INDEX OF CONTENTS.

JANUARY TO JUNE, 1884.

ABIES Fortunei, 240, 348, 419; A. no-bilis, 712; A. Nordmanniana, 220 Acacia pulchella, 456 Acanthamentha ilicifolia, 647 Achimenes, the propagation and culture of, 218; in baskets, 384 Acmosporium tricephalum, 317 Adiantum mundulum, 646; A. rhodo-phyllum, 327 Adiantum mundulum, 646; A. rhodo-phyllum, 372.
Acrides Röbelenii, 510; A. Rohania-num, 205; A. Veitchii, 609
Æschynanthus tricolor, 247
Æschynanthus tricolor, 247
Æschynanthus tricolor, 375
Æschynanthus tricolo

Allium neapolitanum, 280; A. oviflorum, 212
Almond, the, 346
Almus cordifolia, 30
Aloes, Socoutine, 775
Alpine Pinks, 808
Alpine Pinks, 808
Alpine plants: the Ranunculus, 284
Alpine Pinks, 808
Alpine plants, 614
Amaryllis belladonna, 646
Amaryllis, Dr. Bonavia on the, 38, 70;
cultural notes on, 286; at Hillingdon
Flace, 278; at Messrs. Veitch, 338;
hybrid, 349; hybrids raised by Messrs.
Veitch, 378; notes on hybrid, 307,
347

347 Amateur, What is an ?, 580, 618, 649, 681 American cut flowers, 86; forests, 812 American, West, forest trees, 668 Ampelopsis hederacea and A. Veitchii,

Americani, 11-43

A. Vervaeneanum, 693; new hybrid, 516
A. Vervaeneanum, 693; new hybrid, 516
Antirihinums, notes on, 800
Ants in houses, 752; in Trinidad, 280
dous gracillima, 668
Apple, the American Summering, 21, 89, 153; Golden Spire, 80, 316; Herefordshire Beefing, 283; Landsberger
Reinette, 372; Reinette Rouge Etoilé, 523; Royal Russet, 523
Apple trade in Nova Sentia, 808
Apple tree, a large, 251
Apples and Pears in the Carse of Gowrie, 639
Apples and Pears in the Carse of Gowrie, 639
Apples, and Pears in the Carse of Gowrie, 639
Apples, and Pears in the Carse of Gowrie, 639
Apples, and Pears in the Carse of Gowrie, 639
Apples, and Pears in the Carse of Gowrie, 639
Apples, and Pears in the Carse of Gowrie, 639

639 Apples, the cause of distortion in, 312; cracking, 349; Russian, 582; notes on the, 285; in Northern France, 646 Appropriateness, beauty of, 84, 152 Apricots, French, 108

Aquilegia glandulosa, 807 Aralias, the culture and propagation of, Araucaria imbricata, 481, 523; height of, 712 Arboretum, the, 21, 49, 411, 454 Arctostaphylos alpina, 183 Ardisia japonica, 280 Arpophyllum giganteum, 770 Arpopnyium grganceim, 770
Artotrogis, 544
Arundina bambusifolia, 674
Ascott, flowers for cutting at, 833
Asparagus Kale, 456
Asparagus plumosus nanus, 550
Asplenium adiantum nigrum var. caudi-Asplenium adiantum nigrum var. caudi-folium, 185 Asam tools, 490 Astragalas Bigelowii, 278 Astraprae Wallichii, 119 Aubrietias, 178 Aubrietias, nates on, 412 Auriculas, 386, 583; alpine, 647, 800; notes on new, 555 Azalea indica at South Kensington, 487 Azalea obtusa, 412; A. sinensis, 639 Azara nicrophylla, 242, 282

BACTERIA again, 345
Balantium antarcticum, 182
Baptisa lupinoides, 827
Barberry and Wheat mildew, 767
Barnda, a new garden at, 318, 800
Barya aurantiaca on ergot, 176
Baskets, flower, 552, 618
Batatas paniculata, 247
Banhinia purpurea, 380
Bean Æcidium, the, 490
Beans, Broad, 46
Bearberry, the black, 183
Bedding, winter, at Halton, 142
Bees and intercrossing of species, 456, 489; and their relations to fruit and flowering plants, 522, 586; duration ot life in, 80

nowering pants, 522, 500; duration of life in, 80 Begonia Lubbersi, 452; B. Lyncheana, 774; B. manicata, 314; B. Rex var. Comtesse Louisa Frdódy, 517 Begonias, Messrs. Laing'is, 445 Bejjerinck, Dr., on gumming in fruit trees,

238
238
Belgian Campine, Conifers in the, 217
Belgian Campine, Conifers in the, 217
Belgian history, a little bit of, 244
Belrath Bury, the garden at, 476
Berberis aristata, 21; B. Darwinii, 452;
B. hybrida antumnalis, 670; B. Thunbergi, 345
Bessera elegans, 177
Biennials, notes on, 480
Biota orientalis pygmea, 381
Birds and Peas; a curious fact, 349
Birds: a plea for mercy, 584
Blackthorn, the, 486
Blechnum rugosum, 408 Blackthorn, the, 486 Blechnum rugosum, 498 Bodnant Hall, the gardens at, 207 Bochmeria nivea, 20 Bogotá, and how to get there, 778, 830 Boiler accident at Harefield Grave, 54 Boleyn Nursery, Upton, the, 382 Bomarea conferta, 516

Books:—Antoine's Atlas zur Phyto-Icon-ographie de Bromeliaceen, &c., 245, 610; Baillon's Traité de Botanique Médicale Phanérogamique, 776; Baltet's Fruit

Borneo, vegetable products of, 745 Boronia megastignia, 174 Botanical excursion, a, 766 Botanical ammes, 774
Botanic gardens, Dijon, 87; Glasgow, 265; Nelbourne, 286
Bongainvilleas, 5414; note on, 619; at Mentone, 672
Bouquet, a vegetable, 417
Bowenia spectabilis, 88
Box and Ity propagation, 184
Bramble, rooting terminal buds of the, 56, co

50, 50 Brisbane, Queensland, 544 Bristol House, Putney, 47 British Epiphytal Orchids, 144 British Ferns, a plea for, 281, 349, 383; and their varieties, 680, 712

British Ferns, a pice tos, 2017, 397, 397, and their varieties, 680, 712
British Honduras, 631
British Honduras, 631
British Honduras, 631
Brocadlands, market gardening at, 11
Broccoli, Late Queen, 50; Sander's
Autumn Mammoth, 111; sprouting, 456
Brockhurst, notes from, 542
Brockirea congesta, 827
Bromeliads, 88, 214
Brownea, a new, 647
Brugnon Nectarine, 522
Brussels Sprouts, 138, 216, 246
Bulb culture at Mentone, 672
Bulb s, Dutch, and Phylloxera, 214
Bull's, Mr., nursery, notes from, 247
Bunt spores, germination of, 420
Bunyard & Co.'s nursery, Maidstone, 768
Burnham Common, planting, 646
Butter, Kokum, 320

С

CABBAGE, caterpillar, the, 777
Cabbage, Ellam's Dwarf Spring, 488, 552; Early Heartwell, 712
Cabbage worms, 216
Cabbages, early, 650; spring, 586; notes on, 679

Caladinus, on the propagation and cul-

Catadinins, on the propagation and enture of, 47
Calamander wood, 246
Calanthe porphyrea, 76; C. proboscidea, 476; C. Regnieri, 411; C. Sandhurstianax, so; C. verattifolia, 609; C. vestta Williamshi, 514
Calcolaria, herbaccous, 646; at Read-

Calcolarias, herbaceous, 646; at Reading, 709.
California, Truffles in, 832.
Calcohortus Benthami, 574.
Calopogon multiflorus, 338.
Camelha Donckelant, 120; C. M. Raymond Lemoinier, 280.
Camellias at South Kensington, 214; outdoor, 306; on propagating, 373.
single-flowered at Kew, 433.
Camphor in India, 38;
Campanda, farmers' prospects in, 251.
Canarian Campanula, 103.
Candyfuffs, notes on, 710.
Canker in fruit trees, 132, 185, 216, 312; in Apple trees, 509.

Canker in fruit trees, 132, 185, 216, 312; in Apple trees, 505
Canna Liliillora, 479
Canterbury Bells, 834
Cape Bulls, 531
Cape Gladioli, hybrid, 476
Caragana arborescens, 240
Cardmine rotundifolia, 380
Carmichelia, new species of, 512
Carmations and Picotees, 286, 583
Carnations, new tree, 647; seedling, 710; at Tring Park, 606; at Messrs, Veijeli's nursery, 737
Carnivorous plants, 775
Carpets for trees, 122
Carrots, early frame, 79
Carse of Gowrie, Apples and Pears in the, 653

Caryopteris mastachanthus, 148

639
Caryopteris mastachanthus, 148
Catalpa, the golden, 21, 49
Catalpa, the solden, 21, 49
Catalpa trees in New South Wales, 646
Catalpas, golden and other, 80
Catleya Caskelliana, 82; C. labiata Percivaliana, 770; C. luteola, 16; C. Mendelli, 609; C. Mossate Hardyana, 310; C. M. reticulata, 641; C. Fyreivaliana, 18, 82, 178; C. Reineckiana superbissima, 600; C. Skinnerii, 548; C. species from Popayan, 50; C. speciosisima regina, 372; C. Titane var. Emiliee, 342; C. T. Var. Leeena, 411; C. T. Massangeana, 178; Popayau varieties, 243, 377, 448;
Cattleya-house, Mr. Lee's, 676; Messrs Veitch's new, 768
Cattleyas, Mr. Lee's tollection of, 271
Cathiliower, Snow ball, 50
Ceanonium vehicular, 736
Cetter, Colonel Clarke's red, 50, 90, 111; the White Planne, 78
Cephaletaxus Fortunei and C. pedunculata, 113
Creaus Fisendo-Cerassus, 256

Cephaletaxus Fortunei and C. peduneu-lato, 113 Cerasus Fseudo-Cerasus, 276 Ceylon Botanic Gardens, 177; report for 1883, 781 Ceylon in 1833, 418 Ceylon fin 1833, 418 Ceylon finits, a chat abnut, 550 Chameedorea scandens, 183 Charcool, the use of, 314 Chatsworth, 244 Chemistry, agricultural, 612 Cherries, double flowering, 550 Cherry, the Cornellan, 175

"Chick "house, on Human Cardian Chinase vegetable products, 7,44 Chionodoxa Lucilire, 383, 419 Chiosya ternata, 20, 226, 646 Christmas Roses, 76 Christmas Roses, 51 Bridgid's, 78 Chrysanthemum Ceres, 140; Meg Merrilies, 22, 90; segetum, 807, 835 Chrysanthemum, the, 344; "at home," 54; late flowering, 278, 86; a15; prematurely flowering, 778, 8tr.; stimutants for, 522 lants for, 522 Chrysanthemum Society, the National,

614

614 Chrysanthemums, annual, 582; culture, 56 Cinchona cultivation, 119 Cinchonas in the Nilgiris, 183 Cineraria, what is to be the future of the?

HARRISONS' NEW EARLY "ECLIPSE"

A grand new Early Pea, introduced by us last season,

The haulm is of a peculiar light green colour, only a feet in height, the pods of a lively green and well filled, and is the heaviest cropper for an early variety we have ever seen. The seed is blue and similar in appearance to the "Kentish Invicta," but it is hardier and even earlier than that excellent variety,

Retail Price-Per Pint, 1s. 6d.; per Quart, 2s. 6d. Trade Price-Per doz. Pints, 12s.; per doz Quarts, 21s.

TESTIMONIALS.

Prom Mr. John Swift, Manchester. "October 24, 1883.—I consider your New Early Eclipse Pea to be the best early Pea I have ever grown, both for earliness, size of pods, and appearance."

From Messrs. Taber & Cullen, Rivenhall.
"October 25, 1883.—The New Pea, 'Early Eclipse,' we had
from you last season is a good early blue, and valuable for
podding, all coming in together."

Pounney, an coming in together.

From Mr. Samuell Taylor, Pershore.

"October 23, 1832.—I found your New Early Eclipse Peaver early and profile. Sown by the side of Kentish Invicta, they were ready to pick nearly a week before that variety, and I picked nearly 4 pots (40th, per pai) off the little patch of ground, and had &s. per pot for them; when the other early ones were ready the picke had dropped to 5x. I hope you will be able to spare the 4 bushels I spoke for in the summer."

"October 38, 1883.—Your New Early Eclipse Pen is the best early Pea I even had, it is a good cropper, very early, and gave me every satisfaction. I hope those you have sent me will prove as good."

"July 5, 1883.—I find your New Early Eclipse Pea an early and good cropping variety. When you are quoting the price per bushel for the coming year, I should like a quarters of the same stock of Pea."

The above Testimonials are only a few from the large number we have received.

CONSERVATORIES, VINERIES, ORCHID and PLANT HOUSES, &c. HOT-WATER APPARATUS for all purposes.

BOILERS and HOT-WATER CASTINGS of all kinds kept in Stock. BOILERS SET on the shortest notice by experienced workmen.

ABUNDANCE

We have much pleasure in introducing to your notice Messrs. BLISS & SON'S, of New York, NEW PEA, which bids fair to rival in popularity the "AMERICAN WONDER" introduced by the same firm.

Height, 15 to 18 inches; large dark green foliage. Pods 3½ in. long, containing six to eight large Peas of excellent quality. Second early, ripening one week after the earliest kinds. The most striking feature is its remost striking leature is to markable tendency for branch-ing directly from the roots, form-ing a veritable bush. Many ing a veritable bush, Many plants throw out six and more branches, each of which becomes literally covered with blossoms and pods in such abundance that the quantity produced by each would be considered a bountiful yield for an entire plant of many of the older varieties. Owing to this habit it should not stand closer than 6 inches apart in the rows, requiring only one-third the seed usually sown to produce the same result.

HALF-PINTS, SEALED, 2s. 6d. each.

×

BUSS'S SINGLE PLANT ABUNDANCE PEA FROM A PHOTOGRAPH

This sketch may appear exaggerated, but Messrs. Bliss have forwarded us a sample Vine, which, although damaged in transit, even now shows 67 pods, and they assure us that some have borne over 100.

They thought so highly of this Pea, that they paid at the rate of £200, or One Thousand Dollars, per Bushel for the Stock Seed.

LANE, LONDON, W.C. MARTIN'S 85, ST.

ARTHUR

THE COVENT GARDEN BOILER.

This new Wrought Welded Amateurs' Boiler is intended for fixing flush in the wall of the greenhouse, the feeding door and flue pipe being left on the outside. A considerable amount of heat which is lost with other Boilers is thus given off into the house—a great advantage; and the necessity of a stoking-hole is thus dispensed with. The Boiler is strong, durable, and cheap, and we can thoroughly recommend it.

arge and Small Hot-water Apparatus erected complete in Town or Country, or Materials only supplied. HILL

VERY SPECIAL NOTE.

Our Establishment is open at 6 o'Clock every Our Establishment is open at 6 o'Clock every Tuesday, Thursday and Saturday Morning, for the Special Convenience of Nurserymenand others who come to Covent Garden. Customers are thus enabled to take back in their empty vans any goods they may require, and save cost of extra cartage from the City, or Rail Carriage and Breakage. By this means we are able to sell at more favour-able prices than any House in the Trade.

Novelties in Seeds for 1884,

POST-FREE.

The undermentioned Novelties are now being offered for the first time, and are far in advance of anything hitherto

CYCLAMEN GIGANTEUM ROSEUM (New).

A spleadid variety, of compact habit, with magnificent flowers of a high rose colour, havong a dark crimson eye. The effect formed, withis variety is interspersed amongst the other varieties, is very telling. No collection should be without it. Sold only in sealed packets bearing my trade math.

Per Packet, 3s. 6d. and 5s.

CYCLAMEN PERSICUM CRIMSON KING (New).

This beautiful new ariety belongs to the persicum type, but it is the representative of a great advance and improvement in this type. It produces its flowers in great profusion, which are of a very brilliant crimson colour, deepening at the base to a very dark red. This gives the plate a very effective appearance. The foliage is very beautifully marked, and the plate it are marked, and the plate it are marked, and the plate it are produced to the plate it are plate in the plate it are produced to the plate it are plate in the plate in the plate it are plate in the plate in the plate in the plate it are plate in the plate i

DIANTHUS CHINENSIS HEDDE-WIGII BRILLIANT (New).

A new and very fine variety, producing large, stont, rich-coloured flowers of an intense crimson, extremely showy in the sunshine; most effective in the open border; dwarf habit, very free and continuous blooming. Sold only in sealed packets bearing my trade mark.

Per Packet, 1s. 6d.

LUCULIA GRATISSIMA.

HAVID JAN TECHNOLOGY THE MANUTE STATEMENT AND THE MANUTE STATEMENT AND

PRIMULA SINENSIS FIMBRI-ATA ROSE QUEEN (New).

A very effective and distinct variety. The flowers, which are produced on stout dwarf spikes, are large and of good substance, of a bright row, public colour, and are carried well above the foliage. The foliage of th

MELON BASING PARK HYBRID (New).

This new Hybrid Melon is a fine Scarlet-fleshed variety, of round shape, and heautifully netted, with deep flesh, highly coloured, and of fine flavour. It is a free setter, very early, prolific, and hardy. It keeps a long time after being cut.

Per Packet, 2s. 5 dis.**

TOMATO WILLIAMS' NE PLUS ULTRA (New),

This new and valuable variety is one of the finest and best ever introduced. It is a very vigorous grower, and produces a heavy crop of handsome fivit, which are very even, and attain a large size. The skin is very smooth, and the flesh solid, of the flavour, and deeper in colour than any other variety. It is sure to commend itself to horizout the control of the c

THE OUEEN'S SEEDSMEN, READING.

Gardeners' Chronicle.

SATURDAY, JANUARY 5, 1884.

THE NEW PLANTS OF 1883.

NE of the many signs of the advance of horticulture, and one which affords a pretty good test of its reality, is the constant influx of novelties, since they, of course, come in obedience to the law of demand and supply. Year after year our enterprising nurserymenimporters are chiefly traders now-find it to answer their purpose to have novelties to offer, and always at considerable cost, sometimes also at great risk to the agents employed, they continue to get them. If there were no spirited patrons of gardening pursuits, and horticulture were in a quiescent state, this would not be so; hence it is always a satisfaction to us to have a well filled muster-roll of new plants of the year, these being the class of novelties with which we have here more particularly to deal, and we think those of 1883 will bear favourable comparison with those of most of its predecessors. We shall commence our summary notice of the more important acquisitions of the year with the aristocracy of the floral kingdom-

THE ORCHIDS.

There is no hesitation about what plant is to occupy the premier position-the post of honour. By universal consent it would be accorded to Vanda Sanderiana (Gardeners' Chronicle, xx., 440, figs. 67,68), which has bloomed in this country since our reference to it twelve months ago, and which Professor Reichenbach has described in our pages as "the grandest novelty introduced for years"—an opinion which those who have seen its gorgeous blossoms will endorse, and those who have not seen will assent to as soon as the opportunity of doing so offers. Imagine a dense branched tuft of an evergreen epiphyte, with the usual recurved, channeled, obliquelytipped leaves of a Vanda, and from their axils the racemes of 8-12 flowers, each measuring nearly 5 inches across, the flowers flat, in the way of those of Odontoglossum vexillarium, and the upper sepal and the upper half of the petals of the same bluish-pink colour, while the larger lower sepals are of a bright greenish-yellow, longitudinally and transversely marked with crimson-red lines, forming a close squarish series of reticulations; the small brownish-crimson recurved lip serves as a foil to the other colours. This plant, which comes from the Philippine Islands, and was first flowered in Europe by W. Lee, Esq., will not easily be dethroned from its A 1 position. Another handsome form of the same genus, Vanda suavis Schröderiana, has made its appearance; it differs from the type, which is one of our finest Eastern Orchids, by having the sepals and petals of a pure unspotted lemon-yellow, and the lip and column pure white; and this is an abundantly distinct and a charmingly beautiful addition to our collections. A very high position must be given to Acrides Lawrencie, a grand new Eastern form, related to A. odoratum, and for the original plant of which the sum of 235 guineas was obtained, at a public auction sale. It produces long racemes of thirty or more levely blossoms as long as those of A. crispum, white changing to yellowish, and tipped with rosy-purple, the sepals and petals being cuneate-oblong, the lip with high oblong-dolabriform side to lobes, and the centre lobe with two purple lines running back to the mouth of the conical incurved spur. The name is given in compliment to Lady

Phalænopsis Sanderiana hears a very high character, and is no doubt a very fine thing. is intermediate between that of P. amabilis and P. Schilleriana, and the plant has elongate-oblong green or mottled leaves and panicled flowers, roundish in outline, 4 inches in diameter, the sepals and petals varying in different forms from whitish-rose to rosepurple, the lip white stained with yellow, and marked with cinnamon or purple stripes, and its tendrils assuming an anchor-like form. It appears to have been first flowered by Sir N. M. de Rothschild, having been introduced from the East by Messrs. Sander & Co. P. lencorrhoda alba is a chaste and delicate form of this rare species, which has slightly mottled oblong leaves and drooping spikes of handsome flowers, which are of a pure white, except that the lower side of the base of the sepals is spotted with purple, and the upper side of the lateral lobes of the lip marked with dots and streaks of a deeper rosy-purple; the cirrhi of the lip are prominently developed. It won for Messrs. Low class Certificate in the early part of last year, when exhibited at South Kensington.

Turning to another magnificent group-the Cattleyas-we find several additions and acquisitions. First, there is Cattleya nobilior (fig. 120, p. 729 of our last volume), a dwarf species allied to C. Walkeriana, but larger flowered; the flowers of a hright magenta-rose colour, the lip white on the throat and disc, with the front lobe edged and tipped with rose. This Brazilian plant was introduced through the Compagnie Continentale d'Horticulture. Then Mr. Beckett's C. superha splendens is a plant of extraordinary heauty, its colours being intensely rich deep rosy-purple, with a lip of rosyviolet, flushed with maroon, and having a velvety lustre on the surface, which adds very much to its attractiveness. The C. Sanderiana referred to last year appears to be a form of C. gigas-C. gigas Sanderiana-and is a superh form, the glowing purple of the lip, and the contrast with the two well defined yellow blotches towards the mouth of the tube being most effective. Other fine Cattleyas which have been offered during the year are-C. Trianæ formosa, C. Mendelii selbornensis, C. Warneri sudburyensis, and C. Mossiæ Hardyana, the latter a beautifully striate or mottled flower, which has proved to be constant in the production of its curious streaked or particoloured flowers. Our French neighbours are beginning to turn their attention to the cross-breeding of Orchids, and a very pretty hybrid, named C. calummata (not calumniata), recently figured in the Revue Horticole, has been obtained by M. A. Bleu by crossing C. amethystina with C. Aclandiæ (not Acklandiæ, as often written). It is of dwarfish habit, with rather large flowers resembliog Aclandiæ in form, the sepals and petals white, slightly flushed with pink and green, and heavily spotted with violet, the lip with the lateral lobes white and spreading, and the prominent wedge-shaped middle lobe of a rich velvety purple-crimson.

Amongst the Lælias we have the delicate and charming L. amanda, with large pallid blush flowers traversed by purple veios, the lip being more heavily marked, and having the few stronger central veins parallel, the rest being divergent, and variously netted, and extended to the crispulate margin. L. Wyattiana, a lovely Orchid, was imported with a batch of the short-bulbed form of L. purpursata; it has large flowers, with the sepals and petals white, and the lip fredy undulated in front, with its lateral lobes light yellow, and its front lobe of a fine light purple, veined with dark purple. Then we have the L. anceps Hilliana, which has pure white sepals and petals, the lip light purple and bliobed in the anterior part, marked with strong radiating veins, and a hright orange disc, and is a charming variety, disputing the palm for heauty with the superb anceps Dawsoni itself.

To another popular group, the Masdevallias, but few additions of importance have been made, and these rather in the form of new varieties than of species. One, however, M. Schlimii, which has been flowered in this country by Sir Trevor Lawrence, appears to he an exception, being regarded even in the imperfect manner in which it has as yet bloomed, as a promising plant, and having won its First-class Certificate. The leaves in the wild specimen exceed a foot in length, and the plant produces a raceme of six or eight flowers, which issue one above the other from sheathing bracts; the flowers have a short cup, with spreading sepals, the two lower oblong, the upper shorter, all having loog yellow tails, and the broader

portions being yellow, closely dotted over with fine reddish-brown spots, while the petals and column are white, and the lip yellow. The brilliant M. Harryana, which is very prolific of varieties, affords two splendid and distinct forms in M. H. atrosanguinea and M. H. miniata; the former is of a glowing tiot of crimson flushed, with magenta, which being well contrasted with the orange-yellow of the tube, is very charming. Not a whit less charming is the latter, which has flowers of a bright vermilion-red flushed with scarlet, the orange-yellow tube here also forming a yellow eye to the bright and beautiful flowers.

Of the favourite and deservedly favoured Odontoglossum crispum (Alexandræ) heautifully spotted forms continue to appear, some of the districts ransacked for them appearing to yield a hetter class of forms than others. One of the grandest spotted forms is that called O. crispum Cooksoni, on which the flowers are spotted throughout with hold blotches of rich dark brown, the colour forming a strong contrast to that of A. crispum Stevensii in which the spotting, though ahundant, is of a very pale hue of brown. O. crispum Marianæ, and O. crispum reginæ are two other splendidly spotted sorts. Some forms of this species, possibly hybridised forms, are giving us an approach to a yellow ground colour; of these, O. crispum aureum magnificum, and O. crispum Scottii, with noble flowers having a creamy-yellow ground, have been exhibited. In some cases, doubtless, this yellowish hue is due to the stage of development at which the flower has arrived. O. Pescatorei is also yielding some strikingly handsome varieties. Besides the charming O. P. Veitchianum noticed last year, we have now an O. P. aurantiacum in which the yellow at the hase of the lip is replaced by deep orange; and an Schröderianum, which is in the way of Veitchianum, and scarcely second to it in beauty, but which differs in having the markings of a more decided purple hue, and not extended so far over the segments of the perianth. A new and handsome Odontoglot is O. eugenes, which is supposed to be a natural hybrid between O. Pescatorei and O. triumphans, and in which the sepals and petals are orange-yellow, spotted with chestnut-brown, the lip being white, spotted with brown, and having a yellow blotch on the disc; it is a New Grenadan plant, which has found its way into the now famous collection at Trentham.

A splendid form of Oncidium Papilio, named Eckhardti, with flowers which in their size are very much beyond those of the ordinary type—twice the size—and which are consequently much more showy and attractive, has been figured recently in the Illustration Horticole. In this new form the three erect narrow linear sepals, 5 inches in length, and the lip 2½ inches broad, clear yellow in the centre, with a half inch border of bright brownish-red, are very attractive features of the flower.

Of Dendrohes we may particularise Dendrohium Wardianum giganteum, which is remarkable alike for its bold habit of growth and its enormous and richly-coloured flowers; and we must note of the more recently introduced species, D. Dearil, that it is of very free-blooming habit, with largish white flowers, marked only by a small green spot in the centre; it is an Orchid which, as it becomes better known, will certainly become more popular, as it is proving itself to be more useful. This is naturally a white-flowered species, but it is singular to notice that white-flowered varieties of many choice Orchids are turning up, sometimes where least expected, and they are always great favourites with cultivators, who seem to be fascinated by the delicacy of their flowers.

We have two or three new Calanthes of considerable merit with which to credit the past year. They have come from Cochin China, and are nearly allied to C. vestita, if indeed they should not be regarded as varieties of that highly ornamental plant, which they also resemble in flowering from the leafless pseudobulbs, and in their tall bracteate many-flowered erect or nodding scapes. In C. Regnieri the flowers are about 2 inches across, with the sepals white, the petals white, with a faint rosy central stripe, and the three-lobed lip, the front lobe of which is emarginate, of a lovely rose-pink, having a deep crimson central spot. In C. Stevensii the sepals, petals, and lip are all white, the latter marked by a rosy-purple central In C. Williamsii, a new introduction, the dorsal sepal is white, the base of the lateral ones white on the upper side, and pinkish-rose on the lower; the petals are white, hordered with rosy-pink, and pencilled with the same colour in the lower half, and the lip is entirely of a deep rose-colour, with the discal region of a much deeper rose.

Perhaps there is no more remarkable species to be recorded than Paphinia grandis, the flowers of which, naturally spreading out, measure 7 inches both in width and depth; the sepals and petals are $3\frac{1}{2}$ inches long, and 1½ inch broad; the dorsal sepal, which is oblong-lanceolate, has the lower half yellowish-white, with narrow, irregular, transverse bands of chocolatepurple, the upper part being wholly of this chocolatepurple hue; the lateral sepals are subfalcate, and marked in a similar way, but less fully, and less regularly handed; the ovate acuminate petals are narrowed to the base, and marked like the dorsal sepal, except that the hands are more concentric, and are small at the base, larger upwards; the lip is most oddly shaped, having a blackish-purple claw, attached to a cordate disc of lighter chocolate colour, with a cream coloured centre, the point of the heart forming another narrowed isthmus, beyond which are two spreading recurved filiform lohes of blackish-purple, and beyond all a roundish creamy white terminal lohe, which is covered with thread-like processes. Its gigantic size and the remarkable form of its lip mark this out as a flower never to he forgotten. Not quite so pro-digious, but reaching an expansion of 5½ inches, is the Batemannia Wallisii major, as flowered for the first time by Sir T. Lawrence, so that the chances are that when better established it may more closely rival the Paphinia. In this Batemannia the sepals are ovatelanceolate, acuminate, of a rich reddish-brown, fleshy, with a surface appearing to he tessellated from its veiny-like unevenness; the petals are similar in colour, white at the base, with a central white spot on each side of the column; the lip is ovate-acuminate, appearing of a darker brown from its reticulate markings of blackish-purple, and it has a claw onefourth of an inch long, hearing in front an erect crest of numerous white filamentous processes. Anguloa eburnea is another novelty amongst the large-flowered sorts; it is in the way of A. Clowesii, but white-flowered instead of yellow, and was important enough to win a First-class Certificate in September last at South Kensington. Lycaste Harrisoniæ eburnea is an Orchid likely to find favour with growers, its ivory-white waxy flowers showing out very distinctly. They are of the typical form, full-sized, the sepals and petals white, and the erect lateral lohes of the lip yellow, closely veined with forked lines of reddish-purple, the front lobe being white, with a few finer purple veins at the It is a really good thing, and quite different from Lycaste Harrisoniæ alba.

We had intended to have said a few words in commendation of Messrs. Veitch's splendid new hybrid Cypripediums of which C. Seden is the parent, three of which were shown at a recent meeting at South Kensington, and carried first-class awards by acclamation. We allude to C. cardinale, C. calurum, and C. Schüderæ. Mr. O'Brien has, however, treated of them so effectually in a recent number, that to economise space we here forbear. We however endorse every word he has written in their praise. They are a wonderful advance over any of the natural forms known, and show at how great an advantage the cultivator who has the riches of our Orchid-houses to draw upon works in the modern creation of new species, for, for aught we know, they may prove to be as good species as nine-tenths, if not ten-tenths of those which are concocted by herbatum botanists.

We must not close these notes on new Orchids without referring to two magnificently cultivated examples of an old one which have bloomed during the past year. We allude (1) to the specimen of Renanthera (Vaada) Lowii bloomed by M. Bergman, in the collection of Baron Rothschild at Ferrières, which had eleven flower-stems, giving a total length of 110 feet, and bearing 280 blossoms (see p. 656 of our last volume); and (2) to that bloomed by M. Skope e at Pechau, in the collection of Baron Hruby, which bore twenty-two spikes of its very remarkable blossoms. T. Moore.

(To be continued.)

BEDDING SANIFAGES AT CHISWICK.— Some of the close-growing species and varieties at Chiswick are very effective just now, presenting cheerful patches of bright green colour, clothing the grey rockwork at the west end of the large vinery. There are several forms, all close-growing and spreading. They have two seasons of acceptable service—when they are in flower, and in winter, when their foliage is pleasant to the eye.

New Handen Plants.

ODONTOGLOSSUM DORMANIANUM, n. sp.*

FOR a long while I have been puzzled by this plant which stands as a kind of connecting link between the old Odontoglossums crocidipterum, blandum, and nævium, Rchb. f., that neogranadian fine type with the clearest colours, the single raceme, the velvety lip with the two calli usually with the longest tooth in front. Dr. Lindley's nævium is a mixture of gloriosum, my nævium, and Oncidium nigratum. The bulbs and leaves appear to afford good characters. I have my reasons for believing more in the leaves than in the bulbs. The leaves of Odontoglossum Dormanianum are always very narrow and short, those of O. crocidipterum are much longer and broader. The bulbs appear very distinct. The bulb of Odontoglossum crocidipterum is oblong, blunt, ancipitous, narrower at the top, with few furrows, and several transverse impressions, which are deeper, but smaller, than those which we know in Odon toglossum nævium. The typical bulb of Odontoglossum Dormanianum is elliptical, blunt, ancipitous, nearly as wide at the top as at the base, covered with grooves and wrinkles, quite like the margins of certain undulate, marginated, epidermoid cellules. You may discover a very few lurrows, but they are not straight. Mr. Sander sent me quite lately a bulb that is much less wrinkled; is it only a younger one? Mr. Day remarks, in Gardeners' Chronicle, 1871, p. 1129, about Odontoglossum crocidipterum that the bulbs are nearly elliptical, oot tapering to the apex as most do, shorter and rather blunter at the edges than in most other Odontoglots. In age the bulbs shrivel and wrinkle all over irregularly, and never get sulcated in the grooves as the other. Such an acute observer as Mr. Day certainly knew what he wrote about. His peduncle, exactly labelled with "Day, 1871," as well as the leaf, are quite those of Odontoglossum crocidipterum. O. crocidipterum appears to have always a one-sided second raceme, while the inflorescence of our proposed novelty bears its flowers turned to all sides. The flowers of the older species are larger, have narrower and longer sepals and petals, lightest ochre-coloured, usually with sepia-brown spots, a brown tip to the lip, which is yellowish-white at the superior part.

Those organs are far more like those of Odontoglossum nævium and blandum in our novelty. Their colour is usually white, or whitish, rarely of the lightest ochre, and the numerous spots are darker, making a more elegant impression. The base of the lip is in some flowers of the purest yellow, and marked sometimes with a few red stripes. The tip of the lip is usually adorned with a larger blotch. The column is freckled at some places with brown, and the wings of the column, which are less fimbriate than in crocidipterum, are lightest sulphurine. Sepals and petals are shorter and broader than in Odontoglossum crocidipterum. I have a wild specimen of this from Mr. Sander, and a wild crocidipterum from poor Bruchmuller.

My ardent wish to see fresh materials of Odontoglossum crocidipterum for comparison was most liberally fulfilled by Sir Trevor Lawrence, who sent me a fresh bulb with leaves, and a fine inflorescence of his "best varieties," so that there would appear to be various varieties at Box Hill. If I remember well I had two or three times a variety with very pallid blotches.

The species is dedicated to Mr. C. Dorman, The Firs, Lawrie Park, Sydenham, London, S.E., one of our most iotelligent and ardent orchidists, and my excellent correspondent. H. G. Rehb, f.

OBERONIA CYLINDRICA, Lindl,

A very fine specimen, a well-grown plant, was kindly sent by Mr. O. O. Wrigley, Bridge Hall, Bury, Lancashire, imported from Manilla. I believe it has not been seen alive in Europe since 1840, when it

flowered at Hackney, imported from Manilla by Messrs. Loddiges, and described by Dr. Lindley in Bot. Reg. 1840, Misc. 23, p. 20.

It is interesting to see that the original note has some superiority over what is said in Folixa Orchidacca, viiii., Oberonia No. 2. "Bracteis serratis" being much better expressed by "bracteis subcilitatis." A very just remark of Dr. Lindley, omitted in Folia, is this:—"Each flower appears to consist of a labellum only, the sepals and petals being so closely turned back as to be unobserved until carefully looked for." The inflorescence is bent down, just as in Dr. Lindley's herbarium specimen. This may be typical. H. G. Rohb. f.

ISMENE ANDREANA, Baker.*

This is a very fine new species of Ismeoe, which was discovered by M. Edouard André in his expedition to the Andes in 1876, of which he brought home bulbs which have just flowered in his greenhouse at Lacroix in Touraine. Of species already known the only one that approaches it closely is I. teouifolia, Baker, in Bot. Mag., t. 6397. This has the same slender, one-flowered scape and narrow leaves, but in the present plant the perianth tube, segments and corona are all considerably larger, and the marginal lobes of the corona are much smaller and not toothed. It was found on the banks of the Rio Ambocas, in Ecuador, at an elevation above sea-level of 2500 metres, and bears in M. André's herbarium the number 4546. For drawing up this description M. André has kindly sent me not only the flower and leaves of the cultivated plant, but also his two original wild examples, with the notes he made from the fresh plant at the time of gathering it.

Bulb as large as an Apple, with pale brown membranous tunics. Leaves several to a stem, cotemporary with the flower, lloear, pale green, glabrous, 12-15 inches long, under I inch broad. Peduncle sleader, one-flowered, shorter than the leaves. Spathevalves three, linear, white, membranous, 2 inches Ovary oblong-trigonous, sessile, 1-3 inch long; perianth-tube green, cylindrical, erect, 41-5 inches long, curved at the top; limb white; segments linear, 31-4 inches long. Corona broadly funnelshaped, nearly 3 inches long, 3-4 inches broad at the throat, white, with green stripes, the marginal processes rounded, not toothed, 1-1 inch long. portion of the filament abruptly reflexed, I inch long; anthers yellow, linear, versatile, & inch long. Curved style exserted about an inch from the corona, green; stigma capitate. J. G. Baker.

INSTITUTE OF PAINTERS IN OIL COLOURS.

THE first exhibition of the works of this Society is now open in the newly erected building almost oppo-site Burlington House, Piccadilly. There are nearly 800 pictures in the three rooms, and although many of these works are far from being of a high class, yet there are many really fine works upon the walls, and some excellent examples of flower, fruit, and landscape painting. The pictures (as is generally the case in the Academy) are much too crowded, and it is wearisome and painful to pass over the many works which call for no special notice in the search for the more carefully studied and better executed amples. The figure subjects we must pass over with mere mention. There is one small and admirable work by L. Alma-Tadema; another by Mrs. Alma-Tadema; one work by R. W. Macbeth; one by F. Barnard (whose name is omitted in the index of names); two trifles by R. Caldecott; two works by W. Small; one by R. C. Woodville, and various other figure subjects by less known men. The usual imitations of the works of L. Alma-Tadema are on the walls-imitations of Roman people, imitations of imitated marble, imitations of L. Alma-Tadema's classic architecture, furniture, and costume. The difference between the works of the master and his imitators is just as great as between Madame Tussaud's waxworks and Phideas' sculptures on the Parthenon. There is plenty of history belonging to the Saxon, Norman, and Mediæval times of this country, and plenty of architecture, furrilure, and costume available for any artist disposed to strike out in a new line. Every one is satisfied with L. Alma-Tadema's "Rome;" if other artists must give us Romans and Roman things, let them give them according to their own ideas, and not as transparent copies from the one acknowledged great master. H. Fantin, the famous flower painter, is at his best in six Roses and twelve Poppies. These are two of the best examples we have yet seen of this artist's work. Near these pictures are two other works, both of a high class, viz., 4, "Black Diamonds," W. L. Wylie—black coal-barges under a brilliantly coloured sky; and, 7, "Waves Breaking by Moonlight," A. Severn.

Most of the flower subjects in this exhibition are well done; and the "Single Dahlias," 39, by Miss C. M. Parsons, is no exception. "Azaleas," 41, Catherine M. Wood, is also well done. 79, "Empress of India Chrysanthemuns," Charles Low, is also a good picture. 122, "The Daylight Dies," is an excellent picture by the well-known landscape artist, Alfred Parsons. 160, "Roses and Lilles," by Mrs. M. B. Miller, is a good painting of orange-coloured Lilles and Tea-scented Roses contrasted with a plate of deep blue colour. 223, "Marigold and Poppies," is a good work by T. R. Way, 203, "Treasure Trove," Briton Rivière, R.A., is an admirable and dryly humorous picture of 60gs. 598, "Autumn Gatherius," is a good picture of Pomegranate, Pears and Apples with Ivy. 608 is a good work of China Asters, by Adā Bell. 650 is one of Henry Moore's fine works—"Summer-time, Coast of Cornwall."

The gallery will well repay a visit, for there is an unusual number of good flower, garden, and landscape pictures. It would be well if, another season, a smaller number of pictures could be placed upon the walls, the less excellent pictures being altogether elimioated.

A LONDON MARKET GARDEN.

To those interested in gardening pursuits, and others who are not, Covent Garden has always been looked on as one of the sights of London, and this in spite of its ridiculously inadequate accommo-dation, for if there is one place in existence more than another where continually each morning may be seen several thousand people struggling with the impossible task of squeezing four times the amount of material into a given space that the said space can be made to hold, it is Covent Garden Market. Under the disadvantage of a confusion that looks inextricable, with the untold thousands of tons of vegetables and fruit and flowers piled and heaped together in a way that does not admit of half the quantity being noticed, enough is to be seen to excite wonder in the minds of those unacquainted with the market gardens round London as to where it is al Especially is this the case in the spring and summer months during the height of the season, when Rhubarb, Cabbages, Broccoli, Cauliflowers, Peas, Beans, Turnips, Carrots, Lettuce, and salad of all kinds, with Strawberries, Gooseberries, Currants, and other fruit, pour into the market in an endless stream of waggons and vans, that keep up a heavy rumble through the nights on the various roads leading from the country towards London. The vast quantities of garden produce that regularly flow to this centre need excite little surprise when it is remembered that in addition to supplying the 4,000,000 of people within the metropolis no inconsiderable quantity passes through the market to the leading provincial towns.

There is an extensive tract of level land, beginning at Tottenham, and extending through Edmonton and Enfield, in the direction of Waltham and Cheshunt, forming a wide valley, with a deep rich alluvial soil of the right texture, neither too light nor too heavy. Under this, at a depth of 5 or 6 feet, is a thick bed of clean shingly gavel, iosuriog perfect natural drainage, but down to which, from the character of the soil, the water does not pass so quickly as to carry with it the manurial elements from the surface, or to leave it deficient in moisture. The valley collectively may be described as a sort of half farm, half market garden, gradually becoming less of the former and more of the latter. Many of these gardens are of large size, and, as those at all acquainted with market garden work will suppose, very well done. In a well man-

Odnitoglossum Dormanianum, p. sp.—Aff. Odontoglosso occivo, Rchb. f. Pseudobulbo bumii ancipiti elliptico acolato usculo: speame quaquaverso densiusculo: speame servici sepame ancienti sumicio accidita culturio colori speame ancienti sumicio accidita culturio della culturi

aged market garden there is at all seasons of the year something worth seeing, but to give a fair idea of the work carried out, and the crops obtained, perhaps the best time is about the end of June, when these pales were taken.

The late Mr. Mitchell, father of the present owner, Mr. William Mitchell, began at Broadlands about 1839 with some 40 acres, which have from time to time since increased until now there are about 450 acres under cultivation. Some 25 acres are occupied with Pears and Apples, the rows of which stand far enough apart to admit of Gooseberries or Currants being grown between them, with, in some cases, Rhubarb. Of Pears, Williams' Bon Chrétien, Brown Beurré, and Hessle are the principal; Apples are confined mainly to Keswick Codlin, Manx Codlin, Gloria Mundi, and Monster Reinette, the last a large white cooking sort and a good keeper. The Pears were carrying a moderate crop; Apples plentiful. Only one variety of Gooseberry is grown-a large, long fruited, white kind, without a name, that I believe the late Mr. Mitchell picked up many years ago in the West of England. It is a good grower and an enormous bearer; the crop, as well as the Currants, was very

This Gooseberry rarely fails to yield abundantly, appearing to be more hardy than other sorts. Plums to some extent are grown along with the Apples and Pears, and a large breadth alone, except the usual bush fruit: between Victoria and Pond's Seedling are the principal varieties.

Raspberries are largely grown-a prolific red kind that has been long here is the only sort depended on. The land is perfectly adapted to Strawberries. Last year 27 acres were in bearing, consisting nearly all of one sort-Sir Joseph Paxton-which, being a heavy cropper and carrying well, is best liked. The rows are far enough apart to give plenty of room for cleaning and gathering; stable litter used to be employed for mulching, but now clean Barley straw alone is put io. The crop was very heavy. The young plantations of Strawberries are always made amongst Onions, of which there were last year about 20 acres. The Onions (White Port) usually follow Cabbages, the land being ploughed-up deeply in autumn, and left to mellow through the winter. A heavy dressing of manure is then put on and harrowed in and the Onion seed sown broadcast about the end of February or beginning of March, when the Strawberries, consisting of last year's runners, taken up from the bearing beds, are at once planted. Nothing could exceed the promising condition of the long rows of plants through this 20-acre piece. The thinning and weeding of the Onions is done by piece work, £10 per acre being the price paid for the work. The crop this season looked well, but was not quite so even as could have been wished for. Mr. Mitchell grows his own Onion seed, 2 or 3 acres at a time, about every other year.

Of Broad Beans there were some 7 acres by themselves, and nearly the same extent in alternate rows with Peas; the Pea most grown is Laxton's Supreme. The Beans and Peas were as even and fine a crop as could be imagined: the Beans are cleared off as soon as picked, leaving more room for the Peas, the rows of which are about a yard apart. Fifteen acres were occupied with Scarlet Runner Beans in rows a yard asunder: these are grown without sticks, the pnints pinched out so as to keep them dwarf; the plants were strong and vigorous, promising an abundant yield. Near these was a grand piece of Oats, about 15 acres, as free from weeds as the Onion ground; here, also, was about half an acre of Broccoli for seed -Mitchell's Late White, an old, well-known variety, hardy, and in every way a sort that may be depended on. The stumps of this Broccoli that had occupied some 8 acres were just cleared off, and the ground planted with Wallflowers, a noted deep red strain grown here very early. The plants were put in 12 inches apart in the row, and 18 inches between the rows.

At this point were 8 or 10 acres of Rhubarb—Mitchell's Early Albert, an excellent sort raised here, and which has been tried against the different kinds that bave been sent out with a character of being early. Side by side with St. Martin's Early the Albert is eight days in advance—an important consideration in market work. Grey Eagle is here looked on as the best favoured of all the varieties of Rhubarb: it is a medium-sized sort. The Early Albert and Victoria are the kinds grown for early work; some 8 acres are covered early in the winter

with 6 inches of straw, which brings it in considerably sooner than that left uncovered.

Last year's crop of Potatos occupied about 15 acres: Champion, Magnum Bonum, and Schnolmaster, are the sorts grown, and they looked very promising. Great attention is paid to Cabbages, of which there were breadths in various stages in different parts of the grounds; there were dozens of acres without a plant amongst them that was not true to the variety. During the season the crops are gone over, and a selection of the best marked; when cut the stumps are taken up and planted together for seed. About half an acre of these selected stools are grown on for seed each year. In one place a piece of several acres had I een cleared and again planted with Cabbages; these were from spring-sown seed. Another breadth of 14 acres had been put in after winter Tares, and a space something less was in course of being marketed-an even and weighty crop. Each year a piece of from 6 to 8 acres is grown especially so as to be first in the market, which I understand Mr. Mitchell generally succeeds in by as much as two or three weeks. As may be supposed, these are sent in before they are near the size the later crops are let to grow to before cutting, consequently they are planted closer. I understand that a thousand dozen of this early crop goes to one waggonload. I saw about 6 acres the past spring just as they were heading, and they were nearly a month earlier than any met with elsewhere. From this it would be supposed that some variety with a character for extraordinary earliness was grown, but such is not the case, for after trying the various sorts that from time to time have appeared, Enfield Market is the only kind grown. Mr. Mitchell finds that with his time of sowing and after-treatment it will beat any other variety. Sown as early as the Enfield Market the other reputed early sorts would every plant bolt. Six or seven acres of Cos Lettuce, which for weight and the even description of the crop it would be difficult to surpass, were just coming in.

Some 16 acres of Brussels Sprouts, from autumnsown seed, were at this early period 15 inches high. These were intended to come in early in the autumn, and were planted about 2 feet apart in the rows, which were 2 feet 6 inches asunder. Ten or 12 acres of Savoys had been recently planted. About 8 acres of red Clover had just been cut, with more to follow, and 4 or 5 acres of spring Tares—all heavy crops. Another large piece of Tares was following Wallflowers cleared off in spring.

Of Parsley one might have supposed there was enough to furnish sauce, and to do the garnishing, for half London. Some 6 acres are grown in rows between the lines of Gooseberries and Currants that occupy a space in addition to those amongst the larger fruit trees, and 4 acres more in the open. Sage occupies some 2 acres, and a similar extent of Asparagus is grown in rows 3 to 4 feet apart. There is half an acre of Souvenir de Malmaison Rose, and as much of Sénateur Vaisse and Gloire de Dijon, the latter in immense bushes, with stems nearly as thick as a man's wrist, yielding flowers in such size and quantity as I have not before seen equalled.

It must not be supposed that because so few varieties are grown of any particular thing—often, as will be seen, only a single sort—that it is through a partiality for old favourites, or in ignorance of what in the shape of new varieties is in existence, but simply that after all the so-called improved varieties that make their appearance have been tried they are found not equal to the kinds grown.

There are two things apparent in a well managed London market garden—the cleanly condition of the ground, and the immense amount of manure used. Through the large extent of different crops here scarcely a weed was to be seen; everything vegetable way is grown in rows, that admit of horsehoeing, which, so long as a weed appears, is kept constantly going, with hand hoes to finish the work. Manure is used in vast quantities, much of it from the tram stables, where compressed moss is used for bedding the horses; none where sawdust is employed, neither is the sawdust manure liked. But there are other sources from which the most powerful of fertilising materials are obtained. The London police stations supply Mr. Mitchell, by contract, with the carcases of the stray curs that are unfortunate enough to be taken in charge by Her Majesty's representatives of law and order, and which, after their speedy dispatch by strychnine, are carted to Broadlands at the rate of 1000a week (!) during the summer months,

They are put in between thick layers of hot fermenting stable manure, which material is laid thickly round and on the top, so as to keep down the smell that would otherwise arise; here they lie until fully decomposed, when the whole, bones and all, are carted on and plouped into the land.

From what has already been said, it will be seen that horse-power is more used in the cultivation than manual labour; to favour this the land is laid out in long stretches, but, nevertheless, a great deal of hand labour is required, even in picking the various crops. Much of this is done by women, of whom, during the busy season, from fifty to sixty are employed, mostly well trained active hands. The work is nearly all done by the piece; with some kinds of crops the best hands can earn as much as 7s. 6d. per day, working from about five in the morning until six in the evening. T. B.

SEEDSMEN'S NOVELTIES.

EVERY New Year, as our advertising columns show, come long lists of novelties offered in commerce by our enterprising seedsmen, most of whom, possessing that essential business faculty, sharpness, are keenly alive to the necessity of keeping pace, not only with the times, but also with the requirements of horticulture, As regularly also comes from some one or more of the many horticultural growlers or slow-coaches found in life a wail over the additions thus made to our already large lists of garden products, and because there is thus thrown upon these growlers, though only if they please, the necessity of selecting from the apparently enlarged lists the best, they burst out into a bitter cry against novelties. Just as though all things found in a trade list were not novelties at some time or another. Perhaps some of these growlers find in the "novelty lists" useful pegs upon which at a dull season to hang a sermon that might be more correctly described as a snarl. If no one notices their diatribes they have at least been enabled to let off a little spleen, and to pose in their favourite posture as garden purists, However, these individuals are very small fry indeed, and their wails over the formidable expansion of trade lists will be about as impotent as Mrs. Partington's broom. we doubt very much whether seed lists especially are, after all, so very largely growing. 'Tis true, novelties are being constantly added, and we have no doubt in the honest conviction on the part of the vendor that they are distinct improvements upon some older kind. Thus, when old kinds are superseded they die a natural death, and disappear from the lists; whilst if retained it is certain that they are asked for, and therefore are trade pecessities. growler is too apt to think that because he does not want some kind or other no one else does; but those behind the trade scenes know that the diversity of opinion which exists with regard to the merits of this or that kind or sort is remarkable, hardly any two gardeners being of the same mind. Novelties may not always be improvements, though, doubtless, honestly believed to be so; still, many are, as our existing stocks show; for, let the slow-coaches say what they may, we are, in the matter of quality, fertility, and general excellence, in many thiogs miles ahead of the previous generation of gardeners.

DINNER-TABLE DECORATING.

In this, the busy season of hunting and shooting parties, the resources of a great many gardens, and their responsible chief, are frequently taxed to the uttermost, not, it may be said, in one single department, but in all; and in none probably is the strain greater than in the one devoted to the growing of plants, both ornamental - foliaged and flowering - the demand for these, as many of your practical readers are aware, being greater at the present day than at any previous time of their lives. This, we may say, is in the highest degree encouraging, and for more reasons than one, it is sincerely to be hoped such a state of things may be long-lived. The art of table decorating is particularly agreeable and pleasing to the man of refined taste, inasmuch as it affords him an ample supply of healthy food-if we may use the term-for his imaginative faculties to work upon, and presents him with opportunities of expressing himself by deeds (i.e., so far as floral decorating is concerned), much better than he might be able to do orally or in writing.

