state of affairs is gloomy. Cherries give every promise of a heavy bloom. Gooseberries, Currants, and Raspberries call for no special comment, except, perhaps, that the first named bave been sistality free from the depredations of birds—more so than for years past, bullfinches seemingly being very scarce, whist that boldest and most voracious of our feathered enemies, the sparrow, seems to have found other food more congecial to his taste. Although we are enabled to speak thus encouragingly of the present, it may be otherwise in two months hence, and there is no gainsaying the fact that a week's frost just now would do an incalculable amount of good. J. Horsefield, Heytetbury.

Magnum Bonum Potato: the Time to Use.—I have heard two experienced agriculturists differ as strenuously about the quality of this Potato as the travellers did in the proverbial story of the colour of the chamcleon. As in that case, "both were right and both were wrong." We are just now removing Magnum Bonum from the pits in the field to come into use

management of the wood and upon whether it has been properly ripened or not. I have been very successful in the cultivation of the Peach and Nectarine on open walls during the last six years, and all the protection given to the trees here is 1-inch wide boards at the top of the walls, which are 14 inches thick, and only about to feet high. The boards were placed in position last October, my object being to keep the walls and the trees as dry as possible during the winter and spring months, as I find it helps to retard the bloom-buds at the present time. Our trees are very little forwarder than they have been at this time in past seasons. I also find when the trees are in flower that the leaf-buds are ready to start into growth, so that the sap is in full play. I find the wall boards throw off moisture very quickly, as the boards are given a coat of black varnish every year and placed in a slanting position. I have often onticed how dry and warm our trees have looked after a storm of hail, snow, or rain. The boards have been in use for ten years, and are in good condition now, so that cheapness is another point in its favour. Beyond the board coping I look upon the use of any front protection as a great evil, and, having been successful without the application of any such things,

I would suggest that others should try and do the same. I give every encouragement for the shoots to get a good start in spring, keep them growing fast and always clean, and lay in only what I am likely to want the following year, so that the wood becomes well ripened, and in that case the trees are in good condition to withstand rough weather during spring. Robert Smith, Kenvaard Gardens, Yalding.

ACMOSPORIUM TRICEPHALUM.

Some forty-five years ago Corda established his genus Acmosporium for the reception of one species, A. botryoideum, Corda, which he found growing on mouldy plants near Prague, and figured in his Icones Fungorum (III., fig. 52). I found a mould in the winter of 1882 on fallen leaves of Cryptomeria japonica, which resembles Corda's plant so much that I venture to regard it as a new species of the same genus, and propose to call it Acmosporium same genus, and propose to cair it Acmosporum tricephalum. As one knows not what part this minute parasite may hereafter play, it is as well to present a portrait of it to your readers, much on the same principle as photographs are sent round to police-stations of "suspects," that a watchful eye may be kept on them for the future. There is no serious accusation against this plant at present; in fact, it presents itself to us as an exceedingly elegant and harmless thing, whose only province would appear to be that of hastening the decay of the fallen leaves of Cryptomeria japonica. It appears as small white oval tufts, about one-eighth of an inch long, on leaves that lie lowest under the mass nearest the damp soil. The tufts are formed of a layer of loosely interwoven, colourless hyphæ, from which arise simple, erect, septate stems, once or twice branched in the upper part, the extremities of each branch again divided into three short branchlets, which are slightly enlarged upwards, and each terminated by a globose head on which are seated several globose spores. Total height of the plant, 25 mm.; width of stem, .o. mm.; diameter of globose head, 014 mm.; diameter of globose spore, .005 mm. William Phillips.

AGRICULTURAL RESEARCH.

CLUB-ROOT DISEASE.—We have just received the third annual report of the Sussex Association for the Improvement of Agriculture, and although there may be many who will differ from the conclusions which have been drawn from these experiments, there will be few who will not accord to Professor Jamieson the merit of immeose perseverance and energy in the way he has conducted them.

Perhaps the part of the report which will most interest the readers of this journal is that which refers to the disease in Cabbage and Turnips commonly known as club-root, sometimes called finger-and-toe disease, anbury, canker, &c.—terms, however, that prohably include other forms of disease as well as clubroot—a disease that affects and often almost ruins Turnip and Swede crops, also Cabbages, Rape, and other members of the Cruciferse family.

Mr. Jamieson states that the Sussex experiments have shown plainly that there are two substances abounding in manures that do indeed injure plants. an injury that was not previously apprehended, and the knowledge of which now obtained may lead to great changes. It need not cause surprise if, in this case, as in the case of the "Battle of the Phosphates," the doctrine may be quietly assumed without recognition. To the work of the Sussex Association it belongs at least to have demonstrated it, and that too at a time when the doctrine of the day, and the custom of the trade, permit and strongly recommend the abundant use of the one poison, and tacitly permit the use of the other. These plant-poisons, as Mr. Jamieson designates them, are sulphur and chlorine, the one given usually as sulphuriand acid and sulphate in dissolved or soluble manures; the others given in chloride (or muriate) of potash, and in common salt. He further advises agriculturists not to use manures containing these elements—sulphur and chlorine except when the soil happens to be unusually black, that being the only condition of soil which he believes may be depended upon to correct the evil; while the only class of crop that does not appear to be hurt is the cereal class. Mr. Jamieson says—"How often do we hear of such remarks as—"My Potato crop is being ruined by disease;?" The Mangels are sicklythey can't come to much; 'Canker has got in among my Turnips—they won't be half a crop; 'What is wrong with the Cabbage?—they don't heart, and the leaves are yellow or blanched.'" All these are stern realities, and Mr. Jamieson is bold enough to assert that he has sufficient proof that sulphur brings on club-root disease and sickliness in Turnips, and that chlorine blanches and renders sickly both Peas and Swedes; also that sulphur almost always abounds, and that chlorine frequently abounds, in most manures sold.

The Professor goes on to state that three years ago the injurious effects of sulphur were unexpectedly demonstrated by experiments in pragress at Aberdeen, and that were too numerously duplicated to admit of explanation by accidental circumstances. Yearly since that time his attention has been specially called to this subject, and that more or less satisfactory evidence of the same evil tendency has been accumulating.

Probably the first clue to definite knowledge of this disease was afforded by the data given by M. Woronin in St. Petersburg,* who satisfied himself that the club-root in Cabbage abounded in, and was caused by, a fungus, which he described and named "Plasmodiophora Brassicæ," and he believed it affected similarly other members of the genus Brassica, which includes the Turnip.

In the report of the Aberdeenshire Agricultural Association for 1850, Mr. W. Jamieson says:—"1 am of opinion that the facts and considerations afford sufficient ground for the belief that a predisposing cause of this clubbed-root disease is the use of manures saturated with sulphuric acid, a feature which characterises the great bulk of phosphatic manures sold; and that what might have ranked merely among the moderate injuries to which all plants are subjected is so aggravated by this predisposing influence as to acquire the serious character which it now bears."

From the report of 1881 the following table is extracted, which gives the ultimate effect, and brings out clearly the excessive number of diseased plants in those three where vitidated manure—or manure containing sulphuric acid—has stimulated or encouraged

the work of the fungus :-

	Dissolved bone ash and sulphate ammonia.	Dissolved bone ash and nitrate soda.	Dissolved bone ash	Bone flour and sul- phate ammonia.	Bone flour with its or-	Dung, bones, dis- solved bones.	Coprolites.	coprolites.
Original plants	600	600	600	600	600	600	600 6	00
1880	592	545	594	1394	179	429	170 1	48
Diseased plants (1881	574	555	583	425	161	158	117	27

Taking these facts into consideration, Mr. Jamieson is of opinion that the following theory suggests itself:

— The sulphur in the manure (in whatever form) accelerates the elaboration of the delectable sulphurous material, in which the dormant spore index abundant sustenance; at the same time, by the readily available form of the mineral food, a flush of premature growth pervades the cultivated plant, and consequent weakness; simultaneously the fungoid enemy, at the expense of the higher plant, increases in myriads, war is waged, in which the assailing foe—the fungus—is never subdued, but may have either a complete victory in the death of the higher plant, or only partial victory, resulting in more or less of a clubbed root, and a more or less normal bulb above.

In August, 1883, in the experiments at Hassocks, in Sussex, a conspicuously unhealthy appearance is said to have been observable in all the Turnips of the superphosphated plot, although it had been stated that the club-root disease was previously unknown in Sussex.

In October the plants were taken up from all the plots, with the following results:—

Manu	Total Diseased and Killed Plants.				
Ground coprolite	- 0				11
Ground bone-ash					16
Superphosphate					51
No phosphate					45
Steamed bone-flor	ır				1 6
Coprolite and stea	med	bone-f	lour		3

^{*} Jahrbucher sur Wissenschasstliche Bolanik. Pringsheim, 1878.

Mr. Jamieson concludes this part of the report as follows:—"The results now before us plainly warn against the use of sulphuric acid in manures, for whatever the true explanation of the evil action, that evil action is evident."

FORESTRY.

TREES AND RAINFALL.—In my last paper on this subject (January 5) I promised to resume it in order to show what the true and real effects of trees upon the moisture and climate of the country are, and how they are produced, but whether I shall succeed or fail in this the reader will best judge. Having in my last, to some extent at least, shown that certain effects are generally attributed to the influence of trees upon climate, &c., which they do not actually possess or exert, I shall now endeavour to show what effects they in reality do produce both upon soil and climate, by way of increasing on the one hand or diminishing on the other the volume of water in springs, streams, rivers, lakes, &c. It is probably both clearly and well known by some, but not so sufficiently as it ought to be, that the ground, or perhaps it had better be said the soil ioside a plantation fence, is in general much drier than it is outside and distant from it. Incontestable proof of this might be adduced were it necessary, but as no one will likely dispute this who has paid ordinary attention to the subject, it may be left in abeyance for the present.

The late Lord Lovat, of Beaufort Castle, Invernessshire (than whom few geotlemen were better able to give an opinion upon such subjects, being a close observer of things in general, but specially such as were in any way connected with the subject of forestry), told the writer that he used on many occasions to creep on all-fours through a large area of Scotch Fir plantation on his estate when deer-stalking, and that even in wet weather the ground was sufficiently dry to enable him to do so without inconvenience or uncomfortably wetting his clothes. The plantation, however, having ultimately attained ma-turity bad to be cut down, and shortly thereafter his lordship having occasion to travel over the same ground, found it impossible to do so for the presence of large pools of water which stood on its surface, sufficient to sail a boat on. This information was given quite gratuitously by his lordship, who knew nothing of the writer's interest in or views of the subject at the time. I knew personally also of two extensive plantations on the Marquis of Lotbian's estates in Roxburghshire, in which, while the wood was growing, the soil was perfectly dry and comfortable to walk upon, but after the wood was cut and cleared the ground became so very wet that extensive draining had to be done before it could be replanted which is a common result experienced by every forester. On the same estate I knew also of two springs of water which from information obtained from old people, proved that they had increased from that of nearly damp surface spots to that of very copious springs, both of which, after the plantations in which they were situated were cut down after attaining maturity, entirely dried up. I could multiply examples of these ad infinitum, but I believe it to be unnecessary to do so, at least at present.

It may appear both strange and unaccountable to many (though true to demonstration) that while the soil inside a plantation is drier than it is outside of it, yet the grass and other herbage upon the surface retains moisture, and remains wet hours after similar herbage is quite dry beyond its boundary. The temperature of the soil of a plantation in winter is also higher than that upon which no trees are growing, but in summer the order is reversed, especially in very hot weather, when it is found that the soil in the plantation is colder than that in the open field. It may perhaps be argued that since snow does not melt so fast in a plantation as it does in the open plain, therefore the soil cannot in reality be so warm; but it must be borne in mind that the melting of snow depends more upon exposure to the wind than upon any other cause. The practical and vital question for consideration however, is this - Do plantations attract rain and moisture more than the open fields and plains do? and do they also retain moisture longer? If, on the one hand, plantations retain moisture more than the open field, it must be inferred, as a natural result, that the soil in the plantation must

be wetter than it is elsewhere; but, as has already been shown, as the soil of a plantation is not wetter, but drier than it is elsewhere, it remains therefore still to be shown wherein and how the moisture exists, which is proved beyond doubt to increase and enlarge our springs, streams, lakes, and rivers. It has already been shown that the soil in a plantation is drier than it is outside of it, also that the herbage in a plantation remains wet hours after it is dry elsewhere; again, that certain springs in plantations grow stronger as the trees grow up and cover the ground, and the same springs dry up altogether when the trees surrounding them are cut down. With these facts before us, strange and conflicting though they appear, it yet further remains to be shown how and in what way the foregoing results are brought about, and in what way they are produced. To these apparently contradictory statements we may add others, such as woods and forests drying soil, and yet tending materially to increase water springs, &c. The cloud of difficulty seems rather to gather than disperse as we look at the saturated ground converted almost into ponds and lakes as the result of cutting down and clearing the woods, while at the same time the ultimate result is the serious diminution of our water supplies in springs, &c.

Having endeavoured to show, though it is feared but very imperfectly, the many-sided aspects and phases of the subject, there yet remains to be pointed out what appears to the writer the most important fact of all—namely, the shade which trees produce, thereby preventing the solar rays from unduly heating the ground in summer weather, and also by the same or corresponding means preventing evaporation, which undoubtedly are the principal, if not the only causes of the drying up of springs and diminishing the volume of water in our streams, lakes, and rivers, which has been the subject of much prolonged discussion and bases of many theories for ages past, and probably also may be for time yet to come. C. Y.

Michie, Cullen, Banffshire.

A NEW GARDEN AT BARODA.

THE Baroda (India) Public Garden is situated between the ancient city of that name and the British camp. It consists of about 100 acres of good alluvial soil, and is traversed by the Vishwantir irver its whole length, by many winding and graceful curves in a most picturesque manner, and its banks being studded with Hindoo temples adds much to the beauty of the scene, and says much for the good and enlightened taste of his Highness the young Gaekwar and his able late Prime Minister, Sir J. Madav Rao, in selecting such an admirable site for a garden. The garden was formally thrown open, and presented by his Highness to his subjects in perpetuity, in January, 1879. The main cutrance is on the city side, and is adorned by massive and handsome cast-iron gates and finely carved stone pillars, each surmounted by an ornamental lamp.

On entering there is a flower garden on either side, which is always kept gay with flowering plants. If your visit be in the monsoon months, splendid Balsams, Zinnias, Cockscombs, Marigolds, &c., meet your gaze in all the brilliant colours of the rainbow; if you gaze had no triman consistence and weather, Nasturtiusas, Phlox Drummondi, Petunias, Stocks, Verbenas, &c.; and if in the very hot weather of summer, Portulaccas, Sunflower, Calilopsis, &c., keep a continual succession of flowers, with an evergreen turf kept so by constant watering. Passing on over a fine stone bridge which crosses a small tributary of the Vishwamtri, you perceive the Gackwar's pavilion, or pleasure-house, which alone is kept for his Highness' private use. On your right and left are extensive undulating lawns with magnificent specimen trees of Tamarindus indica and Mangifera indica; in front of the pavilion is a very large circular flower garden all on turf: it is divided into a very neat plan of eight large diamond beds, twenty-four smaller angular beds, and one large circular bed in the centre, which is intended for a fountain hereafter. Taking the road to your right brings you to a large plant-house in the shape of a cross, each arm 100 feet long by 50 feet wide, with a handsome stone tank, 30 feet in diameter, with rocky scenery for fountains, their sides clothed with Ferns, Caladiums, and other moistureloving plants, with fine jets of water playing from among the rocks in delightfully cool sprays. The other parts of the house is filled with the luxuriant vegetation of more moist climes, such as Palms, Crotons, Dracconas, Anthuriums, Dieffenbachias, Marantas, &c.; it is in such places you see the Eucharis in its full glory, with its dark pea-green foliage and snow-white flowers.

Leaving the plant-house by the opposite door from that which we entered, we pass on to the west through lofty clumps of Bamboo and finely-kept lawns, studded here and there with a nice standard Rose, or a stately Fourcroya, rearing its flower-stem some 20 to 30 feet high. A little further on we come to a small irregular lake with a small island and a pigconcot on it; we have now a straight avenue of Guatteria longifolia, and on either side a rosery, planted mostly with standards of the Noisette and Tea sections, which appear to thrive much better than the hybrid perpetuals. They are also all grown on the Rose Edouard as a stock, which renders them much hardier. At the end of this rosery stands a little ornamental hexagonal summer-house to all appearance, but it is the Superintendent's office, and about 50 yards further west stands a pretty little aviary, the dome of which is surmounted by a spread eagle. About 50 yards further on we come to the end of this avenue; when we turn sharp to our right before us is another avenue, but this time of Poinciana regia, on a slightly raised piece of ground. To the right of this avenue there is a fine band-stand, where music is freely discoursed once a week to all who like to come and hear it; over the bandstand climbs many a handsome creeper, prominent among which is the Bougainvillea glabra, Quis-qualis indica, Dalbergia scandens, &c.; round the bandstand is a portion set apart for pedestrians only, where horses and carriages are excluded : ornamental stone and cast iron seats are plentifully placed for the use of the public under the shade of fine clumps of Bamboos, and the magnificent Teak tree (Tectona grandis). Leaving the bandstand and following the Poinciana avenue for 200 yards we come to the North or Camp Gate, where there is another lawn and fine flower garden, gay at all seasons with flowering plants; on either side are fine shrubberies to divide the three carriage drives that here meet, and then branch out through the garden. We will leave the gate on our left, and follow the drive that leads east through a fine grove of Babool trees (Acacia arabica), which when in flower scent the air for a long way with their sweet aroma. Having traversed about 100 yards, having on our left a tropical jungle which has been assisted by art to shut out the camp from view, we come to the River Vishwamtri : the carriage drive now follows its natural winding, and curves for nearly two miles through shrubheries of tropical luxuriance, past artificial mounds with winding paths to their tops, where fine views of the garden and surrounding country are obtained, the sides of which are planted with succulent plants and large stones for rocks. In a hollow of the bank is a fine clump of Arundo donax, with the variegated form in the foreground; to the right between us and the bandstand are three bowers, each 75 feet long, covered with twelve different varieties of creepers each, affording a cool and grateful shade from the mid-day sun. Passing on through groves of Cocoa-nut and Orange trees, we come out on a pretty little marble summer-house such as only Orientals indulge in, of beautiful and chaste carved workmanship. Still following the river we come to a large iron bridge which spans it, 200 feet long, with very handsome stone cupolas at each end. This bridge connects the garden proper with the zoological part, which is still in its infancy. At the east end of this portion stands a pretty little cottage covered with creepers, at one end of which is the Antigonon leptopus, covering over 1000 square feet of the roof. To the south of the Superintendent's house are the quarters for all the under-gardeners, of whom there are about forty, the rest of the labour required being supplied daily by about a hundred prison "hands," and who look the most contented of labourers.

We will now return over the bridge and resume our walk along the river bank. On our right is a maze, with dense hedges of Juga duleis, from which you hear the hum of voices as the people in their holiday attire try to thread its intricate paths. Past this we come to three fine lawn tennis courts, where morning and evening, parties enjoy themselves. Divided by a shrubbery of Neriums from the lawn tennis courts is the general nursery, which has been a scene of activity for the last four years. When we remember that most of all the plants in this large garden have been raised from seeds and planted out into their permanent sites, we can fancy there has

been work, but the climate has assisted also; every thing grows with tropical luxuriance and rapidity.

As we pass round the nursery we observe a large square tank elevated some 25 feet above ground level, and naturally ask, What is this? Without this there could be no garden. Through this and a lower masonry tank passes the water for the whole garden. engines and two pumps work twelve hours every day all through the dry weather (that is, for eight months of the year), each throwing over 6000 gallons per hour. The tanks are connected with the underground system of piping, which supplies the whole garden, and there is no part more than 300 feet from a The water is distributed over the ground standpipe. by means of canvas hose from these standpipes. greater portion of all this has been done under the present Superintendent's directions. Some four years ago a few carriage drives and a few footpaths were all that could be seen of this now splendid garden, present incumbent, J. M. Henry, is one of our northern gardeners who, after being through many of our good gardens at home, was sent out as a young man Kew to the Madras Agri-Horticultural Society. After serving his contract time with the above Society he travelled a great part of India, and finally settled down under the enlightened and good government of one of India's most promising young rulers. Hortus.

VEGETABLE PRODUCTS OF SMYRNA.

In a very elaborate report on the trade and commerce of Smyrna for the years 1877 to 1881 the British Consul has given some very interesting details on the products of the country. The following abstracts under their respective heads will, no doubt, prove acceptable to our readers. Thus we are informed that dried fruits are the most important of the many exports of Smyrna, employing a vast amount of labour, and giving an adequate return for the outlay of capital. Foremost among them are

RAISINS.—Those growing in the district of Smyrna are of four descriptions — black, red, Sultanas, and Currants. The black, which are exported chiefly to France, are used exclusively for wine making, and for the distilling of spirit. The red and Sultanas are for the table, and fetch a much higher price than the black. Currants are shipped in insignificant quantities, but are necessarily included in the general export.

The exportation of this fruit has increased greatly during the last few years. The ordinary crop some years since did not exceed 25,000 tons, but the cultivation having been extended to meet the demand the export in 1877 and 1878 advanced to 28,500 tons each year, and for the three following years it averaged 48,600 tons, and in value nearly £1,000,000 sterli The production of black Raisins especially has been largely developed since 1877. In that year France consumed little more than 7000 tons of this species of fruit; in 1879 her consumption rose to nearly 20,000 tons, and it advanced in 1880 and 1881 to an average of 25,500 tons. As the demand from France-in consequence of the ravages of the Phylloxera in her own vineyards, and a succession of bad vintages-still continues, and appears likely to increase year by year, the cultivation of the Vine in the district of Smyrna is extending, even in a ratio disproportionate, it may be, to the future demand, and there is some danger lest the supply should overrun the demand, and the profits go to the consumers rather than to the producers.

Smyrna Raisins are of four qualities. The hest are grown on the peninsula of Carabournon, at the entrance to the Gulf of Smyrna; the second quality at Vourlah, within the Gulf, and at Phokes, just outside it; the third at Chesmé, on the coast, opposite Scio; the fourth, called Verli, in the neighbourhood of Smyrna, and inland. Between the value of the first and last qualities there is a difference of from 50 to 60 per cent. Currants are grown only at Phokes.

VALONEA.—This well known tanning material is composed of the acorn cups of Quercus Ægilops, and the quantily exported is said to have fluctuated much of late years. The crop begins to reach Smyrna at the end of September, and continues to arrive until the August following. Each year's export, therefore, comprises the crop of the preceding year. It is necessary to dry the cups for some months before shipment in order to avoid fermentation, which would greatly

diminish the value. Shipment is made from December to August. England takes at least two-thirds of the entire export, and chiefly of the middling qualities, while Austria will have none but the finest, and Italy is content with the refuse, Venice, however, demands the best. The Valonea Oak grows wild all along the west coast of Asia Minor from the Dardandles to Adalia, and for about 200 miles inland. There are three different growths—first, that of Nazli, Davas, and Ghiunda; second, that of Aidia, Demirjik, Borlo, Budrum, and the Dardanelles; and third, that of Ushak. The quality of the Valonea depends on its being thick and heavy and of a light ash colour.

MADDER ROOTS (RUBIA TINCTORUM).—Madder, or Alizari, was some years since one of the principal exports of Smyrna, the yearly shipment reaching 65,000 to 70,000 quintals; but it has now fallen almost entirely out of demand, being superseded by cochineal. The average annual export of five years was only 1678 bales of about 800 lb. each. The root used to be largely cultivated in Asia Minor for its red dye—the garance of the French; but the cultivation has almost ceased, and the root is now dug up merely to make room for some more profitable crop, and is sold to cover the expense of its extraction. The average price of Smyrna during the five years has been 13s. 6d. to 14t. per cwt. free on board, Germany, England, and the United States being the customers.

OPIUM (PAPAVER SOMNIFERUM) .- The export of this, the most costly product of Smyrna, has varied considerably during the five years in question, for the crop depends entirely upon the season. The export of 1881 was the largest ever known in one year. Opium is grown in the valleys and plains of the interior, and also in the highlands, throughout a wide extent of country, from Kutaya and Balukhissar in the north to Islarta and Koniah in the south, quality varies in different localities, and depends on the quantity of morphice it contains. Thus the best that is grown at Balukhissar and Ushak, for it contains II to II per cent, of that principle; that from Akhissar and Kirkagatch contains from 8 to 10 per cent.; that from Asium Karahissar from 71 to 9 per ceat.; that from Kouiah only from 7 to 8 per cent. The best customer for the opium of Smyrna is England, though but a small quantity is consumed at home, the greater portion being reshipped to the United States, Cuba, and British Guiana; indeed, the larger part of the export to America goes by way of Liverpool. A considerable quantity is also shipped, vid Egypt, for China, Hong Kong, Singapore, and The average value of the opium exported from Smyrna during the five years in question was £517,300

POPPY SEED. — Notwithstanding the abundant opium crop of 1881, the export of Poppy seed has experienced no development, but has fallen off since 1877, when it reached 4220 tons, to 1493 tons in 1879, to 836 tons in 1880, and to 283 tons in 1881. This is owing both to the extension of the cultivation and to an increased home consumption of the seed, the oil of which is largely consumed by the Turkish peasantry of Asia Minor. This oil is used in Europe to grease machinery, for which it is well adapted, as it does not readily congeal, and in the manufacture of soap. The seed is exported chiefly to France, Germany, Holland, and Italy; none to England or the United States.

TOBACCO AND TUMBERI .- Though the cultivation of Tobacco has greatly extended of late years in the district of Smyrna, its exportation has not affected to any material extent, as the foreign demand is limited. The greater portion of the crop exported is sent to Egypt and other parts of the Ottoman The principal foreign consumers are the Empire. Russians, after whom come the Germans. England takes but a trifling portion of the export. Anatolian Tobacco is of three qualities; the best grown at Lighda, in the district of Eudemish, and at Ayaslouk, near Ephesus, both in the valley of the Cayster; the second comes from Baindyr and Thyra, in the same valley; from Pergamos, in the Caicus valley; and from Denizli, in the Meander valley; the third from Magnesia, Cassaba, and other spots in the plain of the Hermus, although Magnesia also grows some of the finest quality. The export was very large in 1880, and it was valued at £310,400; but in the following year it fell off enormously, not reaching one-tenth of

that sum in value. This decline was in part nwing to the drought and locusts in that year, but also in great measure to the fact that the Russians, having begun to grow Tobacco in Circassia and in the Crimea, have raised the duties on foreign growths, and thus take a much smaller supply from Smyrna. The entire crop from Eudemish and Ayaslouk has hitherto gone to the Russian market. Tumbeki is a description of Tobacco grown in Persia, and imported both through Trebizond and vid Bushire, on the Persian Gulf. A large quantity is consumed in the district of Smyrna, but much is also re-exported to Egypt and other parts of Turkey. It is much stronger than ordinary Tob and cannot be smoked in the usual way, therefore it is used exclusively for the narghileh.

OLIVE OIL (OLEA EUROPÆA) .- The oil of Smyroa is rudely pressed and carelessly prepared, so that it is not suited for the table, but only for ordinary purposes, yet it finds a ready market in the North of England, however, is the largest consumer, followed by France, Germany, Holland, Italy, Austria, and Russia. It is exported in barrels, which contain on an average 5 cwt. or 63 imperial gallons. on an average 5 cwt. or 03 imperior 5... The export varies greatly according to the crop. In 1879 it reached 6550 tons, valued at £261,440. following year it fell to 310 tons, worth £11,184, but rose again in 1881 to 4200 tons, and in value, £135,336. Olive oil is of three qualities. The first comes from Airah and Adramyti, the second from Mitylene, which is inferior only on account of its greenish hue; the third quality from Aidin and Baindye. All three qualities are produced in the neighbourhood of Smyrna.

LIQUORICE ROOTS (GLYCYRRHIZA GLABRA). This export, which is a natural product, and not the result of cultivation, is largely increasing year by year. The plant grows wild throughout vast districts of the interior, and the only cost is the labour of digging it up, drying and packing it, and transport to the coast for shipment. The entire export, with the exception of a small quantity sent to France, and an insignifi-cant one to England, goes to the United States in the state of roots, where it is boiled down and converted into paste, the Liquorice of commerce. The roots are packed in hales by hydraulic pressure. recently the bales were of different sizes; now they are generally uniform in size, containing 10 or 11 cubic feet, or about a quarter of a ton by measurement, and weighing 280 lb. to 340 lb. This export advanced from 44,700 bales, valued at £53,608, in 1877, to 63,000 bales, worth £127,600, in 1881. The demand for the root in the United States was very heavy in 1880 and 1881.

LIQUORICE PASTE, - The principal exporters of Liquorice roots, Messrs. McAndrews & Forbes, have a large factory in New York, to which they send the roots they collect in Asia Minor to be converted into paste. In America the paste is used for preparing tobacco; the leaves are soaked in the melted paste to give them the flavour which chewers of that weed most relish. The paste is also used in the United States as a remedy for scorbutic affections. In England it serves to flavour porter. In France it is used to make syrups and drinks for the sick. The juice expressed from the root is also used in France to flavour wine. Previous to 1873 some 30,000 or 40,000 cases of paste were shipped annually from Smyrna to the United States, where a very small duty was imposed on it, but in that year the American Government put a duty of 10 cents per pound on it, while admitting the root free. The consequence is that no paste is now sent direct to the States, but the greater part goes to British America, where it either serves for local consumption, or is smuggled into the States. Though the export of the paste bas fallen off greatly of late years a considerable quantity is still manufactured in the Meander and Hermus valleys. The roots when dug up are left to dry throughout the summer, by which process they lose some 60 per cent. of their weight, and are then ground to powder and boiled with water, and the liquor being poured into boxes to cool, becomes liquorice paste. It is in a mass, not in sticks, for it cannot be made to keep that form without sor traneous ingredient, although the superior and more valuable liquorice of Sicily and Calabria can be made into sticks, and is so exported into England. The Turkish liquorice is not so sweet as that of Spain or Sicily, but generally keeps better, and requires more sugar, which is the only ingredient mixed with the paste. Liquorice paste is shipped in cases weighing about 2 cwt. and worth from £3 to £4 each.

(To be continued.)

Variorum.

KOKUM BUTTER .- The following interesting note on Garcinia indica is contained in Dr. Dymock's recently published Vegetable Materia Medica of Western India. It is of value because it corrects a statement often made in books, that it is used to adulterate "ghee," or liquid butter. states that the tree is common on the Western Coast between Damaun and Goa. It grows wild upon the hills of the Concans, but is often seen in gardens close to the sea. It is in flower about Christmas, and ripens its fruit in April and May. The fruit is largely used all along the Western Coast as an acid ingredient in curries, and in a dry state as an article of commerce. The usual mode of preparing it is to remove the seeds and dry the pulp in the sun; it is then slightly salted, and is ready for market. In Goa the pulp is sometimes separated from the skin and made into large globular or elongated masses. oil is extracted from the seeds by pounding and boiling them; it becomes solid on cooking, and is moulded by hand into the well-known egg-shaped balls, or concavo-convex cakes, known as Kokum "The natives occasionally use it for cookbutter. ing, but the statement that it is largely used in Goa to adulterate ghee (liquid butter) is incorrect. first place no ghee is made in Goa; the bulk of the inhabitants, who are Christians, obtain their ghee (lard) from the pigs which abound in that territory, and the Hindoos import theirs from Bombay. few cattle are kept in Goa that it is difficult to obtain milk, and still more so butter."

TAMARINDS: TAMARINDUS INDICA .- There are but few people to whom the flavour of preserved Tamarinds is not agreeable, but do those who frequently use Tamarinds know how they are prepared? They come into commerce both from the East and West Indies; the latter, it would seem, are simply the fruits, or, rather, pods from which the shell or epicarp has been removed, and the pulp, together with the strong fibrous framework upon which it is built, and the seeds are placed in alternate layers with powdered sugar in a cask or jar, over which hoiling syrup is afterwards poured. In the East Indies it seems they are prepared by first removing the epicarp and seeds by hand, after which the pulpy portion is usually mixed with about 10 per cent. of salt, and trodden into a mass with the naked feet. Of these Tamarinds several qualities are known in the market, the best being free of fibre and husk, and the worst containing both, together with the hard stonelike seeds, which are commonly eaten in the East Indies after being roasted and soaked to remove the outer skin, and then boiled or fried, when they are said to be tolerably palatable. West Indian Tamarinds are alone officinal in the British Pharmacopaia; while on the Continent those from the East Indies are alone employed. Besides the Tamarinds sent to Europe, they are also shipped in large quantities from Bombay to Persia and other northern countries.

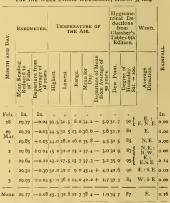

TONQUIN OR TONGA BEAN. - Mr. Prestoe, in his report on the Trinidad Botanic Gardens has some interesting notes on what he supposes to he a new species or form of Tonquin Bean from Venezuela. He says the high price ruling for Tonquin or Tonga Beans in a prepared state has attracted much attention to it as a tree of some promise under cultivation, and in consequence inquiries have been made for supplies of plants. The roots of the large trees in the garden are said to be seriously affected at the roots by fungoid growths, all attempts to suppress which have hitherto proved only partially effective. On the subject of this Venezuelan plant, or "Sarapia," as it is called, Mr. Prestoe says: — "It has long been known that there existed in Venezuela a much larger variety of Tonga Bean than that produced on the garden trees, and differing considerably from that described as Dipteryx odorata, inhabiting the British and Dutch Guianas; and, steps being taken to obtain supplies of fresh seeds, several lots have been received in the form of entire fruits, which are uniformly of this larger and very superior variety. The fruit is usually twice as large again as the Demerara Tonga Bean and that figured by Aublet. The habit of the tree bearing this superior Bean resembles that of the Mango, having much less the character of a forest tree than that bearing the smaller leaves. The pre-sent high commercial value of the Sarapia," Mr

Prestoe says, "arises from a widespread and ever increasing appreciation of its use in Europe and America as a flavouring material in articles of im-mense consumption, such as tobacco, cigars, cacao, confectionery, &c., but more particularly the former; so that its consumption will rather increase than This paragraph, though it mentions the Sarapia, we presume alludes to the Tonquin Bean of commerce (D. odorata). It is suggested that as a plantation of these trees would partake more of the character of a forest than a plantation, such, for instance, as Cocoa, the only cultural requirement would be such clearing as to render easy the collecting of the fruits as they fall to the ground.

GUM SARCOCOLLA.-A new light on the source of Gum Sarcocolla, which is also known in Bombay as "Gujar," and in Arabia and Persia as "Auzeroot," is given by Dr. Dymock in his Vege-table Materia Medica of Western India. For a long time this substance has been doubtfully referred to a species of Penæa, belonging to the natural order Penæaceæ, but it has always been felt to have a very shaky position there, inasmuch as the species are all African. Dioscorides describes Sarcocolla as the tear of a Persian tree, that the gum resembles powdered frankincense, with a bitterish taste and a reddish colour. It is seldom seen in Europe at the present time, though it is still largely used in the East as a drug. "It is also used internally as an antirheumatic and anthelmintic, and the Egyptian women eat it on account of its fat-tening properties." It is imported into Bombay from the Persian port of Bushire in bags containing about 2 cwt. Dr. Dymock says the total quantity imported must be considerable, as from twelve to twenty bags may often he seen in a single warehouse. From pods and other portions of the plant taken from bales of the gum, he is strongly of opioion that its source will prove to be one of the desert Leguminosee, not far removed from Astragalus. From the entire absence of leaves in the bales it would seem "that the Sarcocolla is collected by heating the bushes after the leaves have fallen."

The Meather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON FOR THE WEEK ENDING WEDNESDAY, MARCH 5, 1884

Feb. 28.—Cold day and night, overcast generally. Slight fall of snow in alternoon.

— 29 —Fine day and night.

March i. —Fine bright day, overcast at night.

— 3.—Fine cold morains, slight rain falling nearly all day in the cold morains, slight rain falling nearly all day to be place at midnight.

— 4.—Very slight rain from early morning till 1.30 p.m.

— Fine bright morning, overcast afternoon. Fine charming.

LONDON: Atmospheric Pressure,-During the week

the level of the sea increased from 29.48 inches at the beginning of the week to 29.95 inches by 9 A.M. the beginning of the week to 29,95 inches by 9 A.M. on the 26th, decreased to 29,94 inches by 3 P.M. on the same day, increased to 30.04 inches by 9 A.M. on the 28th, increased to 30.05 inches by 9 P.M. on the 28th, increased to 30.05 inches by 9 P.M. on the 28th, increased to 30.05 inches by 9 P.M. on March I, and was 30.04 inches by the end of the week. The mean reading of the barometer for the week at the level of the sea was 29.93 inches, being 0.17 inch higher than last week, and 0.06 inch above the average

higher than 1887 of the week. Temperature, — The highest temperature in the shade in the week was 47°.5, on February 24; the highest reached on February 28 was 39°.5. The mean of the seven high day temperatures was 44°.7. The lowest temperature was 28°, on March 1; on the seven 24 the lowest temperature was 39°. The

February 24 the lowest temperature was 39°. The mean of the seven low night temperatures was 32°.6. The greatest range of temperature in one day was 16°, on March 1; the smallest was 8°, on the 28th. The mean of the seven daily ranges was 12°.1.

The mean of the seven daily ranges was 12.1.

The mean temperatures were—on February 24, 43°; on the 25th, 39°.9; on the 26th, 39°.7; on the 27th, 37°.5; on the 28th, 34°.2; on the 29th, 36°.6; and on March 1, 35°.8; of these the first two were above their averages by 3°.7; and o°.4; respectively, and the rest were below by 2°.4, 5°.9, 3°.6, and 4°.5 respectively; the 26th was the same as its

The mean temperature was 38.1, being 5.1 lower than last week, and 1.8 below the average of the week.

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 94°.5, on March 1. The mean of the seven

readings was 75°.7.

The lowest reading of a thermometer with its bulb placed on grass was 20°.5, on March 1. The mean of the seven readings was 24°.1.

Rain fell on the 25th to the amount of 0.03 inch. Hail fell on the 25th. Fog prevailed on the 26th and 27th. Snow fell on the 28th.

ENGLAND : Temperature .- During the week ending March r the highest temperatures were at Plymouth, 53°, 5, at Truro 52°, at Cambridge and Sunderland 50°; the highest at Bradlord was 45°.6, and at Bolton and The general mean was 48°.6. Preston 46°.

The mean of the seven low night temperatures was highest at Truro, 49°. 5, at Plymouth 45°. at No. 12°. at Plymouth 35°. 6, and at Brighton 31°. 3. The general mean was 20°. The greatest ranges were 24°. 5 at Sheffield, 24° at Cambridge, 23° at Wolverhampton, 26°. The greatest ranges were 24°. 5 at Sheffield, 24° at Cambridge, 23° at Wolverhampton; the smallest ranges were 12° at Truro, 16°. 1 at Liverpool, and 17° at Preston. The general mean was 19°. 6.

The mean of the seven high day temperatures was highest at Truro, 49°. 5, at Plymouth 45°. 2, at Nottingham 45°. 4, and was lowest at Bolton, 41°. 2, at Liverpool 41°. 9, and at Bradford 42°. 1. The general mean was 44°. 3.

The mean of the seven low night temperatures was highest at Truro, 42°,7, at Plymouth 39°,2, at Bristol 35°,8; and was lowest at Hull 30°,4, at Wolverhampton, 30°,6, and at Cambridge 31°,3. The general mean was 34°,1.

The mean daily range of temperature was greatest at Cambridge, 14°, at Wolverbampton 13°,3, at Nottingham 13°,1; and was least at Truro, 6°,8, at Liverpool 7°,6, and at Sunderland 8°. The general mean was 10°,2.

The mean temperature was bighest at Truro, 45°.6,

The nean temperature was bighest at Truro, 45°.6, at Plymouth 43°.1, at Brighton 39°.5; and was lowest at Bolton and Hull, 36°.2, and at Wolverhampton 36°.6. The general mean was 38°.6.

Rain.—The llargest fall, was 1.34 inch, at Truro, 0.86 inch at Plymouth, 0.47 inch at Preston; the smallest fall was 0.03 inch at Blackheath. No rain fell at Brighton or Wolverhampton. The general mean fall was 0.29 inch.

SCOTLAND: Temperature.—During the week ending March 1, the highest temperature was 48°, at Edinburgh; at Paisley the highest was 44°. The general mean was 46°.1.

general mean was 46°.1.

The lowest temperature in the week was 23°, at Perth; at Aberdeen the lowest temperature was 30°.4.

The general mean was 27°.

The mean temperature was highest at Edinburgh and Aberdeen, 37°.7; and lowest at Perth, 35°.9.

The general mean was 36°.9.

Rain. — The largest Iall was 0.85 inch, at Edinburgh. The general mean fall was 0.06 inch, at Edinburgh. The general mean fall was 0.36 inch. JAMES GLAISHER, F.R.S.

Obituary.

DR. GEORGE ENGELMANN,-We greatly regret to have to announce the death, on February 4, of Dr. George Engelmann, who for many years had resided at St. Louis, Missouri, taking a leading part in all matters relating to his profession, to science generally, and botany in particular. Dr. Engelmann was born at Frankfurt-on-the-Maine in 1810, graduated in that city, but soon took up his residence in the United States. It thus happened that he was of necessity almost as well known to British botanists as his associates and fellow labourers, Torrey and Gray, ant those of a younger generation. Engelmann, indeed, has helped forward in divers ways the botany of his adopted land. On the Conifers, the Oaks, the Agaves, the Cactuses, the Vines, the Cuscutas, and sundry other groups he had come to be looked up to as the leading authority. He was a hard worker, and his time and his knowledge were always at the service of his friends and colleagues. To these pages be was a frequent contributor, and a referee in whose authority on certain subjects we were in the habit, like others, of placing implicit confidence, the more so as he was entirely free from dogmatism and ready at once to admit an error or oversight.

His reputation, of course, extended beyond the Eoglish speaking countries, for he had become the leading authority on Conifers and other subjects. So completely had he identified himself with systematic hotany that his earlier morphological work has been forgotten by most people. Nevertheless, it was in his academic essay on plant monstrosities, De Antholysi Prodromus, that the indications of that "calmness and clearness of perception and judgment" that characterised him were first made evident. The work in question preceded by a dozen years or more that of Moquin-Tandon, and though written in rugged Latin, which contrasts unfavourably with the elegant French of Moquin, is remarkable for its clearness of statemeet and simplicity of method. At that time the theory of the metamorphosis of plants enunciated by Goëthe, and which, from a purely morphological point of view, is unaffected by the more modern conceptions of evolution, was making but slow headway. Engelmann's treatise must have been grateto Goëthe, as it furnished numerous confirmations of his views, and elicited from the great philosopher, in February, 1833, that remark as to Engelmann's mental powers which we have placed in inverted commas. At this period Engelmann was the friend and fellow labourer with A. and Schimper, the leaders of morphological botany in Germany. Later nn, as we have seen, Engelmann made his morphological knowledge subservient to his work as a descriptive botanist and systematist; but though subservient, there are frequently traces of it to be met with, which, with the fuller indications given in his private letters, show that to the last he not only retained his interest in morphology, but kept himself informed as to the latest stages of its development.

Engelmano's communications to our own columns related principally to Conifers and Agaves, and it will be within the remembrance of some of our readers how the enthusiastic botanist, at a time of life when most people would have preferred to remain at home, or not wandered away from the comforts of town life, accompanied Professor Sargent, Dr. Parry, and Mr. Skinner in a visit to those forests whence fifty years previously Douglas had sent so many fine Conifers and other plants. Much remained to be cleared up about these plants; their nomenclature and synonymy was a matter of constant discussion, and with constantly varying results. On this expedition Engelmann was enabled to gather many of the plants in the very localities indicated by Douglas, and, more, he was enabled to study their distribution and their modifications as they diverged in one direction or another, or occupied different stations from the coast to the slopes of the mountains. The whole account of this journey is eminently worth reading by persons interested in the trees and shrubs of California and Oregon, and of special interest was the discovery that Cupressus Lawsoniana was the source of a large proportion of the timber used in Oregon under the name of the Port Orford Cedar. Lawson's Cyprus (150 feet high), Douglas Fir, Abies amabilis, grandis, nobilis, Tsuga Pattoniana, Chamæcyparis nutkaensis, Thuia gigantea, and other interesting trees were met with, and their peculiarities noted on the spot. A brief narrative of this memorable expedition, from the pen of one who took part in it, and portraits of three of its members, including Engelmano, was given in our number for July 2, 1881.

Dr. Engelmann occasionally visited this country, when his aid was eagerly sought in settling questions of nomenclature-as may be seen from the numerous notes and memoranda with which he has enriched the national herbaria at Kew. Last summer we were looking forward to another visit from him, but while in Germany, at Kreuznach, he became so feeble and ill that it was feared that he would not live to return to America. On improving somewhat he gave up the inten-

tion of visiting this country, and returned to St. Louis. Here he soon resumed his usual avocations, professional and otherwise. He took cold during the month of January (which, as be himself recorded in our columns only a few weeks since, was very severe), but paid little heed to it, or to the warning of his friends, being, in fact, to all appearance much less ill than in the preceding summer. On February 2-the anniversary of his seventy-fifth birthday-he was persuaded to keep his room, working all the while, partly on meteorological matters, with which he was in correspondence with us at the time, but on the 4th inst. he succumbed to the effect of cold on the lungs. Thus closed the career of an able physician, an acute botanist, an indefatigable labourer in the field of science, and a simple-minded, warmhearted, sympathetic friend.

Enquiries.

"He that questioneth much shall learn much."-BACON.

LABEL.—A correspondent asks what has become of the plant-label that was awarded the 1st prize in the Society of Arts competition two years ago? He thinks a label that was thought good enough to receive a silver medal should have been worth bringing out before now.

Answers to Correspondents.

ACACIA: P. M. It is not exactly known what species of Acacia—or, indeed, if it was an Acacia at all—that is alluded to (not used) by the people you mention. Three species of Acacia are common in Bible lands—A. Seyal, A. nilotica, and A. arabica; and the former, as well as probably the two latter, is believed to be the tree mentioned in the Scriptures (Exodus xxv.) as the Shittah-tree, or Shittim-wood. For an illustration of Acacia Seyal see our number for June 6, 1874, p. 729.

Anthurium Scherzerianum: IV, P. & Sons. C tainly not. It has nothing to do with Orchidaceæ,

CINERARIAS: R. P. Your double Cinerarias are very fine indeed. We should add, however, that there are others of the same colour.—W. W. The flowers are large enough, in all conscience, but very rough.

FURZE: Enquirer. Old Furze may be cut down to the ground-level any time during the months of March and April, and if not of very great age will spring up again during the early summer months.

GINGER BEER PLANT: C. S. We have no knowledge of any plant bearing this name, and from which a good wholesome beverage can be made.

good wholesome beverage can be made.

MUSHROOMS: P., Bristol. The Mushrooms are very curious, and in their present state, although eatable, not excellent. The woolly ting round the stem is very large, and the flesh is thin, dry, and rather tough. The mycelia of two or three different fungl can be seen on the Mushrooms with a microscope, together with an enormous number of Diplodia spores, probably blown on from neighbouring dead twigs or leaves. These mycelia have probably caused the abnormal growth. Under a lens the tops are sprinkled all over with very fine black dots. The curious point is, that under the microscope these black dots resolve themselves into groups of haccidia-bearing Mushroom spores. It is very uncommon to see the spores growing outside serves into groups or faccional-nearing winds from spores. It is very uncommon to see the spores growing outside a Mushroom, and we do not remember having seen then before growing in little clusters all over the pileus, as in your examples. W. G. S.

NAMES OF FRUITS: W. M. B. 1, Baldwin; 2, Warner's King; 3, Royal Somerset.

NAMES OF FRUITS: W.M.B. 1, Baldwin; 2, Warner's King; 3, Royal Somerset.

NAMES OF PLANTS: F. T. Urecolina aurea, T.S. C.
Eurya latuloila variegata. — T. E., Serview. The
Cattleya is a nice form of C. Trianæ. The Oneidium
is O. sculptum; and the Dendrobium only an ordinary
form of D. nobile.— A. T. 1, Davallia solida; 2,
Cytromium falcatum; 3, Goniophebium appendiculatum; 4, Asplenium obtusatum; 5, Polypodium vulgare cambricum; 5, Niphobolus Lingua.— W. Williams. The Thuiopsis is rightly named dolabrata,
but we cannot name the specimen of Pinus, which
so to sufficient. It does not appear to be P. excelsa, of
which you will find an illustration in vol. xix, p. 249.
— P. M. C. Probably Cedrus atlantica, but in poor
condition.— W. Priest. Spiranthes picta.— C. G. M.
Angraceum eburneum.— C. H. P. 1, Veltheimia capensis; 2, Glidia carinata; 3, Osmunda regalis.—
A. B. Kerria japonica.— P. We think it is the
Corsican Pine, Pinus Laricio, but we cannot be certain
without seeing a good specimen.— An Old Subscriber,
1, the Dog's-tooth Volck, Erythronium Dens-canis;
2, Milla bildora, 3, next week; 4, Cryptomeria
next week.

ORCHIDS: Ireland & Thomson. The Cattleya Trianæ

ORCHIDS: Ireland & Thomson. The Cattleya Trianæ is a very good variety; as good as many that have been named. The colour in the lip is very rich. The Odontoglossum triumphans is also a very good form, very bright in colour, and of good size.

PRIMROSE: C. S. The appearance is due to the union, in a very early stage of growth, of four flowers. Thus, we find twenty sepals instead of five, and so on

PROF. REICHENBACH: J. IV. No; but if he is a stranger to you we should advise you to adopt the usual custom observed among gentlemen of getting an introduction, and asking his permission, before you trespass on his time.

SAND: T. G. B. We can see nothing the matter with it, except that it is rather dirty, and think there must be something wrong in your management to account for the Begonias going off.

STRUE: E. L. S. This is a market name for thin, weakly grown Asparagus, generally early forced produce, used for making soup. The prefix "French" indicates that it was imported from France. A dictionary of gardening slang would be more useful than Webster!

WILD STRAWBERRIES: Mons, Blicq. The wild Straw-berries your friend saw growing on trees in Guernsey were in all probability the fruits of the Strawberry tree (Arbutus Unedo), but certainly not of any species of Fragaria.

- Cut flowers from France are being sent in large quantities.

SEEDS.

SEEDS.

LONDON: March 5.—The market for farm seeds is steady, and, as regards values, there is no change to be noted. The sowing demand is fairly active, and the small stocks remaining of foreign Clover seed are being rapidly reduced. With favourable weather business must shortly become very brisk. Of fine English red the supply is falling off. White Clover seed is in good request at the late advance. Askie and Trefoil continue dull. For Italian and perennial Rye-grasses the market is weak. Spring Tares realise 1s. per quarter more money. Canary and Hemp seed are without quotable variation. John Shaw & Soans, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

CORN.

At Mark Lane on Monday English Wheat was firmly held, the extreme of the previous Monday's rates being paid. For foreign Wheat the demand was quiet, but prices steady. Flour was dull of sale, without change in value. Malting Barley met only a limited enquiry, without alteration; grioding was rather against buyers. Beans and Peas met a quiet demand, at previous rates; Beans and Peas met a quiet demand, at previous rates; Coats advanced, but very slowly; and Maize was very firm at 3d. to 6d. above the rates of Monday se'might. —On Wednesday transactions in Wheat were only of limited exteot, but the tone fully steady. Flour was quiet and unchanged in value. But little was done in either malting or grinding Barley, yet prices were very steady. Beans and Peas sold in moderate quantity at Monday's currency. Maize was firm, and Oats were steady, with a moderate demand, —Average prices of corn for the week ending March 1:—Wheat, 37s. 3d.; Barley, 31s. 7d.; Oats, 15d. 10d. For the corresponding period last year:—Wheat, 42s. 6d.; Barley, 33s. 8d.; Oats, 21s. 9d.

CATTLE.

At Copenhagen Fields on Monday there was a firmer tone at opening, but without resulting in any quotable change in either cattle or sheep. Of the former Danish sold at 44. 64. to 54. 44., and Swedish 44. to 44. to 6. The sheep supplies included a large proportion of clipped, which appeared to be preferred, and realised 52. 84. to 65. 44. and 55. 64. to 58. 46. To 59. 51. 60. Since 55. 50. Since 55. 50

Tuesday's Whitechapel market report states that trade Tuesday's Whitechapel market report states that trade was very dull in consequence of the wet weather, more especially for Clover, which was difficult of sale at top prices. Quotations:—Prime old Clover, 955, to 1955, inferior, 603, to 755, i; prime second cut, 903, to 1055, i; inferior, 803, to 1957, inferior, 803, to 1957, inferior, 804, to 865, inferior, 804, to 804, to

POTATOS.

The Borough and Spitalfields Markets reports state that good supplies were on offer, but trade ruled slack, Quotations:—Magnum Bonums, 70s. to 80s.; Regents, 70s. to 80s.; Champions, 50s. to 60s.; Victorias, 70s. to 80s.; and Rocks, 40s. to 90s. per ton.—The imports into London last week were 746 bags 202 barrels from Harlingen, 222 bags Hamburg, 166 Boulogne, 172 boxs. Malta, 120 sacks Bordeaux, and 135 sacks from Rouen.

COALS.

The following are the prices current at market during the week:—Ravensworth West Hartley, 14, 9d.; East Wylam, 75,; Walls End—Haswell, 165, 6d.; Hetton, 165, 6d.; Hetton, Lyons, 155.; Lambton, 765.; Walls, 155.; Caradoc, 165. 6d.; East Hartlepool, 155. 9d.; South Hartlepool, 155. 3d.; Tees, 165. 9d.; Thornley, 155. 0d.

at 101% to 101½ for delivery, and 101½ to 101¼ for the account. The prices of Tuesday and Wednesday were, for delivery, 101¾ 101 101¾ for the account; the same figures were recorded on Thursday.

E UREKA!!! INSECTICIDE, To Brotles, 1s., 2s., and 3s. 4d. each. 7s. 6d. per Gallon. Special quotations for large quantities.

VINES AND VINE CULTURE

By ARCHIBALD F. BARRON,

Superintendent of the Royal Horticultural Society's Gardens.

Opinions of the Hortlcultural Press:-

The Journal of Horticulture says:—
"It is the most complete, and it will be accepted as the standard work on the Vine."

The Gardeners' Chronicle says :" It is eminently practical and useful."

The Garden says:—
"It is undoubtedly the most exhaustive volume upon
Vines and Vine culture ever published."

The Gardeners' Magazine says:
"It will certainly take, and probably keep a leading place in the class of literature to which it beloogs."

The Florist and Fomologist says:

"There is nowhere to be found in our language so complete and thorough a descriptive list of the best varieties of Grapes.

The Midland Counties Herald says:—

"The whole subject is dealt with exbanstively and authoritatively in plaio, expressive, and singularly concise language."

The Irish Farmers' Gazette calls it —
"The most complete work of its kind that has ever been issued from the British Press."

JOURNAL OF HORTICULTURE OFFICE, 171, Fleet Street, London, E.C.

Also to be had of A. F. BARRON, Royal Horticultural Gardens, Chiswick.

BREAKFAST.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast-tables with a delicately flavoured beverage which may save us many beavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until a region of the maladies are floating sound us ready to attack wherever there is a weak pount. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame." Civil Series Gazette.

GREEN'S PATENT "SILENS MESSOR" AND OTHER LAWN-MOWING, ROLLING and COLLECTING MACHINES for 1884.

THE WINNERS OF EVERY PRIZE IN ALL CASES OF COMPETITION.

Patronised by Her Most Gracious Majesty the Queen on many occasions, His Royal Highness the Prince of Wales, the King of the Belgians, the late Emperor of the French, the Emperor of Russia, and most of the Nobility, Clergy, and Gentry of the United Kingdom.

Royal Horticultural Society's Show, South Kensington, London, June 3 to 7, 1881

The "Yournal of Horticultura", of June 9, says: — "Mowing Machines," Alter a critical seamination the Silver Medal was grained to the old firm of world-wide fame, Messrs, Trocen & Soc. of Leeds and London. As the Machines are known in all lands where good lands the complex of the

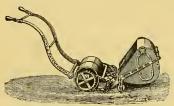

Upwards of 115,000 of these Machines have been Sold since they were first introduced in the year 1856, And thousands of unsolicited Testimonials have been received testifying to their superiority over all others.

They have been submitted to numerous practical tests in Public Competition, and in all cases have carried off every Prize that has been given.

The following are their advantages over all others:

1st. Simplicity of Construction—every part being easily accessible. 2d. They are worked with much greater eases than any other. 3d. They are the least liable to get out of order.

4th. They make little or to noise moveling; 2th. They will cut either short or long Gross, we not ety. CINCLE-HANDED LAWN MOWER

SEND FOR A PRICE LIST OF

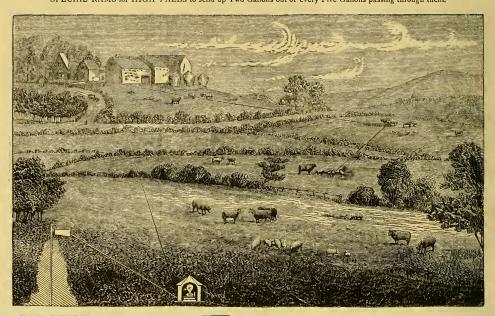

JOHN BLAKE' RAULIC RAMS.

FOR RAISING WATER FOR THE SUPPLY OF

TOWNS, VILLAGES, IRRIGATION, RAILWAY STATIONS, MANSIONS, FOUNTAINS, and FARMS.

No Cost for Motive-Power, which is obtained from a Stream of Water passing through the Rams, NO OILING OR PACKING REQUIRED.

Made in Sizes to Raise from 300 to 500,000 Gallons per day. Will Force to a Height of 1500 feet. SPECIAL RAMS for HIGH FALLS to send up Two Gallons out of every Five Gallons passing through them,

BLAKE'S PATENT HYDRAULIC RAM, worked by water, rising from a 2-inch bors-hole, 90 fest deep, and forcing 3600 gallons per day through 400 yards of delivery pipe to a cistern at the house, at an elevation of 150 feet, from which cistern the water is gravitated to several drinking troughs in the farmyard and fields, the last trough being at the lowest level.

RECENT AND OTHER TESTIMONIALS.

From Mr. A. J. RUTHERFORD, Agent to C. E. H. Bolkoov, Eq. Lettet Office, Marton Hall, Middletorough, Sptember 26, 285,—"Dear Six,—I am glad to say that the Rams von put down on the Hambledon Estate, for Mr. C. F. H. Bolkoow, zare working very well. You undertook, with 16 gallons per minute, to send up 1500 gallons a day, and with enough water to work the Rams as full power, 2000 gallons a day, and with enough water to work the Rams as full power, 2000 gallons per day are sent up to a height of nearly 400 feet. They made a clear start and have gone well since."

The Delivery Fig., in the above case, is 5000 feet in length.

From Mr. HENNY ROBINSON. Engineers to the Succeptor District Waterworks Co., September 10, 1000 feet of the start of the supply of Discreptible of the two Hydradiic Rams we have fixed by your instructions for the supply of Discreptible of the two Hydradiic Rams we have fixed by your fixed to the bolt of 65 feet, but on esting them 1 am convinced that 50,000 gallons is not the limit of their power, whilst the quantity of waste water used in driving them is not equal to half the capacity of the 6-inch pipe by which they are feed, and I am inclined to the belief that a more sumple and deficient pump cannot be found."

From Capital TOWN-SHEND, Wincham, February 10, 1877—" In answer to your inquiry.

them is not squal to half the capacity of the 6-inch pipe by which they are fed, and I am inclined to the belief that a more sample and efficient pump cannot he found." In an architecture of the belief that a more sample and efficient pump cannot he found." In answer to your inquiry I am glad to say the Hydraulic Ram you seek me in Novembert, 1875, is working exceedingly am glad to say the Hydraulic Ram you seek me in Novembert, 1875, is working exceedingly during this winter, forcing up water through a delivery pipe 600 yards long at the rate of 80,000 gallons per day, although you only promised 60,000."

From J. SPENDER CLAY, ESG, Ford Manor, Lingfield, Surrey, August 9, 1880.—"In reply to your letter of inquiry I am glad to be able to asy that the two Hydraulic Rams which you fixed here are working satisfactorily, and that out of 12 gallons 3 quarts per minute, the maximum yell of the spring, 48,185, and 1875, and 1875,

From HORATIO R. B. PEILE, Ed., Commissioner to Six Michael Shaw Stewart, Bart, Mansion House, Gerencé, Aguett a., 1833.—"I am glad to any the Ram you fixed at Caste Farm in November last for Six Michael Robert Shaw Stewart, Bart, continues a great success. The smallness of the driving water—3½ gallons per minute—in sont more wonderful than the large proportion of water it sends up. v1z., 720 gallons per day, through about 400 yards of delivery pipe, to an elevation of 75 feet."

From FRED. J. TURNER, Esq., Agent to His Grace the Duke of Portland, Man. Woodhours, August 20, 1881.—" Dear Sir.—I have much pleasure in stating that the Hydr Rams which you rected last year for His Grace the Duke of Portland, at Lyadhurst, near Man and at Skeldon, Ayrshire, are working very well, and they are most satisfactory in every way

and at Section, Ayrasine, are working very weil, and they are most astistactory in every way.

From Sir A. WOODIWISS, The Pastures, Derby, January 15, 1883.—"Dear Sir,—In reply to your enquiry, I have much pleasure in informing you that the Hydraulic Ram you supplied and fixed for me in July last is working as satisfactorily as could be wished, and has fully realised my expectations, and I have no hesitation in saying it is a decided success."

reasses my expectations, and I nave no heatation in saying it is a decided success."

From Sir ROBERT MENZIES, Bart. of Meuzies, Rannoch Lodge, Rannoch Lodge and Camesurich, two houses three quarters of a mile apart, is a complete success. The extreme distance the water is carried as 3/f, mile, and it is raised fully not obet, and though the elevations of the houses are different, there is a regular supply of y quarts per minute to the properties of the prop

From Mr. WILLIAM LAIT, Architect and County Surveyor, Compton Veruey, Warwick, January 16, 1882.—"I have much pleasure in stating that the Patent Hydraulic Ram I had from you for the Rev. J. Cardwell Gardener, of the Vicarage, Butlers Marston, and which you fixed there, is, I consider, remarkably successful, as indicated below:—42ao galloos of water per day are passing through the Ram with a descent of 13 feet 8 inches. Out of this small quantity 1080 gallous are sent up to a height of 41 feet, showing 18 per cent. of useful effect, and the nise of its working is so slight as to be almost inaudible."

JOHN BLAKE, ENGINEER, ACCRINGTON, LANCASHIRE.

rs. 6d. and 2s. 6d. per packet.

WEBBS' Superb Calceolaria From Mr. HATHAWAY, Gr. to Capt. J. Beavan.

"The Calceolaria seed was a magnificent strain in almost every shade of colour." 15. 6d. and 25. 6d. per packet.

WEBBS' Excelsior Gloxinia.

LACCIOID (IDAIII)
From the Head Garbener to
the Marquis of Ripon.
"Webbs' Excelsior Gloxinia
is a remarkably fine straio.
Every plant has beed good,
with a splendid variety of beautiful flowers."
Is. 6d. and 2s. 6d. per packet.

WEBBS' SHOW PANSY.

From Mr. WALTER CHILD, Gr. to the Earl of Coventry.

"The flowers of Wehhs' Show Pansy are quite unique in colour; the strain is very good."

1s. 6d., and 2s. 6d. per packet.

WEBBS' TUBEROUS ROOTED BEGONIA.

A. D. COCHRANE, Esq., writes : "Begonia seed from your special strain is worth 1000 gs. per ounce." 15. 6d. and 2s. 6d. per packet.

THE

Gardeners' Chronicle.

SATURDAY, MARCH 15, 1884.

LAWNS.

A MONGST the numerous things in a representative English garden that present themselves to those who hail from lands of sunnier skies than we are favoured with, there are none that attract greater attention than our green grass, which soil and climate alike favour. Respecting the latter, which we so often grumble at for its fickle behaviour, it is well to bear in mind that to its changefulness we owe the perpetual greenness of our lawns, the long spells of uninterrupted brightness in the sunnier climes we frequently are inclined to covet being fatal to the justly-prized verdure which is undoubtedly the first feature in a garden, as in its absence the brightest flowers are like pearls in an unworthy setting. Still, with the favourable conditions of alternate sun and shower, with the soil suited to the growth of grass, our lawns are still far from being in all cases what they should or would be, if their construction and after-treatment were not at fault.

Confining the question to the means requisite to secure good permanent grass, it is all but needless to add that in making a lawn, as in all other things connected with the construction of a garden, local circumstances necessarily influence the proceedings. A course that would be expedient to follow in one place would be wholly unsuited in another. Whether turning or sowing be adopted, if a satisfactory lasting green sward is looked for, there must be a sufficient depth of soil, of fair quality, neither too dry nor too wet. In the southern counties, where the rainfall is so much less than in the north, when the subsoil is of a sandy or gravelly nature, unless there is sufficient fairly holding top soil the grass is sure to burn in dry sum-A depth of 15 inches is not more than needful to avoid this, and in making a lawn where a dry bottom such as above-named exists, and the surface-soil is insufficient, enough of a suitable description should be added to bring it up to the required depth; the cost incurred will in the end be found to have been well spent money. The patchy, unsightly appearance often seen in lawns, where the grass appearance the stein in places is poor and weedy, or burns in dry weather, is frequently traceable to faulty con-struction. Where inequalities of the surface bave required removal, sufficient of the undersurface is frequently not removed to allow the needful depth of top soil, thus entailing the mischief named. The effects of this kind of defective work are oftenest seen where the subsoil is of a clayey nature, for although grass does not burn trayey nature, for animogn glass does not so readily on a cool bottom of this nature, still it must have enough depth of soil to sustain the roots and admit their descending low enough in search of the moisture required during spells of dry weather.

On the other hand, there is frequently too much moisture present in land that has to be converted to a lawn, and with some who happen to be engaged in such work there is often a reluctance to drain, if it can be avoided, on account of the subsidence that not unusually takes place afterwards, the end of which is not seen the last of for years, but of which there is not the slightest reason to have misgivings if only sufficient care be taken to ram the material in properly as the work of filling the drains proceeds. In draining a lawn, as in the case of land for any other purpose, it is necessary to be guided by the nature of the soil, and also to bear in mind the particular purpose required. deep, 5 or 6 feet drains that sometimes find advocates, filled up with solid earth, and that can only draw off the water slowly, are all but useless in a lawn where the land is at all of a retentive nature, and the object is to get quit of the water with the least delay, so as to make the surface fit to walk on in the least possible time after a heavy rainfall. With this intention, whatever depth the character of the land may require the drains to be, they should be filled up over the pipes with some kind of porous material to within a foot or 15 inches of the surface, or, in some cases, nearer, so as to take the water off readily. The advantages in lawn draining, where trees are present, of filling in over the pipes with rubble, ballast, clinkers, or similar open material, are twofold, as in addition to its accelerating the passage of the water it enables the drains to act even if the roots, as they usually do, get into the pipes so as to choke them. In heavy retentive soil it is mistaken economy to underdo the work by placing the drains too far asunder; if 15 feet apart they will, as a matter of course, dry the ground so much quicker than if a greater distance intervene.

SOWING .- In the important question of turfing or sowing, here again local circumstances will in each individual case decide. Where a lawn of considerable size is being made, sowing effects a great saving in expense, beyond which it has many advantages, not the least of which is that where the requisite judgment is brought to bear in selecting a mixture such as best suited to the nature of the soil the result will be more satisfactory than with turf, such as is procurable in most localities, for if the land has been properly prepared and effectually cleaned from weeds there is a certainty of an immunity from weeds and coarse grasses, such as have usually more or less to be contended with where turf is used. The idea that there needs be much waiting in getting a good close surface when sowing is adopted is a mistake; providing enough good seed of the right kinds is used, and the work collectively is done as it should be, an unexceptional surface will soon be the result. Again, where the nature of the land and the climate are such as to favour burning in dry summers, sowing has much to recommend it, as grasses which can be selected naturally strike deeper into the soil than are procurable in turf from cultivated land which is always sown with a view to pasturage, rather than with any intention of its being used for the purpose in question. But when sowing is determined on care should be taken to give time for all the seeds of the worst kinds of weeds, such as Docks and Plantains, that are near enough the surface to admit of their vegetating, to make their appearance, and be destroyed. By this means future hand-weeding, which otherwise would be necessary, will be avoided. This is a matter of no slight importance, as the getting out of these and similar pests necessarily entails the disturbance of the young grass, which can ill afford to have its roots interfered with. As to the time of sowing, there is little to choose between the latter end of March and the early part of September. Much depends on the un-foreseen in regard to the weather; the rains usually looked for about these periods are requisite to get the seed to vegetate evenly.

The weight of seed required per acre necessarily depends on the character of the land in its needing a greater or less proportion of heavy or light seeded grasses. Where turfing is decided on the best will invariably be found the cheapest. A good clean article, free from weeds and coar c grasses, is cheaper at the top

figure of its worth than weedy indifferent material is, if obtainable for nothing, as more than the first cost will have to be expended in after-weeding.

TURFING. — When possible turf should always be laid in autumn after the ground has been well moistened by the rains we generally get then, as when carried out at this season the roots have time to take hold before winter; the next best time is in the winter—early enough to avoid the watering that usually has to be resorted to where the work is done in spring. When deferred to spring the ground should be well watered before the turf is laid, giving it a good soaking immediately after, and mulching the surface over with an inch of fine soil, which latter in itsell is worth two or three waterings, by preventing evaporation and encouraging growth. The best course in the way of aftertreatment is not to mow oftener through the ensuing summer than needful to prevent an untidy appearance, not to cut the grass too close, and to do the work with the scythe, dispensing for the first season with the mowing machine.

RENOVATING OLD LAWNS .- In the matter of old lawns, there are many to be met with that are not so good as they once were, and that cannot rightly be described as an ornament to the respective gardens in which they should play no inconspicuous part. The soil in a lawn that has to support the grass that is constantly close cut, in time becomes so poor and exhausted that it cannot keep the crop it is intended to sustain alive, which in dry seasons succumbs, and its place is taken up by weeds and Daisies. This kind of exhaustion is well understood and usually provided against in the case of other things except lawns, which are often subjected to this impoverishing proeess for scores of years without the thought of ever giving them assistance, whereas if an inch or two of fresh loam, free from the seeds of weeds, with a couple of hundredweight of fresh lime added to each cartload, were applied occasionally in the shape of a top-dressing, the con-dition in question would be avoided. Many old lawns are reduced to such a state by the neglect described that they are beyond recovery except by digging over and subjecting the soil to a thorough cleaning and resowing—an opera-tion that need not be costly providing the right course is adopted.

As to the way in which lawns have been disfigured by making croquet or lawn tennis spaces on them, since these games have come into fashion, all that can be said is that where the ground slopes naturally, so that for the games in question one of these dead level deformities has to be made, as they often are, in a prominent position, the effect is so tar hideous as to completely destroy the natural appearance, which is the greatest charm in any garden.

CALOPOGON MULTIFLORUS, Lin:ll.

This has been recently imported by Mr. B. S. Williams, our excellent orchidic patriarch. The fine slender peduncle at hand bears five small lovely flowers, which are comparable to those of a diminished Bletia verecunda. They are of the finest amethyst-purple. The stalk of the lip has on each side at the base an auricle, and on the broad, irregularly square, retuse, emarginate, anterior blade there is at the base a rich tuft of hairy lamellæ (De Bary's "Zotten"), golden-yellow, often purplish at the base; and before these are some purple calli. It is a lovely gem, and I think it has not been seen alive before in Europe in flower. H. G. Rekbb, f.

DENDROBIUM NOBILE (Lindl.) var. ALBA, n. var.