To excel in the art, two things are absolutely necessary, viz., good taste, and sufficient material to work with; the first of these cannot be acquired by reading, or by attempts to imitate the work of others, neither can we say how it is to be obtained. We can only define it as a gift and an innate quality possessed by some and not by others. As regards material there is an abundance well adapted for the purpose, both of British and exotic. Those who can command a good supply of the latter have undoubtedly a great advantage over those who cannot, for, by its use, the most elegant, chaste, and telling floral effects and combinations are produced, such indeed as cannot be had-no matter how skilful the operator-with our own native plants, notwithstanding the fact that there are many subjects amongst the latter which are well nigh indispensable to a well decorated dinner-table. For convenience we may say there are three distinct systems of table decorating, strictly speaking-viz. (for want of better names), heavy, light, and medium-each of which affords endless scope for enthusiasts in the art to display their taste and abilities. To carry out the first named in its entirety plants, flowering and ornamental-foliaged, must predominate; cut flowers, leaves and grasses answering for the second; whilst the last named is simply a combination of the other two.

The most common plan of employing plants for decorative purposes is that of putting them in vases and other ornaments, singly, and covering over the soil with moss. In many places, it is true, owing to the limited number of plants grown, this is by far the best course to take; but where matters are left to choice more than to force of circumstances, a decided preference should he given for arranging them in pyramidal groups on circular boards, varying in diameter from 12 to 24 inches. When it is men tioned that eleven such groups would be required for a table large enough to dine twenty-four personsthree large ones along the centre, with four of the small ones down each side-it will at once be seen that an extensive and varied collection of plants must be available for the purpose; otherwise such work, owing to the fact of the great majority of plants having to be turned out of their pots, and, in some cases, the roots and soil having to be slightly reduced, would soon tell its own tale, and result in a state of things the reverse of healthful and vigorous. In the arranging and making up of groups, some little tact and skill, as well as taste, are required on the part of the operator, for unless he has previously studied and fully matured his plans, so as to enable him to see the effect and completion of his work in his mind's eye before it has been begun, there will frequently be both loss of time and labour, and much pulling to pieces and putting together again; it therefore becomes a matter of the highest importance, never to attempt the decorating of a dinner-table in a haphazard or chance fashion, but always go to work with a definite object in view: this we would strongly impress upon the minds of beginners.

For the benefit of those who have not hitherto had any experience in this style of decorating, we will arrange a mixed group in writing, so to speak. As a centre plant take some Fern or Palm of graceful habit, say Cocos Weddelliana: this must not exceed in height 3 feet, better 2 feet; next to this place two plants of Dracæna Cooperi, and two Croton angustifolius, with single stems and well coloured foliage, the points of these to lean slightly outwards, securing them in their positions by wedging a little damp moss about their roots. Four flowering plants are now wanted, and may consist of two each of Lycaste Skinneri and Odontoglossum crispum, the spikes of the latter to be tied into their proper position to neat short stakes, the outside row of plants to be of Adiantum cuncatum and panicum variegatum. by arranging a row of Fern fronds round the edge of the board, half their length resting on the cloth. only now remains to be said that all roots and soil must be covered over with a layer of green, neatlooking moss. We have here a group which has taken something over a dozen plants to form, but whatever time and labour have been expended upon it is more than counterbalanced by the grand effect and noble appearance it has when placed in position on the table.

By way of a change—a very necessary and desirable thing in decorating—only one species or variety, as the case may be, should be used in each individual group. Say, for instance, we have a table requiring eleven, the centre one of the three largest

may be made up of Dracæna Cooperi or D. terminalis, and the next two of Croton angustifolius; of the eight small ones four may consist of young plants of Adiantum farleyense, these to be placed at the corners, and the next four, which must be placed midway between the large ones and slightly outside of the same line, may be made up of either scarlet or white Bouvardias, or of some other choice flowering subject. To complete the arrangement, each group-A. farleyense excepted - should be fringed round with either Selaginella Kraussiana or Isolepis gracilis, and round the three large ones eighteen, or say six to each, small globular glasses of cut flowers and leaves may be placed. It seems hardly necessary to add that a dinner-table decorated in this fashion requires, on the part of those who are responsible, an abund ance of time and patience. Moreover, all groups should be made up in the gardens, and taken direct from thence to the dining-room, to avoid making litter and dirt contingent upon such work where i is not wanted. In direct contrast to the above system is that of cut flowers, leaves, and grasses; the latter to be cut late in the summer months, and dried in the sun-Glyceria fluitans, Carex paludosa, Trisetum flavescens, Holcus mollis, Poa pratensis, Phalaris arundinacea, and Bromus sterilis being amongst the most useful for the purpose. For the dressing-up of epergnes, trumpet-shaped glasses, shallow dishes, and other ornaments, no specific rules can be laid down, so much depends upon individual taste, material at hand, and other circumstances. Notwithstanding this fact, however, there is in the minds of many an ideal standard of excellence which is indescribable in

One golden rule to observe, at all events, is, stringently avoid overcrowding, and everything pertaining to stiffness and formality. We have frequently seen epergnes made up with the most chaste and beautiful Orchids and other flowers literally spoiled through this fault alone. Although we write this in condemnation of overcrowding, we would at the same time counsel the inexperienced against the other extreme; it looks equally had to see anything with a niggardly appearance; such work invariably gives one the idea that "you would if you could," and that there is a lack of material at hand. From the foregoing it is obvious that the "happy medium" is the point never to be lost sight of. A due regard to the proper blending of colours must always be borne in mind, and all excesses in the using of Fern fronds dried grasses, and sprays of climbers must be rigor-ously guarded against. It is only by a judicious use of material, so that one kind shall not predominate over the others, that the best results are accomplished.

When cut flowers form the chief feature, a row of highly coloured leaves of Berberis aquifolia or of the common Bramble laid on the cloth in an unbroken line round the table, will be found to add greatly to the effect, so also will Selaginella Kraussiana arranged in the same way round the dessert dishes. The employment of leaves of various kinds in this way has now become very popular in many places, and in our opinion deservedly so. Where decorating is taken up in earnest and carried out thoroughly, a complete set of shallow tin troughs, made of various shapes and sizes, should be looked upon as a sine qua non, These are filled to their rims with moist sand, and dressed with leaves and cut flowers. Trusses of pink and scarlet Pelargoniums are admirably adapted for this purpose, and when the tins are arranged on the table so as to form various geometrical designs-as they always should do-the effect produced is very striking, and the appearance both pleasing and interesting.

As an arrangement of this kind might prove too formal and monotonous for those who are inclined to be fastidious, something by way of a relief should be introduced. This may easily be afforded by placing at a distance of 3 or 4 feet from each other down the middle of the table a few mounds, made up as follows: -On a 24-inch circular board place an inverted 4-inch pot, on this stand a small well-grown plant of some kind with dark coloured foliage-Aralia Veitchii would be a suitable subject. From the edge of the board to the base of the plant fill in with newly gathered green moss, such as may be found growing under trees in almost every plantation; the surface must be made smooth and even, with a gradual slope from top to bottom; face over with Selaginella denticulata, in which arrange a few cut flowers and Maidenhair Fern. Eucharis amazonica and Gar-denias always look well on a green surface, and are eminently suited for this purpose; coloured berries of

various kinds may also be used; hips and haws are now plentiful, amongst the latter those of Cratægus Azarolus are the most showy: when these are arranged, as they easily may be, into different geometrical figures and designs, they are certainly very attractive, and ought to have a more extended use than they have. A row of Fern fronds placed round the edge of the board will complete the mound. To further enhance the effect of the latter when placed on the table, arches may be made to span from one to the other; these are best made of wire or of long Bramble shoots, round which should be entwined some flowering or ornamental creeper, such as Lapageria alba and rosea, or Cissus discolor. As indoor floral decoration has made great progress during the last few years, and is annually growing in importance, the younger members of the fraternity would do well to bear in mind that in many of the best places proficiency in this branch of gardening is now a very necessary qualification, and one which demands their close study and attention. J. Horsefield, Heylesbury.

GARDENIAS.

FEW flowers are more popular or held in greater esteem than those of the Gardenia, and well they deserve the position they occupy, for besides being well formed and of exceeding purity, they exhale a most delicious perfome, and these qualities reoder them of great value for "buttonholes" or for working up in bouquets. What adds to the value of Gardenias is that they may be had in bloom nearly, or quite, the whole year, as all that is necessary to get them at different seasons is to have a fair stock of plants, with plenty of heat, so that they may be grown on and rested as occasion requires.

As it is best to start at the beginning, I may as well commence with their propagation, which is very easy, provided one has only a nice healthy plant at hand from which to take cuttings. These should be made from the young half-ripe shoots, taken off about 4 inches long. After being trimmed and prepared in the ordinary way by the removal of the lower leaves, and cutting off the base close to a joint, the cuttings should be inserted round the edge of a pot that has been drained and filled with a mixture of peat and sharp sand. The pot containing the cuttings should then be plunged in another a size larger, so as to admit of its being covered with a bell-glass, and if then plunged or stood in strong moist heat in a stove the cuttings will soon strike and he ready for potting singly in the same kind of soil as before. To give them a start and encourage fresh roots a propagating-box or handlight will be found good for them for a week, when any light shelf in a hothouse will suit them; but if they can be accommodated in a Cucumber-frame or a tan or dung-bed so much the better, as there the atmospheric conditions are just what they want, and under the genial moisture their growth will be rapid and strong.

As soon as they have filled their pots with roots, the plants should at once be shifted into others, using good fibry peat and sand, as before. Although peat is best for Gardenias it is not essential, as they do very well in leaf-soil or light fibry loam, or the two mixed, as also loam and peat, but whichever is used it is important to have free and good drainage, that water, when given, may pass quickly off and not sour the ball. If the plants are required for flowering during the winter, they cannot well be too liberally treated in summer, and the thing then is to push them on quickly by shutting up early, before doing which they should be heavily syringed and the walls and surface of the pit or frame they are in wetted, so as to render the atmosphere healthy and moist. continuing this treatment daily during sunny weather, and keeping the plants plunged in warm leaves or tan, they will have attained a large size by the autumn, when to give them a rest the syrioging should be discontinued, and the plants kept cooler by having more air and exposure. This will harden and ripen up the young growth on which the flower-buds form. To get these to open during winter all that is requisite is to subject the plants to stronger heat, and if they can be plunged where they can enjoy a temperature of about 75° at the root there will be no difficulty in inducing the blooms to expand. In cutting great care should be taken not to remove more of the wood with the flower than is absolutely necessary, as otherwise buds are sacrificed, and rather than destroy these in that way it is better to mount the flowers, which may easily and quickly be done by the use of a little fine-drawn wire and moss.

When the plants go out of bloom they should for a time he kept drier at the roots, so as to rest them, when, if they are as large as is wanted, they may be pruned-in a bit and thinned by the removal of any weak shoots, and after this is done shaken partly out, and then re-potted in the same sized pots as before, This done the thing to be aimed at is to get them to break strongly again, which they will do if plunged in mild bottom-heat and kept syringed with tepid in the way already touched on above. Another plan of growing Gardenias-and it is a very excellent one -is that of planting them out; and any one having the convenience for doiog this will find that they will meet with much better results, as the plants, having such an increased root-run and so much more liberty, grow far stronger, and are therefore able to produce many more flowers. When planted-out, a moderately narrow bed or border with a pipe under is the best position for them, but failing this a few bricks may be laid roughly round on the floor of the house and the inner space then filled with rough peat and sand and the plants planted therein. By elevating them in this way, they will be in a more favourable position nearer the glass, and air will pass readily under the

Whether planted-out or in pots, Gardenias are much benefited by weak liquid-manure when growing and blooming, the best being soot-water, and if this is perfectly clear it is not only an excellent stimulant to the roots, but is of great value for syringing over the tops, as it is an excellent antidote against mealybug, which is the most trying and troublesome of all insect pests that affect the Gardenia. For destroying these parasites there is no known remedy equal to paraffin oil, which, if used in the proportion of a wineglassful to 4 gallons of water, and this applied at a temperature of 90°, dissolves the bugs and does no harm to the plants. To prevent any risk of this, it is always advisable to give a good heavy syrioging about half an hour after, so as to thoroughly wash it off and away, and if the plants are in pots it is advisable before using the paraffio to lay them on their sides and so keep it out of the soil. By doing this, not only is it safer, but the plants may be got at better, as they may be assailed at the heads and points of the shoots and under the leaves, and any insects or ex creta from them can be rinsed off and the foliage left clean. J. Sheppard.

WEATHER PRECAUTIONS.

LITTLE capital is needed to set up in the business of weather prophet, and if one happens to fail, as is more likely than not, there are no heavy accounts to settle. Uncertain as we ever are in this part of the world as to what the next forty-eight hours may bring, it still requires no foresight into the future to predict with all but certainty that such weather as we have had almost wholly through the autumn, and especially up to the close of the year, will not continue. With the grass green and growing, Primroses in flower, bulbs coming through the soil, Roses with young growth on them an inch long, and scores of other things that we expect to find at this time quite at rest, all more or less growing and tender, it behoves every one who has a garden to be prepared with the means of warding off the effects of severe frost should the Icy King put in his appearance, for surely many things were never in a worse condition to bear a very low temperature, such as it is possible we may yet have. With many plants that can ill be spared, a little protection often makes all the difference between destruction and little or no

Large specimens of Pampas-grass that have taken years to bring to an effective size, if left to them-selves in exceptionally severe frosts are frequently killed, whereas if the little trouble of tying up their heads and putting some straw round them had been taken they would have escaped. A few barrowfuls of leaf-mould, peat, or ashes, put round the collars of a border of favourite herbaceous plants will usually see them through a severe time, when in the absence of one or other of these inexpensive materials there may be nothing left but dead roots and lamentations. A bed of Spinach or young Cabbages, or a quarter of Broccoli, may often be saved by laying a few Peasticks thinly over them, with a thin scattering of Gorse or Fern, Pea-haulm or branches of evergreens on the Pea-sticks. A few boards in front of the Lettuce intended for spring at the foot of a wall will frequently keep them all right, and make a good deal of difference in the salad supply. The same holds good with many other things, the destruction of which, when it occurs, causes so much inconvenience, and which by a little torethought and keeping the weather-eye open may often be avoided. One important thing is to keep such protecting materials as dry as can be, in which condition they are so much more effectual.

ORCHID CULTIVATION FOR AMATEURS.

ORCHIDS were never so popular, never so generally grown as at the present time, and at no other period since their first introduction to our gardens have amateurs been more anxious for practical information as to their culture than they are at this moment. As to the Orchids themselves, we now-a-days find them everywhere-in plant-stoves, warm greenhouses, and in conservatories, in cold frames during hot weather, and even outdoor cultivation during the summer months has recently been advocated, and under certain conditions practised by Messrs, Backhouse, Smee, and others with some success. What is of especial interest, however, is the lact that many of the most beautiful of all Orchids succeed equally well under quite a variety of cultural conditions, in plant-houses of various aspects and of different structure or of temperature. Indeed, while well aware that separate and properly constructed "Orchid-houses" are undoubtedly best suited for, and most likely to aid us in attaining perfection in Orchid culture, yet we cannot shut our eyes to the fact that specimens of many Orchids of remarkable excellence are to be met with growing in vineries, Peach-houses, Melon and Cucumber pits, and even in warm greenhouses throughout the country. of the best grown plants of Cattleya Dowiana I ever saw was grown in a span-roofed stove house, mainly devoted to the culture of Dracænas and other table plants. The finest of Disas may be grown in a greenhouse from which frost is excluded during winter, and in a cold frame or pit during the summer months.

We must, however, have something besides houses of the right temperature, and that something must be cultivators (be they amateurs or professional gardeners) who have some sympathy with (or, better still, a "bit of a craze" for) the plants they wish to grow. No mere written directions will compensate for cultural watchfulness, or for care and keen observation. It is not sufficient to knownames and native countries, but either master or man (if both, so much the better) must be a keen observer of each individual plant in the whole collection, be it large or small. This was the main secret of poor Spyers' success; no Orchid grower I ever knew had such an intimate knowledge of the behaviour of Orchids under different conditions, and of their individual wants at different times and seasons; and his Calendar, written in these pages, in 1879, remains one of the most remarkable and trustworthy guides on Orchid-growing ever penned, and as such should be constantly referred to by amateurs and others most interested.

The best and most careful of Orchid growers, I notice, are often men who have "sown their wild onts," by which I mean men who have started with "a bit of a craze" about florists' flowers, stove and greenhouse plants for exhibition, or even "hedding out plants!" Success in plant-culture rarely comes except as the result of experience, and not a few failures; hence the names of some of our most successful modern Orchid growers are also the names of men who commenced life with some other 'bee in their bonnets' than a liking for the Orchids they now cultivate so well.

The whole progress of Orchid culture in our gardens reminds us of the swing of a pendulum. At first the main tendency was towards high temperatures; then came the reaction, and the day of "cool treatment;" but at the present time our pendulum oscillates less erratically, and we have reached a "happy medium," under which "the happiness of the greatest number" of Orchids is secured. The various cultural conditions and surroundings are more in unison; all barsh extremes are avoided. Heat, air, light, and moisture are regulated more equally; they work more effectually, and so the general sum of Orchid culture reaches to-day a grand total it never reached before. We have in force now what may be called the temperate system of Orchid culture, the plan under which most Orchids are found to succeed, and now carried out by many of the best of modern

cultivators. If I were asked to point to any one collection as illustrative of the temperate plan it is my purpose to advocate and to describe more in detail in future papers, it would be that of Dr. Paterson, at the Bridge of Allan. The worthy Doctor is an amateur of the first water, and is, I believe, his own Orchid grower, his collection being as remarkable for its variety as for its healthy and floriferous growth. Some idea of its extent and condition may be formed when we remember that in the autumn of 1882 the surplus plants contained in it-many of them fine specimens -realised £800 at a public auction in Edioburgh. Practically this collection has been cultivated with its owner's own hands, aided by members of his own family, and by a "lady help," in the form of an old woman who damps down the houses or attends to the ventilation and stoking necessary. The remarkable success achieved by Dr. Paterson ought to be of some encouragement to other amateur Orchid growers; at any rate, future papers will embody an attempt on my own part to show as plainly as possible how others may go and do likewise. F. W. B.

(To be continued.)

CLOVER AND GRASS SEEDS.

FROM the annual circular just issued by Messrs. Hurst & Son, of Houndsditch, we learn that of English red Clover and Cow-grass there has been quite an average yield; but it is feared the greater portion of the sample will lack colour and boldness of grain; the stocks saved from the first cut-generally termed maiden seeds-show the best colour, and will no doubt command good prices. The produce of the second cut, excepting those few lots that were secured before the showery weather of last summer, will be brown and not well matured. There promises to be a strong competition on the part of fine Continental seeds, and so English red Clover will he had at very moderate prices. Good gennine pedigree Cow-grass is not plentiful. The crops of foreign red Clover, both in France and Germany, have proved large, considerably above the average in both countries, and the samples generally are very fine. seed obtained in the North of France, which, next to home-grown, always commands the highest price in the English markets, is very fine this season, well matured and cleaner than usual. There are conflicting reports as to the character of the American crop; it is believed to be not up to the average; but there are such good crops in Europe, that the quantity of American seed usually taken will not be required, and as the quality is reported to be by no means good, it is expected that present prices will recede somewhat. The smallest crop of white Clover for many years is reported from Germany, consequently prices have gone up to a very high figure; it is, however, very difficult to get a de-finite idea of the crop until the middle of January. The area of production is very large, and threshing does not take place until frost sets in; but it is not unusual to have larger crops of white Clover than were anticipated. Alsike is not a large crop, but some parcels of very fine quality have come to hand. Of Trefoil there are large crops, both in this country and in France, but of poor quality. The French samples from the chalk districts show the best colour, and are commanding prices equal to home-grown. Of Lucerne there is a medium crop of fair quality. French Giant Sainfoin is reported a short crop, but prices are reasonable. In some districts English Giant Sainfoin has yielded well. The French crop of Italian Rye-grass is large, but the quality varies, so much of it being evidently damaged by raio that really fine samples are scarce. Low prices are ruling at present, but it is expected that before the end of the season they will materially advance. The English crop is an average one, the Irish crop a large one, consequently prices rule low. Both in Scotland and Ireland large crops of perennial Rye-grasses have been secured in good condition. Unfortunately, owing to the wet season, the objectionable Holcus has become very much intermixed with all perennial grasses, and the cost incurred in separating it adds considerably to the prices of higher weights, while very few of the lower weights can have it entirely separated from them. As prices are generally very low it is recommended that only the best double-machined samples be secured. Natural grasses are very scarce and dear, excepting Timothy, which

is good and plentiful, and which seems to be steadily working its way into favour as a forage grass in this country. In America it is the most important grass they have. Of other seeds white Mustard is a fair average crop—samples medium, and prices low. Rape is much below the average, of poor quality generally, and good samples now command high prices.

FORESTRY.

TREES AND RAINFALL.—More has probably been said and written upon this subject of late than upon any other connected with forestry, nor is this to be won-

have an affinity for, and draw towards them the vapour from the passing clouds. It now may just as well be affirmed that a pane of glass, a sheet of galvanised iron, or a board of varnished wood, attract moisture hecause we find streams of water running from them when breathed upon in cold or frosty weather. Condensation of vapour is one thing and the attracting it quite another, and very different thing; yet, from the circumstance of not discriminating between the two different phenomena, much has been made to pass current for fact in connection with the subject that should more properly be classed as pure fiction. By way of proof—and I am persuaded any amount can be adduced to show that there is really no special condition between trees and rainfall—the following are given as preliminary examples. Some of

FIG. 1.-THE CORSICAN PINE, P. LARICIO. (SER P. 18.)

dered at when we consider the immense importance of the theme and its far-spreading consequences. It is perhaps more interesting than instructive to hear some of the various theories advanced and methods of reasoning adopted to prove and substantiate them. It is more stoutly maintained than satisfactorily proved by various theorists that trees, woods and forests attract rain and moisture, but that woods and forests do in some way, whether explained or not, improve and ameliorate the climate of a country is evident. That such is the case few if any will dispute or gainsay, but some of the arguments employed to prove and establish this as a fact would be quite inadmissible in proving any other. For example, it is maintained that since by the one fact, that vapour is condensed upon the leaves and branches of trees, and is experienced falling in drops as we pass under them, that therefore the trees

the most bare and treeless districts of Scotland, such as Eskdale Moor, in Dumfriessbire, and the whole of the Cheviot range on the border between England and Scotland, as well as that of the Grampians, are proverbial for rainfall, snow, and Scotch mists. And on the other hand the district including the lower part of Morayshire, to the west, south, and east of the town of Forres, and on through the lower part of Banfishire, though densely wooded, more so probably than any similar area in Great Britain, is yet drier, and less rain falls there than in many districts in the United Kingdom. It may be said, and that truly, that areas so comparatively small as those mentioned can have no appreciable influence in attracting or repelling rain, but if this be admitted then it is to be feared that in an island so so small as ours we can neither afford to plant sufficient areas to produce the desired effects of attracting

rain, nor effect such clearances of trees as to ward it

Some who are very strong believers in the great affinity trees have for rain, can see through their own medium the tops of the trees tapping the passing cloud and the watery elements streaming forth.

Hot and dry seasons in our naturally cold and damp climate are less frequent than is often desirable—for as is pretty well proven cold and wet do more harm in this country than heat and drought. When, however, excessive and hurtful droughts do occur, there is at once a cryraised, loud and plaintive, not to Providence to send rain, but to landed proprietors to plant trees that their magnetic influence may attract rain from the cloud whether it contains vapour or no!

If, however, we have more cold and wet seasons than dry and warm ones, and trees have the supposed influence of producing or procuring rain, in that case instead of planting we should require to cut down, and clear off much of our present woods and plantations.

Although trees, plantations, woods, and forests, have no perceptible influence in producing rain, and the clearing of them no appreciable effect in producing dry weather, yet they have their beneficial and ameliorating influences in a cultivated and civilised country, and what these influences are, and how they are produced, the writer will endeavour to show in a succeeding paper. C. Y. Michie, Cullen House, Cullen, Banf.

FOREST WORK FOR JANUARY.—Press on general planting operations during favourable weather on ground that is either naturally dry or which has been previously well drained. For the most exposed situations select strong well-grown plants, and be careful in planting to direct the best and strongest roots to the most exposed or windy aspect. This is more practicable in pit-planting, but not so readily attended to where notch-planting is pursued. Examine carefully those plantations formed during the autumn, and put firm and in an upright position all plants that have been swayed or knocked about with the wind. In the nursery dig over or trench up plots as they become vacant, and top-dress and otherwise prepare for the succeeding crop.

Nursery ground that has been frequently cropped with forest trees should be heavily manured, and planted with green crop, which will much improve the quality of the soil, and leave it in good condition for seedling forest plants.

A coating of fresh clean earth applied to nursery borders in early winter will be found highly beneficial, and is specially valuable where the ground is limited, and required for immediate refilling.

Continue the thinning of plantations, and cutting and removing of heavy timber in the park or policy grounds. Remove dead or broken branches, especially those alongside walks or drives, as in such places they are often a source of annoyance, as well as dread, to passengers. Complete the pruning and dressing of hedges, and plant up gaps with strong well-rooted Quicks. As the Hawthorn is one of our first plants to break into bud, it should be planted early in the season—indeed, autumn-formed hedges always succeed best, and have a considerable advantage over those formed later on.

The weather has been extremely mild for the season, and already many plants are pushing into bud. A few days ago 1 saw the Broad Bean in full flower, and in the nursery many plants seem to have lost reckoning as regards their flowering season.

Collect all kinds of Fir cones as they become ripe, and store away in a dry airy loft until the sowing season. I cannot remember having seen so plentiful a crop of cones on the new and rarer Coniferæ as this season, and for berries—especially the Holly—they are extra abundant [not so near London]. Towards the end of the month, during open weather and in dry soils, seeds of Beech, Plane, Ash, &c., may be sown.

Prepare heds for seed-sowing next month by digging roughly over, and exposing to the ameliorating influence of the weather. Overhaul and repair fences of all kinds, tree-guards, and rabhit-proof

Gravel and repair walks and carriage-drives; and, as time permits, ground work operations of all kinds, such as levelling, excavating, turf-laying, and road making, may be proceeded with. A. D. Webster, Penrhyn Castle, North Wales,

Prehid Potes and Pleanings.

ORCHIDS AT ST. ALBANS -At Messrs. F. Sander & Co.'s new Orchid nursery house after house has been completed in such rapid succession that it has become a very extensive place, and still three more very large houses are in the course of building. The whole place being worked to a plan, an opportunity is afforded of making it as complete as possible, and up to the latest conceived ideas in every respect-a chance which never presents itself where already existing houses have to be adapted, rearranged, or added to. The houses are all spans, varying from 240 to 300 feet in length, and from 20 to 30 feet in width, each of them being separated from the other by a wide walk between. The houses run from north to south, and are all joined together and protected on the north end by a broad lean-to corridor at the one end, and a spacious and well-fitted shed for potting and other work at the other, so that the visitor can go the whole round of the houses without once going into the open air. Great provision has been made for the storage of rain-water in each house, and in many of the details of veotilation and other matters an amount of skilful economy has been exhibited which might well be copied by others who are about to build. The bottom ventilation of most of the houses is capitally arranged, and will no doubt be greatly fancied by all Orchid growers, as it renders the exhaustion of the pure air in pure air the houses impossible. It is arranged thus :- In the brickwork midway between the ground line and the staging a 41 inch opening (the size of a brick-end) at intervals of 9 inches, is left on the same course of bricks right round the house, so that it is quite perforated to the open air with small openings which equalise the inlet of air and prevents those currents which must occur where large bottom ventilators are put in at wide intervals. There is no means of shutting off this bottom ventilation, neither is it desirable to do so, but in order to qualify the temperature of the air let in, in cold weather, each opening is blocked at the inside end with a brick cut wedge-shaped, thus forcing the air to ascend to a hot-water pipe which runs close to the air openings all round the house. When we consider that the bulk of the Orchids which die are smothered for want of that pure air which they require quite as much at night as by day, this plan of bottom ventilation should recommend itself to all. The rough concrete sides to the beds in the houses, instead of brick, form another noteworthy feature, as it is cheaper than brick and more efficacious in giving off moisture. The fine new Vanda-house is nearly finished; it is 180 feet long and 31 feet wide, the woodwork is of Pitch Pine, oiled and varnished, but not painted, and the fine structure has many improvements which may better be noted when the staging is finished.

All the finished houses are full to overflowing with great quantities of good things, and all in the best of The specimen Cattleya-house (240 feet by 31 feet) contains quantities of specimens of Lælis elegans, with from fifty to three hundred pseudobulbs each-a size hitherto unheard of-Cattleya Percivaliana showing between them over 1000 sheaths with buds up, and soon to prove for itself that it is worthy to class with our favourites; immense plants of C Trianze, also with plenty of buds; numbers of good C. Mendelii, C. Mossize, C. Gaskelliana, C. amethystoglossa, and C. gigas Sanderiana, as well as many fine masses of Lælia purpurata, L. autumnalis atrorubens, and other good things. Then follows another long Cattleya-house for smaller plants, and after that the specimen Odontoglossum-house, filled with over 20,000 very stout and vigorous O. Alexandræ and its hybrids. Alongside are three more houses of O. Alexandræ, so that a total of over 100,000 plants of that kind alone is attained, and all are stated be from the right quarter-a statement which the excellence of the flowers of those in bloom well bears out. The last house is filled with many thousands of O. Pescatorei, O. Rossii majus, &c. Among remarkable plants in bloom are a magnificent form of Oncidium unguiculatum, with the sepals of a clear purplishclares, and the petals prettily blotched with the same colour. The lip is large, and bright yellow, indeed much finer in every respect than the ordinary form; the spike has four branches, which are each again branched. A very fine hybrid Odontoglossum of the O. Wilckeanum section, some distinct pink and spotted O. crispum, a fine white form of L. purpurata, with violet lip margined with white, a new Saccolabium of the S. giganteum class, and the bristling spikes of many white forms of Lælia anceps may be noted. Here also the entire stock of the new hybrid Cattleya calummata (Bleui) will be found. The old nursery is occupied by the Masdevallias, improved plants and things under observation, and it is as full as ever of good things.

CATTLEYA LUTEOLA. - The clear yellow flowers of this epiphytal Orchid present a colour that is of rare occurrence either in this genus or the allied Lælia. It was introduced from Brazil in 1853, and described in the Gardeners' Chronicle, p. 774, for that year. The nearest approach in colour then was seen in Lelia flava, a plant at once distinguishable by its tall racemose peduocle. Lælia xanthioa, introduced six years afterwards from the same country, resembles it very closely, but may be recognised at sight by its being proportionately larger in all its parts, stalked pseudobulbs, and by having a white labellum slightly tinged with yellow on the lower part. C. luteola flowers more freely, and the labellum is of a deeper yellow, marked internally on the sides with a large purple blotch, and white only on the margin. It seems to be known in some gardens under the name of C. Holfordi. A well flowered specimen has lasted for many weeks in the Cattleya-house at Kew.

CYPRIFEDIUM ROBELINI.—This is not one of my own discoveries, but comes from the Philippine Islands, and I give here only the communication which I have from its discoverer, M. Rocbelin. The plants are to be found near the sea, growing on stones, without any shade. The strongest and most compact plants are those which are exposed entirely to the full sun. During their growth they require very much water. M. Roebelin states that be collected this splendid new species on a small island where neither he nor any other collector had ever been before, and which is several degrees distant from the locality of the old C. lævigatum. R. Ffau, Chisveick.

Che Titchen Garden.

ORDERING SEEDS .- Now that the time for ordering the annual supply of seeds has arrived, and with it a goodly number of trade catalogues, it may not be inopportune to indicate a few of the leading sorts which are indispensable in every establishment. Therefore, with catalogue in hand, let us repair to the seed-room and examine the contents of the individual drawers, entering, as the inspection of the stock of seeds remaining in store proceeds, in the catalogue or order sheet, the quantities required:—Asparagus: Connover's Colossal. Broad Beans: Carter's Leviathan and Taylor's Broad Windsor; and in the dwarf and tall sections, Canadian Wonder and Champion Runners. Beet: the Pine-apple Short-top variety may be depended upon as possessing all the essential points of this esteemed root. Broccoli—spring varieties: Brimstone, Chappell's Cream, Frogmore Protecting, Carter's Champion, Cooling's Matchless, Model, and Cattell's Eclipse; for autumn use, Veitch's Self-protecting, Grange's Early White Cape and Early Purple Cape; and lor the present season, Snow's Winter White, Backhouse's Winter White and Early Penzance. Borecole or Kale: Cottagers Dwarf Curled and Scotch. Brussels Sprouts : Aigburth Selected, and Scrymger's Giant. Cabbages: Wheeler's Imperial, Carter's Early Heartwell, and Gilbert's Chou de Burghley, and the Rosette Colewort. Savoys: Drumhead, Dwarf Green Curled, and Early Ulm. Carrots: Altringham and Long Red Surrey are among the best long, and Early Nantes and James' Intermediate the best short-horn varieties. Of Canliflowers the Early London, Dean's Snowball, Walcheren, and Veitch's Autumn Giant, are unquestionably the four best. Celery: Leicester Red and Turner's Incomparable White are excellent varieties.
Capsicums: the Chili, or Cayenne, and Long Red. Endive: Batavian Broad-leaved and the Green and Moss Curled varieties. Leeks: Musselburgh and Carentan. Cabbage Lettuce: All the Vear Round and Grand Admiral for summer, and Hammersmith Hardy and Stanstead Park for winter and spring use. Cos Lettucy: Paris Green and Paris White for summer, and Hicks' Hardy White and Cooling's Leviathan for winter and spring cultivation. Opions for spring sowing: any good strain of the White Spanish. and for long-keeping qualities, James' Keeping, Danvers' Yellow, and Deptford, should be included; for autumn sowing : the Queen, Early White Naples, and Red Flat Tripoli. Early Peas: American Wonder and Sutton's Bijou, from 12 to 15 inches high, are good varieties for early work, either planted in shallow pits or grown in pots; and for the same purpose for sowing or transplanting out-of-doors, Laxton's Earliest of All, Day's Early Sunrise, Ringleader, and William I.; as second early and mid-season varieties we would recommend Laxton's Supreme, John Bull (3 feet high, and having from ten to thirteen Peas in a pod), Laxton's Evolution (a fine new Pea, from 3 to 4 feet high, of the Pride of the Market type), Carter's Stratagem, and Telephone; and the late section should include Veitch's Perfection and Ne Plus Ultra-the latter, in our experience, the best late Pea in cultivation. Potatos-Kidneys: Hammersmith, Woodstock, and International; Round varieties: Champion, Schoolmaster, and Reading Russet. Turnips: Early Purple-top, Munich, Early Snowball, and Carter's Jersey Lily. Tomatos: the Stam-fordian and Acme for cultivation under glass, and the Trophy for out-of-doors. And among Vegetable Marrows and ridge Cucumhers Moore's Cream and Stockbridge are the best.

PEAS AND BEANS .- Noe time should be lost in making a sowing of early Peas in 3-inch pots, three parts filled with light soil. Put nine or ten Peas into each pot, and cover them with soil of the same com-The pots should then be removed to an early vinery or Peach-house, and thence, when the Peas have attained a height of a couple of inches, to a cooler house, where they can be gradually hardened off preparatory to being finally transplanted out-ofdoors next month in a favourable situation. A sowing of William I., Laxton's Supreme, John Bull, Evolution, and Carter's Telephone should also be made out-of-doors in properly prepared ground, in rows running north and south, and 8 or 10 feet apart-the intervening space being planted with three or four rows of Cauliflowers in February. There should also be made a sowing of Carter's Leviathan Broad Bean in boxes, for transplanting in a favourable situation out-of-doors when it is considered safe to do so. At the same time there should be a sowing made in a south border, at 4 feet between the rows. These, like the Peas, will make a succession to those raised in pots and hoxes.

HORSE RADISH .- The present is a good time to make plantings of this useful though much neglected root in the following manner :- Open a trench 2 feet wide and about 18 inches deep; this fill up and raise to the height of 18 inches from the surface with well decomposed dung and leaves, say from an old hot-bed; tread the whole well together, and make up into the shape required; put the line down 6 inches from either side of the ridge, and cover the whole with soil, so as to form a good ridge 18 inches wide on the top, with the centre 3 inches lower than the side and end, forming a kind of basin for the water. In planting, select the second-size roots, and plant them in their entirety with a long dibber in two rows, I foot apart, and 8 or 9 inches asunder in the row, on the ridge, and slanting slightly to the interior of the latter, with the crowns about I inch under the surface. A planting should be made every year, so as to always have a supply good in quality and

FORCING DEPARTMENT. - See that pits and frames in which Potatos, Carrots, and Radishes are growing have sufficient air to prevent them from making a weakly growth. If they are inclined in the latter direction, it will be advisable to draw the sashes off for a few hours on fine days, and to leave a little air on to the frames at night. Shift young Tomato plants into suitable-sized pots. Put a stick to each plant for support, and then put them back in heat near the glass. Where hot-water pits are not provided for forcing French Beans, the seeds had better be sown in the pots in which they are to nod at once. in order to prevent the plants receiving any check subsequently in the process of re-potting. The 8-inch pot is the most suitable size for this purpose. However, in the event of being rather limited in this sizewhich is sometimes the case-it will be necessary to raise the desired number of small plants in small pots or boxes, and as soon as the most advanced lot of

plants have done hearing throw them out, wash the pots, and transplant the young plants into them. See that the supplies of Asparagus, Rhubarh, and Seakale are equal to the demand for the same by introducing batches of the respective roots into heat at intervals of a fortnight or three weeks. II. W. Ward, Longford Castle, Wills.

FRUITS UNDER GLASS.

I UNDERTAKE to write the Calendar of operations in this department for the benefit of those who, from various causes, have not had an opportunity of obtaining the necessary practice to give them complete confidence in their own ability, and in doing so I will endeavour to explain my own experience in a manner which I hope will enable them to derive as much benefit as I have done from the practical remarks of some of those who have preceded me. I may, however, mention that those who look to Calendars for guidance must not expect to find rigid lines laid down that it would be practical for every one to follow to the letter—climate, aspect, as well as structures, varying so much as to make this impossible.

PINES .- No fruit is more constitutionally sensitive than the Pine, or more tardy in showing the injuries it receives from various kinds of neglect. It may, because of the nature of its leaves, receive irremediable injury without indicating for a considerable time any signs of distress. It is, therefore, indispensable to the grower, who is anxious to excel in the cultivation of this noble fruit, that he should at all times have a watchful eye upon the plants under his charge. Pines are too generally carelessly treated when they are suckers. Fruiting plants require more heat than any other section at the present time, and the tem-perature for these should be kept at 70° at night, with a rise of about 5° in the day from fire-heat, with the bottom-heat ranging about 90°. Watering must be regularly attended to, and the plants prevented from becoming dry, as this would cause a check which could not be retrieved; water must, however, be withheld from each plant when its fruit commences to colour. A moderately moist atmosphere should be maintained, and the practice of daily syringing between the plants followed, but avoid damping them over their heads, as this would cause at this season, when little air can be given, an unsightly enlargement of the crowns. Succession plants, which are intended for late summer and autumn use, as well as suckers, must still remain quiet, which they will do if their night heat is kept at from 55° to 60°, with only a proportionate rise during the day, and a bottom-heat of 78°, water should als be administered, and atmospheric moisture created with discretion in this department. Young plants that were shifted into their fruiting pots in the autumn, and which will produce fruits next winter, should likewise be kept at rest in a similar manner to the above. In order to meet a demand for ripe Pines early in the summer, we make it a rule to start on New Year's day a house of plants which have been prepared for the purpose, consisting of Queens, S.nooth Cayennes, and Charlotte Rothschild. former is the most valuable for very early use, but as the others form a succession, such a mixed house is very serviceable. To excite these the bottom-heat is raised to between 85° and 90°, the atmospheric night temperature to 65°, and in very mild weather to 70°, with more fire-heat; in the day no air is given unless the sun runs the thermometer up to 78°, and then it is admitted with care in order to avoid cold draughts. Early closing is studied, and the plants are gently dewed over head early in the afternoon on bright days, and the moisture in the house increased, but not too freely. The plants are all well watered, having been kept rather dry previously while resting, guano-water being used at a temperature of about 85°.

VINES.—At the present time, with the sun so rarely seen, Vines must be forced with care and judgment, for although the weather is unusually mild, exceedingly high temperatures should not be permitted. Those that are fairly on the move, and have broken regularly, will have been fastened into their proper places, so that the process of disbudding can be carefully carried on, as the strongest and best placed shoot on each spur can be distinguished. With gentle syringings early every afternoon, and the maintenance of a steady heat accompanied with a genial

moist atmosphere the shoots will make safe and The night temperature where the bunches can be perceived should be raised to about 58°, and be gradually increased with the usual rise in the day, as the growths lengthen and foliage developes. A house for succession should now receive attention, by being cleansed and closed; the immediate surface of the internal border should be replaced with sound fibrous loam, mixed with crushed bones, wood ashes, and old lime mortar, well broken, which should be trodden down firmly-the horder, it at all dry should be soaked with tepid water, and the rods he regularly syringed two or three times daily until their huds burst. We make it a practice to top-dress our outside horders every autumn, and cover them with a firm coating of dry leaves, over which glass shutters are placed, thus preventing them from be-coming excessively wet and cold, as otherwise they must do, being composed of heavy soil. The cover-ings are removed in spring, after mild weather sets in, and mulchings of cow and horse manure are substituted. The bunches of Grapes still hanging in late houses should now be gathered, with their entire laterals attached, and be bottled. The Vines should be pruned at once, and thoroughly cleansed; apply styptic to prevent bleeding, water copiously, and topdress the borders as above recommended; clean the houses, and put everything in order preparatory to closing them at the proper time.

PEACHES AND NECTARINES.—The continuance of mild weather is very favourable to development in those houses that were closed at the beginning of last month, and the trees are now at the point of bursting their buds. If the present weather continues little, if any, fire-heat will be required at night to maintain them at a temperature consistent with safety. We find that keeping up to 50°, with both the front and back ventilators sufficiently open to promote a beneficial circulation of air, is a suitable night temperature for the present. In the daytime an increase of 5° with the aid of fire, and 10° more from the influence of the sun, every gleam of which should be made the most of by early closing and syringing, is sufficient. The trees should be syringed every morning and afternoon, the pathways and borders damped more or less according to the state of the weather, and the borders, if inside (which are the best for early houses, although they need close attention) examined, and watered if necessary with tepid water. Immediately before the blossombuds expand fumigate with tobacco-paper in order to carry the trees safely through their flowering period without an attack of aphis. I have seen the prospect of an excellent crop severely damaged simply through the neglect of this precaution. A successional house will have been prepared ready for closing before this time, and later ones should have their necessary winter attention without delay. Thos. Coomber, Hendre Gardens, Monmouth.

pants and thein fultune.

GENERAL REMARKS .- Those cultivators of plants who, like ourselves, are located in close proximity to a large town have very many difficulties to contend with, and overcome in every possible case, that our brethren in the craft so fortunately escape when in charge of establishments in the pure air of the country. Never in our experience do we recollect a more trying time for plants under glass than the concluding week of the past year. It was dull, damp, and foggy in the extreme, and the glass on the exterior of all our houses is coated with a thick deposit of soot and blacks, precipitated there during the last few days. So intense is the shading caused thereby that, if we were at once lifted on into the sunshine of summer, we should not require any artificial shading material to counteract its bright rays. We were in hopes that a heavy shower of rain would have intervened to wash away some of this deposit, but up to the present we have been doomed to disappointment; the wind, now blowing from about due east, has dried up the exteriors, causing the blacks, &c., to adhere more tightly than before. If no rain falls within the next few days we shall have to syringe the roofs and then remove the deposit with a hair-broom as cleanly

TEMPERATURES. - During such spells as that we have just experienced we find it answers best to keep the temperatures at the minimum point, is unwise to unduly excite p'ant life such times, ending frequently in exha such times, ending frequently in exhausted vitality and never yielding satisfactory results at in exhausted the hest. A night temperature of from 58° to 60° for the stove proper will be ample, rising about in the morning, then slacken the fire for the rest of the day. The intermediate-house or cool stove will be quite safe at about 5° lower than the above quotations, or even a little less. The greenhouse it will be advisable to keep also at the minimum point; to prevent damage from damp, a little heat in the pipes early in the day will be a good preventive, having at the same time a crack of top air on to let off the superfluous moisture. The use of the syringe can nearly be dispensed with at such times as these in the stove and other like houses; for with a reduced temperature, and no great amount of firing required even to maintain that, the atmospheric moisture will not be so easily dispelled, and some amount of injury may be apprehended if every precaution be not taken. are now keeping the evaporating troughs quite dry, and shall do so for some weeks to come if no frosty weather intervene to necessitate sharper firing. Close attention must be daily given to remove any decaying leaves or flowers before injury is caused to

IN THE GREENHOUSE a sharp watch must be kept against any harm from mildew to the Cape Heaths and other hard-wooded Cape and New plants. Cinerarias will also need close looking after against the same pest, and the sulphur duster brought into use as soon as detected. The operation of watering in all houses will be considerably reduced, of watering in all houses will be considerably reduced, and greater discrimination exercised in the performance of the same, especially with all plants that are not in an active state of growth. Many inmates of the greenhouse (excepting those in small pots) will go a long time without wanting any water. It is not advisable to hurry over this work in any case, but with large specimen plants that have taken years to bring to perfection, it is absolutely necessary to look most observations that continue the condition and requirements before closely into their condition and requirements before water is applied. There are exceptions certainly, in which the watering-can may be freely used, for instance with Tree Ferns, Palms, and such gross feeding and fast growing plants that are brought on to the specimen stage much sooner than in the case of delicately rooted greenhouse plants. To this cause more than any other we attribute the scarcity of many of the finer types of greenhouse plants that were a few years ago to be seen in collections. Where now do we find a well grown Leschenaultia, Acrophyllum, Brotonia, or Roella ciliata? They are few and far between. The present requirements of a greater supply of cut flowers at all seasons has also had its closely into their condition and requirements before between. The present requirements of a greater supply of cut flowers at all seasons has also had its effects in decreasing the cultivation of the choicer hard-wooded greenhouse plants. But we think there is as much pleasure to be derived from a well assorted collection of these subjects as there is in a sorted concerns of these subjects as make it in the other hand, are so planned for the cultivation of fuite, that plant culture is rendered quite subservient to their production, whether amenable to the same course of treatment or not. This is a great unitatke in the long treatment or not. This is a great mistake in the long run, the mix-medley system has brought ruin into many a fine house of Vines by the ravages of the mealy-bug, introduced therein by the plants infested with this pest having been injudiciously removed thereto without a thorough cleansing. Proof of this is abundant in the frequent complaints that are so frequently before our readers of mealy-bug in Vices, whereas not very many years back it was a raitly for even mention to be made of this insect in connection with Vine value. this pest having been injudiciously removed with Vine culture.

MEALY-BUG.—Use every available means, and begrudge not the labour spent on the thorough destruction of this pest; where the utmost is expected in all kinds of produce from under glass, a lar when an incessant warfare has to be waged against when an incessant warfare has to be waged against this exotic insect, which none of us like to see. We are thankful to be entirely free from this pest, and have been so for several years past. It was an uphill fight for a long time, but patience was at length rewarded. Now we can remove our plants into any fruit-bouse without fear of taking the bug along with them. A week or two may be well spent at this season of the year before active growth commences amongst the plants in thoroughly cleansing each and all that are infested. Spare not the plants, whether bushes or climbers, if they stand in the way, or are too difficult to effectually clean, is our advice to all who are troubled with the bug. A fresh state with a clean stock will soon repay for all extra labour and expense that may have been incurred. Fames Hudson, Gunnersbury House Gardens, Acton.

Sale of Rooms.

NOW that the question of PLANTING is receiving somewhat of the attention the merits of the case demand, it is important to review the resources at our command. This is more particularly urgent in those cases where the Larch, from one cause or another, is found to be unsuitable. During the last century a very large number of coniferous and other trees have been introduced, many of which, of course, are merely of importance from a decorative point of view. Others are yet too small in size, or too limited in numbers, for any fair estimate to be made as to their qualities for the purposes of the timber merchant. In the case of the Corsican Pine, Pinus Laricio, however, the time seems to have come when its merits and suitability for particular purposes may be gauged with some degree of accuracy. The experience of Mr. Webster, Forester to Lord Penrhyn, has been given in a former issue. Mr. WEB-STER speaks of it in the highest terms so far for its hardihood and its suitability for exposed and maritime situations; Mr. MICHIE, on the other hand, with a more limited experience and under less favourable circumstances, is by no means as warm in its praise. One difficulty consists in the long tap-root produced by the seedling plant which renders the plant troublesome to manage in the early stages, and which must enhance its price in the nurseries. Still, if all be true that is said in praise of the tree by our foresters, this difficulty is more than compensated.

Like all other Conifers the individual plants vary very much, and a whole field of most important observation lies open to the grower to ascertain the differences between these forms. and more especially to note the different qualities of the wood. Every one knows how greatly the character of the wood varies in the case of the common Scotch; it is most desirable, therefore, that accurate knowledge on these points should be obtained. Reverting to the Corsican Pine, we may, without entering into full details, state some of the characteristics which have struck us on personal examination of the trees in various localities. As to the general habit of the tree, it is a fast-growing species in favourable localities, with a tall, symmetrical bole well developed in proportion to the branches, so that the trunk is readily visible between the tiers of branches, while in the Black Austrian (a form of Laricio) the trunk is usually considerably more concealed by the The bark of the trunk is dull reddish or smoky brown, peeling off in thin irregular flakes. The branches, small in proportion to the trunk and loosely disposed, the lower ones spreading more or less horizontally, but upturned at the tips; the upper branches are often thicker and shorter than the lower, and ascending. The shoots of the year are glabrous, either clothed with young leaves all the way down, or naked for a short distance. The young wood is of an olive or chestnut-brown colour, the buds ovoid-conic, with a long point, reddish, and not very resinous. The leaves are in pairs, about 4 inches in length, rather slender, dark green, with resin canals scattered through the central tissues of the leaf, as may be seen by microscopic examination. The male catkins are ovate, greenish-yellow, the scales of the anthers marked with a purplish-violet spot. The cones are about 2-21 inches long, by 11 inch broad, ovoid-conic, chestnut-brown, or in some cases duller; the blunt end of the scale (apophysis) narrow, transversely elliptical acute, with a small four-sided pyramidal shining projection or "umbo" in the centre, tipped with a minute point (see fig. 1, p. 15).

The species is widely distributed in the mountainous districts of Southern and Eastern Europe and of Western Asia, and various forms have been described, most of which are in cultivation in this country. We have notes of most of these, which we shall probably mention on another occasion; it may suffice for the present to say that they are all reduced by PARLATORE to three varieties-(1) tenuifolia, including forms with slender, paler, and less rigid leaves than the type. Of this division the best known in this country is the form known as Laricio pyrenaica, which must be carefully distinguished from the true pyrenaica, which is quite a different thing. Laricio pyrenaica may be distinguished by the very bright orange-brown colour of its young shoots. In habit it is more frequently branched from the base than the type, so that the clear bole is shorter than in the type, and more concealed by the foliage, and leaves are longer. The young shoots are clothed to the base, the buds pale yellowish-brown, acuminate. There are other marks of distinction, which we may refer to on another occation, which we may refer to on another occasion. The variety (2) nigricans has shorter and more rigid dark green leaves. The most marked form of this is the Black Austrian which does so well by the sea, and which we have already figured, and to which we shall have again to refer. PARLATORE also includes under the variety nigricans sundry other forms, such as Fenzlii, Heldreichii, taurica, &c., which, no doubt, are mere forms, but which may be distinguished in our Pineta by marks which we shall mention at another time. Lastly, there is the variety (3) Pallasiana, with leaves as in the preceding variety, but with larger cones. To this belongs the form Laricio Pallasiana, of which we have already given an illustration. Unfortunately nothing is known at present as to the relative value of the timber of these varieties; the first thing to do is to point out the distinguishing characters of the trees in growth, and this we propose to do in subsequent articles. In the meantime we may say that all the varieties have the same leaf structure as that already mentioned.