A very pretty variety, kindly forwarded by our orchidic Crossus, Mr. W. Lee, Downside, Leatherhead. It has very pallid purple edges to the sepals and petals, a very pallid purple base and tip of the lip, and a dark purple auther sitting on the green column. It comes very near to Mr. J. Day's favourite variety. II. G. &chb. f.

THE AMARYLLIS AT CHELSEA.

THE recent fine weather has had the effect of pushing forward the Amaryllis bloom in Messrs. Vencu's nursery at an astonishing rate. About the end of January the bulbs were potted, being then in their dry and dormant condition. In four weeks a number of choice varieties were in flower, and in two or three weeks more the general collection has, as it were, burst at once into full beauty. The principal feature in this large collection, and in which most interest centres, is the large number of seedling forms. These become more numerous year by year, and it is needless to say that the quality of the blooms is better this year than it has ever been before. certain to be the case, considering that as soon as a flower has been raised possessing all the requisite properties in a more highly developed state than any obtained heretofore, it is at once used as a seed or pollen-bearing parent. A large proportion of the best seedlings raised in previous years have been sent to the Royal Horticultural and Botanic Societies for certificates, and since the first hybrid form was certificated, fifteen years ago, no less than thirty-nine First-class Certificates have been obtained by the Messrs, Veitch. This, of course, does not represent all the varieties that have been raised worthy of certificates. Every day during the time the seedlings are opening their flowers to the light some choice variety or varieties may be singled out as worthy of the highest awards given to seedlings; but if they are not in good condition at the time the meetings are held they are not exhibited. Last year there was a specially fine seedling form in flower about two weeks before the first show in March. This year again the same thing occurred. The variety in question is not less but more valuable for its early flowering; owing to this babit, however, it fails to obtain a certificate. Almost the very first seedling to bloom this year about the end of February we noted it as first-rate and worthy of a certificate; but, of course, it could not obtain one, as it would be over by the first meeting of the Royal Horticultural Society in March.

It is to be observed that the constitution of the plants has not deteriorated at all, as the form, colour, and quality of the flowers have been so remarkably im-proved. Indeed, it is quite safe to say that the plants have never before been so vigorous as they are this year. The reason of this is not far to seek. If Messrs. Veitch bad continued to cross and intercross their own seedlings only, the vigour of constitution would not have been maintained. They have not done this, but have procured more vigorous constitutioned varieties even than their own seedlings, which have had a very marked effect. Empress of India, for instance, has given form, substance and colour to the seedlings; others have been obtained that produce six large well formed flowers on one umbel, and as many as sixteen from one bulb. The remarkably fine variety named Ne Plus Ultra, which obtained a First-class Certificate from the Royal Horticultural Society on the 11th, was raised from Macbeth × with Empress of India. It is quite of the pollen-parent type, but an improvement in form of that variety. Three more very fine varieties were exhibited with Ne Plus Ultra, and they were all from one seedpod. Horace was the seed-parent, the pollen-parent being Auber. The committee certificated General Graham, a very fine flower, of a crimson colour with a greenish band in the centre of the petals. For our part we thought General Gordon the better flower of the two. The lower petal was not quite so well formed, but the greenish band in General Graham was replaced in this by an ivory. white one, with a very slight tinge of green at the base, William Goldring, from the same cross, is a well formed flower of great substance, crimson-scarlet, with broad greenish-white bands at the base of the segments. The colour is broken up in lines and spots on each side of the bands. We may be over-sanguine, but we should also place this in a first-class position.

The best seedling forms in flower on the 11th in the nursery were Pickwick, a large finely-formed flower, 7 inches across, the petals densely veined and spotted with crimson, showing a creamy ground on the lower petals, also densely spotted. Minerva, another large flower of a delicate purplish-rose colour; the petals very broad, forming a handsome flower. Serrano, a fine smooth flower of the Juoius type, the petals crimson at the base, shading off at the point to crimson-scatlet. Cerise is a very fine slightly modified form of Leopoldi. Polentia, a showy flower,

with scarcely any green at the base of the petals, which are of a luminous rosy-crimson. Corsair is a well-formed flower, of a decided scarlet tinge, with a creamy band down the centre of each petal. Dido, a decidedly improved form of Leopoldi, the creamywhite ground being richly overlaid with crimson. Ajax is not a Chelsea seedling, but it is a very distinct and handsome flower; the colour is crimson-scarlet veined with maroon, through which the yellowish-white ground shows in irregular flakes and blotches. Eldorado, a vigorous form of the crimson and scarlet shade of colour; the petals have a yellowish-green band in the centre; the tube is longer than usual, and the petals slightly reflex. Bayard, intense crimson-scarlet, the base of petals rich dark crimson, petals nicely formed with a creamy blotch at the top of the petaline segments. James Douglas was passing out of flower, but it maintains its first promise of goodness. Terence, light scarlet, large broad petals, with distict greenish centre. The general collection is now finely in flower, and will be at its best during the ensuing week.

DRINKSTONE PARK.

MANY of the Orchids for which this place is deservedly celebrated were in bloom at the time of our visit, which was soon after the middle of February, and they certainly presented a sight well worth going a long way to see. Drinkstone has long been dis tinguished on account of the successful cultivation of these remarkable plants, and its celebrity in this respect does not by any means diminish. giving the names, however, of some of the more remarkable species then in bloom, it may be worth while to give a few particulars regarding the place in general. It lies some 8 miles south-east from Bury St. Edmund's, and is the seat of T. H. Powell, Esq. The mansion or Hall is a large old-fashioned edifice, a large portion of its south front being covered by a magnificent specimen of the Magnolia grandiflora, not less than 40 feet in height, while other portions of its walls are covered with the finest varieties of climbing Roses and other suitable plants. The surrounding country, although somewhat flat, is well wooded, and the soil is a rich loam upon a substratum of gravel, and is consequently admirably suited to the development of the finer kinds of coniferous and other ornamental trees and shrubs, so that the park and grounds contain a fine and well selected assortment of such plants.

Conferous trees are sometimes considered as out of place in park scenery; this, however, does not hold good at Drinkstone, where Mr. Powell has displayed excellent taste in the way of improving the landscape and creating a really charming effect by so skillply blending the dressed grounds with the rich greensward of the park that it is not easy to tell where the one terminates or the other commences.

The park, which covers some 200 acres, including a fine lake over 8 acres in extent, contains also various large groups or clumps of such species the Sequoia gigantea, Taxodium sempervirens, Cedrus Deodara, Picea Douglasii, P. Pinsapo, &c., interspersed with groups of ornamental deciduous trees, producing a warm and very pleasing effect at all seasons of the year. Among species which are conspicuous in the grounds are fine well grown examples of Araucaria imbricata, some 30 feet high; Cedrus Deodara, 60 feet in height; Abies Pinsapo, 40 feet; and fine specimens of Ahies grandis, nobilis, and A. Nordmanniana, &c.; together with Ahies Albertiana or Mertensiana, a fine free growing species; also Libocedrus gigantca, Thuiopsis borealis, Thuia Lobbii, Juniperus recurva, Taxus adpressa, fine plants; with fine Golden Yews and equally fine examples of the various kinds of variegated Hollies, &c.

In addition to a unique fernery under glass, devoted to the culture of the exotic or tender species of these plants, there is also a fernery in the open air for hardy species. This is placed in a somewhat shady and suitable situation, and is formed principally of the roots of large trees. All the plants, like their more tender congeners under glass, succeed admirably; but we were hardly prepared to find in a sheltered corner of this department a fine Todea superha, thriving under the slight protection of a hand-glass, where it has been for several years.

Particular attention is here paid to early spring flowers, many of which, on account of the con-

tinuous mild weather, were in an unusually forward condition. Driokstone is also celebrated as a fruit growing establishment, more particularly as regards the Grape Vine: the weight and quality of the crops of Grapes which are annually produced here are very remarkable.

But we must now mention a few of the most striking Orchids at the present time in flower, and in the first place may be mentioned the Phalzeopsis-house, which is in close proximity to the residence of Mr. George Palmer, the intelligent gardener, and which is the first to attract attention. It is a span-roofed structure, originally used as an early forcing-house or pit, the larger roof facing the south, and even at the present season it is considered necessary to cover this with a single thickness of Haythorn netting in order to throw a slight shade upon the plants during sunshine.

Along the front of the structure is a chamber or pit over hot-water pipes to furnish bottom-heat, and over which most of the plants are suspended. The pipes are now covered by a strong iron grating, which is loosely covered with a few inches of tree leaves kept constantly moist, and through this medium the warmth from the pipes ascends into the house, the temperature of which is carefully regulated by the admission of external air, the ventilators being seldom, if ever, altogether closed. This arrangement appears to suit the plants admirably in all respects, and they have occupied this structure for some twelve months or more.

Most of the Phalænopsis are grown in very handsome cylindrical baskets, some 14 inches in diameter, by about r8 inches deep, and those baskets are all the work of Mr. Powell, who, in addition to his love for Orchids, and his knowledge of their re-quirements, as well as of horticultural pursuits in general, is also an amateur mechanic of no mean order. In these baskets were suspended some twenty or more fine plants of Phalænopsis Schilleriana, together with plants of P. amabilis and P. grandiflora. part of the plants were in full flower, but at the same time there are not a few to succeed them. The ground colour of the flowers was exceedingly pure, and at the same time of a deeper hue than they are generally to be seen in the neighbourhood of London and other towns. This may possibly be ascribed to the more pure condition of the country air. The plants were all pictures of health, without any indications of "spot," or other drawback, while on many of the spikes might be counted as many as forty fully expanded blooms, emitting a most delicious perfume.
The house contained also fine plants of P. Luddemanniana and P. leuchorrhoda, together with the pretty little Angræcum citratum with its numerous spikes of pure white flowers, also grand specimens of Dendrobium Dalhousianum, Oncidium Lanceanum, Saccolabium Blumei majus, &c.

The plant stove is a span-roofed structure, about 30 feet by 15 feet, and is in a great measure devoted to Orchids, which are chiefly suspended from the roof, under which are grown large specimens of fine-foliage as well as flowering stove plants, a portion of the brick stage at one end of the house being devoted to some very fine specimens of Vandas, Aërides, Saccolabiums, Angræcums, Cypripediums, &c., and we noticed also two remarkably fine specimens of the old Phaius Wallichii in full flower, also Phaius grandiflorus, together with Angræcum sesquipedale, very fine; while suspended from the roof are a fine selection of the hest varieties of Dendrobium just coming into flower, which by their free growth and healthy appearance show how much they appear to be at home in the situation which has been assigned to them. There are also suspended along with them some very fine Acrides and Saccolabiums, particularly some large specimens of S. ampul-laceum majus. This house contains some remrk-ably handsome and healthyplants of Adiatuth Farleyense in baskets, suspended along with the

The next division is what is known as the Odonto-glossum-house, and is also span-roofed, with an open water-tank under the central stage. This house presented an extraordinary display of floral beauty, although the plants were not all in full flower, but were all fast approaching that condition, and giving promise of an abundant and long-continued supply of charming flowers, if we may judge by the healthy and robust appearance of the plants, and the numerous unexpanded blooms. Of those at that time in flower, Odontoglossum Alexandere and O. Pescatorei were

remarkably fine, and the same may be said as regards O. cirrosum, O. Halli, O. triumphans, O. pulchellum, O. tripudians, O. cordatum, O. roseum, and O. Rossi majus rubescens, the last-named a remarkably fine specimen (see fig. 63, p. 345). There were also in fine flower in this house plants of Coelogyne cristata, Zygopetalum Mackayi, Pilumna fragrans, and there were in full flower several fine pots of the old Cypripedium insigne, which, grown and flowered as done here, is hy no means to be despised. We also noticed some fine pans of the best Masdevallias in full bloom, while M. tovarensis was just over, but had every appearance of having been fine. Several large masses of Pleione were fast pushing up their growths, together with a very fine specimen of Maxillaria grandiflora in full flower, along with Epidendrum vitellinum majus. Among species not yet in flower, but fast approaching that condition and giving every promise of being fine, were Odontoglossum madrense, O. nebulosum, O. Lindleyanum, O. gloriosum, O. pardinum, O. Cervantesii, O. maculatum, O. citrosmum, &c., with Oncidium concolor, Marshalli, cucullatum, and incurvum, Mesospinidium sanguioeum and vulcanicum. There were also here several Dendrobiums, &c., in a state of rest. The mean temperature of the house, we were informed, does not exceed 48° in summer; of course it may exceed this, but the low temperature of the structure does not prevent such varieties as D. nobile, D. Wardianum, D. crassinode, D. heterocarpum, D. Devonianum, &c., from pushing their blooms freely and strong. The next house or division is devoted chiefly to Cattleyas, and C. Trianæ in great variety alone renders this structure very gay. But in addition to the Cattleyas there were also in bloom large specimens of Cymbidium ehurneum, Lælia anceps, with twenty or more plants of Lycaste Skinneri in almost as many varieties, many fine Dendrobiums in pots, as well as in baskets, such as nobile, thyrsiflorum, Wardianum, crassinode, heterocarpum, crepidatum, Ainsworthii, chrysanthum, &c.; also Sophronitis grandiflora, Cypripedium Argus, and C. villosum. Several plants of Odontoglossum vexillarium were conspicuous on account of their robust and healthy condition. In addition to the species mentioned this house also contained many other varieties of orchidaceous plants not in flower, and to which it may not be necessary to further

The greenhouse is furnished with a fine collection of well grown specimens of the best varieties of hard-wooded and other greenhouse plants, among which we observed pans of Disa grandiflora in fine condition.

The fernery has been mentioned, but it may be further stated that it is a lofty lean-to structure, with a northern aspect, and contains many fine tree and other Ferns, including many Todeas and other filmy varieties. All are planted out, or if any are retained in pots or tubs the same are entirely concealed by various species of Selaginella.

The high back wall, as well as the front and end walls, are cased with virgin cork, and so enduring is this material when used for such purposes that although it has been done for upwards of ten years, no symptoms of decay are perceptible, while Sclaginellas of all kinds cling fondly to it, as does also the pretty little Nertera depressa, which was in full flower; the flowers, it is true, are small and inconspicuous, but will soon be changed into its bright scarlet fruit, and will then present a very pretty appearance.

The gardens and grounds at Drinkstone Fark are not extensive when compared with some garden establishments in this county, but they contain a great deal; indeed, they are brimful of interest, and, taken altogether, reflect much credit upon the taste of the proprietor, as well as upon the skill and industry of his gardener, Mr. George Palmer, to whom we are greatly indebted for his kindness in showing us over, as well as pointing out the many interesting objects contained in the place. P. Grieve, Burry St. Edmunds.

KNIPHOFIA FOLIOSA.—This is closely allied to the ordinary Tritomas of the garden, but is more robust, has broader leaves, and the deose spikes of flowers are of a yellow colour, with very long stamens. It is a native of Abyssinia, and is figured in the Estancial Magazine, 1884, t. 6742, from the garden of H. J. Elwes, Esq.

THE PROPAGATOR.

A CUTTING FRAME: ITS CONSTRUCTION AND MANAGEMENT —The spring is the best time for the propagation of most plants, and at present many gardeoers are at their wits' end to know how to get on with the work fast enough. Year after year numbers of them suffer trouble and disappointment for the want of that first necessity to a propagator, a cutting-frame, and yet it can be simply and easily arranged in any warm house in the following manner:—

The case or frame should be made about 6 feet in length, 3 feet in width, and $2\frac{1}{2}$ feet in depth, or, rather, its highest points should be $2\frac{1}{2}$ feet from the base of the case (or of any modified dimensions to suit convenient places). It should be made in the shape of a half or three-quarter span—i.e., both sides of the case should be made to slope upwards to the centre of the case, and the slope to commence from half or three-quarters of the depth of its sides. If the slopes are not made la equal degrees on both sides it is better to make the longer slope in front. A suitable piece of wood should be fixed into, and thus run across from, one apex of the case to the other—i.e., from end to end—forming the ridge.

Pieces of wood a quarter of an inch square, and cut into lengths of a foot, should be fixed with small nails along the outer edge of the top of the two long sides of the frame, to prevent the panes of glass, which will form the roofing, from slipping off. A space of about half an inch must be left between each piece of wood, to allow the condensed moisture from the glass a free passage.

The covering or roofing of the frame should be of pieces of glass, each about 8 inches wide and of the length requisite to reach the wooden rail running across the top of the case. Thin plate-glass should be used if possible, although ordinary glass can be employed. The bottom of the case must be formed of slates, resting on a framework sufficiently strong to bear them, and although no apertures should be left between the slates, quarter-inch holes should be drilled through them to allow the heat to pass into the cocoa-nut fibre, which is placed 3 inches deep inside the case. A frame so constructed should be put in a Cucumber-house or stove in such a position as to have two or three hot-water pipes running beneath it. The case should he about a foot higher than When finished it will resemble a small the pipes. house or frame, but having loose glasses in place of

When the case has been filled with cuttings the front row of glasses should be removed early each morning for two hours, and the cuttings that are dry should be watered with a finely-spouted pot, while all of them should be gently watered overhead with a finerosed pot to wash off the condensed vapour that has gathered upon them the night before.

If this be neglected a large number of the cuttings will not arrive at maturity. The cocca-out fibre in the bottom of the case should be well mixed together and watered twice in a week, and the glasses on the frame should be washed weekly. This will prevent the former becoming a concrete mass, and will allow the condensed vapour to pass freely off the latter. The old cocca-nut fibre in the case should be exchanged for new at given intervals.

Experience has shown that a propagator can produce a larger number of plants in a frame constructed and worked on the principles we have laid down than in any other we know of. In it the cuttings root quicker, and few of them die from the continual drip which hangs to and drops from " lights."

After the construction of a cutting frame it is most important to have all the plants intended for cutting purposes brought into the propagating-house. A part of the house should, if possible, be set apart for this purpose and kept at an equable temperature, and all the plants should be placed on a moderate bottom-heat. If the latter instruction is followed it will oot only ripeo the old plants but will also be a stimulus to growth in the cuttings taken therefrom.

It is a fact worthy of notice, that cuttings taken off plants previously prepared by being placed in the same house as the cutting case is in, will strike more freely than those taken from old plants not so prepared; and in the case of things difficult to propagate it is absolutely necessary to acclimatise the plants before taking the cuttings. As a rule, cuttings

will strike best in a cutting-pot; there are, however, some exceptions, such, for instance, as the cuttings of Dracenas, Ficus, Aralias, and such-like plants, and these will strike better and quicker when they are inserted in the moist cocoa-nut fibre in the bottom of the case. Many other plants also which are very stubborn in pots will root under these conditions.

In conclusion we may point out that the cuttings when they have been removed from the frame and potted-up, must not under any circumstances be taken from the propagating house, but should be allowed to remain in order to gradually harden and strengthen them. T. O.

The Henbageous Honden.

SCILLA SIBIRICA .- Your correspondent, " Quercus," p. 310, is evidently in a fog with Squills. I presume he refers to bifolia, and not biflora, because that name is untenable, as he will see if he ex-amines the racemes of flowers. My experience of this is very favourable; it increases freely by offsets when planted in light sandy soil well enriched with manure. S. sibirica is rather slow to increase; if in health the bulbs develope to a good size, and ultimately split up into several. The best way to get up a large stock of this is by seed, which, as a rule, is produced freely enough, and it should be sown as soon as ripe in a sunny position, about 2 inches deep, sprinkling a little sharp sand with the seed. "Quercus" evidently regards Chionodoxa as a "form " of Scilla. How does he prove this? Mr. Baker, if I mistake not, is the authority for the genus Chionodoxa, and I feel certain that if these charming plants could have been classed with the Scillas, Mr. Baker would have been the last to have manufactured a fresh name for them [Boissier was the first to establish the genus. ED.]. Further, I am bound to say C. Luciliæ is worthy of the beautiful designation given to it. Probably if "Quercus" could see broad masses of this gem under natural conditions he would concur with what he now regards as a " pretentious "appellation. Granted that many have expressed disappointment about Chionodoxa, but, as I have repeatedly stated, I believe this is due to the fact that the bulbs bitherto distributed have not yet arrived at their full development, and consequently do not produce such well-flowered spikes as they will do in a few years. It delights in a well drained position in rich light soil, and is as hardy as possible. Daf.

SEEDLING HEPATICAS.—At p. 283 you have an article about Hepaticas, in which the writer says he enver saw a seedling near the plant. Now I have a lot of blue and red Hepaticas in a border under a very high wall, and there is one large plant of blue Hepatica in full bloom on the top of the wall, evidently carried there as a seed by a bird. I never saw one so grown before. Charles Tower, Bathford.

THE LEUCOJUMS.—It is curious to note how our old-fashioned plants become forgotten and overlooked; and, when their names occur in florists' catalogues, how difficult it is obtain the true plant when you order it. This is especially true with regard to the Leucojums—the "bulbous Violets" of 200 years ago, and the Snowflakes of our day. Old Father Parkinson wrote in his Paradisus, c. x.:—"The bulbous Violet is a plant that doth challenge a place next unto the Daffodils, as most oearly partaking with them, and a little with the Hyacioths. I must of necessity interpose them, and show their descriptions and differences, whereof some are early, of the first spring, others later, and some of the autumn." If et then gives:—

"1. Leucoium procox majus, the great early bulbous Violet, which hath one white flower, hanging down its head by a very small foot-stalk, made of six leaves of an equal length, every one whereof is tipped at the end with a small greenish yellow spot.

"2. L. bulbosum pracox minus, the lesser early bulbous Violet, bearing one small pendulous flower, consisting of three white leaves, which are small and pointed, standing on the outside, and having three other shorter leaves, which seem like a cup in the middle, being each of them round at the ends, and cut in the middle, making the form of a heart, with a green tip or spot at the broad end or edge." This plant, he says, came from Constantinople.

"3. L. bulbosum vernum minimum, the small bulbous Violet of the spring. This Leucoium sendeth up his small and long green leaves like hairs in autumn and before winter, which abide green until April, and then wither away quite, and about May there ariseth up a naked slender stalk, at the top whereof break forth two small white flowers, made of six leaves apiece, hanging down their heads, the three inner leaves being a little longer than the three outer, and a little reddish near the stalk, and very sweet. This came from Spain and Portugal.

"4, L. bullosum autumnale, the final autumn bulbous Violet. As the former smaller Leucoium sprang up with his leaves in autumn, so this, contrariwise, riseth up with his slender brownish stalk of flowers in autumn, before any green leaves appear, whereon stand two or three very small, snow-white, pendulous flowers, consisting of six leaves a-piece, a little reddish at the bottom of the flower, next unto the stalk, so like unto the former, that one would take them to be both one.

"5. L. majus bulbosum serotinum, the great late flowering bulbous Violet, with a flattish stalk, being thicker in the middle than at both edges, at the top whereof three or four flowers hanging down their heads, consisting of six leaves apiece, all of equal length and bigness, wholly white except that 'each leaf hath a green tip at the end of them.'"

Now of these, I is clearly L. vernum; 2 I cannot identify, but think it must be a Snowdrop, probably Galanthus plicatus; 3 I cannot make out, as I am not aware of any Leucojum from Spain or Portugal. [L. autumnale, L. grandiforum, and L. trichophylum are stated to be natives of Spain or Portugal. Eb.] Parkinson does not appear to have had much acquaintance with it, as he says it was so tender that "scarce one in a score sprange with me and would alike." 4 is our L. autumnale, and 5 is our L. sestivum.

We have a good many more varieties of the Leucojums now, but it has been difficult to make them all out, and to recover many of them from the wrong names and the oblivion into which they had fallen. Having, however, got the whole collection together, I submit the following notes and descriptions of them to your readers.

So far as I have at present made out, the Eoglish name of the bulbous Violet, which was clearly inappropriate, was changed by Curtis. In vol. ii. Eot. Mag., tab. 46, he says:—"The blossoms of Leucojum and Galanthus, or Snowdrop, are very similar at first sight, but differ very essentially when examined, the Snowdrop having, according to the Linozean description, a three-leaved octary, which is wanting in the Leucojum. The two genera, then, being very distinct, it becomes necessary to give them different names; we have accordingly bestowed on the Leucojum the name of Snowdlake, which, while it denotes its affinity to the Snowdrop, is not applicable to the meaning of Leucojum.

1. L. vernum, the spring Snowflake, is beautifully figured in Bot. Mag., plate 46, and still better in Reichenbach's Flor. Germ., No. 804. These two plates give us the typical flower, having the corolla segments of equal length, with a clear green spot on each, exactly like the Snowdrop. There is, however, another well marked and very beautiful variety, figured in Wooster's Alpine Plants, vol. i., plate 95, with a larger mass of leaves and larger flowers, the corolla having golden spots, and the interior of the flower a lovely golden hue. This plate was reproduced in the *Garden*, vol. vii., p. 156, accompanied by an interesting note on the Leucojums by the late Mr. Niven. The plants from which Wooster's figure was taken were supplied by Messrs. Backhouse, of Vork; I therefore wrote to ask if they still had this variety, and received half a dozen bulbs, all of this character. In all other respects the plant appeared to be the ordinary form of vernum, but this golden hue is so beautiful and distinctive that for our garden purposes I propose to distinguish it as L. vernum var. lutescens.

There is also a double form, L. vernum multiplex, which is exceedingly scarce, but which is in Mr. Loder's collection at Floore.

2. L. carpathicum.—This is also figured in the Botanical Magazine, pl. 1993. It has a much larger bulb than L. vernum, which has a bulb like a Snowdrop, whereas the bulb of carpathicum is more like a Daffodil, and its mode of increase is similar. The plant has, therefore, a thick tuft of leaves, and from amid these arises a curved stalk, which carries two flowers on slender peduncles. These flowers begin to show

almost as soon as they emerge from the soil, and continue to expand until the full height is reached, some 6 inches from the ground. The flowers are larger than those of vernum, and the spots a rich golden-yellow. The scapes are not always two-flowered, and sometimes you find single and twin flowered in the same clump, but generally it is two-flowered. The plant from which Curtis' plate was taken had been collected on the Carpathian Mountains. It is called by Curtis L. vernum, \$\textit{B}_{\text{carpathian}}\$ Mountains. It is called by Curtis L. vernum, \$\text{B}_{\text{carpathian}}\$ Spring Snowflake. Dean Herbert, writing twenty years later, referred to this plate in description, and said:—"I have not been able to obtain a sight of this plant. I see no reason for confounding it with the one-flowered green-spotted vernum. I believe that vernum does not ever produce a two-flowered scape, and that the L. præcox majus of Clusius is carpathicum" (Amaryflitáe,

3. L. fulchellum.—Taking the Snowflakes in order as they come into flower this comes next, as it blooms with the spring Snowflakes. This, again, is comparatively a scarce plant. Dean Herbert says he had never seen it. It resembles the summer Snowflakes, having a scape about 12 inches high, with three to seven flowers, narrower than any other, and less campanulate. It has the small green spot at the tips of the white perianth segments. Altogether it is a delicate looking and lovely flower. Niven says it has a more campanulate flower than æstivum; but herein I think he is wrong. It is more correctly described in Robinson's Alpine Flowers, as having the flowers smaller than æstivum, and the perianth segments more incurved, so that the perianth is somewhat ovoid, and its flower urcolate.

4. L. astivum forms the subject of plate 805 in

It had escaped my notice that we had two forms of assistum until Mr. Tyerman visited Brockhurst last summer, when he pointed out that we had abundance of Hernandezianum, and very few of the true assistum. I find this is frequently the case hereabouts. This variety has yellower green spots than the other. Mr. Niven does not name this variety, so I suppose he was not acquainted with it.

6. L. autumnale.—This I have, but have not yet seen it in bloom. It is figured in Reichenbach's Flor, Germ., No. 906. It has slender pink stalks, carrying three slender white flowers, pink at the base of the perianth, and with grass-like leaves—a delicate-looking and very pretty flower.

Mr. Potter, of York, tells me there is one other variety, L. hyemale, which is in the York Nurseries, Wm. Brockbank, Brockhurst, Didsbury.

FIG. 62.-THE SNOWFLAKE, LEUCOJUM VERNUM.

p. 331). Mr. Niven, writing in 1875 (Garden, vol. vii., p. 156), says there is a variety known by the title of carpathica, which to my mind is sufficiently distinct to rank as a species. Its bulb is twice the size of our plant, its stature considerably greater, and it frequently produces its flowers in pairs. It is rare in cultivation.

It is strange that so interesting a plant should not have attracted greater notice, but I have searched in vain for it in all the leading catalogues. One of our very first florist firms replied to my note that they had it, but on receiving bulbs from them I found they were only the ordinary vernum, with the green spots and single scapes. After trying in every likely quarter I at length obtained it in quantity from Messrs. James Dicksons of Chester, in whose nurseries I found they had it in quantity, but under the name L. vernum. It had been growing there for a long time and is, "without doubt, the true L. carpathicum.

Reichenbach's Flor. Germ., and it is well thus to refer to a standard illustration, as there are again two candidates for the name in our gardens. In this plate we have a scape with four flowers, and with the green spots, as in the typical L. vernum, figured on the same page. The flowers of æstivum are a little smaller, which is quite correct. This is a well-known plant, growing from 12 to 20 inches high, and blooming in May or June. It is one of our most lovely summer flowers, and is deliciously fragrant. It is said by Mr. Niven and others to be a British flower; but this is very doubtful, although it is to be found in moist meadows in Kent and some other counties.

5. L. Hernandezianum.—I have not been able to for August and any illustration of this variety. It was found by Dr. Herdandez in Majorca. Herbert says it differs from astivum in having flowers about half the size, and a more oblong germen. I believe this is far more common in Lancashire than the former one.

LEUCOJUM VERNUM.— I am under an impression that there are four varieties of Leucojum vernum in cultivation—1, L. vernum, L., from Germaoy; 2, L. vernum, fl.-pl.; 3, L. vernum var. carpathicum, Bth.; 4, a variety with yellow spots, similar to the Carpathian in colour, but only producing one flower on a stem, the strongest grower and largest of the four. The true species is by far the most beautiful of the lot, the bright green spots giving the flower a much more graceful appearance than the yellow-spotted varieties. While on the subject, may I ask if the small Leucojum trichophyllum, Brot., is yet cultivation? It was introduced in 1820, and figured in the Botanical Register, plate 544. Being a native of Barbary it is more tender than the others. Floore.

THE NORTHAMPTONSHIRE HORTICULTURAL SOCIETY'S SHOW will be held in Delapre Park on August 2 and 4.

ORCHIDS AT ST. ALBANS.

WHERE the spread of this extraordinary Orchid establishment will end it is impossible to say, so fast do the houses range themselves up one after the other. Already twelve fine structures are up, having an aggregate length of nearly 3000 feet, and varying in width from 14 feet to 31 feet, and, with the exception of the last three, filled with a valuable and healthy stock. Such a vast establishment, backed by the resources and great facilities which Messrs. F. Sander & Co. possess for importing good and new things, cannot fail to assist in giving stability to the trade in the luture, as it has done in strengthening the love of Orchids among amateurs in the past. The last two houses, each 100 feet in length, are designed for the reception of Phalænopsis and other plants requiring similar treatment. They, like all the other of the later built St. Albans houses, are built of Pitch Pine, not painted, but oiled and varnished. The effect of the varnished woodwork is very good, but its main object is to get rid of the inconvenience and expense periodical painting, and the pernicious influence which paint has on the plants for so long a time after each time it is freshly put on. A novel feature in the Phalænopsis-house is a hot-water tank, 18 inches in depth, hermetically sealed, which occupies the greater part of the surface of the middle bed; it will materially assist in keeping up an even temperature, and will not give off an inconvenient amount of moisture. Rain-water tanks also run on both sides the entire length of the house. Another noticeable feature, which would give many who are in search of it an idea of how to bottom ventilate a sunk house, is the sinking of little shafts at intervals on the outside of the house down to the ground line, where openings in the brickwork admit the air at the bottom of the house and directly among the four hot-water pipes. This is, no doubt, the proper way, and yet builders do not seem to understand the matter. Only last week we saw a well-built cold house spoilt by having the ventilators placed on a level with the plants.

On the upper part of the middle stage of the large Cattleya-house (240 feet by 31 feet) a rare sight is now to be found. On the right-hand side, the whole length of the house, many hundreds of blooms of the favourite Cattleya Percivaliana are arranged, and on the left an equally large number of the best forms of C. Trianæ of all shades and descriptions of marking; some with the large-frilled and yellow-veined lips of C. Mossiæ, some with crimson and yellow or mauve and orange lips, one like C. T. Russeliana, but superior to that variety, and many pure white and delicate pink forms, all the plants being well bloomed, and one of them having three spike of four flowers each, two of three and two of two flowers. Viewed from the entrance the effect is indescribable, the extraordinary length of the house allowing the eye to follow the flowers almost to the vanishing point. Arranged about the house are also some fine plants of Lælia elegans (some with 100 to 200 bulbs), wellflowered plants of Cattleya amethystoglossa, and Cœlogyne cristata, among the last being a new form, superior in size, shape, and substance, to the famed Chatsworth variety, and that is saying a great deal

In the Odontoglossum-houses another good innovation has been introduced; it consists of a \(^1_2\)-inch glass tube with holes drilled in it at about I foot apart. It runs down the middle of the house on the top of the middle bed and underneath the open woodwork stage; its object is to convey water along the whole length of the house, and taps are arranged so as to have the supply at the command of the operator. Such an arrangement must effect a great saving in labour over the old plan of syringing under the staging, &c., in summer, and at the same time must be more effectual. It is needless to say that a great show of fine blooms of remarkable size, form, and substance, are now as always to be lound among the 100,000 fine masses of O. Alexandræ which this firm possesses; at the present time, too, there are in the end of the house set apart for them the tarest and most beautiful batch of hybrid Odontoglossum sperhaps ever brought together. Many of these are quite new, and very lovely; to attempt to describe them would be u-eless. Among the new plants also is the lovely snow-white Odontoglossum Iruhyanum, a telling new Pescatorei, with flowers of a rich claretmanve, and a curious form of Odontoglossum with singularly undeveloped floral segments and labellum; this last is very interesting, as it may be a reversion to the normal form which existed ages ago, and from which have been evolved all those grand forms which

Prehid Notes and Hleanings.

DENDROBIUM MICANS ×.—This pretty hybrid is now io flower in Messrs. Veitch's nursery at Chelsea. The seed-bearing parent was D. Wardianum, the pollen parent, D. lituiflorum. The growths seem to be intermediate between the parents; the flowers greatly resemble a good form of D. lituiflorum; indeed, at first sight it might be taken for a good form of the pollen-bearing parent.

PHALMINOPSIS STUARTIANA.—This distinct and handsome species is well represented in Messrs. Veitch's musery; one large plant had a three-branched spike with twenty-flowers open. A similar plant had twenty-one flowers on a spike, but some of them had been removed. It seems in its style of plant and habit of growth to be most nearly related to P. Schilleriana, but lacking the peculiar flattened roots of that species. There are many small forms of it, all differing in the character of the flower and the peculiar spotting. 3. D.

CATTLEYA TRIANÆ VAR. EMILIÆ.-At Downside may now be seen a display of Cattleya Trianæ in flower which has rarely if ever been equalled. For some years past Mr. Lee has been collecting at high figures the most beautiful Trianæs he can obtain. Upon entering the Cattleya-house the eye is caught by a plant on the centre stage with some twenty flowers open, and a magnificent form it is, and alone worth the journey to Leatherhead. The name it bears is Emiliæ. The sepals and petals are light blush, almost white, and the petals, over 21 inches broad, stand well upright. The great charm lies in the contrast of colourand broad fully-open Mendelii-like lip, the colour of which is a deep crimson-plum, margined with a broad rose fringe; the two sides of the throat are deep rose, and between them and the actual dark lip there are two large yellow eyes, as in Cattleya gigas, the throat being again yellow. The tube of the lip is extremely short, perhaps not above 14 inch long, giving the variety a very distinct appearance, and placing the actual lip very close to the lower petals and sepals, thus producing the perfect round shape so much admired in all Orchids. It is a variety of extraordinary merit, and of which Mr. Lee is justly proud. A. B.

DENDROBIUMS AT BROOMHALL FIELD, SHEFFIELD, -Permit me to record the successful culture of a few Orchids, imported within the past two years, at this place, which is within the smoke-radius of Shesiield, a town which, in a smoke and sulphurous-acid-producing competition with Rawtenstall (see Mr. Swan's note at p. 210) would in all probability carry off the 1st prize. This comparison is not carry off the 1st prize. intended to be derogatory to the beautiful Orchids at New Hall Hey, but to support the implied proposition of Mr. Swan, that the vicinity of ironworks, railways, factories, &c., need be no deterrent to the successal cultivation of Orchids. In the conservatory at Broomhall Field, and standing underneath and around a beautiful Tree Fern (Alsophila excelsa), is a charming group of Orchids and Lachenalias edged with Isolepis gracilis. The principal feature of the group is a very fine specimen of Dendrobium Wardianum bearing 113 fully expanded flowers on five growths, the most floriferous pseudobulb producing thirty-two flowers. Next to this example is a smaller plant of the same species, but one of the very best varieties. Other prominent plants in the group are Cœlogyne cristata, Odontoglossum Rossii majus, O. Pescatorei, Cattleya Trianæ, and Dendrobium Farmeri var. aurea flava. In the East Indian-house are splendid examples of D. Devonianum, with thick growths 3 to 4 feet long and flowering to within 6 inches of the base; strong plants of D. primulinum D. Paxtoni, D. lituislorum, D. thyrsislorum, and D. Dalhousianum, to which last-mentioned I drew attention last spring. The pseudobulb then noticed made a double "break," and has developed and matured two strong growths, each about 5 feet long. In a low pit previously used for the cultivation of Melons, Cucumbers, and Tomatos-the warmest end being partitioned off-are some healthy intermediate and cool-house Orchids; in the former division, only some 9 feet square, is a large plant of Odontoglossum vexillarium with eight strong leading growths and

without spot or blemish; a very fine piece of Cattleya gigas, as also C. Trianæ and C. Walkeriana, Cœlogyne occellata, Oncidium ornithorhynchum, Chysis aurea, and Dendrobium Falconeri, all worthy of mention. The cool division contains some dozens of healthy established and semi-established plants of Odontoglossum Alexandræ, O. Pescatorei, O. Rossii majus, O. cirrosum, &c., and floriferous examples of Lælia albida. Sufficient has been said to indicate the small but varied and interesting collection of Orchids now being formed by B. P. Bromhead, Esq., and the amount of pleasure and success attending the judicious expenditure of a few pounds when the purchases are followed up by intelligent cultivation; moreover be it noted that no expensive preparations have been made or elaborate houses erected for the special accommodation of Orchids. As they arrived they were placed in the structures devoted to the production of fruits and flowers, until at last the original occupants have been, and are being, ousted by them. The general health of the Orchids and stove and greenhouse plants, as well as the crops of fruit annually produced in the vineries and Peach-houses testify to the care and ability of Mr. Walker, the head gardener. F. U. S.

ODONTOGLOSSUM CORADINEI. — Messrs. Veitch have sent me a very well kept flower of this. There is nothing astonishing in this. But it is not of Chelsea origin; it comes from Mr. A. R. Smith, Troy, U.S., and has travelled 4000 miles! This is the cardinal point. Amateurs now send flowers across the Atlantic just as one sent them fifty years ago from Glasgow to Kew! H. G. Rehb. f.

THE ORCHID MARKET,—There was a fine display of Orchids in flower at Stevens' Rooms, on Wednesday, and a good attendance of buyers. The best prices realised were for Cattleya Triance vars., 12½ gaineas, to 5 gaineas; Odontoglossum crispum, a fine large white-flowered variety, 15½ gaineas; O. Rossi majas, Trentham variety, 12 guineas; O. Pescatorei, 7½ guineas; Dendrobium Jamesianum, 65 100; ½ Lycaste Skinneri alba, small plant, 10 gaineas; Dendrobium nobile, fine var., 5 guineas; an Odontoglossum hybrid, 12 gaineas; Cattleya sp. with a fine lip, 105 guineas; an unnamed species of Odontoglossum, 16½ gaineas.

FRUITS UNDER GLASS.

PINES.-Shading should now be got in readiness as the time is approaching when it will be required, for Pines, although light-loving subjects, will not thrive well under glass when exposed to powerful sunshine. The Smooth Cayenne is the first to show signs of suffering from this cause by its foliage becoming browned and wiry, and plants that are allowed to undergo this strain do not give such good results as those that are judiciously protected with thin tiffany, or some similar material which enfeebles the sun's force, and diffuses its light without unduly darkening the structure. many cases the Early Queens will now be coming into blossom, and as low temperatures, cold draughts, or moisture-laden atmosphere would prove fatal to perfect fertilisation, and a single unfertilised blossom means a deformed fruit, no pains should be spared to preserve the plants and their surroundings in a favourable condition. When the blossoming period is past, the amount of moisture should be increased; in large airy houses where there is a difficulty in keeping up an adequate amount, evaporating pans filled with guano-water are of great service, and in all cases where pans are not employed the pathways should be daily sprinkled with this agent after the house closed, at the same time in hot weather overhead damping with tepid rain-water will also be beneficial; it should, however, be followed with discretion, especially in low close houses. Water at the roots will be in more frequent request now, and the importance of stimulating food in the form of liquid manure should on no account be undervalued. Where the second house has not yet been started it should now be seen to if the plants have not been arranged and replunged since the autumn. The pots may have become unlevel or loose in their beds through the decomposition of the plunging material. Such defects must be remedied, and the bottom-heat in each department should be frequently tested to avoid a mishap in this direction. recently potted will demand vigilant management in the way of a moderate degree of temperature, careful ventilation to prevent elongated growths, and a limited

amount of moisture at the roots until they have ramified in the fresh soil. These remarks respecting moisture also apply to newly potted suckers, which should be kept rather close, and slightly shaded until they have taken root.

VINES .-- The second Hamburgh and early Muscathouses will now require frequent attention in the disbudding, stopping, and tying of shoots. The latter operation, as I have previously remarked, necessitates patience, for much mischief often results by the loss of spurs through the disjointing of shoots from too much haste in this matter. In many instances the trellis is placed too near to the roof; where head-room will allow, a space of 18 inches or more should be afforded; this admits of considerable length of growth, and, of course, strength before tying is requisite, as well as a free current of air between the ge while the glass, thereby diminishing the risk of scalding, and the weight and quality of the crops are in no way impaired through being produced in this position. Hamburghs in blossom now should have a temperature at night of 65° with a constant cir-culation of warm air through the house; Muscats should he allowed 5° more, and be assisted with Hamburgh pollen. To those who are unsuccessful in setting Muscats, I would recommend the practice of syringing we ventured upon this last season, by carefully applying tepid rain-water on several successive sunny days at the time of closing the house with a warm temperature, and were well pleased with the issue. I ought to mention, however, that Hamburgh pollen was administered each day when the Vines were dry before the syringing took place, and it would not be advisable to syringe in dull weather, or with a low temperature. The Lady Downe's and other late varieties will now be moving, and should be assisted by frequent dampings until they break into growth, when they must be encouraged with increased warmth, and the overhead damping be reduced to one daily application given at closing time. Disbudding should he proceeded with, as has been directed, for the earlier houses, and the borders be well supplied with tepid water. Young Vines intended for planting should be started into growth so that they may soon be in a suitable state for turning out into the borders, while those that are intended for inarching should be brought forward in the same stage as are the Vines to be operated upon.

STRAWBERRIES .- In forwarding these this season we have had to depend principally upon our own resources, for the sun, which is a valuable factor, has given us but little assistance. When the colouring of the fruit commences, overhead syringings and the use of liquid-manure should cease, but the plants must not be allowed to suffer from the want of clear water at their roots. One favourable feature in the Strawberry to those who have to meet an early demand, is that when the fruits are set the plants will withstand great pressure in the form of high temperatures, and will freely swell their fruits when subjected to this treatment providing a liberal amount of moisture is maintained, but in pursuing this mode of culture when once there is a sign of the berries changing colour the temperature should be gradually lowered, less moisture be afforded, and a free circulation of air admitted, for without these conditional changes both high colour and flavour will be sacrificed. Where there is no Strawberry-house proper, and accommodation has to be provided in other fruit houses, such as vineries, the plants should have an unshaded situation as near as possible to the ventilators, as the air from them will accelerate more perfect fertilisation of the blossoms, and colour and flavour of the fruit. Thomas Coomber, Hendre Gardens, Monmouth.

The Pitchen Garden.

SEEDS of Connover's Colossal Asparagus should now be sown in drills 2 inches deep and 12 inches apart, in a border where the soil is of a light, rich, and sandy nature, for transplanting the following year. Seakale seeds should also be sown, either in a nursery bed, in drills 2 inches deep and 12 inches apart, in patches-about three seeds in each patch (which subsequently should be thinned out to one, 6 inches apart in the row), or in the situation in which the plants are ultimately to be forced, in rows 2 feet

apart, and 18 inches asunder in the rows, in light rich soil, from 2 to 3 feet deep. Plantations may also be made from cuttings, which, if cut into lengths of about 4 inches and placed in a box, intermixed with sand when the plants were taken up for forcing last autumn, should be dibbled in from 10 to 12 inches apart in the rows, and 18 inches between the rows. These thongs, or root cuttings, will furnish plants to be taken up for forcing next winter; but if they are intended to be forced in their permanent situation by the aid of pots and fermenting material, then the distance should be 2 feet between the rows, and 18 inches from plant to plant, and these should be set about an inch under the surface of the soil. A sowing of Chervil should now be made in shallow drills; also another breadth of Turnips, Radishes, and All the Year Round Cabbage, and Paris White Cos Lettuces. A small sowing of each should be made at short intervals, so as to always have a good supply of young plants wherewith to make frequent plantings. Make another sowing of Peas every fortnight for the next three or four months of such varieties as Carter's Stratagem, Carter's Telephone, and Ne Plus Ultra; also Carter's Leviathan and Taylor's Broad Windsor Beans, and Spinach in sufficient quantity to meet the demand for the same at the proper time.

FORCING DEPARTMENT.-Tomato plants, whether growing in pots or planted out and trained like Melons to a trellis under the roof will now, especially in the latter case, require frequent attention in the way of pinching out lateral growths and thinning the leaves, as anything like over-crowding of the shoots and leaves would be prejudicial to success. The application of water to the roots must be guided by the space allotted to the latter, together with the condition of the plants and the weather, and no stimulants should be applied until the plants have set their fruit, when they should be thinned out, leaving, of course, all the best shaped and most even sized fruits. When the plants are in flower a drier and more airy atmosphere should be maintained. Plants which are intended to fruit in pots should now be ready for shifting into 12-inch pots, which should be amply drained. The plants should be thoroughly watered the evening before being shifted into the larger pots, after which they will not require water again until the roots have pushed into the new soil; the latter should on this occasion consist of three parts of good loam and one of well rotted manure. A stiff stick, between 5 and 6 feet long, should then be put to each plant, and the latter be secured to it. All lateral growths should be pinched back to within one joint of the main stem, and in other respects treated as recommended in the case of those planted out. Let the temperature at night range from 55° to 60°, and by day 70° to 75°, running up to 85° with sun-heat. H. W. Ward, Longford

Plants and thein Jultune.

GREENHOUSE PLANTS .- Many of the hard-wooded section of Cape and New Holland plants will now be making advances towards the flowering stage. will necessitate closer attention being given to their requirements with regard to watering and other minor details. The sun also now having greater power, will cause extra regard to be paid to the ventilation, to keep in check a too rapid advance; shading however will not be needed for some time to come; in fact the less shade the better for plants indigenous to the Cape of Good Hope and New Holland, except just when in full bloom. A sturdy, short-jointed and hardy growth will yield the best return in flowers. Reverting, however, to the watering, it is necessary to say that a thorough knowledge of the individual wants of specimen plants is requisite to ensure success. This work should not be shifted from one pair of hands to another indiscriminately, or the plants will quickly suffer. Those who are well acquainted with their plants can tell nearly to an hour when they will their plants can tell nearly to an hour when they will appearance in regard to health, watering should be done with still greater caution. Any plants that are now coming into flower, in whatever stage they may be, should not be allowed to suffer. Cape Heaths will generally tell their own tale if neglected in this respect, by deformed or crippled flowers. Azlae indica will cease to develope their flower-buds, the same turning brown in some instances whilst the vigour of the plant will be concentrated in the young growths. Aphelexis flowers will cease to grow, or else develope into puny examples. In a general way, once filling up the flower pot with water is not sufficient when a plant is in robust health, a second instalment, though, perhaps, not so much, will be the best plan to pursue, so that the entire ball may be well penetrated. These plants dislike dibblings more than any we know; and natice dibblings more than any we know; and patience exercised with them will be abundantly repaid. Rain-water will be found the best for them, and it any

Rain-water will be found the best for them, and if any scarcity is apprehended somewhat later on, this should be held in reserve for their special requirements. If a later crop of flowers is needed in the case of Dracophyllum gracile or Pimelea Hendersoni and P. mirabilis, this can be obtained by pinching out the flower trusses that will soon be showing. They will quickly break afresh, and push up another lot of flower-heads; these will be smaller than the first would have been, but the desired end will have been statistical. Any other greenhouse plants that are adattained. Any other greenhouse plants that are advancing too last should be kept at the coolest end of vancing too last should be kept at the coolest end of the house or be removed to a north aspect before they are too far developed. The earliest of the Epacris that have heen giving good returns will soon need cutting back, so also will the winter-flowering Cape Heaths of the soft-wooded section. Small stock of Fleromas and other Melastomaccous plants should be kept pinched; nearly all of this type of plants are apt to run away with a few strong shoots if not thus seen to and checked in time. Kalosanthes that will in all probability flower this season must be kept near the glass to keep them stocky. will require the same treatment to intensify the colours of their beautiful flowers. Statices will soon be showing their flower-spikes; those of vigorous growth should not be allowed to run away in an upright manner, but be pulled down carefully to a point position, the strength of the residence of the spikes. away in an upright manner, but he pulled down carefully to a horizontal position, the strength of the spike being thus better distributed throughout its entire length. All tying operations that require attention amongst the specimen greenhouse plants should be seen to without needless delay. Some require more than others; the two extremes, however, are easily to be seen; either the plants have scarcely any regard paid to this cultural detail or it is very much overdone, making them look as if they had been clipped with a pair of shears. Give Boronia serrulata and all other plants that are susceptible to white-scale a close looking to before other work becomes too a close looking to before other work becomes too pressing. In a mixed collection of greenhouse plants pressing. In a mixed collection of greenhouse plants the greenfly will soon be troublesome, these and thrips be disposed of at the same time by a few frequent fumigations.

Attention should be given to the requisite stock of soft-wooded plants. Of Pelargoniums some of the best should be culled from the stock for Leddlog purposes and potted on, not omitting the scented-leaved varieties. The Fuchsias will also need attention to pruning and potting, securing a batch of cuttings as soon as available. The show and fancy Felargoniums should have all the light and air possible; now that they are rapidly filling themselves out with robust growth more room will be needed to give them fair play. Pinching for late bloom should not be practised later than this, or an undue proportion of leafplay. Pinching for late bloom should not be prac-tised later than this, or an undue proportion of leafitised later than this, or an undue proportion of leaf-growth will be made. As the earliest begin to knot for bloom liquid-manure should be given them. A batch of cuttings from the Tree Carnations should be got in without delay; if taken from those plants that have been in a little warmth a more speedy strike will ensue. A little attention given now to the best strains of Chioese Primulas, to assist better ferti-lisation, would be amply repaid in a greater yield. As soon as the double Primulas are past their best, propagation should be taken in hand. This can be done either from cuttings in a little warmth, each one done either from cuttings in a little warmth, each one in a small pot, or by layering them in a little fresh soil placed around the old stool. As these plants soil placed around the old stool. As these plants quickly suffer from an excess of moisture, pay atten-tion to any symytoms of damp, and check the same by keeping them drier. An early lot of single varieties might now be raised from seed, they will be useful in

the autumn.

COLD PITS .- The latest of the Cinerarias should now be in these, with the herbaceous Calceolarias, if at all pressed for room in the houses. Do not let the at all pressed for room in the total latter plants suffer for want of water, a damp pit will latter plants suffer for want of water, a damp pit will latter plants suffer for want of water, a damp pit will latter plants suffer for want of water, a damp pit will latter plants suffer for want of water, a damp pit will latter plants suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, a damp pit will be a suffer for want of water, and water for wa latter plants suffer for want of water, a damp pit will also be best suited to their requirements. Should the Chrysanthemums be still standing in their cuttiogpots do not lose any more time in getting them potted, neatly labelling each one to prevent any future confusion. As soon as they are established keep them well aired, to secure a good dwarf plant at the commencement. Any plants of Carnation Souvenir de la Malmaison that have been wintered in the cold pits should have a shift into a size larger pot, provided they were potted up from layers into 60's in the autumn. The common Musk is beginning to peep through the soil, a few pots should be prepared from promising tufts for decorative purposes. Fames Hutson, The Gardens, Gunnersbury House, W., March II.,

APPOINTMENTS FOR THE ENSUING WEEK.

Monday, Mar. 17 Sale of Natural History Objects, at Stevens' Rooms, Floral Meeting in the Town Hall, Manchester.

"A RE they the fashion this year?" asked a police magistrate the other day, referring to DAFFODILS. The question was asked in connection with a case in which some one who loved money better than he loved Daffodils was brought to a court of justice for exercising his felonious instincts at the expense of his neighbour's property. What answer the magistrate received we do not know. Whether "in fashion" or no they are always welcomed for their beauty and their associations, and the more opportunities people can get to see them the better, with certain reservations. No one who loves a flower would care to see it "in fashion" in a bad sense. We have had enough of that absurdity in the sunflower craze, enough to illustrate the truth that the surest way to degrade and vulgarise a flower is to bring it into such-like fashion. This is a procedure only one iota less degrading than that of making flowers the symbol of political strife and party feeling. Fashion of this kind merely leads to the unintelligent sequacity of geese, or to the felonious proclivities of men who must live and do not much care how, and to the ultimate destruction of what is beautiful in Nature or in Art.

But there is another sort of fashion which is as much to be encouraged as the other is to be deprecated-a fashion which originates in intelligent curiosity as to the structure and habits of life of flowers, and in real admiration of their beauty. From this point of view we get all the good that flowers are capable of giving us without of necessity one unworthy thought-we had almost said, without covetousness or risk of felony. To err, however, is one of the commonest characteristics of humanity, and hence it is to be feared that sometimes some weak brother might look over the hedge and covet the Daffodils in the copse-it might be soand if the temptation proved too strong the consequence might be, as we have seen, an appearance before the police-magistrate. That functionary would doubtless administer the law with all correctness and discretion, but it would hardly occur to him to act on the axiom that "prevention is better than cure;" in fact, it would be ultra vires for him to do so. Cultivators, however, have it in their power to satisfy the demands of fashion in a way that does no harm to any one, that ensures an adequate supply, and prevents the tendency to appropriate other people's property. By all means let us grow Daffodils by the score, the hundred, the thousand-we can scarcely have too many of them; and let us not expose ourselves to the temptation of coveting our neighbour's property, or what to our minds is, if possible, a worse enormity, run the risk of exterminating from their native haunts the gems which have been the admiration, the solace of so many generations of men. If a poll could be taken on the question whether we should retain the Daffodils and Primroses of our woods at the expense of handing over Central Asia to Russia, we strongly suspect a large number

would by their votes say, Let Muscovy have Central Asia and leave us our Primroses! As we have said, the art of the gardener steps in to relieve us of any such dread necessity, and brings Daffodils and other flowers to the homes of thousands who, but for this aid, would not be charmed by their grace, nor enabled to comprehend their ineffable subtleness of association.

We may, then, say that Daffodils are in season this year, and in a good sense too; and if any further proof be needed it may be found in the announcement we are enabled to make, that a CONFERENCE of DAFFODIL GROWERS will be held on April 1, in the conservatory of the Royal Horticultural Society, when it is expected that many of the leading growers of Holland, no less than of our country, will be present to weave a cloth of gold such as FROISSART would fail adequately to describe. The exhibition, which adequately to describe. The extinuity, mich is sure to be a very extensive one, will not be confined to Daffodils proper, but will be extended to all members of the Narcissus family, and we have no doubt a few friends will be invited to join. The Conference will, it is expected, be opened with a paper by Mr. BUR-BIDGE, upon which discussion will be invited, and in which it is hoped that some of our leading grovers will take part.

leading growers will take part.

The whole scheme is to be organised by the Council of the Royal Horticultural Society, aided by a few experts from outside. No prizes will be offered, the love of flowers being, as it should be, the greatest incentive.

This action of the Council will, we think, be welcomed by reason of the soundness of the principle manifested. They have gauged the feelings of the specialists, and met them considerably more than half way. In this way they obviate the segregation and disintegration of the parent Society, and prevent that spectacle which the special societies are rather apt to present, one which we may illustrate appropriately in this case which we may illustrate appropriately in this case which we may inustrate appropriately in this case by the fable of NARCISSUS admiring his own image in the limpid stream. It ought surely to be more satisfactory for him to be the cynosure of all eyes than to be merely the subject of unbecoming self-admiration.

- WHAT IS TO BE THE FUTURE OF THE CINERARIA?-This is a question which might well be asked in remembrance of the group of extraordinary flowers Mr. J. JAMES submitted to the view of the committee on Tuesday last. The canons of the florist, as formulated by the National Floricultural Society twenty years ago on the foundation of those laid down by GLENNY, are practically as dead as CÆSAR. The Floral Committee appeared to pass over the flowers that were characterised at least by some of the qualities that used to be favourably regarded hy florists, and made awards to flowers of prodigious size, but lamentably coarse. Thirty years ago Lady Mary Lahouchere and Optima were sent out, and they were regarded at that time as varieties of great beauty and comparatively perfect, of fine shape, pure in the white ground, with a dark disc, and a Picotee edge of hlue or purple. These varieties, as figured in the Florist, were represented by pips quite up to the natural size, and nearly 11 inch in diameter. One of Mr. JAMES' varieties certificated on Tuesday last was named Pollie Charming: it had a large disc, a zone of white, and a broad marginal colouring of bright magenta-rose, but with regard to form it was sadly wanting in the symmetry we have been accustomed to see in named Cinerarias, and which was present in a few of the splendid selfs shown by Mr. JAMES on this occasion. The pips of Pollie Charming measured $2\frac{3}{4}$ inches in diameter, dimensions inconsistent with perfect symmetry. The committee evidently go for size; the blue purple self Challenge, with its grey disc and petals awry, had nothing else to recommend it. But it must be admitted Mr. JAMES has a wonderful strain of great decorative value, with self colours predominating, and a few of these of very fine form; some were of rich maroon shades, altogether new and striking; there were also hues of shaded magenta-purple, dark plum, dark purple, very rich crimson and pale bright magenta, quite a new and pleasing shade. Then the plants, of robust and yet very dwarf growth, with remarkable heads of bloom. Is there any demand for these named Cinerarias? Probably the day for them has passed, for

the present at least. Who knows but at no distant date named Cinerarias may he once more in the ascendant, for certain subjects have their season, fall into neglect, and become raised again to a new popularity, as if amenable to the laws, if any, which regulate the eccentricities of fashion,

- PRIMULA QUEEN VICTORIA. - This was shown by Mr. ODELL of Shepherd's Bush on Tuesday last, and it served further to illustrate the fact that the high-coloured varieties raised from Chiswick Red do, for some reason, fail in not a few instances to throw their flowers well above the foliage. was a large group of plants, but this defect was observed in all—the plants were robustly grown, but the flower scarcely rose above the finely developed leaves. Probably Mr. H. LITTLE has been as successful as any one in remedying this defect. He has one or two at least, of very rich-coloured varieties that throw up fine trusses of bloom well above the foliage, he having devoted himself as a raiser to realising this result. He has also secured, not only size of pip, but great substance also, which is a requisite in the high-coloured varieties; and they possess another characteristic, that the rich vermilion colour deepens as the flowers age, which is a quality of great value. "Dying well" is a term much em-ployed by the old florists: it means that a flower should maintain all its best qualities until it fades.

- PROPAGATING DAHLIAS .- March, and during the early part of the month, was always considered the hest time for taking cuttings of Dahlias, for the reason that a forced growth is not necessary to make them forward enough, as is the case with some late-struck cuttings, and they are not too early to become stunted. This is a casualty that sometimes occurs in the case of cuttings struck in February, Probably what are termed "pot roots" of Dahlias are much more used for planting-out than they used to he. The older Dahlia growers preferred young green plants formed of spring-struck cuttings, and employed pot roots only in the case of certain varieties that produced better flowers than from cuttings. "Pot roots" are the unsold plants of cuttings of the previous spring, stood in a frame all the summer, and allowed to grow as they please, but kept well watered. In the autumn these are turned out of the pots and stored away for sale, and when in a dormant state they can be sent long distances if secure from frost, Pot roots are generally potted about the end of March, placing them in a gentle heat, and moistening them once a day. When the shoots are pushed an inch or so in length they are potted into 4-inch pots, using rich soil, draining the pots with a little coarse leaf-mould instead of crocks. The roots should he covered with soil, and care is requisite not to fill the pots with earth within an inch or more of the rims, as the roots increase in size rapidly, and it is difficult to water them unless space is left for it. Pot roots treated in this way make excellent plants to put out into borders, as they flower early; or any one wishing to get up a stock of a certain variety can obtain pot roots. Secure two or three cuttings from each by placing them in a hrisk dung frame, and potting the roots afterwards as above directed.

- THE CHRYSANTHEMUM. - Those who make a speciality of Chrysanthemums state that there is a very large demand for plants. Always a popular flower, it has at the present time reached a height of popularity almost equal to that of the Rose; and many persons who cannot grow Roses can grow Chrysan-themums. It gilds the autumn and early winter months with so much of floral heauty as to rob them of some portion of their terrors. Then Chrysanthemum shows appear to he spreading on every hand; this gives an impetus to culture, and it is worthy of note that spring exhibitions appear to decline just in the same ratio as the autumn shows extend; the popular sentiment appears to go out towards the latter rather than the former.

STAUNTONIA HEXAPHYLLA. - A figure of this highly interesting climher appeared in our columns for 1876 (vol v., p. 597). The eight years that have elapsed since that figure was drawn have allowed us to make comparisons of the relative value, from an outside garden standpoint, of the present species and its Himalayan ally, S. latifolia. The former has, as far as our experience goes, always proved the hardier of the two, and has thriven where the other has utterly failed. Both species are perfectly safe in a corridor, or as inmates of the cool conservatory, and both have deliciously scented flowers, the foliage of S. hexaphylla being the bolder and more striking.

PRUNUS DIVARIGATA.—A fine specimen of this handsome early-flowering species is now so laden with blossoms at Kew that at a distance it might be supposed the tree was hidden beneath a canopy of snowy-white. The tree in question is of singularly graceful habit, and forms a bemispherical mass a dozen or more feet in height by as much through. It was procured from OSBORN's nursery, and planted by the ex-curator, Mr. J. SMITH, more than forty years ago. The flowers are somewhat smaller in size than those of the Cherry Plum, P. cerasifera, of which P. divaricata is considered by some authorities to be a wild form. According to BOISSIER the distribution of P.

high, and as much in diameter, was covered with trusses of brilliant scarlet blossoms, an object of surpassing beauty; bushes of R. Falconeri, R. eximium, and others of a similar size, and full of books ready to expand, and all growing in the open air."

BACTERIA AGAIN. — When seeds begin to grow and buds to sprout, one essential preliminary is the conversion of the insoluble and indigestible into the soluble and digestible. In the seed and in the bud starch is stored up, having been formed by the conjoint agency of solar light and the green matter of the leaves (chlorophyll), the previous season. This starch is insoluble, but through the agency of a nitrogenous ferment called diastase, secreted by the protoplasm of the cell, the insoluble starch becomes converted into soluble sugar or mallose. So much has been known for a considerable time as a general

there can be little doubt, and especially the former, because we too seldom grant to Mimuluses those merits of hardiness which they deserve. Still, no one would risk the lives of fine kinds that it was desirable to preserve all through ordinary winters out in the open ground especially when the plants can be in the autumn pulled to pieces, and the best shoots dibbled up for the winter in a cool frame, where they will grow, and presently make huge well-rooted plants. Really, no spring-sown seed can produce plants that will for a moment compare with those thus saved through the winter; indeed, it is the common experience of those who thus winter Mimuluses, that about March it is necessary to lift the plants and give them more room, or some may go into pots for house decoration, whilst the rest will do for the open borders, though perhaps better left in the frame till the end of April before planting out. All these plants should

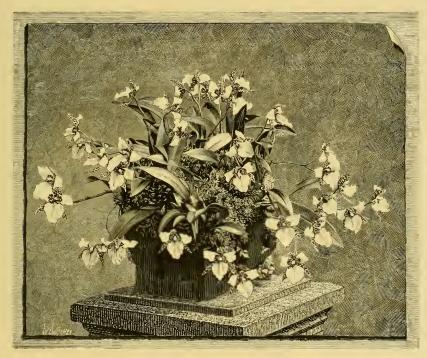

Fig. 63 .- Odontoglossum rossi major var. Rubescens, at drinkstone park. (see p. 339.)

divaricata in a wild state is from Macedonia to Caucasus and Northern Persia. A figure of the Kew plant appeared in the *Botanical Magazine*, tab. 6519.

— BERBERIS THUNDEREO is a very distinct and beautiful Japanese Barberry, and one of the earliest to flower in the genus. It makes a very compact low bush, and the red-brown bark, the simple straight spices, the entire leaves in crowded tufts all along the branches, and the drooping flowers, with pale straw-coloured petals suffused with red, combine to render the species markedly different from all its allies. It is quite hardy in this country; specimens are now in flower at Kew. A figure appeared in the Botanical Magazine, tab. 6646.

— RHODODENDRON BARBATUM.—A Welsh correspondent, "Tafiy" by name, writes:—"You must come to South Wales to see the most glorious examples of the Sikkim Rhododendrons. The other day, in Mrs. VIVIAN's famed garden at Singleton, a specimen of Rhododendron barbatum, 10 or 12 feet

fact, though the subsidiary details have and still continue to tax the patience and ingenuity of chemists. A further complication is brought about, in some cases at least, by the agency of Bacteria. It appears that these minute germs secrete either diastase itself or something like it, by means of which they dissolve the starch and appropriate its carbon, setting free in so doing some oxygen, which is used up by the germinating seed or sprouting bud.

— MIMULUS. — Few things seem just now to present a more instructive comment upon the average temperature of the winter through which we have just passed, than do large patches of the rich grand flowered Mimulus that have stood out all the winter, and that too on a north border, and in the neighbourhood of London. The fresh and vigorous growth, and the patches from single roots some to inches to 12 inches across, serve to show, either that the grand Mimulus is hardier than it is usually esteemed to be, or else that the winter has been unsually mild. That both have to be fully estimated

have the centre or main shoot removed early, and then the base shoots produce a well grown specimen. It is better to sow seed late in the autumn even, and keep the seedlings in pans for the winter, than to leave the sowing till now.

— STRAWEEREV CULTURE.—It is commonly held that few plants more thoroughly exhaust the soil, and, as a consequence, need change of place every few years, than Strawberries; it was therefore something of surprise to learn the other day from Mr. R. CLARK, of Twickenham, that on one border a rod in width and roo yards long Strawberries had been grown for forty years in succession, and that still the crops were magnificent. Mr. CLARK's garden is near Strawberry Hill, and it may be that the soil there is peculiarly fitted for the culture of this delicious fruit. Still, our preconceived notions as to the exhaustion of the soil through such long culture of any one crop are somewhat shaken, and it seems as if nothing traditional in gardening could be taken for granted. That this border is deeply worked

every two or three years, and heavily manured, goes for saying, and our metropolitan growers do manure most heavily; still it pays, and a warm border of this nature turning its crop in rather before the bulk of the early kinds are in, often gives a return that to many may seem fabulous. It is all a matter of high culture, and getting superb examples of fruit, and it is due to Mr. CLARK to say that no grower perhaps commands for his produce a higher price in the market. "Having 2000 more rooted runners in pots of President than I wanted for forcing, I planted them out on the border in August, and the crop resulting was marvellous," Such were Mr. CLARK's words, and yet this border has grown Strawberries for forty years. Really we do not know one-half of the capacities of the soil till we fully test it.

- PROLIFERATION IN SCIADOPITYS VERTI-CILLATA. -At the last meeting of the Linnean Society (March 6) Mr. F. O. BOWER drew attention to a figure published in the Gardeners' Chronicle for i, representing a case of proliferation of the so-called double needle of Sciadopitys verticillata. He alluded to the various views which have been put forward as to the morphological value of the "double needle," and concluded that the one first propounded by Professor ALEX. DICKSON, and afterwards discussed by Von Mohl in an adverse sense, and by GOEBEL favourably, is most in accordance with the history of its development. He pointed out that the figure in question represents a monstrous form, which bears out this view. The lower part of the phylloclade is here developed in the normal manner. About one-third from the base a leaf is given off, similar to the needle of Pinus, and without emargination of the apex. Higher up a second similar leaf is given off from the opposite side, while the axis continues its growth, and forms organs in a similar manner to any main axis of the plant. Such proliferations were obtained by M. CARRIÈRE from the apices of cones which had been "grown through," and the explanation probably is that the axillary axes at that point are provided during their development with an excessive supply of nutritive material. This brings about a stronger development of the apex of the axillary shoot, which is, under normal circumstances, almost, it not entirely arrested. If the double needle be regarded as a phylloclade with arrested apical growth, this case of proliferation may be readily explained as an example of continued apical growth, accompanied by a displacement of the normally more intense intercalary growth. In the normal condition this growth is strongly localised below the apex of the axillary In the abnormal example in question growth has been distributed, not only at the point, but also in the leaves themselves, and also in the apex of the shoot, with the additional organs which it bears.

—— INDIAN SPECIES of CYPERUS.—At the last meeting of the Linnean Society the Secretary read an abstract of an important contribution "Oo the Indian Species of Cyperus," by Mr. C. B. Clarke, with remarks on some others that specially illustrate the subdivisions of the genus. The author divides his men.oir into three sections:—1. A descriptive account of each part of a Cyperus, viz., the culm, inflorescence, &c., comparing these successively in all the Indian species; 2, a discussion of some difficult species and disputed genera; 3, a systematic arrangement with descriptions of the Indian species, with short citations of some non-Indian species that more particularly illustrate the subdivisions and groups.

- THE ALMOND .- What beautiful objects are the fine trees of Almonds so frequently met with in gardens near London! In early spring the Almond certainly rules supreme in British gardens. One of the forms has snow-white flowers, another-the one most commonly met with-rose-tinted or flesh-coloured blossoms. A weeping form, too, is an ornamental low-growing tree, of great value where the ordinary type would require to be cut back and cramped in order to confine it to a space which is sufficient for the weeping variety. What country, or countries, can claim the Almond as a true native? DE CAN-DOLLE, in his extremely interesting work, L'Origine des Plantes Cultivées, inclines to the belief that parts of Western Asia can claim this honour, and that in Sicily, Greece, Italy, France, and elsewhere, where the Almond occurs in an apparently wild state, it has become naturalised more or less recently. HASSEL-QUIST, the friend and pupil of LINNÆUS, in the interesting account of his Travels to the East, quaintly philosophises about the Almond. "Why," says he, "does the Almond tree, which hath white flowers blossom on bare boughs? not for the same reason as the Hazel; perhaps the fruit, having a stone, requires a longer time to grow? They adorn the rising grounds, and according to Nature's order ought to afford much fruit, as they bloom at a time of the year when the sky is constantly serne, and if neither rains nor is there any kind of bad weather, which in many countries prevent a fine blossom from giving the wished-for fruit."

—— DICHOPOGON STRICTUS. — This is a very attractive sweet-scented Liliaceous plant, like an Asphodel, with tuberous roots, long linear grass-like leaves; linear bracts, and pale violet flowers of regular form, about 1 inch or 1½ inch across, and arranged on long stalks in loose terminal clusters. The anthers have two curious purplish lobes or appendages at the base. The plant is a native of a large portion of Australia and of Tasmania. The specimen figured in the Botanical Magazine, 1, 6746, was grown in the Cambridge Botanic Garden.