-GLASGOW BOTANIC GARDEN. -- Our centre illustration (fig. 2) represents a fine plant of Musa Ensete in one of the new houses of the Glasgow Botanic Garden. As a decorative plant the Ensete, or Abyssinian Banana, takes first rank, its noble foliage at once arresting attention by its boldness of form and by the rich red colour of the midrib. As a contrast to the lace-like fronds of Tree Ferns, or the feathery foliage of Palms, nothing can be more striking, and it is specially well adapted for what is now called sub-The Ensete differs from all the tropical gardening. other Musas in having a capsular, not a fleshy fruit, on which account it is less valuable as a fruit-bearing plant than many others. Great additions have been made to the Glasgow Botanic Gardens recently, and various changes made, with a view of enhancing its value as a botanic garden, presided over for several years by the late Sir WILLIAM HOOKER. We hope at an early date to give illustrations and full details as to the new buildings in the garden.

- THE ALMANAC. - We are in doubt as to whether the Welwitschia has ever before been made to do duty as part of a conventional device, though that it is not unfitted for the purpose may be seen from the legend-bearing scroll at the top of the Almanac given with the present number. The Welwitschia remains, perhaps, the strangest production introduced into European gardens, though it must be said that it is in museums that one must look to see the oddity in its full proportions. The garden, how-ever, has served to dispel one mistaken notion as to this extraordinary plant. From the examination of adult dry specimens, it was concluded that the single

pair of gigantic leaves that the plant produces were to be considered as the seed-leaves, or colyledons, persistens, and enormously increased by age. not so, however. We remember to have been shown the seedling plants at Kew by Messrs. Nicholson and Lynch, some time before Mr. Bower described the mode of germination, and previous to the publication of the illustrative drawings in our pages by Chevalier MONTEIRO. The association of the Welwitschia from the Transvaal, the Lapageria from Chili, the brilliant Anthurium from New Grenada, the Lilies from Japan, is a fair representation of the cosmopolitan tendencies of British gardeners. So far as nationalities go, at any rate, gardeners are not particular; and even as to other matters, although he may have his preferences, the gardener should not allow himself to be swayed by his antipathies, nor forget that the meanest weed that cumbers the ground is a document as precious as any Moabite stone to those who can read it. The Calendar contains a list of the usual horticultural appointments up to date. The mean temperature for each day of the year is that adopted by Mr GLASHIER, from the revision of the long-continued observations of the late Mr. ROBERT THOMPSON, at Chiswick.

THE VEITCH MEMORIAL TRUSTEES have decided to allot the following medals and prizes during the present year (1884), viz. :- I. A Veitch Memorial Medal and prize of £5 for each of the following subjects-(1) The best specimen Orchid in bloom; (2) the best stove or greenhouse plant in bloom; (3) the best dish of two bunches of Grapes, one variety. These to be offered at the Dundee International Show, which takes place on September 11-13. II. A Veitch Memorial Medal and prize of £5 for-(1) The best specimen Orchid in bloom; (2) the best stove or greenhouse plant in bloomthese to be offered at the Royal Botanic Society's Show on May 21; and for-(3) The best dish of three bunches of Grapes, to he offered at the Royal Botanical Society's Show on June 18. III. A Veitch Memorial Medal and prize of £5 were also placed at the disposal of the respective committees of the National Auricula Society (Southern section); of the National Carnation and Picotee Society (Southern section); and of the committee having charge of the National Dahlia Show. These prizes are only eligible to be competed for by amateurs and bona fide gentlemen's gardener s.

- IPOMÆA THOMSONIANA.-We are informed that this plant, which we figured in our last, has been in the country some years, and that Mr. B. S. WILLIAMS has a stock of it, which he intends to distribute this year. The stigma, as we suspected, has two rounded lobes, though not so shown in the illustration.

- THE FIRM OF BARDET BROTHERS, 472, Senator Street, Warsaw, was mutually dissolved on December 20, and Mr. FREDERICK BARDET is now sole proprietor.

- CATTLEVA PERCIVALIANA .- This lovely winter flowering Orchid now being established among us promises to be one of the finest things recently introduced, producing, as it does, its neat rose-coloured flowers with their intense blue tinted crimson labellums at this season. It is one of Mr. SANDER'S happiest introductions. At Mr. Percival's there are many fine plants of it in bloom, and we have before us a lovely spike of three flowers from Messrs. IRELAND & THOMSON, of Edinburgh,

- TRYING IT ON .- Secretaries of horticultural societies are receiving a printed circular emanating from a seed firm in Glasgow, which informs them that, in conjunction with a seed grower of Erfurt, Germany, they are prepared to offer at the summer or autumn show of their respective societies in 1884 certain prizes for the best blooms of Stocks and Asters, twelve of each, "grown from our seeds," and they offer the large sum of 15s, in two prizes for twenty-four blooms, and then follow certain conditions, viz., "The Stocks and Asters exhibited for these prizes must be grown from the collections of our Stock and Aster seeds (which are marked for this purpose in our catalogue, 1854), by members of the society, or in the society's district. A ticket of qualification for competition for these will be furnished with the seeds, which ticket, being simply numbered,

Fig. 2,-musa ensete in the glasgow botanic garden. (see p. 18.)

must, to prevent any mistake, and as a qualification for competition, be laid down, clearly visible, during the show beside the flowers exhibited." Thus far, the Glasgow firm is simply following the lead of some London and provincial seed bouses, but they are found travelling a little beyond the scope hitherto allowed, inasmuch as they make it a further condition that the "printed schedules of the society giving the particulars of our prizes" state

"for the best blooms of Stocks and Asters," &c, "(actalogues with particulars free on application); "also that the schedule be sent to use arily after publication." And now comes the climax! In the communication to the secretary there appears this paragraph:—"We shall be glad to send you (carriage paid) any number of our catalogues for distribution you may be pleased to mention;" and all this—advertisement, advertising agency, distribution of catalogues,

&c.—for the munificent sum of 15:.! How many secretaries are likely to be enticed by this? Horicultural societies of all kinds are largely made use of for trade purposes, but that the secretary should be made a gratuitous distribution agent is a little too strong a dose for a useful body of men to swallow. It will be noticed that not an extra penny is offered by this enterprising firm towards the cost of printing their prizes, or circulating their catalogues.

— CHOISVA TERNATA.—The market growers of cut flowers are taking up this plant for blooming in summer. Let it be stated that it will not force, but requires to be grown and flowered in a cool-house. The Continental nurserymen appear to be managing this plant remarkably well. A few days since we saw a batch of nice little bushy specimens that were well grown and appeared to have set their numerous flowerbuds in the most satisfactory manner.

— LILIUM CANDIDUM.—It is surprising to what an extent this plant is grown for forcing purposes and for flowering in the open air. Mr. JOHN KREVES, at Acton, calculates that he has about 10,000 plants, a large number of them in pots, and these are introduced to heat ic successional batches, and flowers are had from January until such times as the plants bloom naturally in the open ground. At the Whitsun season there is a large demand for white Lilies for church purposes, and it has happened that the spring has proved so early and Whitsuntide so late that the white Lilies in the open ground have bloomed and decayed before the date for holding the festival.

- DUNDEE HORTICULTURAL ASSOCIATION .-The following is the programme of this Association for the present year :- January 4: Opening address, the President; Special Exhibition of Chinese Primroses. February 1: "Ben Lawers, its Geology and Botany," Alexander Hutton, F.L.S., Arbroath; Special Exhibition of Cyclamens and Vegetables. March 7: "Insectivorous Plants," Robert Lindsay, Curator, Royal Botanic Gardens, Edinburgh; Special Exhibition of Cinerarias and Fruits. April 4: "Scottish Alpines," Rev. W. W. Peyton, Broughty Ferry; Special Exhibition of Hyacinths, Tulips, and other Spring Flowers. May 2: "Hardy Fruits," P. W. Fairgrieve, The Gardens, Dunkeld House; Special Exhibition of Narcissus, Hardy Primroses, Polyanthus, &c. June 6: "The Leaf," part 2, the Hon. President; Special Exhibition of Auriculas and Pelargoniums.
July 4: "Notes of a Tour through the London Nur-William Allison, Seaview Gardens, Monifieth; Special Exhibition of Roses, August 1: "Scandent Plants," John Stewart, F.B.S., Arbroath; Special Exhibition of Lilies and Hardy Border Flowers. September 5: "Some Poisonous Plants," J. S. Crichton, M.D., Arbroath; Special Exhibition of Dahlias—Single and Double. October 3: "Some of the Physical Conditions of Plants," Frank W. Young, F.C.S., Dundee; Special Exhibition of Apples, Pears, and Plums. November 7: "Peach Culture,"
A. M'Kinnon, The Gardens, Scone Palace;
Special Exhibition of Hardy Autumn Flowers. December 5: Annual General Meeting; Special Exhibition of Chrysanthemums. These meetings will be held in the Young Men's Christian Association Rooms, 10, Constitution Road, at 7.30 P.M.

LYCOFODIUM CLAVATUM.—Surely it would be worth the while of some enterprising person to obtain at the Christmas season, if it were possible to do so, quantities of this handsome Club Moss of Scotland for decorative purposes. The long, handsome tresses are well suited for the purpose, and so durable is it that it deserves to be classed among the everlastings, hanging in a dry state for years. It grows on the mountains of Scotland with great luxuriance, and doubtless it could be obtained in large quantities. It is too dry in this country for the cultivation of this truly handsome moss, else it would, no doubt, be largely grown. Some fine examples were sent southwards to Mr. A. F. Barron at Christmas.

— A CHARMING FORECOURT GARDEN IN WINTER.—This was seen in one of the more fashion-able thoroughfares at Chiswick on Chistmas Day. A detached mansion, with the front entrance in the middle of the house, afforded space for two panels of forecourt gardens, with an ornamental tile walk leading from the road to the front door. In both these panels the beds were uniform and margined with stone. They were planted with specimen hardy evergeren plants, but wide enough apart to display each fully to view. The whole was carpeted with Ivy, which had made a dense growth and formed a perfectly even groundwork of dark olive-green, which did not in the least degree hide the outlines of narrow, well-kept graved paths. The variegated Aucubas and Hollies looked quite bright against the dark groundwork; and though darkness and fog were overhead and around, there was a colour and a cheerfulness

about this arrangement in contrast with which dismantled forecourt gardens close by, with their ruined beds and decayed fragments of bedding-plants looked very melancholy indeed. The window-sites on the outside of the windows were also filled with boxes of Ivy, and so the furnishing appeared to be complete; and there is this advantage about an arrangement of this kind, that it is cool in summer and cheerful in winter; and while rain disfigures the flowers used in ordinary flower-beds, the evergreens are brightened by passing showers, which cleanse the leaves of any sooty and dirt deposits. Some may think that such an arrangement partakes too much of sameness, and were this true it yet possesses advantages that more than counterbalance these.

THE WEEK .- The death of Mr. SPEED, of Chatsworth, is marked by additional pain, owing to the dreadful circumstances under which it took place. We only received the intelligence in time to announce the fact in our last issue, though too late to allude to the circumstance in our brief summary of the principal events of the past year, but we now refer to a fuller notice of his career in the obituary notices of the present number, where will also be found an intimation of the death of that much-respected nurseryman, Mr. B. MALLER .- A company is to be formed to work the China-grass or Rheea (Boehmeria nivea), by a process devised by Professor FREMY, and which demands neither skilled labour nor plant of any kind. The fibre, it is asserted, can be produced at half the cost of Flax, at the same time that the Indian cultivator would secure a larger profit than from any other crop. The preparation of the fibre so as to clear it from undesirable material is a signal instance of the value of chemical and botanical knowledge, and of their importance when applied practically. Supposing the assertions now made prove only half true, we have in the application of Rheea fibre a source of industry hardly second in importance to Cotton itself. The proposals emanate from the Lini-Soie Syndicate, Gresham House, Old Broad Street .- A correspondent suggests that we should set apart space exclusively for the contributions of foremen and under-gardeners, Such contributions, he points out, would be useful in developing latent talent, and would bring to light a large amount of practical knowledge. The suggestion is a good one, but our correspondent must be well aware that we are always anxious to secure communications on practical details of culture and observation from any trustworthy source. communications are always welcome, but considerations of fitness and space, such as must, of course, he left to ourselves, must influence us in the selection of what shall be published. It by no means follows that, because a particular communication is not inserted that it is necessarily inferior. It may be kept out by a variety of considerations, which only those familiar with the exigencies of the Editorial department and of the printing office can appreciate. One objection to the present state of affairs is that we meet with the same writers in all the horticultural journals-a fact which tends to show that the supply of competent writers is more limited than it ought to be. -For the first time within our remembrance we have received a report of the Oxford Botanic Garden, and in so far an interregnum seems to have advantages over a regular government. The chief features of the report before us deal with the herbarium, which has recently been enriched by the donation of several thousands of specimens, formerly the property of the late Mr. WILLIAM BAXTER, whose services to British. and especially to Cryptogamic botany-great in their time-will now fructify in the future. Mr. BOSWELL and Mr. DRUCE have done good volunteer service in the herbarium. Physiological lectures have been delivered by Mr. Chapman during the year. As to the garden itself, but little is said beyond the record of the flowering of Agave americana and the variegated variety. In both cases the flower-stem attained a height of 24 feet. The plants are believed tobe about ninety years old. Botanists are looking with much interest to the forthcoming election to the Professorate by recent alterations endowed with a sufficient income. Let us hope that while the teaching of Botany in Oxford shall at last be put on a footing in accordance with the requirements of the times, the old Botanic Garden may be made to fulfil its proper office.-A rival to the Eucalyptus is announced from Tonquin. It is called in Tonquinese "V-dizi," and is stated to be, not only a food plant. but one serviceable in destroying miasma and purifying water. The V-dizi is used as ten, while the seeds boiled in water afford a refreshing beverage. The plant grows to a height of 6 feet and upwards near streams and pools. The Agri-Horticultural Society of Madras is making inquiries as to this V-disi, and we trust they may be successful.

- ERYTHROTIS BEDDOMEt. - The trailing or prostrate stems of this pretty Spiderwort, known in some gardens as Cyanotis kewensis, render it interesting and desirable as a plant that can be employed in various ways for basket-work, the front row on the staging, or even to cover the surface of large pots where the plants grown do not hide them. The leaves are fuscous and hairy on the upper surface, of a bright red below, and all arranged on one plane or nearly so, showing in the aggregate the upper and under surfaces respectively. The small blue flowers with their curious bearded stamens open successively on the tip of the shoots, and are not uninteresting. may be seen in the stove at Kew grown as a basket plant, and is figured in the *Botanical Magazine*, t. 6150, under the name of Erythrotis Beddomei. The Genera Plantarum refers it to the section Dalzellia, and describes it as a remarkable species differing from the normal section in having its petals distinct to the base (not connate) and without claws. The whole section also differs in habit and inflorescence, but is closely connected by the ovules and

— ROYAL HORTICULTURAL SOCIETY OF IRE-LAND,—The following are the dates fixed for the shows of 1884 in Dublin, viz.:—Thursday, April 17; Thursday, May 15; Thursday, July 3; Thursday, August 28; Thursday, November 20.

CHINESE PRIMULAS,—From Mr. B. S. WILLIAMS we have received some blooms of the various fine strains of Primulas with which his name has been so long identified. The whites and reddish-purples, by their yearly improvement in shape and substance, prove careful selection on the part of the grower, and are different things from what we used to grow years ago under the same names. The strain of fimbriata alba identified by the name of magnifica is in every way a good one, and worthy of high praise. Chiswick Red, which Mr. WILLIAMS also introduced into commerce, is finer than ever, and has a purple ring round the cye, which we do not remember to have seen in the original flowers.

-- THE WEATHER.-General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending Dec. 31, 1883, issued by the Meteorological Office, London :- The weather has been fair in Scotland, but dull in Ireland and England, with thick wet fog over the eastern, central, and southern districts. The temperature has been above the averdistricts. The temperature has been above the average in all districts excepting "England, E.," the deficit varying from 1° to 3°. The highest readings were recorded either on the 25th or 29th, when the thermometer reached 51° in "Scotland, E.," 54° in "Scotland, W.," and 55° in Ireland. The lowest readings was believed do in the additional of the week has were observed during the early part of the week, but no severe frosts were registered. The rainfall was less than the average in all districts. Over England the fall, which was very slight, was in the form of thick, misty drizzle. The bright sunshine amounted to 20 per cent. of the possible duration in "Scotland, " and " Ireland, S.," but was very deficient everywhere. In "England, E.," and "England, N.W., there was none at all. Depressions observed :- During the greater part of the week an anti-cyclone has lain over our islands, and the winds have consequently been light, and somewhat variable. On the 28th and 29th, however, a series of depressions skirted our extreme western and northern coasts, occasioning moderate to strong southerly winds in Ireland and Scotland, with some rain.

— GARDENING APPOINTMENTS.—Mr. HENRY BIRCH, lately Gardener to Baron ROTHSCHILD at Waddesdon Manor, as Gardener to the Maquis of NORTHANPTON at Castle Ashby, in succession to the late Mr. GBOGGE BEECH.—Mr. C. J. GOLDSMITH, lately Gardener at Sandhills, Eletchingly, Surrey, as Gardener to C. A. HOARE, Eq., Kelsey Manor, Beckenham, Kent.—Mrs. DAVIES, Foreman at Enderby Itall, Leicester, has succeeded Mr. G. A. DRUMMOND as Gardener at that place. Mr. DRUMOND has gone into business in the village of Enderby.

The Arboretum.

THUIA OCCIDENTALIS VERVAENEANA.—This is a singularly beautiful variety of the American Arborvitæ, and one, too, that possesses a good habit and constitution. The slender branchlets during the growing season are tinged with a deep golden-yellow, which in winter changes to a brownish-orange. This variety, one of the most distinct of the very numerous garden forms of Thuia occidentalis, originated some years ago in the nursery of M. Vervaene, at Ghent. Some specimens of it at Kew are amongst the most conspicuous objects in the collection of Thuias, &c., in the Arhoretum

THE GOLDEN CATALPA.-The golden-leaved variety of the Indian Bean, or Catalpa, C. bignonioides var, aurea, is well worth the attention of planters, The foliage, even when mature, is a decided rich golden colour, and, moreover, it does not scorch readily, as is the case with several golden-leaved variations from green-leaved types. In fairly rich soil, under conditions which suit the type, this grows freely, and soon forms a very attractive object. It is evidently a form of recent origin, as neither Loudon nor Koch make any mention of it. Will any of our readers communicate their experience of this tree?

BERBERIS ARISTATA,-At Kew there is a clump of this Indian Barberry which at the present time is although leafless, very conspicuous, by reason of the deep orange-red colour of the branches. Planted in a mass it certainly produces a good effect, and is worth growing for the bright colour of the bare twigs and branches. It is a most variable species; in this respect it is not surpassed by our European B. vulgaris. a native of temperate Himalaya, at elevations of from 6000 to 10,000 fect. The flowers are produced freely enough during the summer months, either in simple racemes or umbels or in compound racemes, and vary in different individuals from clear pale lemon-yellow to an almost golden tint. The fruit, too, differs a good deal both in colour and size, some specimens at Kew bearing black fruit, and others red ones double the size. The variety micrantha seems the hardiest of the Indian Berberries, and is well worth a place in the select shrubbery.

MAHONIA GLUMACEA.-This pretty dwarf evergreen is thoroughly deserving of a place in the front of the shrubbery border or in a nook of the rockwork. The dark green of the leathery pinnate leaves and the red colour of the leaf stalk make the plant and the red colour of the least stalk mase the plant conspicuous enough during the winter months. It bears its bright yellow copious spikes of blossoms, which are beautifully nestled in the foliage, in the very early spring. About sixty years have clapsed since Douglas sent seeds of this species to the Horticality of Society by whom plants were liberally districultural Society, by whom plants were liberally distri-buted. At the present time, however, it is far from common, although worthy of general cultivation. In a wild state it occurs in shady Pine forests along the Pacific coast from Monterey to Vancouver Island. A good fegure of the plant anneared in the Balancial good figure of the plant appeared in the Botanical Magazine, tab. 3949.

PLANT LIFE .- It has been shown by Professor Schubeler, a Norwegian plant-geographer, that most plants in high latitudes produce much larger and heavier seeds than in warmer regions nearer the neaver seeds that in wanter regions because equator. This effect he attributes to the prolonged influence of smallph during the long summer days of the high latitudes. The difference of seed development was very remarkable in some cases. Dwarf Beans taken from Christiania to Drontheim—less than Beans taken from Christiania to Drontheim—less than 4° further north—gained more than 60 per cent. in weight; and Thyme from Lyons, when planted at Drontheim, showed a gain of 71 per cent. The grain of northern fields is heavier than when grown in more southerly localities; and seed from Norway planted at Breslau decreased greatly in the first year. The leaves also of most plants are larger and more deeply coloured in higher latitudes, as was first noticed by Griesbach and Martins. The same is true of flowers, and many which are white in the southern climates become violet in the far north. While on this subject of the changes in flowers, it may be mentioned that a chameleon sort of flower which grows in the United States is white in the morning and red at the United States is white in the morning and red at night. It has been named the Consederate Rose, on account of its blending these two beautiful colours. The plant is odourless, it grows in great bunches, and is susceptible of a high degree of cultivation.

VEGETABLE PRODUCTS OF SIENA, ITALY.

THE following notes on the products of the province of Siena, Italy, have been furnished in a Government report by Mr. Consul Colnaghi, Writing on the Vine, he says too many varieties are cultivated in the province, but that there has been an improvement on this point of late years, and in new plantations the following qualities predominate:-Black Grapes: San Gioveto Canaiola, Mamniolo; white Grapes : Trebbiano and Malvasia. Throughout the province the black qualities known as Gorgotesco and Prugnolo arealso largely cultivated. The soil of the province being very varied, both topographically and geologically, the method of cultivation differs much in the various localities. In some places the Vine is attached, or "married," as it is termed, to trees, most frequently the Acer campestre, planted in rows along the fields, and pruned "a paniera;" in others they are grown low, and fastened to stakes. The plantation of vineyards on the French system, instead of growing the Vines in the fields with other crops, is on the increase, but, generally speaking, the latter method prevails, which accounts for the small yield of Vine as compared with the large area under cultivation. For planting Vines in rows in the fields trenches 1.20 metre in breadth by 1.20 metre deep are dug, the drainage being effected by means of a layer of stones or of fascines. The trenches are filled in with earth, and planted with slips or layers which have already thrown out roots at intervals of 60 to 70 centims. for low Vines, and of some metres for plants intended to be attached to the trees. The ground requires to be dug up and hoed every year, and manured every two years, or else Lupins are sown and dug in. The vineyards on the French system are dug up in the spring, and manured in August. The plants are laid down in ground well broken up, generally to the depth of 1.20 metre, the largest stones in very stony soil being selected for drainage, or to form terrace walls on the steeper hillsides.

The Olive is cultivated to a limited extent only on the hills of the "Cute," In the Val di Chiana it is grown in plantations, elsewhere the trees are generally planted in rows along the fields in combination with other cultures. There are three principal varieties grown in the province. The trees are raised from slips cut in the spring, and they are planted in holes in ground that has been well broken up, covered with mould and watered as required. The hardiest shoot is subsequently, and may be permanently, planted in three years. The Olive is also raised from seed. In the district of Siena when a tree is about to be cut down the "eyes" on the roots are detached and placed in a separate plot of ground, plants being obtained from them in three years, which can then be transplanted. In the wooded districts, where the wild Olive is pleatiful, grafting is commonly employed.

The trees are usually planted in holes or ditches of more than 2 metres square and 1 metre deep, drained with a layer of stones 20 or 30 centims, deep. the Olives are planted in rows in the fields they are generally pruned a paniera, nearly all the inner branches being cut away from the centre to enable air and light to penetrate freely. The trees are pruned every two or three years. The most careful cultivators apply a special manure when the trees are between the ages of five and eight years, composed of straw mixed with woollen rags, the whole saturated and moistened with sewage; but this custom does not appear to be general, the trees profiting by the

not appear to be general, the trees profiting by the manure laid on the fields.

The yield of oil is abundant, and the quality generally good. In some parts of the province, especially near Siena, it may be doubted, however, whether this culture is really remunerative, owing to the capriciousness of the climate. In the Chianti oil is a

capriciousness of the climate. In the Chianti oil is a principal product, and the quality is excellent; that of the Val di Chiana is somewhat inferior. The Olive prospers in the district of Montepulciano. Under the head of fruit trees we read that an improvement has taken place in the production of fruit, but that it is not so great as could be desired. The principal obstacle to the progress of fruit culture in Tuscany is the fact that the varieties generally cultivated are few. The principal futils grown in the vated are few. The principal fruits grown in the province are Apples, which give a good yield; Pears, Apricots, Peaches, Pluns, Cherries, Almonds, Japanese Medlars, and Walnuts.

Home Correspondence.

Plants in Flower at York .- The number of Plants in Flower at York,—The number of plants in flower in the open ground in our nurseries during the past week (25th to 31st, inclusive) has been unusually large; about seventy species have either been gathered or distinctly noted in bloom. For some time past the weather has been mild and foggy, with comparatively little rain. The species in flower were as follows:— Daisy, double white and red Myosotis dissitiffara Roses, several Hepatica triloba, blue and pink

Crocus biflorus , Sieberi Botryanthus pallens " compactus Pansies, many vars. pink , angulosa Rhododendroo dauricum Stocks, red and white Cyclamen Atkinsii (ibericum Geum minimum Centaurea montana Doronicum caucasicum Chrysanthemums Stenactis speciosa Aubrietia græca album)

Anemone fulgens .- I cannot remember noticing the Anemone flowering at this season of the year so far north as at Vork. It is now doing so on the rockwork. The tubers planted in the open beds (where they have not been disturbed) are unusually forward this season, and promise a brilliant display in spring. Anemone blanda is also finely in blossom.

The American Summering Apple.—I think Mr. Murdoch will find the American Summering Apple in Leicestershire; at Woodhouse, near Loughborough, it used to be quite common, and I believe there are trees of it there still: it is an excellent early there are trees of it there still; it is an exceinent early table variety. The Eve Apple used to be grown at the same place, but I have never seen it elsewhere; it is a small dessert Apple, very highly coloured, and of good flavour, flattish in shape, not unlike a Court Peadu-Plat in miniature. I think they are both what may be termed local varieties, but they are very cool one. Then Morelly Althrech they good ones. Thos. Woodford, Atherstone.

Epiphyllum truncatum,-Whatever method of growing this lovely stove plant be adopted, it is well deserving attention for decorative purposes. I cannot, however, opine with "S. J." (p. 794 of your last volume) that it is as useful for cutting purposes as he there represents. Perhaps the most general way of growing the Fninbullum is not the Paraghia stock. the Epiphyllum is on the Pereskia stock, as it can then he had any height required; but if grown on its own roots it is none the less useful, especially for hanging baskets; and if some are grown in 60-size pots they form most useful subjects for furnishing jardinières, baskets, &c., or for a front row in the conservatory, in which way its charming blooms are seen to great advantage. E. Morgan, The Butts, Harrow-on-the-

The Land.—The writer at p. 747 of your last volvme says that the land ought to be very much more [productive than it is at present, I, as a landed proprietor, am anxious to make my estate as productive as possible, and shall be very grateful to any new that it can be made to any one who can show me that it can be made much more so than it is at present. He says that it would become so by dividing it into smaller holdings, such as could be worked with the spade, and that an such as could be worked with the spade, and that an additional advantage would be the encouraging a much larger rural population. Would either of these things result from dividing the land as you propose? From all that I have seen and know I should say, certainly not. Market gardening is out of the question where I live, and next to that I believe that the way to make the land productive is to rear and feed as much stock of all kinds as possible, and this can be done better on large holdings than small ones. be done better on large holdings than small ones. In France the land is subdivided as he proposes. he proposes. The French are a very industrious and frugal people, yet, with fully as good soil and a finer climate than England, the produce per acre is very little more than

half that of England. [What about Belgium?] I have seen the attempt made to give labourers small holdings, and the result was not satisfactory. Of course they should have good gardens attached to their cottages—all mine have that; but if they have enough to make them small farmers, or something between that and labourers, their families as a rule are harder worked and worse off than those of day labourers. In fact I believe that no one is in a better position than a labourer with constant employment and fair wages and a good cottage and garden; and now that (thanks to machinery) labour is worth more and therefore is better paid than formerly, I much doubt about most of the schemes which I hear proposed and sometimes have seen tried for altering the present arrangement of landlord, tenant and labourer. C. W. Strickland.

Chrysanthemum Meg Merrilies.—A writer in your issued for December 22 (p. 797) deals, I think, unjustly with this flower when he classes it against some sprawling kinds which might very well be discarded. To my mind it is one of the most valuable we have—not for exhibition, for of that I know nothing, never having exhibited one, nor intending to do so; but after all other Chrysanthemums, save Princess of Teck, are out of flower, this is in perfection. I have now a plant of it in my greenhouse which has over been disbudded, and it has now upwards of fifty blooms on it, touching one another, and although so ragged, yet that gives it an air of lightness and elegance which many of the same orthodox blooms do not possess; and the soft, cloudy look this plant has, with its delicate primrose and white blooms, leave now little to desire in the way of refined beauty. So I would say, by all means retain Meg Merrilies, 117tld Rose.

Pyrethrum aureum selaginoides,—This new and distinct form of Pyrethrum is to be highly recommended for bedding purposes, especially carpet bedding, on account of its exceedingly dwarf and compact habit, combined with good colour, its flat foliage resembling theirforms of Selaginella Martensi, which overlay each other, thus giving a level and uniform surface. E. Morgan, The Butts, Harrow-on-the-Hill.

Ensilage.—The Spaoish word "silo," from which "ensilage" is derived, comes from the Greek σφ6s, "a pit," the liquid "r" being changed, as is so commoolly the case, into "1". I enclose an extract on the subject, which may serve to interest your readers. Hubert Ac. Holdan:—"Quelques peuples, comme les Thraces, les Cappadociens, ont leurs greniers sous terre, dans des fosses qu'ils appellant "siro" (σμοψ1); *d'autres dans les puits, comme les habitants de l'Espagne citérieure les Carthaginois et les habitants d'Osca. Ils en couvrent le fond de paille et ils ont soin que l'air ai l'humidité n'y puissent y pénétret. De cette manière leur grains sont a l'abri du charançon, et le blé se conserve cinquante ans, le millet plus de cent années,"

— The word "silo" has interested me, because there is a genus of insects so named: a "cavity" or groove would answer admirably to a point of structure in this particular genus, but re "silo" economically—I take down my several (three) Greek Lexicons, and I cannot find either other or or others, but I find xthos "green food for cattle"—"food, forage, fodder." R. McL.

Eucharis amazonica.—Lately in one of the gardening papers there was a very instructive treaties on the flowering of the Eucharis, by Mr. Kemp, with most of whose remarks I entirely agree, especially with regards to the number of times he advocates flowering the same bulbs in the year—e.g., twice only; for how frequently are we not told, in the pages of the various gardening papers that, if you only do so-and-so, you can flower the same batch three if not four times in the year. I am induced to offer these few remarks from the fact that I have just lately seen what twelve or eighteen months ago was perhaps one of the finest batches of Eucharis in the kingdom, but which, sad to say, are no longer so, from the one cause, I believe—"hard forcing." I was saked to look at the batch the other day. Among other questions I asked had they had a severe chill, or liquid manure too strong, or any artificial stimulant, or was there seand used in the compost? This last question I was induced to ask from the fact that I myself lost about 300 bulbs from, I believe, no other cause than the use of sand from the shore. The reply to my last question closed the cross-examination—Have they been hard forced? "That," replied the partywho had charge of them, "I fear is the cause; we have driven them too hard, to get them in flower at Christmas and again at Easter." This is the simple story of a collection of

several thousand bulbs. But the curious part of it is, bulbs of all and every size seemed to be suffering alike. I have been making many enquiries, and find a very great number complaining of their Eucharis going off without any apparent cause, the manner of exit being something like the following:—The top or crown of the bulb seems to begin to rot, the scales or skin layers each in turn become affected with this rot, the bulb in the meantime making every effort to send up a leaf, which, when it attains the height of a few inches, turns yellow and goes off, each subsequent effort becoming weaker and weaker till the final collapse. It thus becomes a serious question, for I here learnt that not only in these parts, but in other districts, similar calamities among Eucharis bulbs are happening. I have great doubts whether the system of keeping Eucharis bulbs for several years undisturbed in the same pots does not tend to exhaust the bulbs more rapidly than they otherwise would do. I adopt the system of under-potting, and thereby give an annual shift. If any of your numerous readers, veterans in the culture of Eucharis, can throw any light on this subject, many I know will be deeply grateful. A. E., Dawilish.

Vine Mildew.—Mr. Broome, having kindly undertaken to examine and sketch the fungi on the Vine leaves sent from Washington, and having found on them, together with the Unchula, a species which seems to be identical with Erysiphe communis, a very widely distributed species, which may after all be the true result of Oldium Tuckeri—as no figure has been

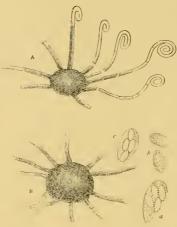

Fig. 3.—A, Uncinula spiralis—a, ascus; b, sporidia. B, Erysiphe communis—c, ascus.

published of Uncinula spiralis we lay before our readers one (fig. 3) copied from Mr. Broome's sketch, which gives as follows, more or less highly magnified:—A, Uncinula spiralis; a_i ascus $\{a_{33}$ inch long) with the enclosed sporidia; b_i , the sporidia, more highly magnified, being about $\frac{1}{100}$ inch long. B, Erysiphe communis, with ascus, and enclosed sporidia. M. \mathcal{T}_i , B.

Plant Labels.—Much has been written about plant labels. Your correspondent last week (Mr. Potts) properly recommends the use of permanent kinds for all sorts of plants. This is very desirable indeed, but gardeners are usually content either to have the proper paper label attached to new plants as they arrive from the nursery, or at most substitute a wooden one, which soon decays and probably is not renewed. Gardeners cannot be expected to keep on hand a supply of permanent labels suitable for all sorts of plants. Mr. Potts recommends for wall treesstrips of lead with the name punched in by means of an iron set of the alphabet. Unless for a very extensive garden indeed such an apparatus would be seldom used. It seems to me that the most effectual way of preserving names would be for nurserymen to send suitable permanent labels along with plants, making a charge for them. For wall trees the sort of label described above might, perhaps, be best; for shrubs, Roses, fruit bushes, and such-like, hanging zinc labels written with chemical ink would probably answer better, and so on. The hanging labels ought to have copper wire, &c., complete, so that they might be at once attached to the plants. These inexpensive zinc labels properly prepared and written will last a life-

time. Were this plan adopted there would be less complaint about want of names. By the way, what about the "permanent label" competition which was advertised to take place some six months ago by the Society of Arts? I have seen no report on the subject. P. Neill Fraser, Rockville, Murrayfield, Edinburgh.

Impatiens Hookeriana, — This fine species is perhaps the largest-flowered of the genus, and it flowers so rarely in cultivation that the event is worth recording. It has just been flowered by Mr. Hutchisson, gardener to Mrs. Peed, of Lensfield, Cambridge, who has great regard for intrinsic merit in plants, and cultivates some which many gardeners would pass over. This plant has been grown near the glass, in a high stove temperature, with plenty of atmospheric moisture, and liberal root treatment. A number of buds were formed, which fell off, and this indicates a difficulty on account of the dull weather of this season, but the plant is quite young, and, the one inflorescence perfected this fyear apparently promises much better success another year, with the same treatment. Roots have descended from the stems of the plant almost as thick as quills, and the treatment it has received, as already mentioned, is no doubt the most conducive to success. The flowers are pure white, with splashings of red on the two lower petals, and spots of the same colour in the throat. They measure 21 inches in the direction of greatest width; the spur is unusually long for the size of the flower, and tapers to a length of nearly 3 inches. This species was introduced to Kew, where it flowered for the first time in the summer of 1852. It is a native of Ceylon, whence seeds were sent by the late Mr. Thwaites. An excellent figure was published in the Betanical Magazine, t. 4704. R. F. L.

Mr. Cooper's Collection of Succulent Plants:

—To the passer-by of Mr. Cooper's modest little establishment in the Brighton Koad, Red Hill, Surrey, there is nothing externally to attract or invite the attention, and probably very few would expect to see anything beyond the class of plants that are usually to be found in such small establishments; but seekers after fancy Pelargoniums, Fuchsias, Calecolarias, Acacias, Primulas, Azaleas, &c., would find but the barest sprinkling of them there; but seekers after fancy Pelargoniums, Fuchsias, Calecolarias, Acacias, Primulas, Azaleas, &c., would find but the barest sprinkling of them there; but they will find an excellent collection of succulent plants, which are contained in an old greenhouse, about 20 feet square; and so closely packed and crowded are they as to produce at first a feeling of bewilderment; and those accustomed to see plenty of room given to plants would imagine that they could not be kept healthy in so crowded a condition; yet an inspection will show that most of them are perfectly healthy and robust. At the first glance it becomes quite evident that the South African element predominates over that of all other constries in Mr. Cooper's collection; and this is not to be wondered at, since South Africa was the field of Mr. Cooper's travels, and from whence he introduced many plants into our gardens, of some of which he still has the only specimens. Among the most noteworthy of the plants may be mentioned a fine specimen of Aloe drepanophylla, 7 to 8 feet high, which flowers annually, and is the type specimen from which the original description was made; another of A. sigmoidea, also the type, and unique in Mr. Cooper's collection; as likewise are A aristata var. supralævis and A mitterformis var. pachyphylla. Besides these are numerous species of the Aloe and some remarkable hybrids. Of Ilaworthias there is a good series, and among them some very fine specimens, including the remarkable seeding very fine plants, and some of them are probably undescri

Helleborus niger altifolius. — Seeing some articles in your columns on Helleborus niger var. altifolius, and the statement that Aberdeenshire was one of its northern garden-habitats, I endeavoured to find some specimens of the plant in rural cottage gardens, and now send you a flower and leaf from one of these growing in a garden where it has been for more than forty years—a small garden beside a fisherman's house. The people say it has been there as long as they can remember. They also tell me that some fifty years ago the young maidens were wont to put the

^{*} See Varro de re rustica, i., 57; Columella, i., vi, 15; Piny, Nat. Hist., xviii, p. 73; Hertus, Bell. Afric, i., 65; M. Durcau de la Malle in Memoires de l'Académie Royale des Inscriptions, vol. xiii, p. 461.

flowers in their dress when enjoying their Christmas dance on Auld Yuyll Day. For this purpose it was largely cultivated in cottage gardens, where no other flowers were to be seen at that festive season in so northern a climate; but it has now become quite a rare plant, and is not in such request. Fames Taylor, Clashfaryuhar, Portlethen.

Dimorphanthus mandschuricus.—At p. 798, Dec, 22, Mr. C. Wissenbacb expresses a doubt as to the identity of this plant with Aralia chinensis. If we are to take for granted that the range of distribution ascribed to the latter by various authors, and also its almost extraordinary variation, are correct statements, then it would be an easy matter to conceive of two plants presenting an appearance so dissimilar, and differing in constitution as stated (P. 798), and yet be nothing more than mere varieties of the same species. The more important specific characters of A. chinensis are—stem arborescent and, as well as petioles, more or less prickly; leaves bipinnate, leaflets ovate, oblong, acuminate, rounded and unequal at the base, sharply serrate and villous, and panicle of flowers branched with numerous umbellules. There is no record in gardening books of its having been introduced to this country prior to 1865 or 1866, when a plant described and distributed under the name of Dimorphanthus mandschuricus is stated to be synonymous with it. The plant in the neighbourhood of London agrees exactly with the characters given above, and descriptive of A. chinensis. Blume says the latter is a native of Java, on the mountains; Linnæus says of China; and Loureiro, of Cochin China. The latter describes it as procumbent, or scandent, climbing in the hedges, and proving itself of great annoyance to travellers, on account of its numerous hooked prickles. Some allowance must be made for this apparent laxity of description, as it would probably be more botanically correct to say that the plant was found scrambling in the bedges amongst other subjects, competing for the same space. There is no such best prickles of variation in the plants cultivated here; but the stems and leal-stalks seem to become much best probably be more botanically correct to say that the plant was found scrambling in the bedges amongst other subjects, competing for the same space. There is no such scrambling in the bedges amongst other subjects, competing f

Late Chrysanthemums,—I send you some flowers of Chrysanthemums cut to-day (December 31), and which I think you will consider of fair quality for so late in the season. If the National Society could give us a show in December I think good blooms would be forthcoming, and the Society would be doing something in prolonging the season of this beautiful autumn and winter flower. At present the chief aim of exhibitors seems to be to get all into bloom, if possible, say, from November to to 20, both early and late varieties. J. Hill, Patter's Park, Chertey. [Mr. Hill sent us some very fine blooms of Hero of Stoke Newington, John Salter, Princess Teck, the finest late white; and Meg Merrillies and Dr. Masters, Japanese. Ed.]

Very Late Chrysanthemums. — Any plant which naturally opens its blossoms in the dull and gloomy days of winter is always welcome, seeing how difficult it is to keep up a plentiful supply of flowers at such time of the year. The Chrysanthemum has, in the hands of clever hybridisers and cultivators, come wonderfully to the front rank in this respect of late years. The variety of colours, the endless forms, together with their easy cultivation, make them at once every one's favourite autumn flower. I send the names of a dozen of those I call January Chrysanthemums, these being in perfection in that month:—Rose Marguerite, Progne, Fulton, Virginal, Ethel, Comtesse de Beauregard, White Globe, Princess Marguerite, Yellow Dragon, Meg Merrilies, Late Duchess, grandiforum. There is some skill required to bloom the two last kinds. They should be in their flowering pots soon after midsummer, be plunged in the full sun, and when frost is expected placed in a light house without heat, and no liquid manure should be given them after they are housed till the buds appear. I have made the list in the order in which they bloom, and hardly too much could be said in praise of Late Duchess, as it opens with the new year, and is truly lovely. I shall be very much obliged if any one will add to this list of sorts flowering in January. J. Rust, Eridge Castle.

Primulas at Andley End,—These are now in great beauty. There are several hundreds of plants, in forty or more varieties, all in full bloom and tastefully arranged in a light commodious span-roofed house, forming at once a grand sight. Mr. Vert gives Chiswick Red the first place in this shade of colour, and considers alba magnifica to be a great advance

on all other whites, while he has hopes of obtaining a new race from the blue Holborn Gem. Gilbert's doubles are in good form—dwarf, sturdy, and well bloomed. Marchioness of Exeter and the Earl of Beaconsfield are two of the best. Mr. Vert attributes his success in blooming these so freely to keeping them in comparatively small pots, and to careful watching in their propagation. The whole collection shows that they not only have been carefully watched, but that they have been zealously and intelligently handled. Hortus.

The Native Country of the Mangosteen.—At pp. 753 of your last volume, in reference to the "Forest Flora of Cochin China," you observe, "Among the plates is one devoted to the Mangosteen (Garcinia mangosteen), which, it appears, is not known in a wild state." I have no doubt whatever but that this delicious tropical fruit is really native in the island of Borneo, where I met with it in the forests beside the Lawas and Meropok rivers. In its wild state the interior of the fruit consists of four divisions only, all four containing each a perfect seed (fig. 4), whereas in the much larger cultivated fruits there are seven or eight divisions, and of these rarely more than one contains a perfect seed, as shown in the accom-

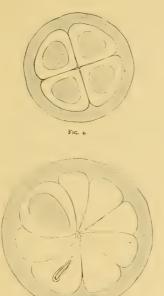

Fig. 5. — THE WILD AND CULTIVATED MANGOSTEEN: FAULT SECTIONS.

panying diagram (fig. 5). This as a wild fruit is well known to the natives, who call it Mangoosta. Beside the Lawas river another species of Garcinia is not uncommon, with a long-nosed or top-shaped fruit, containing eight divisions of a rather acid tasted pulp. Four segments are abortive, the other four containing each a perfect seed the size of a Kidney Bean. Its fruit is hight red, turning nearly black when ripe. Its native name on the Lawas is "Prada-prada." F. W. Eurbüdge.

Late Roses.—The following kinds were in bloom here a few days before Christmas, and some still have beautiful buds:—Gloire de Dijon, Cdine Forestier, Souvenir de la Malmaison, Cramoisie Supérieure, Miniature, Smith's Yellow, pink China, or monthly, Marèchal Niel, in bud; Homère, and others. To all lovers of flowers I would say, grow them all, but especially the pink and crimson Chinas. They are within the reach of all, as they do not require much attention, and many old buildings, walls, or fences, might be made gay and pretty with flowers nearly all the year round by being covered with these old but now much neglected Roses, instead of being as now unsightly objects. I can look back more than thirty years and find very few seasons when we have not had them in plenty at Christmas and much later on in mild weather, and again in early spring. W. Divert, Wierton, Dec. 26, 1883.

ROTHAMSTED EXPERIMENTS.

THE current number of the Journal of the Royal Agricultural Society contains two contributions from Sir J. B. Lawes, Dr. J. H. Gilbert, and Mr. R. Warington — the first being an account of the nitrogen existing as nitric acid in the soils and subsoils of some of the fields at Rothamsted, and the second is some new determinations of ammonia, chlorine, and sulphuric acid in the rain-water collected at Rothamsted.

From the results recorded we find that soils of three drain gauges, 20, 40, and 60 inches deep respectively, which have now remained without manure and without crop for thirteen years, have during the last six years yielded nitric acid in the drainage-water equal to an average of 40.2 lb. of nitrogen per acre per annum. The production of nitrates is stated to be greatest during the summer months. The minimum amount in the drainage-water occurs in the spring; the maximum in July, or in the first month after wards, in which considerable drainage takes place.

NITRATES IN FALLOW LAND,—In three soils at Rothamsted in fair agricultural condition, cultivated in bare fallow since the harvest of the previous year, 56.5, 58.8, and 59.9 lb. of nitrogen as nitric acid per acre were found in September or October, to the depth of 27 inches. When no excess of rain has fallen during the summer, the nitrates in a fallow soil are chiefly found in the first 9 inches, where nitrification principally takes place, but after much rain they occur at a lower level.

NITRATES IN LAND GROWING CEREAL CROPS. -The results relating to land growing corn crops, receiving no excess of nitrogenous manure, show that only very small quantities of nitrates will remain in the upper layers of the soil through the summer, the crop having assimilated the nitrates formerly present. If rain follows after harvest, and especially if the land be ploughed, a considerable formation of nitrates will occur. Nitrates will continue present throughout the winter, notwithstanding loss by drainage, slow production being always in progress. In late spring or early summer the nitrates will again disappear it the land is once more under crop. On analysis the quantities of nitrates found in the soil generally bore a distinct relation to the amount of crop yielded. Comparing the total nitrogen in the first 9 inches of the permanent Wheat-field soils with the quantity of nitric acid found to the depth of 27 inches, it appears that the nitrogen of permanently unmanured land nitrifies with more difficulty than the nitrogen of land that has yielded large crops, or has received rape-cake or farmyard manure. The old nitrogenous capital of the soil is thus shown to be more slowly oxidised and converted into plant food than the more recent residues of crops or of organic manure.

NITRATES IN LAND GROWING LEGUMINOUS CROPS,—A comparison of the quantity of nitrates found in soils cropped with Beans or Clover with that found in corresponding land in bare fallow showed that nitrates are assimilated by leguminous crops, but that the quantity of nitrogen in luxuriant crops of these plants appears too great to be accounted for by the quantities of nitric acid at present recognised in soils.

From these facts it seems that the amount of nitrates in the different Rothamsted soils points to the conclusion that in the case of cereal crops (Wheat, Oats, or Barley) the nitrates of the soil are a sufficient soil different when we come to the leguminous family of plants, although crops of Beans or Clover do assimilate nitrates from the soil in considerable quantity, is sufficiently established.

It may be mentioned that from determinations made in samples of soils collected in 1833 to the depth of 108 inches, that those which had grown white Clover showed more than 50 lb. of nitrogen as nitrates per acre below 45 inches of depth, while adjoining umanured laud in fallow showed less than 20 lb. in the corresponding layers.

The question arises, whether this be due to the possession by the leguminous crops of a power of utilising nitrogenous substances existing in the soil in a condition of combination, as well as of distribution, not available to cereal crops.

Turning our attention now to the second paper under consideration, we find that 152 analyses of rain, snow, dew, and hoar-frost, representing the daily collections from June 22, 1881, to January 5, 1882, gave an average of 0.248 of nitrogen as ammonia per million of water; the extremes observed were 5.491 and

0.0.43. The following table gives the whole of the determinations in monthly mixtures, grouped according to the quantity of the rainfall; and the results for the summer months (April to September) are given separately from those of the winter months (October to March). The sulphuric acid (SO₀) contained in the rainwater collected in glass vessels has averaged in two years 2.41 per million of water, amounting to 18.5 lb. per acre per annum. This quantity would appear to be about sufficient for the demands of ordinary cereal crops, though unequal to the requirements of Turnips. A part of the sulphuric acid in the Rothamsted rains will be due to coal smoke, and a still smaller portion derived from sea spray. The considerable quantity

The gradual decrease in the proportion of ammonia per million of rain as the rainfall of the month becomes greater, is plainly shown by these figures; the quantity of ammonia brought down per acre nevertheless rises with each increase in the quantity of rainfall; but, taking the figures for the whole year, it requires the rainfall to be increased about sixfold, in order to double the quantity of ammonia contributed to an acre of land.

Six years determinations of chlorine in monthly mixtures of rain gave an average of 1.99 per million of water, or 14.92 lb. per acre, equal to 24.59 lb. of pure common salt. Two-thirds of the chlorides fall in the six winter months—October to March. The minimum quantity falls in July; the maximum in October and November.

In the next table the chlorine determinations in

In the next table the chlorine determinations in seventy-two mouthly rainfalls are grouped according to the amount of the rainfall, and according to the season of the year.

found in the summer rain points to the fact, that the sulphuric acid in rain is largely derived from the products of the decay of animal and vegetable matter, which is, of course, most active in the warmer months. Yohn Y. Willis, Harpenden, Dec., 1883.

THE VINEYARD NURSERIES, GARSTON.

WHEN at the recently held exhibition at Liverpool I took the opportunity of paying a visit to these celebrated nurseries, now belonging to the Liverpool Horticultural Company (John Cowan), Limited, and the first thing that strikes one is the vast difference in the place to what it formerly was—once proverbial for the production of the finest Grapes, but fruiting Vines are all but obsolete; there is still, however, a very

From the ahove results it would appear that in summer the supply of chlorides is very limited, for a large increase in the rainfall is attended with but little rise in the quantity of chlorine brought upon an acre. In winter, on the other hand, the supply of chlorides in the atmosphere is so constantly renewed, that an increased rainfall results in a considerable addition to the supply per acre.

Determinations of sulpburic acid in the rain of two more above since see of a trace willow feedened.

Determinations of sulpburic acid in the rain of two years have given a mean of 2.41 per million (reckoned as anhydride), or 18.5 lb. per acre per annum. The sulpburic acid occurs in nearly equal quantity in summer and winter.

fine Madresfield Court Muscat, which occupies two houses, and which produced last season 420 bunches, actuaging from 1½ lb. to 2 lb. each, and it promises well for a heavy crop next season if allowed to hold its own. What a village of glass there is at these aurseries! You are conducted from one house to another until you fancy it is time to stay, and are sure you have quite tired out the person leading the way. It is difficult to estimate the stock of good things which here find a congenial home; thousands of Palms, Ferns, Crotons, Dracensa, Roses, Ericas, all

in the best possible condition, meet you everywhere, for Mr. Cowan, with untiring energy, caters for all classes of the community, the market of the populous Lancashire city, swallowing up an enormous number of plants every month; at the same time a large business is done in a retail way and with the trade, while furnishing is done to a great extent, for which purpose a large number of plants are grown and reserved, so there is no difficulty, if a large demand is sudden, to meet the matter withoutinconvenience. All classes of purchasers will find something to meet their wishes, as such a varied and well grown stock is provided for selection; at the same time there are certain specialities which are successfully handled, of which we note the leading ones.

VINS IN POTS.—These are a speciality and well done, all the leading kinds being grown in large numbers; about 6000 are annually grown, the huge Vine-house being crammed with them, and we were informed by a well-read old comploye that this house is 204 feet 4 inches long, with 41 feet span—ample accommodation for a large batch; the wonder is to myself where all the Vines are got rid of every year, but there is an enormous demand. The Vines are this season very nice stuff, well ripened and short-jointed; indeed, just the canes to give satisfaction. This large house was filled with Chrysanthemums, &c., in full flower, representing a wealth of bloom, daily consigned to the market.

TEA ROSES.—The stock of these was very large and unusually fine this season, about 10,000 being specially grown in pots for sale, including all the more useful kinds, such as Gloire de Dijon, Niphetos, Perle des Jardins, Maréchal Niel, Cheshunt Hybrid, Madame Falcot, Isabella Sprunt, &c., and bette stuff I never saw, especially the Niphetos, Gloire de Dijon, and Maréchal Niel; the former was unusually strong, while the Gloires were surprisingly fine, each plant with several long well-set shoots. Well might the stock of such plants become exhausted rapidly, and it is intended to considerably augment the number during the ensuing season. Fairy Roses, including the Pet, Mignonette, and Paquerette, are much encouraged, especially the latter, which is a great favourite.

Palms,—These are raised in enormous quantities, the stock being estimated at the present time at from 25,000 to 30,000 in all stages of growth; thousands of young seedlings in the finest health of such useful kinds as Seaforthia elegans, Latania borbonica, Areca lutescens, A. rubra, &c.; and I was pleased to see a very fine batch of Calamus ciliaris, which presented a most distinct and desirable appearance. This, and several of the other Calami, are extremely pretty in a young state, and should be much more extensively grown. Many other rater Palms are also grown, but space will not permit me to mention other than the leading and most useful of them.

FERNS .- Ah! here is a treat! What is that broad mass of a dwarf Adiantum — surely it is not A. Pacottei? Ves it is, really; this is surprising, and all raised from spores. What a charming thing it is; well may it take the fancy of all comers. I was informed the stock at one time consisted of over 5000 plants in all stages of development. I thought the plants had a more compact habit than the original A. Pacottei even, while the pinnules and ultimate segments seemed rather broader; but these are only differentiations to be anticipated by spore-propagation, especially when the parent is of hybrid origin. Another beautiful Fern, named Pteris serrulata cristata Cowani, is largely grown, and when in character it is impossible to have a better form; it produces immense broad crests, which gives the fronds a drooping disposition; it is a most valuable Fern for decorative work. P. serrulata major is also very largely growo. I have never seen this in such quantity outside London before. Didymochlæna lunulata is here in large numbers, and a charming species it is; while, as one would expect, Adiantum cuneatum, A. gracillimum, Lomaria gibba, and many others, are grown in quantity, as well as a large number of less common kinds. The Fern-propagating-house was quite a pleasure-finding spot; here are being raised tens of thousands of young Ferns from spores of all the leading varieties, as well as many very rare ones, the work being accomplished in a most systematic and painstaking manner, and the reward will be sure.

CROTONS AND DRACENAS,—These are grown in large quantities, and while propagation is the watchword at Garston, selection is also clearly made, and a further reduction of varieties will result, so that only the best will be retained. Of the former we noticed good batches and beautiful young specimens of Queen Victoria, Mortei, Hawkeri, Disraeli, Lord Derby, &c., while Dracenas were largely represented by terminalis, Cooperi, Baptisti, Pinardi, rubra, &c. Among other stove plants deserving attention were Aralia filicitolia, Chabrieri, and elegantissima. Bambusa Fortunei variegata struck me very much as grown in the stove.

Among other plants grown in quantity Genistas hold a foremost place, there being at the present time about 10,000 plants in different stages, charming bushy stuff, looking well for a future rich display. Erica hyemalis and E. Wilmoreana are well grown, indeed quite equal to London-grown stuff; but the Company have in Mr. Easton one well qualified for the production of such stock. Many say it is impossible to grow E, hyemalis outside during the summer at Liverpool, but the plants here disprove that statement in toto, as they were grown on flats of ashes, and more copiously flowered stuff one could not wish to see. Epacrises are also largely grown, and are looking very healthy. A large stock of the beautiful and comparatively scarce Acacia Drummondi is being worked up-already it is reckoned by four figures; it is one of the best for decorative purposes. Grevillea robusta and Aralia Sieboldi are grown in enormous quantities, especially the former, thousands of it being disposed of annually. Zonal Pelargoniums for winter flowering are encouraged; two span-roofed houses, each over 100 feet long, were a blaze of colour at the time of my visit, although cut hard every day-a grand testimony to the value of these throughout the year. No one has brought them into greater prominence than Messrs. Can-nell, of Swanley. Orchids are represented in good numbers and healthy young plants, and this is a growing feature of the nurseries. Cinerarias form a very important feature, and it is impossible to see a finer strain than exists here-very dwarf, with immense heads of large even flowers, with very fine colourslarge numbers of which were in bloom, and a multitude coming on. Thousands of bulbs are forced every season, including not less than from 15,000 to 20,000 Roman Hyacinths, and at the time of my visit these were a fine feature. Tulips were also coming in in full force, and will produce a long display with Lily of the Valley, Spiræa, Azalea mollis, &c., for months to come. Visitor.

GOLD-LACED POLYANTHUSES .- Your correspondent "North Norfolk" (p. 796 of vol. xx.) writes of Pearson's Alexander as if it might have been exhibited lately, and I know from several correspondents that it is being offered for sale at about 15s, a plant. I desire, however, to caution the public against spending their money upon plants which must be of doubtful pedigree and quality. I doubt very much if there are many Polyanthus growers who know really of the existence of this grand old flower. In ISS1 I mentioned in the Garden (October 1, p. 340) that Pearson's Alexander had just been recovered from an old garden, and might shortly he expected upon our exhibition tables. In 1882 (Garden, February 11, p. 90) I again referred to it in the following words:—
"Pearson's Alexander is mentioned by 'Exile' as if he had seen it lately, but I am pretty sure that he does not know where it exists. It is a long time since it was seen by the public. It has certainly been found again, and its authenticity established, and it will be a pleasant surprise when it can be shown in true form.

It would be interesting if we could hear if your correspondent has seen this Polyanthus lately, and if it is really obtainable. It will be odd if our Lancashire florists are unaware of it, for they are ready to pay long pri es for good flowers. That Pearson's

Alexander exists I am well aware, as I have thus watched it for three years. The late Mr. Read, of Market Rasen, had a truss of Maud's Beauty of England submitted to him in 1882 for his opinion, and he identified it as true. In his note he thus describes this variety and Pearson's Alexander:-"Pearson's Alexander has a fine circular pip, setting close on the calyx, the size of a halfpenny; fine circular tube, low, nearly filled with anthers; eye a deep yellow, not circular, nor yet a pentagon, between the two, the same colour as the lacing, which is well developed and continuous. The ground colour is very dark, but not black. It makes a very The ground showy flower, bright and lasting, robust and free Maud's Beauty of Eogland is an improved Alexander, colour black, eye good, nearly circular, lacing perfect, tube perfect, raised. Rather larger than Alexander, and perhaps a slight improvement in some of its features, still very similar in its general character; considered by some to be the best of all."

Read was well known as the raiser of Acme and other standard Auriculas, and I have no doubt that the above descriptions of these two famous Polyanthuses had been noted down from actual observation, and may be relied upon as correct. It will be seen that Maud's Beauty is a slightly better Polyanthus than Pearson's Alexander, and this is found now to be the case when the two are placed side by side. is curious to note how celebrated Polyanthuses nearly die out and are again plentiful. This is now the case with Lancer, which was scarce five years ago and is now abundant. Cox's Prince Regent is another instance of a first-rate Polyanthus long lost and again in plenty. Even Cheshire Favourite had its season of scarcity, and was only recovered in the original garden where it had been accidentally discovered by Saunders as a chance seedling. Congleton Queen had its season of trial in 1883, and was lost by hundreds, and is even yet scarce. Latterly Lord Lincoln has had its numbers thinned by death until it is exceedingly scarce, and letches fancy prices. George 1V., which is perhaps the very best red ground Polyanthus we have, is also very scarce this season.

I have often thought that all this comes of the overdivision and over-propagation. Saleable plants are cut up every year and have an unbroken struggle for existence, which certainly impairs the vital energy of the plant, and in trying seasons such as we have had of late the losses are universal. You have then to go back to the place where the plant originated, and where perhaps it has been allowed to grow on naturally. The cultural instructions we have lately had under the heading "Florists' Flowers" in the horticultural papers will lead any one to suppose that the Polyanthus is a delicate plant, only to be grown in pots and frames, and needing excessive care and attention. It is so, truly, where plants are divided late in autumn into the utmost single crowns, placed in pots where the roots get frozen before they get hold, and it is a marvel how a tenth survive.

Mr. Douglas recently stated in your columns that the finest frames of Polyanthuses he ever saw were at Brockhurst, and he asked me to state how we managed to get such results. My answer is, By growing them naturally. We seek soil from places where Primroses We grow Polyanthuses in places where Primroses would grow well. We do not over-divide them; and when we divide at all it is when the plants are ripe for it, and where they divide naturally. We encourage root formation, and never coddle the plants; and we never "risk all our eggs in one Some plants are grown in the wood walks where Primroses grow; others are under Apple trees in the orchard, in properly prepared soil; others are planted out in frames in carefully prepared soil; and, lastly, we have a complete set in pots, plunged in red sand and covered with glass, but open all round, and sheltered from cold winds.

Our stock is divided into these four classes, a few of each plant under each sort of treatment, and thus we have four chances. The tendency with us is to give up pot culture altogether, and to keep to the natural method. Such delicate Primroses as the Double Crimson and the Double Crimson Velvet Madame de Pompadour are growing in our wood walks with amazing vigour, whilst in the open borders they languish.

We are trying the same methods now with Auriculas, but in this case we mix large gravel with the soil, so as to imitate the native habitat of the plant. It is only thus that our "hobby" flowers can be made true garden flowers. Wm. Brockhank, Brockhurst, Didsbury.

POLYANTHUS PEARSON'S ALEXANDER. - This variety was raised by Mr. Pearson, of Chilwell, Notts, great-grandfather of the present head of the firm of Pearson of Chilwell. I well remember my father bringing home a plant he purchased from Mr. Pearson some fifty-five years back, which we grew for a number of years; and a grand variety it is if you get it true. Some three or four years back a plant under this name, and one called Beauty of England, came into my hands from a Southern grower of some repu-It turned out a poor thing, after the Black Bess style, and Beauty of England equally wrong. I do not believe this is now in cultivation, although it has got a representative in the trade. Alexander is yet to be found in a few hands in the North, and I can tell "North Norfolk" he will yet have a hard nut to crack to beat Alexander when well grown. King-

Pearson's Alexander Polyanthus was raised by my great-grandfather, the founder of the Chilwell nurseries, who was considered to be one of the best growers and raisers of florists' flowers in this country. He considered the Alexander to be one of his greatest successes; that it was thought to be a good thing is evidenced by the fact that he sold fifty the first season at a guinea each, and a hundred the next at ros. 6th each—not a bad price for a Polyanthus. I am pleased to hear that this old favourite is still in existence, having considered it to be extinct for many years, as my father made many inquiries for it, and offered a guinea for a plant for years, without avail. The other varieties I have never heard of. Charles E. Pearson, Chilwell.

The Poultry Yard.

A POULTRY KEEPER'S EXPERIENCES .- The question of the raising of eggs and poultry for public consumption is one of exceeding interest, but the item of profit has by many been regarded as so problematical that I take the opportunity offered by the close of the year to give some of my experience as to the profitableness of poultry-keeping in a small way. often read statements similar to that which I am about to make; and whilst admiring the industry shown by some writers in the elaborate statistics furnished, have often doubted their correctness. However, to put them to the test as fairly as possible, I induced my "better half," who is my poultry-keeper, to keep an exact account during the past year of all eggs brought in daily. No account was kept of chickens sold or eaten, as the object of the enquiry was chiefly to ascertain how far, by means of eggs alone, fowls could be made to pay their way. Any further profits arising from chickens eaten or sold may therefore be set against losses from death and other incidental though trifling deductions.

My stock consists now of nineteen hens and a cock of the present year. Perhaps the average of hens has been twenty for the year, certainly not more; but whilst some of the older ones were either killed because hetter for table than for the nest - or, perchance, died-other younger ones came in to take their places as the summer advanced, and no doubt to these younger ones we are chiefly indebted for what eggs we have had of late. My poultry run is about 20 rods in extent, although the hens sometimes get into the adjoining road and field, but their enclosed run does not exceed the space mentioned. They are housed in one corner of a large shed, and are kept clean by means of an oft-raked coal-ash floor, whilst there is ample air. No doubt these are important elements in poultry keeping. Both shed and run bave a northern aspect; and though the shade and comparative coolness is grateful in summer, it is hardly the position I should select for a winter run if I could have my own choice. The food of the poultry consists of Maize and Barley in equal quantities, mixed, given moderately twice a day regularly. To this are added occasionally boiled Potatos, house refuse, a little barley meal to render it palatable, and at times some dry boiled Rice. The fowls are not fattened, but are always in good condition for the table if needed. The entire cost of food purchased for the year amounts to £3 15s.; but if we allow £5 for food of all kinds, and rent of shed-space and run-the latter otherwise almost valueless—a full margin is admitted sufficient indeed to cover all expenses for the year. In previous years I had given the preference to Dorkings, but the

lack of eggs in winter, and the good account of Leg-horos as winter layers I received from a friend, induced me to make a gradual change in my stock; and during the year past I have had as layers quite twothirds white or half-bred Leghorns, a Dorking or two, and a half-bred Bramah or two; the latter of the greatest possible use as setters, for Leghorns are not often broody. During the present year I shall clear out the Dorking blood entirely, and keep Leghorns for layers only.

26

It may not be out of place here to remark that, except in the case of a useful mother hen, it is not desirable to keep any beyond the second year; and if hens that have laid well during the summer be caught up and killed in the autumn to make room for yearlings, they can be profitably utilised. These hens, if hoiled for an hour first and then roasted, will be found as tender as chicken, and if in good condition they make first-rate market birds. No doubt myriads of such hens are sold as chickens, the little wrinkle in thus cooking them rendering the flesh tender, if not juicy.

An old lady is reported to have complained that as soon as eggs became dear her hens left off laying them; but the dame's notions of supply and demand were doubtless misty. In any case, it is evident that if some poultry-keepers can obtain eggs when they are dear they will make their fowls much more profitable than will those whose fowls are but fair-weather layers. It is in this respect I have found Leghorns to be such profitable fowls; for whilst they may beand, indeed, are-inferior to Dorkings for table purposes, they still make good plump birds when killed. But, after all, from the egg-raising point of view, the question of table quality is of trifling importance; no one can ever in this matter hope to have their bread buttered on both sides, and if eggs are abundant it is most probable that table quality will not be of the highest. The white Leghorns are of fair size, and lay eggs of good size, and of the best quality relatively, being well fed, having a good run, and being healthy. I doubt whether any eggs excel those we have from our fowls for solidity and quality.

Now as to the egg produce from the twenty hens, as I have said, chiefly Leghorns, during the past year. January gave us 145; February, 165; March, 225; April, 266; and May, 279. This was the highest number obtained during any month; but, allowing for May having more days than April, perhaps that month shows as good a return. Then in June there was a fall to 234; July gave 202; August, 186; September, 178; October, 137; November, 133; and December, 140—thus showing a trifling increase upon the preceding month, due perhaps to the one day more, and to the beautiful mild weather which prevailed for a considerable portion of the time. It will thus he seen that our total of eggs for the year was 2280, giving an average of nearly 120 per hen.

Probably some readers can show far more sensational figures than these, but I am content to tell simple facts that will hardly be doubted, One of these facts is most remarkable; it is that we had eggs few or many, every day in the year-not one was a blank. Of course it must be remembered that 1883 was throughout open and mild, but still it is equally a fact that eggs became very scarce generally in January and February, November, and December; so that it is evident a mild season did not universally help to laying. The best months-March, April, May, and June-gave 1004 eggs, which at an average of 1d, each were worth £4 3s. 8d., whilst the four winter months above mentioned gave but 583; but these sold at 2d, each, and were therefore worth even more than the larger number-thus evidencing the value of winter layers,

Moderately estimating the value of the 2280 eggs at 14d, each, we get as gross receipts the sum of £11 17s, 6d., and, deducting £5 for expenditure, the absolute profit is £6 17s, 6d., or more than 100 per That such results may follow where poultryfarming is adopted in a large way is questionable, but it is absolutely certain that, given a good run of a couple of acres of rough land, a large roomy fowlhouse, food fairly cheap, and refuse abundant, there is no reason why 200 hens, if of the right breed, should not be found nearly as profitable, at least. course those who undertake poultry-farming, whether largely or otherwise, must have some knowledge of their vocation, but the elements of knowledge are simple and easily learned. Gardening and poultrykeeping are closely allied, and both should more often be found in unison. Chanticleer.

Obituary.

LAST week we had the melancholy duty of announcing in a few lines the death, by his own hand, of one of the very best of gardeners, and one of the kindest hearted of men-THOMAS SPEED, of Chatsworth. At the inquest, which was held on Thursday week, evidence was given by a surgeon to the effect that Mr. Speed suffered greatly from gout, and had been in the habit of taking a medicine which had the effect of causing depression, and the jury returned a verdict of "Suicide during temporary insanity." That poor Speed suffered a martyrdom to gout was well known to a wide circle of private friends and professional acquaintances, and as certain was the knowledge that the loss of one of the most helpful of wives, that he had to sustain a few years ago, preyed heavily on his mind, he being helpless at times through the gout, and left with six children dren to care for. Poor fellow! Deep is the regret of his dren to care for. Poor fellow I Deep is the regret of his many friends that his career should have been terminated in so sad a manner. The deceased was born at Abingdon, in Cambridgeshire, on December 19, 1832, his father being at that time gardener and steward at Abingdon Hall. Here the son commenced his gardening education, leaving in 1851 to take service under his brother, Mr. Joseph Speed, who was then gardener at the Pymmes, Edmonton, and had a high reputation as a skilful plant cultivator. In the following year (1853) Speed was engaged by Mr. William Thomson (now of Clovenfords) as a journeyman in the kitchen garden at Wrotham Park; and twelve months afterwards he became foreman of the department. Subsequently he took came foreman of the department. Subsequently he took came foreman of the department. Subsequently he took charge of the flower garden, conservatory, and forcing departments, and altogether was with Mr. Thomson about four years. In 1856 Mr. Speed became foreman to Mr. Ingram, at Belvoir Castle, and in 1859 he obtained his first head place, being engaged as gardener to the late Sir Edward Walker, Berry Hill, Mansfield, where he made a name for himself as a Grape grower of the highest repute, his practice and his success as a cultivator being then nimself as a Grape grower of the nighest repute, his practice and his success as a cultivator being then a theme of general admiration, Grapes of such size and general excellence as surpassed all that had been seen before in the Midland districts being yearly the result of his skilful management. When Mr. Taplin left Chatsworth in 1868 Mr. Speed was engaged by the Duke of Devonshire to take charge of that prizes were described by the property of the property the Duke of Devolshire to take charge of the princely gardening establishment, and at the Palace of the Peak, notwithstanding his afflictions, he well maintained his reputation. No one who visited him will forget the warmth of the welcome that he will forget the warmth of the welcome that he accorded them, or the evident pleasure that he telt in showing a "practical" the treasures in his charge. We feel as we write these words, as many others we know must feel, the greatest sorrow that so sad a fate should have befailen so good a man.

— We have also with great regret to announce the death on New Year's Day of Mr. BENJAMIN MALLER, of the Burnt Ash Lane Nurseries, Lee, Kent. Mr. Maller had been ill for some time, and at the end of last week appeared to be somewhat better, but he experienced a relapse on Sunday even better, but he experienced a relapse on Sunday evening from which he never recovered, and died on
Tuesday morning, his malady being a diseased liver.
He was a native of Ashling, io Sussex, and in early
life was employed as a journeyman in the gardens at
Stanstead Park, when Mr. Jones was gardener at
that place. From Stanstead he came to London,
and held one or two situations as gardener before and held one or two situations as gardener before commencing business on his own account some years ago. In the nursery trade he soon won the respect of his comperers, being a first-class cultivator, and a thoroughly straightforward man of business. His particular like in business was the cultivation of winter and spring flowering Heaths, and other plants, for what is known as the autumn trade, and in this branch he met with great success, his stocks, which of late years regularly came under he hammer of the auctioneer, being of the very best quality. About five-and-twenty years ago be became a subscriber to the Gardeners' Royal Benevolent Iostitution, subsequently becoming a member of the Committee of Management, an office which he held at the time of his death. He was also one of the founders, and an enthusiastic supporter, of the Lee and Elackheath Horticultural Society—one of those flourishing suburban societies which owe so much of their prosperity to the labours and well-directed energies of men of Mr. Maller's stamp. He enjoyed some practice, too, as a landscape gardener, and in this connection beautified more than one of the old London churchyards. His manly presence, sterling honesty, and thorough good-nature, were qualities that endeared him to many friends; so that his loss will be much more widely felt than by members of his family only. his stocks, which of late years regularly came under his family only.

22.—Fine cold day; slight raio at night.

LONDON : Atmospheric Pressure .- During the week LONDON: Atmospheric Pressure.—During the week ending December 29, the reading of the barometer at the level of the sea increased from 20,00 inches at the beginning of the week to 30.53 inches by 3 P.M. on the 24th, decreased to 30.51 inches by 3 P.M. on the same day, increased to 30.59 inches by 9 P.M. on the 25th, decreased to 30.25 inches by 3 P.M. on the 29th, and was 30.26 inches by the end of the week.

The mean reading of the barometer for the week at the level of the sea was 30.45 inches, being 0.35 inch higher than last week, and 0.37 inch above the average of the week.

Temperature. - The highest temperature in the Temperature. — The highest temperature in the shade in the week was 48° 5, on the 24th; the highest reached on the 27th was 40°. The mean of the seven high day temperatures was 43°.6.

The lowest temperature was 32°, on the 24th; ton the 25th the lowest temperature was 36°.4. The mean of the seven low night temperatures was 36°.4. The mean of the seven low night temperature in one day was 16°.5, on the 24th; and the smallest was 2°.2, on the 29th. The mean of the seven daily tanges was 7°.4.

The mean temperatures were—on December 23, 40°; on the 24th, 24°, 7; on the 25th, 41°.85°.

40°; on the 24th, 42°7; on the 25th, 41°.8°; on the 26th, 30°.8°; on the 27th, 37°.3°; on the 28th, 30°; and these were all above their averages, excepting the 27th, which was 0°.3 below, by 1°.0, 4°.5, 3°.8°, 2°.1°, 5, and 1°.5 re-

Spectively.

The mean temperature was 39°,9, being 0°.8 lower than last week, and 2°.1 above the average of the

week.

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 55°, on the 23d. The mean of the seven readings was 48°.6.

The lowest reading of a thermometer with its bulb placed on short grass was 22°.5, on the 24th. The mean of the seven readings was 31°.1.

Kain.—Rain fell on the last four days of the week to the amount of 0.10 inch.

to the amount of o.10 inch.

ENGLAND: Temperature .- During the week ending December 29 the highest temperatures were \$4°.2 at Nottingham, and \$4°.9 at Truro and Sunderland; the highest at Bristol was 48°, at Blackheath 48°.5, and at Cambridge and Bolton 49°.1. The general mean

The lowest temperatures were 30° at Sheffield, 30°.6 at Wolverhampton, and 32° at Blackheath and Leeds; the lowest temperature at Truro was 36°, at Plymouth 35°.4, and at Liverpool 34°6. The general mean was

35°.4, and at Liverpool 34°6. The general mean was 33°.

The greatest ranges in the week were 23° at Sheffield, 21°.8 at Wolverhampton, 21° at Sunderland; the smallest ranges were 15° at Bristol, 16°.1 at Cambridge, and 16°.5 at Plymouth and Blackheath. The general mean was 18°.1.

The mean of the seven high day temperatures was highest at Truro, 51°, at Plymouth 49°.1, at Sunderland 48°; and Iwas lowest at Hull, 41°.9, at Cambridge 42°.5, and at Blackheath 43°.6. The general mean was 45°.4.

The mean of the seven low night temperatures was highest at Truro, 41°.1, at Plymouth 40°.3, at Sunderland 38°.7, and was lowest at Wolverhampton, 33°.5, at Sheffield 33°.6, and at Hull 34°.9. The general mean was 36°.9.

The mean daily range of temperature was greatest at Sheffield, 11°3, at Wolverhampton 10°,8, and at Truro 2°,9; and was least at Wolverhampton, 6°,6, at 11ull 7°, and at Blackheath 7°,4. The general mean was 8°,5.

The mean temperature was highest at Truro, 46°, at Hymouth 44°.7, at Sunderland 43°.3; and was lowest at Hull, 38°.4, at Wolverhampton 38°.9, and at Cambridge and Sheffield 39°.2. The general mean was 41°.2.

Rain.—The largest falls were—0.19 inch at Truro and Plymouth, and 0.15 inch at Sheffield and Bolton; the smallest falls were 0.02 inch at Bradford, 0.03 inch at Wolverhampton, and 0.04 inch at Hull and Sunderland. The general mean fall was 0.09 inch. Rain fell on every day in the week at Plymouth.

SCOTLAND: Temperature.—During the week ending December 29, the highest temperature was 58°, at Peth 1; at Greenock and Paisley the highest was 51°. The general mean was 52°. S.

The lowest temperature in the week was 36°, at Leith; at Glasgow and Perth the lowest temperature was 26°. The general mean was 31°.1.

The mean temperature was bighest at Leith, 45°; and lowest at Aberdeen, 40°.5. The general mean was 40°6.

was 42.56.

Rain.—The largest fall was 0.93 inch, at Paisley and the smallest fall was 0.09 inch, at Leitb. Ti general mean fall was 0.47 ioch.

JAMES GLAISHER, F.R.S.

Answers to Correspondents.

JUMPING SEEDS: Scotus, Yes, in 1859. The correct reference is p. 909 of our volume of that year, where you will find this curious phenomenon explained and

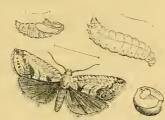

FIG. 6 .- CARPOCAPSA SALTITANS.

the iosect—Carpocapsa saltitans, described. We reproduce the illustration then given, fig. 6.

AENORMAL ACARICS: H. T. Soppitt. We have many times seen double Mushrooms of the character of that you send us, and some triple ones. You will find an interesting article on the subject, and some illustrations from the pen and pencil of Mr. Worthington Smith, in our issue for July 26, 1873.

CIDER APPLES: Not Blue. Apply to the Cranston Nursery Company, Hereford, or some other nursery-men in the West of England.

EDGING TILES: M. Y. The best plan is to dig out a trench of the required depth, level and well ram down the bottom, and on this lay a course of bricks on which to place the tiles in a straight line, ramming the soil down firm on either side.

FREESIA REFRACTA ALBA: S. S. This is a native of the Cape of Good Hope, having a fibrous-coated bulb about the size of the bulb of a Jonquil, linear

lanceolate leaves, and the white finnel-shaped flowers borne on a one-sided curved spike. The flowers open in succession, four to six being open at one time. It does not require any forcing to flower it in winter, a digit position in a temperate house being sufficient light position in a temperate house being sufficient

for it.

HATING MUSCAT-HOUSE: E. W. Jones.— For a house of the width and height stated you would require four rows of 4-inch pipe near the front wall, and two rows at about the same level, forming a parallelogram with two short sides, occupying the rest of the house, leaving space for a path at the back, and one about 4 feet from the front wall. This arrangement will distribute the warmth pretty evenly; but the greater quantity of pipe is placed where the roof is lowest, and consequently, owing to the ascent of the heated air to the highest point, it is most required. A house for any other sort of Grape would do with one-third less pipe, buttils better to have too much than too little heating surface. A saddle boiler exposing 8 feet of surface to the direct action of the fire—that is, exclusive of side fine exposure—would be large enough. HEATING MUSCAT-HOUSE:

NAMES OF FRUIT: C. IV. S. Your Apple is unknown to us, and we suspect with you that it is a local variety only.—R. G. Fig. White Ischia.

NAMES OF PLANTS: J. E. The yellow flower is Cassa corymbosa; and the Orchid Trichosma snavis. Please send better materials next time.

send better materials next time.

Vines: A Learner. If you wish for Grapes without the expense of fuel, you can plant Black Hamburgh, Foster's Seedling, Buckland Sweetwater, Red and Grizzly Frontignan—the two last if you place any value on fine flavour. These would do tegether in one house if thought desirable. For late use and for keeping over the winter the sorts named below may be planted. If started into growth every year early in the spring months they will require fire-heat to start with, and the latest will be benefited by fire-heat in September and October, if not sufficiently ripe in early September. Black Hamburgh, Black Allcante, Madresfield Court, Muscat of Alexandria, Mrs. Pince's Black Muscat, Lady Downe's, and, as a big showy kind, without much else to recommend it, Gros Colmar.

** All communications intended for publication should be addressed to the "Bātiar," and not to the Publisher or to any member of the staff personally. The Editor would also be obliged by such communications being arritten on one side only of the paper and sent as early in the week as possible. Correspondents seeding newspapers should be careful to mark the paragraphs they wish the Editor to see.

SEEDS,
LONDON: Jan. 2.—Messrs, John Shaw & Sons,
Seed Merchants, of 37, Mark Lane, report that
more disposition for business in farm seeds is shown
now that the holidays are over. Red Clover seed in all
positions exhibits considerable firmness. In white seed
a substantial rise has been established. In Trefoil there
are but few transactions. Canary and Hemp seed in the
absence of dealings show no variation in values. Spring
Tares meet at present with scarcely any attention.
Feeding Linseed continues firm.

CORN.

At Mark Lane on Monday there was very little business in any kind of grain. For both Wheat and flour quotations were nominally unaltered Marking Earley series were steady but slack. Beans the turn in buyers' favour. Peas 17, and Maize 6d, cheaper on the week. Oats supported late value, but were slow of soile.—On Wednesday English Wheat was held for steady value, but met very little attention. Foreign tended in favour of buyers. Flour remained nominally unaltered. Both malting and grinding descriptions of Barley were firm, with an upward bias. Beans and Peas moved off in small quantities at Monday's casier rates. Maize remained dull at Monday's quotations. Oats were quiet at unchanged values.—Average prices of corn for the week ending Dec. 29;—Wheat, 391; Barley, 311, 7d.; Oats, 191, 1d. For the corresponding period in 1882;—Wheat, 401, 11d.; Barley, 321, 3d.; 304s, 221, 5d.

POTATOS.

POTATOS.

The Borough and Spitalfields Markets reports state that there are fair supplies and moderate demand, at the following prices:—Magnum Bonums, 80x. to 90x.; Regents, 90x. to 80x; I Champions, 60x, to 70x; and Victorias, 70x. to 90x. per ton.—The imports into London last week consisted of 295 bags from Harlingen, 56 Bruges, 240 Brussels, 20 Boulogne, 105 Hamburgh, 30 bags 187 sacks from Rouen, 70 barrels Boston, 20 eases Malta, 92 tons Erquey, and 4 barrels from New York.

SEASON 1884.

In again calling the attention of Market Growers, Gardeners, and Amateurs to Clay's Fertiliser, we feel a pride in stating that it has increased in popularity year by year, until it has attained the position of being considered an absolute necessity for the production of Fruit, Flowers, and Vegetables of the highest excellence.

Unfortunately, this success has induced some unprincipled persons to adulterate the Manure, causing great disappointment to users and serious annoyance to ourselves. We have therefore decided, after the 1st of January, 1884, to send out all Manure (except 1s. packets) in Scaled Bags; and we trust buyers will, for their own protection, insist on having it in our bags with our Trade Mark and Seal attached, for which alone we shall be responsible.

SON & HEWITT DAY.

SILVER MEDAL from the Doncaster Agricultural Show, June, 1882. Also

GOLD MEDAL from the International Show, Christchurch, New Zealand, March, 1882, FOR THEIR "ORIGINAL"

STOCK-BREEDERS

Which contain every Essential to give Health to Weakly, Sickly, and Prostrate Animals, to cure the ever-dreaded Diarrheea in Sheep and Lambs, the most unhealing Wounds and Sores, the worst forms of Colic and Gripe Pains in Horses and Cattle, and lastly—though not least—that fearful malady, the Husk or Hoose in Lambs, Heifers, and Calves.

In fine, the Chests contain which (to use a metaphor) disease shudders to combat, for health (in all curable cases) invariably comes out of the encounter. It may be said of these unswerving Medicaments that they stand out in bold relief from all others, of whatever country or clime, for their unerring safety, marvellous rapidity of action, and great fame, thereby opening a large field for the plagiarist and the daring imitator, against whose practices perpetual caution is needed.

Price of Chest complete, including "Key to Farriery," £2 16s. 6d., sent carriage paid throughout Great Britain.

CAUTION.-Beware of Imitations, and see that the name, DAY, SON & HEWITT, is on all Bottles and Packets.

"PERSIAN FOOD." Fat-forming. Easy of Digestion.

"PERSIAN FOOD" is recommended by the most eminent Members of the Medical Profession.

INDIGESTION ABOLISHED.—Those who suffer from the tortures of indigestion should not fail to try "PERSIAN FOOD." It is pleasant to the taste, thoroughly satisfying, and easy of digestion. It is, in fact, the most remarkable Food that was ever introduced.

Equal to Meat for Delicate Stomachs.

REGISTERED.

REPORT OF J. MACPHERSON, Esq., M.A., M.D.

"Dear Sir,—I have not employed any "35, Curzon Street, London, W., January 17, 1883.

"Dear Sir,—I have not employed any the the PERSON FROUD to shock you have sort me a speciment, but I have made a trait of the the PERSON Froud to the supplying a light, bland and pleasant form of natramed in an amount pleasant with it, as supplying a light, bland and pleasant form of natramed.

"Yours faithfully," "J. MACPHERSON." " J. MACPHERSON."

FOR CONVALESCENTS.—Aged Invalids who have tried this remarkable Food have found it most health restoring and re-invigorating. It is pleasast to the taste, and has a rich aroma. A very small quantity of "PERSIAN FOOD" rapidly produces a most marvellous effect on even the most aged and infirm systems. "PERSIAN FOOD" is of the purest quality, and is perhaps the greatest hoon to bealthy as well as suffering humanity that was ever offered to the public.

OPINION OF W. B. O'SHAU HNESSY, M.D., F.R.S., &c
"Two drachms afford a sufficient meal for an invalid. Good 'PERSIAN FOOD,' carefully
prepared, is in truth one of the best articles of diet a convalescent can use." Sold in Bottles, 2s., 3s. 6d., and 10s. 6d. Directions on each Bottle.

To be had of all Chemists, Medicine Vendors, &c., or sent by Parcels Post on receipt of Remittance.

AND FLORICULTURAL YEAR BOOK FOR 1884.

EDITED BY SHIRLEY HIBBERD.

THIS issue contains complete classified descriptive Lists of all the New Flowers, New Fruits, New Vegetables, &c., of the past year, with estimates of their several values and uses. The New Plants of the past year are described sufficiently to facilitate their identification.

A Complete Catalogue of varieties of Potatos, including the latest introductious, and the results of Trial Culture and Exhibitions. This list is designed to be of permanent value, and the greatest

care has been taken to ensure fullness and accuracy of details, An abstract of the Agricultural Holdings Act, prepared with a view to set forth its purposes and provisions free from legal technicalities.

The Exhibitions of 1884: a List of the most important Meetings and Competitions in process of organisation, with the dates, subjects, and other particulars.

A Business Almanac and Diary pages, with all the usual Astronomical, Postal, and Statistical information, render the Garden Oracle invaluable for handy use and reference throughout the year.

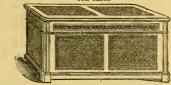

The "Gardeners' Magazine" Office, 4, Ave Maria Lane, E.C.; and Sold by all Newsagents, Nurserymen, and Seedsmen.

HILL AND SMITH'S BLACK VARNISH, for Preserving Ironwork, Wood, or Stone. (Registered Trade Mark)

This VARNISH is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the Advertisers, and its genuine good quality, notwithstanding a host of unprincipled mitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labouer, requires no mixing or thinning, and it used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many handreds of the Nobility and Gentry, from whom the most Sold in Casts of about 30 gallons each, at 12, 64 per gallon at the Manufactory, or 12, 84, per gallon carriage paid to any Station in the Kingdom.

Station in the Kingdom.

"Fiercefield Park, Tune 21, 1876.—Sirs.—I have this day forwarded from Chepstow to your address a black varnish cask, to be filled and returned with as good Varnish as the last we had, which I candidly admit was the best we ever had. Address Varnish to Piercefield Park, Chepstow.—I am, Sirs, yours reCAUTION—Hitl. & Surns would particularly warn their Customers against the various cheap Varnishes now so much adversieed.

Customers against the various cheap various:

H. & S. s Varnish has been an article of common use on most of the large estates in the kingdom for upwards of thirty years; and their constantly increasing trade in it, and the unmerous Every cask is legibly marked with their name and Registered Trade Mark as above, without which none is gennine.

EPPS'S COCOA.

"By a thorough howledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Coco, Mr. Rypg has provided our breakfast-tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution tendency to discusse. Howdrad of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well furtified with pure blood and a properly nouri-hed frame." Civil Service Gattette.

Made simply with boiling water or milk. Sold only in Fackets, ishelled thus:
JAMES EPPS & CO., Homeopathic Chemists, London, England.

London, England.

HOLLOWAY'S PILLS.—Easy Digrestion.—

These admirable Fills cannot be too highly commended for the wholesome power they exert over all disorders of the stomach, liver, bowels and kidneys. They instantaneously relieve and steadily work out a thorough cure, and io its course dispel headache, biliousness, flatulence and depression of spirits It is wonderful to watch the daily improvement of the complumpness to the face which had lost both flash and colour, Pitches Pills combine every excellence desirable in a domestic remedy. The most certain and beneficial results flow from the cocasional use of this regulating medicine; even persons in health, or when following sedectary occupation, will find it an invaluable aperient.

GARDEN OF ENGLAND-KENT

How correct both in flowers and fruit! Kent is known as the most fertile county in England. Yes, sun and soll are most tropical-like, and the glorious sunny summer of 183 has again more clearly confirmed this fact. Flower seeds before unheard of in this country have injected in the open, which clearly shows our favourable position. This, together with our usual carry applied to carry out our business, has brought us many Medals for excellency of flowers. Nearly all the numerous Flower Seeds that we offer are of our own saving, and, either for germinating quality and superior strain, have never before been offered. There are some fancy that unless they have their Seeds from foreign parts they cannot be good nor possess ment and novely, and nowhere in England can they be had so good.

WHAT A FALLACY!

We have searched out nearly every garden in Europe and tested their specialities, and we ask all to visit our garden at Swanley, at all seasons, see and compare our varieties with any ers in the world. We not only grow the best, but we apply all scientific means possible to improve every flower year by year—not in one feature, but in all points and ways, so as to give customers the best and most pleasing results of what they purchase.

THE UNITED KINGDOM SAYS THUS:

And on February 2 we hope to show what the Horticultural Press says of our

PLANTS AND SEEDS.

From Mr. W. COLLINS, Ballonatray, Irriand, 7 on. 3, 1831.—"I have the greatest pleasure to testifying to the excelent quality of your Dahliss, which I received from you last April (1832); they were decidedly the most beautiful flowers dever saw. I should be willing to tell you some I though to be the best, but I am afraid I would not be doing justice to the others."

sell before writing you. Then size and common my expectations, Thom Mrs. SHRUBB, Boldre Grange, Lymington, Hants, From Mrs. SHRUBB, Boldre Grange, Lymington, Hants, Mrs. 2, 1882. "I hope if you are ever in my neighbourhood with me. They are the admiration of every one for miles and miles round, and every one who sees them says they never know there were such flowers; they have enormous trusses, and enormous flowers on the truss, many of the latter considerably exceed: a laches, across. They ought to be one of your best distributions."

enormous Howers on the truss, many of the latter considerably exceed z inches across. They ought to be one of your oest advertisement and they ought to be one of your oest advertisement. TRANTER, Esq., 54, Woodstide Terrace, Great Lever, B. TRANTER, Esq., 54, Woodstide Terrace, Great Lever, B. TRANTER, Esq., 54, Woodstide Terrace, Great Lever, B. The Month of the plants; they are of excellent quality, and give great satisfaction."

From Mr. T. ANDERSON, 7, Powys Street, Tyldesley, Road, Tyldesley, near Manchester,—"Verbenas all right, and in first-class condition; they looked quite fresh, just as if they out pack them is wooderful."

From Mr. S. WOOD, 21, Mankland Street, Middletbried, May 14, 1833.—"I may say that although I could have obtained from other sellers the same variety at perhaps a less figure. I am quite coordineed that ever since I commenced business with you I have never received any stuff that has given me more complete substantial and the study of t

ANTS AND SEEE

From C. FOWLER, Esq., Brilish Boys School, Chickster,
June 27, 1883.—"Roses arrived this morning as fresh as the
proverbal Daisy. They are beautiful. Many thanks."

From J. H. OSBURNE, Esq., Northélid, Bromley, Kent,
June 23, 1883.—"Thanks for sending me the plants to my
ellas; I believe the speedad contrion, the packing marvellas; I believe the production of the packing marvellas; I believe the production of the packing marvellas; I believe the production of the packing for days
without taking harm."

From Mr. WM. THOS. HAYES, Elmowood, Sudbury, Harrom.—"I beg to say that the Roses arrived safely, and have
given great satisfaction."

The plants arrived quite safe. The Chry
santheniums are spendid plant."

Longraigne, Foulks Mills, Wesleyd, Irelant, July 17, 1883.

"Ms. J. W. DEANS is much obliged for the cuttings and
plants received, not only safely, but so beautifully fresh, last

PRIZE COB FILBERT TREES,—Gentle-men destrous of obtaining the true WEBB'S PRIZE COB FILBERT TREES for present planting, should send their olders to
Mr. COOPER, F.R.H.S., Calcot Gardens, Reading, of whom
alone the various soits can be obtained.
Price LISTS oo application.

PICEA PUNGENS.—The Blue Spruce of Colorado; see Gardeners' Chronicle, Dec. 8, page 735. Fice plants of the true glaucus variety, with blush tint, 12 to 18 inches, 55. each. Fice plants of the green variety, 22 to 18 inches, 15. 6d. each. Piced LISTS of California Coolies seat free on application.

MORRISON BROTHERS, Aberdeen.

JAMES SMITH AND SONS, Darley Dale Nurseries, near Matlock, beg to offer the following to cice plants:—n 42ALEA PONTICA, to 1½ foot, 20x. per 100, or 283x. per 1000.

BERBERIS DARWINIL, 10 1½ foot, 28x. per 100, or 160x. per 1000; 1½ to 2 feet, 28x. per 100, or 226x. per 1000; 1½ to 2 feet, 28x. per 100, or 226x. per 1000, or 226x. per 1000.

EAST INDIAN ORCHIDS.

THE LIVERPOOL HORTICULTURAL COMPANY

(John Cowan), LIMITED,

Have pleasure in announcing to their numerous Patrons and the Public generally, that their first consignment of EAST INDIAN ORCHIDS for this season will be to hand in a few days.

The Company's Collectors, in forwarding this consignment, state that it includes many splendid Specimens and several New and Rare Varieties.

Full particulars will be sent on arrival of this consignment to all who kindly send their Name and Address to

THE LIVERPOOL HORTICULTURAL CO. (John Cowan), LIMITED, THE VINEYARD, GARSTON, LIVERPOOL.

ORCHIDS. RARE

DENDROBIUM RHODOCENTRUM.

HEATH & SON are now offering this rare Dendrobe, from 10s. 6d. to 21s. each, flowering plants.

- 1 ODONTOGLOSSUM DELTOGLOSSUM, with spike of 13 Flowers.
- 1 ODONTOGLOSSUM CORADINEI.
- 1 ODONTOGLOSSUM BAPHICANTHUM
- 1 LÆLIA ALBIDA SULPHUREA (New).

For description, see New Plants. Sizes and Price on application.

HEATH & SON,

ROYAL EXOTIC NURSERIES, CHELTENHAM.

THURSDAY NEXT.—(Sale No. 6567.)

ODONTOGLOSSUM EDWARDI. CATTLEYA TRIANÆ-IBAGUE VARIETIES.

R. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY NEXT, January 17, at half-past 12 o'Clock precisely, by order of Mr. F. SANDER,

The grandest importation ever offered of ODONTOGLOSSUM EDWARDI; the masses are in altogether extra health. ODONTOGLOSSUM EDWARDI is the most difficult species in existence to import, hence this sound lot will give a good opportunity to purchase this rare and superb Odontoglossum.

Also a grand lot of CATTLEYA TRIANÆ, from the same locality whence we have had the grand varieties now in collections; together with some other excellent imports.

On view morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET COVENT GARDEN, LONDON, W.C.

FRIDAY NEXT.

ONCIDIUM MACRANTHUM HASTIFERUM. ODONTOGLOSSUM HALLI. ODONTOGLOSSUM HRUBYANUM (in Flower).

MESSRS. PROTHEROE AND MORRIS have received instructions from Mr. F. SANDER to SELL by AUCTION, at their Central Sale Rooms, 67 and 68, Cheapside, E.C., on FRIDAY NEXT, January 18, at half-past 12 o'Clock precisely,

A specially grand lot of ONCIDIUM MACRANTHUM HASTIFERUM, in splendid condition

And the finest importation ever offered of the white-lipped ODONTOGLOSSUM HALLI, among them the finest masses yet seen of any Odontoglossum.

ODONTOGLOSSUM HRUBYANUM, in flower. A lovely yellow ONCIDIUM; ODONTOGLOSSUM SANDE FRAGRANS, and ODONTOGLOSSUM ALEXANDRÆ, finest type. ODONTOGLOSSUM SANDERIANUM, PILUMNA

On View morning of Sale.

TRADE. THE

Dwarf-trained and Maiden Fruit Trees and Roses, of fine quality, grown on fresh land at Bush Hill.

APRICOTS, trained, 30s. and 36s, per dozen.

CHERRIES, in variety, trained, except May Duke and Morello, 21s. and 24s. per dozen.

PEACHES and NECTARINES, trained, £12 105. p. 100. PEACHES, Dwarf Maiden, £3 15s. per 100.

PLUMS, trained, £7 10s., £8 15s., and £10 per 100.

PLUMS, Dwarf Maiden, £2 105. per 100. ROSES, Standard and Half-standard, £3 10s. to £4 per

HUGH LOW & CO., CLAPTON NURSERY, LONDON, E.

OOLING'S NE PLUS ULTRA by the Royal Horicultural Society, and is the earliest and most productive Dwarf Bean in existence. Invaluable for forcing. In sealed pint packets, as: 6d.; post-free zs. gd

COOLING'S LEVIATHAN COS LETTUCE.—A decided improvement upon all Bath Cos varieties. The largest and hardiest Lettuce in cultiva-tion. In sealed packets, 15., post-free.

COOLING'S OMEGA BEET.—
The richest coloured and most delicately flavoured variety. In sealed packets 1s., post-free.

COLING'S MATCHLESS BROC-COLI.—The original stock of this splendid mid-season variety. Per packet 18, post-free.

ROLLISSON'S TELEGRAPH CUCUMBER, 12. 6d, per packet.

VEITCH'S TENDER and TRUE CUCUMBER, 12. 6d, per packet.

Both the above Cucumbers are very pure stocks, which we have selected with special care for several years past, and we recommend them with every confidence to the Market or Private Grower.

Trade prices on Application

GEO. COOLING & SON., NURSERYMEN AND SEEDSMEN, BATH.

CABBAGE PLANTS,—One Million of Early Rainham and Enfield Market, 32. per 1000 of 1200; Red Dutch, for peckling, 52. per 1000; all from the very best seek. ASPARAGUS ROUTS, three years old, 182. per 1000; two years old, 192. per 1000; First-class Roots best Sonereign st. per dozen. FENNYROYAL and RUE ROUTS, 51 per 32. per dozen. PENNYROYAL and RUE ROUTS, 51 per 500. ONION SEED, White Spanish, 32. per pound; Nuesham Park, 32. 64, per pound; all new and genuine. From 701 os 1000 in the Magnum Boumm POTATOS, £4 per 101; and 82 toos of true Magnum Boumm POTATOS, £4 per 101; and RICHARD WALKER, Market Gardens, Biggleswade, Beds.

RICHARD WALKER, Market Gardens, Biggleswade, Beds.

HOUSE'S PERFECT MARROW.—Growth large handsome pods, well filled with large Feren Marrow Peas, after the "Ne Plus Ultra" type. After several years trial and comparison with other Wrishded Peas, this Pea has proved to with confidence be recommended for Esthbilion and Market with confidence be recommended for Esthbilion and Market purposes. When so many good Peas are offered, it is a difficult task to impress upon the minds of the public the superiority of one Pea over another. In offering this Pea, allow me to say that it was raised by the late Mr. F. Stevenson (Gardener over 50 years). He kept it for several years, and compared it over 50 years). He kept it for several years, and compared it with all the best sorts, but I cannot find any so god for cropping and quality; also several experienced persons in the trade, who have seen it growing and tested the quality, confirm the same. This gives me confidence in recommending it.

A few Testimonals as follows:—

the same. This gives me confidence in recommending it.

A few Testimonials as follows:—
From Mr. HARDING, Gardener, Orton Hall, Peterborough.— Sir.—I have tried your Perfect Marrow Pea, and I
borough.— Sir.—I have tried your Perfect Marrow Pea, and I
strooper grower, and heavy cropper, with well filled pods, and
excelled quality."
From Mr. CHESHIRE, Gardener, Conington Castle.—
"Dear Sir.—Your Perfect Marrow Pea is the sort I have long
desired to have—a heavy cropper and excellent flavour."
From Mr. VERDON, Gardener, Harlanton, Hall, Granstam.— Sir.—Your Perfect Marrow Pea is the finest I have ever
see the second of the principal shows in the coming season.
Secretaries of Shows will oblige, before filling up their Schedules, by communicating with me.

Orchids a Speciality.

The stock at the Clapton Nursery is of such magnitude that, without seeing it, it is not easy to form an adequate conception of its unprecedented extent.

HUGH LOW & CO.

very cordially and respectfully solicit an inspec-tion by all lovers of this interesting and beauti-ful class of plants, whether purchasers or not.

CLAPTON NURSERY, LONDON, E.

HARRISONS' **NEW EARLY "ECLIPSE"** PEA.

A grand new Early Pea, introduced by us ast season.

The haulm is of a peculiar light green colour, only 2 feet in height, the pods of a lively green and well filled, and is the heaviest cropper for an early variety we have ever seen. The seed is blue and similar in appearance to the "Kentish Invicta," but it is hardier and even earlier than that excellent variety.

Retail Price—Per Pint, Is. 6d.; per Quart, 2s. 6d. Trade Price—Per doz. Pints, 12s.; per doz Quarts, 21s.

TESTIMONIALS.

From Mr. John Swift, Manchester.
"October 24, 183,—I coosider your New Early Eclipse Pea
to be the best early Pen I have ever grown, both for earliness,
size of pods, and appearance."

From Messrs. Taber & Cullen, Rivenhall.
"October 25, 1883.—The New Pea, 'Early Eclipse,' we had
from you last season is a good early blue, and valuable for
poddiog, all comiog in together."

poddiog, all comog in together."

From Mr. Samuel Taylor, Pershore.

"October 23, 1832.—I found your New Early Eclipse Peaver early and protific. Sown by the side of Kentish invicta, they were ready to pick nearly a week before that variety, and I picked nearly 4 pots (40th ger pat) off the little patch of ground, and had 8s, per pot for them; when the other early ones were ready the pick had dropped to 5s. I hope you will be able to spare the 4 bushels I spoke for in the summer."

From Mr. W. Hull, Evesham.

"October 28, 1883. - Your New Early Eclipse Pea is the best early Pea I ever had; it is a good cropper, very early, and gave me every satisfaction. I hope those you have sent me will prove as good."

"July 5, 1833—I find your New Early Eclipse Pea an early and good cropping variety. When you are quoting the price per bushel for the coming year, I should like 2 quarters of the same stock of Pea."

The above Testimonials are only a few from the large number we have received.

IRELAND & THOMSON. 20, WATERLOO PLACE, EDINBURGH.

WAITE, NASH, HUGGINS AND CO.'S NOVELTIES AND SPECIALITIES FOR 1884.

WAITE'S NEW EARLY CABBAGE.

A new and distinct variety, equally adapted for spring or autumn sowing, and coming unto use fully ten days before any other kind. The habit of the plant is dwarf and compact; the heart is of medium size, very firm, and with very few loose leaves. The colour is a distinct pale green, and the Cabbage, when cooked, does not possess the coarse flavour so objectionable in the dark-leaved varieties.

Price, 1s. 6d. per packet.

WAITE'S IMPROVED LONG-POD BEAN.

The improvements which will be found in this variety of the well-known and ever popular Long-pod, fully justify us in saying that it is the finest, most productive and most useful Bean ever raised. The pods are very long, containing seven to eight fine Beans in each, and are borne in great profusion on plants of branching habit, in clusters of three and four at a joint. Although the pods are not so large as those of the Seville and Aquadulce, the Bean is in reality much more prolific, for as many as forty-seven pods were counted on one plant in August last. In addition to this it is much superior to the varieties named, as the Beans remain tender and juicy for a very much longer time.

Price, 2s. per quart.

WAITE'S NEW CABBACE LETTUCE,

A splendid and distinct variety, especially adapted for summer use, and destined to take the same high position among Cabbage Lettuces as is occupied by Waite's Alexandra among Cos varieties. It has the same pleasing colour and general appearance as "All the Year Round," but is quite distinct from that variety, both in colour of seed and the habit of the plant, as it grows to nearly double the size, and stands for a very much longer time before running to seed. Although it attains to such a large size it forms nice tender hearts in the earliest stages of its growth, remaining sweet and crisp to the last. In our trial grounds this season it remained fit for use nearly three weeks later than any other variety.