- CORYLOPSIS HIMALAYENSIS .- On the wall of the herbaceous ground at Kew a vigorous young plant of this newly-introduced species is now in flower. When better known this will doubtless become as great a favourite as the charming little Japanese shrub, C. spicata, which was first introduced to British gardens some score years or so ago by Messrs. VEITCH, and figures of which have repeatedly appeared in these columns. As far as appearances go at present, C. himalayensis seems a more vigorous grower than its Japanese relation, the Cowslip colour as well as the Cowslip fragrance being equally as marked in the former as in the latter species, pendulous racemes-subtended by large pale strawcoloured bracts-of C. himalayensis seem larger than those of C. spicata, but the anthers of the last-named species are more conspicuous on account of their bright red colour. A figure of C. himlayensis has been prepared for the Botanical Magazine.

- CLIMATE, -The following extracts, taken from the last report of the Botanic Garden, Trinidad, will be of interest to cultivators as showing the comparative uniformity of conditions and the slight range under which tropical plants grow. The mean maximum temperature for the three years, 1880—1882, was 90°, the range being from 83° in January, 1880, to 92° in April, 1881. For the same period the mean minimum temperature was 61°.7, the range being from 60°.7 in February, 1880, to 68°.4 in April, May, 1881, and in September, 1880. The extreme range between maximum and minimum for the three years was 38°.3 F. The mean temperature for twenty-one years is given as 77°.7, the highest being 79°.5 in May, the lowest 76° in January and February. The maximum humidity for twenty-one years is registered as .885 in August, 1880; the minimum in April, 1869, as .572-1000 representing saturation. average amount of rainfall for twenty years is 65.85 inches, the maximum being 85.2, the minimum 44. The average amount of cloudiness (ranging from o total clearness, to 10 total cloudiness), is given at 5.2 for the whole year, the range being from 4.5 as a monthly mean minimum in January to 64 in October. Where, as in countries like Trinidad, the range is so small, records of mean temperature are valuable, but for climates where the conditions are more variable and the extremes wide apart mean temperatures are misleading. A ready method of recording the relative duration of any given temperature or other meteorological phenomenon is still a desideratum.

—— ROYAL HORTICULTURAL SOCIETY. — The President, Lord ABREDARE, has nominated the following gentlemen Vice-Presidents for the ensuing year, viz., Sir Trevor Lawrence, Bart., M.P., J. II. MANGLES, Esq., ROBERT HOGG, Esq., LL D., F.L.S., and Sir P. CUNLIFFE OWEN, K.C.M.G., C.B., C.S.E.

—— GARDENERS' ROYAL BENEVOLENT INSTITU-TION.—TO Mr. J. E. PERKINS, of the Billing Road Nurseries, Northampton, is due the credit of originating a new method of making life-members of this Institution. From a schedule of prizes before us, of the Northamptonshire Horticultural Society, we learn that at the third annual exhibition, to be held in Delapre Park, on August 2 and 4, Mr. PERKINS offers as a first prize "a Life-Membership of the Gardeners' Royal Benevolent Institution, value £10 10s.," in a class for a group of miscellaneous plants suitable for conservatory decoration, open to gentlemen and gentlemen's gardeners in the county of Northampton. Special prizes of this kind are highly to be commended, and we trust many others may see their way to doing likewise, during the ensuing season.

— The Wood Trade in Konigsberg.—It is stated in a recent report from Konigsberg that the trade in wood is increasing every year. The shipment of wood at Konigsberg is much kept back by the shallowness of the channel in the Frische Haff, between Konigsberg and Fillau, which prevents large vessels loading up at Konigsberg. It is, however, hoped that this will shortly be remedied. Billet wood, Birch and Eech, is shipped in considerable quantities to Scotland to make herring barrels, and Alder wood to the Weser to make cigar boxes.

ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to he held at 25, Great George Street, Westminster, on Wednesday, the 21st inst., at 7 F.M., the following paper will be read:—"Brief Notes on the History of Thermometers." By Robert H. Scott, M.A., F.R.S., President. After the reading of this paper the meeting will be adjourned, in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of thermometers, and of such new instruments as have been invented and first constructed since the last exhibition.

— PRESENTATION TO MR. GEORGE EYLES.— The late Honorary Secretary of the Richmond Horticultural Society, Mr. GEORGE EYLES, was last week presented by the subscribers with a silver tea-kettle, stand, and lamp, in recognition of the manner in which he had discharged the duties of his office.

— THE WEATHER.—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending March 10, issued by the Meteorological Office, London: — The weather has been very unsettled and changeable generally, with a good deal of rain, sleet, or hail. Over the greater part of England, and in some parts of Scotland, however, the first few days of the period were fine and bright. The temperature has been 1° below the mean in Iteland, but 1° above or about equal to its normal value elsewhere. The maxima were registered in most places on the 6th; and ranged from 49° in most places on the 6th; and ranged from 49° in "Scotland, N." to 55° in "Scotland, E.," the "Midland Counties," and "England, S." The minima, which were recorded on different days in the various districts, ranged from 27° in "Ireland, S.," and 28° in "England, N.E.," and the "Midland Counties," to 32° in "Scotland, E.," and "England, N.W." The rainfall has been more than the mean in all districts, the excess over then north of England and south of Ireland being large. At Valencia the total fall has amounted to as much as 4.84 inches. Bright sunshine shows an increase in duration in most places. The percentage of possible duration was greatest, 51, in the "Channel Islands," and least, 11, in "Scotland, F.," while in "Scotland, N.," 30 per cent, in "Scotland, W.," 31 per cent, in "England, S.," 32 per cent, and in "England, S.W.," 36 per cent, in "Scotland, W.," 31 per cent, in "England, S.," 32 per cent, and in "England, S.W.," 36 per cent, in western stations on the 4th and 8th, has consequently been between south and west. On our western and outhern coasts thas blown freshly or stongly, and during the latter part of the week the force of a fresh gale (from the southward was readened in Ireland, and a very strong gale in the north-cast and east of Scotland, and a very strong gale in the north-cast and east of

— GARDENING APPOINTMENTS.—Mr. G. RAMSAY, lately Foreman at Huston, Argylshire, as Gardener to Viscount Ashbrooke, Castle Durrow,
Queen's County.—Mr. Richard Parker, Foreman
to Mr. McIndor, Hutton Hall, Guisborough, as
Gardener to J. Corbett, Esq., M.P., Impney,
Droitwich.—Mr. E. Bryan, for the last three years
Foreman at Hackwood Park, Basingstoke, as Gardener to Lord Thynny, Culver House, Stroud.—
Mr. W. Clayton, for the last two years Foreman at
Baldersby Park, Thisk, as Gardener to Lord
St. John, Melchbourne Park, Sharnbrook, Bedford.

HYBRID AMARYLLIS.

Concluded from p. 307.)

I WOULD now ask the following questions:—
(a) Is it a good or a bad practice to attempt to fertilise a pistil with more than one kind of pollen?

The following facts will, perhaps, give some answer to the above question:—

1. It is evident that in a state of Nature promiscuous fertilisation of some flowers appears to be the law. There is no provision in the Amaryllis for preventing a moth or other insect from carrying pollen to a pistil which had already come in contact with another kind of pollen, nuless it be the closing of the petals over the pistil, alter fertilisation. This, however, is insufficient. There is no way of preventing different kinds of pollen being carried to a stigma before fertilisation actually occurs, and the subsequent closing of the petals. In fact, a moth, visiting flower after flower, cannot help taking to an unfertilised pistil a mixture of pollen grains at one and the same time.

2. In 1875 I crossed promiscuously, that is, I applied on the same pistil, at different times, the pollen of a number of varieties, sometimes more than half-a-dozen. The result was satisfactory, both as regards quantity of seed, and germinating power. As to flower, some wonderful novelties were produced.

3. In 1882 I did the same thing, and the result, as to number of seeds and germinating power, was equally satisfactory. As to flower, however, I am not yet able to judge.

yet abuse to judge.

4. In 1833 I acled differently, that is, I applied one kind of pollen only to each pistil, selecting, as a rule, those varieties the qualities of which I wished to combine. The result was a failure, as the following list will show:—

Padsbah x Dilfarèb	1 c seeds	r germinated and
Sita × Acramaoni	11 11	I germinated and

S. Marco × Lucy	Un- }	2 germinated and
	counted 5	perished

Here is a lot of twenty different pistils crossed with the pollen of their peers, and apparently producing among them upwards of 167 seeds, and all of them worthless; and another lot of seven pistils, also crossed with the pollen of their peers, producing upwards of 103 seeds, eleven of which only were visible; while, on the contrary, eight pistils of the common kinds, crossed with some of the above, produced among them 359 seeds, of which 154 germinated, and 123 are now living, that is, more than a third.

Promiscuous crossing has, in my opinion, this advantage—if the pollen of the desired flower, which should, I think, be applied first, to give it a better chance, do not take, you may have other chances of getting seed, by applying other kinds of pollen afterwards. If the first succeed, I think no harm will result by some of the ovules being fertilised by other pollen also.

It will be seen from the above experiments that in some kinds, even when the pollen sets up some action, it is only in a small number of the ovules contained in the seed vessel that fertilisation actually occurs. If you limit yourself to only one kind of pullen per pistil and wait for the result, the opportunity of obtaining any seed from a plant that is, for getting a large amount of seed with the chance of new kinds coming out of them—I should say, fertilise promiscuously.

(é) The other question I should like to ask is this: —Is it possible for an ovule to be fertilised by more than one pollen grain, either of the same or of different flowers? This, I think, could only be decided by the microscope, and by carefully made experiments on prolific individuals. By watching the result it might be perhaps ascertained whether two distinct characters belonging to two pollen-bearing Amaryllis could be blended with those of a third, used as a seed bearer.

I would conclude by statiog that all the seeds obtained in 1882 and 1883 were subjected to the same treatment, and therefore the want of germinating power, and in some cases speedy death after germination, must have been due either to a want or a deficiency of vitality.

a deficiency of vitality.

After writing the above I read an article on "Sterility in Plants," by Dr. Matthews Duncan, published in the Lancet. It is interesting, and he comes to the conclusion that sterility may result from a large number of opposite causes, besides from interbreeding. E. Bonardia, M.D., Elawah, 7an. 19. [See Gardeners' Chroniele, p. 344, vol. xix.]

NOTES FROM MR. BULL'S NURSERY.

WHAT astonishes one at the entrance to this place this year is the stout growths observable on the Tree Ferns, Zamias, Encephalartos, that constitute the imposing attractions in the big conservatory. This growth is the more remarkable from the fact of the excessive amount of ventilation that is given from a constantly open door next to the street, and the uniformly cool, humid temperature that is maintained. This early and strong growth is doubtless owing in a great measure to this and the large amount of air that is admitted, and to the unusual mildness of the weather up to this time. In a house off from this one the white and blue Iridaceous plant, Marica pacifica, had one of its striking blooms open. It is certainly as handsome as many an Orchid, although belonging to species of the easiest culture. The remarkable Godwinia gigas still continues in bloom, and shows but little if any change in its appearance. Some fine Sarracenias were throwing up their sparsely distri-buted but conspicuous globular blooms in a cool house . of these we noticed S. flavum maximum with a lemon-tinted flower, S. Drummondi alba carrying a fine bold spike, and almost equally tall pitchers. This is a variety of S. Drummondi, the better known plant from Florida, but instead of carrying the rich crimson flowers of that species, it has white sepals and petals with finely mottled leaves or pitchers. S. atrosanguinea, with creamy-white blooms and green style; S. crispata, with broadly marked reticulate pitchers and whitish flowers, and S. psittacina were also to be seen in bloom, the whole collection forming a seldom seen exhibition in itself. Tillandsia Lindeni vera, of the most beautiful purpleblue, and bright rosy bracts, had a flower open in a warm pit, the beauty of this plant exceeding, if anything, that of T. Lindeni.

In the Masdevallia-house the pretty M. Harryana acanthilolia was throwing up a few of its shining flowers of rosy-pink, the bright M. splendens, M. ignea Massangeava, M. militaris, and the more curious yellow and brown M. triangularis—this last being literally loaded with bloom, that was decidedly effective as a mass. In a house where Cattleyas formed the major portion of the contents, and where some very large plants of well-known and rarer kinds were standing in most vigorous health, as was indeed the whole of the collection, we saw a particularly fine C. Trianæ regioa, the rosy-lilac sepals and petals, and intensely dark purple lip and yellow throat, marking a beautiful and distinct thing. A very finely coloured variety, named C. T. splendida, had superh colours; but the choicest seen open was C. T. magnifica, with dark maroon lip that contrasted finely with the creamy-white tints of the rest of the blooms. Another fine Cattleya, exhibiting a much larger yellow mass in the throat and very large rosy sepals, is C. T. aurea grandiflora; this is very distinct and choice. In this division the somewhat rare Lælia Lindleyana had opened a few creamy-white, faintly spotted with crimson, blossoms. The great banks of Vandas, Lælias, and Cattleyas have an appearance of splendid health rarely seen. The Chatsworth var, of

Coclogyne cristata, so useful as extending the flowering season of these beautiful white bloomers, had a great mass of flowers open on several plants, as had the yellow-throated and somewhat earlier C. Lemoniana. The richly-coloured Miltonia cuneata could also be seen, but its beauties had begun to fade.

Of Cypripedium novelties not many had opened their blooms, or we failed to observe them, C. Hartwegii being apparently the most striking thing out, for although lacking the deeper hues and white of other kinds, the long and branching habit of the flower-stalk, surmounted with the elegant, long-winged green flowers, make it a pleasing addition to collections. We noticed a beautiful lot of Odontoglossum Phalenopeis, fine stocky plants, evidently at home near the glass in a well-ventilated cool house. Without attempting the enumeration of all the fine Odontoglossums to be found now in bloom here, it must suffice to point out the more noticeable of this remarkable collection. O. Halli leucoglossum, O. crispum roseum-the latter with a rosy suffusion in the petals; O. membranaceum, similar to an O. Cervantesi, but without spots, and with fewer of those circular bar markings; O. Ruckerianum, having also the pink shading notice-able in O. crispum roseum; O. Œrstedii, a rarer kind, pure white, with a yellow eye; O. Jenningsianum pauciguttatum; the pretty O. Chestertoni, and O. Pescatorea aurantiaca, a variety with the additional attraction of having a distinct orange crest; many O. crispum of varying form and tints, made with the before-named varieties, and several of O. luteum, an elegant kind; O. odoratum, O. hystrix, and O. Roezlii, a charming exhibition; the house, owing to the foreshortening of the perspective, as seen from the end, appearing to be quite filled with bloom; and there are, in fact, more than 200 spikes open, or about to become so. The O. vexillarium houses contain many splendid plants, and an immense number of smaller ones, in perfect health, dwarf, stocky, well furnished, and which, when in bloom, must form a fine exhibition in themselves.

An Oncidium Marshalli is about coming into bloom; it has many flower-spikes, and should be a fine object in a short time. O. Edwardi, with a hundred flowers open, was also a pretty sight, as was also a group of Sophronitis aurantiaca, but conspicuous among which was S. coccinea, a variety of far more brilliant colour, and against which the former appears of a rusty-red.

In the house appropriated to Dendrobes chiefly several D. crassinode, and foremost amongst these last D. c. Barberianum, by far the richer of the type; D. Paxtoni, and the beautiful rich golden D. fimbriatum occulatum. A few D. Wardianum were also in bloom, and the handsome, easily managed Phaius Blumei.

Amongst the more miscellaneous plants were to be sen some of the latest additions to useful hardwooded plants, Epacris onosmeflora, flore-pleno alba, and E. o. plena nivalis producing pretty minute rosettes of bloom on loog flowering shoots, the first-named being blush-white and the latter pure white. Another plant likely to prove of considerable value for early forcing, and possibly for out-of-doors planting, is an Azalea cross between A. indica and A. mollis, the foliage being that of the latter, and flowers rosy-lilac, in clusters. M.

COLONIAL NOTES.

ADELAIDE, SOUTH AUSTRALIA.-Presentation to Dr. Schomburgk.-In September last a meeting was convened of the friends and admirers of Dr. Schomburgk, Curator of the Adelaide Botanic Gardens, for the purpose of considering the best means of practically recognising the valuable services rendered to the colony by that gentleman in the cause of botany. It was then decided that his portrait should be painted and permanently placed in some portion of the Gardens under his care. A committee was formed, subscriptions were obtained, and the task of producing a painting of Dr. Schomburgk was entrusted to Mr. L. E. Tannert, Master of the School of Art. All the necessary preliminaries having been completed, it was that a public presentation of the painting should be made to the Board of Governors of the Gardens, and his Excellency the Governor was requested to perform the formal ceremony. On Janu-

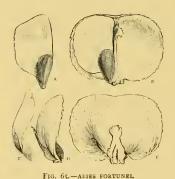

ary 30 the Museum of Economic Botany, situated in the very centre of those beautiful Gardens in which Dr. Schomburgk takes so much pride, was converted into a temporary hall. The painting was hung over the northern interior door, and bore the following inscription: - "This portrait of Richard Schom burgk, Ph.D., &c., is presented to this Museum by a number of his friends, in appreciation of the zeal energy, and skill which he has devoted to rendering the Botanic Gardens an ornament to the City of the botanic Gardens an ormanent to the City of Adelaide, and the pride of the Province of South Australia."—His Excellency the Governor having made the presentation in terms highly eulogistic of the valuable service rendered by Dr. Schomburgk, and the portrait accepted by Dr. Wyatt, the oldest Governor of the Botanic Garden, Dr. Schomburgk said he could not, even if he so desired, appropriate to himself the credit which was also due to those who had been instrumental in bringing the Gardens to their present state. Firstly, much was due to the Legislature for its liheral annual vote; secondly, a considerable amount of praise belongs to the late Mr. George Francis, who was the first Director of the Gardens, and who planned and designed the first portion of them. He need not say that when a good and substantial foundation had been once laid it became a comparatively easy task to add to the superstructure, the only difficulty to avoid being that

FIG. 64. -ABIES FORTUNEI: CONE.

The Arboretum.

ABIES FORTUNEI,—Thaoks to the courtesy of Messrs. Rovelli, of Pallanza, we are now enabled to give illustrations of the foliage, cone, seed-scale, and bark of this remarkable Conifer (figs. 64—67). A fine tree exists in Messrs. Rovelli's nursery, from which they have secured seed. This tree is little known in this country, where the climate seems generally unsuitable for it, but in the south and west coasts, in southern Ireland and the Channel Islands, as also in many of our colonies, this tree ought to find a congenial home. It is a singular fact that up to this time but one tree of this kind is known in its (presumed) native country—that originally met with by Fortune in the vicinity of a temple at Foo Chow Foo, in China. Fortune speaks of it as a magnificent tree with the habit of a Cedar of Lebanon, with beautiful erect purple cones, thickly grouped like rows of soldiers, on the branches. No other tree of this species, is, as we have said, known, except those raised from Fortune's seeds. From this circumstance, and the fact of its situation in the grounds of a temple, it is probable that the tree was introduced to Foo Chow Foo, and that its native habitat will sooner or later be discovered. Meanwhile, it is satisfactory to know that Messrs. Rovelli can supply seed and plants sufficient to obviate the risk of extermination of so remarkable a tree. It was introduced to this country under the erroneous name of A. jezoensis, and to the late Andrew Murray is due the credit of disentangling the consistency of the produced in our columns, 1851, p. 311, is approximately correct, but the coose are decidedly erect, not pendulous. It was considered to form a link between the Spruces

A, Seed; B, Seed scale and seed; C, Side of seed; D, Side of seed-scale, showing bract; E, Bract and seed-scale.

particularly thick corky character, quite unlike that of any other Conifer that we can recal, and much more like that of a Cork Oak. M. T. M.

Home Correspondence.

Tree Protection on Open Walls.—Mr. Smith (p. 317) seems to place great dependence on copings as a protection to wall trees, and, I think, rightly too, as it is of the utmost importance that the walls and blossoms be kept dry, in which condition the bricks are many degrees warmer, and frost and cold have much less effect. A board coping, however, is only a makeshift, as, though it answers the purpose of throwing off wet, it excludes the light from the tops of the trees, the shoots on that part of which, when under tis influence, seldom set any blossoms, and the young growth comes weakened and poor. Some object to glass copings on account of their being permanent or immovable, but those who are against them on that score cannot have experienced their great utility at the time fruit is ripe, when it frequently happens we get a glut of rain, as we did last year, with much wind, when Peaches and Nectarioes that were exposed were sorely damaged, and mary spoiled, while those

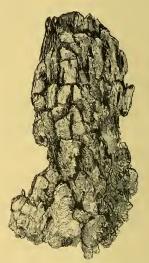

FIG. 66.—ABIES FORTUNEI: PORTION OF THE BARK.

of spoiling the design by attempting too much. The services of Mr. Francis have not been altogether forgotten, and an obelisk has been erected to his memory in the Gardens. It would be a source of gratification to him if he could see his portrait placed side by side with his own. Much was also due to the Board of Governors of the Gardens, to whose support and assistance he was indebted for a great part of his success. He had been associated with most of the present members of the Board ever since he was appointed to his present office eighteen years ago. For the whole of that long period, during which he had laboured under those gentlemen, their intercourse had been one unbroken chann of cordiality, earnest co-operation, and kinduess. Indeed the confidence they had reposed in him had supported him through many difficulties, and rendered his labours comparatively light. The founding of this Museum of Economic Botany (in which his portrait has been placed) had been one of the many objects of his great solicide. The high estimation in which he left proud to say it is held by the public, and the never failing interest it excites and maintains, was a substantial reward for all the pains he had taken to make it what it is.

THE BASINGSTOKE HORTICULTURAL SOCIETY'S eighth annual exhibition will be held at Goldings, Basingstoke, on August 19.

(Picea) and the Silver Firs (Abies), but, in truth, it is very much more nearly allied to the latter, of which it has the flat leaves, the smooth stem, and the erect cones. The scales of the latter, however, are stated to be persistent not deciduous, but in our specimens the scales manifest a tendency to fall away—if we would let them! The male flowers we have not seen, but at present the evidence seems to point to the fact that this is a true Abies, and that the genus Keteleeria, formed to receive it, is not really necessary. The buds are small, vooid, covered with orange-brown scales, the lower of which are prolonged into a long thread-like point. The branches are glabrous, of an orange-red colour; the leaves are of a pale yellowish green on both surfaces, dispersed more regularly round the stem than is usually the case in species of Abies, that is to say, they are less twisted at the base; and this circumstance is probably due to a difference in the arrangement of the branches—a point on which we cannot speak with certainty. The leaf structure shows a double layer of hypoderm beneath the upper epidermis, a single layer above the lower skin with two resin-canals close to the latter and near to the margins. A central fibro-vascular bundle, surrounded by a "whonle-sheath," traverses a mass of "transfusion tissue," and there are palissade cells on the upper surface. The cones vary considerably in size, and when dry are of a dull bluish colour, with a glaucous bloom, like those of Pinus Cembra. The bracks vary in shape and size, but when young are lanceolate and acuminate, the point being broken fast she cone ripens. The brack for the trunk is of a

under shelter escaped, and were none the worse for the weather. Apricots, when ripe, are very tender in the skin, and if they get wet at that time perish wholesale, a striking proof of which we had here some years ago when one of our walls was coped and the other unprotected, as the fruit on the latter became hadly specked and damaged, and had to be used for jam and cooking, while that on the trees with glass over them was perfect and nearly all fit for dessert. The thing in putting up copings is to have them proportionate to the height of the walls, which, if 10 feet or so, should not have a coping wider than about 18 to 24 inches, as, when they project far, the air is too confined, and becomes very hot during the summer. To counteract any bad effect from loss of night dews and rain on the foliage it is necessary to syringe or use the garden englies so as to well wet the leaves during the afternoon in summer, which, with the requisite watering of the trees when swelling their fruit, will keep them in a high condition of health. Mr. Smith, though advocating copings, says he looks upon any front protection as a great evil, in which I entirely differ from him, as the coping, though of great use to secure dryness, will not keep off beating rains and driving hail or soow, which, unless the trees have something before them, are carried on to the face of the wall, and the object and purpose of the coping in a great measure defeated. Thick opaque screens I hold quite a mistake, unless they can be put up and down quickly night and morning, and not used to obstruct light and sun, every portion of which the

blossoms need to keep them healthy and strong, Fishiag-nets, strained tight, applied double for the meshes to cross, keep off so little of either, that I am quite in favour of them, and have some on contoually; as not ooly do they ward off hail, snow, and rain, but they sift the keen wind, and take out its sting, for, open as they are, it is surprising what a difference there is in temperature behind them to that prevailing in front of a wall where nets are not used. 7. Sheppard.

Birds and Peas: a Curious Fact,—In November, 1882, I sowed two lines of Peas, old Daniel O'Rourke and Carter's First Crop, to come in extra early, in my experimental vegetable garden. There is a wall convenient, where crows, jackdaws, &c., perch, and during the winter months have an unholy propensity for everything peeping above the ground. My early Peas soon disappeared, and I tried Hun-

There is no difficulty in obtaining pollen from almost any variety, but some varieties will not take it. Some of the most difficult are the finest forms of the Leopoldi type. I have a seedling hybrid form of Leopoldi which I have tried with all sorts of pollen, and at all times, and failed to get a single seed from it. The variety in question might be hybridised by the pollen of a common form, but it would not be worth while to try it except by way of experiment. It is a very expensive business raising seedling Amaryllids in sufficient quantity to obtain good results, and labour would be wasted in trying to raise seedlings from other than the very best varieties. J. Douglas, Great Gearies.

The Gooseberry Caterpillar.—As every year this pest is more or less abundant, a little trouble at this season of the year will completely exterminate them. Get some fresh tan from the tan-yard, and

in the habit of every day cutting sections of one or more tubers, and I have never once found a Potato diseased by Peronospora in the centre when its exterior did not show traces of infection. Many years is an indefinite period, but I can assure Mr. Smith these observations have been continuously carried on by me for the past thirty years; rarely have I missed a day. As a rule, more than one Potato has been sliced by me; so that 30 × 365 = 10,950 tubers examined, not one of which has shown the centre diseased by Peronospora, while the exterior remained sound. I admit these tubers had been subjected to a temperature of 212° F. before I sliced them, but although Mr. Jensen tells us 77° C. is fatal to the vitality of the Peronospora, yet it requires a higher temperature than 212° F. to obliterate all traces of the disease. Before I sliced these 10,950 tubers each one had been washed, and in most of them the epidermis had been removed; during these processes the disease was almost invariably discovered, and the tuber rejected; but if the disease had commenced inside first then it would have escaped detection during the preliminary processes, and it would not have been observed until the sections were made. I do not deny that it is possible for Potatos to decay in the centre first—decay may begin anywhere; but I am only speaking of that form of decay induced by the presence of Peronospora infestans. Charles B. Ploweright, 7, King Street, King's Lynn, March 4.

Peculiar Tree Growths,—When at Aber last week a rather curious case of the junction of an Oak

Peculiar Tree Growths,—When at Aber last week a rather curious case of the junction of an Oak and Ash stem was pointed out to me. For over 2 feet in height these stems were so closely united that unless by a very careful examination the junction could not be detected. It is quite possible that as the trees were growing close to each other and alongside a public pathway they may, when of a small size, have been inarched and bound together by some one in passing. At Gwydyr Castle I noticed another curious case, in which the branch of an Oak tree terminated in the main stem at a distance of 3 feet from the point whence it originated. The diameter of the branch is about 6 inches, and so uniform in size that it is rather a difficult matter to state from which end the branch sprang out. A. D. Webster.

Saxifraga oppositifolia var, splendens,—Of the many varieties of this pretty native rock-plant I know of none to equal this in depth of colour and for producing a mass of bloom. I helieve it was originally found by Mr. Backhouse on the Welsh mountains. At the present time it forms grand sheets of rosy-crimson on the rock garden at Vork. It prefers being planted on raised mounds, or in crevices, &c., in sandy loam. R. P.

British Ferns.—Mr. Druery (p. 281) has done good work in bringing before your readers a plea for that much neglected class of plants—our native Ferns. It is certainly to be regretted that so few take a direct interest in these plants, and their almost numberless varieties, many of which equal, if not excel, in point of beauty, as well as ease of culture, their exotic brethren, on whom so much care is usually lavished. The high price of British Ferns is no doubt, at least in many cases, a serious drawback to the forming of anything like a large collection of these plants, for it is not every one who would care or can afford to pay at the rate of a couple of shillings each for most of the kinds coumerated in the choice list which Mr. Druery has kindly placed before your readers. But, on the other hand, those who really take an interest in these plants will find ways and means, apart from buying, of obtaining even the most choice varieties, as many kinds may be readily enough raised from spores, while the plant exchange system affords peculiar advantages for the obtaining of new and rare specimens. In this county (Carnarvonshire) one of the best districts in Britain for Fern collecting, I am above the mark in stating that there are not halfadozen collections worthy of the name, or that would repay one for the trouble of a visit. In conclusion, I hope Mr. Druery's remarks will have the desired effect, in not only promoting a desire for, but in furthering the cultivation of this elegant and interesting class of plants. A. D. Webster.

Apple Cracking.—The peculiar split or sutured form seen on Mr. Bunyard's Apples referred to at p. 313 by Mr. Berkeley, the samples of which I saw, seem to be peculiar to certain of the Russet family, though more abundant in some years than in others. Probably few familiar with Apples but can remember, even from their earliest years, the sutured Russets, so crisp and sweet, seeming almost like split Cherries, all the sweeter for the contortion. I would refer, however, to the fact that very much in excess of ordinary experience this splitting or suturing was seen in some kinds of Potato, especially round ones, during the past season, quite deforming them out of all knowledge and usefulness. This peculiarity was ascribed first to checked growth and setting of the skins by drought, and then to forced expansion by

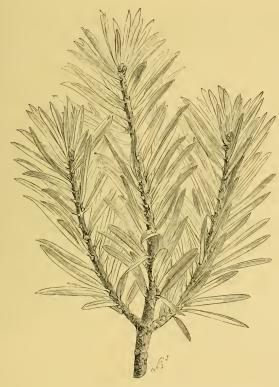

Fig. 67.—Foliage of abies fortunei. (see p. 348.)

dredfold, rolled in red lead, about January, as I thought mice were helping the rooks; these were wouldly thinned too, though I put some hundreds of yards of thread over the lines. Lastly, I put down, about the middle of March, Pride of the Market and Stratagem, without any protection at all, and they were unmolested; in fact, the birds did not appear at all. I have come to the conclusion that about this time those destructive birds are so engaged in nest building, and have so much field food, as not to come near houses, so I am only sowing my Peas now this year. W. 7. Murphy, Clonnel.

Hybrid Amaryllis—Are we to understand from the remarks of Dr. Bonavia, at p. 307, that hybrid forms of the Amaryllis cannot be fertilised with their own pollen? If the Dector thicks so I should say that his experiments have not been sufficiently exhaustive. I fertilised seven blooms of a highly-bred variety with their own pollen two years ago, and from those seven pods raised 750 plants. With the pollen of that variety I tried to cross other hybrid forms, and failed in some cases, but was successful in others.

cover the surface of the ground all round the Gooseberry bushes, 2 or 3 inches thick; let it remain till the autumn or winter, then dig it in. Care must be taken that the tan is fresh, or the result will prove a failure. \mathcal{T} . G. Hill.

Potato Disease.—In a communication upon this subject at p. 283 Mr. Smith says of the Potato disease "that in a very large number of cases the disease starts from the interior of the Potato tubers and finds its way to the outside, often after storing, and during the winter and spring mouths. At the time of lifting it is by no means uncommon on cutting open an apparently sound Potato to find a small disease patch in the middle." While I agree with Mr. Smith that the mycelium can and does hybernate in the tubers throughout the winter and produce condida in the following spring, yet I am certain he is wrong in supposing it ever commences in the centre of the tubers. I am sure it invariably begins from the outside, and works its way inwards. I am in a position to speak confidently upon this point, for the very good reason that for many years past I have been

warm rains and healed soil. Whatever may have been the operating cause, however, the features referred to were seen in unusual abundance. A. D.

Zinc Labels.—A capital label for pot plants is sold by Messrs. Veitch, of Chelsea, under the name of "the Glenny garden label." It is 5 inches long of "the Clenny garden label." It is 5 inches long and 1 inch broad, rounded at the top, well pointed, and neatly finished. These, if written on with 0 sman's indelible ink and thinly varished, are practically indestructible. For the hardy border I find them too small, and get some made 8 inches long by 14 inch wide, out of ordinary sheet zinc. They can be readily cut out with a timman's shears, and, though rather rapph asswer their nuroose very well, and are inficut out with a tinman's snears, and, though rather rough, asswer their purpose very well, and are infi-nitely superior to wood labels. The point to remember with these labels is to get a clean and bright surface to the zinc immediately before writing on it, for if dirty the ink will not readily "take" to the label, neither will it stand so long. The surface can be easily cleaned with a bit of fine glass-paper. For outdoor use varnish is nuncecessary. John C. Tallack, Prideaux Place, Padstow, March 10.

Peports of Societies.

Royal Horticultural : March 11.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker, K.C.S.I., in the chair. Present: Lord Enfield, Messrs. Smee, Grote, Loder, Houston, Mangles, Wilson, MacLachlan, Murray, Ridley, Professors Church and Foster, Drs. Lowe and Masters.

Mushroom Spawn.—A letter was read from the Rev. M. J. Berkeley, referring to the capriciousness of the mycelium of Mushrooms under cultivation.

of the mycelium of Mushrooms under cultivation,
Alteration of Habit in Pellia,—Mr. G. Murray
showed plants of Pellia epiphylla which in consequence of being grown under a bell-glass had assumed
an erect habit, very different from its usual condition.
Abite (Keteleria) Fortunci.—Dr. Masters showed
foliage and cones of A. Fortunci together with slabs
of its corky bark received from MM. Rovelli, of Pallanza, in whose nursery the tree assumed large proportions (see p. 348).

portions (see p. 348).

Pica Omorika.—Dr. Masters showed cones, &c., of the Servian Spruce, procured through the mediation of Mr. Nicholson, and figured in the Gardeners' Chronicle, p. 309.

Burr-knot in Ribes.—Dr. Masters showed from Mr.

Webster, The Gardens, Gordon Castle, a specimen of red Currant in which there was a large production of ted currant in white there was a range processor buds and shoots, the main stem being arrested in growth, thus producing an appearance like that of the knots in the Beech now recognised as the work of a mite (Phytoptus). The specimen was sent to the Kew Museum.

Phalanopsis Stuartiana.—Mr. O'Brien showed

flowers of this species grown by Major Lendy, and in

flowers of this species grown by Major Lendy, and in which the lateral petals presented in the centre of the upper surface indications of a crest like those on the lip. The important point was, that this peculiarity was constant in this variety.

Hyacinths Grown in the Dark.—Mr. Smee showed flowering bulbs of a red, blue, and almost white Hyacinth respectively, which had been planted and covered with a drain-pipe, the mouth of which was covered with a drain-pipe, the mouth of which was covered with a drain-pipe, the mouth of which was covered with a cool and perfume of the flower were lanked, and the size not greatly below the averwell marked, and the size not greatly below the averinches. The colour and perfume of the flower were well marked, and the size not greatly below the average; the leaves were of a sickly green at the top, yellowish at the back. It was pointed out that the experiment was bardly a crucial one, inasmuch as the nutritive matter out of which the colouring principles were formed was already contained in the bulb. Gumming in Fruit Trees.—Referring to the article of Dr. Beijerinck, summarised by Sir James Paget in a recent oumber of the Gardener's Chronicle, Mr. Plownight sent specimens received from Profession.

Mr. Plowright sent specimens received from Prolessor Oudemanns affected with Coryneum Beijerinckii,

sor Oudemanns affected with Coryneum Beijerinckii, together with a sketch of the spores, of which we shall shortly give an illustration.

Canker in Apples, &c.,—Mr. Plowright sent specimens of three different affections, each called canker. One on Hawthorn was perhaps the consequence of insect puncture; a second, on the Apple, caused by Nectria ditissima, alias N. cicatricula, which is not uncommon on the Beech. The third form is a distinct affection, of which nothing can be predicated. As the Coryneum is stated not to be able to pierce the bark without the help of an insect, why, asks Mr. bark without the help of an insect, why, asks Mr.

the Coryneum is stated not to be able to pierce the bark without the help of an insect, why, asks Mr. Plowright, may not the Nectria be in like case?

The Jensenian Plan of Preventing the Potato Discase.—Some suggestions as to practical experiments to be carried out at Chiswick with reference to this subject were read from Mr. Plowright, and it was suggested that a sub-committee, consisting of persons specially interested in the matter, should be appointed to watch the experiments. to watch the experiments.

Apples Preserved in Sand .- Lord Ducie sent speci-

mens of Courl-pendu Plat and Duke of Devonshire

mens of Court-pendu Plat and Duke of Devonshire Apples preserved in dry sand.

Epidendrum rhicofhorum.—The Hon. and Rev. **International Professional Profess

FLORAL COMMITTEE. — Present in Section A. G. F. Wilson, Esq., in the chair; Messrs. T. Moore, J. Hudson, J. Fraser, H. Herbst, J. Woodbridge, H. Ballantine, J. Dominy, J. O'Brien, E. Hill, J. Laing, Dr. Masters, and the Rev. G. Henslow, Section B. J. T. D. Llewlyn, Esq., in the chair; Messrs. H. Eckford, H. Bennett, W. Bealby, J. Douglas, J. James, J. Child, G. Duffield, H. Turner, and H. Cannell. The chief points of attraction at the meeting on Tuesday last were almost identical as regards the genera of plants shown with those of February 12, Cinerarias, Cyclamen, Primula sitemsis forming the major portion, with but few Orchids or other subjects to relieve them. Mr. Anthony Waterer, Knap Hill, Woking, showed two large, well bloomed specimens, and a few small ones, of Andromeda japonica, which were greatly admired; also a large collection of hardy Polyanthuses and Primtoress, some of the forms of which, as well as the colours, being particularly good; two of the prettiest of the hardy Frimroses were named Princes of Wales and James Douglas. Mr. H. B. Smith, St. George's Nursery, Ealing Dean, had a fine well-grown collection of Cyclameos, principally persicum giganteum varieties, and including most of the shades of colour now seen in these flowers. The flowers of the show were, undoubtedly, the Cinerarias of Mr. James, Woodside, Farnham Royal; a more beautiful FLORAL COMMITTEE. - Present in Section A .: of colour now seen in these flowers. The flowers of the show were, undoubtedly, the Cinerarias of Mr, James, Woodside, Faraham Royal; a more beautiful lot, whether in regard to the size of the individual blooms, their perfection of form, or richness of colour observable can hardly be imagined. There was once the fear that the Cineraria had lost position as a greenhouse plant; but in view of these ine seedlings such fear is now quite illusory. A few of the most distinct and perfect in form had received names, vir., Pollie Charming, with even, overlapping florets of a rosy-purple, and a white ring round a dark eye. Royal Standard, a rich crimson sell, and Challenger, a full metallic-blue, very intense. From Messrs, Veitch & Sons, Chelsea, came four specimens of their hybrid Amaryllis, good in shape and colouring, and showing eminently the decided advances made by them in these plants, of which more may be known by reference to p. 328. decided advances made by them in these plants, of which more may be known by reference to p. 338. A sort oamed Ne Plus Ultra, a very large scarlet, with somewhat reflexed segments and a not too regular outline, and General Graham, a dark crimson, with but little green colour in the throat, were very superior. General Gordon, a dark crimson, and Wm. Goldring, a flower having much green in the centre, were but little behind those first enumerated. This firm showed also a very pretty rose-pink flowered variety of Azalea ameena named Little Beauty, and which was raised by Mr. C. M. Hovey, of Boston, U. S. A.; also a lemon-coloured Freesia, named Leichtlin, likely to be as useful as L. refracta alba, as it is apparently equally free blooming. named Leichtlini, likely to be as useful as L. refracta alba, as it is apparently equally free blooming. Rhododendron Priocess Beatrice, a lemon-shaded pink variety, of the tender section of these plants; a pretty group of Staphylea colchica, nicely in bloom, the pure white of this being much admired; the rosy-purple Pinguicula caudata and Prunus tomentosa, a vary floriferms, early bloomer, the flowers white with the pure white of this being much admired; the rosypurple Pinguicula caudata and Prunus tomentosa, a
very floriferous early bloomer, the flowers white with
a pink envelope. Messrs. Barr & Son hadi a large
quantity of the handsome Narcissus pallidus przecox,
which were intermixed with Anemone fulgens; and
A. F. multipetala, the latter forming an almost
double flower, at least in early morning. Messrs.
Collins Brothers & Gabriel, 39, Waterloo Road,
showed a bright mass of the Tenby Daffodil,
also associated with Anemone fulgens multipetala.
Messrs, Cannell, Swanley, showed a pair of plants of
the little known Streptosolen Jameson; that attracted
considerable attention, the colour being a pretty shade
of orange, the habit free, and the cultivation of the
easiest. A collection of Cinerarias and the Begonia
Carriert, this last being in the way of floribunda, a
decidedly useful winter bloomer, with pure white
blossoms, that are produced in great oumbers, which
if they do fall off in great quantities, are reproduced
equally as rapidly. Mr. Henry Bennett, Shepperton,

brought two of his new pedigree Roses—Grace Darling, a hybrid Tea, of a very bright shade of pink, the reflex of the petals being creamy-white, the flower being fairly full for a winter Rose and delicately scented; Cleopatra, the other, somewhat past its best, but very sweet. Some enormous Amaryllis came from Messrs. Paul & Son, Cheshunt. Tree flowers were rather coarse, and green preponderated in the colouring, still the plants have an imposing appearance, and would be capital subjects to place amongst robust plants in big conservatories. Mr. Wiggins, gr. to W. Clay, Esq., Kingston-on-Thames, exhibited three named varieties of Cinerarias and three also of Cyclamen, but not distinct enough to obtain the recognition of the jurors. Mr. R. Dean had twelve Polyanthuses and Primroses of surpassing colours and form—Cloth of Gold, yellow, with an brought two of his new pedigree Roses-Grace Darhad twelve Polyanthuses and Primroses of surpassing colours and form—Cloth of Gold, yellow, with an orange eye; General Gordon, crimson, with a yellow eye; Royal Purple, purple, with a yellow eye; and Kovelty, a puce, beiog amongst the best of these. This exhibitor had also the hose-in-hose Polyanthus, which later on served the Rev. G. Henslow as a text for an interesting between Asserting the Company of the Company of the Rev. G. Henslow as a text for an interesting between Asserting the Company of the Company This exhibitor had also the hose-in-hose Polyanthus, which later on served the Rev. G. Henslow as a text for an interesting lecture. A group of Primula sinensis named Queen Victoria, a bright crimson, was staged by Mr. J. Odell, florist, Hillingdon, Saxifraga oppositiolia major, S. sancta, a pretty yellow, oicely in bloom; the slate-blue coloured hardy Primrose, Scott Wilson, rather pretty and dwarf; It is reticulata, and Soldanella montana, were shown by Messrs. Carter & Co., Holborn. A large plant of Lealia superbiens, with thirty blooms, came from Mr. G. W. Cummings, gr. to A. II. Smee, Esq., The Grange, Wallington, with the pretty Ceology nor sparsa, and other small specimens of Orchids. A Violet with the general appearance of The Cara, named Wellsiaca, was shown by Mr. Wells, Fern Hill, Windsor Forest. Mr. Ballantine, gr. to Baron Schrueder, Egham, showed that perfect gem amongst cool Orchids, Odontoglossum Pescatorei Veitchianum, which was furnisbed with one long spike of its remarkable beautiful blossoms; and Mr. Salter, gr. to J. Southgate, Esq., Selborne, Streatham, Dendrobium Findlayanum giganteum, a very fine variety, with four blooms. An Azalea, a hybrid, came from Mr. Todman, gr. to J. Connel, Esq., Eushey Downs, Streatham, the colour being white, with a lemon suffusion in the cectre. Mr. J. Edmonds, florist, Hillingdon, exhibited there new hybrid Cyclamens, of which one called Princess Ida, a delicate blush-tinted one, was most pleasing. A splendid variety of Cateleya Trianz, named splendidissima, came from Mr. Hillingdon, exhibited three new nybrid Cyclamens, of which one called Princess Ida, a delicate blush-tinted one, was most pleasing. A spendid variety of Catleya Triane, named splendidissima, came from Mr. B. S. Williams, Victoria Nursery, having four beautiful blooms, the petals of which were of transparent white, very broad, sepals also white and narrow, and intense dark purple lip without margin. A good scarlet-flowered Abutilon Scarlet Gem came from Mr. Steveas, nurseryman, Futney, which should prove a good thing as a bedder, the outside colour being quite equal to that of the iosade. J. H. Mangles, Esq., Valewood, Haselmerce, exhibited a plant of Rhododendron grande, a massive-looking variety, with very large flower-heads, the individual flows having a resemblance to those of Yucca gloriosa—the young truss is lemon-rose, afterwards becoming pure white when fully open. The same gentleman showed cut blooms of Rhododendron grande argenteum, a grand truss, baving large creamy-white blossoms, and the foliage measuring nearly a loot in length.

The awards were : -

FIRST-CLASS CERTIFICATE.

Princess Ida.

FRUIT COMMITTEE.—Present: II. J. Veitch, Esq., in the chair; Messra. P. Crowley, J. Lee, J. E. Lane, G. T. Miles, W. Paul, J. Burnett, G. Eunyard, S. Lyon, G. Goldsmith, A. Howcroft, and

J. Roberts. Messrs. Veitch & Sons were awarded a bronze medal for their collection of fifty varieties of Apples grown on their Southfield nursery. These exhibit in an admirable manner the capabilities of the Apples grown on their Southein unitery. These schibit in an admirable manner the capabilities of the light land at Fulham when well manured and carefully managed. The fruit was clean, free from speck or blemish, and had been well preserved, but few kinds showing a withered condition. Mr. J. Burnett, gr., The Deepdene, Dorking, contributed a somewhat smaller collection of Apples, amongst which were Shepherd's Seedling, a conical, useful-looking fruit, with a yellow skin; good-sized Calville Blanc, Norfolk Beaufin, and Wellington. A nice-looking seedling Apple was exhibited by Mr. Allan, gr., Gunton Fark. Mr. Gilbert, gr., Burghley, showed a new hybrid Cabbage, the result of a cross between his Chou de Burghley and a Savoy: which variety of the latter had been made use of was not stated. The Cabbage shown was firm, white-hearted, and of a medium size; if it is as hardy as the best strain of Chou de Burghley it will prove of considerable value in hard winters. Good useable specimens of the Chou de Burghley were also shown by the same exhibitor. the same exhibitor.

Manchester Horticultural Mutual Improvement: March 6.—Mr. Bruce Findlay, the President, in the chair. This was the closing meeting of the first session, and the report of the committee, read by the Secretary, Mr. Swan, congratulated the members upon the work done since the Society was formed in October last. The number of members at present on the books was 123, and Mr. Robert Tait, the Treasurer, said the session ended with the balance on the right side. A brief discussion ensued upon the class of papers it was most desirable to have read at the meetings, the general opinion being that as heretofore they should be of a mixed character, and include bottany and practical horticulture. The motion was then agreed to, and a member suggested that a branch should be established in connection with the Society for the benefit of members in sickness or in needy circumstances. The idea seemed to find lavour with the meeting, but at the subject should be brought forward for consideration next session. Manchester Horticultural Mutual Improve-

Chemical.—"On the Composition of the Ash of Wheat Grain and Straw, grown at Rothamsted in different Seasons and by different Manures." By Sir J. B. Lawes and Dr. J. H. Gilbert.—This paper gives an account, including duplicates, of 253 analyses. The ashes were prepared at Rothamsted, being burnt in oblong platinum dishes by surface heat, in order to prevent, as far as possible, any fusion. Every ash is from produce of known history of growth as to soil, season, and manuring. The experiments are arranged in three series. The first illustrates the influence of fluctuation of season from year to year, under three known, but very different, conditions of manuring during sixteen consecutive seasons. The second shows the influence of dour characteristic seasons, two favourable and two unfavourable, under nine different conditions as to manuring. The third demonstrates the influence of continuous exhaustion or supply of certain constituents as it

consecutive seasons. The second shows the influence of four characteristic seasons, two favourable and two unfavourable, under nine different conditions as to manuring. The third demonstrates the influence of continuous exhaustion or supply of certain constituents as it represents the proportionally mixed produce for the ten years 1852-961 and the ten years 1852-97 from ten differently manured plots. In the first series the three plots were respectively—(r) unmanured; (a) treated with 4 tons farmyard manure per acre; (3) treated with about 200 lb. of ammonium sulphate and 200 lb. of ammonium chloride per acre annually. The principal points of interest in the analyses are the relative quantities of potash and phosphoric acid.

The chief conclusions are—that with normal maturation the grain is of nearly uniform composition whatever the manure; that the deviations from normal mineral composition are associated with deviations from normal examples of the product of the product of the product of the product of the grain grown by animonium salts alone shows on the number of the grain than the manure. There was nevertheless an obvious difference in the average composition of the grain in under the different conditions as to manuring. Thus the grain grown by animonium salts alone shows exhaustion of potash, and especially of phosphoric acid. In the second series of analyses the following four seasons were selected: 1852, ad, both as to quantity and quality of produce; 1856, quantity fair, but quality indifferent; 1853, quantity moderate, quality above the average; 1863, very good as to both quantity and quality of produce; 1856, quantity fair, but quality and quality of produce; 1856, capanity fair, but quality and quality of produce; 1856, quantity fair, but quality and quality of produce; 1856, quantity fair, but quality and quality of produce; 1856, quantity fair, but quality and quality of produce in the grain is nearly fair, but quality and quality of produce in the grain shoule; and potash sold and magnesia salt;

deficiency of one or more constituents, having regard to the amount of growth which is induced by the liberal supply of others.

London: Atmospheric Pressure.—During the week ending March 8, the reading of the barometer at the level of the sea increased from 30.04 inches at the beginning of the week to 30.07 inches by 9 A.M., decreased to 30.06 inches by 3 F.M., and increased to 30.09 inches by midnight on the 2d, decreased to 20.04 inches by 3 F.M. on the 4th, increased to 30.28 inches by midnight on the 5th, and was 29.61 inches by the end of the week.

The mean reading of the barometer for the week at

The mean reading of the barometer for the week at the level of the sea was 29.93 inches, being the same as last week, and 0.15 inch lower than the average of

Temperature. — The highest temperature in the shade in the week was 51°, on the 4th; the highest reached on the 3d was 43°.2. The mean of the seven high day temperatures was 48°.5.

The lowest temperature was 27°, 5, on the 3d; on the 4th the lowest temperature was 42°. The mean of the seven low night temperatures was 34°, 1.

of the seven low night temperatures was 34°.1.
The greatest range of temperature in one day was 18°.6, on the 7th; the smallest was 9°, on the 4th. The mean of the seven daily ranges was 14°.4.
The mean temperatures were—on the 2d, 37°.4; on the 3d, 37°.3; on the 4th, 45°.4; on the 7th, 41°.3; and no the 8th, 41°.8; of these the first two were below by 3° and 3°.2, and the last five were above by 4°.9, 1°.7, 1°.1, 0°.8 and 1°.3 respectively.
The mean temperature was 41°, being 2°.9 higher than last week, and 0°.5 above the average of the week.

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 99°, on the 7th. The mean of the seven readings was 80°. 6.

The lowest reading of a thermometer with its bulb placed on grass was 20°, on the 3d. The mean of the seven readings was 26°.3.

Rain .- Rain fell on three days to the amount of 0.35 inch.

ENGLAND: Temperature.—During the week ending March 8 the highest temperatures were 57° at Sheffield, 55° at Truo, 53°.7 at Nottlingham; the highest at Bolton was 50°, at Bradford 50°.2, and at Brighton, Bristol, and Blackheath 51°. The general mean was 52

The lowest temperatures in the week were 21°, at

The lowest temperatures in the week were 21°, at Hull, 26°, 42 th Cambridge, 27°, 4 at Wolverhampton; the lowest at Preston was 33°, at Plymouth 32°, 8, and at Liverpool 32°, 1. The general mean was 20°, 6. The greatest ranges were 31°, at Hull, 28° at Sheffield, 27°, 1 at Cambridge; the smallest ranges were 18°, 44 Bradford, 19° at Prestoo, and 19°, 2 at Plymouth. The general mean was 22°, 7. The mean of the seven high day temperatures was highest at Truro, 52°, t, at Plymouth 49°, 8, at Cambridge 31°, at Cambridge 31°, at Cambridge 32°, at Cambridge 33°, at Camb

bridge 49°.3; and was lowest at Bolton, 45°, at Sunderland 45°.2, and at Bradford 45°.3. The general mean was 47°.4.

Sunderland 45.2, and at Bradlord 45.3. The general mean was 47.4.

The mean of the seven low night temperatures was highest at Truro, 40°, at Plymouth 37°.7, at Sunderland 36°.9; and was lowest at Wolverhampton, 31°.3, at Cambridge 32°.9, and at Bolton 33°.3. The general mean was 35°.

The mean daily range of temperature was greatest at Cambridge, 16°.4, at Bristol 15°.1, at Wolverhampton 14°.5; and was least at Sunderland, 8°.3, and at Bradlord and Preston 9°.4. The general mean was 12°.4.

The mean temperature was highest at Truro, 45°.2, at Plymouth 42°.9, at Blackheath and Liverpool 40°, and was lowest at Wolverhampton, 37°.8, at Bolton 35°.4, and at Hull and Bradford 39°.8. The general

35.4, and at 11011 and Diaglord 39.6. The general mean was 40.5; set all was 2.09 inches, at Bolton, 1.69 inch at Truro, 1.58 inch at Plymouth; the smallest fall was 0.35 inch at Blackheath, 0.41 inch at Cambridge, and 0.58 inch at Nottingham. The general mean fall was 1.16 inch.

SCOTLAND: Temperature.—During the week ending March 8, the highest temperature was 55°, at Leith; at Perth the highest was 48°. The general mean was 51°,7.

The lowest temperature in the week was 28°, at Perth; at Aberdeen the lowest temperature was 33°.6. The general mean was 30°.8.

33°.6. The general mean was 30.0. The mean temperature was highest at Leith, 41°.1; and lowest at Perth, 36°.9. The general mean was

Rain.-The largest fall was 1.41 inch, at Perth; and the smallest fall was 0.53 inch, at Glasgow, general mean fall was 0.99 inch.

JAMES GLAISHER, F.R.S.

Enquiries.

"He that questioneth much shall learn much,"-BACON.

PLANT LABELS.—Your correspondent last week asks what has become of the plant label that was awarded the rst prize in the Society of Arts competition two years ago. I would ask further what has become of the Society's award for last year's competition for permanel labels.) Surely it is time some decision were arrived at. F.

Answers to Correspondents.

CATTLEVA TRIANÆ: Peter Massey. Yes; a very good variety.

CINERARIAS AND VINES: M. J. T. The largest flower is of remarkable proportions, but not so fine in form, nor so good in substance, as the smaller ones, which are first-rate. The cause of the Vine being fasciated is a little over-development through an excess of nutrition.

CONIFER SEEDS: Y. B. You had better write to Messrs. Vilmorin & Co., 4, Quai de la Mégisseric,

FUNGUS: R. B. L., Longhborough. The name of the fungus invading your friend's Mushroom-bed is Nylaria vaporaria. It generally occurs in the condition in which you have sent it—f.e., like nodular lumps of some sucker belooging to a tree, or like pieces of the noderground stem of some perennial plant. It should be gathered together and burnt, for it often proves an intolerable nuisance in garden as well as Mushroom beds, and is sometimes so abundant that it has to be pulled up in long cords and carted away in wheelbarrows. IV. G. S. FUNCUS

Darrows, IV, G. S.

INSECTS: The Mug. The "beetles" are the too well known Otiorhynchus sulcatus, a weevil which shams death when disturbed, and which is easily captured by spreading a sheet uoder the plants and shaking then off at night.—W. H. B. We can find no insects at the root of your Pancratium fragrans, the bottom of which is much gnawed (certainly more so than would have been done by the larvæ of the weevil (Otiorbynchus), I. O. IV.

JUNIPER: C. M. O. It is impossible to say with certainty what your plant is from the fragments seat. Judging from the locality, it may be Juniperus canadensis, the Canadian form of the common Juniper.

NAMES OF FRUITS: A. B. Apple: Striped Beaufin. NAMES OF FRUITS: A. B. Apple: Striped Beaufin.

NAMES OF PLANTS: C. IVIIIliams. 1, Prenis cretica;
2. Thuis gigantea; 3, Arabis alpha; 4, Franciscea
calycina.—7. W., Gordon Cartle. Your Holly is flex
dipyrens, from Himalaya.—H. Farrant. Your Fern
is a variety of Preits serrulata, aspective to the service of the service tricolor.—W. B. Jeffreys. Dendrobium barbatulum. —M. P. S. 1, Lastrea Filix-mas crispa; 2, L. quin-quangularis; 3, Asplenium fontanum.

ORCHIDS: H. M. S. Your Cattleya Trianæ is a very good variety—one of the best—and in the way of C. T. Osmanni, but smaller. The Dendrobium is a good ordinary variety.

PEARS BITTER FLAVOURED: G. W. H. sent is nearly rotten, so cannot give any opinion as to flavour. The "peculiar bitterness" of which you speak may be owing to dryness last season at the roots, or a want of vigour in the tree.

HODDDENDRON AGENTEUM (GRANDE).— Mr. Mangles, Valewood, Haslemere, would be obliged if those who grow this plant would send him a flower of this species with the parts of the flower in fives, viz., five sepals, five-lobed corolla, ten stamens, &c. RHODODENDRON

* All communications intended for publication should be addressed to the "Editor," and not to the Publisher or to any member of the staff personally. The Editor would also be obliged by such communications being unritten on one side only of the paper and sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

FOREIGN SUBSCRIBERS sending Post-Office Orders are requested to send them to the Fublisher of this journal, 44, Wellington Street, Covent Garden, and to make them payable to William Richards, at the Post Office, Drury Lane, London, W.C.

INTELLIGENT READERS, PLEASE NOTE: — Letters re-lating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the Publisher, and NOT to the Editor.

DIED, on February 23, at Harrietsham, Kent, John Cutbush, Seo., in his eighty-ninth year; for nearly forty-five years gardener and confidential servant in the family of the late W. W. T. Baldwin, Esq., of Stede Hill, and for thirty-six years clerk of the parish church of Harrietsham, greatly respected and esteemed by all who knew him.

Markets.

COVENT GARDEN, March 13.

[The subjoined reports are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list weekly, and are responsible for the quotations. It must be remembered that these quotations are averages for the week preeding the date of our report. The prices fluctuate, not only from day to day, but often several times in one day, and therefore the prices quoted as averages for the past week must not be taken as indicating the price at any particular date, still less can they be taken as guides to the price in the coming week. Ed.]

SEEDS.

SEEDS.

LONDON: March 12.—The sowing demand for farm seeds is at present much retarded owing to the soddened condition of the land in many parts. Values in the meantime remain unchanged. English red is cheap and abundant. White Clover seed continues firm, but Alsike and Trefoil are dull. The low rates ruling for Rye-grasses have at last attracted the attention of buyers. Sanfoin, Millet, and Rape seed well sustain the late advance. Full prices are realised for spring Tares. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday no quotable advance occurred in Wheat, the demand being slow, but prices were fully steady, and sales were not pressed. Flour was were fully steady, and sales were not pressed. Flour was considered to the property of the property o

CATTLE.

At the Metropolitan Market on Monday trade was dull in every department. Rates for cattle generally slack, and quotations reduced 2d. per stone. For calves rates were unchanged, and there was no quotable change in the pig market.—Quotations:—Beasts, 4s. 65., and 5s. 4d. to 5s. 6d.; calves, 5s. 10 7s.; sheep, 4s. 1od. 5s. 6d., and 5s. 1od. to 6s. 8d.; pigs, 4s. to 4s. 6d.—On Thursday there was no fresh leature in the trade. Both beasts and sheep sold slowly at Monday's currencies. Calves and pigs were quiet.

POTATOS.

The Borough and Spitalfields Markets reports state that good supplies were on offer, and met a slack demand, as follows:—Magnum Bonums, 8oz. to roos.; Regents, 6os, to 8oz.; Champions, 5oz. to 6oz.; and Victorias, 7oz. to 8oz. per ton.—The imports into London last week consisted of 48t bags from Hamburg, 24 from Boulogne, and 2 bags I case from Jersey.

The following are the prices current at market during the week: — East Wylam, 15:, Ravensworth West Hartley, 14:, 9d; Walls End—Hetton, 15: 6d; Hetton Lyons, 14:5; Lambton, 15:1; Wear, 14:; Caradoc, 15:, 9d.; Tecs, 15:; 9d.; East Hartlepool, 14:, 9d.; South Hartlepool, 14:, 3d.; Thornley, 14: 9d.

Government Stock.—Consols closed on Monday at 101½ to 101½ for delivery, and 101½ to 102 for the account. The figures for Tuesday and Wednesday were 101½ to 101½ for delivery, and 102 to 102½ for the account. Thursday's figures were as on the previous day for delivery, and 102½ for the account.

Oil Paint No Longer Necessary. HILL AND SMITH'S BLACK VARNISH, for Preserving Ironwork, Wood, or Stone.
(Registered Trade Mark)

This VARNISH is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced unwards of thirty years ago by the Advertisers, and its genuine good quality, notwithstanding a bost of unprincipled minitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mising thinning, and is used cold. It is used in the grounds at Windson Castle, Kew Carden out, from whom the most flattering testimonials have been received.

Sold in Casks of about 30 galloos each, at 11, 6d, per gallon at the Manufactory, or 12. 8d, per gallon carriage paid to any Station in the Kingdom.

PRELIMINARY NOTICE.-For a long

deners of all classes, both Professional and Amateur, have ex-perienced the want of a full and reliable book of reference, of simple arrangement, to which they could turn with conden-for an accurate description of any plant of horticultural value and practical instruction in its cultivation.

Such awark is "THE ILJUSTRATED DICTIONARY OF GARDENING: a Practical Encyclopedia of Horticulture for a great length of time, and having been revised by a num-ber of the highest botanical and horticultural authorities of the day, is about to be issued in Monthly Parts.

the day, is about to be issued in Ronthly Parts.

'THE ILLUSTRATED DICTIONARY OF GARDEN-ING' will be the most complete work of the kind ever published, as it will give full information about all Flowerier and Foliage Plants for the Open Garden, Ferns, Palms, Orchids, Cacti and other Succulents, Genebiouse and Sivee Subjects, Eulos, Trees, Simbs, Fruits, Herbs, and Vegetables, as well as particulars of the various Garden Structures and Ingle-

In fact, as far as it is possible to do so, "THE ILLUSTRATED DICTIONARY OF GARDENING" has been made complete. In furtherance of this aim the Proprietors have added upwards of 1500 first-class Illustrations, thus in this feature nione surpassing any previous work of the kind.

Full Prospectus now ready, and may be had of all Booksellers, to whom Orders should be sent at an early date. THE ILLUSTRATED DICTIONARY OF GARDEN-ING" will be published Monthly, price 15.

London: L. UPCOTT GILL, 170, Strand, W.C.

THE GRAND OLD DAHLIA,

THE GRAND OLD DAHLIA,

DICTA FORMOSISSIMA, THE FLOWER

AND SURPRISE OF THE YEAR, and also the NEW

WHITE CACTUS. These are the most interesting and useful

coming Dahlias. The former cansed quite a furore fifty years

ago, and was everybody's flower, and looked upon as the love
lest in the world, and like our Paragon, which we re-intro
duced, must be grown in every garden, not only for its exatte
beauty, but for its real use. The shift, as yeary superior for

weaths, house, and church decoration. For coloured plate and

full description see Floral Guide, post-free.

The Best Standard Book on the Chrysanthemum.

THE most complete Illustrated Book, and how they should be when in perfection; also correctly describing the whole family, and the best varieties for exhibition, with a great deal of original information. Post-fee with the property of the four stamps,

From the Champion Grower, Mr. MOLYNEUX, Swanmore Park, Bushops Waltham, March 8, 1884.

"I give you my onioino no practice entirely. Yours is certainly a wonderful Catalogue, and the most complete 1 have seen."

NEW POMPON SINGLE DAHLIAS.

IT is an admitted fact that Messrs. Moore, T is an admitted fact that Messrs, Moore, Callingford, Teesdale's, and our own Seedlings are many years in advance of all other raisers. These dwarf midget varieties, producing flowers of brilliant and distinct un-Dahlailke colours and shapes, and mostly possessing lovely Fern-like foliage; more persistent in petals; so very different to the ordinary kinds; are of more real use, both in the garden, the home, and the bouquet, and will give us a splendid change in our flowers during the autumn. Seed, 11, per packet. For full particulars see Catalogue, 2nd post-free.

Violets in 5-inch Pots, full of Flower-Buds. WE have large quantities of NEAPOLITAN, sr. per dozen; MARIE LOUISE, 6s. per dozen, SWANLEY WHITE (Count Brazza), 12s. per dozen, 2s. per dozen. Frice per 100, and for smaller plants from ground on application.

PICOTEES, CARNATIONS, CLOVES, and PINKS.

WE have again purchased all the spare years the Champion Amaturu and greatest Raiser and Grower that ever lived; these, together with our own 16,000 plants a challes us to supply better than any other frm. Send for a CATALOGUE. The extraordinary bed of these at Hampton Court was supplyed by us, and just to shw the sensation they made, we are specially appointed to supply a similar collection for Hyde Park for thay year.

CATALOGUE POST-FREE.

SHANKS'S PATENT LAWN MOWERS FOR 1884.

The only Lawn Mower fitted with Double-Edged Sole Plate, which enables the cutting parts to last twice as long as in other Machines,

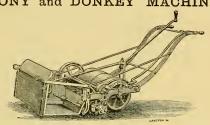

These Machines are in use in the Royal Gardens at Kew, Hampton Court, Osborne and Balmoral, in most of the Public Parks and Gardens in the Kingdom, and in almost all the Royal Gardens in Europe.

SHANKS'S PATENT LAWN MOWERS are the most suitable for English Lawns. They have now been before the Public for many years, and stand unrivalled. see Machines are easily worked, not liable to get out of order, and will make the Lawn as smooth as velvet.

Gardeners' Chronicle.

SATURDAY, MARCH 22, 1884.

WINTER BEDDING.

WE give in another column (see p. a representation of a portion of the terrace garden at Heckfield, and which exhibits in a somewhat pronounced aspect the value of a style of flower-bed decoration in the winter months. The summer bedding, always amongst the best of its kind in the kingdom, has been more than once illustrated in these pages, and the winter bedding has also been referred to, but this is the first time that it has been thus pictured. That gardens and trees give beautiful pictures even in the winter months the present example testifies. Not only at Heckfield, but in some few other good gardens, winter bedding of the style here depicted is well done. Still, in the doing of this, or, indeed, of any other kind of decorative bedding, very much depends upon the peculiar requirements of the family associated with the respective Thus it happens that Viscount gardens. Eversley, whose attachment to his beautiful place is well known, seldom leaves it from the end of June to the middle of February. During that time the summer and autumn bedding is at its best, but by means of Mr. Wildsmith's arrangements, towards the end of October, when the tender plants have passed their best, and the beauty of the designs is becoming dimmed, these plants are removed, leaving all the hardy plants which generally indicate the designs, while the vacant spaces are filled up with various ornamental shrubs, Heaths, and other suitable subjects. In a few days the gay pompadour dress of the garden has given place to the sombre but more seasonable velvet attire, and the garden stands arrayed in fitness, but still in exceeding beauty for the winter months.

Then, by-and-bye, in the early spring, when the family has gone to town, the house is closed, and the gardens are no longer enlivened by the presence of those who love them so well, the shrubs that have done such good service are again returned to their summer quarters, and even then not promiscuously, but in pleasing and effective arrangement. Even in modest retirement, as well as in public view, they thus play some part in the general deco-rations of the gardens. We sometimes hear objections to any forms of bedding-out in gardens, on the ground that a large amount of labour is needed that might be otherwise employed. That is naturally a matter for em-ployer and gardener to decide upon, and not But if other garden departments were neglected that one specially favoured section should be attended to, a critic might reasonably find fault, but that is not the case at Heckfield, nor at other places where proprietor and gardener take pride in their work.

Objections are also made to the bedding system of a more reasonable kind, because all criticism based upon garden art, or even on garden practice, has a right to be heard. Unfortunately, the class of objectors or critics have little to offer in place of the bedding beyond certain stereotyped styles of planting and arrangement that may admirably suit some places, but be just as unfit for others. Still farther, nothing could tend more to detract from pleasure in gardening than the existence of monotony in garden-arrangements. Thus we find the terrace garden at Heckfield is peculiarly fitted for the style of summer and winter decoration so beautifully carried out there, and which, if to some extent uniform, is yet from year to year so far varied as to render it always pleasing. Certainly, whatever may be the correct thing in gardening high art -and of that even its most pronounced professors are not quite assured-lovers of gardening endowed with broad tastes and practical views will never cease to admire the beautiful effects that well-managed bedding-out, whether of summer, autumn, or spring plants, can give.

The Heckfield terrace garden includes on the north side some six raised oval basket beds, filled with tall and spreading Conifers, Hollies, Aucubas, Mahonias, Japan Honeysuckles, &c, all well covered and elegant; then eight long beds, four on either side of the baskets, have neat designs worked out in them, in which golden Hollies, Aucubas, small Conifers, Euonymus, Heaths, and carpets of short Heath, fill in with other carpets of Sedums, Herniaria, &c.; indeed, every bed in the garden has a raised edging of the Herniaria, the deep rich green hue of which stands out in striking contrast to the paler hue of the grass. Eight round beds also are found in this garden, some of which show on the green carpets star-shaped raised centres margined with Echeveria secunda, the bed dotted with golden Yews, silver and golden Enonymus, Erica herbacea purpurea in charming bloom, and as centre plants finely variegated Phormium tenax, in robust health and vigour. Other variations of this style are adopted, but literal descriptions of all are unnecessary.

On the east terrace we find the beds chiefly arranged in four distinct blocks of four each, with large vases for centres; but in one lot, the block that forms the angle of the terrace, the vase is now replaced by a bed that is most effectively planted with a choice selection of decorative shrubs, and the surrounding four beds are in charming keeping. Next that block comes one of a diverse pattern, and then the block, as seen in the foreground of the picture, in which the large vase planted with shrubs forms so prominent a feature. The plants which so strongly reflect the light are Mahonia aquifolia, the glossy purplish leafage in the picture coming out almost white. On either side of these blocks of beds run in admirable keeping specimens of Retinospora squarrosa, about 5 feet in height—all handsome and even. Of centre plants, besides the Phormiums, of which there are several, there are also very fine Dracæna australis lineata, and Phormium Colensoi and P. sanguineum, all very striking and unusual objects in the winter garden.

Specially charming as dot plants on the carpets left over from the autumn are fine specimens of the green Chamæpeuce, and in many beds Retinospora plumosa aurea and R. pisifera alba, with small plants of Cupressus Lawsoniana, are exceedingly effective. The east terrace comprises some thirty-four beds and vases, so that the quantity of shrubs needed to fill all effectively may be imagined. Even in the always pretty borders that run through the kitchen garden small shrubs, Coniferæ, and Heaths play an important part. Our sketch is necessarily a condensed one, but enough has been said to show that winter bedding as done at beds Retinospora plumosa aurea and R. pisifera said to show that winter bedding as done at Heckfield is very beautiful gardening indeed. X.

APPLE LANDSBERGER REINETTE. - This useful APPLE LANDSBERGER REINETTE.—Ins such Apple was the subject of a coloured illustration in the Florist and Pomologist for December, t. 600. The fruit is of moderate size, globular, or somewhat conical, with a short stalk and shallow eye; the skin. ls pale straw-colour, flushed with orange-red on the sunny side; flesh white, tender, brisk. The tree is a good bearer; season October.