Price, 1s. 6d. per packet.

THE WARMINSTER ONION.

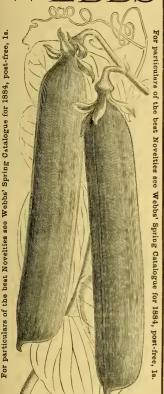

Originally selected from the White Spanish this variety possesses, in a marked degree, all the merits of that well-known kind; in addition to which there have been developed, by continuous and judicious selection, increased size and weight, earliness, purity of colour, symmetry of form, mildness of flavour, and good keeping qualities.

Price, in sealed 1 ounce packets, 1s.

May be obtained from any respectable Seedsman throughout the Kingdom.

THE BEST NFW PEAS.

PEAS IN 1833.—"The Stourbridge Feas always turn out well, and Electric Light, Kinver Gem, and Stourbridge Marrow are amongst the finest of our Peas."—J. Murr in the "Journal of Horticulture," Sep-tember 13, 1883.

STOURBRIDGE MARROW.

The finest second early Pea—either for ordinary garden cultivation or exhibition purposes—that has ever been offered to the public. It is a remarkably strong and vigorous grower, and an enormous cropper; it attains a height of from \$10.45 feet, and bears immense pods, which are produced in pairs, and each pod contains from nine to eleven large Peas of the most delicious flavour.

3s. 6d. per pint.

WEBBS' NEW PEA, THE WORDSLEY

This valuable new Pea is the result of crosses between Advancer, Little Gem, and Prizetaker, and whilst possessiog all the good qualities of the two former varieties, it has both the constitution and productiveness of the latter.

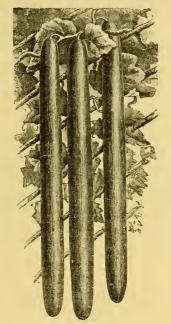

3s. 6d. per pint.

THE QUEEN'S SEEDSMEN,

WORDSLEY, STOURBRIDGE.

CHOICE

SPECIAL SUTTON AND SONS desire particularly to call attention to the fact that they are scrupulsoly careful out to introduce anything as a way and they are scrupulsoly careful out to introduce anything as a way are of other kinds in cultivation. Their Trial Graume advance of other kinds in cultivation. Their ities at home, but by the leading seedsmen in Europe and America, to be the most extensive and complete in the world; and here, under Messrs. Sutton's own personal supervision, some Soco trials of Vegetable Seeds, Flower Seeds and Potatos are anonally made in a most complete and exhaustive manner.

SUTTON'S PURLEY PARK HERO

Awarded a Special Certificate and 1st Prize against twelve competitors at the Reading Horticultural Society's Show, May 17, 1883; was also awarded a Cultural Commendation from the Forey Horticultural Society on Baly 22, 1883; and took ist Furg at the Summer Show of this Society at South Kensington,

SATURDAY, JANUARY 12, 1884.

THE NEW PLANTS OF 1883.

(Continued from p. 10.)

N resuming our brief sketch of the novelties of the past year-that is, of new plants which during the year have either made their first appearance, or which have been brought into prominent notice-we next take

THE FERNS,

of which the number has been more limited than usual, though one or two very interesting additions have been made. The Andean Cyathea microphylla will probably prove to be the most valuable and important acquisition of the year in this family. It is a small Tree Fern, with a slender caudex, which attains some 4 feet in height, and no doubt assumes an erect position, though the plant shown by Messrs. Veitch & Sons, and recently certificated, had the stems curved and ascending, which we suppose to be either an accidental or juvenile state, probably the latter, it being similar to the mode of growth seen in the stems of young plants of Cyathea dealbata, which, though in the young state at first prostrate and then ascending, ultimately become quite erect. The fronds of this new Cyathea are gracefully spreading, 2 to 3 feet or perhaps more in length, but never attaining a large size, ovate in general outline, tripinnately divided, and peculiarly neat-looking from the small size of the ultimate pinnules, which are ovate-oblong, deeply pinnatifid, with oblong blunt-ended, entire lobes, each traversed by a single vein, at the base of which, on the fertile part, is seated a solitary sorus. It comes from the Andes of Peru and Ecuador, and is remarkable for its compound fronds and minute pinnules, which are the smallest and neatest to be found amongst the Cyatheas at present known.

Perhaps even more remarkable, on account of its dissimilarity of aspect from the usual forms assumed by its congeners, is the Adiantum novæ-caledoniæ, which was first shown in 1883, by Messrs. W. & J. Birkenhead, at the great summer show at Manchester, and certificated, and which afterwards obtained a similar award in London from the Floral Committee. Its aspect is that of Adiantopsis rather than of Adiantum, only it is normally tripinnate instead of being radiately branched; thus the fronds have something of a stellate character, while the increased size of the stellate character, while the increased size of the posterior basal pinnule gives it a pedate outline. Altogether its aspect is peculiar. The caudex forms a small erect crown, from which spring the stipites of the usual blackish-purple colour, and supports the pedato-pentangular lamina, which is roundish in circumscription, tripinnate in composition, and of a darkish green colour; the pinnæ all, however, have narrow elongate pinnules, which are lanceolate in form, drawn out at the point in an attenuated caudate slightly falcate form, and thus they rather resemble those of some Cheilanthes in form, but have the truly adiautoid fructification-that is, resupinately borne on the cordate orbi-Two other Adiantums of garden origin cular indusia. are worthy of mention here. The one, A. Weigandii, is of American origin, whence it was acquired by Messrs. Veitch; it has something the aspect of the useful decorative A. decorum, the fronds being of a moderate size and of a similar triangular form, and divided, like that, in a tripinnate manner, but the divided, like that, in a tripinate mainter, but the pinne and lower pinnules are long-stalked, so that the centre of the frond is open, while the apical parts both of frond and pinne are crowded; and thus, together with the distinct form of the pinnules, ovate from a broad base, and freely and conspicuously

lobate, yet appearing little divided, in consequence of the narrowness of the sinuses, the plant takes on a thoroughly distinctive aspect, more evident to the eye than can be readily word-painted. The other is a new garden hybrid raised between A. cuneatum and A. Bausei, and is of the stature and general character, with small wedge-shaped pinnules, of the former, and deflexed pinnules those of the latter, thus taking on a truly intermediate character; from this peculiarity it is called A. cuneatum deflexum. The variety, hybrid or otherwise, was raised by Mr. F. Bause, now of Portland Road, South Norwood, whose name is familiar to hybridists.

From the New Hebrides, thanks to the intervention of Messrs. Veitch, there has been added to our collections the fine and evergreen Hare's-foot Fern, Davallia brachycarpa. This species belongs to a small set which is closely allied to the Darcoid group of Asplenium, and is distinguished from the more typical Davallias by their short oblique solitary sori. It will be found a very ornamental stove plant, with large arching fronds, firm in texture, having a broad ovate quadripionatisect lamina, of which the ultimate segments are wedge-shaped, trifid or bifid, bluntish, the fertile ones falcate, with a solitary sorns on the ioner side of the vein.

Closely related to the Ferns are the club mosses, among which we have to make the addition of Selaginella canaliculata, the S. caudata of Spring. This is one of the climbing species, with the habit of S. Willdenovii (known as S. cæsia arborea), growing to a height of 5 or 6 feet, with stout pale brownish red stems, which root freely from the lower parts, and above bear pinnate branches a foot long, the smaller branchlets of which [are also pinnately divided; the lower are entire, ribbed, and semi-ovate, the smaller intermediate ones being similar in character.

STOVE AND GREENHOUSE PLANTS.

One of the most interesting and richly coloured of the plants of this section is the Rhododendron Curtisii, introduced from Sumatra. It is a dwarf, bushy evergreen shrub, growing about 2 feet high, and clothed with lance-shaped leaves and terminal clusters of brilliant crimson bell-shaped flowers, small in size, as compared with more familiar sorts, but borne in such profusion as to render the plant a highly conspicuous object, and well worthy of the certificate voted to it at South Kensington in November last. Another interesting plant, ornamental in character, and of a profusely-blooming habit, is the Medinilla Curtisii, from the same country, and introduced by the same collector. It is dwarf, bushy, and much branched in its manner of growth, as well as extremely floriferous, the flowers being white, with purple stamens, and produced all over the plant in terminal and axillary corymbose heads. The leaves are opposite, sessile, ovate acuminate, deep green, the margins and mid-rib red; it is remark amongst other peculiarities, for its coral-red rachides and pedicels. The Anthurium ferrierensex, of which we had previously heard, has been shown in flower during the past year. It will be recollected that it is a hybrid, raised at Ferrières, between the scarlet Andreanum and the white A. ornatum. It will doubtless be a favourite plant when well established, the foliage being of large size and heart-shaped, in this respect taking after A. ornatum; while the spathe, which is heart-shaped and nearly 6 inches long, is of a beautiful rosy or cherry-red colour, the spadix being about 4 inches long, and erect, of an ivory-white, becoming orangeyellow at the tip. Wormia Burbidgei is a striking looking stove plant for a large collection. It is a Dilleniad, with very large leaves sometimes 11 foot long, and of a bright green, and clear yellow circular flowers nearly 4 inches across; and has been intro-duced from Borneo by the collector, whose name it bears. M. André's Caraguata sanguinea, from the Andes of New Grenada, is a fine Bromeliad, though passed by by the Floral Committee, who do not appreciate the beauties to be found in this particular family, which are certainly not general favourites in this country. Here we have a moderate-sized plant, with a dense tuft of rosulate leaves, of which the inner ones are of a deep blood-red colour, with which the small white flowers nestling deep down in the centre are in strong contrast. It is beauty of a special type, and if not appreciated in this country the more's the pity, Of another type, that of the Asclepiads, is the Hoya linearis sikkimensis, a remarkable species, well adapted for growing in baskets, having slender flaccid pendent hairy stems, with soft fleshy subterete leaves, and terminal umbels of white wax-like flowers, with a small corona of five yellowish lobes.

We turn next to a series of bulbous plants, which are worth attention, and as a class are becoming more so every day. The most useful is probably the Eucharis Sanderi, a species of well marked character, clearly distinguishable from its allies by its plicate ovate leaves and smaller white flowers, which, however, are in other respects much in the way of those of E. amazonica; notwithstanding their smaller size the plant is fully as useful, and quite as handsome as its congeners. Crinum ornatum, possibly the same as C. Kirkii, is a handsome stove bulb from tropical Africa, and produces many-flowered umbels of shallowly bell-shaped flowers, which are white, with a broad stripe of red running through the centre of each of the six segments of the perianth; both have been certificated, and are certainly very handsome objects for stove decoration, though, like all bulbous plants, now considered less generally useful and acceptable than other plants, such as those of shrubby habit. They are, however, again making way in public estimation, and possibly may soon achieve a wide popularity. Crinum zeylanicum reductum, a new form from Zanzibar, has, as Mr. Baker puts it, the special merit, from a horticultural point of view, of possessing "a dwarf, compact habit, and large showy flowers." The ensiform leaves form a rosette of about a dozen about the scape, which is under a foot long, supporting an umbel of four flowers, which have a green tube, 5-6 inches long, and a limb of elliptic segments, which are white, with a red central band, just as in the typical zeylani-It is not improbable that these three forms, which have turned up in different places, at different times, may have a very close relationship.

One or two interesting new Cycads have been recently brought under notice. There is the Indian Cycas Beddomei, which is in the way of C. circinalis; the stems of the plants grown at Kew are only a few inches high, the leaves 3 feet long, the petioles quadrangular, having a few minute teeth in the upper part, the leaf-segments about half-an-inch wide, and the cones (anale) about 13 inches long and 3 inches in diameter, these having the sides acuminate from a deltoid base, those of the upper half being deflexed. It is found in the peninsula of India. Cycas elegantisma has been shown and certificated, and is an elegant plant, with recurved pinnate leaves of a deep shining green; but we are not aware if it has undergone botanical scrutiny. Finally, in Dioon spinulosum we have a truly distinct Mexican novelty, differing from Dioon edule in the segments of the leaf being much broader, and armed with thorny teeth, the number of those found in fully developed leaves of D. edule. T. Moore.

(To be continued.)

SARCANTHUS LENDYANUS, n. sp.*

THIS Annamite novelty is rather near to Sarcanthus termissus, Rchb. f., but it may be immediately distinguished by its linear, blunt, bilobed leaves, as well as by the distinct structure of the flowers, which stand in a small loose panicle. Sepals and petals greenish, with a fine purple disc. Lateral lacinize of the liproundish, with introse angles, orange with two purple lines, central lacinia oblong, white with purple spots. Column white with purple spots. The blunt spur is as long as the purple ovary, and has a small septum in its apex. The characteristic Sarcanthus callus under the column is oblong, retuse at its apex, where it runs out each side in a spreading angle. It was imported from Saigon by Major Lendy, Sunbury House, Sunbury-on-Thames, and whose a name it justly bears. H. G. Robb, f.

SACCOLABIUM GIGANTEUM (Wall.), VAR. ILLUSTRE, nov. var.

I have been often asked about Saccolabium illustre. I learn from Mr. Sander, who sends me a

* Sarcanthus Lendyanus, n. sp.—Affinis S. termisso, Rchb. f. Folis linear-ligulatis apice obtine bilobis, particula paululum for the property of the property

very rich inflorescence of it, that this is the name of an elder friend of mine, I having named it in January last Saccolabium gigantenm for Director Linden. I could indeed not foresee then what appears to be the case, that, by richer colours, larger spots at the tops of the sepals and petals, and a brigher-lip, it was most probably superior to the elder Birmese plant, just as the Assamese Dendrobium Wardianum appears constantly superior to the Birmese one. I also hear the illustrious variety has longer and broader leaves. H. G. Rekh f.

BOUVARDIA SCABRA, H. and A.*

This novelty is an exceedingly attractive and pretty species, and one of the handsomest of the genus. It is a valuable acquisition as a decorative at this season of the year-the flowers, which are larger (1/2 inch in diameter) than those of most of the other species of Bouvardia, being of a bright cheerful pink colour, and very freely produced. grows 12-18 inches high, and has terete, hairy, herbaceous stems, with distant whorls of acuminate leaves, narrowed at their base into a very short petiole, generally three, rarely four in a whorl, subscabrous on both surfaces, the midrib and veins very prominent beneath, the lower leaves 2-3 inches long, I-I1 inch broad, the upper gradually smaller. Flowers in dense corymbose cymes; the pedicels, bracts, and calyces pubescent; calyx lobes subulate, recurved, spreading, 3-3½ lines long; corolla glabrous, the tube 10-12 lines long, marked with four grooves at its apex, whitish; limb of four spreading, broadly elliptic-ovate, subacute, bright pink lobes, throat of tube whitish. It is a native of Mexico, where it was first discovered by Hartweg. The characters which mark this elegant species are the prominent veins on the under-side of the leaves, the long, slender, squarrose calyx-lobes, and the broad spreading lobes of the corolla. N. E. Brown.

SABAL UMBRACULIFERA.

HORTICULTURALLY this is a Palm of great importance, and its value in that respect must be estimated not only by its intrinsic merit as a decorative plant, but also by the great range of temperature in which it will give satisfaction, and the multitudinous variety of purposes for which it can be utilised. may be grown in either stove or conservatory, and in summer it may be placed out-of-doors, or used in the decoration of any building, dwelling-house or otherwise. For table decorations the leaves are rather gross in their dimensions, but the plant can easily be replaced for this purpose by others of a similar habit but more graceful in their leafage. The most important feature of this Palm, however, and the one that will give the best impression of its bold and majestic proportions, is when it developes a trunk, and bears aloft its tuft of enormous fan-shaped leaves.

In order to develope this character rapidly, it must be kept in a moist stove temperature. It is one of the tallest of the genus, although it will by no means rival its closely related ally the Tallipot Palm of Ceylon, annely Corypha umbraculifera, conceroing which travellers are wont to relate many wonderful stories. This latter moreover is seldom cultivated, and is by no means so ornamental in a young state, owing to its slowness in development from seed. There is an important distinction however in the flowering stage—that whereas the Corypha flowers only once, yielding up its life a sacrifice to the production and perfecting of fruit, the Sabal, after attaining a fruiting size, remains almost constantly laden with it in various stages of progressive maturity.

A fine specimen in the Palm-house at Kew, with a trunk about 25 feet in height, will bear out this statement. There are several much taller Palms, but none of the fan-leaved type will match it in hold and massive outline. The great branching panieles of fruit hang from the axils of the leaves, eliciting well merited admiration from thousands of visitors. The berries remain in a green state for a long time, but when in a state of incipient decay they assume a black colour, and being about the size of Cherries, many visitors seem impressed with the idea that they are Grapes, or something similar, and consequently out of place. They are sweet and similar in taste to Dates; but the succulent and juicy matter is too scanty to be of any consomical importance. The greater part of the berry, economical importance. The greater part of the berry.

^{*} Bouvardia scaora, Hook. and Arn., Bot. of Beechy's Voyage, p. 427.

which is somewhat pear-shaped, is occupied by a hony globose somewhat depressed seed—flattened on the underside.

As the flowers are perfect so are the seeds, and in this iostance the minute embryo embedded in the bony perisperm may be detected with the naked eye, in the shape of a small knob or protuberance, showing the position of the radicle on one side, towards the flattened base of the seed. If these seeds were somewhat larger the bony perisperm could be utilised for the purposes of turnery, in the same manner as that of the vegetable ivory Palm or even that of Corypha.

ORCHID CULTIVATION FOR AMATEURS.—II.

In visiting gardens or nurseries where Orchids are largely grown, and uniformly well grown, one important fact must perforce receive the attention of a careful observer. In no two places are the houses, the temperatures, or the composts employed alike. As a fact, general results are better and more alike than the variability of the cultural means employed lead one to expect. In a word, the amateur cannot too soon learn the great central fact in "good garden "-a fact exemplified every day in horticultural practice-viz., that there is more than one way, indeed there are often many ways and means, of attaining success in Orchid culture, as in other gardening operations. It is this fact which renders it so difficult to give detailed advice in print, since the exact practice adopted under one set of conditions becomes wrong partially, even if not wholly so, amid other surroundings. To be equally successful with his plants under different circumstances is the true test of the gardener, be he amateur or professional.

Now, if I were asked what of all others is the most important factor in connection with Orchid growing, I should unhesitatingly answer, the atmospheric conditions of the house or houses. You may pot your plants when and how you like, but you will have no permacent success if your atmosphere is not right. I do not mean to say that if the atmosphere be genial you need not be careful of your time and manner of potting, but what I wish to impress on the amateur is, that of all the conditions essential to success this question of temperature—the due balance of heat, air, and moisture—is of all others the first to demand attention.

In December, 1882, I wrote to Dr. Paterson, asking him for some particulars as to the temperature in which he had grown those magnificent Vandas which attracted so much attention when sold in Edinburgh. Here is his reply, under date December 26:—" My warmest house during the last two months has ranged about an average temperature of 50° in the morning (sometimes as low as 45°), and I find that Vandas, Aerides, Saccolabiums, &c., grow and flower splendidly, and Phalænopsis Schilleriana and P. Luddemanniana do well with the same treatment. Whenever the temperature outside (i.e., in the open air) is at or over 50° I always give plenty of air at all times. The air of an Orchid-house should be fresh and sweet—never 'siufly,' dry, and burning, as we too often find is the case in many house. Such an atmosphere favours the development of all sorts of insect pests and disease, and ultimately destroys many valuable and rare plants."

Now 45° in the morning sounds very low, especially when we remember the plants named, and that it occurs (occasionally, miod) in the warmest house; but then we must remember that the fall has been gradual during the wintry night, starting, say, at 60° or at 65°, and slowly cooling down, until the minimum is reached, so that the thermometer has not been at 45° more than an hour or two at the most. Now even in tropical regions a fall of 20° is not unusual at night, and although 50° is a safer and better minimum or morning temperature for a warm house I would much rather see the glass at 45° than have the "hurning" smell from the pipes to which Dr. Paterson and all good growers have the strongest objection.

The way in which a plant-house is heated is most important. Amateurs, as a rule, at the beginning of their experience are simply in the hands of a local hot-water engineer or hothouse builder who contracts for the work at the lowest trade prices. If the latter knows his business he will recommend that sufficient piping be employed, and will see that it is properly distributed, so as to act most efficiently, but it happens in most cases that too

little piping is employed in the first instance, and this results in much trouble and annoyance. A little extra "first cost" expended in piping will soon be saved in labour and fuel. Wherever too little piping is used trouble comes in several ways. very cold weather the fire must be driven at full blast, and scorching hot pipes are the result. You complain, only to hear that the heat must be "got early in the night, otherwise the glass is too low in the morning. This system of "firing up" at night is wrong in theory and practice alike, for it is now an accepted fact that the highest temperature is only really beneficial to the plants during the earlier part of the daytime, when sunlight is most active. On the other hand, the lowest temperature should be that of the night time, and "firing up" should begin in the morning, not at night, as is too often the rule at present. In many cases the boiler is blamed, and a more powerful one is put in, all to no purpose, for if a small boiler could heat the water to boiling-point, or nearly so, a large one can do no more; and in nine cases out of ten it will be found that an insufficient radiating surface or length of piping is the cause of irregular heat. A large body of water heated, say, to 160°, is far better, and gives a more genial tem-perature at less cost. Less labour in stoking and less fuel are required than when an insufficient supply of piping necessitates a roaring fire, and water as near boiling-point (212°) as possible whenever there is a cold wind or a sharp bite of frost. Even although many amateurs know all this without the telling, it is astonishing how rarely we find "slow fires, geoial low and airy night temperatures in actual operation. Only, however, where such are the rule can Orchids be easily, permanently, and economically grown, F. W. B.

NURSERY NOTES.

THE EXOTIC NURSERY, EDGBASTON, BIRMING-HAM.—Amongst a number of plants that are most useful during the autumn and winter, and particularly well grown here, is Centropogon Lucyanus, a plant that has been several times lately favourably spoken of, and which deserves to be much more generally known than at present. Mr. Spinks strikes it in the spring, growing it on in 6-inch pots through the summer similarly to other soft-wooded autumnflowering stove subjects. The shoots are each sup ported by a short stick for about half their length thus allowing the extremities to arch over; in this way the numerous bright crimson tube-shaped flowers stand straight up above the leaves, having a telling effect. It is here largely used for furnishing, for which purpose it is well adapted, the bright flowers and neat habit of the plant admitting of its being employed where coarser growing things would be unsuitable. It is equally seviceable for cutting.

Euphorbia jacquiniæsfora, as grown here, would surprise any one who has only been accustomed to see this grand winter blooming plant done in an ordinary way. The cuttings are put in in spring, five or six together, in small pots, and when well rooted the whole, without separation or disturbance, are at once transferred to 5 or 6-inch pots, in which they are grown on and flowered; they are never stopped, but let to extend as far as the liberal treatment they receive enables them to do. In each pot two or three of the plants take the lead of the rest and keep it, the strongest reaching from 6 to 7 feet, and are as thick at the hottom as one's little finger, bearing grand sprays of flowers. When the plants are as strong as these they produce a second or third lot of bloom finer than those forthcoming in the first instance from weaker examples. The principal portion of the stock forms a long row in one of the houses with their heads close up to the roof, in which position they are all through the summer, lowering the pots as the tops grow. In such little pots these big heads naturally get too topheavy to stand; to meet this at the latter end of the season they are plunged in larger pots, but do not root through. They are liberally fed through the summer with Clay's Fertiliser, and occasionally with soot-water. Foinsettias are well and extensively grown, both the old P. pulcherrima and one here grown under the name of P. superbiens, a much finer sort than the old one, with broader flatter bracts, the colour bright crimson shaded with violet.

Some of the hest managed Lily of the Valley we have seen in December was here just coming to its best; 30,000 crowns are forced. Eucharis of the different kinds are made a speciality, and grown in quantity so as to keep up a continuous supply of their pure white scented flowers. Amongst a large stock of the best kinds of Palms suitable for furnishing Phœnix rupicola is particularly well managed. This is one of the handsomest species in cultivation, and is worthy of a place in every garden where elegance of form is duly appreciated. In Ferns, of which the best decorative kinds are much in demand, Adiaotum Lathomii is an especial favourite, as it deserves to be, with the distinct and handsome form of A. tenerum. It combines a beautiful arching habit in the fronds, which adds much to its appearance. Of other things grown for decorative use is the elegant twining Myrsiphyllum asparagoides, which is planted out in a bed at one end of a house, where its roots, in the form of suckers, run freely, pushing up quantities of shoots, which are trained to thin strings. Where green garniture of a flexible light character is wanted this plant stands unequalled; its thio thread-like stems clothed with their pretty leaves can be employed where most things would be too heavy. It is much used in this way in America, where, we understand, it is sold by measure, fetching about 20 cents per yard of the shoots.

THE JENSENIAN METHOD OF POTATO CULTURE.

To reply to Mr. Worthington G. Smith's remarks upon the Jensenian method of Potato culture is to me a very pleasant task, because these remarks embody the views of one who, having made a special study of the subject, does not adopt that tone of supercilious superiority which is sometimes affected by great men. On the contrary, he is not above discussing other people's statements, and has been at some little trouble in the matter of microscopic measurements and numerical calculations. There is no doubt of the beneficial results practically obtained by a sufficiently high and a sufficiently early moulding of the Potato plant as a preventive against the disease. No one has called Mr. Jensen's statistics in question upon this score; the difficulty, however, is to make them harmonise with our Anglican notions of the lifehistory of this parasite.

Mr. Jensen, writing to a contemporary last year," says :- "Before publishing my treatise I placed the manuscript before Mr. Carruthers, the consulting botanist to the Royal Agricultural Society of England, soliciting his assistance in revising the treatise. He owned that he had been impressed by the very extraordinary practical results of my experiments, and returned a very polite and kind answer; but as he was quite certain that the spores (or their sprouting germs) were not able to penetrate the skin or corky layer of the tubers, he thought the whole foundation of my system was wanting, and he could therefore, of course, not recommend or assist the publication of my treatise. So that, having three of our leading scientists against it-Mr. Smith, Mr. Carruthers, and Mr. Murraythere is no fear of the Jensenian method dying out from "over credulity."

The first point Mr. Smith raises is concerning the tube experiment, in which a layer of compressed earth is claimed to have filtered out and retained a certain number of spores that were contained in water poured into the upper end of the tube. As for the diameter of the tube, and the exact way in which the lower end was closed, I cannot at the present moment When this tube say, but will endeavour to find out. had r inch of earth compressed to three-quarters of an inch placed at its bottom, water containing 30,000 spores was poured into the upper end. The water percolated through the earth and escaped below, was examined and found to contain 2000 spores; hence 28,000 were retained in the earth. As I understand from Mr. Jensen's letter to me in which he describes this experiment these numbers are only approximate. He does not pledge his word of honour as a Danish gentleman that the number of spores poured in was exactly 30,000; it might have been 30,001. or 29,999. He counted, as I understand him, the number of spores in a drop of the water he poured into the tube, and he also counted the number in a drop which came out at the bottom; most likely he counted the number in several drops, and took the mean, and so obtained the approximate numbers above given.

Mr. Smith thinks it is an impossible task to count the number of spores in a drop of water, and goes into

an elaborate calculation as to how many feet a drop of water would appear to measure when magnified 400 diameters, which comes to a "sphere of above 8 feet in diameter !" This may be perfectly true, and doubtless is, if Mr. Smith says so; but there is the fact that we are constantly viewing spores in drops of water, and are never practically inconvenienced by this enormous aqueous spheroid. To count a flock of sheep is by no means easy to a novice, and even practised hands, when absolute accuracy is demanded, mark each one as it is counted with a spot of red paint; but I do not suppose Mr. Jensen adopted this plan. The facility with which the spores contained in a drop of water can be counted depends on the size of your drop for one thing, and upon the number of spores in it for another. You can let fall a drop from a capillary pipette on a cover glass for a hanging drop culture, in which the spores can be counted, as I am sure Mr. Murray will bear me out, with the greatest ease. If there are only ten or a dozen spores in a much larger drop they could be enumerated easily enough; but if you took a drop charged with hundreds instead of units, the process would be

The second great difficulty Mr. Smith finds is the great size of the grains of the finest sand as compared to that of the zoospores. This idea, too, seems to have enamoured Mr. Murray* in his lecture upon the Potato disease at the Parkes' Museum. Mr. Smith has told us how many zoospores can lie upon a grain of Croydon, Reigate, Gray's Thurrock, and Stoke Newington sands respectively. Both these gentlemen seem entirely to forget, however, that it is not the size of the grains of sand we have to consider, but that of the interspaces between them. I readily admit that a single layer of grains of sand would practically offer no resistance to the passage of zoospores, but how many millions upon millions of layers would there be in 4 inches of compressed sand? Mr. Smith tells us accurately enough the size of each grain, but he has not calculateddoubtless a mere oversight-the diameter of the interspaces between the grains. Professor Tyndall found cotton-wool an effectual filter for the germs of putrefaction contained in the atmosphere. Now these germs are infinitely more minute than the zoospores, yet a plug of cotton-wool is a complete barrier against them. I am not aware that Professor Tyndall ever calculated the number of germs that would have to be laid side by side in a row to equal in length an ordinary cotton fibre, but I am sure if this were done Mr. Smith's figures would sink into insignificance beside

As Mr. Jensen gives a figure in his pamphlet† of the conidia and zoospores side by side, so I think we may credit him with knowing something of the physiology of the subject. The figure is taken from De Bary, but I know it does not follow that because a writer makes use of De Bary's figures, therefore he knows as much about the subject as this great master himself does. Mr. Jensen, however, in this part of his pamphlet describes the formation of zoospores, and in various places refers to them by name. At p. 55, for instance, he describes an experiment in which he employed them.

I really cannot agree with Mr. Smith that the common-sense view of the case is that the skin of every diseased Potato has been injured by a wire-worm, snail, insect, bird, rat, mouse, rabbit, or other animal. On the contrary, the vast majority of diseased tubers are, according to my experience, without any mark of external injury.

When a discovery of any sort is made, it usually has to pass through three stages before becoming generally accepted. At first it is pooh-poohed as unworthy of attention, then it is laughed at as being so utterly ridiculous, and then people say it is no discovery at all, but a simple and obvious fact known to every one for years.

When this stage is reached the discoverer may congratulate himself that the world is ready to believe him. I have anxiously looked out for some indication of this final stage in connection with the Jensenian system, but hitherto with little success. It seemed to me, if Mr. Jensen's method of Potato culture be a efficacious as he says it is, amongst the thousands of Potato growers in this country, some one must have noticed the advantage of high moulding, even if they did not understand the precise reason for it. There were, it is true, a few correspondents at the time Mr. Jensen's pamphlet first appeared, who indicated in an

indefinite sort of way, that the idea was not new to them, but nothing that I saw had the ring of authority about it. It was not until this summer that the first claim for precedence came. It was from a horticulturist in whose garden I did an experiment in high moulding in July last. He told me that many years ago he had observed the fact, that some Potatos he grew in the West of England were accidentally moulded much higher than usual, and that as a consequence they escaped the disease, while those of his neighbours suffered severely from it.

I was, therefore, greatly pleased when Mr. Smith was good enough to bring Dr. Lang's papers * under notice in the Gardeners' Chronicle (vol. xx., p. 697). In this essay, to which a prize was awarded in 1858, presumably by the Royal Agricultural Society, Dr. Lang, after treating of the various methods of Potato culture, goes on to speak of the disease. All the facts with which everybody is now familiar concerning the structure and physiology of the Peronospora were evidently unknown to him; for he speaks of its attacking the Mulberry, Lilium lancifolium, &c. He refers to the inutility of chemical and other manures in checking the disease, excepting lime and salt, which he considers to some extent beneficial, and then proceeds to say (p. 74):-" It was remembered that in 1847 and 1848, when the disease appeared to be greatly on the increase, and threatened to be, as it really was, most destructive, a man at Whilborough, on dry days, in order to save his Potatos, instead of digging them up, made the earth very fine, earthed the stalks up very high, and saved his crop most effectually." + He then mentions the case of a friend of his who from carelessness on the part of his men had a large number of Potatos left in the ground: in the following year, at Dr. Lang's suggestion, these plants were earthed up many times, so that "this piece of ground looked as if it were studded with bee-bives scattered at random over it. He had such a crop as at that time I had never seen. Dr. Lang seems to have been led to adopt this plan from reading a paper by T. A. Knight, of Downton Castle. (What true Woolhopean can hear the name of Downton without experiencing a thrill of joyous memories !) The essayist goes on to say (p. 77), "Failing them all chemical remedies, when applied on a large scale . . . the experiment at Whilborough became important. It was observed on taking up many acres of Potatos by many men, that no Potato covered with more than 3 inches of soil was ever diseased." Again, "I have seen scores of bushels of Potatos dug, but I have never seen or heard of one diseased Potato being found 4 inches under the surface of the ground. It will be at once seen-and too much stress cannot be laid on the fact—that the disease is in an exact ratio to the proximity of the tubers to the surface." The author then gives an experiment On September 18, 1857, three pits were made 10 inches deep, and about the same diameter; three white kidney Potatos were placed horizontally on the bottom of each pit, and just covered with a little fine earth; then another layer of Potatos, similarly covered; and then a third layer, so that the whole consisted of three layers of Potatos, with just earth enough between them to keep them from touching each other, the uppermost layer having about 21 inches of earth over it. One of the pits (No. 3) had a large slate laid over it; upon the others a quantity of diseased leaves and stems were placed, and then watered with half a small watering-can full of water poured upon them through a fine rose. On September 28 pit No. 1 had all three of its upper tubers evincing signs of the disease. three pits were opened on January 23, 1858, with the following results :-

No. 1. Three upper tubers quite rotten.

No. 1. Three upper tubers quite rotten.
No. 2. Three upper tubers much affected.

No. 3. Three upper tubers not diseased. "In all three pits both the under layers were free from any taint,"

Although Dr. Lang does not give the measurements of the grains of sand in the soil, yet I think Mr. Smith must admit that this primative experiment is to the point.

The essay concludes with this sentence:—"That earthing up repeatedly with fine earth is the only effective preventive to the ravages of the disease." Of course, this repeated moulding is too expensive to be of practical use to the Potato grower, but the

principle is the same as that employed in the Jensenian system.

It would seem that to "a man at Whilborough" belongs the credit of first observing the value of high moulding; to Dr. Lang that of confirming his experience and making it public; to De Bary for showing us the why and the wherefore; and to Mr. Jensen or putting it into a practicable shape. Charles B. Plawright, 7, King Street, King's Lynn, Dec. 10, 1883.

BROAD BEANS.

11ow is it that catalogues emanatiog from seedfirms that lay claim to be well informed, still put forward the Mazigan Bean as a first early variety? It is not so: the trials made at Chiswick a few years ago settled this in the most conclusive manoer. It is true it is a very hardy variety, and those who make a practice of sowing in November are exhorted to use the Mazagan; but it is very probable that if the Mazagan were sown in November, and the Seville Longpod in the middle of February, on the same piece of ground, and under similar conditions, excepting the period of sowing, the last-named would prove the earliest. It is this Bean that should be sown for an early crop, and with it Beck's Dwarf Green Gem to succeed it. are dwarf free bearers, and of high-class quality; indeed, it is difficult to over-estimate the value of the Seville Longpod Bean, and at exhibitions held in July and the early part of August it is quite taking the place of the other Longpod varieties. A very fine Longpod Bean of Continental origin, named the Aquadulce, is not nearly so much grown by gardeners and exhibitors as it deserves to be. It is a variety hearing very fine long and symmetrical pods, without the coarseness we sometimes see in the Seville Longpod, It is also known as the Leviathan Longpod; but it is possible a good stock of Johnson's Wonderful is sent for Leviathan though the purchaser does not get all that he wishes for. Selections from the Aquadulce and the Seville Longpod are being made and sent out under new names, which is only what might have been expected. A good selection is always worthy an enhanced price, and especially to exhibitors. The finest selection we have seen is Sutton's Mammoth Longpod; pods of this were last summer surprisingly fine: and the same may be said of Carter's Giant Longpod.

The Windsor Beans, or Broad Beans proper, are, no doubt, giving place to the Longpods to a great extent, but it is satisfactory to note that selections are doing much to improve this strain. Taylor's Broad Windsor by this means is being lengthened into handsome pods, of five and six beans in each. Carter's Leviathan is one of the finest selections, and is frequently found on the exhibition table. In all competitions with pods of Beans, the Longpods should always be separated from and made a distinct class from the Broad Beans or Windsors. for the best pods of the latter seldom hold their own against the superb pods of the Seville or Aquadulce Longpods. In many country shows, where the cottagers exhibit extensively, the two classes are divided. In cases where only one class existed-that of Broad Beans-we have known judges disquality all the Longpod Beans on the ground that they are not properly Broad Beans. This has led to a good deal of confusion and irritation, previous judges having admitted the Longpods to competition. In some country shows it is not uncommon to have a class for shelled Broad and Longpod Beans, and a great competition ensues. One cannot but commiserate the judges who are called upon to make the awards in such a competition. It is scarcely an advisable one, as it might require a large number of pods of Beans to select twenty-five or fifty of the very finest Beans, and perhaps the largest would be found in pods containing only one or two seeds.

MURALTIA HEISTERIA. — This is a shrubby Polygalaceous plant from the Cape of Good Hope, It has somewhat rigid needle-like leaves, giving the plant quite the aspect of some species of Ulex, and the lilac-purple and white flowers are borne singly in the axils of the leaves. As a greenhouse plant it decidedly is worth growing, as it bears stopping or cutting well, and can easily be kept to any size. Specimens of this species, a figure of which is given in Paxton's Mugazine of Botany, vol. iv., p. 150, are now flowering in the conservatory at Kew.

The Poluto: its Culture, Production, and Disease. By Jeffery Lang, M.D. Price Essay, Journal of the Royal Agricultural Society, vol. xix., p. i, No. xlı. (1858), pp. 65-81.
† The italics are Dr. Lang's.

THE PROPAGATOR.

THE PROPAGATION AND CULTURE OF CALA-DIUMS .- Among the many varieties of stove plants the Caladium holds an important place. admiration is not unduly lavished on it for its beauty, its delicacy, and its graceful and ornamental appearance. The many mingling shades of colours in its leaves, and the delicate grace of the plant itself, merit and secure a prominent place in hothouses and conservatories, and play not an unimportant part in indoor plant decorations; for bouquets, too, the leaves of many of the smaller species lend a good effect. But our immediate object is not to deal with the beauties and uses of Caladiums, but to state when and how to multiply them by propagation, and to give such hints and practices which experience has pro-claimed to be the best. There are three ways by which Caladiums may be multiplied-by propagation from the leaves, by cuttings, and by division.

- t. PROPAGATION FROM THE LEAVES .- This is a new and good method of multiplying Caladiums, and though it requires the greatest skill and care, success will undoubtedly result if the following instructions be carefully observed. It is of primary importance that proper leaves should be selected for propagation -i c., what propagators term hard leaves, and of medium size. The leaf should be severed at the junction of the leaf-stalks with the bulb, without cutting away any portion of the latter; then with a sharp knife trim the sheathing which surrounds the bottom of the leaf-stalk. Great care should be exercised not to cut too much of the sheath away, because here it is the bulbs will form. The cuttings should be put in the pots directly they have been cut because they are not likely to make good plants if once allowed to flag. Having cut some leaves, put six or eight in a 48-sized pot, burying them about $2\frac{1}{2}$ inches in the soil, so that all the sheathing surrounding the bottom of the leaf-stalk may be covered, and that portion above the soil should be tied to a small stick. Sandy peat sprinkled with loam, passed through a fine sieve, is the best soil that can be used; and when placing the leaf-cuttings into the pot put a layer of sand about & inch deep on the top of the soil. The leaf-cuttings are now ready to be placed in a frame or case; and it is from this time that great care, attention, and patience must be exercised to ensure The leaf-cuttings must be reared on a gentle bottom-heat, and well watered and ventilated; the covers of the frames should be removed for one hour only in the morning and at night. If this is not done they become too moist, and decay for want of proper ventilation.
- 2. By CUTTINGS, -This is perhaps the most productive way to increase Caladiums, and January is the month to commence propagating. selected bulbs about the size of a penny will produce, if treated in the following manner, from 120 to 150 plants during the season. The twelve bulbs should be placed separately in small pots in the same soil as recommended above, but in this case it is especially necessary to have the soil passed through a fine sieve, in order to prevent the roots becoming entangled with large pieces of soil in the many times each bulb has to be shaken out. These also must be put into a frame under a gentle bottom-heat. As soon as the shoots which the bulbs send out are 6 inches long shake out the bulb, and with a sharp knife scoop out this growth, at the same time taking great care to see that the surrounding eyes or young shoots are not disturbed or injured. Pot the young cuttings with a little sand around their base, and repot the bulb, and as fast as it sends out new growths 6 inches in length treat them in the same manner as stated in the preceding paragraph. It will be found to be a good plan, when labelling your cuttings, to make a small notch in the labels, and thus distinguish the cuttings from the old bulbs.
- 3. By Division.—This is the simplest method of multiplying Caladiums. Having selected a number of strong bulbs just before the time of starting into growth, divide each of them with a sharp knile into six or eight pieces. Each piece should be potted up in small pots with a little dry sand round it in the soil previously mentioned; or, if pots are not used, they can be placed in a frame with a slight covering of ecocannt fibre, only just enough to hide the bulb,

until they break into growth, when they must be potted in suitable sized pots.

CULTIVATION. — It will be readily seen that Caladiums are easily multiplied, yet the good results of propagation are considerably moderated if the greatest care is not bestowed on their subsequent culture. It will not be out of place to add a few remarks respecting their proper culture, for it requires great care, patience, and attention to rear successfully the Caladium from the cutting period to its maturity. The following method is perhaps the best:—When the cuttings which had been put in the frame are well rooted they should be removed and placed upon the bed upon a bottom-heat. This will strengthen the young cuttings for potting. After three or four days they are ready to be potted in 48-sized pots. Soil composed of one half turfy loam, one-third peat, and one-fourth sand is the best for the purpose.

The plants should now be placed in a good growing house upon a brisk bottom-heat, and the pots partly plunged in occoa-nut fibre, or other material used for that purpose. When these plants have well rooted they should be put in 32-sized pots, and replaced in the occoa-nut fibre, and potted again into 16-sized pots as occasion requires. This done it is not necessary again to repot them before they have arrived at materials.

If the Caladiums are required for show or other decorative purposes, and io particular sized pots, Clay's Fertiliser, a 48-sized potful to a barrow of soil, should be used in potting the plants on, and a little of Clay's Fertiliser may be sprinkled over the surface of the soil about once a fortnight afterwards as soon as the pot is full of roots, but under no other circumstances. When making a collection of plants it is always desirable to have in it those varieties which are recognised to be the best, and to those gardeners who are about to make a collection it will not perhaps be out of place to mention a few select sorts.

Of the new varieties, Raoul Pugno, a plant with transparent leaves of delicate texture, of a pale rose colour bordered by dark green; Auguste Carpentier, with flat leaves of glistening scarlet, with carmine-red both in the centre and on the margin in a darker shade, and a bright green edge; Rubrum Metallicum, with leaves of violet-red excepting a blue tinted rose centre, and borders merging into a copper-red. Aida, with spear-shaped leaves of transparent and silken texture, of red-rose colour, with green ribs distinctly marked; Sirius, bright leaves often dotted with bright green and rose red spots; Bellone, the flesh-rose centre deepens into carmine-red and metallicbrown towards the border; Albo Luteum, with unusually long leaves of a green tinted and whiteyellow colour; Candidum, with large bright white leaves, and with finely marked green ribs and border; Van Dyck, elegantly shaped leaves of crimson-lake colour, a pale rose centre, and a faint grey-green margin; La Titien, with pure lake ribs passing through a network of red adorned with rich green; Mithridate, dark ribs upon crimson-lake ground, and a deep bronze-green margin; Cardinale, most brilliant red dotted with bright and green-yellow spots; John R. Box, with dark carmine ground intersected by carmine ribs and a centre of soft violet-rose, beautifully laced, and a dark crimson border.

Amongst the old varieties Louis Duplessis, with white ground and red veins; Argyrites, white and carmine spots on a light green ground; Madame Alfred Mame, rose centre, with white spots on a light green ground; Baraquinii, a crimson centre enclosed by a dark green margin; Laingii, a pure white leaf with a crimson centre; Meyerbeer, red midribs on a white ground; Princess Teck, a fine golden-yellow leaf with a red centre; Mrs. Laing, with rose centre and veins on a white ground; Princess Alexandra, green veins finely marked on a rosy-salmon ground; Madame Hungels! Chaptinii and Duck de Morra.

and veins on a white ground; Princess Alexandra, green veins finely marked on a rosy-salmon ground; Adame Hunnebell, Chantinii, and Duc de Morny, While writing on the propagation and culture of Caladiums it is necessary to make a few observations as to the best means of wintering them. Winter is the critical period for the Caladium, and the time when they die in greatest numbers; yet, with a little well-timed care, and by a method whose greatest recommendation is simplicity, they may be so well preserved that not more than one bulb in a hundred will die. When the leaves of Caladiums flag and decay place the plants underneath the stage of the honse, the temperature of which must not be below 55', and from that time it is only necessary to spiriakle them with a rose pot twice in a week. It is almost as fatal to saturate them with water as to allow them to become too dry. In the latter case the bulb not only decreases in size, but very often decays altogether by what is termed "dry rot." T. O.

DIOON SPINULOSUM.

In your issue of September 22, 1883, is an interesting account of a new Mexican Cycad, Dioon spinulosum, but, strange to say, in the somewhat detailed narrative of the manner in which dried leaves and the first specimen are supposed to have reached Europe, the name of the discoverer is not mentioned. Know ing that this credit is due to Mr. Hugo Finck, of Cordova, I immediately wrote to him in regard to it, and I herewith send you an extract from his reply. I may add that Mr. Finck is a botanist of no mean acquirements, and a citizen of Cordova for the past twenty-five or thirty years. He is a collector in whom entire confidence can be placed, and has added many new plants to the gardens and greenhouses of Europe America. He has just written a Flora of the Canton of Cordova, for the director of the agricultural school in the city of Mexico. It will be published by the Government, and will be of great value to botanists and collectors. T. G. Richardson, M.D., New

"On my way back from a visit to the Gulf coast near San Andres, Tuxtla, in the autumn of 1880, I noticed in a private house at Tlacotalpan several well-grown stems of a Dioon which was entirely new to me. Endeavouring to ascertain where they had been obtained, I learned that they had been brought by canoemen down the river Papaloapan from the foot of the mountains, but the locality could not be precisely defined. However, having a friend at Theotalpan who had a number of boats plying upon the river, I applied to him for assistance, and he promised to make farther enquiries, and if possible to bring me specimens of the plants. Accordingly, in June of the following year (1881) he brought me eighty plants, mostly small. I immediately offered them by letter to a London nurseryman, and to certain horticulturists in Belgium and Germany, but received no answer, although specimens of the leaves were enclosed in my letters. About this time Mr. Hoege was in Cordova, and on intimate terms with my son, who may have given him a specimen. In 1882 Mr. Edmund Kerber came to Cordova, and after I made him acquainted with the new plant he sent on our joint account forty-three specimens to Professor Dr. Eichler, Berlin. Since then I have shipped twenty additional specimens to the same. Hugo Finck, Cordova, Mexico, Oct. 1, 1883

BRISTOL HOUSE, PUTNEY

WHILE flowers of most kinds are not so abundant as we shall see them in a few weeks time in showhouses, the Cineraria, when well grown, and the sort the dwarf, big-trussed, robust one sent out by French growers, is not to be despised for enlivening the sombre masses of foliage in cool-houses. saw some nice plants of this strain at Bristol House (T. D. Galpin, Esq.) that were as dwarf as the greatest stickler for stunted plant growth could wish, the individual flowers being broad petalled, circular, ot good substance, and of very rich colours, that ran through all the varying shades of purple and blue. An excellent extra low-growing white-flowered kind was parti-cularly noticeable for the size of its flowers and the contrast between the pure colour of the florets and the purple eye. This would be a very telling plant sunk in masses in a carpet of Selaginella, beneath the eye, in a naturally arranged conservatory, with a little blue or scarlet from Roman Hyacioth, Scilla, or Tulip, for contrast.

A new Rose-house has been erected here, in which a novel method of training Teas and others will be put into practice by Mr. Harding. It is intended to grow these in the ordinary way, on the wall at the back of the structure, and also on trellises running across the house from the wall to the front, as is done in Peachhouses, with varying success. It is thought that by this means less shadow will be thrown on the plants that are attached to the back wall, and that the Tea Roses, which do not suffer from some little deprivation of sunlight, will get enough to ripen their wood thoroughly.

We found here well managed fruit-houses, in which thrifty Vines, Peaches, and Nectarioes, were already started, or being got in readiness for a timely start. The Dryden Nectarine was very highly spoken of as being a good forcer, and an uncommonly fine-looking well-flavoured fruit. Many useful small houses are scattered about the kitchen garden here, occupying very varied aspects—an arrangement of which a clever gardener can avail himself with much

advantage in the growing of a variety of subjects with dissimilar requirements. Here, as in so many other gardens, the skill of the gardener is tested more in the direction of supplying quantities of the usual furnishing and house decorating plants than in growing plants of any especial interest or beauty. Amongst these, Draceenas, Pandanus variegatus, Crotons, Eucharis (very well managed), Ferns, Acalypha, Cypripedium insigne, Poinsettias, and the like, filled the warm divisions; Azaleas, Roses, Primulas, the cool ones. Cleanliness, neatness, and good order were features of the management of this pretty suburban residence, of which the visitor is reminded from first to last.

CROSSHILL COTTAGE.

ONE of the most charming residences within a radius of seven miles from Glasgow is that of Crosshill, the property of Mr. Robert Ward, the well-known railway contractor. It is situated on the outskirts of the village of Bailleston, and although of unpretending internal features, is commodious for its size, and provided with every modern convenience for the comfort of a household. Its genial proprietor, now retired, is an ardent horticulturist. As he says himself, his flowers are his life; and accordingly he has erected a set of houses which, for general style and usefulness, might be equalled, but could not be excelled. The erections, internal fittings, heating, paths, tables, &c., are all of first-class order, and, what the whole horticultural fraternity agree upon, cleanliness is conspicuous by its presence in every department. "I won't have it otherwise," says Mr. Ward to bis chief gardener; and as he supplies a sufficiency of help his instructions are scrupulously obeyed.

Another excellent feature in connection with the arrangement of the houses is that from Mr. Ward's business room you can enter the corridor and go through the whole of the range, comprising about fifteen different houses, without going outside into the open air at all. The wisdom of an arrangement of this kind, where indoor or glass gardening is a conspicuous feature, and where the proprietor makes it an afternoon-of-life pastime, is obvious. The hale octogenarian can, heat off or on, walk through and inspect much or little, ad libitum, no matter what the weather may be in this fickle, uncertain climate of ours.

As to the houses themselves and their contentsfirst and foremost the corridor into which you are ushered is draped by much the handsomest plant I have ever seen of Cobæa scandens variegata. know there are plants covering a larger space, but not in the same perfect condition of foliage. No matter when you go, be it winter or summer, the drapery is faultless. This may be attributed to the corrugated glass overhead, which interposes a sufficient obstacle to the sun's rays in summer, without obstructing too much light in winter for the benefit of this green and gold-edged climber. It covers a space about 80 yards in length, and the drooping twigs that are produced from the main shoots, tied along neat wire trellising, would cover quite a mile, if sewed together and extended. It is planted along one end of the corridor, and its roots must have extended to the open garden, to enable the plant to carry such a weight of foliage.

At one end of the corridor is the Camellia-house, a handsome structure of Pitch Pine, and containing a lot of plants both planted nut and in pots. Adjoining this is what was meant to be an aquarium, but which is now chiefly tenanted by Camellias, some handsome Tree and other Ferns, and a miscellaneous assortment of ornamental plants. This is a highly-finished structure, with the roof supported by ornamental columns, and surmounted by elegant designs in elaborate tracery. The front panels are filled in with dis-coloured glass, and the whole structure is of Teak wood. The back wall is taken advantage of, and filled in here and there with Ferns, and if it be turned into what it was originally designed for-an aquarium -it will be a most interesting house for any visitor to Next to this is the original greenhouse, which Mr. Ward has attached to this range, and which is filled with useful flowering plants, the back wall being covered with the Swansonia, the Allamanda, and the Acacia lophantha, which latter, with its pinnate leaves, looks even handsomer than many Ferns. These set into a border with tile kerb, and grounded with tiny Ferns and Lycopods, make a wonderfully pretty wall and border.

Next in order is the Fern-house, which, like the houses already described, is ranged against the high boundary wall, and is 90 feet long. Ranged along the back are noble examples of Cycas revoluta, some good Zamias, the beautiful fronded Cyathea dealbata, several Dicksonia antarctica, and that best of all rare Palms, from its hardiness and general usefulness for decoration, Kentia Fosteriana. Along the front is almost every description of dwarf Ferns of the hardier sorts, along with the climbing Lygodium and fellows of the tasseled race, which break the monotony of even the beautiful nutline of the general ruck of greenhouse Ferns. What adds to the general attractiveness is the fact that the bench in front is faced up with a series of arches of virgin cork, which gives the whole a more natural appearance, and the gravel bed in which the polts rest gives off moisture more naturally than any set of staging unprovided for in this

FIG. 7.-PINUS MURICATA.