ADIANTUM RHODOPHYLLUM, n. hyb. ?

FRONOS smooth, evergreen, nearly or quite a foot long, spreading, with very slender black stipites and rachides, triangular tripinnate; pinnæ few, the lowermost longest and most developed, pinnate or bipinnate, the upper undivided ones about 1½ inch long, and, as well as the 1-inch pinnules, rhombeo-trapezoid, and set on long hairlike pedicels, the margins deeply inciso-lobate, the lobes often toothed; sori rather small for the size of pinnules, occupying the apices of the lobes, but much broken up, so as to be various in form-round reniform oblong or elongate oblong; indusium smooth, narrow. Caudex erect, free from scales; stipites and rachides ebeneous

A beautiful hybrid Fern raised by Mr. Bause, and now in the hands of Messrs, Veitch & Sons, of Chelsea. In aspect it is somewhat intermediate between A. Victoriæ and the larger-pionuled forms of A. tenerum, and, being of free and vigorous habit, though not large in stature, it is one of the most ornamental Maidenhairs yet obtained. The fronds grow up together and form bushy tufts, which, in the largest plants yet seen, are not quite a foot in height and about a foot across, the individual fronds numerous but not overcrowded, and having a certain degree of boldness of outline, and a very pleasing and grace-fully curving habit, on account of which it will be a valuable decorative object. The great beauty of the Fern, however, resides in the brilliant colouring of the fronds during the earlier stages of their development and in the succession of lovely tints it puts on until they become fully expanded. The younger fronds are of a most attractive tint of rosy-purple, much stronger and brighter than in any other Fern of the same character, this tint lasting for a considerable period, and eventually passing through various shades of a soft coppery hue until it acquires firstly a pale green and then the full green colour which marks the mature fronds. These red-tinted Adiantums are all very handsome plants, and the present is certainly one of the finest amongst them. T. Moore.

CATTLEYA (LABIATA, &c.) SPECIOSISSIMA REGINA.

This is indeed a grand Cattleya, kindly sent me by Sir Trevor Lawrence, who calls it a speciosissima. It is, indeed, identical with the typical flower, kindly given me by Mr. S. Low in March, 1868, and carefully labelled and kept in my collection. It has the same broad sepals, immense petals, great column, and the, relatively, smaller lip. This has the lateral light yellow eye-spots, a reddish ferruginous line between the light rose side laciniæ, a dark mauve-purple anterior lacinia. The grand beauty consists in the rich purple colour of ovary, column, sepals, and petals. I have only once seen such a colour in Mr. Thompson's celebrated ill-known Cattleya, which is totally distinct by its shape.

Some of the best orchidists believe Cattleya speciosissima to be the same as Cattleya Luddemanniana. My excellent friend, Mr. G. Luddeman, who has always been the same kindhearted most useful correspondent during thirty-two years, gave me in September, 1882, fresh materials. I think Luddemanniana is unique in its long, narrow, equal emarginate lip, manve-purple at the top, with two ochre blotches and light purple diverging bars in two leng rows on the disc. Herr Franz Kramer, of Klein, Flottbeek, sent me as speciosissima Lowei something that pertains much better to the narrow lipped Luddemanniana, though distinct in colour, the anterior part of the lip not being mauve-purple, but covered with purple.

I think our young queen, "regina," one of the grandest Cattleyas ever seen. H. G. Rchb. f.

LACHENALIA TIGRINA VAR. WAREI, Baker.

This is a handsome new form of Lachenalia, well worth the attention of cultivators. It has the variety of bright colouring with which we are familiar in L. quadricolor, Jacq., Ic., t. 396; Andr., Bot. Reg., t. 148; but it is not a variety of tricolor at all, but in all essential points of botanical character agrees with an entirely distinct species, L. rubida, Jacq., figured Bot. Mag., t. 993. It is much more handsome than the type or either of the two varieties (tigrina and

punctata) known already, so that it is to be hoped that Mr. Ware, from whom the specimens came, may succeed in multiplying it.

Leaves two, oblong-lanceolate, 4-5 inches long, with copious darker green round spots on a dull glaucous green groundwork. Scape green, sparingly mottled with bright red-brown. Flowers 10-12, in a dense raceme; pedicel jellow, \(\frac{1}{a} - \frac{1}{6}\) inch; bracts lanceolate, looger than pedicel. Perianth 1\(\frac{1}{6}\) inch jong; outer segments two-thirds as long as the inner, bright red at the base, bright yellow in the middle, tipped with green; inner segments protruding \{ incb beyond the outer, the orbicular blade & inch broad, greenish-yellow, with a reddish-brown margin. J. G.

PHALÆNOPSIS STUARTIANA HRUBVANA, nov. var.

A glorious variety, having petals and sepals purple at the back, with a white broad margin on the petals, a narrow one on the upper sepal, the inner border of the lateral sepals also white. It has just flowered with Herr Baron von Hruby, Peckar, near Colin, in Bohemia, the most intelligent possessor of a very fine collection grown by Mr. Skopec. There also is most probably the grandest specimen of Renanthera Lowei, and which has given an opportunity for very interesting experiments, about which we may soon he instructed, H. G. Rchb, f.

ONCIDIUM PRÆTEXTUM BELLUM, n. var.

This has a glorious yellow lip, with numerous brown spots on the disc, and an interrupted border of similar partly semilunar blotches. Its tall column, widely extended tabula infrastigmatica and calli prevent its being O. Forbesi; the shape of its lip is against regarding it O. crispum. It has a very broad, furrowed pseudobulh. I have to thank for it Dr. Wallace, of the New Bulb Company, Lion Walk, Colchester. H. G. Rchb. .

RHUBARBS.

I HAVE the following sorts of Rhubarb, all growing on one piece of land here, under similar conditions, except that Paragon and Stott's Monarch have only had one season's previous growth, while all the others have had two. They are in rows side by side, so that comparisons regarding some of their respective merits may easily be made. As regards earliness they take the following order :- Ist, Royal Albert; 2d, very slightly later, Scarlet Defiance; then Champagne, followed at a greater distance by Linnæus; after which comes Johnston's St. Martin's, then Paragon, then Victoria, and, lastly (only just-March 14-beginning to show above-ground), Stott's Monarch.

The latter, certainly the monarch of all as regards The latter, certainly the monator of an as regards size, will, I imagine, when the merits of Rhubarb generally are better recognised, be more heard of than it is now. From what I have seen of it at present it appears to mark a great advance in Rhubarb culture, despite its lateness. None of the varieties on the before-named piece of land had been pulled from at the date of these observations (March 14), but Royal Albert was just ready to pull, and the grada-tions in point of forwardness seemed nearly equal tions in point of forwardness seemed nearly equal from this to the last, except that Scarlet Defiance was very close on its heels, and that Scarlet Defiance was very close on its heels, and the step from Champagne to Linneus was wider than the rest. Faragon has only lately been sent out, and is still being advertised as an extra early, as well as an extremely productive variety, but compared with the other storia associated with it on light sandy soil, manured with house sewage from a neighbouring dead well, it is here apparently the latest of all, excepting only Victoria and the gigantic Stot's Monarch.

I hope to test all for flavour shortly. I should much like to know, and pethaps you or some of your correspondents can inform me, if chemical analyses of Rhubarb stalks of various sorts in various stages of growth have ever been made, and, if so, where

growth have ever been made, and, if so, where information on the subject can be obtained? What is the Royal Horticultual Society doing, that it does not offer its members information on matters of this kind? Comparisons are no doubt sometimes apt to kind? Comparisons are no doubt sometimes apt to be odious, and if subscribers of 21s, per annum each to the Royal Horticultural Society and the Royal Agricultural Society make one, as to what they get in return for that sum annually from each of these two societies respectively, this comparison will not be at all in favour of the lormer. F. E. Eving, Eaton, Korvuich, March 14, You will find an analysis of the stem and leaves of Rhubarb quoted in Watts' Dictionary of Chemistry, vol. v., p. 1085; but the analysis of the ash alone is misleading for practical authorized.

purposes. ED.]

WHICH IS WHICH?

GENDERS are very apt to go astray in garden catalogues, and the complications and accretions of botanical nomenclature frequently bring about a very "mixed" condition of affairs. The other day we had to note, for instance, a Narcissus minor major, which, after all, is no more remarkable than a white blackbird. One very general rule is that the names of trees and plants are feminine, and, as in the case of Rosa, demand that the qualifying adjective shall be feminine also; but unfortunately Greek nouns ending in "a" are neuter, and then the rule will not apply. Again, though the rule is as we have stated it, the exceptions wherein the name of the plant takes a masculine or a neuter form are extremely numerous, and nothing but an acquaintance with the Latin and Greek grammars, or a reference to some scholarly friend, will suffice to help the puzzled ones out of their difficulties. Another complication arises when the name of a variety has to be added on to that of species-e.g., Narcissus Bulbocodium var. monophylla. Here we have all three genders together-the generic is masculine, specific is neuter, and the varietal feminine. It would seem as if they could not all be right, yet it would be difficult to prove that any one of them is

No one will question the masculinity of Narcissus, even though he had one reputedly feminine qualification. Bulbocodium is an old name once used in a generic sease, and, therefore, entitled for distinction's sake to the use of a capital letter to begin with, and also to retain its original neuter termination. Whether the varietal name is rightly placed in the feminine or no depends on circumstances. If the specific name is feminine, of course the varietal name must follow suit, but if it is neuter the varietal name should he neuter also. How, then, can the term Narcissus Bulbocodium var. monophylla be justified i To this question the reply is, that the insertion of the abbreviation var. for varietas, which is feminine, demands a feminine termination; but if the word var. be omitted, then the rule would be for the variety to follow the specific name—neuter if masculine if masculine, and so on. But in order to elicit the views of the distinguished codifier of hotanical nomenclature, we solicited an expression of opinion from M. Alphonse de Candolle, who obligingly responds to our request in the following terms:—"I have sometimes put to myself the same question as to the gender of the names of varieties, and it is most likely that in practice I have it sometimes in one way sometimes in another, but I have just been looking to the practice of authors of repute, and I observe that, in general, they have made the varietal name conform to the gender of the generic name, thus :-

- " Nasturtium amphibium, a indivisum, DC., Syst., ii.,
- p. 117. "Thymus Serpyllum, β montanus, Benth., in Prodr., xii.
 "Phyllanthus simplex, β oblongifolius, Müller, in
- Prodr., xv., &c.

If the word "varietas," or the abbreviation 'var,' be employed, it seems most correct to make the adjective feminine. The use of Greek letters to indicate varieties, thus: a, B, y, corresponds to the employment of figures, which have no gender. On the other hand, when the idea is expressed by a qualifying 'var.' or 'varietas,' a sentence is made which must be constructed in the correct grammatical manner. The name of the variety becomes in this case an adjective qualifying 'varietas,' and should, therefore, take a feminine termination. Eoglish writers generally use the abbreviation 'var.' LINNÆUS indicated the varieties by the Greek letters, α , β , γ , without, as a rule, adding any other epithet. Continental authors have mainly conformed to Linnean usage, and do not write 'var.' This is in conformity with the omission of 'gen.' before the genetic, or 'sp.' hefore the specific name. Alph. de Candolle."

The plan of using Greek letters only would not commend itself to catalogue makers who have a special affection for superbissima, splendidissima, nobilis fl, plenissima, and all the rest of it.

Perhaps the simplest and most easily recollected rule would be to make the varietal name feminine in all cases, whether the "var." or "varieta" were expressed or understood. This at least would be intelligible, and would conduce to uniformity of practice.

TRANSPLANTING TREES AND PROPAGATING THE CAMELLIA. SHRUBS.

WITHOUT pretending to having found an infallible method, I wish to describe a plan that has been found of considerable value in a variety of soils, and especially in those that are brashy, or containing coarse gravel or large studes. In these soils the most essential point to observe, next to seeming all the roots possible lying beyond the range of the ball, is to see that the ball itself is compact and firm, and that it remains so until it is placed in its new station. We will suppose a tree or bush has to be moved that will require a ball of 3 feet in diameter, and 11 foot in depth. A trench should be marked out, either circular or square, at 6 feet from the stem; and 3 feet deep, shovel this out clean, taking care of all roots, binding them with matting and tastening them up to pegs of 11 foot high stuck in the ball: now carefully fork down in a perpendicular direction the soil right to the bottom (3 feet), and keep the trench quite clear, and so continue to work inwards till the ball is of the size at which it is intended to move it. The sides of the hall should he upright, and be made roughly regular. For a ball of this diameter a dozen bits of board (generally called packing), nearly as deep as the ball, three-quarters of an ioch thick, and 4 or 5 inches broad, should be placed perpendicularly at short intervals against the sides, and be firmly kept together with a stout piece of rope and a short wooden lever. Now all is safe, it is ready lor the next step-that of undermining, which should he carefully and gradually done with the spade and pick :

larger balls require special tools.

This undermining should be carried on till nothing remains but a pillar of earth directly under the centre of the tree, the bottom of the ball being made quite level. This is now ready for removal on a broad sheet of stout iron plate with hooks at the four corners to which chains can be fastened. can usually easily be placed under the ball by tipping it backwards so as to get the plate in the middle of the weight. The short chains can be attached to the corners, passed over two stont carrying levers of Ash, and the ball heaved over still more, so as to allow of a stout plank being shoved underneath on which the iron plate will slide easily upward out of the hole, especially if the plank be made wet. When a ball is very heavy, and the way out of the hole steep, as it will be in some cases, a horse can be attached a chain passed round the ball, and the ball thus pulled up the plank. When the plant is once out of the hole it can be run along on wetted planks, or be slid up the plank upon a low two-wheeled truck, and transported to its new site. For larger trees than those with balls of 3 feet diameter sets of oaken boards, six in number, are the best to employ. These are usually made so as to form platforms 3 feet square for balls of 4 feet diameter, 32 feet square for 41 feet diameter, and so on; but for trees of more than 5 feet diameter other and stronger appliances and special machines are required, of which I will not speak at this time.

The boards above-mentioned are best made of inch stuff, free from knots ; the breadth may be from 8 to 10 inches, and should have their inner edges slightly hollowed out, so as to let the little convexity of the ball drop easier on to them. Four of these boards have screw-holes passing through iron plates near the ends, so that by passing a bolt through they can be screwed tightly together with a thumb-screw The undermost pair of boards are provided with rings fastened on with longish iron straps and screws, to which chains for heaving can he attached. The third pair of boards that are used loose are unprovided with screw-holes or rings, and are also slightly hollow on one edge, are useful to push under the ball to keep it in an upright position and to steady it.

When such a platform as the above described one has been placed piecemeal under a ball properly prepared, it can be blocked up with wooden blocks placed under it; then the middle pillar of earth can be shovelled away, two stout planks pushed under the hall so as to form an inclined plane, up which the tree must be drawn and pushed, as with the ball on the iron plate. Such simple appliances as the above iron plate and hoard platforms, with a few stout planks, wooden blocks of varying thickness, and a low two-wheeled truck for small specimens, and a four-wheeled one for large ones, should be found on all well-appointed places. M.

ONE way in which the gardener desirous of increasing his stock of these is by procuring seeds of C. simplex or cuttings, and thereby raising his own stocks for grafting purposes. The stocks are easily raised from cuttings of the above-mentioned sort, struck in heat in late spring in a propagating pit on a bed where the bottom-heat is not higher than 85°. They can be struck in pots or shallow boxes; but the sand-bed lying on boards or tiles immediately over the bottom-heat pipes affords equally graded warmth to every cutting in it, and so the rooting takes place simultaneously. Such stocks when potted must be accorded greenhouse temperature for the ensuing summer. They may be planted out in a frame, and be allowed to stay in it during the first and second summer, when they must be taken up and potted in September. Sometimes stocks are found to be strong enough after only one summer's growth to be taken in hand and grafted, and, in fact, exceptionally well rooted cuttings potted off in May may be worked the same summer; but the stocks make stronger growth, and consequently more roots with which to sustain the future scion, when not worked so

Ordinary practitioners, who will not perhaps possess an air-tight case within their propagating pit, will manage very well by sinking a two-light box inside of a larger or a three-light one, the distance between the lights of the one and the other not being less than 2 feet. This will make a very close shady pit that will also require closely shading during the hours of sunshine. One-year-old wood is the best, but it may be two years old; the scions may be side-grafted, or the stock may be cleft or whip-grafted. should be tied in moderately firm, and the united parts well smeared with grafting wax to keep out water; the tip of the scion, if the bud has been cut off, must be sealed with the wax as well as the cut-The stock must retain some portion of over stock. its foliage till a junction has taken place, when it may be cut off from time to time, so as not to check growth or endanger the health of the plant. must be taken that each plant as soon as grafted be placed in a frame, and be securely shut up, and, if requisite, shaded. On this much depends, as flagging of the foliage of the scion is oftentimes fatal to it, and invariably makes the uniting process more tedious.

The inner frame must be made very damp by a copious watering, the plants themselves must get one thorough saturating at first, and all must be made close with no broken panes or ill-fitting joints or lights. There should be no examination of the frame for two or three weeks, the admission of air being usually followed by bad results, and, the air being at satura-tion point within it, there will be no need for watering or syringing.

Plants must be kept in the frame till they have made some 2 inches of growth, which they will do in four or five weeks. When a plant has grown so much it is better removed to airier quarters, shaded and syringed, and thus gradually inured to greenhouse regimen. The frame may require a thorough watering about the fourth week, but the other points of management must be persevered in till it is seen that all those that are likely to succeed have made the required amount of growth, and it may be taken for granted that those which will do so will not need more than six weeks from first to last. The proper time to begin is the end of June, when the current year's wood has got firm, but not ripe. Y.

LIÈGE BOTANIC GARDEN.

Some time since we had occasion to comment on the miserable condition of certain of the Continental hotanic gardens, and of the lamentable results as regards scientific botany. In Belgium, of late years, an advance has been made, especially in the Brussels Botanic Garden, and the illustrations we are now enabled to give (figs. 68-71) will testify to the fact that well-directed zeal and energy are not lacking in Liège, and that they are recognised by the State. the city, sometimes called the Birmingham of Belgium, much has been done of late to construct new buildings and to put the Botanic Garden on a proper footing, thus M. Morren, the Director, has had the happiness of completing what his eminent father, Charles Morren, began. The new buildings are arranged in two divisions, separated by a terrace of

fine proportions. The upper group consists of a centre devoted to large plant-houses, and wings containing the rooms necessary for scientific instruction. In one wing to the right, in the subjoined plan, is the lecture-room, capable of holding over 200 students. Adjacent is the laboratory, in which practical demonstrations by the aid of the microscope and dissecting needle are given of the subjects which bave been discussed by the lecturer, and in which the students can

is filled with economic and other plants. In the left wing are the museums of economic botany, libraries and physiological laboratory. The terrace is supported by a well-designed wall, carrying a balustrade with pilasters and ornamental vases. From the centre proceeds a flight of steps to a central space, in which the pits and frames and the experimental plots will be established. On three sides of this central enclosure are the smaller bot-houses, forming

But the completion of the Botauic Garden is only one of the many improvements and additions made to the University of Liège. Institutes of Pharmacy, of Technical Electricity, of Zoology, of Medicine, are completed or in progress. Liège has thus the start of the sister University of Ghent, where last spring, at the time of the Quinquennial, it will be remembered that the foundation stone of new buildings of a similar kind was duly laid. At Ghent has our readers know, is

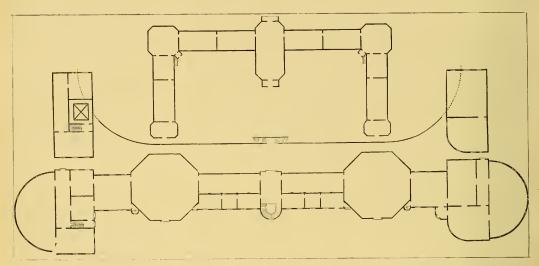

FIG. 68,-LIÈGE BOTANIC GARDEN: PLAN SHOWING THE ARRANGEMENT OF THE UPPER AND LOWER RANGES, SEPARATED BY THE TERRACE.

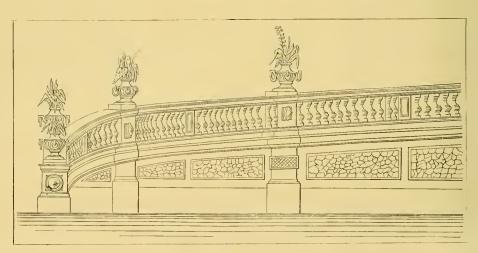

FIG. 69.-LIÈGE BOTANIC GARDEN : PART OF THE TERRACE WALL

work for themselves. In the centre of this block of buildings are the Director's office, and three rooms in which the herbaria are deposited. The Director's office communicates with a work-room, destined more particularly for the use of advanced students and others desirous of undertaking original research. One of the rotundas in the principal range contains a collection of Paims and other tropical plants, and is provided with a gallery running round the building. A new rotunda has been built at one end, to correspond with the old one, and this

a continuous range. At each angle are elegant pavilions, and in the centre of the range an oblong structure to serve as an aquarium for the cultivation of fresh and salt-water plants. The details have been fully considered by the Director, Professor Morren, and well carried out by the architect, M. Noppius. In the centre of the garden is a large rockery, with compartments for plants of different requirements as to soil, moisture, &c. The new buildings were formally opened in November last.

also a regularly equipped School of Horticulture for instruction both in the principles and in the practice of horticulture, and connected with the University. The Belgian Mioistry have acted on the axiom, that the duty of the State to the people consists of three parts—"the first is education; the second is education; the third is education, the Government has felt it their duty to expend public money liberally in support of the Universities, which were formerly a charge upon the municipalities, with a view to raise them to the level

of the neighbouring German Universities—an arrangement which could not be carried out with the meagre funds provided by the municipal treasuries. Liège last year had no fewer than 1400 students (as against 240 in 1840), and this number is about the average in acach of the four Belgian Universities—a much larger number than in the corresponding establishments of Holland or Switzerland; and among the twenty-one Universities of Germany only six have more than

Foreign Correspondence.

Notes from a Sicilian Garden.—The unique and richly planted garden of the Conte Tasca, near Palermo, situated on the Corso leading to the mountain town of Monreale, is one that is laid out in the so-called English or natural style. As might be imagined from its geographical positioo, the bulk of

the floral display is the scantiest. In the month of May we saw a group of Senecio, purple, bordered with a rose-coloured Bellis, the whole being margined by an orange-flowered Echeveria. Another bed consisted of Libonia floribunda, half-hidden under a growth of dwarf Papyrus. Still another of Primula sinensis dotted about amongst the greenery of a carpet of Isolepis gracilis, having an edging of Poa pratensis variegata. A bed of Cineraria mixed with Russellia

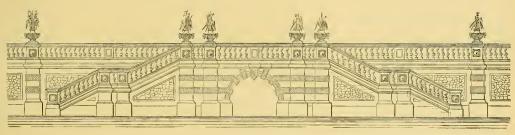

FIG. 71.- CENTRE OF THE TERRACE WALL, SHOWING THE STEPS LEADING TO THE GARDEN.

1200 students. One special characteristic of the Belgian Universities, as we have remarked, is the association of technical institutes such as that now on the point of completion at South Kensington, where the practical details of science in its bearing on industry and manufactures may be learnt, while in other departments of the University instruction in the principles on which the practice is or should be based is given. We cannot doubt that the future will bear witness to the sagacity and value of these proceedings.

the subjects made use of for its embellishment are trees, and other plant-forms, that we recognise as well known inmates of our plant-houses, and which we in our northern climate dare only to place out-of doors in the warmest months, although there they are planted out permauently. Among the Palms are Corpha australis, Latania borbonica, Araucaria Bidwilli and A. Cunninghami, that grow into grand specimens. The climate is such that there are no fears that they will suffer from inclemency of the weather, and it is not easy to say in which month

juncea; also another of flowering Alpinias and Hedychiums surrounded with a band of Maranta zebrina and pretty Adiantum associated together. Farticularly charming was a group in the shade of Palms of Sobralias, interspersed with Begonias with handsome foliage.

B

Yucca draconis and Yucca Treculeana were associated in singular looking groups with Cycads, magnificent Dioon, and fruiting Encephalartos. Passifloras in variety, Cobceas, Solanum jasminoides, Tecoma and Bignonias, coil and creep over the

verandahs, and climb the stems of the trees uncontrolled.

We have extracted these few notes on the specialities of this charming Sicilian garden, from the Garten Zeitung of the present month, in the impression that they might furnish our subtropical gardeners with a few new ideas and novelties in graceful combinations of flowering and foliage vegetation, and so add interest to that portion of the garden embellishment. We cannot have Cycads, Aloes, and the like, planted out permanently, but it is possible to employ these plants in more pleasing ways than in growing them in ugly tubs, and stationing them in single or double file on a terrace walk, to which they are but little ornament,

The Benbageous Bonden.

NARCISSUS PSEUDO NARCISSUS MINOR. -- In spite of the opinion of recent botanists, that all the Trumpet Daffodils are natural or garden varieties of one species, the names which botanists early in this century endeavoured to attach to fixed varieties are still retained in gardens. The varieties themselves are many of them of very old date, and have been preserved the same for at least 250 years; for when once they got into the hands of the Dutch cultivators, who seldom attempt to hybridise or to grow varieties of Daffodil from seed, they remained the same through many generations. It is certain, however, that Salisbury, Haworth, and Herbert, who are still considered authorities on this subject, are at variance both as to the characters which are most important in determining differences and as to the names to be adopted for the varieties which they describe. Of these three, I believe, Herbert has been thought to be the best botanist, so it may be worth while briefly to notice what he says about this. On p. 295 of Amaryllidacece he says:—"Mr. Salisbury had a remarkable intuitive perception of differences, though he was unable to give any account of the existing marks of distinction. I am indebted to him for nothing in this order but naked names of genera." Mr. Haworth says that "his own characters are founded on the solid laws of botanical proportions; but it is utterly impossible that the scientific public should ever adopt his generic characters. The erroneous features on which he has built are the relative proportion of the tube, limb, and cup, the form and margin of the cup, the colour of the flower, the length of the filaments and style; and though his names, which Mr. Salisbury first published without any definitions, will be properly retained, they must be attached to generic characters very different from those given by Mr. Haworth." Herbeit then gives us his own views on p. 294:- "An equal or unequal adherence of the sepaline and petaline filaments, a decided difference in the form and attachment of the anthers, a decided upward flexion compared with a decided rectitude or connivance of the stamina, may be generally relied upon as signs of a generic diversity.

It is evident from these extracts that in dealing with garden varieties the characters adopted by Haworth are far more important, as well as more easy to recognise, than those proposed by Herbert; consequently, in spite of the utterly ungrammatical Latin in which Haworth's monograph is written, made worse by frequent misprints, it is far more easy to work with Haworth, and to recogoise the flower he describes, than with Herbert. Moreover, however sound Herbert's principles of arrangement may be, he was not satisfied with the way in which he had himself applied them, but in the year during which his Amaryllidaceae was in the press he changed his opinion about many of the Trumpet Daffodils, and in a postscript on p. 415 proposed quite a different arrangement of them from that adopted in the body of his work.

In some notes on Trumpet Daffodils recently printed in the Gardeners' Chronicle I mentioned a few of the older varieties which were larger than the typical N. Pseudo-Narcissus. I now mention a few which are smaller. The smallest of them, N. minimus, is interesting as being the only one of the golden-yellow selfs, except the Tenby Daffodil, of which I have obtained truly wild specimens. It was, I believe, the only true Daffodil met with by Mr. G. Maw and Mr. Harpur Crewe in early spring during a tour through Spain made about five years ago, Mr.

Harpur Crewe gave me specimens, which agree with those I have had from English gardens. It seems rather delicate of constitution, and hardly increases with me at all. N. minor is remarkable for its dwarf stature and the large prominent lobes of the trumpet. In form and colour it resembles minimus, and is distinct from it in nothing but size. Both these Daffodils have narrow perianth segments, not imbricated, being quite free from one another when opened at an angle of 45° to the trunk. Nanus is the common dwarf Daffodil of English gardens, being far more general in cultivation than the other two, probably because it is hardier, and in most soils far more rapid of increase. It has broad imbricated perianth segments, lighter in shade than the trumpet, but not so light as in the common wild Daffodil, between which and N. minor it seems to be an intermediate form. There are one or two others, one sold by Messrs. Krelage as pumilus, which seems distinct, but which I have not yet fully studied. These have all the outer petals darker than in the common wild form; the South of France, near the Pyrenees, several varieties occur which come very near typical N. Pseudo-Narcissus in form, size, and habit, but have all the parts of the flower lighter in colour, and in some instances have the mouth of the trumpet nearly or entirely even and plain. I have many of these now flowering in my garden, and hardly any two of them are exactly alike. Some approach near in colour to moschatus, and I believe that on farther investigation a series may be obtained from the habitat I have mentioned connecting the so-called white flowered Daffodils with the common type in colour. In fact, there is a field in Oxfordshire where white and yellow grow mixed up together; and from these, and a large number of varieties of white flowered kinds collected from different gardens, I hope in time to convince Mr. Barr that these albifloræ amongst Ajax Daffodils owe their origin to accidental variety of colouring. A box of Daffodil flowers just received from the Pyrenees confirms this opinion. C. Wolley Dod, Llandudno,

DOUBLE DAFFODILS. - I see the Editor placed a query to the paragraph in my last note (p. 309) where I said it was possible that a double Daffodil, is a species having the power of perpetuating its quality by seeds. Well, who dare say it is impossible? Upon the same page are some very interesting notes on double Stocks, which may help to throw light also upon the question of double Daffodils if we substitute the one name for the other. The writer says :- "In the case of double Stocks both stamens and pistil are changed into petals; seed cannot, therefore, be had from full flowers in these sorts, and the only resource is to save seed from those single flowers in which a tendency to fulness has com-menced by having a petal or two more than usual." Now here, I think, we have a clue to the formation of doubles; for if this slight tendency in Stocks gives seed which produces actual doubles, as is the fact on an enormous scale commercially, why not so in Daffodils I noticed last year a large number of bicolor Daffodils, chiefly Horsfieldii, which had been grown on highly manured and otherwise rich and suitable soil, and which contained eight or more petals, or perianth segments, iostead of the typical six. These flowers were thus in the first stage of doubling, and probably seed from such flowers might produce doubles. have also observed that the double Rocket becomes single, and when this happens the florists hereabouts carefully save the seed from such a plant, believing it will again yield a proportion of doubles. No doubt it will be the case that if the whole of the stamens and pistils in a double flower are converted into petals, no seed can be produced; but a flower may be double and yet not all its seed-producing organs have been thus altered; and in the latter case we should have a chance of propagation by seeds. I apprehend this is the experience with many flowers, such as double Cinerarias and Primulas. for example. By analogy we may perhaps get at the truth with regard to Daffodils also, Wm. Brockbank, Brockhurst, Didsbury.

LEUCOJUM TRICHOPHYLLUM, OR ACIS TRICHO-PHYLLUS.— In last week's Gardeners' Chronicle "Floore" asks if this plant "is yet in cultivation." I am afraid this is doubtful, since Mr. Brockbank, who has been studying the genus, and inquiring for the different species, does not appear to have met with it. I observe that it is given in Donn's Catalogue of 1823, two years after Mr. Griffin flowered it at South Lambeth. It does not necessarily follow that it was at that date actually in the Cambridge garden, but it was there a few years ago, and between the years 1868 and 1872 there was a nice patch of it at the foot of a rockwork; I understand, however, that it is no longer there. The flower was smaller than represented, 544 Fol. Reg.; white, with hair-like twisted leaves, spring-blooming. It appeared to be quite hardy, fully as much so as L. autumnale. If lost to cultivation I apprehend it will have to be sought for, not in Portugal or Barbary, but in the eastern provinces of Russia, whence, by way of Moscow, Mr. Griffin procured his bulbs, T. H. Archer-Hind, South Devon, March 17.

RANUNCULUS ACONITIFOLIUS.—Mr. Brockbank asks (p. 310) whether the single form of Ranunculus aconitifolius is good? We got it a lew years ago, I think from the College Botanic Gardens, Dublin. It increases slowly, and is less pretty than the double form (the Fair Maids of France), or than the larger single-flowered R. amplexicaulis, which does but badly here, though in some soils it appears to grow luxuriantly with no special care. We are now trying it in a bog bed. C. M. Oven.

SCILLAS. - Scilla sibirica grows here luxuriantly in a rich light soil, the bulbs increasing quickly, and it often sows itself freely. If planted in groups or in small beds, especially if the latter be bordered with Narcissus nanus, the effect is one of the prettiest bits of colouring in a spring garden. The singular beauty of Chionodoxa Luciliæ increases year by year as the bulbs become established. A good group of Scilla bifolia taurica left undisturbed for five or six years shows how superior this form is, both in size of flower and depth of colour, to the type, or to the pink and pretty white varieties. The succession of various kinds of Scillas will now continue almost without intermission till it winds up with the small S, autumpalis, S, ameena (not one of the prettiest) and S. italica quickly succeed the early spring kinds. When grown in well established groups S. italica is very effective. S. nutans and S. campanulata, with their varieties, S. veroa and some of the large flowering kinds, are all worth a place in some part of the flower or wild C. M. Orven. garden.

--- That biflora was a slip of the pen for bifolia must have been evident to all. My remarks as to the comparatively slow rate of increase of sibirica, however, seem rather to be supported than otherwise by "Daf," who, in being successful in raising bulbs from seed, is perchance more fortunate than most others. Technically it is not correct to call the most others. Technically it is not correct to call the Chionodoxa a Squill, but it is less inexact than calling it "Glory of the Snow" [the English equivalent of the Greek name given by Boissier]. Now if I wanted to find a flower that merited such a term, it would surely be the lovely white-flowered Primula nivalis, that I have in small pots, blooming so charmingly that I should regard a mass of it as even more glorious than the soow. I find this year that plants remaining in the small pots for the second season without shifting are blooming far more freely and more beautifully than they have done in previous years. A few plants in a cool house, just now blooming as mine are, will challenge our admiration even with Orchids. And again, how very pretty is the yellow-flowered Anemone ranunculoides in pots, too, and in a cool house. Really it is difficult to say how many of these spring gems one may not have in a small house, and how exceeding may be the enjoyment obtained from such a collection. The vellow Anemone thrives well in the same pots for two or three years; mine indeed are better this year than ever. Specially fitted for a cool house are the numerous forms of Primula Sieboldi. These in big pots and pans are now coming freely into bloom, and will give a beautiful show of flowers for several weeks. But the denizens of any wellfilled house of hardy plants are, or at least should be, legion. Quercus.

DIRCA PALUSTRIS (THE LEATHER-WOOD).—
Though once, perhaps, common, as Loudon observes, it is now rather a rare shrub. It is more curious than beautiful, but its habit is quite distinct. The flowers are pale yellow, and appear before the leaves. They are tubular, and the leaves are oblong, of yellowish-green, forming a dense foliage. There is a fine specimen in the Cambridge Botanic Garden, 26 feet in circumference.

Prehid Notes and Hleanings.

ORCHIDS FROM CAMDEN WOOD .- Mr. Vanner kindly sent us on Monday from Camden Wood, Chislehurst, the finest spike of Phalænopsis Stuartiana that has come under our notice. It was five-branched, and bore thirty-two flowers of a very good type, the white being pure, and the spotting on the greenishlemon-coloured ground bright and well-defined. With it came a flower of a white Cattleya Trianze without a tinge of pink on the lip, and two blooms of a glorious variety bought at Stevens' early last year, and believed to be one of Chesterton's importations from the Popayan district. It is the finest of this hatch that we have seen, being as large in all its parts as Mr. Woollright's flower described by Professor Reichenbach in the next paragraph, but with a more richly coloured lip, the lovely shade of purple being distributed over a larger surface. Two magnificent wax-like blooms of Cymbidium ehurneum, and a fine spike of a very fine form of the Hawthorn-scented Odontoglossum gloriosum, completed a quartet of singularly beautiful objects.

CATTLEYA TRIANÆI POPAYAN.-The first flowers I had from Mr. De B. Crawshay, Rosefield, Sevenoaks, Kent, from Mr. John Woollright, The Hollies, Mossley Hill, Liverpool, and Mr. B. S. Williams. All were equally remarkable for a certain shade of the lilac, that I venture to call lilac with a certain homoeopathic brush of ash colour, or, for painters, lilac with too much strong white. One of the flowers sent by Mr. Woollright was exceedingly grand and sur-passed all others. I feel very disappointed to say we had in the Hamburgh Botanic Gardens three Popayans in flower, which were quite the ordinary Trianæs, with good pure lilac. It might be dangerous for many personal reasons to give an especial name to this variety. I have most enthusiastic letters about it, which leads me to suppose that there are still disposable specimens for sale, H. G. Rehb, f. [Mr. Woollright sent us a very fine bloom from the same plant, which had been expanded five weeks without any shade. ED.]

ODONTOGLOSSUM ELECANS (POLLETT'S VAR.).—
—The lovely hybrid of O. Hallii, which was illustrated in the Gardenees' Chronicle in June, 1853, is again in flower with Mr. Pollett at Fernside, Bickley, at is one of the most elegant of the genus, as well as one of the ratest, and seen as at Fernside, with three spikes, bearing altogether forty-five flowers, it leaves but one thing to regret about it, viz., that it must for years to come be beyond the reach of many who would like to possess it. The flowers are creamy-white, heavily blotched with crimson-brown, and having the yellow crest of O. Hallii at the base of the labellum, In outline and in the curl of the long-pointed sepals and petals they much resemble a large form of O. cirrosum. It is strongly scented of Hawthorn.

PHALENOPSIS STUARTIANA, Rehb, f. — Major A. F. Léndy, Sunbury-on-Thames, has kindly forwarded me a very great botanic wonder. It is a five-flowered raceme of Phalenopsis Stuartiana, with very good colours. The merit of those flowers, however, is to have universally unguiculate triangular obtusangled petals, with a toothed ancipitous keel, decidedly similar to the callus of lip. The whole flower is covered with spots and dots. This is to be regarded as a case of intended trilabellia, as three lips are no doubt were intended. When the petals wholly change in lips, then the anther disappears, and a terminal stigma ends the style. May we hope Major A. F. Lendy will kindly observe the avenir of his great curiosity. Will it keep constant? How long? H. G. Rehb, f.

SACCOLABIUM GIGANTEUM, IVall.—My expectation that all the eastern individuals of this plant would be the improved variety, lilustre, only to be discerned by far larger blotches of the flowers, may be a mistake, provided there have not taken place confusions about the origin of the specimeos, as is said to have been the case in Cattleya Dowiana and aurea. Mr. De B. Crawshay, of Sevenoaks, has just sent me four flowers with small spots, called illustre, but not surpassing the old Birmese plant. Another variety from the same correspondent had only very minute spots. Mons, Godefroy Lebeuf sent me a, no

doubt, Cochin Chinese spike with crimson lips. I thought them very fine, till I had the crèveaur of seeing spikes of common giganteum, assuming similar crimson lips on my table after having had them purple before. I hear that at some places all the old Saccolabium giganteum have disappeared, and nothing but illustres have taken their places. To avoid being regarded the cause of these guid pro quos, I would warn collectors not to give higher prices for varieties, if they are not seen in flower. If this rule were well followed, all parties would benefit. If I were in the trade, I should dislike having given a unique grand variety for a low price, and if I were a collector I would not like to pay for rubbish at high prices. II. G. Rehb. f.

The Flower Handen.

THE SPRING GARDEN has now recovered from the effects of the heavy storms of wind and rain which prevailed through January and February, and as spring frosts have not yet been sufficiently severe to do any mischief, the general appearance of the spring garden is charming. The most important work now consists in keeping every part clean and in perfect order. Everything should bear the stamp of neatness and good keeping. The surface soil should be carefully loosened between the plants, so as not only to destroy weeds, but also to prevent the surface of the beds from becoming hard and impervious to air and moisture. Where required, the plants should be pegged down, or tied, so as to cover as well as possible the earth underneath them, as well as to protect them from heavy storms of wind or rain. The flower-stems of Hyacinths, Tulips, and other bulbs require particular attention in this respect, as they are so easily broken off. There is, perhaps, at this time no plant so bright and beautiful as the dwarf scarlet Wind-flower (Anemone stellata fulgens): it is so charming at mid-day as to arrest the attention of the most casual observer. No spring garden is complete without it. Another very beautiful plant, blooming most abundantly at this time, is Chio-nodoxa Luciliæ, the pale blue flowers of which, although not so deep in colour as those of the Scilla, which it closely resembles, are still very charming, and as it is perfectly hardy, and when established blooms most profusely, it is a great acquisition. Iris reticulata is also a gem at the present time, especially where it is favoured with a warm sunny border. As hardy and most useful plants for small beds Dean's deep coloured crimson Primroses are most effective. No one can form the least idea of their beauty till they see them in masses. Seeds should be sown now in boxes and placed in a cold frame; the plants should be pricked out in a sandy, somewhat shady border when large enough to bandle, where they will make good strong plants for blooming next spring.

Roses.—The time has now arrived when many of the early kinds must of necessity be pruned: great caution should, however, still be exercised, in not pruoing too closely, but rather shorten the branches by degrees, so as to keep the still unbroken buds dormant as long as possible. Protection to the Teas and Noisettes should now be provided, as one night's frost at this time, in their present tender and unusually succulent condition, would without protection not only destroy the buds, but the plants also would most probably be permanently injured. No kind is more susceptible to injury than Maréchal Niel, which should always receive protection of some kind. For this purpose there is no more useful materials than either Frigi-Domo or Britain's Elastic Netting. If neither of these can be obtained, common garden mats or even evergreen branches may be used for the purpose, taking care to remove them when danger from frost is past.

SUMMER BEDDING PLANTS.—The required stock of these having now been obtained, they should be potted off as quickly as possible; and when established, by giving them the advantage of a little heat for a few days, they should be placed in cold pits or frames to harden. Seeds of hardy and half-hardy plants should now be sown, and placed either in gentle heat or cold frames. When rufficiently large

to handle they should be pricked out in cold frames, where they should receive plenty of air and light, so as to keep them hardy for transplanting when the weather permits, T. S. C.

The Handy Anuit Garden.

AT length the Fig claims our attention, the gradual rise in the temperature baviog set the sap flowing. Where the trees are covered up for the winter no time should be lost in getting the covering removed.
Perhaps no fruit tree is more impatient of the knile, and it should never be too rigidly trained to the wall, A good strong tie here and there, and spurs from 6 inches to a foot long, will be found the most prolific mode of treatment. Where extra strong growth is manifested, a good root pruning immediately after the crop is gathered will induce greater fruitfulness. Fig delights in a good space to ramble in, therefore a lofty wall with a broad coping and a south aspect suits it exactly; sometimes there is the wall of a stable or other building adjoining the garden, which can be used for this purpose. The Castle Kennedy is our earliest Fig here, but it wants a large breadth of wall; we also grow Marseilles, Brown Turkey, and Brunswick; Osborn's Prolific is also a good kind; but the best Fig in cultivation is Negro Largo, which, however, does best under glass, when it becomes a perfect sweetmeat: In warm localities, such as Worthing in this county, the Fig does well as a bush and standard, but a dry situation and subsoil are indispensable; indeed these two conditions are much more necessary than a great depth of soil.

NUTS.—At pruning time we recommended that the branches of these should be left thicker than usual to insure an abundance of male catkins, and, a "good set" being now secured, many of these extra branches can be removed. Grafting may still be successfully carried on, choosing morning and afternoon in preference to noonday, and let the clay or grafting wax be promptly put on as soon as the scion is fastened to the stock. In some cases this very dry weather will cause the clay to crack and let the air in to the union: damp moss tied on will prevent this.

The continued mild weather has brought bush fruits unusually forward, and one cannot help being somewhat concerned about the coming crop. Oftentimes on very short notice we find that the caterpillar has made himself more free than welcome with our Gooseberry bushes. To be forewarned is to be forearmed, therefore order through your nearest chemist such a quantity as will be required of Hellebore powder. A dusting of this soon rids us of such troublesome neighbours. It must not be used upon bushes where the fruit is being gathered. 7. Rust, Exidge Castle, Sussex.

THE WEATHER OF 1883.—Few things are more readily forgotten than the state of the weather of the preceding year. As gardeners we are obliged to look forward, but few of us care to look backward. Neverthelesses, inasmuch as present effects are the result of previous causes, often remote, we can but be thankful to Mr. Mawley for giving us year after year in so convenient a form as he does in his pampblet entitled The Weather of 1883—the record of the year's weather. For each month the records of the barometer and thermometer are given with corresponding indications for the humidity, wind, rain, and susshine, and the excess or deficiency of temperature from the average. The tables are followed by a few general remarks on the more remarkable phenomena of climate, the prevalence of disease, &c. July was evidently an unusually cold month, but Mr. Mawley's statement that the 16th was 1° colder than last New Year's Day apparently refers to the mean temperature of the day, for on reference to the tables we find the minimum on July 16 to have been 43°-1, while on January 1 the minimum was 51°.6. Now that sunshine recorders are in use, is it too much to hope that we may speedily have some device wherley the duration of frost may be ascertained? In the early days of photography we remember that self-recording as well as self-registering thermometers were in use, but the apparatus was too costly and too complicated for use by private individuals. Since that time so great improvements have taken place in the manufacture of sensitive paper that by the aid of a clockwork apparatus the desired record might surely be obtained at less cost of labour and money.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESUAY, Mar 25

Royal Infriedutral Society: Fruit and Floral Committees, at 11 A.M.; Scientific Committees, at 12 A.M.; Spring Show at Scientific Committees, at 12 A.M.; Spring Show at Scientific Committees, at 12 A.M.; Spring Show at 12 A.M.; Spring Show at Committees, at 12 A.M.; Spring Show at Committees, at 12 A.M.; Spring Show at 12

AT length we are enabled to congratulate Conifer lovers, subscribers, authors, and publisher, upon the completion of the Pinetum Britannicum. The work is one of great magnitude and beauty, and one that has involved labour and pecuniary outlay, it is to be feared, beyond hope of recompense. In the preface Mr. RAVENSCROFT, the enterprising and chivalrous publisher and part author, tells the story of the book-how it grew out of a small catalogue raisonné prepared for Messrs. PETER LAWSON & Co. As a considerable amount of materials had accumulated, the larger work, with its large-sized coloured plates, was undertaken. Messrs. LAWSON lent substantial aid by taking a hundred copies; the Emperor NAPO-LEON distributed thirty copies among the Schools of Agriculture and Forestry in France, and royal patronage was not wanting in our own country. Such aids, however, were not sufficient to secure the uninterrupted progress of the work. The firm of PETER LAWSON & Co. met with misfortune, the French Empire underwent still greater disaster, and as a consequence the publication of the work was necessarily for a time suspended. In order, however, to keep faith with the remaining subscribers, Mr. RAYENSCROFT lately resumed the publication, and has now, as we have seen, brought it to a close; thus fulfilling all his obligations to his subscribers, if not fulfilling the whole of the ambitious programme with which he set out. ROBERT BROWN, LINDLEY, and specially ANDREW MURRAY-all of whom have passed away-contributed the botanical descriptions, the latter ones having been drawn up by another hand; numerous Conifer lovers and cultivators have also lent their aid. What we have now, then, is three handsome folio volumes with coloured plates, illustrative woodcuts, photographs, and full descriptions, botanical and arboricultural, of a selection of the best and most remarkable hardy Conifers. In a work which has been so long in hand, and which has been elaborated by so many different writers, there must necessarily be some want of proportion, and some discrepancy between the older and later parts, but none, we believe, that at all seriously impair the value of the book as one of reference. It affords, however, one more illustration of the fact, that the value of these colossal and expensive books, which can necessarily only be in the hands of the few, is not proportionate to the cost and labour bestowed on their production. It is hence satisfactory to learn that Mr. RAVENSCROFT contemplates the production of a smaller treatise supplementary to the present one, and intended to contain descriptive accounts of those hardy species not included in the larger book. As we shall probably have frequent occasion to refer to this "monumental" work, as the French would call it, we need now only add that the parts now issued in completion include descriptions and plates of Cupressus macrocarpa, Pinus ayacahuite, and Cedrus Libani, together with title-pages for the three volumes, prefaces, indexes, &c.

— ROYAL HORTICULTURAL SOCIETY. — We understand that the next spring show, to be held on the 25th inst., promises to be a specially good one. Hyacinths will be strongly represented, and they are

exceptionally good this season. Special prizes are also offered for Amaryllis, and it is expected that there will also be a fine display of Primroses and Cinerarias. On Tuesday, April 1, there will be a special exhibition of Daffodils, and from the favourable season a most interesting exhibition is expected. A paper will be read by Mr. F. W. BURBIGER at a meeting to be held at 1 o'clock, Prof. MICHABL FOSTER, F.R.S., in the chair, when the principal English and Continental cultivators of this charming flower will be present.

- International Health Exhibition is shown by the fact that application has been made, by British exhibitors is alone, for space five times as great as that actually at the disposal of the Executive Council. The first goods were admitted on the 15th.
- —— SINGLE ANEMONES.—Messrs. JAMES CARTER & Co. have sed us a fine bunch of flowers of single varieties of Anemone hortensis, which they designate Empress Poppy Anemones. The colours range from white to regal purple, and the blooms are fine in size and perfect in form.
- MR. WILLIAM HODGSON,—We understand that Mr. WILLIAM HODGSON, schoolmaster, of Watermitlock, near Fenrith, Cumberland, has been elected an Associate of the Linnean Society. Mr. HODGSON is author of "A Flora of Ullswater," and other botanical papers, in the Transactions of the Cumberland Association, and otherwise is well known for his extensive local knowledge of the plants of the Border Counties.
- PRIZES FOR PEAS.—Messrs. Webb & Sons, Wordsley, Stourbridge, offer valuable prizes for the best dish of their new Pea, the "Wordsley Wonder," to be competed for at the Royal Horticultural Society's show, South Kensington, on July 22 next.
- SHROPSHIRE HORTICULTURAL IMPROVEMENT SOCIETY.-The members of this Society held their first meeting on the 12th inst., under the presidency of Mr. WM. PHILLIPS, who delivered a very interesting inaugural address to a fair attendance of members. In the course of his remarks Mr. PHILLIPS referred to the great assistance such societies were to the gardening profession, and to the valuable services rendered to horticulture by eminent amateurs. He also made some brief remarks on some of the various diseases to which plants are subject, such as the Potato and Hollyhock disease. address was followed by a short but animated discussion on the Potato disease, its probable cause, and the best means of prevention. The meeting closed with a vote of thanks to the President for interesting address, and the next meeting was arranged for Wednesday, April 2, at half-past 7, when Mr. W. H. HARRISON, B.A., will read an original paper (to be followed by a discussion) on the "Cultivation of the Strawberry.
- POTATOS .- The coming season bids fair to be one of the most productive known for many years. Of course we cannot assert such will be the case, but merely state that all things are tending to that end. Seldom have we had a spring that so strongly invited to early planting, seldom a spring in which so much planting has been done so early. truth, the Potato trade in home-raised produce seems to have taken a new lease of life and vigour, for everybody is planting Potatos, and planting more and more from year to year. It may be that with the increase of population the Potato is becoming a more important article of food; it may be that with less hard drinking and more temperance amongst the masses there is growing up a greater demand for garden products, and specially for Potatos. Certain it is, that if the home supply is enormous it does not seem to be excessive. Again, the greater the quantity of Potatos grown the greater relatively the stocks of seed-tubers on hand, and these, to be made profitable, must be planted, and so growers are increasing rather than diminishing their breadths. Farmers find Potatos to be not only a good change from corn or pulse, but also a good cleaning crop; indeed, once get a big breadth of Magnums or Champions established, and weeds have no further chance. Finally, the lifting leaves the soil in a loose clean condition. Thus large seed stocks, an early and singularly favourable spring, and the large demands of the

population, are all tending to briog us this year, all other things being well, a monster crop of Potatos.

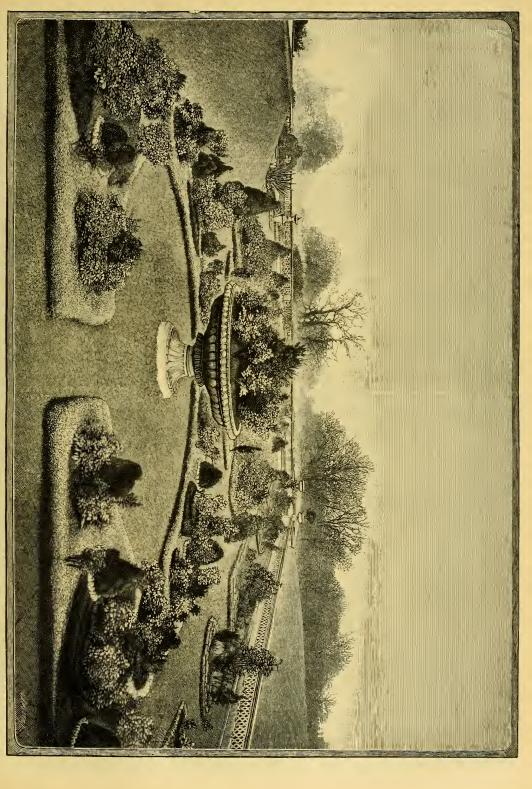

— AMARYLLIS.—For the benefit of future historians or monographers of the genus Amaryllis we publish the following list of hybrid varieties, exhibited by Messrs. James Veitch & Sons, and certificated by the Floral Committee of the Royal Horticultural Society, on the dates given:—

We should add, that with the exception of Mrs. Baker and Storr's Beauty the above were all raised by Messrs. VEITCH.

· CYPERUS PROPAGATION, -The two varieties, C. alternifolius and C, a. variegatus, so useful in the hothouse in winter and greenhouse during the summer months, and among the prettiest of room plants, can be increased either by seed, that will be found to ripen freely on plants in a warm house, or by cuttings. The seed may be sown in early spring on sandy soil in pots standing io saucers, so that they are kept constantly moist. The young plants that soon appear must be potted off as soon as they reach I inch in height, and grown on in warmth till large enough. The variegated variety is better propagated by the second method, as it is merely a sport from the first, and is very liable to revert to it; leaves taken off with about 4 inches of stalk, and floated in an inverted bell-glass or flower-pot full of water in the propagating house, throw out young plants in quantity, which then emit roots into the water. When these roots are I inch long the plantlets must be severed from the parent leaf and carefully potted in finely sifted light mould, and afterwards treated as places from seed. The old leaves throw out young plants when fastened down to a panful of sand, but hardly as freely as in water. Papyrus antiquorum, the well-known waterplant, is another graceful subject, and will grow when shifted repeatedly into rich soil in spring and summer to the height of 7 or 8 feet. This may be increased in the same way as the Cyperus, which it much resembles, or by division of the root-a method that can be adopted with all, although for the production of plants for small arrangements in plaot-houses or dwellings the other named methods are to be preferred. The mealy-bug affects the Papyrus, and, being very difficult to eradicate when once allowed to establish itself, it should be assiduously sought for and destroyed. All these plants will flourish even when standing in water of moderate depth, and are much benefited by being grown in loamy soil with a good proportion of sand and humus, the pots being stood in saucers holding water, although neither sancers nor water in which to stand are essentials to growth,

- THE NEW IVV-LEAVED PELARGONIUMS,-We do not find that these useful and pretty plants are so much grown as their many good points qualify them to be. They periodically appear amongst nurserymen's exhibits at the larger horticultural shows, but it is seldom we find handsome plants in private gardens. This neglect into which they have fallen is perhaps owing to the increased impatience of gardeners, which impels them now to cast out any plant which will not respond to a forcing treatment. grown on small trellises, in hanging baskets or pans, as columns or the like, or even used to run up the rafters or walls of small conservatories, the plants are in their right position. When planted in narrow borders or in tubs, &c., the plants require a dry treatment during the autumn and winter, as it is found that moisture is particularly injurious at this point in

such positions. They can be recommended for small beds and for clothing wire basketwork in out-of-door designs. Some of the best are those with double flowers, like Abel Carrière, a large-trussed rosy-carmine; La Rosiere, also a rose colour; Congo, rosy-lilac; Come II. de Choiseul, salmon, a fine double flower; Jeanne d'Arc, the prettiest of white kinds; Vice-President Joly, a pleasing pink flower; and M. Pasteur, a crimson-magenta.

— THE SEEDLING POTATO EXHIBITION, in connection with the Northamptonshire Horticultural Society, will be held in the Corn Exchange, Northampton, on September 24 and 25.

· CRASSULA JASMINEA .- This variety of Crassula (Kalosanthes) is a pretty miniature example of a favourite class of flowering succulents of easy growth, and should form a good useful summer blooming plant for the dwelling-house. The Crassulas and Rocheas are among the most brilliant of greenhouse plants, and should be grown in larger numbers. The above named kind possesses white Bouvardia-like flowers, arranged as a broad flat corymb, having an odour of honey. Cuttings strike in a dryish atmosphere in summer, and may be left in the cutting pots unless struck in June ; in that case they may be potted in sandy loam, a little peat and leaf-mould, and grown on in a frame till September. They require wintering in a cool-house, with but little water given them till March, in which month the plants may be brought into a house with a night temperature of 50°, and receive a soaking of water, so as to induce an early growth, shifting the plants, if they are oot of flowering size; but if they are intended for flowering the same season, surfacing with soil similar to that in which it is growing will be sufficient. Later on the plants may be grown in a cold pit or frame, as near to the glass as possible. When the flower plants have finished blooming the faded trusses and half the length of the shoots on which they grew must be pruned off, the plants remaining in a sunoy place out-of-doors till they show signs of breaking, when these and the young stock may receive their summer repotting; the old stock may remain out-of-doors still longer, if the season is warm, otherwise the whole were better under glass, as the plants, especially newly potted ones, are likely to be injured by much rain. Young plants up to the beginning of July should occasionally have their shoots stopped to induce a more bushy habit than is quite natural to the species, and should be watered with much care, especially till the pots are filled with roots.

— PRUNUS MYROBALANA (THE CHERRY PLUM).— This is the second earliest of the Amygdaleæ in the Cambridge Botanic Garden; and a fine tree it is, with its myriads of small white blossoms. It precedes the Almood, however, by a few days only, and the association of pink and white is now most beautiful. The fruits, rarely produced in England, are used in India to dye black.

— LACHENALIA LUTEOLA.—The most effective way of growing this plant is in baskets, as it gains much in appearance by the free pose of the leaves, which they acquire by spreading easily in all directions; the flowers, too, seem brighter, as no doubt they are, by the full light they have near the glass. For greenhouse baskets there are few plants finer, and one of the best in the Cambridge Botanic Garden had lately from sixty to seventy spikes, the basket being about 1 foot across.

— HYOSCYAMUS ORIENTALIS, — Amongst the most showy of all the hardy perennial herbaceous plants now in flower, excluding bulbous and tuberous ones, the Oriental Henbane certainly takes a foremost place. In the herbaceous department at Kew a good tuft of it is now conspicuous for its grey green stalked leaves and its large cymes of delicate lilac-purple flowers, surmounting leafy stems about a foot in height. This species, a native of the Caucasus, is thoroughly worthy of a place in the herbaceous border, the colour of its flowers and the peculiar greygreen of the hairy leaves forming a very pleasing combination.

—— STYLOPHORUM OHIOENSE. — Under this name—which, according to WATSON'S Index, is a mere synonym of S. diphyllum, the common Celandine Poppy—there is a plant at Kew which, for garden purposes at any rate, appears to be distinct

enough to have a separate name. It has large handsome golden-yellow flowers, and neat, glaucous, Celandine-like leaves. The Kew plant was received under the name quoted at the commencement of this note from Messrs, FRCEEL.

— VIOLA CLABELLA.—Imagine a plant like a medium-sized British Wood Violet (V. sylvatica), but with glossy leaves and bright yellow flowers, and a pretty accurate idea will be formed of what this lovely little Californian species is like. Plants now in flower at Kew in a cold frame suggest the suitability of V. glabella for the decoration of the cool conservatory during early spring. In any case, the species is a very pretty one, and it is worth a place even in the most select collection of herbaceous plants.

— OMPHALODES YERNA VAR. ALBA. — This charming little perennial, or, rather, the type with its blue Forget-me-not-like flowers, is a favoured denizen of many a garden border and shrubbery. It is a plant which does well in shade, and in many places is quite able to hold its own by the woodland walk and in the wild garden. A white-flowered form, otherwise not differing from the type, is now blooming at Kew; when this becomes more widely known it will probably he as largely grown as O. verna itself.

—— PRIMULA DENTICULATA.—In company with another Himalayan Primrose, the yellow-flowered P. feribunda, which has been continuously in bloom for about a year, and a good pot of the pretty Japanese species, P. poculiformis, which for the last two years has never been without quite a crop of its delicate flowers, there is a very handsome form of P. denticulata now blooming in the cool compartment of the new range at Kew. The globular compact heads of rather small purplish flowers form an agreeable and striking contrast to the larger-flowered umbels of paler-coloured blossoms of P. poculiformis, and the bright golden-yellow ones of P. floribunda.

— THE TAUNTON AND DISTRICT GARDENERS' ASSOCIATION will hold a Chrysanthemum and fruit show in Taunton on November 20 next.

- BAUHINIA PURPUREA .- In the Palm-house at Kew a fine specimen of this handsome Indian species is now in flower, and a figure of it will appear by-and-bye in the Botanical Magazine. Although a number of Bauhinias are in cultivation in botanic gardens and elsewhere in this country, the species, at any rate the majority of them, by no means flower freely. What glorious objects some of them are when treated properly will at once be seen on referring to the figure of the rosy-lilac-flowered climber, B, corymbosa, which was figured in these columns (from the richly stored gardens of Sir GEORGE MACLEAY, at Pendell Court), and also in the Botanical Magazine, tab. 6621. The South African B. natalensis, a dwarf shruhby species with white flowers, blooms annually at Kew, but these two are exceptions in a large and certainly showygenus. B. purpurea has much larger flowers than either of the two species just mentioned, and if means could be found to induce it to flower freely and regularly it would doubtless become a favourite in large structures. In colour the flowers are a deep rosy-red, in size and form having a superficial resemblance to those of the common Hibiscus rosa sinensis. A very nearly allied species-if it is not quite identical with B. purpurea-is represented in picture No. 235 in the "North" Gallery at Kew.

- GAGEA LUTEA .- This species, a rare and somewhat local one, indigenous to Great Britain but absent from Ireland, is certainly worth growing in any collection of hardy bulbous plants. In a wild state it often flowers but spariogly, and even then the flowers are not nearly so fine as when the plant is removed to a garden and the struggle for existence considerably lessened by the absence of the numerous wildings which share the soil of the copses or pastures where it occurs naturally. The English name, the Yellow Star of Bethlehem. is a pretty and suggestive one, for the yellow or greenish-yellow flowers are much like, both in form and arrangement, those of the common Star of Bethlehem-the whiteflowered Ornithogalum umbellatum. There are about a score species in the genus Gagea, and our indigenous plant is probably one of those which can boast the most extended geographical distribution, being found along through Europe, North Asia, and in the Himalayas. It is now flowering in the Kew collection.

—— PRIMULA ROSEA. — The bright rosy-red flowers of this beautiful Himalayan Primrose are now being freely produced in the open air on the rockery and elsewhere at Kew. Scarcely any other hardy herbaceous plant—perhaps none at so early a period—cao compare with this in richness and delicacy of colour. Under favourable conditions it seeds freely, and it is better to keep up a succession of seedling plants than to depend entirely upon the old ones, as these latter are apt to go off after a couple of seasons or so.

—— CARDAMINE ROTUNDIFOLIA, or the Mountain Watercress of Pennsylvania and other parts of the Northern Uotied States, is well worth a place in the herbaceous border for its dwarf habit and the pure white flowers which are produced in early spring. It has a weak or decumbent branched stem and stalked leaves—with just the taste of the true Watercress—rounded and angled, somewhat heart-shaped, not unlike those of young plants of our common hedge Garlic, Sisymbrium Alliaria. The species is easily grown, but thrives best in a cool damp place. Now in flower in the Kew herbaceous department.

—— Orobus vernus.—A number of varieties of this early-flowering and good old-fashioned perential are now in flower in the herbaceous department at Kew. The type itself, with its purple and red flowers, is one of the best of early spring-flowering plants; var. albus has white flowers, and cyaneus metallic-blue ones. A form with double flowers is also cultivated at Kew. The Hungarian O. flaccidus is a rather distinct variety, with very narrow leaves and red flowers.

— KEERSAL, OR CATECHUIC ACID.—Under the above name a peculiar substance is described by Dr. DYMOCK, which, he says, he has not seen any notice of in books on Indian Materia Medica. The substance is obtained from cavities in the wood of Acacia catechu, and occurs in small irregular pieces similar to pale catechu mixed with chips of reddish wood. It fetches a high price in consequence of its heing only occasionally met with, and it is collected by men who split firewood. Keersal is completely soluble in boiling water and rectified spirit. It is used in native medicine in chest affections, and to promote expectoration.

-- NEW ECONOMIC PLANTS IN JAMAICA.Mr. D. MORRIS, the Director of Public Gardens and Plantations in Jamaica, has drawn up a report on the collections of seeds and plants made by him during his absence from Jamaica last year. Mr. MORRIS points out that in making these collections his aim was chiefly in favour of economic and industrial plants, so that they might in course of time, when properly established, contribute to the wealth and resources of the country. Amongst the plants so collected by Mr. MORRIS, and now introduced for the most part for the first time to Jamaica, may be mentioned Cinchona Ledgeriana, C. calisaya, and C. Calisaya var. Josephiana; Scammony (Convolvulus Scammonia), well known for the resin which exudes from its roots, and which is a valuable medicine; Aloe socotrina, one of the sources of Aloes; Mangosteen (Garcinia Mangostana), which is, however, already established in the island; Agave Ixtli, the source of Sisal Hemp; Quillaia bark (Quillaia saponaria), about which a good deal of interest has recently been excited, in consequence of the saponaceous principle being used in the arts and manufactures. Piper methysticum, the Kava Pepper plant, which besides its use by the Fiji islanders for making their favourite beverage, kava, has of late attracted some attention amongst the medical profession in America and Australia. carpus elongatus, or Cape Yew, described as a "fast growing tree, suitable for the higher lands, and yielding excellent timber known as the Cape or Yellow Wood." Melhania erythroxylon, or Red Wood of St. Helena, a handsome tree of 20 feet high, the flowers ol which are large and pure white when they first appear, but change after a day to pink and then to a brownish red, the tree bearing flowers of all three colours at the same time. The wood is extremely hard and of a rich brown colour. "As one of the fast disappearing indigenous plants of St. Helena, Mr. MORRIS says, "this is a very interesting tree, and its naturalisation in Jamaica would be an event of considerable botanic and economic interest." Aberia caffra or Kei Apple, a plant of the Cape of Good Hope has a fruit about the size of a small Apple, of a yellow colour, used for making preserves; the plant is moreover valuable for making feaces, in consequence of its being covered with hard, stiff spines. The above are only a few of the plants enumerated by Mr. Morkis, and amongst those of more generally acknowledged economic value we may mention the Olive (Olea europea), and Cork Oak (Quercus subert); of this latter a few Acorns were obtained, which are stated to be likely to grow. The tree on the higher hill slopes should become common in Jamaica.

— THE COVENT GARDEN LIFEBOAT.—On Taesday night the annual concert in aid of the Covent Garden Lifeboat Fund was given at St. James's Hall, and we are glad to record, first, that there was a good attendance, and, secondly, that the entertainment was of a thoroughly enjoyable character. The Lifeboat sustained by the Fund is stationed at Caister, and has already been the means of saving 195 lives. Since the Fund, of which Mr. James Webber is the Honorary Secretary, has been established, it has paid over to the National Lifeboat Institution nearly \$\frac{7}{2000}\$, independently of the proceeds of Tuesday night's entertainment. As usual, at this concert, the front of the orrchestral platform was decorated with flowers, and, in accordance with a pleasant custom, the committee presented each of the lady soloists with a beautiful bouquet.

- AMPELOPSIS HEDERACEA AND VEITCHII.-How many gardeners increase their stock of this common and useful creeper? Very few, if we may form an opinion from the enormous quantities disposed of by nurserymen. We do not put this plant, nor its ally, Ampelopsis Veitchii, to half as many uses as we might, and that because we do not propagate it in quantity; for beyond covering a piece of wall, or an arbour-although in our climate the arbour is almost out of place, as we want a waterproof covering overhead, and close sides to keep the winds away-we do not find them much employed. The larger growing species make good summer bands or broad margins to walks, and look well all the season, and are wonderfully pretty in autumn. As screens hanging down from a height, in front of carriage portals, or to screen a window or doorway, without being allowed to become attached to the object, they look very well; for such use they need spurring in closely, and almost all annual growth to be cut away at the wioter dressing. A. Veitchii trained round a dwarf pillar of wood, or wire, makes a pretty solitary plant in a hed; but it looks hetter when repeated regularly in a pattern or design of flower-beds. The propagation of A. hederacea is by cuttings, taken off in October. These should be of thoroughly ripe wood of the same year's growth, or of the former year, and should be cut to 15 inches in length. It does not matter if they are cut at a joint or not, as they root from any portion that is below These should be inserted in good but the ground. unmanured ground that has been double-dug, and should enjoy partial shade in a warm position. cuttings will form roots the next year, and will be ready to pot or to plant at wider distances in the nursery in October or later; but they are best in pots, as when left in the ground their roots wander long distances, and can never be got out entire. similar cuttings can be got from A. Veitchii, they can be treated in the foregoing method; but when not, the growing tips can be struck easily in warmth during May and June, and potted off when rooted, or it may be obtained in the open border by layers.

—— CAMPHOR IN INDIA.—In an article on camphor in the Vegetable Materia Medica of Western India, Dr. DYMOCK records a peculiar fact in connection with the resublimation of the article in India. The object of this resublimation, he says, is to get as much interstitial water as possible into the camphor cake. After describing the process, he says, "Camphor sublimed in this way is not stored, but distributed at once to the shopkeepers before it has time to lose weight by drying. It is sold at the same price as the crude article, the refiners' profit being derived from the introduction of the water."

— THE DUTCH HYACINTHS.—A correspondent at Haarlem informs us that the unusually fine weather has brought the Hyacinths into bloom much earlier than usual. They are usually at their best about April 10 or 12, but an inspection from the main roads on the 19th inst. showed them to be almost at

perfection, while the air was laden with itheir perfume, and the various shades of colour were magnificent to behold. The Crocuses are nearly over, and the early single Tulips are coming on to succeed the Hyacinths. Intending visitors should cross over before the end of March to prevent disappointment.

- Ensilage : Spurry (Spergula arvensis). -On Monday night the Prince of WALES presided over a meeting of the Institute of Agriculture at the South Kensington Museum, at which Mr. WOODS, of Merton, delivered a valuable lecture, on the question of "Ensilage: its Influence on British Agriculture. In the course of his remarks, Mr. Woods said that "On light, sandy soils, Spurry (Spergula arvensis) may be profitably cultivated, and an experimental crop grown at Merton, under Lord WALSINGHAM'S direction, yielded a most excellent food for sheep and On 20 acres of blowing sand, so poor in quality that it had seldom produced either corn or roots, and was for the last two or three years abandoned to a state of Nature, Spurry gave 51 tons per acre; the ensilage came out in excellent order, and sheep and cattle fed upon it, mixed with straw-chaff, preferred it to grass ensilage. The trial was so satisfactory that arrangements have been made to seed upwards of 120 acres for the present year." Messrs. JAMES CARTER & Co. ioform us that they have supplied to Mr. WOODS, for Lord WALSINGHAM, seeds of Spergula arvensis to sow 50 acres (at the rate of 14 lb. per acre), and that they will be pleased to answer any enquiries as to this seed.

— THE IMPORTS OF WOOD INTO BREMEN.—