The uper figure shows the reflexed cone cut lengthwise; below from the side; to the fruit-scales with the seed seen from the side; to the right is shown the inner surface of a similar scale with the two wioged seeds; and below a cross section of the cone.

way could do. The next house is a greenhouse, always kept full of flowering plants in season. It is about 70 feet long, and at the time of my visit was a blaze of Chrysanthemums, Cinerarias, Eucharis, Deutzias, and a host of bulbs, while there were also some of the finer Rhododendron hybrids of the Veitchianum and Duchess of Edinburgh order. This house is fitted up exactly in the same way as the Fern-house above described.

Continuing down the range, for it has a slope of about 1 in 30, we come to the fruit-houses; first a Peach-house, about 56 feet long; and then a couple of vineries, each about 30 feet. These all show well considering the time the trees have been planted, and form a pleasing feature even among the piles of houses of flowering and other plants; all are capitally heated, and the ventilation, both back and front, is of the most approved and easy self-acting method. A

Cucumber-house adjoins these, about 45 feet long, which does duty in winter for French Bean forcing, and even now is fairly forward with Cucumber fruit. There is a batch of Thyrsacanthus rutilans in this house, quite a sight, with a forest of depending flower-stans, which when fairly in flower will be quite magnificent.

Next to this is a stove 30 feet long, which Mr. Ward means eventually to convert into an Orchidhouse; as it is there are several good plants of Cattleyas, among which we noted Warneri, Mossies, intermedia, &c., and Dendrobimus of sorts, Ladies' Slippers, &c. There was a beautiful flowered example of Oncidium varicosum, of the broad bright-lipped form, commonly known as Rogersii. These, along with several excellent Crotons and other ornamental-leaved plants, made up a most interesting house.

The last house in the range is one made particularly to cover the stokehole. It is of the same breadth as the others, but in the interior is a complete glass wall, which shuts off the stokehole, thereby allowing a front beuch for plants and a potting bench along the boundary wall. Every available foot is thus utilised, and plants as well as people do not suffer from the vicissitudes of climate.

About the middle of the range at right angles spring two magnificent span-roofed houses, the one for specimen Azaleas, the other for ornamental stove plants with a corridor between them. The Azaleas as specimens are as good as are seen anywhere, and they comprise some of the best sorts in cultivation. These houses for style, lightness, and at the same time durability, are quite conspicuous. They are lofty without being too much so for the plant inmates, and they are tied together with a series of iron rods. Being painted green, and the woodwork white, they are exceedingly eye-pleasing. Moveover, the paths are all of granolithic, and the stages are covered with shingle and adorned with virgin cork in arches, which gives them always a clean stylish appearance. The stove-house is centred with some grand Palms, conspicuous among which are Areca lutescens and Baueri. Latania borbonica is of the handsomest certainly; pity it sometimes grows beyond house dimensions. Adiantum farleyense is here in specimen size with excellent frondage, and the grand ornamental Pancratium ovatum, than which there is not an easier grown or more ornamental subject in our stoves; while the Dracænas, Aralias, Crotons, et hoc genus omne, make up an attractive forest.

The whole of these houses is heated by two large

The whole of these houses is heated by two large boilers, the one a conical one, and the other a saddle, and thoroughly so in every respect, no matter what weather. Gas is also introduced into every house of the range; indeed, no place could be more completely fitted and appointed in every way. Mr. Millar and his staff of assistants, while evidently doing their daty thoroughly, must feel pleased at seeing the result of their labours.

Adjoining the drawing-room is a semicircular outlined house devoted entirely to Feros. In the centre is a very tasteful design in virgin cork, with lots of pockets for the tioler Ferns. It forms an excellent quiet resort, and anything new and gnod that is likely to thrive in the pockets is made available. The wall is covered also with the cork, and the style of placing it so as to show off the various forms of Fern life is attractive. Corresponding to this arching outlined house is one adjoining the dining-room, which is fitted with staging, and kept full of flowering plants. Both houses are of Teak-wood.

In a detached homes are come for the contractive of the contract

In a detached house are some fine examples of the now-a-days all but neglected Todea superba. One scarcely ever sees it named in a gardening paper now, although some twenty years ago every one was "daft" on Todeas. They are grown at Crosshill, caged in a compartment warded off from the passage, and seem to enjoy the atmosphere provided for them.

The grounds outside are limited in extent, being about from 2 to 3 acres, but are utilised, and are in as thorough good state of keeping as the houses. Mr. Ward himself is chief engineer for his own alterations and extensions, and from the business knowledge he has what to many would be uphill work is to him no toil but great pleasure, and he seems to delight in showing his houses and plants to all true lovers of gardening. J. A.

HORTICULTURAL CLUB.—The usual monthly dinner took place at the Club rooms, Henrietta Street, Covent Garden, on Tuesday last. There was a good attendance, and an interesting paper was read on the inhabitants and productions of Borneo by Dr. Haughton, who has resided there for twenty years as Government Medical Officer at Sarawak, and who is about to return there in September.

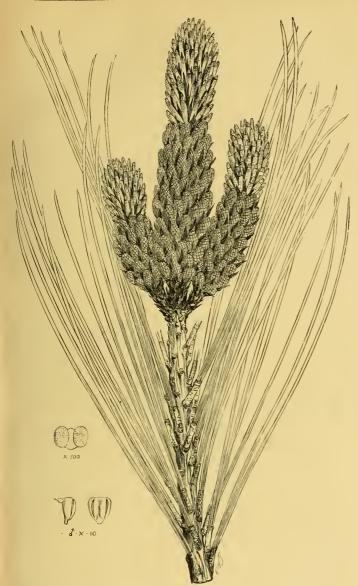

Fig. 8.—pinus muricata: foliage and male flowers nat. size, separate stamen and pollen-grain magn.

Çhe Trboretum.

PINUS MURICATA, Don.—For the specimen whence our illustrations (figs. 7, 8, 9, pp. 48, 49, and 53) were taken, we are indebted to Mr. D. T. Fish, who sent it to us last summer under the name of P. radiata, under which name also we have met with it in other gardens. P. radiata, however, is one of the 3-leaved section closely allied to P. insignis, and quite distinct from our present plant.

The special interest attaching to the present plant lies in the circumstance that the cones cling around the branches and the main trunk for an indefinite time. So long as the tree or the branch is uninjured, or its health is unimpaired, so long do these cones hang on. But the "hanging on" is the least wonderful part of the matter. Not only do they remain on the tree, but the fruit-scales, as a rule, remain closely pressed one against the other, and only liberate the seed when a forest-fire or some other injury causes the cones to crack open. The vitality of the seed is thus preserved for an indefinite time. Owing to this circumstance the trees of this species when growing together are all of the same age. The circumstance that induced germination in one case was common to all, and thus all the trees of this and other species of like habit, in a particular locality, whether they originate from cones, formed many years since, or from cones of the last season,

are equal as to precedence, so far as that is determined by age. "After a grove," says Mr. Muir, in an American journal, "has been destroyed by fire the ground is at once lavishly sown with all the seeds ripened during its whole length." That suggests an interesting subject of enquiry for some one on the spot, viz., to study carefully the kind and amount of variation in habit, quality of timber, &c., that trees of this peculiar habit present, and to ascertain, as far as possible, what, if any, co-relation exists between the phenomena.

The illustrations give a sufficient idea of the appearance of the branches, with their persistent cones. The tree itself is of low or moderate stature, and of hushy spreading habit, with rich green foliage. It was originally described from imperfect material by Don in the 17th (not the 18th, as erroneously cited in some hooks) volume of the Transactions of the Linnean Society, p. 439 (1835), and has been taken up by all subsequent writers on Conifers; so that as there is no doubt about the plant, we need bardly cite them in this place. Suffice it to say that it was called by Hartweg P. Edgariana, but that name was abandoned when it was found that the plant bad been previously named. Gordon, in the Journal of the Horticultural Society, vol. iv., p. 216, gave a woodcut of the cone, while Parlatore cites the figure given by Greville in the Oregon Committee Report under the name of Pinus Murrayana as truly belonging to this species—an opinion with which we can by no means coincide, although we have seen the tree grown under the name of Murrayana. The buds push early in spring, the young shoots being naked at the base, and the colour of the young wood cinnamon-brown. The primary leaves persist on the branches for a long period, and are upturned at the tips. The leaves are in pairs. The resin canals are immersed in the substance of the leaf (parenchymatous), and are not surrounded by any strengthening cells. orange-yellow or brownish male flowers are horne in erect close catklns, each about half an inch long, rather larger in the cultivated than in the native specimens. The hracts at the hase of the male flowers are deltoid lanceolate, toothed, rich chestaut-brown. The anther-crests are pale orange, rounded, reflexed and slightly toothed. The form of the cone and of the fruit-scales is sufficiently indicated in the woodcut, but there is considerable variation in the size of the cone, the form and thickness of the scale, and its spinous termination, which is sometimes quite slender and needle-like.

Our notes have been taken from trees and specimens at Kew, Hardwicke, and Dropmore. The tree is a native of Upper California, growing, according to the information given by Dr. Engelmann in Watson's Esdamy of California (vol. ii., p. 128, 1880), only near the coast, where it is exposed to the sea-winds and fogs, to an altitude of 2000 feet from Mendocino, where it grows tallest (in peat bogs), to Tomale Point (in the most sterile soil), Monterey, and San Luis, Obispo,"

The peculiar habit of retaining its cones ucopened is shared by various other members of the genus, notably in P. tuberculata, of which Sir J. D. Hooker brought home an excellent illustration, now in the Kew Museum, M. T. M.

THE GOLDEN CATALPA.—As one of those who have had some experience with the Golden Catalpa, I may say that some plants of it were planted here in the spring some years since, and grew to very fine plants in the following summer, which was warm and bright. The following winter was not severe, although we registered 24° of frost. This frost killed all the growth of the previous summer. The following winter the thermometer fell to zero, consequently the plants were killed to the graft. The Golden Oak planted at the same time lived through it all, but it requires a pair of spectacles to detect one year's growth from another; still the leaves are very grad among dark foliage plants. The only good hardy golden deciduous plant that I know fit to plant in quantity as a mixture among common trees in the pleasure-ground is the Golden Poplar. This plant is truly grand, and stands the thermometer at zero without a stain. Many of the golden coniferous plants are very fine, and should be freely planted. A plant of the Golden Cupressus Lawsoniana over 4 feet high svery fine, and should be freely planted. A plant of the Golden Cupressus Lawsoniana over 4 feet high svery fine, its brightness almost equalling a yellow Calceolaria, and very hardy. William Culverwell, Thoree Perrovo.

FOREST ADMINISTRATION IN INDIA. — Dr. Brandis, F.R.S., has consented to deliver a lecture on this subject at the Society of Arts, on a date to be fixed hereafter.

Orchid Notes and Cleanings.

CATTLEYA SPECIES FROM POPAYAN .- A plant out of Chesterton's importation from this district is now in flower with De Barry Crawshay, Esq., at Rosefield, Sevenoaks. It evidently belongs to the C. Trianæ section, but it has the expanded and frilled labellum as in C. Mendelii, as stated by the collector. Under whatever denomination the plant may be placed, it is certainly one of the finest of our highcoloured Cattleyas; and opening as it did with Mr. Crawshay in the week in which the sunshine was registered as nil, it is a wonder how it could attain such a rich magenta-violet tint as that displayed in its labellum. The petals are rose coloured, with a dark but not so conspicuous a feather in them as that in C. Trianæ Backhousiana, their width at their greatest expansion 71 inches, width of petal over 2 inches, labellum broad at the lower half, rich magenta-violet, the colour running 1 1 inch upwards and far into the throat, which has some dark crimson and orange lines in it. Compared with the known varieties which have been named and obtained a reputation in our collections, Mr. Crawshay's variety is second to none in its class. When more of these Cattleyas are seen they will no doubt give us ready means for their identification, as do most of the other local forms. The Popayan Cattleyas are reputed to be rich in white forms, one of which, out of Mr. Lehmann's importa-tion, was rececently sold at Messrs. Protheroe & Morris'. It was a lovely white variety with just a lilac tinge on the lip, and although it was but a small plant the substance and form of its fine flower were nearer to C. Mendelii than to C. Trianæ. There is also another, a grand white variety, out of Chesterton's lot, just open with Mr. James, at Castle Nurseries, Norwood; it is like a massive pure white Mendelii, and certainly one of the finest of white Cattleyas

CYPRIPEDIUM LEEANUM × (C. SPICERIANUM AND C. INSIGNE MAULEI).—This charming and distinct variety, the first of the C. Spicerianum crosses, was exhibited by Messrs. James Veitch & Sons at the Royal Horticultural Society's meeting on Tuesday, when the committee unanimously awarded it a Firstclass Certificate. In its neat habit and handsome appearance, and in many other of its features, C. Leeanum partakes more of the savourite C. Spicerianum than it does of the other parent, and it would be preferred by most people to either, but in itself it is so beautiful and so distinct from any other Cypripedium that a comparison is unnecessary. The plant has the fresh green leaves of C. Spicerianum, the flowers being borne on rather longer stalks than those of that variety. The dorsal sepal is large and flat, broadly oval, not reflexed at the two sides, as in C Spicerianum, pure white, with bright purplish-red dotted line down the middle. The base of the dorsal sepal is bright emerald-green, and from it a pretty radiation of small mauve spots runs upwards into the pure white. The petals and column are nearly as in C. i. Maulci, but the former are marked with more bright reddish-brown longitudinal stripes. The pouch is very distinct, and a marked improvement on that of either parent, it being of a shiny brownish-red, which contrasts well with the snowy dorsal sepal above it. The plant does great credit to Messrs. Veitch for their address in availing themselves so quickly of the services of C. Spicerianum, which is itself only a new comer, and to Mr. Seden for his skill and untiring patience in raising and bringing to maturity such a pretty treasure. It was named after William Lee, Esq., of Downside, Leatherhead, the friend of all good Orchids.

ONCIDIUM JONESIANUM.—A fine spray of seven flowers of this handsome novelty comes from J. Charlesworth, Fsq., of Heaton, near Bradford. The sender thinks a great deal of the plant, as he states that he considers it the best Oncid he knows, except O. macranthum. This is, perhaps, saying too much for it, if we take into consideration the beauty of O. Lanceanum and a few others; but, nevertheless, the flowers are beautiful and distinct. Professor Reichenbach, in his description (Gardeners' Chronicle, p. 781, vol. xx.) says that the first glimpse of the flowers calls O. Limminghei to mind. That is so. The outline of the flowers is much like it. To me the spike resembles one of a fair ordinary form of Odontoglos-

sum Rossii majus, with more than the usual number of flowers on it, and that likeness will suffice to call it to the mind's eye of any Orchid grower. main difference is that the Oncid has a smaller round labellum, and that the floral segments are bluntly rounded instead of pointed, as in O. Rossii. Who would expect to see such a pretty light-coloured inflorescence on a terete-leaved Oncid? While on the subject of this plant it is but justice to my old correspondent, Mons. Luis de St. Léger, of Ascension, Paraguay, to say that to him is due the credit of its discovery and introduction. Mons. de St. Léger is known to many as an enthusiastic "voyageur, who of late years has given Orchids some attention. More than two years ago I got flowers of this Oncid from him, but as they were badly dried I could say nothing about them. Since that Mr. Sander got flowers of it from him, which he sent to Professor Reichenbach as Oncidium maculatum, but which were not taken any notice of, probably for the same reason. Last May Mons, de St. Léger arrived with a curious collection, which was sold at Stevens' Rooms. The greater part of the plants were botanical curiosities, and this Oncid, from its resemblance to O. Cebolletii, was passed over as that variety, and consequently Mr. Charlesworth, and all others who chose to buy, obtained this pretty new plant at a merely nominal rate. Dr. Luis de St. Léger (for such is his Paraguay title), in his travels up the Parana, the Paraguay to Matto Grosso, and other journeyings, has run over many a new plant, no doubt, and there is yet another of those which fetched so small a price last May (seemingly a terrestrial Orchid), which will probably prove new and good if ever the plants get over the journey. James O'Brien, Harrow on the

CALANTHE SANDHURSTLANA×.— I send you a small spray of a hybrid Calanthe raised by P. H. Gosse, Esq., between Limatodes rosea and Calanthe vestita rubra, and which he has named C. Sandhurstiana. You will observe the very deep colour, much deeper than in C. Veitchii, which is a similar hybrid. Morton Sparke, Rooklands, Toryuay. [An interesting plant on account of its parentage, and will be valuable if the dark tiot should prove lasting. Ed.]

TRICHOCENTRUM PFAVII. - This would become without doubt, a general favourite among the smaller Orchids if it would flower as freely in England as it does in its native country. I have often found very small plants with three or four leaves only, but with hetween sixty and 100 flowers; and on one plant with seven leaves I counted once nearly 200 flowers. It is a charming sight to find in the dark interior of the forest large masses resembling snowballs, whose pure white colouring is bespeckled with purple and brown spots, and growing always on the smallest twigs of the underwood, so that it appears to be suspended in the air. It is extremely rare, but there is a form of it-the Trichocentrum Pfavii zonale-which is much more common, and which, when not in flower, it is almost impossible to distinguish from the type. This is, however, not the case with the flowers, those of zonale being in size, as well as colour, very distinct and much inferior to the type. This plant is to be found on the Pacific side of the Cordillera, in the midst of the dense forests, where during the rainy season they are almost always, as it were, in a bath. Also in the dry season their leaves remain full and soft, and therefore care should be taken in cultivating them not to let them ever shrivel, also to keep the plants the whole year perfectly shady. It requires the intermediate-house. R. P/au.

UTRICULARIA ENDRESI. - This belongs to the family of the Lentibulariacere, but requires the same treatment as epiphytal Orchids. It is of more recent introduction than U. montana, but is already generally known for its elegant spikes of flowers, varying from a delicate lilac to a deep violet, or even blue. The plant has deciduous leaves, and during the whole dry season is quite invisible, its very small and watery bulbs being concealed under the moss and the crevices of the bark of the big tree, their host. In April or May, with the first rains, the leaves appear, but the flowering takes place only in September and October, which is the period of the most tremendous rains, and it finishes immediately with the commencement of the verano (dry season). proves that the inflorescence requires plenty of water for its perfect development. As to the light, this very delicate plant is somewhat particular, fearing the excess of both light and shade. The Cattleya-house will suit it the best. R. Plau.

PESCATOREAS, WARSCEWICZELIAS, &C.—In my article on Central America (Cardenary Chronicke, Nos. 514 and 515 of last volume) I had occasion to speak of this singular bulbless group of Orchids. Growing in the very interior of the virgin lorest, they require perfect shading and moisture on their roots all the year round. During the growth the leaves also should be kept constantly more or less moist by frequent dippings, and there should be always some drops of water in the heart of the growths. As to temperature, the Pescatoreas will require in general the intermediate or even Cattleya-house; the others, principally the Bolleas, as they are growing at an elevation of 5000 to 8000 feet, want a cool treatment. Richard Pfun, Chimeick.

ANGRÆCUM SESQUIFEDALE.—Amongst the many noble types of vegetation from Madagascar, including several other magnificent Orchids, this takes a leading place, and to the adept in Orchid culture is of primary importance. Its great waxy-white blooms are exceedingly welcome at this season, but unfortunately for them the atmospheric conditions as to light and heat are very unproputious in our island. The latter is an exceedingly difficult matter, and the cold damp fogs op prevalent about this time in the neighbourhood of London never leave without more or less evident and baneful effect. Nevertheless, to have this Orchid in prime condition well repays any extra trouble or watchful care on the part of the grower to secure that end. Even if the spur of the labellum does not attain the maximum or reputed length of a foot and a half, one of 12 inches is by no means despicable. The specimens grown in the East Indian-house at Kew are unusually good this season.

NOTES ON VEGETABLES.

SNOWBALL CALLIFLOWER.—Those who have not grown this splendid Cauliflower should not let another season pass without trying it. I have grown it each year since it was first sent out, and it does so well that I save my own seed of it every year, being afraid I should not get it true again if I once lost it. Until I grew the above I seldom got good Cauliflowers, owing to our soil being light and near the rock. It is the earliest and dwarfest variety I know. If sown in January and grown on in pots in cold pit or frame, and planted out in favourable weather in March, it will be ready to cut in May. It should be planted 20 inches apart each way F. II.

LATE QUEEN BROCCOLI AND COLONEL CLARKE'S REO CELERY.—Mr. Ward's selection of vegetable seeds in last week's number is not complete I consider without the above. The former is the best late Broccoil I ever grew, being very dwarf; it withstands severe winters better than any other variety, and is also very late. I have cut beautiful heads of it in June. The latter I consider the best flavoured Celery grown; it is not a large exhibition wairely, but quite large enough for table purposes. All who visit here and taste it say that it is by far the best flavoured Celery they ever ate. % II. [Our correspondent is quite correct in his estimate of the qualities of Colone! Clarke's Red Celery; but we must add that the Leicester Red mentioned by Mr. Ward is the same sort. ED.]

THE ADIRONDACK POTATO.—Last year I bought 2 lb. of this Potato from Messrs. Veitch & Son, of Exeter, and planted them in exactly the same way as I did all my others, but when lifting time came I was perfectly astonished to see the enormous crop. I weighed them, from curiosity, and found that from the 2 lb. of tubers I had procured 240 lb. It appears that the sort is very little known amongst gardeners, and I should certainly think it will prove to be a valuable Potato, being of a good shape and quality, and with me perfectly free from disease. S. Satway, Field Gardion, Psybridge.

LETTUCES AND CAULIFLOWERS.— It is often desirable to hasten the growth of these without being at the trouble to construct a regular warm bed for the purpose; it will be found then of advantage to sow them thinly in shallow light deal trays or boxes, covering them with brown paper or a slate, and placing the boxes, when duly watered, on a shelf within a foot of the roof of a pit or house at work, where the night temperature does not exceed 60°. Here the seeds will soon vegetate, and the boxes should still be kept in the same position for a day or two, when they should be taken into a slightly lower night temperature, and be pricked off as soon as large enough to handle into similar boxes, and still to be kept close to the glass. They can in February be transferred, if large enough, to dung frames, to produce the earliest crops.

The flower Handen.

JANUARY is essentially a month of preparation and provision for the ensuing year, and the provident gardener will take careful stock of his stores and available resources, with the object of noting the deficiencies, and providing beforehand every requisite for future use. Just in proportion to the care and judgment exercised in doing this, and in having every detail and requisite previously arranged and placed conveniently ready for use, so in proportion will his after labours and disappointments he lessened, and his pleasures and successes increased and guaranteed. This looking ahead, and making due provision for the future is at all times particularly desirable in flower garden management, where anything approaching perfection is to be attained, and especially is this requisite at the commencement of the year, when each design should be reconsidered, and due provision made to meet any alterations which may be thought desirable.

Due attention should first be paid to the note-book of the last and previous years, in which should be found recorded those brief yet valuable observations made while the living picture was visible in all its beauty, nor should these potes he confined solely to the home garden, but they should also include those useful notes or hints made and gained during the pleasant excursions which Knights of the Shalloon are sometimes apt to indulge in. From these notes should be selected such designs and new arrangements as will not only be suitable to the home garden and its surroundings, but such as will give the greatest change from previous arrangements, and more particularly such as will be most likely best to gratify those for whose pleasure they are specially intended. Having properly digested these notes, and decided on the changes to be made, it will then be necessary to prepare the requisite number of

PLANTS FOR BEDDING OUT, to suit the altered conditions. In doing this provide sufficient in cumber, especially where spring hedding is also practised in the same garden, so that when the spring plants are removed the beds may be replanted sufficiently thick to give an immediate effect, otherwise, in consequence of the spring plants remaining in the beds beyond the usual time of planting, the summer season will be far advanced before the beds become sufficiently refilled so as to be effective. perhaps one objection to be urged against this practice, i.e., in the growing season the plants, owing to their having been placeted thickly, are apt to become choked, but this evil can be easily counteracted by timely and judicious thinning. It is true that the number of extra plants required is considerable, still it is the only way to meet the difficulty occasioned by making one garden do permanent duty for the four seasons of the year; but as it is chiefly a question of convenience of storage and a little extra labour, it can generally be met, as gardeners' resources in these two matters are exceedingly elastic and accommodating. In propagating the majority of plants, such as the various kinds of Pelargonium, Verbena, Heliotrope, and all similar kinds that cannot be raised conveniently nor correctly from seed, cuttings must be taken from plants that have been in a moderate beat for about a fortnight, and have made slight growth. The cuttings, after being made and potted, should be plunged in the propagating pit or frame, and subjected to a bottom-heat of 80° to 85°, in which they will strike root quickly. They should be removed immediately they are struck, and after being in a cooler temperature for a day or two, should be potted singly or in pairs, so as to become quickly established.

THE PROPAGATING PIT should at this time receive constant attention, and every effort should be made to obtain the required number of plants as quickly as possible. Many kinds now used can, however, be raised from seeds with greater facility; by this means time and expense will be saved, and the space which they would occupy as cuttings can be utilised for other purposes. Some of these kinds which take longer time to vegetate and grow should be sown in paos at once, and placed in an intermediate house or pit; the majority of them, however, should not be sown till

February or March. Not only should the cuttings and plants receive attention at this time but also the different kiods of soils, manures, and other requisite materials should also be prepared and placed in a convenient situation, ready for immediate use when needed. In like manner the different sizes of labels, stakes, pegs, and tools should be selected and placed in the most convenient form for use as required. The true value of these pre-arrangements, so easily made at this dull eason of the year, will be fully appreciated when the busy season arrives, as they will then tend to help forward the work immensely, and cause it to progress systematically and pleasantly.

ROSE STOCKS .- If seeds of the Dog Rose have not yet been collected, this may still be done, as they are this year particularly abundant. After gathering, the seed should be placed in boxes of sand made secure from mice till the pulp begins to decay, when the seeds may be cleansed by washing. They should then be sown in a well-prepared sandy border. Many of the seeds will germinate this year, but some will not do so till the following year. When they are sufficiently large they should be transplanted in rows about 18 inches apart, and 3 inches from plant to plant, adding plenty of sand if the soil be at all wet or heavy. They will soon form stocks sufficiently strong for budding the best kind of dwarf Roses on, and for the Teas and more delicate kinds of hybrid perpetuals they are preferable to any other. of Manetti as well as the Dog Rose should also be prepared as stocks for budding. In doing this select hard, well-ripened wood about the size of an ordinary Cedar pencil in thickness. Cut them into lengths of 9 inches, taking care to remove all the buds on the lower half. Plant them in rows 18 inches apart, and about 3 inches from plant to plant, except where space is limited, when they may be planted about 1 inch apart. The latter must be taken up in the autumn, have their long roots trimmed off, and then be planted at the greater distance given, for budding the following year.

IN PLANTING THE CUTTINGS select a sandy, somewhat dry soil, and place a little sand at the bottom of each trench, so as to cover the base of the cutting; tread them in very firm, and then earth them up within 3 inches of the top. If severe weather ensue place a mulching of dry litter along the sides of the trenches. I have always (ouod, however, that the cuttings planted at the greater distance, if left undisturbed, succeed much the best and produce the strongest plants after being budded. 7. S. C.

The Hardy Fruit Garden.

To grow hardy fruits to perfection three conditions of things are necessary, viz, shelter, soil, and drainage, and before we begin our Calendar for the year we would wish to say a few words respecting these. First, without either natural or artificial shelter really good and handsome fruit cannot be grown. By natural shelter we mean surrounding hills, which protect the valley from injurious winds, which are thereby tempered and rendered less ungenial. By artificial we mean hedges, fences, walls, and plantation trees, the last two being indispensable, and should be planted in quantities sufficient to break the force of the violent winds ere they reach the fruit walls and orchards; the Scotch or Austrian Pines are the hest to plant for the purpose, and if their sombre colour is thought objectionable, sufficient deciduous trees can be mixed with them to make it less so. Where the soil is stiff and the subsoil clay, artificial drainage must be employed, not only for carrying off the superfluous moisture, but to raise the temperature of the soil by lowering the subsoil water-a most important thing, especially in spring, as thereby root action will commence sooner, and frost will act less injuriously on the blossom, so that early fruit may with more certainty be looked for. As regards the soil, it is almost needless to say that the deeper and richer it is the finer will be the fruit.

The planting season will soon be over, and we would therefore direct attention to this part of the subject, more especially in reference to fruits on walls. Apricots, Peaches, Figs, and late Pears require the favouring influence of south walls, Cherries those of east and north aspects, while Plums do well on

either west or north sides. By adopting this arrangement means to protect the trees from frost can be methodically employed, more especially if care is taken at planting time to have the trees so arranged as regards site that they will ripen in succession. Where the soil is stiff, Pears will be more fruitful if grafted on the Quince stock, and as the fruits of many kinds are of short duration this stock enables the cultivator to have greater variety and a more certain succession. In the southern parts of the kingdom no summer or autumn Pears should be planted against walls, as these kinds will grow and ripen properly on trees in the open, thus enabling the grower to retain his walls for other varieties of fruits. If the orchard is cultivated for other purposes, the Apples will be best on the Paradise and the Pears on the Quince stocks, and both will come into bearing in a few seasons after planting; but if the orchard is under grass the trees are best on the free stock, and they will be much longer in coming into bearing, but they will live to a greater age.

By planting the standard trees in orchards at wide distances the cultivation of bush fruits can be successfully carried on under the protection afforded, oftentimes saving them from spring frosts and also helping to prolong their bearing season. A dressing of m nure should be applied every winter; and on no account should the ground be dug with a spade, thereby cutting off quantities of fine surface roots, but should be forked over a few inches in depth; and the same method applies to fruit tree borders in the kitchen garden, especially where Cherries are planted, as these are most impatient of having their roots injured. Any trees either on the walls or orchard which made more growth last year than is desirable may still be root-pruned. J. Rust, Eridge Castle.

The Poultry Yard.

POULTRY KEEPING EXPERIENCES .- I have read with interest "Chanticleer's" experience with poultry as given in your issue of the 5th. If it is of any interest, I would ask a little space to state my experience. I will only premise that I do not look for profit from my poultry, but strive to get them to pay as nearly as I can. I live in a border county of Scotland, the climate of which, though comparatively mild, is damp. My poultry were formerly housed in brick house-they are now boused in a wooden house. I keep twenty-two hens and two cocks. I also keep twelve ducks and six Muscovy ducks, and I do not keep a separate account of the expenditure for each. I take the cost of the fowls and the ducks at half-and-balf, though I fear I am doing the former an injustice. I find I paid in 1882, £10 7s.; in 1883, £10 15s. for bought stuff. My fowls roam over about 3 acres altogether-that is, they can do so. In 1882 I had 2425 hens' eggs-January, 35; February, 232; March, 259; April, 350; May, 340; June, 268; July, 255; August, 282; September, 205; October, 110; November, 56; December, 33; Taking the eggs at 1/4 a 1/4 a piece, 1 get 4/10 22; 1/4 1, too, do not take into account chickens eaten. I do not sell any, as we can always consume in my family sell any, as we can always consume in my family more than we rear. My fowls are common grey Dorkings. In the past year (1883) I have had only 2012 eggs, the numbers being—January, 60; February, 183; March, 332; April, 358; May, 264; June, 212; July, 196; August, 184; September, 195; October, 54; November, 195; December, 0. In other words, though the feeding has been fully on the same scale—in fact, 46; more spent—I have bad december, 2013. same scale-in fact, 4s. more spent-I have had 463, or thirty-four dozen and five eggs, less. This is at first sight the more remarkable, as on the five months, January to May inclusive, I had in 1883 but a very few eggs less than in 1882. But at the latter end of May I had with great regret to place the fowls under new hands, owing to the inability from want of health of their old attendant to continue the charge of them. The figures speak for themselves as to something more than want of care, for the seven months of 1883 give month by month a marvellous decrease. Still, 2012 eggs at 1d. give £8 7s. 8d.—a difference from the previous year cer-2.8 78. 88.—a difference from the previous year tainly, but from circumstances since to my knowledge perfectly accounted for. The falling off in the eggs from my ducks has been more marked, as in 1882 1 got 1553 eggs, in 1883 1 had but 810. The greater got 1553 eggs, in 1883 I had but 810. The greater portion of the deficiency ought to have gone into consumption in the house, but have gone elsewhere. I look upon poultry keeping as a profitable amusement, inasmuch as it does not entail everything out of pocket, but gives a very pleasant return in fresh eggs, chickens to eat, and, if the management is in the hands of an honest servant, it will repay the outlay, J. A. C.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Jan 14

Fotheroc & Morris' Rooms.

Sale of Flowering Orchids, at Stevens'
Rooms.
FRIDAY, Jan. 19

Sale of Flowering Orchids, at Trotheroe
& Morris' Rooms.
Saturday, Jan. 19

Sale of Flowering Orchids, at Trotheroe
& Morris' Rooms.
Saturday, Jan. 19

Stevens' Rooms.

Some commotion was experienced at the meeting of the newly-appointed Committees of the Royal Horticultural Society on Tuesday last by the discovery that the FLORAL COMMITTEE was henceforth to be divided into Section A., dealing with plants in general; and Section B., to which florists' flowers in particular are assigned. Each section has its own Vice-Presidents, Mr. G. F. WILSON being President of the whole. The division took everybody by surprise, and is likely to elicit much criticism. For our own part, while fully sympathising with the underlying principle involved, we have very grave doubts whether, in the particular form in which it is attempted to be put into practice, the proposed remedy will not prove worse than the disease. To begin with, we do not think a change of such a nature should have been introduced without explanation, and without any opportunity having been taken of discussing the matter, and of eliciting the opinions of those most concerned. It is true that the Council is, and ought to be, all - powerful in the matter; still, considering that the members of the committees give their services without fee or reward, and really do a very large share of the most important work that the Society does, and which the Council could not get so satisfactorily done by any other means, we think it would have been only courteous if the step taken had not been quite so suddenly resolved upon. It is true that the decree was made during the interval between the cessation of the labours of the old and the resumption of the labours by the new committees. We say resumption, because the work to be done by the new body is the same as that effected by the old, and because many members of the new committees formed part of the old ones. This, however, is a relatively unimportant matter.

What is of more consequence is the considera tion of the causes which presumably have led to this change, and its probable efficiency in meeting the objections that have from time to time been raised against the former system. The causes are not far to seek. While there is no question in the main that the rules of the Floral Committee are judicious in certain cases, there is no doubt that in other cases they operate injuriously and serve to bring the Society's awards into contempt in certain quarters. Under the present—we ought to say under the old system-a new plant, it may be one of great interest, and even beauty, gets but a poor chance against the hosts of new Chrysanthemums, Dahlias, and such-like things of which we have already too many, and which present as a rule merely kaleidoscopic variations on what we have already. But we need not go into the question now whether too many certificates have been given to these classes of plants. We are content for our present purpose to assume that no more attention is given to them than their merits demand, and that it is not disproportionate to the interest which the horticultural public at large feel in these plants, Let all this be granted for the sake of argument, there still remains a large class of plants which, to our thinking, are most unfairly treated. We will take a recent case by way of illustration. At the December meeting

of the Society a very remarkable Bromeliad, new to gardens, and new to science, was sent by a foreign exhibitor. The Floral Committee, in the exercise of their judgment, entirely passed over this plant, which certainly, as shown, was not, nor could it be, in the highclass condition the committee is in the habit of seeing in plants submitted to it. At the same committee a Tree Carnation, three Chinese Primulas, a double Pelargonium, and a variegated Holly received First-class awards. We have not a word to say against the propriety of those awards by themselves; we only wish to draw the contrast between the favour shown to such well-known plants, which for the most part are merely slight improvements upon what we have already in profusion, and the disregard of a plant of very considerable beauty, more interest, and one, moreover, quite new. We do not wish to go into the merits of this particular case further than to cite it as an illustration of the way in which the rules of the committee operate unfairly. Every one who has watched the proceedings of the committee for some years must remember numerous similar cases. The truth is that the rules which are very properly appplicable to some plants, should not be applied to others.

Let us take another illustration. At almost every meeting Mr. GREEN brings from the rich collections of Sir GEORGE MACLEAY fine specimens of some of the handsomest and most interesting of plants, but, in the form in which they are of necessity shown the committee, is by its rules compelled to pass them over with a vote of thanks-genuine enough in this case, but which in some other instances conveys about as much sense of appreciation as the recommendation "to send it to the Scientific Committee." Such circumstances as these have been frequently the subject of complaint, particularly on the part of outsiders, who do not know the rules by which the committee works, and so lately as the twentyninth of last month we gave expression (p. 818 of our last volume) to the views of some of the complainants. Possibly to remedy this state of things the division of the committee into Section A. and Section B., as above stated, has been effected.

This arrangement we can hardly be-lieve is likely to work well; we fear that, while the main evil will be untouched, the confusion that will arise will be great. It is not a mere division of labour that is wanted, it is the formation of a separate independent committee with rules of its own, as well adapted for its own purposes as those of the other committees are for theirs. If Section A. is to be guided by the same regulations as Section B., what possible good can come of the separation? If, however, an entirely separate committee for plants, trees, &c., be objected to, these subjects might be committed by " devolution" to a sub-committee with its own rules, but whose decisions should be submitted to the general body for confirmation. In any case we think it is essential, not only that the names of those attending the committees should, as now, be published, but that the names and numbers of those voting in each particular case should also be placed upon record.

THE WEEK.—The meetings of the several committees of the Royal Horticultural Society were well attended on Tuesday last. The chief interest attaching to them was the division of the Floral Committee into two sections, of which more is said in another column. The meeting of the Scientific Committee was especially interesting in relation to the Jensenian plan of high moulding of Potatos. It is much to be desired that careful experiments should be made at Chiswick with reference to this important subject.—The discovery of Phylloxera in Vines from Victoria is also a matter of very serious importance not only as regards that colony, but it may have a prejudicial effect

is henceforth to be known as Sir RICHARD OWEN, K.C.B.-Among new books just issued we note a reprint of the Hon. Mrs. BOYLE's articles in these columns on a Buckinghamshire garden under the title of Days and Hours in a Garden. Mr. ROBIN-SON has issued his work on the English Flower Garden. Miss ORMEROD'S Guide to the Methods of Incect Life is likely to be of great value to cultivators, and the same may be said of Mr. SHIRLEY HIBBERD'S Garden Oracle. Rev. H. H. D'OMBRAIN has issued the Rosarian's Year Book, with a portrait of Mr. MACINTOSH. Of these books we shall have more to say on another occasion .- Mr. R. M. CHRISTIE, writing In Nature with reference to the effects of earthworms in modifying the condition of the soil-a subject first ventilated many years ago by Mr. DARWIN in these columns-points out that in the prairies of North-west Canada the earth-worm is not known. The writer attributes the absence of the worm to the prairie fires which destroy the vegetable matters on which the worms feed. In the same journal Mr. W. T. T. DVER has some remarks on DUCHESNE'S Histoire Naturelle des fraisiers, a work published in 1766, and in which the writer points out the hereditary descent with modification of the races of Strawberries, thus anticipating by nearly a century the views of DARWIN, though no mention is made of that potent factor, the struggle for existence. The subject was incidently mentioned in Dr. MASTERS' Vegetable Teratology, p. 396.-With reference to the poisonous qualities of the leaves of Rhododendrons, Mr. PAR-KINSON records in the Pharmaceutical Journal a case wherein several sheep met their death from eating the leaves of these shrubs .- Mr. MERHAN points out in the Gardiners' Monthly how many trees famous for longevity in Europe are shortlived in the Atlantic States of America. The English Oak, for instance, has run its course at Philadelphia within a very short period, and the same holds good of some of the Spruces and the Silver Fir. A much lower temperature in America suffices to kill certain trees, like the common Cherry Laurel, and it is believed "by reason of the drier atmosphere causing a heavier drain for moisture on the vital powers of the plant." On the other hand, Alaska, in a very high latitude on the north-western shores of America, has a relatively warm, moist climate, favourable to longevity in trees .- The American horticulturists are puzzling themselves to know how the conditions under which Mr. BENNETT's Rose was purchased by Mr. Evans, of Philadelphia, are to be fulfilled. The stock of the Rose, W. Francis Bennett, was sold for 3750 dol. by Mr. BENNETT, coupled with the condition that no cuttings or plants are to be sold for three years. Mr. EVANS looks for his profit from the sale of cut flowers, and the question arises how such cut flowers are to be sold withont leaf-huds attached, as it appears that "Rosebuds cannot be sold unless cut with long stems. Great difficulty exists in destroying the vitality of such buds. We may add, however, that Mr. BENNETT is under no apprehension on this score, provided due care be taken. Mr. BENNETT also mentions the extraordinary freedom with which the plant flowers, and the early season at which the flowers are produced. Mr. BENNETT and his grower are confident that they could recognise the buds and shoots of the Rose in question from amid a large quantity of others. -Mr. PETER HENDERSON indulges in strong language against the idiots "and senseless old grannies" who swayed the Berne Convention, and counsels retaliation. If Potatos and Tuberoses from America are to be prevented access to European markets America is counselled to grow her own "Dutch bulbs," We do not think our American friends are well posted up in this matter, though we entirely sympathise with them in their opinions as to the utility and mischief of the Convention laws. Unfortunately all this has been pointed out again and again to the "idiots and grannies," but without

— NEFENTHES RAJAH.—An enthusiastic cultivator of Nepenthes points out that as most growers fail to get this wonderful plant to grow satisfactorily it would be of great advantage if those who have succeeded with it would relate their experiences through our columns, at the same time giving full details of their respective modes of treatment, and mentioning particularly the temperatures, degrees of moisture, soil used, &c. We need hardly add that we shall be glad to publish any information of value on the subject that may be sent to us.

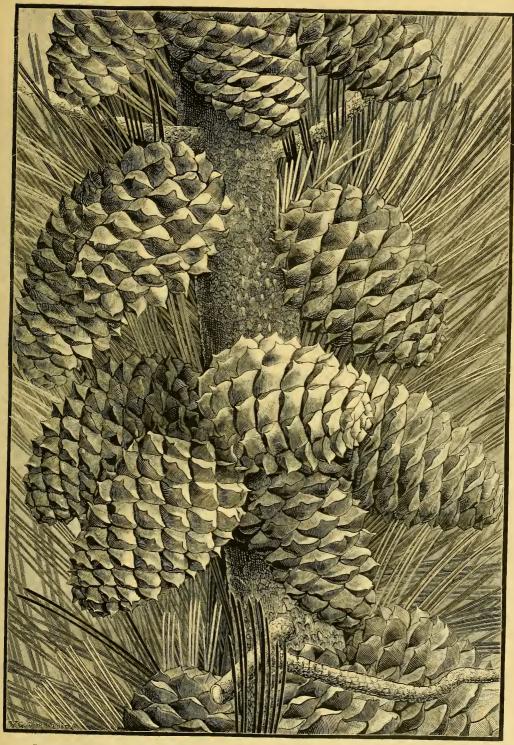

FIG. 9.—PINUS MURICATA: PORTION OF BRANCH BEARING CONES, WHICH REMAIN ON THE TREE FOR MANY YEARS. (SEE P. 49.)

— A NEW AMARYLLIS.—There is in flower at the Victoria and Paradise Nurseries a fine new winter-floweting Amaryllis, named Miss Evelyn Holford. It is one of the best we have seen as regards shape and colour. The flower is very large, of fine form, 6 inches across, of a brilliant crimson scarlet, having a short whitish stripe half way down each petal. It has some of the Aulica blood in it; although a long way apart from that species, yet there is no doubt that it is this cross that has given it its winter-blooming qualities. Amaryllis Mrs. Garfield is also in flower, as indeed it is all the year round.

— DESTRUCTION OF PLANT-HOUSES.—During the last gale Mr. THOMAS ROUTFORD had the great misfortune to have three large new span-roofed houses blown down in his new place at Turnford, near Broxbourne. The glazing had just been completed, and the glass was completely smashed, and much of the woodwork spoiled. Being busy preparing plants for the coming season such a disaster at this period is much worse than if it had happened earlier.

—— SPECIMEN PRIMULA SINENSIS FIMBRIATA.—
A half dozen remarkably good plants of these came
from Messis. H. CANNELL & SONS, the Swanley
Nurseries, on Tuesday last. They measured nearly
2 feet in diameter, were grandly furnished with
healthy leaves, and crowned with fine heads of bloom.
They were two-years-old plants, full of vigour, and
of great decorative value. They are just the kind of
plants one likes to see on the exhibition table. The
varieties were—Emperor, carmine, fine and distinct;
Swanley White, with pure white flowers and dark leafstalks; The Queeo, delicate blush; Chiswick Red,
fine in colour; the old white Four-leaved, very fine
indeed; and Swanley Purple, rich crimson-purple.

— FAIRY FLOWERS.—Our attention has been called to a paragraph in a former number, which gave the impression that Messrs. HOOPER & Co. were the importers of the Fairy Flowers which appeared in Covent Garden Market just before Christmas, whereas it appears the credit of the enterprise is due to Messrs. HOWCROFT & WATKINS, 14, Tavistock Row, who brought the entire stock from America, and who a few days ago received a consignment of pink ones which are novel and pretty.

- FATAL BOILER ACCIDENT AT HAREFIELD GROVE.-An inquest was held at Batchworth Heath, on December 21 last, on the body of SAMUEL FOSKETT, age 40, a labourer employed in Mr. GEORGE WEBSTER'S garden at Harefield Grove, who was killed through the bursting of a boiler on the previous Wednesday. From the evidence given by the head gardener, Mr. GOUGH, it appeared that the boiler in question was obtained from Mr. ROBINson, of the Stewkley Iron Works, Stourbridge, and was put in about six weeks previously by Mr. CLARKE, ol Stourbridge; about 3000 feet of 4-inch iron piping were attached to it, and about ten valves were used for connecting, but none of them were nearer than In consequence of a statement made to him by his son he went to the stokehole, and saw the deceased, who looked very black in the face, and apparently was very badly scalded. A fellow workman of the deceased stated that he and others, about seven in all, went into the stokehole to get their dinners, after which FOSKETT went to light his pipe, and had not been down the steps more than two minutes when a report was heard, and steam came up from where deceased was. Witness then crawled from the top of the boiler and helped FOSKETT out. JOHN SAUNDERS, a fitter employed by Mr. ROBIN-SON, of Stourbridge, had examined the boiler after the accident. It consisted of seventeen or nineteen castiron tubes, and was about 18 feet long. The boiler was of an equal thickness all round, and he had broken one of the pipes to ascertain if there was any stoppage in them, but found none. The opening of the furnace would cause a rush of heat into the boiler, and in his opinion the concussion would cause the explosion. The extreme end of the boiler was blown partly away, leaving the sides of the boiler on the ends of the pipe. They had never had a boiler explode before. Mr. CLARKE stated that he fixed the boilers six weeks previously, and had done nothing else but fix boilers and horticultural buildings for the last twenty years. During the inquiry an adjournment was suggested by the jury in order that a Government Inspector might inspect the boilerhouse; but this was deemed unnecessary, and the jury returned a verdict of "Death from severe scalds accidentally received."

- CUPHEA COMMERSONI,-This South American species seems to differ in many minor respects from the few scattered ones occasionally seen in cultivation. These are mostly of a shrubby character, and suitable either for the decoration of the greenhouse, or for planting out in summer, with equally satis The present species is of low spreadfactory results. ing fruticose habit, and seems to enjoy warm treatment from its flowering continuously for two or three months in the stove at Kew. The slender freelybranching twiggy shoots terminate in a raceme of flowers, which open successively, so that the whole plant is generally well studded with bloom. The caylx, usually the most conspicuous part of the flower in this genus, is small and insignificant, while the petals are unusually prominent and of a pale purple colour somewhat resembling the purple Loosestrife.

- THE CHRYSANTHEMUM "AT HOME."-A travelling correspondent of the Daily News, writing from Tokio, Japan, on November 3, thus writes on the Chrysanthemums in the Mikado's garden :-"Just now the Chrysanthemum is brightening all the highways and byeways of Japan, and the Sovereign Lord, whose family have for centuries worn the flower as their crest, bade some 500 guests to see the show in his palace grounds. Regarded as a flower show there is nothing in the world equal to the spec-Three single plants, occupying a shed of considerable size, displayed between them over 1200 perfect flowers. One counted 413, and the others were less only by a few units. In Japan the art of the gardener seems to be guided in the direction of producing a Chrysanthemum of feathery form and delilong slender petals rising in exquisite fringe. Of these there were abundant specimens, perhaps nothing rare in colour, but in development of size and graceful form beyond anything dreamt of in the Temple Gardens."

- MOULD ON ENSILAGE. - As allusion was made to my having examined the matter from the ensilage communicated by Mr. PIM, I may perhaps be permitted to call attention to the very rough figure given by SACCARDO (fig. 934) of a matter on the bark of Alder, which certainly bears a very strong resemblance to what your correspondent has so admirably figured, and to the correctness of which I can bear testimony. As regards the brown matter from the ensilage, it consisted of various moulds, and amongst them fragments of a myxogast, with spores, but nothing in a perfect state. We may be well content to give up the Greek derivation of ensilage, which is more than doubtful, when there is a Spanish verb, ensilar, "to preserve grain underground," from which it is at once derived. To the information before given, our readers may be reminded that such a preservative of grain was observed during the retreat of the 10,000 in Northern Asia Minor, as recorded in XENOPHON'S Anabasis, and what are called Picts' houses (at least the only specimen 1 have seen in Aberdeenshire) might now be used for the same purpose. SACCARDO's plant is referred with a mark of doubt to Stemphylium, with which it has clearly no affinity. His Saccaromyces coprogenus (fig. 911), on fermented dung, may very well be an early stage of something similar. The whole matter, with a view also to BREFELD'S experiments in nährlösungen, is well worth further investigation.

- THE SEASON. - When a few weeks since the sky at morn and eve was illumined by a beautiful but seemingly weird and unearthly glow, there were not wanting weather seers who presaged in these brilliant manifestations evidences of a coming hard winter. It is true that yet we are not more than half through that season commonly called winter, and the usually worst half is to come; but we may well imagine it difficult to believe that gardeners are anticipating a season of severity, or that there is at present any reason to assume hard weather is in store for us ere the spring comes. Almost as a rule a hard winter begins early. So far, the season has been marked by exceeding mildoess, not by a higher temperature, perhaps, than has marked other preceding winter seasons, but still just of that character which has always preceded it. So far, and most happily, we have had little rain, and the season even up till now has enabled the soil to be worked with remarkable facility, and planting to be done at any moment. We can hardly expect such enjoyable, if perhaps, as we think, unseasonable weather to continue long, and if we do not get frost, then we may anticipate that the coming month will make good its title to the ancient appellation of "February, fill ditch," and cause many a stream and dyke to over-flow on to the land. To such a visitation, even if accompanied by high temperature, we can hardly look with satisfaction. A flood of waters after all the beautiful weather we have had would leave the soil for spring cropping in a sad sodden state, and all the labour of the early winter would be neutralised. Better by far for gardeners come frost and snow, which would at least leave the soil well pulverised and suited for the reception of seed when the winter was passed. Still such is the comparatively unseasoned condition of all vegetable products now growing that we could not regard a visitation of severe frost without dread, even if the soil ever so greatly benefited. We should be glad now to get through without either hard frost or flood, and can but hope for the best. One thing that is clear is that our winter seasons, changing with the times, have given the traditional old winters the go-by for the present, if not for ever. As an illustration of the mildness of the time we may mention that in one of the suburbs of London we noticed lately a hedgerow of Cherry Laurels with the flowers almost expanded.

— THE VINE LOUSE IN VICTORIA. — We understand that a committee of the Entomological Society, appointed in order to examine certain Vine roots received from the Government of Victoria, has decided that Phylloxera is present in considerable numbers upon the roots examined.

- SPECIMEN CYCLAMEN PERSICUM .- The fine specimens sent by Mr. HENRY LITTLE from Hillingdon on Tuesday last to the meeting of the Royal Horticultural Society illustrated in a remarkable degree the value of the Cyclamen as a mid-winter flowering plant. They were of large size, fine in foliage, above which was a superb head of flowers. The larger specimens were three years old, the smaller two years; and Mr. LITTLE stated that though in full bloom now, so continuous is the succession of bloom that he hopes to show these self-same specimens in competition in March next. In fact, a grower of a collection of Cyclamen persicum can have plants in flower from September until May, nearly or quite three parts of the year. Two of Mr. LITTLE'S new varieties shown on this occasion were especially noticeable for their colour, viz., Mrs. H. Little, singularly deep and novel; a kind of shaded bright crimson or burnt carmine-a colour that seems as if it will stand and endure to the end. The other was Amethyst, the most distinctly purple Cyclamen we remember to have seen-crimson on the ground, with a deep and abiding flush of rich purple. Mr. LITTLE has been singularly successful in the production of rich-coloured Cyclamens of high quality, and a First-class Certificate of Merit was awarded to Crimson Beauty, a bright rosy-crimson variety, with a dash of purple, good habit and very free.

NAMING ARTICLES AT FLOWER SHOWS. Is it advisable to make this compulsory under pain of disqualification? We are reaching the time when schedules of prizes are being made or revised, and regulations considered. There is scarcely a schedule of prizes that does not contain a proviso to the effect that all contributions for exhibition must be correctly named, and in some that no award will be made unless this is carried out. But if a judge were to disqualify on this ground the managers would be the first to enter a protest against his action. It cannot be applied in all its severity without working a considerable amount of injustice. Some exhibitors are not aware of the correct names of all the things they grow; and in the case of varieties of any one genus-such as the Dahlia, for instance-things get a little mixed sometimes. Besides, an enemy might remove correct names and substitute incorrect ones, with a view to getting some exhibit superior to his own placed behind his inferior one. It often happens in the case of cut flowers that names are written on thin pieces of paper, when a puff of wind scatters some of them and they are lost. This is a common accident, and one that under the circumstances cannot well be avoided. It is obvious that such a regulation needs to be applied with great care. In some country shows leading exhibitors enter into a good number of classes because they are expected to largely assist in making the show, and they have not sufficient time at their disposal to see that all their exhibits are correctly named. And then there is the matter of incorrect spelling. How many exhibitors are unable to spell correctly? And incorrect spelling is perhaps worse than no names at all. A generous view of this regulation would suggest that it is generally framed with a view to assist as far as possible an accurate naming of subjects, but that it cannot be made justly a cause for disqualification. If this were carried out it would sometimes have to be done in a very sweeping manner, and half the contents of a show might suffer. Judges who are well informed men may sometimes do good service by looking over the exhibits and correcting the nomenclature in cases where it is needed. This supervision is especially needed at country shows. But they must not improve too much, as did that judge who put aside Snowflake Potato as not being a kidney, but an "intermediate" variety, and not to be accepted either as a round or a kidney.

---- EDGING PLANTS,-The continued request to forward the names of plants suitable for forming living edgings proves the universal liking that exists for such edgings to flower-beds and walks in contradistinction to terra-cotta, ship-rope, stone, glass bottles, half-bricks, rough flints, clinkers, &c., that we find constantly recommended as being proper things to use. That such-like materials cost less originally, and in the subsequent keeping in order, than live ones, is undoubted, and there all that can be said in their favour has been stated. As to hiding slugs of all colours and of various degrees of voracity, some of the things above mentioned afford these garden fiends as much covert as the living plants. The same plants we should use in the pleasure grounds would hardly be suitable to form an edging in a kitchen garden, as there space is generally a desideratum, as well as neatness, so that if the Cotoneaster rupestris, C. microphylla, C. Simonsii looked well in the former, they would not look equally so in the latter place. And with all our search after something better we have not as yet found a plant which, bearing in mind the ease with which it can be propagated, its hardiness, and its patience under the shears, is better than Box. The Thymes, such as T. lanuginosa, and the variegated form of Lemon Thyme, wander too far "from home," smother small plants, require frequent cutting back, and are, therefore, more suitable as bordering to beds of shrubs, or large herbaceous plants. Some of the Thuias make good bold edging, and are com-paratively cheap, viz., T. plicata, T. Warreana, T. Lawsoniana and varieties. Golden Yew is a very uncommon plant, looks very bright and fresh, and, like all the genera, hears clipping without apparent suffering. The golden Thuia and gold and silver Retinosporas would make similarly excellent edging stuff, but they are rather expensive yet for such work. The Ericas, such as E. mediterra nea, E. vagans, E. herbacea, are capital edging plants, well adapted for American gardens, in which Box looks quite out of place. Berberis Hookeri, Sanguisorba canadensis, does equally well in such quarters; it makes a fine bold edging to fine leaved plants, or to Rhododen-The propagation of Sanguisorba is by root division, when once a stock is obtained. other herbs suitable for the purpose are Hepaticas, Saxifragas, Gentiana acaulis, Campanula pulla and C. pulla alba, Violets, and Ampelopsis hederacea; this last makes a good summer edge, but is leafless in

— DOUBLE DAISES. — These common hardy garden flowers seem to be the creatures of sport in an unusual degree. Sporting is a common property with many flowers, Chrysanthemums and Dahlias especially, but in most cases the sport is a singular and therefore permanent character. Perhaps evolution would be a more scientific term for this tendency to wariation or changeableness, but a case has come under our notice in association with double Daisies which amounts almost to a complete revolution. Probably few, if any persons can tell which of existing double Daisies was the earliest produced, though it would seem that the large flat-petalled white, the same red and white, and the quilled large red are of those most commonly grown. It is by no means improbable that two of these three are products or sports from one another in some way, but from the fact that only the red quilled kind is found to produce

variegated leaved forms it seems evident that if either is the progenitor of the others it must be that kind. As is well known, the red flowered variety, which has handsome variegated foliage, is a sport from the large double quilled red, the flowers retaining the quilled form. A very common second sport is found in a variegated kind that has still quilled flowers of a dirtywhite colour. That sport, however, no one seems disposed to perpetuate. A much prettier sport, however, originated a year or two since at the Bedfont Seed Grounds, the flowers, curiously enough, being flat-petalled and mottled red and white, whilst the foliage is robust and handsomely blotched. From out of this sport has come yet another evolution, in the shape of reversion to robust green foliage, with flowers almost pure white, so that the result of the diverse changes seems to be an allied form to the large flatpetalled double white. No doubt that fine white quilled kind, White Globe, originated as a sport from the large quilled red kind. That too sported into a variegated form, but the flowers remained quilled and pure in colour. It is a curious fact in connection with the Daisy that all deep coloured flowers should have quilled petals, whilst most light coloured ones have flat petals. That White Globe Daisy is an exception to this rule naturally leads to the inference that it is a sport, and not an original variety from seed.

— OSMANTHUS FRAGRAYS. — Under the name of Olea fragraps this desirable greenhouse shrub was figured a long time since in the Botanical Magazine, t. 1552. It is cultivated in Cochin China, China, and Japan for its deliciously scented but diminutive flowers. In sheltered places, against walls, &c., in many places in the South of England, the species does well in the open air, but it flowers more freely if treated as a greenhouse plant. It certainly seems to possess a somewhat elastic constitution, as one cultivator who succeeds well with the plant states that it pays to give it stove treatment, as under these conditions it flowers almost contiouously.

- GARDENERS' ROYAL BENEVOLENT INSTI-TUTION .- The forty-sixth annual meeting of the supporters of this Institution was held on Thursday evening at the Bedford Hotel, Covent Garden, under idency of the Treasurer, EDWARD TIDSWELL, Esq. The balance sheet presented showed a steady advance in the various items of account. The annual subscriptions amounted to £1196 10s., the donations to £704 10s. 4d., and the dividends on stock to £441, which, with the balance brought forward, £377 17s. 9d., and £47 13s. received for advertisements, brought the revenue account up to £2767 11s. 1d. The creditor account showed that £1312 had been paid in pensions, and that 6600 had been invested in Consols. The working expenses, including the Secretary's salary, printing, stationery, advertising, hire of committee-room, expense of annual dinner, &c., brought up the expenditure to £2401 4s. 9d., leaving a balance in hand of £366 6s. 4t. The amount realised by the simultaneous collection made in aid of the Pension Augmentation Fund, was £634 5s. 9d., showing an advance of about £70 on the 1882 collection, and of this sum £600 has been invested in Victoria The total amount of the reserve fund is now £17,750. From the annual report we learn that ten pensioners died during the year, and that the increasing available income of the Institution enabled the committee to put twelve pensioners on the list that day, thus increasing the roll to 104, the largest number ever on the books of the Institution at one time. Two of the new applicants, Benjamin Dew, Ham, Surrey; and M. Moore, Hadnall, Salop, widow of a former subscriber, baving complied with the rules to the satisfaction of the committee, were placed on the list without election in conformity with Rule VI. The report also alluded in appropriate terms to the loss the Institution had sustained by the deaths of Mr. Wrench and Mr. James Gray, the former Treasurer for thirty-four years, and the latter for twenty-five years a valued member of the committee; and it announced that the forty-first annual festival had been fixed to be held on July 2 next, when George Lambert, Esq., F.S.A., Master of the Worshipful Company of Patten-makers, and Warden of the Worshipful Company of Goldsmiths, had kindly consented to preside. The committee also had the gratifying statement to make, that the Council of the Royal Botanical and Horticultural Society of Manchester had most generously granted permission for a held in their garden at Old Trafford during the ensuing summer, under the management of Mr. Bruce Findlay; and that several noblemen and gentlemen in the neighbourhood of Manchester had also promised assistance, by allowing their grounds to be thrown open for the benefit of the Institution. The report and balance-sheet, laid before the meeting, having been adopted, Dr. Maxwell T. Masters, F.R.S., was elected a Vice-President of the Institution in the place of the late Lord Overstone; Mr. Tidswell was again elected Treasurer; and Mr. E. R. Cutler as Secretary for the forty-second time. Messrs. John Lee, J. F. Meston, and J. Willard, were appointed auditors; and the following gentlemen having been elected to serve on the committee, viz.: - Messrs. Roger, Battersea Park; Fraser, Lea Bridge; Kinghorn, Richmond; Cutbush, Highgate; Woodruff, Harrow Road; and Nutting, Barbican, in the place of the members retiring by rotation, the election of pensioners was pro-ceeded with after it had been decided that, as one of the pensioners had died since the voting-papers had been sent out, the recipient of the eleventh highest number of votes should also be placed on the list. At the close of the poll it was announced that the following candidates had been successful : - Ann Larissy, Thomas Rider, Elizabeth Butters, Ann Hopkins, Ann Dawson, Catherine Williams, Jane Barlow, Robert Kennedy, James Watkins, Thomas Forsyth, and James Hutcheson. The members of the committee and a few friends afterwards took supper together at Simpson's, with Major Russell Gole in

— MR. WILLIAM FRASER, who for the last eleven years has been Gardener to the Eatl of SUFFOLK and BERKS, has commenced business as a market gardener and fruit grower, at The Vineyard, Tetbury Hill, Malmesbury.

- THE WEATHER, - General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending Jan. 7, 1884, issued by the Meteorological Office, London :- The weather has continued very cloudy or dull in all parts of the kingdom. Rain bas been very general, and at our north-western and north-eastern stations unusually large quantities have failen. The temperature has been about equal to the mean in the north of Scotland, but above it in all other districts, the excess over eastern, central, and southern England being as great as 5°. The maximum, which occurred on different days in the various directicts, ranged from 48° in "Sotland, N." to 55° in "England, S.W.," and "Ireland, S." The minima in "England, S. W., "and "Ireland, S. The minima were registered in most places on the 1st, and varied from 26° in "Scotland, E.," and "England, N.E.," to 34° in "Ireland, N.," and the Channel Islands. The rainfall has been a little less than the mean in the north of Scotland, the east, south, and south-west of England, and in the Channel Islands, but more elsewhere. At most of our north-western and north-eastern stations the excess has been very great. Bright sunshine has been even less prevalent great. Bright sunshine has been even less prevalent than during the two preceding weeks, the greatest percentage of possible duration being 7 (in "England, E," England, S, W," and "Iteland, S."), while "England, N.E.," and "England, N.W," have been altogether sunless. Depressions observed.—At the commencement of the period pressure was highest over the North Sea, Denmark, and the south of Scandinavia, the wind in our islands being moderate or tesh from the eastward or south-eastward. By the Scannavia, the wind in Out is assays deal, and or fresh from the eastward or south-eastward. By the morning of the 3d, however, the area of highest pressure had been transferred to the South of France, where it remained until the end of the week. During the next day or two some small and ill-defined disturbances passed eastwards across Ireland and England, causing moderate or fresh breezes between S.W. and S.E. As the period drew towards its close a large and rather deep depression travelled in a north-easterly and easterly direction off our north-western and norther coasts, bringing strong S.W. winds (a gale in the W.) to all parts of our islands on the 5th, and fresh to strong westerly and north-westerly winds on the 6th and 7th.

— GARDENING APPOINTMENTS,—Mr. EDWARD COX, late Foreman in the gardens of A. H. SMITTBARRY, Esq., Fota Island, Cork, as Gardener to The O'DONOVAN, Lissard, Skibereen, Co. Cork. —He O'DONOVAN, Lissard, Skibereen, Co. Cork. —He O'DONOVAN, DAVIES has succeeded Mr. BIRD, and not Mr. DRUMNOND, as Gardener to Captain C. G. A. DRUMNOND, at Enderby Itall, Leiesster, as stated in our last number.—Mr. J. IRVINE, Foreman at Lillord Hall, Oundle, has succeeded Mr. Franser as Gardener to the Earl of SUFFOLK and BERKS, Challton Park, Malmesbury.

Home Correspondence.

Ventilating Greenhouses .- The subject of the ventilating Greenhouses,—The subject of the ventilation of plant-houses occupies at times a good deal of space in the columns of the horticultural Press, and yet I do not remember to have seen it scientifically dealt with. Perhaps science has never devoted much attention to the matter; still, perhaps of the property devoted much attention to the matter; still, perhaps some of your specially scientific correspondents could to some extent illuminate it for the benefit of other minds through the medium of your columns. To the inquiry, Why do we ventilate greenhouses? the following replies at once naturally suggest themselves; —to give fresh air to the plants, to permit the escape of bad gases that may have accumulated in the air of the house, to lower the temperature, &c. These replies are, however, by no means entirely satisfactory to an inquiring mind, and suggest many more questions, such as, Is it possible to ventilate a hothouse in winter or during cold weather without lowering the to an inquiring mind, and suggest many more questions, such as, Is it possible to ventilate a hothouse in winter or during cold weather without lowering the temperature, or without having to expend more fuel in keeping it up? The obvious answer to this is, Certainly not. And then is suggested, As ventilation cannot be given to a hothouse in cold weather without either lowering the temperature of the house or making it necessary to incur a greater expenditure of fale in keeping it up, is it possible to grow plants successfully without any ventilation at all? Because, if it is, economy in fuel results. Practice is beginning to say, Yes, in some instances, at least, ventilation is quite unnecessary. It is becoming quite usual now (to mention one instance only) to hear successful Cucumber growers say that they "never ventilate and never shade." We know human beings in badly ventilated rooms quickly become unhealthy, and science tells us that air in confined spaces breathed over and over again loses its coxygen, that human beings require oxygen, which they obtain by the action of breathing, and that when oxygen becomes seriously deficient in the air to be breathed they at once suffer severely from the effects of its deficiency, and that therefore a certain amount of fresh air is absolutely essential to the life and health of fresh air is absolutely essential to the life and health of human beings, in order that the oxygen, without which they cannot exist, may be provided for them. The question now is, is fresh air as essential to the life and healthy growth of plants as it is to that of animals? Many would, I think, feel inclined to say, and thereby endeavour to settle the matter at once, Of course it is. But it is not so easily settled. Science has now long since discovered that common air is a mixture of the two gases, oxygen and nitrogen, and that it always contains small portions (more or less, according to circumstances) of other gases or combinations of elements in gaseous condition; further, that it is as essential for the life and growth of plants that the air by which they are surrounded should contain at least a small percentage of a gas known by the name of carbon dioxide, as it is for human beings that it should contain a proper proportion of oxygen. that it should contain a proper proportion of oxygen. The scientists who have investigated the subject go on to tells us that a large proportion of the dry matter of plants consists of carbon which is taken from the atmosphere through the medium of the leaves, and atmosphere through the medium of the leaves, and that only a small percentage of the dry matter (consisting of incombustible mineral matter and nitrogen) is taken from the ground by the roots; and that the source of the carbon is the carbon dioxide of the atmosphere, in which carbon dioxide exists only in very small proportion; and that, were it not for movements of the air, such as wind, breezes, &c., sufficient of it would not be brought within the reach of plants to enable them to grow; that the plants decompose the carbon dioxide, seizing on the carbon, and storing it up in the formation of their tissues, and liberating the oxygen into the atmosphere. While vegetation consumes carbon, animals are continually evolving it, and it is being continually taken up into the atmosphere in the form of carbon dioxide from decaying animal and vegetable matter, the consumption of ing animal and vegetable matter, the consumption of fuel, &c.; thus growth and decay are respectively ing animal and vegetable matter, the consumption of inel, &c.; thus growth and decay are respectively continually consuming and producing carbon dioxide, thus maintaining between them the necessary balance in the air out-of-doors. Now, in greenhouses where there is no ventilation, there is no wind, and the movements of air must be of the very slightest. How can plants in structures where no ventilation is provided continue to grow and thrive after the carbon dioxide originally present in the confined air has become exhausted? Is there any source within the structure whence fresh carbon dioxide may be generated in sufficient quantity? and if so, is it necessary that fresh air be admitted for any purpose? Is it likely that under any circumstances an injurious surplus of this gas may be evolved, and in that case is it likely to be produced under any circumstances (and if so what) other gases of an injurious nature which require to be got rid of by ventilation? Science is required to throw light on these matters. Is it possible under any circumstances to grow plants Is it possible under any circumstances to grow plants

for long periods in structures where ventilation is not provided? Of course, no house in which the temperature is constantly varying, and in and out of which an attendant is frequently passing, can, strictly speaking, be said to be entirely unventilated, because the expansion of air by heat, and contraction on cooling, would provide some ventilation as well as movement of air, and the passing in and out of the attendant would make some more, while his breathing would provide a small amount of the before-named gas. When we have a Royal Horticultural Society which can offer to its members for a pound or a guinea per annum as good value for money as the Royal Agricultural Society gives to its members, perhaps questions of this kind may stand a better chance of becoming solved than they do at present. T. E. Ewing, Eaton, Norwich, Dec. 31.

Rooting Terminal Buds of the Bramble,— In the Yournal of the Linnean Society (Botany), xviii., p. 400, Mr. Francis Darwin called attention to the well-knownhabit which several species of Bramble have in the autumn of forming roots around the apical bud of

FIG. 10.-BRAMBLE ROOTING AT ITS FREE END.

those branches which may be near or in contact with the ground. The terminal bud, or rather the apical part of such branches immediately beneath the bud becomes somewhat thickened, and emits roots which strike into the ground, the bud afterwards developes into a stem and another plant is established, whereby the area of the species is extended, in a somewhat similar manner as in the Strawberry, thus affording another link in the chain of evidence, If such were wanting, of the relationship of the two genera. The accompanying woodcut (fig. 10) represents two branches of a Bramble emitting roots around their apices, taken from a plant that overhung a small stokehole, and growing in diffused light, but scarcely in shade. Some of the branches, such as the smallest figure in the woodcut, had their apical buds as much as a foot above the coke in the stokehole, others only 2 or 3 inches above it, and some in contact with the coke; in all there were about a dozen branches, and every one of them was developing roots as represented. W.E. Brezon. [Advantage is taken in country churchyards of this propensity by arching over the gravemounds with the shoots of Brambles, which root at their free ends in the manner above described. Ed.]

Scarlet Pelargoniums and Snow.—It does not often occur during one's lifetime to see scarlet Pelargoniums in bloom surrounded with snow, only leaving the trusses of bloom visible. This occurred here some few years since—but I forget the date now. Also again on December 6 and 7 last we had 5 inches of snow, and 7° of frost; but the snow so protected the Pelargoniums that some are standing now, the contrast between the bright scarlet petals and the pure white snow being very remarkable and conspicuous. W. Divers, Wierton, near Maidstone.

Clematis coccinea.—This remarkably handsome climbing plant, after four years' trial, has proved to be one of the most desirable for any purpose where climbing plants are required. The pland is a herbaceous perennial, the stems dying to the surface each winder (this is an advantage where an unobstructed view is required in winter); the stems attain the height of from 8 to 10 or 12 feet, beginning to flower in June and continuing until frost. Single stems have from twenty to thirty flowers on each, and frequently as many as ten stems will start from one crown each season. The flowers' are bell-shaped, in colour a rich deep coral-scarlet, shining as if polished, and lasting a long time when cut'; indeed, one of the most beautiful plants for festooning is to be found in Clematis occinea, with its peculiar shaded green and elegantly cut and varied foliage; if it never flowered it would be a handsome climbing plant. The plant, during our observation, had no insect pests or enemies; it grows freely in any soil, requiring only one or two hours sunshine to strengthen the stem sufficiently to make a successful flowering season, and, above all, is perfectly hardy, standing exposure in our severest winters without harm. Wallem & Legrand, Ghent.

Chrysanthemum Culture,—In answer to an inquiry made by a correspondent in your issue of December 15 as to the most approved methods of growing Chrysanthemums I give you a brief sketch of the method which I have adopted for some years, and which has been attended with the most gratifying results. I put in my cuttings about the last week of December or the first week of January, and place them in a frame where I have the power to turn on a little heat if the weather should become very severe. I put the cuttings into 5-inch pots, six in each, the soil used being simply loam, leaf-mould, or cocca-nut fibre and sand, with a sprinkling of good sharp sand on the surface of each pot. After the cuttings have sufficiently rooted, which will be in about six weeks, I have them potted off singly into 3 or 4 inch pots, and placed in a pit close to the glass, taking care to avoid undue crowding, which would result in spindly weak growths. In this pit a growing temperature is maintained, but at the same time the plants are allowed plenty of air on all available occasions; the great point to aim at being, as all Chrysanthemum growers know, the keeping of the plants in a sturdy condition throughout the various stages of their growth, and to attain the same careful ventilation, watering, and pinching are essential. As soon as the plants begin to show signs of a shift being required I have them again reported—this time into 6-inch pots—using the same compost as before, with the addition of some old hot-bed manure. Allowing pletty of room between each, and giving abundance of air, and also plenty of water at the roots. At this stage they will be benefited by frequent syringings, and also by occasional fumigation with tobacco-paper to keep green-fly in check. At this time, as soon as the roots reach the edge of the pots, I begin to water them with liquid-manure water, that from a cowyard being by far the best I have tried for rooducing a healthy, vigorous growth, and imparting Chrysanthemum Culture,-In answer to an time, as soon as the roots reach the edge of the pots, I begin to water them with liquid-manure water, that from a cowyard being by far the best I have tried for producing a healthy, vigorous growth, and imparting a dark, healthy tinge to the foliage. About the end of June I prepare to shift them for the last time, and for this last shift I do not use pots, but wooden tubs, and to the use of these tubs in preference to pots I attribute my success. They are simply the tubs in which butter has been imported from Denmark and elsewhere, and which can be had at a cheap rate from any provision merchant. They will last one season quite well just as they are, but I have mine all fitted with an iron hoop, which makes them serviceable for three or our seasons. They also of course require some holes bored through their bottoms with an auger, to allow of sufficient drainage. These tubs being larger than the ordinery flower-pot generally used for Chrysanthemums, give the plants more root space, and it seems to me that the more of this you can let a Chrysanthemum have—other conditions being favourable—the more vigorous it will become, and the more abundant crop of flowers it will produce; and the more abundant crop of flowers it will produce; should further, these tubs being broader at the surface of the soil than the flower-pot, allow of more space for the shoots to expand themselves, and in some cases also allows of more shoots being retained, which is a distinct advantage where large quantities of flowers allows of more shoots being retained, which is a distinct advantage where large quantities of flowers have to be produced. And again, not only are these wooden tubs most suitable in so far as they allow of plenty of root space, but they have another advantage,

viz., the plants in them do not become dry readily, as they do not absorb the sun's rays, and get heated like an ordinary flower-pot. Fas. Wilson, Jun., Florist, Greenside Gardens, St. Andrews, N.B.

Is the Rhododendron Poisonous?—The following case, which occurred here some years ago, should finally settle the above disputed question:—A number of sheep in the park (nearly a score) were taken suddenly ill, six of which died almost immediately. On opening one the stomach was found to contain a quantity of Rhododendron leaves, which proved beyond a doubt that death resulted from eating this evergreen. The remaining fourteen, I am informed by the shepherd, never really recovered from the effects, the poison seeming to have so thoroughly pervaded their system that all attempts to bring them into condition for table purpose were useless. A. D. Webster, Penrhyn, North Wales.

Pears Doyenné d'Alençon and Easter Beurré,—Your correspondent, Mr. A. O. Walker (p. 821 of yourlast volume), is scarcely correct in calling Doyenné d'Alençon the same as Easter Beurré Pear—they are very distinct both in growth and fruit. A Pear Congress in 1884 will help us all if we get a fairly fruitful season. Pears are very much out of season bere this year—our late ones being nearly all gone. Geo, Bunyard, Maidstone.

A Fungus Infesting Sweet Williams.—Enclosed I beg to hand you some pieces of Sweet William destroyed by a fungus. We had about 1000 very fine plants for blossoming next year, all raised from seed last summer, and in the autumn we noticed a few patches of the fungus, and used Gishurt Compound and sulphur mixed with it as a solution, applying it with a syringe. We thought we had destroyed it, but find that all the plants that are not dead are dying piecemeal, and there is not one that has escaped. It is quite as destructive as the Hollyhock fungus. We cannot grow one of these seeds from Japan; immediately they are up in the seed pans under glass, they are attacked and destroyed. Not having noticed it on Sweet Williams before, I thought I would send it to you, to see if you know it. W. H. The name of theflungus infesting your Sweet Williams is Puccinia arenariæ, Schum., (P. lychnidearum, Mont. It is curious that the young seedlings in the seed pans are destroyed by the fungus—a similar fact in reference to seedlings of Hollyhocks and Mallows was pointed out in the Gardeners' Chronicle by Mr. Berschey, Mr. Boscawen, and Mr. W. G. Smith. We Bersched Hollyhocks and Mallows. ED.]

Impatiens Sultani.—I was pleased to see the note in your number for December 29, 1583, respecting this plant, and I am glad to be able to confirm all that "F. S." has said of its good qualities. I add, however, that with me it has grown and flowered very freely up to the present time (January 7, 1584) in an intermediate-house, and I have no doubt but that it will prove to be a very valuable and easily cultivated winter-flowering plant. S. Salvozy, Flete Gardens, Evployledge.

Iris reticulata var, cyanea opened its first bloom with me in the open on January 5. The bulbs came from Messrs. Haage & Schmidt. I do not know the origin of the variety, but the flower bas all the characters of I, reticulata Krelagei as far as form is concerned; but the standards are far as form is concerned; but the standards are light blue, and the falls dark blue with a slight tinge only of red. I may remark that I, reticulata Krelagei is with me not only earlier than the typical form, but much earlier and actually precedes I, Histrio, generally opening about the same time as Crocus alatavicus, and before Crocus Imperatori. This variety is also much more variable in colour than the typical form, and probably before long we shall have I, reticulata var, alba, which will please the Iridophils. M. Foster, Shelford.

Corn Marigold. — Having dug up and potted some of these plants last autumn as an experiment to test their winter flowering properties, I am agreeably surprised to find that they are in every way a success. They are now one mass of bloom, and preferred by some to the Marguerites. The only treatment they received was potting in ordinary soil and housing in a pit. S. 7.

Mushrooms in the Open Air.—It is not often that one can pick a dish of Mushrooms outside and totally uncovered on New Year's Day. This, however, was done here on that day this year, a beautiful plateful of this esculent being cut from round the edge of the manure-heap, where they grew on the ashes upon which the manure stood—not, as far as I could see, being influenced by the heat from the manure-heap. A large Jasminum nudiflorum is also in full bloom on an east wall. I also picked a spray of full blown Pear blossom off a pyramid of Doyenne

d'Eté in the Christmas week, and the whole tree will be in full bloom in a day or two, if the present mild weather continues. I an afraid the consequences will be serious when a change sets in. West Cheshire.

Scolopendrium vulgare var, cristatum O'Kelly (Stansfield),—I have received from Messrs. Stausfield, Sale, near Manchester, a plant of Scolopendrium vulgare var. cristatum (O'Kelly), which has recently been found wild in the West of Ireland, and as a natural sport of a hitherto unknown character among our British Ferns well merits the notice, not of Pteridophilists only, but of British botanists generally. From the accompanying figure (fig. 11) it will be seen that, apart from the symmetrical cristation and somewhat singular semisatitate base, the frond is remarkable for being thickly studded with young plants, after the manuer of Woodwardia orientalis; instead, however, of these plants heing scattered singly over the frond as in that Fern, they are produced in linear groups on the upper surface, along the lines which the sori

Fig. 11.—SCOLOPENDRIUM VULGARE VAR. CRISTATUM O'KELLY (STANSFIELD).

(absent in the plant before me) would follow on the under surface, first appearing as warty protuberaces, which speedily develope into plants, as indicated in the figure. This fructification therefore appears to present a somewhat analogous transformation of spore-producing energy to that recently noted among the plumose Athyria. Sundry well-known varieties of Scolopendrium vulgare bear bubblis on their stipes and elsewhere, but one of those proliferous forms in the least resemble that of O'Kelly in the special characteristic indicated, or vie with it in symmetry and beauty. C. T. Drucry, Fernholme, Feret Cate. [This case is worth considering with reference to the relative position of the male and female organs on the scales of Conifers. Ed.]

Vine Culture.—Kindly allow me a little space to make a few observations respecting some young Grape Vines raised here from eyes put in about the end of January, 1883. Single eyes were inserted in 48-pots, and stood on the beds in a Cucumberhouse, not plunged in a strong bottom-heat as I think is the usual practice, for they did not receive any bottom-heat beyond what came up through the bed (which is 3 feet through) from a 4-inch pipe. The atmospheric heat of the house was kept at this time about 60°. The pots were three-parts filled with a

good rich compost, and the remainder with a coarse saad, which I find the eyes callus in most quickly: they soon emitted roots, and made a quick growth. They were potted twice, the last time into 6-inch pots, in which they remained until the last week in May, when they were taken out of this house and plaoted in the borders which bad been previously prepared for them. The border, which is entirely inside, consists of three-parts loam and one part cowdung, with a good drainage. They were about 3 feet high at this time, and soon took root in the new border, and have made a well matured fruiting cane 22 feet in length. I have cut them back to within 6 feet, and iotend fruiting them this season. The house is a lean-to 72 feet long, with a rafter of 17 feet. It stands due south. We have also another vinery 48 feet long, planted in the same manner as the above. The year after planting there was \$\int 20\$ oworth of Grapes cut, and this being the second year of fruiting we have cut \$\int 48\$ 16°, worth, and also took 1st prize at the local show with fruit cut from the same. I hope I shall not be trespassing on the much valued space of your paper, but I should like to show some of your lookperienced readers—such as the young and old school gardeners—that instead of cutting the Vines quite back the first and second year, and not fruiting them until the third year, so that it is some-times four years from the time the eyes are put in, such practice is not accessary. I have had cases of this sort come under my notice this last four or five

Plants in Flower in Cornwall.—The following list of flowers picked in the garden here on December 26, 1883, may be interesting to some of your readers. M. C. B., Trengwainton, Penzance.

Potato Disease: Protective Moulding.—
In reference to the discussion on Mr. Jeusen's method of protecting Potatos from disease by earthing-up, I would like to state, as the result of long experience in cultivating Potatos on my own land, and of observation on the farms of other people, that—(1.) The Potatos at or very near the surface are more frequently diseased than those at a greater depth, of the same root. (2.) Varieties having a thick skin are less liable to disease than those with a thin skin, the Black Cape Breton Potato and the Red Seedling enjoying almost a perfect immunity from disease, (3.) Soft spongy Potatos (those whose tissue consists of large cells with thin cell walls), such as Jenny Lind and Early Rose, are markedly more liable to disease than solid compact Potatos of high specific gravity. I have recommended the farmers of this province to follow Mr. Jensen's plan as a prudent practical measure to protect their Potatos against disease, whether they believe or dishelieve his theory, George Lawson, LLD., F. Inst. Chem., Frofessor of Chemistry, Dalhousite College, Halfyax, Nova Scotta.

CYATHEA MEDULLARIS.—No idea can be gained of the noble proportions which this Tree Fern attains from specimens cultivated in pots, or where its headroom is restricted in small bouses. In the winter garden at Kew, where it is planted out, and where the temperature all the year round never exceeds that of a cool greenbouse, the great spreading bi-tripinante fronds are quite a feature of the house. Seen from the gallery the immense plumes, of the deepest green, are far more impressive, affording a heautiful contrast to the Araucarias, Dammaras, and other tall cocupants of the house. Besides the root room gained in planting out, the fronds are less liable to damage from the moving about to which those plants in opto are often subject. The specific name is derived from the circumstance that the medulary or pitch visue of the trunk is used as food by the native New Zealaaders.

THE AMARYLLIS.

Some of my hybrids show-first, that fine forms and colours may be obtained by simply crossing some common varieties, and second, that the various forms not considered sufficiently good to retain may, nevertheless, be made to serve a scientific purpose. Thus, not only new and charming varieties for the florist's collection can be raised, but also types which may have great value to the botanist. These various types are either new forms, or reversions to some ancestral types. In the latter case the hybridiser calls them up, as if by magic, from the depths of oblivion, and presents them to the scientific eye as most interesting objects. I think it possible by this means for a botanist, with extensive knowledge of the Amaryllidaceæ, to put together, so to speak, a history of the Amaryllis—or, in other words, to recover the extinct forms through which the Amaryllis has passed. If hybridisers kept a record (a sort of stud-book) of all they did, it would, after five or ten years, give a most interesting collection of facts, by which, very probably, some important laws might be revealed.

I believe that the bars on the petals of A. reticulata are merely a repetition of the stripes along the middle of its green leaves; that A. vittata, which has similar bars on its petals, is a near relative of A. reticulata, and that it got its bars from the same source, viz., the green leaves; but that in course of time the stripes on the leaves of the vittata disappeared, or probably were originally inherited only by the petals. That the one flowers in autumn and is evergreen, and the other in spring and is deciduous, in my opinion signifies In this climate [India] the spring-flowering ones retain their old leaves till and during the time they flower again next spring, and do not get their new crop of leaves till after flowering. Moreover, some of the same spring-flowering ones give a few spikes again in autumo. I have now about a dozen seedlings, obtained by crossing two such last autumn, so that it is not impossible in this manner, and by continued selection, to obtain a breed of autumnflowering Amaryllis from the purely spring-flowering

The Amaryllis equestris, in many of its descendants, produces a distinct incipient bar at the base of each petal. I have a hybrid, named Cavalier, which is scarlet, with a well defined creamy star; each limb of the star has a well defined creamy bar, edged on each side with greeo. Whether this bar belongs to the original equestris or has been obtained in this hybrid by a cross with others I cannot tell.

The Amaryllises which have bars along their petals, or a tendency to them, have their venation rather peculiarly disposed. Here a little dissection may not be amiss. For iostance, let us take Mrs. Garfield. The upper and outer petal has a set of coloured venison each side of the bar, which I would call feathers. The latter petals are, as a rule, the most brilliantly marked. The two lower and outer petals, although of the same size and form as the upper, have only one feather on the upper side of the bar; while the lower and inner petal is quite distinct from all the others, is smaller and altogether of a different character: it is generally without a bar, and often without any distinct venation. It reminds one of the labellum of an Orchid.

I never look at an Amaryllis without thinking of an Orchid. Although at first sight the Amaryllis would seem a regular flower; it is in reality, in some particulars, almost as irregular as an Orchid. In botanical books the structure of an Orchid is referred to a diagram, in which a posterior petal is represented in the inner whorl, but which is stated to be frequently [almost always] anterior by the twisting of the ovary. Curiously enough, I have a hybrid Amaryllis which I named Ulta, and which has most of its flowers upside down-that is, with the odd petal (or labellum) uppermost, while the stamens and pistils repose on the main outer petal, which is lowermost. It may not, therefore, be impossible that Ulta is more like the typical Amaryllis, and that the one usually met with has its ovary twisted, so as to bring the labellum lowermost. Such phenomena are not uncommon. In the Papilionaceæ the vexillum is usually uppermost, but in Clitoria it is lowermost; and in a peloric form of the Clitoria I once had the flower consisted of a whorl of five equal sized vexillum-shaped petals. Orchids have one or two stamens, but it is supposed that the remaining five or four are suppressed. Orchids have a one

celled ovary, but in Aspostasia [and Selenipedium] there are three cells, like that of the Amaryllis. Further, some of my Amaryllises had their pollen in little masses or bars, which would not adhere to the brush; on my pressing them between my fingers they were resolved into the elementary pollen grains. Finally, when in Florence, I saw an Amaryllis which was called robusta. It had the form of a Sprekelia, and its bulb, although planted under the soil, was, they said, invariably pushed above the soil. This character might be taken to point to another link between the Orchid and the Amaryllis.

The distinct character of what I call the labellum in the Amaryllis points, I take it, to some distinct office. The upper three petals, or perhaps five of the petals, were probably intended by their colour and markings to attract insects, while the labellum may have, in some ancestral form, served to protect the stamens and pistil, somewhat after the fashion of the carina in the Pea. It is not unlikely, moreover, that all the three lower petals may have served the latter purpose, or at least the lower halves of the two lower and outer petals and the labellum. There is a feature in the Amaryllis which I have not seen noticed. At the very bottom of the funnel, at the entrance into the nectary, and where the short bristles of the upper petals project inwards, some kinds have a damson-Holland, however, has a deep crimson eye, which contrasts prettily with the green centre. might, in course of time, perhaps, be made to expand, and so add to the beauty of the flower. The bristles above-mentioned appear to serve the purpose of preventing small insects from getting at and robbing the nectar without fertilising the pistil. The long proboscis of a moth, or some such insect, could easily penetrate through the fringe while it balanced itself over the pistil. The damson eye round the fringe has probably served to catch the eye of the insect, so as to enable it to direct its proboscis to the entrance of the nectary.

I would end this notice of the structure of the Amaryllis by observing that most of the leaves are wonderfully adapted to collect the dew and conduct it down to the bulb. They are expanded towards the tip and contracted towards the base. By this form of leaf it would appear that the natural habitat of the Amaryllis is in dry climates, subject to night dews. Is this so? Is this or?

Besides the division of outer and inner petals in the Amaryllis there is another, viz., of upper and lower petals. The former consists of one outer and two inner petals, and the latter of two outer and one inner. This division is seen in an exaggerated form in Sprekelia, in A. robusta of Florence, in my Formosa, San Marco, and others. It is also visible in almost any Amaryllis which has been fortunate enough to have retained its irregular form; the venation of the three upper petals being almost always different from that of the lower three. in Florence in 1880 81 I saw a coloured lithograph of Amaryllis Professor Santarelli. This hybrid was raised by Signor Emilio Bonafedi, gardener to the above Professor. It had the form of the Sprekelia, but the colouring was different, and the petals broader. Its raiser told me it was a cross between A. vittata and robusta. Besides horticultural charm I thought it had great scientific interest. Taking into consideration the A. robusta (of Florence), A. Professor Santarelli, and some of my own hybrids, I have little doubt in my mind that Sprekelia as a separate genus has no raison d'être, and that it should revert to Amaryllis formosissima. While in Florence I tried hard to obtain seeds of the latter, both by self-fertilisation and by crossing it with others I had, but I never succeeded. However, in one of the numbers of the Garden I noticed that a Mr. John Farquharson, of the Acton Nursery, Wrexham, had exhibited in London an Amaryllis which was stated to have been the result of a cross between Sprekelia and an Amaryllis. Very little notice was taken of it, as it was stated it did not come up to Veitch's Amaryllises. I took great interest in this cross, and wrote to Mr. Farquharson. He sent me a bloom to Florence by post. It was rather faded; the colour approached that of the Sprekelia, but the form was that of an ordinary Amaryllis. The possibility of the Sprekelia crossing with the Amaryllis, although with difficulty, is an additional reason for considering it an Amaryllis. The difficulty of effecting this cross may probably be less than that required for self-fertilising any Amarvllis.

As to its being formosissima there can hardly be any question, even in these days of regular florists' flowers. For my part, I think its form lovely, and the splendour and richness of its colour are in my opinion not easily matched. It appears to have been longest known in Europe. According to Shirley Hibberd it was introduced into Spain in 1593. It appears to me very probable that it was the original form from which the "Fleur-de-Lys" of France and the "Giglio Fiorentino" were copied. The latter appears on the coat of arms of Florence, and is to be seen in that city on various shields. [While Iris florentina is common in the fields around the city!

As so many are beginning to interest themselves in the cultivation of the Amaryllis a great desideratum appears to me is a cheap work giving-1st, coloured lustrations and descriptions, history, &c., in chronological order, of all the original Amaryllises, with their habitats and climate, their discoverers and introducers; 2d, coloured illustrations and descriptions of the most striking and distinct hybrids, descendants of the above, with their parentage, raisers, time of flowering, &c., and if possible with the various steps by which the most perfected forms have been obtained. Many of them have been figured and described, they are scattered, and not readily access sible. If any one interested in this matter would collect and publish all that is known about the Amaryllis, with coloured figures, he would, I think, do a great service to the Amaryllis-loving public With sufficient time and patience such a work should not be difficult, but in order to make it as useful as possible its price should be moderate. many amateurs, no doubt, who could tell us a great deal about their experiments in crossing the Amaryllis. Professionals, of course, could tell us much more. have little doubt that many curious forms, the result of hybridising, have been thrown away or are lost, because they did not come within the definition of a florist's flower. These, nevertheless, as I have said, might have been invaluable to a genealogist, in enabling him to decipher the various stages through which the Amaryllis may have passed in its struggle for existence, up to the time of its discovery, when it came under the care and manipulation of man. Instead of throwing them away, these curious, and probably distinct glimpses of the past history of the Amaryllis might be preserved, and made over to some botanical society; thus might be brought together in course of time a collection of immense interest to the student of the origin of species. Here I should like to make a few remarks on the last part of Shirley Hibberd's lecture. He says that the funnel of the Amaryllis is objectionable. I would ask-why? He admires, I suppose, the lovely form of the Convolvulus; then why should not a funnel, approaching that of the Convolvulus, be an addition to the beauty of the Amaryllis? He does not object in toto to the green colour at the bottom of the funnel, am glad to find, because, in my opinion, if the green approaches the shade of the inside of a Melon or Cucumber it is simply charming.

It might be well enough for an individual to encourage a particular type for which he may have a fancy, but I think when a Society does the same thing it becomes different. It is hardly the office of a Society to set a fashion by giving prizes for a particular form of a particular flower. Its office, I should say, is to encourage general excellence in all directions. Would a Society be wise, for instance, in offering a prize for making the form of an Orchid Beauty and excellence, one can safely say, regular? are not qualities that can be restricted to any parti culartype. It does not consist in anything being round, or broad, or large, or this or that. It may have none of these qualities, and still be very beautiful. hear that so and so exhibited an Amaryllis which had all the qualities of what an ideal Amaryllis should be But I would ask of what form is this ideal-that of the formosissima, or that of the Leopoldi? It is evident that the former must have been thought most beautiful, otherwise the specific name would hardly have been given. As far as my own taste is concerned, I really think it formosissima, and should gladly wish to see two or more ideals set up.

See what happened to the Dahlia. First, nothing but a globe—"the great ideal "—was admissible, with each petal disposed as if by rule and square; no Dahlia was perfect unless it submitted itself to this torture. Then came the Cactus Dahlia, which had none of the above qualities. It was nevertheless a

marvel of beauty; and now every one praises the loveliness of the single Dahlia. Probably the time will come when to possess a globular Dahlia will be a sort of crime. It is no wonder that some people rebel against all these vagaries, and go to the fields and mountaios to enjoy the wild flowers just as Nature made them. When a Society puts the "hall mark" on certain flowers with certain qualities a fashion is set up which small horticulturists cannot afford to despise it they wish to sell their plants. But a large horticultural society and amateurs who care not to sell their plants ought to be above this, and should strive for excellence, independently of fashion. I do not mean to say that societies have not done wonders in encouraging the growth, introduction, and improvement of flowers and plants, and in disseminating knowledge of them; but this I say, that societies have been, and may continue to be crotchetty, and prevent us from deriving the maximum of enjoyment we might from the floral world. After all I have said, I fully admit that in the Republic of Horticulture one should do as he pleases with his own. Of course a person who lives by this profession must do what he can, or what pleases others; at the same time I have a notion that there are more ways than one for improving a flower. E. Bonavia, M.D., Surgeon-Major, Etawah.

(To be Continued.)

FORESTRY.

THE DOUGLAS FIR (PSEUDOTSUGA DOUGLASH), -As a substitute for the Larch this beautiful North American Fir has of late years been more frequently brought under notice than perhaps any other. It is a tree that so far seems well suited to the climate of Britain, is perfectly hardy, of easy culture, and not at all fastidious about soil. I am, however, rather dubious as to its value for planting in exposed situations, for several experiments in this way have proved anything but satisfactory; indeed, it is hardly to be expected that a tree inhabiting one of the richest and most delicious valleys in the world would in our variable climate succeed in any but the most sheltered situations. [It is not confined to such spots. ED.] Here a prevailing evil with this tree is the repeated loss of leaders, which on overtopping the surrounding trees are usually broken over, th to many of our finest specimens a flat or table-headed appearance. This might, however, to a great extent be averted, as I believe that a plantation formed of this tree alone, or along with the Silver Fir, whose rate of growth more nearly approaches that of Pseudotsuga Douglasii, would succeed better and be less liable to injury during a storm than when mixed up with the general run of forest trees. This has, indeed, to some extent been already proved here, as in two of our woods, where belts of this Fir alone were planted, they have succeeded better and are not nearly so liable to injury during severe weather as those placed singly throughout the same plantations. With this in view we have at present formed a small plantation of the Douglas Fir in a low-lying, well-sheltered piece of ground, within a short distance of the sea. The plants used were strong, well-rooted, bushy specimens, from 3 to 4 feet in height, and planted at 8 feet apart, the intervening spaces being filled up with Larch for removal at an early date. The Douglas Fir as standards can thus be left at 16 or 24 feet apart, as hereafter found practicable. The soil is good strong loam, from which, as well as the sheltered position, I have every reason to expect more satisfactory results than have heretofore been obtained from this Fir.

This tree has been extensively planted at I'enrhyn—indeed, more so than perhaps any other of recent introduction, Pinus Laricio excepted; but more as an ornamental tree than for general plantation purposes. Within the park are some very fine specimens, which from their large size must have been planted shortly after the introduction of the tree in 1827. Close to the carriage-drive leading from Penrhyn Castle to the model village of Llandegai are three of unusual dimensions, as shown by the following figures:—

No. 1.—Height, 79 feet; girth of stem at 1 foot, 13 feet 6 inches; girth at 5 feet, 11 feet 6 inches; diameter of spread of branches, 66 feet.

No. 2.—Height, 76 feet; girth of stem at I foot, 13 feet; girth of stem at 5 feet, II feet; diameter of spread of branches El feet

spread of branches, 51 feet.

No. 3.—Height, 72 feet; girth of stem at 1 foot,

9 feet 2 inches; girth at 5 feet, 8 feet 7 inches; diameter of spread of branches, 48 feet.

These are well clothed with glossy foliage to the ground, seem in perfect health, and would have been model specimens, had their leaders not been broken over.

As an ornamental tree the Douglas Fir can hardly be surpassed. The dark evergreen, Yew-like appearance of this tree, combined with its rapid rate of growth and massive proportions, rendering it admirably adapted for planting along the outskirts of plantations that can be seen from drives or walks, where it forms a striking contrast to other trees of a more light and airy appearance: The appearance of the tree is usually very symmetrical, with an erect, taper trunk, which, when old, is covered with rough, rugged bark, filled with receptacles of clear, yellow resin, as in the Balm of Gilead. The timber is hard, durable, of a colour almost as deep as Yew, and susceptible of a fine polish. Several spars grown here have been used by boat builders on the Menai Straits, but otherwise the timber has not been generally employed, few trees of a suitable size for planting having been From specimens of the wood, included in a collection of the different kinds grown on this estate, appears strong, firm, and beautifully grained, though more liable to the attack of insects than most other kinds. This I have no doubt is, however, owing to the immaturity of the wood, as I find that most timber cut when in a young state is more liable to dry-rot and the attacks of insects than that felled when of a more advanced age.

From the Pinetum Britannicum I have copied the following regarding experiments with different Pine woods made by Mr. Wilson Saunders, of Lloyds, by which the great superiority of the Douglas over the others experimented upon will be seen.

Lengths of each of the woods commerated in the following table, carefully squared to 1½ inch, were submitted to pressure of weights pendent from the centre, the lengths being supported between standards exactly 6 feet apart. The weight at which each broke, and the amount of deflection from the horizontal line at the time of breaking, are given:—

			Le.	in.	
Douglas Fir			285	4	Fracture rough and long.
Pitch Pine			280	4	Fracture short and even.
Canada Sprud	e		196	4.7	Fracture short and rough.
Red Pine			168	6	Fracture rough.
British Larch			168	5.2	Fracture short and even.
Deodar from t		12-			
layas		• •	154	3.8	Fracture short.

The specimens experimented on were carefully selected from the best description of woods and free from all defects.

The deflection is in inches and tenths of an inch.

Each wood had two trials, and the figures give a
mean result. It will be seen from the above figures
that none of the Firs approached in strength either the
Douglas Fir or the Pitch Fioe, and while these two
were equal in strength there was this great difference,
that while the latter snapped short under a strain of
250 lb, the Douglas yielded unwillingly with a rough
and long beard slowly, toughly, and almost imper-

and rong neared stately occupiedly.

The Douglas Fir is readily propagated from seed, which is borne in great quantity, even by young trees; but it is well to remember that cones collected from medium-sized, healthy trees are always preferable.

It is, however, generally believed that plants raised from British seed are inferior to those grown from seed produced in its native country, and about which much discussion has taken place. In the Transactions of the Botanic Society, Edinburgh, Mr. MacNah published some facts which seem to warrant the conclusion that British raised seeds produced degenerate and inferior plants. Be this as it may, we have raised several lots of strong, healthy plants from seeds collected in the park here, and many of these have been planted-out permanently, the success or failure of which will be carefully noted, and no doubt reported on at a future date. A. D. Webster, Penrhyn Castle, North Wales.

GEUM PYRENAICUM. — A large-flowered form of this pretty rock plant is now in flower on the new rockwork at Kew. Several of the genus are high-class hardy ornamental plants; and this species, with its large golden-yellow blossoms nestling among the rosettes of spreading leaves, is certainly not one of the least desirable.

Floqists' Flowers.

AURICULA.—Writing about the Auricula a few months ago, I stated how useful the alpines were for planting in the rock garden. As soon as sharp frosts and wet touch the plants, the outer leaves decay Time ought to be found to clear off these decayed leaves, and to press the plants firmly into the ground with the fingers. A few of the more common of the show varieties may also be planted out, when they are plentiful enough. The selfs with green leaves are the best for this purpose, as those with farina dusted on the foliage thickly are made unsightly in heavy rains. Those who have the convenience of a house for their Auriculas ought to place them in it at once; and it is as well to keep out frost by means of the heating apparatus. There are some Auriculas which open their flowers very well in frames, others require the aid of a slightly heated house to produce a satisfactory bloom. The seeds of Auriculas will vegetate freely during this month if the pots are in the same house. We have usually sown the seeds in July, in hand-lights in a shady place, where some of them vegetated at once, but others have lain dormant until early spring. We thought it better to keep the seeds in a paper and sow them this year about the middle of January.

THE CARNATION AND PICOTEE.—I have noticed, on looking over a number of collections of Carnations, that the plants are kept usually very dry at this season—dust dry, in fact. Now it is a mistake to allow the plants to become very dry at the roots. I am not sure whether they are not more liable to be attacked by disease, when kept in that state, than if they were too wet. Our plants are plunged in cocoanut fibre relase in cold frames, where they get plenty of air, as the lights are removed all day if it does not rain, and they are tilted at night. They require water once in two or three weeks; this is sufficient to keep them moist enough, and the plants grow freely when the temperature is above the freezing point.

THE TREE CARNATIONS are now in bloom, and their flowers are more esteemed than those of any others we have. These do best in an atmosphere that is rather dry, with as much ventilation as will admit of the temperature at night being kept up to 50° or 55°. A little weak manure-water occasionally causes the flowers to open freely. Cuttings ought to be put in during the month of January. These early cuttings make very strong flowering plants by September, that continue to produce flowers from that time until long after Christmas.

HOLLYHOCKS .- Those who are anxious to get up a stock of plants will begin as early as possible in the new year to propagate either by root grafting or from cuttings. The growths should be taken off with a hud attached, and they may either be grafted on to a bit of root, or be carefully potted in small pots, using a sandy soil. Some persons, with no better accommodation than a hotbed, manage to propagate them, but in that case it is best not to begin propagating until February, as they are very apt to damp off in the moist atmosphere of a frame. They do best in a mild heat in a propagating-house. A gentle hottomheat should be given to them, and they ought to be covered with a hand-glass. If potted in rather moist potting material they will not require any water for a week at least. Careless watering kills numbers of them. For Hollyhocks, Dahlias, Gladioli, &c., the ground should be prepared now by trenching, if it is not already done. It is not possible to grow either of these up to the highest standard of perfection unless the ground is trenched from 18 inches to 2 feet deep. The whole of them are gross feeders, and require plenty of rich manure as well, but it ought not to be placed in immediate contact with the roots. Our plan is to dig out a treoch of the required depth and say 2 feet 6 inches wide. In the bottom of this trench place a layer of manure, then mark off 2 feet of the ground and dig out a good spit of mould on to the manure, then shovel the loose earth on to it, making it level. Another layer of manure should be placed over this, and another spit dug out on to it, with the loose earth added, will usually get to the bostom of the trench. The bottom of the open trench

ought to be forked up before the manure is put into it. In this way there will be from 6 to 9 inches over the top layer of manure. The surface ought to be lightly forked over several times, to thoroughly expose the soil to the air. When the Dahlias or Hollyhocks are planted some good rich soil ought to be placed over the roots.

PINKS .- A week ago we placed a few pots of the forcing Pinks in a house where they will get a little artificial heat without being unduly forced. taste, the best of all this class is Lady Blanche; the flowers are not so large as some, but the petals are well formed and nicely fill the pods without causing them to burst. These are really charming flowers to cut in March and April. A succession of them should be kept up until the middle of June, which would give three months of white flowers, and the sweetest of white flowers withal. Mrs. Moore is also pretty and very sweet. The flowers of this are white, with a dark centre; they ought to come laced, but this they fail to do in a forcing-house. It does not matter much, as for ordinary purposes of decoration or for bouquets they are as useful without the lacing as with Mrs. Pettifer still maintains its place as a good variety of this type. Of the purple or rosy-purple varieties Derby Day is scarcely worth growing in comparison with Lord Lyons; this is a very useful variety, which we place next in value to Lady Blanche. It has the same dwarf habit of plant, and the flowers are of the same character, a good pod that does not burst, but sufficiently filled with well-formed petals. In forcing these Pinks give them plenty of light by keeping the plants near the glass. See that they do not at any time lack for water, and let them have weak liquid-manure occasionally, gradually bringing them on, in a moderate temperature at first, say about 50°, and not more than 55° to 60° at any time. They are liable to be attacked by greenfly, which must be removed by dipping or fumigating. J. Douglas.

Royal Horticultural: Jan. 8.

SCIENTIFIC COMMITTER.—Sir J. D. Hooker, K.C.S.I., in the chair. Present: Messrs. Houston, Church, Ridley, Loder, G. Murray, Smee, McLachlan, W. G. Smith, Boulger, Wilson, Grote, Moore, Drs. M. Foster, Lowe, and Masters; Rev. G. Henslow,

Secretary.

Polato Disease,—A letter was read from Mr. Plowright, in which he asserted that the conidial tube proceeding from the germinating spore will penetrate the corky rind of the tuber when that is moist, as it its other below ground, but only through the eyes when the tuber is dry. Mr. Mursay stated that the question was, not as to the possibility of such penetration, but as to what was the ordinary method of procedure. A communication from Mr. A. S. Wilsoo on the same subject was also read.

subject was also read.

Mr. Worthington Smith read a paper on the subject
of filtering or sifting fungus spores through sand and
water. Mr. W. G. Smith referred to some experiments he had made for reference to this subject. He said spores of the Potato fungus were not readily procurable in sufficiently large numbers wherewith to make satisfactory experiments, but spores belonging to the smut of Corn (Ustilago carbo) he had in large quantities, and with these the experiments were made. Ustilago spores, being nearly black in colour, pos-

osting optics, the first process of the Potato lungs, which were colourless.

Cylinders of glass were taken, each 8 inches long and half-an-inch in diameter; into one of these of inches of fine sand were placed, the bottom of the tube being first tied over with calico to prevent the sand escaping. A teaspoonful of water charged with Ustilago spores was then poured on to the top of the Usuago spores was then poured on to the top of the sand; in ten minutes the water had all run through, and on examination with the microscope as many spores were present in the water which had percolated through the 6 inches of sand as in the water which had not run through.

A second and similar cylinder was taken and charged with perfectly dry earth in fine powder; water was then poured on the earth to make it quite compact, and more powdered earth and water placed in the tube till a compact 6-inch mass was presented. A spoonful of water charged with Ustilago spores was poured on to the top. In two hours no wate had run through, so the tube was left in a perpen dicular position over a saucer all night. In the morning a part only of the water had run through, and this water was thickly charged with Ustilago

Mr. Smith said he was in the habit of filtering Mr. Smith said he was in the habit of filtering collodion through cotton-wool purified with spirits of wine, so that every particle of dust and all minute atoms of grit might be retained in the wool, and he had never found the purified cotton-wool fail; he therefore placed a plug of wool an inch deep in a third cylinder, and poured water charged with Ustilago spores on to the wool. In a short time most of the water had passed through, and there were as many sources or pearly as many, in the filtered as in the spores, or nearly as many, in the filtered as in the unfiltered water.

In these experiments, as was to be expected, all the spnres did not run through with the water in which they were originally held, some of the spores, together with a little water, remained, but on the application of additional water (as must occur in the case of rain) all, or nearly all the spores doubtlessly ran through. In the water which had passed through the earth a considerable number of spores belonging o two other fungi made their appearance—these

have been present in the earth.

Mr. Smith said he had not the slightest wish to depreciate the value of Mr. Jensen's interesting field experiments, or to under-estimate the value of high-moulding in Potatos, he had merely challenged the experiments with sand, earth, and fungus spores. It had been proved, be said, that spores of a fungus (Dactylium oogenum) could find their way through the shells of fowls' eggs and grow on the membrane within the shell. In the face of a circumstance like this—and several others of a similar nature might be added, said Mr. Smith—the reports of spore-filtering through sand should not be received with too much

credulity.

In the discussion which followed, Professor Foster recalled the fact that the spores of Penicillium contained fatter matter, which rendered them difficult to be wetted. Mr. Murray expressed his disbelief in the power of earth to prevent access of the fungus spores. Professor Church pointed out, with reference to Mr. Smith's experiments, that cotton-wool was naturally greasy, and in that condition offered obstacles to the passage of water, but if the grease were removed by ether, water would pass through the cotton with

rapidity.

Phylloxera in Victoria.—Mr. McLachlan showed specimens of the roots of Vines grown in the colony of Victoria, undoubtedly affected with Phylloxera; and what made the matter even more serious was the fact that the insect occurred on roots of old stumps left in the ground. Dr. Masters remarked that it had been found necessary in English vineries to com-pletely remove the soil of the borders when affected with Phylloxera. Such soil, where possible, should be thrown into deep water.

Coltsfoot in Bloom.—Mr. McLachlan mentioned

the circumstance that he had noticed the common Coltsfoot in bloom on January 7 near Lewisham, the same date as in the year belote last.

Supposed New Species of Freesia.—Professor Michael

Foster exhibited a flower of a species of Freesia not hitherto known in gardens, and which was referred to

Mr. Baker for examination and report.

Chlorophyll.—Professor Church then made some remarks upon a paper by Dr. Tschirch read before the Chemical Society on December 20 last. The author stated that chlorophyll may be prepared by reducing chlorophyllan (*Botan*. Zeitung, 1882, 533) by means of zinc-dust. Professor Church referred to by means of zinc-dust. Professor Church referred to his previous use of zinc-dust for the regeneration of llorophyll, with its original spectrum, in the year 878. (See Chemical News, xxxviii., p. 168.)
Orchid Culture Out-of-doors.—Mr. A. Smee related

some results of his experiments in cultivating Orchids in the open air. He had found that Odontoglossum in the open air. It is not lound that Odonicolosisum crispum would bear as low a temperature as 8° of frost (24° F.), but was killed by 11° of frost (21° F.). O. Rossil var, majus had not only resisted the latter temperature with impunity, but had produced its flowers. A thermometer was hung with the plants, which were slightly protected by a few branches.

FLORAL COMMITTEE.— Present:— Section A: G. F. Wilson, Esq., in the chair; Messrs. H. Ebbage, J. O'Brien, J. Dominy, H. Williams, J. Hudson, H. Herbst, J. Woodbridge, J. Fraser, J. Laing, E. 11ill, H. Ballantyne, and the Rev. G. Houslow. Section 11. Bailantyne, and the Rev. G. Henslow. Section B: Shirley Hibberd, Esq., in the chair; Messrs, H. Bennett, W. Bealby, J. James, J. Douglas, J. Child, G. Duffield, D. C. Lathbury, H. Cannell, and W. B. Kellock. A small but very good display of flowers graced the conservatory on Tuesday for the opening day. Mr. B. S. Williams. opening day. Mr. B. S. Williams sent a charming bank of Cyclamens and Chinese Primroses, the former well bloomed and first-rate in quality, and the la including all the strains of plain-leaved and "fim-briata" varieties that with him have so long been a A Bronze Banksian Medal was awarded. speciality. speciality. A Bronze Banksian Medal was awaroed. Mr. Henry Little also exhibited a remarkably pretty group of flowers, consisting of beautifully-grown Cyclamen and Primulas, alluded to elsewhere, and flowering plants and cut flowers of various Orchids. The latter included fine types of Lycaste Skinneri, and Odontoglossum Roezili, the latter especially being well marked; several nice Odontoglots, a good

pan of Cypripedium Spicerianum, &c. A Silver Banksian Medal was awarded. From Mr. Henry Bennett, Shepperton, came a box of twenty-four blooms of Chrysanthemum Princess Teck, each bloom perfect in form, and the purity of the white heightened by the flush of rose on the lower petals. They were cut from plants grown in the open air, and lifted up and placed under glass in October. Messrs. Cannell & Sons had a Bronze Bank-sian Medal for an excellent group of Primulas, com-mented upon in another column. Mr. Mann, gr., Denton Hall, Grantham, sent two very strongly grown heads of Poinsettia pulcherrima, each with three breaks, in which the bracts were long, of good breadth, and perfect in colour, illustrating what good cultivation can be achieved with skill and an 8-inch cultivation can be achieved with skill and an 8-inch pot. From Mr. Ross, gr., Welford Park, Newbury, came several seedling Crotons Joannis x Veitchii, and Joannis x Weismanni; and Mr. H. Eckford, gr., Boreatton Park, Salop, showed a very pretty Primula named Perfection, in colour a flush of purplish-rose with a clear lemon-yellow eye. Mr. Herbst, ol Richmond, brought up a sample half-dozen pots of forced Lily of the Valley, and which won the admiration of all for the perfect development of flowers and foliage. From W. Brockbank, Esq., came a grand plant with a cluster of over 100 white flowers of the Brockhurst variety of Helbeorus niger angustifolius, and which was awarded a Cultural Commendation. R. P. Percival, Esq., Birkdale, Southport, sent a good flowering specimen of the lovely Cattleya Percivaliana, noted in our last; and Lezia anceps Percivaliana, a strong plant of a very the lovely Cattleya Percivaniana, noted in our ias; and Ledia anceps Percivaliana, a strong plant of a very pleasing variety, in which the blush-white is well shown up by the purple-violet on the lip and tips of the sepals and petals. From Messrs, Sander & Co., St. Albans, came a plant of Odontoglossum Hrubyanum, which may be described as a snow-white, almost unspotted form of O. cirrosum, but with enough dif-ference in the labellum and column to make it distinct from that species. It will when well grown no doubt be a fine thing, but on account of the spike being de-formed and the flowers crippled by opening in bad weather, the committee desired to see it again. new Saccolabium giganteum var. illustre, appears to be a giganteum with violaceum growth, and which Professor Reichenbach describes in another column, also came from the same firm. Messrs. James Collind, also came from the same firm. Messrs, James Veiltch & Sons showed one of the prettiest and most interesting hybrid Orchids that has been seen for a long time in Cypripedium Leeanum (see p. 50), and in Dieffenbachia Jenmanni, a speciesfrom British Guiana, one of the most striking new foliage plants that have come under our notice lately. The leaves are long, linear lanceolate, peagreen in colour, with whitish stripes running from the centre to the margin, and mingled with small blotches of the same character over their surface. A particularity weil-nowered specimen of Odontoglossum roseum came from Mr. G. F. Wilson's garden, and a good form of Sophronitis grandiflora was shown by Mr. Salter, gr. to J. Southgate, Esq. Mr. Todman, gr., Bushey Down, Tooting, sent another of his white-flowered seedling Azaleas; and Messrs, Stuart & Mein, of Kelso, sent racter over their surface. A particularly well-flowered some forced flowers of Spiræa confusa, a species with soft grey green foliage and small white flowers.

The awards made were :-

FIRST-CLASS CERTIFICATES.

Section A. To R. P. Percival, Esq., for Cattleya Percivaliana.
To R. P. Percival, Esq., for Lælia anceps Percivaliana.

To Messrs. James Veitch & Son, for Cypripedium Leeanum x. To Messrs. James Veitch & Son, for Dieffenbachia

Section B.

To Mr. Henry Little, for Cyclamen persicum Crimson

CULTURAL COMMENDATIONS.

Section A.

To W. Brockbank, Esq., for Helleborus niger angus-tifolius, Brockhurst var. To G. F. Wilson, Esq., for Odontroglossum roseum. To Mr. J. Salter, for Sophronitis grandiflora superba.

Section B.

To Mr. H. Herbst, for Lilies of the Valley. To Mr. Mann, for Poinsettia pulcherrima.

FRUIT COMMITTEE.—Present: H. J. Veitch, Esq., in the chair; Messrs. W. Paul, G. T. Miles, G. Goldsmith, C. Ross, J. Willard, J. E. Lane, F. Rutland, G. Bunyard, J. Burnett, A. Howcroft, J. Lee, J. Ellam, R. D. Blackmore, J. C. Mundell, W. Denning, J. Smith. and Dr. Hogg. Several varieties of Apples were exhibited by Mr. Taylor, Osborn's Nursery, Hampton, Mr. R. H. Poynter, Taunton, Mr. K. J. Fernle, Chase Lodge, Mill Hill, and Messrs. T. Perkins & Son, of Northampton—none, however, calling for comment except a handsome seedling in the way of Lane's Prince Albert, shown by the lastnamed firm. It is of good size, well coloured, and of high specific gravity, and will be awarded a Certificate if proved to cook well.

LONDON : Atmospheric Pressure .- During the week ending January 5, the reading of the barometer at the level of the sea iocreased from 30.26 inches at the beginning of the week to 30.50 inches by 9 A.M. ou the 31st, decreased to 29.94 inches by 9 A.M. ou the 31st, decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches by 9 A.M. on the 31st decreased to 29.94 inches b the 3d, increased to 30,19 inches by midnight on the 4th, and was 29.87 inches by the end of the week.

44th. and was 29.87 inches by the end of the week.

The mean reading for the week at the level of the sea was 30.18 inches, being 0.27 inch lower than last week, and 0.19 inch above the average of the week.

Temperature. — The highest temperature in the shade in the week was 49°5, on the 3d, 4th, and 5th; the highest reached on January I was 36°1,

The mean of the seven high day temperatures was 42°5.

43°5.
The lowest temperature was 31°, on January I and 2; on the 4th the lowest temperature was 45°.
The mean of the seven low night temperatures was

37°.3.

The greatest range of temperature in one day was and the smallest was 3°, on 11°.5, on January 2; and the smallest was 3°, on December 31. The mean of the seven daily ranges

The mean temperatures were—on December 30, 37.6; on December 31, 36.2; on January 1, 34.7 on the 2d, 38.4; on the 3d, 46.4; on the 4th, 47.6; and on the 5th, 47.1; of these December 31 and January 1 were below by 1° and 32° repectively, the rest being above by 0°.3, 1°.5, 9.7, 11°, and 10°.6 respectively.

The mean temperature was 4t°, being t°.1 higher than last week, and 4°.1 above the average of the

week.

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was \$4°, on the 5th. The mean of the seven readings was 46°.1.

The lowest reading of a thermometer with its bulb hand on weeks and fully exposed to the character of the seven reading was 40°.1.

placed on grass and fully exposed to the sky was 24°.5, on January 2. The mean of the seven readings was

Rain .- Rain fell on six days during the week, to the amount of 0.30 inch.

ENGLAND: Temperature.—During the week ending January 5 the highest temperatures were 55° at Truco, 54°, 7 at Plymouth, and 54° at Bristol; the highest at Brighton was 49°, at Blackheath 49°, 5, and at Nottingham 49°, 9. The general mean was 51°, 2.

The lowest temperatures in the week were 20°, 4 at Wolverhampton, and 30°, 8 at Brighton and Bolton; the lowest temperature at Truco and Plymouth was 35°, and at Preston 34°. The general mean was 32°, 4.

The createst ranges in the week were 20°, 5° at 10°, 5° at 10°

The greatest ranges in the week were 22°,5 at Bristol, 21°.2 at Wolverhampton, 20° at Bolton; the smallest ranges were 17° at Leeds, 17°,1 at Bradford, and 17°,7 at Leicester. The general mean was 18°,8,

The mean of the seven high day temperatures was highest at Truro, 51°.7, at Plymouth 48°.5, at Sunderland 47°.5; and was lowest at Bradford, 42°.4, at Nottingham 42°.5, and at Leeds 43°. The general

at Nottingnam 42: 5, and at Leeus 43. In egeneral mean was 44. 3.

The mean of the seven low night temperatures was highest at Truro, 41.7, at Plymouth 41.5, at Liverpool 39.3; and was lowest at Sheffield, 36.2; at Wolverhampton 36.4, and at Bolton 36.6. The general mean was 38.

The mean daily range of temperature was greatest at Truro and Sunderland, 10°, at Bristol 8°; and was least at Liverpool and Nottingham, 5°.3, and at Bradford 5°.5. The general mean was 6°.3.

ford §°.5. The general mean was 6°.3.

The mean temperature was highest at Truro, 46°.6, at Plymouth 44°.9, at Sunderland 42°.4; and was lowest at Sheffield and Bradford, 39°.6, and at Nottingham 39°.8. The general mean was 41°.4.

Rain.—The largest fall was 1.33 inch at Bolton, 1.28 inch at Sunderland, 1.03 inch at Preston; the smallest falls were 0.26 inch at Cambridge, 0.30 inch at Blackheath, and 0.42 inch at Leicester. The general mean fall was 0.72 inch. Rain fell on every day in the week at Nottingham.

SCOTLAND: Temperature,—During the week ending January 5, the highest temperature was 52°, at Dundee the highest in the week was 47°.4. The general mean was 49°.5.

The lowest temperature in the week was 24°, at Perth; at Leith the lowest temperature was 28°.1.

The general mean was 25°.9.

The mean temperature was highest at Leith, 38°.5; and lowest at Perth, 33°.3. The general mean was

Rain.—The largest fall was 2.14 inches, at Greenock; and the smallest fall was 0.49 inch, at Aberdeen. The general mean fall was 1.06 inch.

JAMES GLAISHER, F.R.S.

Obituary.

WE regret to have to announce the death, on the 21st of last month, of Madame ERNEST BERGMAN, at Ferrières. The deceased lady was in her thirtyfourth year, and was well known to many persons in this country.

Enquiries.

"He that questioneth much shall learn much."-BACON.

British Queen Pea.—I should be much obliged to any reader who will give exact particulars respecting the origin of this Pea. W.

KNIGHT'S DWARF MARROW PEA,—Can any of your readers tell me under what name this Pea lies hidden in the seedsmen's catalogues of the present day? Diss,

Answers to Correspondents.

AMERICAN PAPER: R. L. B. The American Gar-deners' Monthly, published by Ch. H. Marot, 814, Chestnut Street, Philadelphia.

Chestint Street, Philadelphia.

CHOICE EATING APPLES: R. A. Yalland. All land is not equally suitable for Apple cultivation, a medium, well drained loamy soil of considerable depth, overlying rock or gravel, is the best; but almost any soil can be made suitable by drainage, and by the addition of proper composts and manures. Above all, shelter is required for successful orcharding, such as thick plantations of mixed evergreen and deciduous trees, forming wind breaks from N. N. E. and S. W. especially. The site should not be low, for these trees bloom early, and frosts are most damaging in the spring. Plowphing is be had from Fred. Bunyard, 29, Week Street, Maid-

CHRYSANTHEMUM MEG MERRILIES: E. M. You were not the writer whose statement "Wild Rose" questioned.

ERGOT: G. C. J. We believe so, but will get definite information if possible.

information it possible. FENN FRONDS: W. Walters. The fronds sent exhibit appearances consistent with scalding from hot steam thrown off by hot-water pipes that have had water thrown on them; or from cold draughts of air; or from being wetted with very cold water. There are no signs of fungus growth, and the causes are so various that would lead to the same appearances that we are unable to say what has caused the damage.

GRAPES: A Subscriber. With the Muscat you can associate Mrs. Pince's Black Muscat, Madresfield Court, Black Alicante, and Lady Downe's.

MANURE: Orchard. It will be suitable for the Roses and Gooseberries, if trenched into or thoroughly well incorporated with the soil.

MICROSCOPIC PREPARATIONS: H. H. We must really be excused in future from naming badly prepared microscopic specimeso of no special horticultural interest. No. 1 is a Moss in an early stage of development; 2 and 3 are both Jungermannias.

ment; a and a are born jugermannias.

NAMES OF PLANTS: Comon & Reid. Goldfussia anisophylla. — T. W. Barkeria Skinneri. — Morton
Sparke. A yellow form of Odontoglossum pardinum,
so far as we can judge from a solitary flower. — Regrnald Young. Your box was smasshed, and delivered
open, by the postal authorities, and without the Catleya blooms. The Lycaste seems to be only an ordinary Skinneri. The Dendrobe was not recognisable.

NUDIFLORUM: A Constant Reader. It means "desti-tute of leaves." The statement you quote is quite correct. Jasminum mudiflorum always produces flowers while destitute of leaves.

TRYING IT ON: O. P. We do not conceive it to be any part of our duty to advertise the firm in question, nor do we consider the other Berlin seed-growers unable to defend themselves.

SEEDS.

LONDON: Jan. 9.—There is now a fair amount of business passing in farm seeds. Foreign red Clover seed remains firm, but inferior parcels of new English, which now offer more abundantly, are cheaper to buy. In white Clover and Alsike values still point upwards. Trefoils meet a quiet sale at tull rates. For Mustard and Raper seed the sale is exceedingly slow. Hemp seed is easier, and Canary seed is neglected and drooping. More money is asked for feeding Linseed. John Sakaw 6: Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday for Wheat the trade was very dull, with prices in some cases rather easier than last week's. Flour was equally dull of sale, and quotations drooping. Barley was firm all round; grinding sorts were 3d, to 6d, dearer on the week, and malting descriptions showed a large rise. Beans and Peas were stationary; in value, with a moderate demand. Flat Maize was rather firmer, and round corn steady. There was no material change in the value of Oats.—On Wednesday the tone of the Wheat trade was depressed, and but little was done to test quotations, which re-Wednesday the tone of the Wheat trade was depressed, and but little was done to test quotations, which remained nominal. Flour was equally dull, with a similar tendency. Barley was firm on the spot, with a moderate inquiry. Beans, Peas, and Maize remained at late values. Oats were a slow sale at unalered rates.—Average prices of corn for the week ending Jan. 5:—Wheat, 395.; Barley, 32s.; Oats, 19s. 3d. For the corresponding period last year:—Wheat, 40s. 7d.; Barley, 32s. 4d.; Oats, 21s.

POTATOS.

The Borough and Spitalfields Markets reports state The Borough and Spitalhelds Markets reports state that good supplies were on offer, and met a quiet demand as follows:—Magnum Bonums, 80s. to 1005.; Regents, 80s.; Champlons, 60s. to 80s. per ton.; and German Reds, 4t. per hag.—The imports into London last week consisted of 30 bags from Hamburgh, 80o Stettin, 3 Amsterdam, 3 acase from Bremen, 9 boxes Ghemleh, and 9 barrels from New York.

Government Stock.—Consols closed on Monday at roth to roth for delivery, and roth to roth for delivery, and roth to roth for delivery, and as on the previous day for the account. Wednesday's closing prices were roch to roth for delivery, and roth to roth for the account. The closing quotations of Thursday were roth to roth for delivery, and roth to roth for the account—all ex div.

Parters"

STERLING OF NOVELTIES

IMPORTANT FACTS.

It is generally admitted that the Vegetable and Floral Novelties introduced of late years by Messrs. CARTER possess sterling qualities to a degree that finds few competitors. J. C. & Co have only to refer to & Co have only to refer to
the splendld introductions,
Stratagem, Telephone, and
Pride of the Market Peas,
Leviathan Beans, Heartwell
Cahhage, Model Cucumher,
Decham Favourite Tomato,
&c, to confirm the statement, and it is a notable
fact that Messrs. Carters' Noveittes, unlike many others,
do not fade from public
favour, but are generally
recognised as necessary in
every garden, whether for
Celery.—See below. Exhibition or for the Table.

Many of CARTERS' STERLING NOVELTIES were specially recommended in the "Gar Chronicle," January 5, 1884.

CARTERS' TELEPHONE PEA.
First-class Certificate Royal Horticultural Society,
Over 70 1st Prizes at country shows. Mr. MILES
says:—"Excellent for exhibition."
Price, in sealed packets, 22, 64, per pint.

CARTERS' STRATAGEM PEA.
Two First-class Certificates Royal Horticultural Society,
and over fo ste Firsts at country shows. Mr. Gilder says:—"This is a gem."
Price, in sealed packets, 2r. 6d. per pint.

CARTERS' PRIDE OF THE MARKET PEA.—First-class Certificate Royal Horticultural So-ciety; 16 1st Prizes during last year. Mr. HALL writes:—"They grow without any sticks." Frice, in sealed packets, 2s. dd., per pint.

Oil Paint No Longer Necessary HILL AND SMITH'S BLACK VARNISH, for Preserving Ironwork, Wood, or Stone.
(Registered Trade Mark)

This VARNISH is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the Advertisers, and its genuine good quality, notwithstanding a host of unprincipled intuitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at windoor Castle. New Gardens, and at the seats of many finding of the control of

GENUINE

SEEDS.

JAMES VEITCH & SONS, ROYAL EXOTIC NURSERY, CHELSEA, S.W.,

Have much pleasure in directing attention to the following New and Choice VEGETABLES, which are all of great merit, and can be confidently recommended :-

CAULIFLOWER, Veitch's Extra Early Forcing First-class Certificate Royal Horticultural Society.

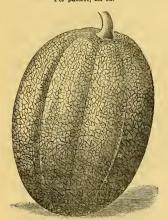

Of dwarf compact habit, with short stems and small leaves; comes into use earlier than any other variety. Highly recommended for forcing or very early use.

Per packet, 2s. 6d.

CAULIFLOWER, Veitch's Autumn Giant. Per ounce, 2s.

NEW CAULIFLOWER, Veitch's Pearl.

This splendid main crop variety has been grown by us for several years, and is the best for general use. The pure white heads are of medium size and of finest quality. Per packet, 2s. 6d.

NEW MELON, The Goodwood.

First-class Certificate Royal Horticultural Society, Aug. 14, 1883. The fruit can be grown to enormous size, Mr. Ruthand having exhibited a fruit weighing 34 lb. 202. It is of handsome form, oval in shape, with a bright orange skin, very evenly netted; flesh thick, very jucy, and of excellent flavour. Per packet, 3s. 6d.

BEAN, Veitch's Improved Longpod.

The earliest and finest of the Longpod section, exceedingly productive, bearing in clusters an abundance of long, well-filted pods. Per quart, 1s.

NEW BEET, Pragnell's Exhibition.

A remarkably handsome and distinct variety, emineutly suitable for exhibition, and one of the best for general purposes. Per packet, 1s. 6d.

BORECOLE, Veitch's Dwarf Late Curled. Per ounce, 1s.

NEW BORECOLE, Read's Hearting. First-class Certificate Royal Horticultural Society, 288

This hardy dwarf variety forms a firm compact beart, and stands longer than any other kind before running to seed. Per packet, 1s. 6d.

CELERY, Major Clarke's Fine Solid Red. The best Celery in cultivation. Of medium growth, robust and compact, forming very solid hearts; very crisp, and of excellent flavour. Per packet. 1s.

Per packet, 1s.

CABBAGE LETTUCE, Veitch's Perfect Gem. A most distinct, compact-growing variety, of a rich deep green colour, forming very early a close solid heart, beautifully crisp, juicy, and tender, and of excellent flavour.

LETTUCE, Veitch's Superb White Cos.
A magnificent self-folding variety, growing to an immense ize, of superior quality, very crisp, and fine flavoured. The sest White Cos variety in cultivation.

Per packet, 1s. 6d.

CUCUMBER, Tender and True.
First-class Certificate Royal Horticultural Society, and
awarded First Prize at each of the Spring Shows for three
seasons. A spleadid variety, very symmetrical in shape, and
growing to about ze to 30 inches in length.
Per packet, 1s. 6d.

NEW MELON, Scarlet Premier.

A superb new and distinct scarlet-fleshed Melon, setting very freely, and producing large, handsome, highly coloured, and beautifully netted fruit. The flesh is very solid, thuck, rich, and melting, of exquisite flexavour and delicate aroma. Per packet, 1s. 6d.

NEW TOMATO, Hackwood Park Prolific.

First-class Certificate Royal Horticultural Society, July 4, 483.
An extremely profile ene and early variety, producing huge clusters of handsom first of a large size, which are remarkably smooth eyes from, and of a bright glowing searlet colour. The fiesh is firm and solid, of finest quality, and excellent flavour.

Per packet, 1s. 6d. Per packet, 1s. 6d.

TURNIP, Veitch's Red Globe,
The finest Turnip for garden purposes, very handsome in shape and of fine flavour.
Per ounce, 6d.

NEW BROCCOLI, Veitch's Model.
The best late variety, coming into cutting in May and June.
The heads are of medium giney compact, beautifully white,
and thoroughly protected. It is perfectly hardy, and as a late
sort cannot be surpassed in quality.

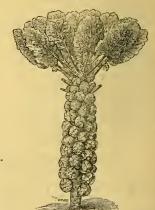

Per packet, 1s. 6d.

BROCCOLI, Veitch's Self-protecting Autumn A most valuable Broccoli for autumn and early winter use. Heads beautifully white, firm and compact, thoroughly protected by the foliage.

Per packet, 1s.

CABBAGE, Ellam's Early Spring. The earliest spring variety, of dwarf, close, compact habit, forming firm solid hearts of excellent quality.

Per packet, 1s.

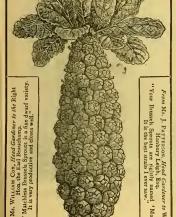

BRUSSELS SPROUTS, Veitch's Exhibition
This grand variety is unequalled for exhibition or for general
use. The stems are entirely covered from top to bottom with
fine large sprouts, which are very firm and solid, remarkably
tender, delicate in flavour, and remain a long time fit for usely Per packet, 1s. 6d.

SUTTON'S

ALL HEART

CABBAGE.

HEART CABBACE

last year, we ventured to say that it would become one of the last year, we wentured to say that it would become one or use most popular early dwarf varieties in commerce. We have received aumerous letters testifying to its superiority over all other dwarf Cabbages. The babit is dwarf and compact, with a remarkable absence of outer leaves; in fact, it is absolutely "All Heart." One great meeting of this Cabbage is that it produces firm heads in less time than any other variety.

Per packet 1s., post-free.

"Certainly the finest type of a garden Cabbage I bave ever seen. The stems are so short that no earthing is needed. The beads are pointed, and so close and compact, even to the outer worts. The quality is excellent, and it is exceptionally early. I sowed on May 8, and at this date, September 13, the whole piece is fit for use."—Mr. W. WILDSMITH, Gardener to the Hight Hon. Viscount Eversley.

"A superb and distinct little Cabbage. It grows about 12 inches bigh, and the stems are so short that the heads appear to be ressling on the ground. It is wholly composed of heads of the bighest quality, and it is a perfect diocer-table Cabbage."—Mr. J. Murg. Gardener to C. R. M. Talbot, Esq., M.P., Margam Park.

"I have tried this Cabbage against a number of other dwarf varieties, and it surpasses them all for earliness and dwarf compact habit, with large firm beads of deheate flavour. It is undoubtedly one of the best Cabbages I have ever tried."— Mr. J. Bunkert, Gardener to Mrs. Hope, Depdane.

SATURDAY, JANUARY 19, 1884.

THE NEW PLANTS OF 1883.

(Concluded from p. 44.)

THOUGH noticed last, the group of plants now to be passed under review is not the least important. It proves to be more limited than usual, but it comprises a few subjects of real value in their respective departments. We refer to the group of

HARDY AND HALF-HARDY PLANTS.

Taking the flowering shrubby subjects first, the most noteworthy which has come under our notice is the Hydrangea rosea, a new Japanese species or variety in the way of H. Hortensia, but a much finer thing, and a superb decorative object. It is of the same bushy habit of growth as H. Hortensia, of which it is probably a variety, since it also has similar soliage, but the heads of flowers are larger, and the colour is a brilliant rose-pink, altogether eclipsing the pale rosy hue of the older and more familiar kind. It comes from Japan, and has been brought into notice by Messrs. Veitch & Sons, to whom a certificate has been awarded for it, both by the Royal Horticultural and the Royal Botanic Societies. To the same firm we are indebted for Leucothoë Davisiæ, a Californian species from the Sierra Nevada, forming a beautiful hardy evergreen shrub, growing 3 to 5 feet in height, and bearing oblong obtuse bright green spioulose-serrate leaves, and erect racemes of small white pendulous pitcher-shaped or ovate flowers, terminal, and from the upper axils forming clusters at the tips of the branches and branchlets; a certificate was awarded to it by the Floral Committee in June last, when it was exhibited nicely in flower, so that it will be a summer bloomer. The plant was named by Torrey in compliment to its discoverer, Miss Davis, who found it near Eureka, Nevada Co.

Amongst the hardy Azaleas some very fine addi-tions have been made known. They are, indeed, English hybridised seedlings, but scarcely come within the group distinguished as florists' flowers, and hence may be included here. Those who know the double yellow Narcissiflora will be aware what a valuable plant this is for forcing, and the same may be expected to hold good of other similar forms of distinct and decided colours. We have, therefore, no hesitation in commending the rubro-plena of Mr. A. Waterer, and the alba-plena of Messrs. Ker & Son, as two of the coming plants for early blooming purposes, and also as good outdoor flowering shrubs for the later spring months. Of the single forms some extraordinarily fine things have been raised at Knapbill. Two of these, already figured in the Florist, are named C. S. Sargent, a magnificent yellow, with orange-yellow blotch; and Henrietta Sargent, one of the finest of the rose-coloured series, with two bright golden blotches on the upper segments. Others, of which portraits will shortly appear, are H. H. Hannewell, a brilliant glowing orange-scarlet, which no painter's pigment can reproduce; and Mrs. Walter Druce, a splendid white, with orange-yellow markings on the upper segments, and a stain of rose colour at the base of the stamens, and on the exterior of the tube. These by no means exhaust the supply, but the rest are as yet unnamed.

A variegated Holly, a variety of Ilex Aquifolium, of distinct character and strikingly handsome, has been brought to one of the Royal Horticultural Society's meetings under the name of laurifolia aureo-marginata; it is a gold-edged variety of the spineless, or almost spineless, group, of which the variety laurifolia is the green type. This plant, which obtained a certificate for Mr. Waterer, has the central portion of the leaves of a dark bronzy-green, with a distinct border of golden-yellow, and is quite an acquisition to the group. Another plant of high merit, and exceedingly rare, if not altogether new, is the Yucca gloriosa variegata of Messrs. Veitch, the leaves of which are decorated with longitudinal bands of yellow tinged with rosy-pink, and forming a conspicuous and effective variegation.

Amongst the deciduous trees and shrubs the first place belongs to Prunus Pissardi, an ornamental deciduous Plum from Persia, having leaves of an intense red colour, as are also the fruits, even in the early stages of their growth. It is not absolutely new, having been figured in 1881 in the Revue Horticole from plants growing in Paris; but it has not yet made its way in England so much as it deserves to do, and as some recent letters in our columns show that it merits (Gardeners' Chronicle, 1883, vol. xx., pp. 444, 472, 504), and as it must do, when more generally The name commemorates the gardener to the Shah of Persia, by whom it was sent to our neighbours across the Channel. Another distinct and interesting tree brought to some of the summer shows is the Acer cratægifolium variegatum, a rather pretty Maple, having the leaves ovate and three-lobed, with acuminate lobes, and variegated with creamy white. This comes from Japan.

HERBACEOUS PLANTS. - This division does not this year give us many additions. The most important probably is the Haplocarpha Leichtlinii, which has been grown in gardens under the name of Gorteria acaulis. It is a stemless South African perennial, with lyrate-pinnatisect leaves, 6 to 12 inches long, bright green above and clothed with white tomentum beneath; the white tomentose scapes, I foot high, bear flower-beads 2½ inches in diameter, having bright yellow-rosy florets stained with purple beneath. It is a showy free-flowering and attractive Composite, not quite hardy, but requiring protection in winter, and not quite new, having passed for a few years under the false name of Gorteria, but its corrected name comes as a novelty, having been only recently assigned to it. Mimulus radicans, from the mountains of New Zealand, is a more decided novelty, and is said to be quite hardy; it has slender branching rooting stems, which creep close to the ground, and bear close-set small obovate obtuse bairy leaves of a bronzy-green, and two-lipped flowers, of which the upper lip is purple and two-lobed, and the lower one three-lobed and white, with a dash of yellow on the palate. Its close-growing carpet-like habit may suggest many decorative uses to which it might be applied. The genus Mimulus has also received some accessions through the aid of the hybridist, the object in the case of these here noted having been to diversify and improve the popular Musk plant. These new varieties were, we believe, raised by Mr. Clapham, and have been brought into notice by Mr. R. Dean; and although perhaps but the stepping-stones to more decided acquisitions, they are in the meantime worth a place amongst dwarf-growing hardy perennials. Two of these improved Musks have appeared, both dwarf and compact in their manner of growth, and both with increased size of flower; the most interesting is the Mimulus moschatus ruber, which has large flowers of a cheerful coppery-red, and may be considered as a fair move towards the acquisition of a scarlet Musk. The foliage is richly musk-scented. The other, M. moschatus grandiflorus, has very large (comparatively) bright yellow flowers, and is altogether distinct from that known as Harrison's Musk.

Amongst the herbaceous perennials of the half-hardy class, to be credited to the past year, are several new hybrid Sarracenias, of great interest, which have been exhibited by Mr. Bull. Two of them have won-firist-class Certificates, namely, Sarracenia Swaniana× and S. Wilsoniana×. The former, raised between S. variolaris and S. purpurea, is a bandsome and well-marked form, with curved funnel-shaped broadly winged pitchers, having a cordate-ovate bilobed lid, which, as well as the inner surface of the tube, is strongly reticulated with crimson veins; it bears most resemblance to purpurea, but the pitchers are more crect.

The latter, Wilsoniana, is bred between purpurea and flava, and is very distinct, the pitchers being quite erect, funnel-shaped, stoutish, constricted below the apex, so that the upper part is campanulate, green, heavily striped with crimson ribs, more or less connected by cross veins, and the lid broadly cordate

reniform, infolded at the sides over the mouth, and strongly marked by dichotomous divaricate ribs, united by smaller veins, the veining all of a deep purple-crimson. Another, S. named Mitchelliana x, a cross between Drummondii rubra and purpurea, is dwarfish and slender in growth, with a particularly refined appearance. The pitchers form a shortish, curved funnel of an olive-green colour, with profuse fine red variegation, the whole surface changing later on to reddish-crimson; the lid is cordate reniform, apiculate, undulated, with a striking network of deep red-crimson. Several other hybrids have been raised, but have not yet been named. They, however, pre-sent very remarkable features, and will add immensely to the interest attaching to a collection of these peculiar half-hardy plants, which have been but little appreciated till within a recent period, when Mr. Stevens and Dr. Moore started their hybridisation. Now we have several beautiful kinds, which have already acquired popularity, and these novelties will assuredly increase their popularity with plant lovers. It is to be noted, too, that in this family, now that their cultivation is better understood, we get magnificent flowers as well as highly ornamental foliage (the pitchers), and therefore there is an inexhaustible fund of interest in the case of the hybrids, since they will in all probability in due time show better still if the flowers increase in diameter, as I expect they will do.

It is very remarkable that the curious wavy lip of Limatodes labrosa should have been replaced by the flat vestita lip, and that these flowers got such a rich universal tinge, when the finest vestita rubro-oculata have but a small red eye, and the colours of Limatodes labrosa are rather light and modest, decidedly by no means dazzling.

This fine thing was kindly sent me by Sir Trevor Lawrence, who has a remarkably fine collection of Calanthe seedlings, quite worthy his Eldorado. H. G. Rehb. f.

PESCATOREA KLABOCHORUM VAR. ORNATISSIMA,

A remarkably fine variety, with very dark mauvepurple tips, and numerous similar spots on the bases of the petals, and a single spot at the base of the odd sepal. It was kindly sent me by Sir Trevor Lawrence. H. G. Rehb, f.

LÆLIA ALBIDA (Bat.) SULPHUREA, nov. var.

A remarkably fine fresh variety, sent me by Messrs. Heath & Son, Exotic Nurseries, Cheltenham. It has very large flowers, with rather narrow sepals. All parts are of the finest sulphur, with some light

Fig. 12.—ROAD-SIDE PLANTED WITH FRUIT TREES—APPLES TO THE LEFT, PEARS TO THE RIGHT. (SEE P. 81.)

novelty and beauty in their inflorescence as well as in their foliar development.

These are but a few of the novelties for which 1883 will be noted in the annals of horticulture, but quite enough to show that there has been no lack of good things. T. Moore.

New Handen Plants.

CALANTHE PORPHYREA, n. hyb.

THIS has a constricted fusiform bulb and a florid hairy peduncle, having the raceme zigzag. The bracts are oblong acute, much shorter than the stalked ovaries. Sepals and petals oblong acute. Lip triclode, side lobes involved, anterior one emarginate, protruded. Spur rising from the suprabasilar part of the column, nearly equal to the stalked ovary. Column hairy inside and outside.

The sepals and petals are of the most exquisite dazzling purple. Lip yellowish at the base, with purple small spots; anterior part fine purple. Spur ochrecoloured.

This is a cross between Limatodes labrosa and Calanthe vestita rubro-oculata, the former being the pollen parent. It is an exquisite thing, and will be mauve hue on each side of the anterior lacinia of the lip. The crests of the lip are orange in front; there are dark purple reticulations at the base of the lip, and dense dark purple lines in front of the column. H. G. Rehb. f.

CHRISTMAS ROSES.

HELLEBORUS NIGER: VARIETIES .- When Curtis commenced his Botanical Magazine in 1790, one of the first plants he selected for illustration was Helleborus niger, the subject of his plate 8. It is an excellent picture, giving all the botanic details, as well as the beautiful appearance of the flowers, and it remains still our best English illustration of the typical form of H. niger. In 1826-7 Robert Sweet published his Hortus Britannicus, or catalogue of plants cultivated in the gardens of Great Britain. To the compilation of this valuable work he was assisted by David Doo. Sweet's Hortus may, therefore, be taken as a very complete list of all garden plants then in cultivation, and no doubt great care was taken to describe the varieties by their proper names, when such notable men joined in the task. Here, then, we find the earliest list of the varieties of Helleborus niger in cultivation, viz. :- 1. H. niger ; 2. H. n. latifolius, broad leaved ; 3. H. n. angustifolius, narrow leaved; the only reference to an illustration being Bot. Mag., pt. 8. The last two of these names appear to have originated on this occasion, and to have been chosen so as to fit the actual specimens before them. What they called latifolius we now call altifolius [which has the right of priority. En.] or maximus; and their augustifolius was probably the greenstalked "true Christmas Rose" of Parkinson and Gerard, the name of which became lost after a few years, to be revived again by Mr. MacNab, wheo Miss Hope's narrow-leaved Hellebore was brought under his notice. Sweet's names are descriptive at any rate, marking well the leaf pecularities of the plants; and it would be easy to make out a pretty long list of leaf names, the variations in leafage being even greater than in the flowers.

Mr. Archer Hind has sent me a number of leaves from seedling plants of H. niger, and they furnish several well-marked varieties. Some have the segments of their pedate leaves narrow, and some broad; some are lanceolate, others obovate; some have the edges entire, others toothed, and with hard, sharp teeth, like miniature Hollies; and others are deeply laciniate. I have also in my garden a series of curions-leaved varieties, raised as seedlings by Mr. H. Brownhill, of Sale, showing all these peculiarities, whereas the flowers vary but little. The colour of the stalks and petioles also varies, as well as the form of the leaf. When first I commenced this inquiry I was under the

to the above conclusion, which had already been arrived at by Mr. Archer Hiod, Mr. Wolley Dod, and probably by others also. The following notes will sum up the conclusions I have arrived at with reference to the varieties of H. niger and their origin:—

1. HELLEBORUS NIGER, the typical form, is the most widely distributed, and as it is annually imported into England by thousands it ought to be plentiful. Messrs. Sander, who import it largely from Austria, tell me that theirs is the ordinary typical form, col-lected in the wild state, and that the leaves vary very much in form. I have received flowers and leaves trom many correspondents, and all have the purple mottled stalks and flowers slightly rose tinted. are several good examples of this in the Kew collection, viz., in J. S. Mill's, Gay's, Bentham's, and Dr. Fendler's herbaria, all of the small, ordinary type, as found wild in the Alps, the Tyrol, and Italy. also growing in Kew Gardens under the name H. niger minor. I suppose the variety major is merely the larger form of this. Of the flowers sent me by Mr. Archer Hind as the typical form there is one which would be large enough to merit this distinc-tion. Some 'nurserymen class an "intermedius,"

FIG. 13.-BUSH-FRUIT GROWING NEAR AMIENS. (SEE P. St.)

impression that the green-stalked characteristic only belonged to our Cheshire variety of H. n. angustifolius. Several others have, however, reached me from various correspondents. Mr. Archer Hind, Mr. Brownhill, and Mr. Geo. Willers, of Cambridge, have all raised green-stalked varieties of marked character. In all cases the flowers are also of a greenish-white. But here again we have no fixed characteristic, as many of the red-stalked Hellebores have nearly as white flowers as those of the green-stalked sorts. The pink stigmas, also, which were considered to be peculiar to H. n. altifolius (Hayne), are also found to be more widely distributed. Mr. F. W. Moore, of Glasnevin, sent me a series of blooms from other forms of H. niger, but of which he does not know the origin, as they have been for some time in the Glasnevin Botanic Gardens, and all of which had the pink styles. Out of some hundred plants of H. n. angustifolius growing at Brockhurst we have also occasionally noticed early blooms which show the pink centres when freshly opened, but which soon become pale and pass into the usual colour. It is thus evident that no botanical characteristic can be assigned solely to one variety, showing clearly that all are closely related, and pass by shades of difference into each other.

By the kindness of many friends I have received in the course of this investigation flowers and leaves from all parts of Great Britain, so that almost every variety must have come under notice, and these have led me which I take to be metely a larger variety of the ordinary niger.

2. H. NIGER MAJOR .- To this class belong our very best Christmas Roses, including also the variety angustifolius, so that we might apply Sweet's names broad and narrow-leaved very fitly to describe the leading divisions. It is to be found figured in our hest botanical works as the niger of Linnœus, the greater size being its only distinction. Plate exi. in Reichenbach's Icones Flora Germanica is a good illustration, and tab. 201 in Jacquio's Flora Austriaca is a most heautifully executed plate, of folio size. both these the name is H. niger (Linne). plate in the former has purple mottled stalks, whilst in Jacquin's illustrations the leaf-stalks are but slightly mottled at the base, and the flower-stalks are shown purely green, thus giving our two varieties. Messrs. Cooling & Son, of Bath, sent me examples of the variety of H. n. major grown in that neighbourhood, and which has great purity of colour and size. The same comes to me from the Royal Botanic Gardens, Edinburgh. These two agree nearly with Reichenbach's figure, and are probably of Austrian origin. Mr. Wolley Dod told me of a very fine form of H. n. major which grew near Hereford, and by the kindness of Mrs. Stanhope, of Byford, I have been furnished with a fine plant and many leaves and flowers. It appears to have been grown in the neighbourhood for a long time, and is

one of the most beautiful Christmas Roses we possess, having fine foliage, large white flowers, with a slightly pink tinge, stouly carried, and in great prolusion. The leaves are intermediate in form between the broad and the narrow varieties, and but for its mottled stalks and slightly pink shade of white, it would come very near indeed to our Cheshire variety. Another good Hellebore grows plentially in Overton parish in Cheshire, in the valley of the Dee. This variety has very large leaves, and smaller flowers than that from Byford, but it is an excellent and very vigorous sort. From Devonshire I have received also excellent examples, and also from Cornwall, all of which may be classed as H. n. major.

3. H. N. ANGUSTIFOLIUS (Sweet) .- Of this there are at least two well-marked varieties. The Wardie Lodge variety is an exceedingly valuable Hellebore, well known to all readers of the Gardeners' Chronicle as almost a fresh discovery of the late Miss Hope's. There is a plate in Hayne (Berlin, 1865), under the oame H. n. altifolius which very nearly represents this flower, having the same kind of root, with purple mottled stalk and petiole, the narrow leaves and the flower being also similar. The pink stigmas, which we now consider the distinguishing feature of altifolius, are wanting, as well as the broad segments in the leaf. I should, therefore, now class Hayne's figure as H. n. major, of the narrow-leaved variety (angustifolius). It has the long petioles and exceedingly narrow leaves which induced Sweet to give the variety that name, as he found the plant in our English gardens. This is a very beautiful Hellebore, and is that to which Mr. MacNab assigned the name angustifolius in 1876, reviving Sweet's nomenclature of 1826. In all probability this variety is of Austrian origin, just as was found to be the case with the other celebrated Scotch variety of altifolius (see Gardeners' Chronicle, November 10, 1883).

The Brockhurst variety differs a good deal from Miss Hope's, although oearly the same in its form of flower and leaf. Of the two it is the finer, having the peculiarly distinctive difference of green stalks and peduncles, with scarcely a trace of purple mottling. I take this also to be a variety of H. n. major. There is a specimen preserved at Kew, in the herbarium Boissier, marked H. niger (Linne), which is extremely like it, and which was found at Lugano. In my former essay on H. o. angustifolius (Gardener's Chronicle, October 27, 1833) I stated that the Irish variety grown by Mrs. Laurenson (and which Mr. Burbidge considered a new sort, to which he proposed to give the Irish name of St. Bridgid's Christmas Rose) was being grown side by side with the Brock-hurst variety for comparison. This trial has resulted in Mr. Burbidge's decision that the two are the

The figure which accompanies this note (fig. 16, p. 85) has been drawn by Mr. W. G. Smith from flowers and leaves taken from each of these trial plants, no difference whatever having been found between them. After seeing examples of almost all the English Christmas Roses, I adhere to my formerly expressed opinion, that this is the most purely beautiful and the best variety of them all. The Rev. H. Tymons has found it in two other Irish gardens, and it appears to be peculiarly suited to the Irish climate, as also it is quite at home in Cheshire.

Mr. Wolley Dod has noticed a very fine variety at Grange-over-Sands, and on obtaining flowers and leaves from thence I find it to be this variety. It also occurs in Worcestershire. This Hellebore appears to have been established for many years in Eoglish gardens. Its deep roots make it most at home in light soils, and it probably obtained a footing in Holland from this peculiarity, and was brought thence to England as far back as the reign of Queen Elizabeth, by the Dutch gardeners who were then employed in English gardens. It does not appear to have thriven in the neighbourhood of London, probably on account of the clay soils, but wherever the conditions were favourable it flourished, and owing to its easy culture it became abundant. Its exquisite blooms, coming just at Christmas time, were eagerly purchased, and for this reason the market gardeners made it a special business to cultivate it. In our neighbourhood it has thus been grown for a very long period. (See Gardeners' Chronicle, November 10, 1883.) This Hellebore, therefore, merits the name of the true Christmas Rose, and I still hold the opinion that it was the variety known to Gerard and Parkinson under

4. II. N. ALTIFOLIUS OR MAXIMUS. - This variety has been so fully described and traced to its original habitat (Gardeners' Chronicle, vol. xx., pp. 527, 686, 762), that I need not dwell turther on it here. It proves to be very widely spread in both Scotland and England, and to have flourished for over forty years in Cornwall, as well as in Devonshire and Aberdeenshire. It is by far the largest and finest of all the varieties of H. niger, and during this season it has worn its roseate hues more frequently than usual. Mr. Tyerman and Mr. Archer Hind find it comes purely white in shady sheltered situations, but wherever exposed to cold winds it loses its pure white colour. I have now on my table a very fine example, with a stall 20 inches long, and bearing two flowers, one of which measures over 5 inches across, being rather larger than the specimen figured in the Gard Chronicle, p. 693, vol. xx. It was grown at Edge Hall, where this grand Hellebore flourishes in a cold clay soil, which is fatal to most others. In nearly all the plants which have been sent to me from English and Scotch gardens, I find the soil adhering to the roots to be a strong clayey loam, as if the plant preferred a strong soil. This is probably the case.

In conclusion, I may say that the culture of all these Hellebores seems to be but poorly understood. I have been surprised to find how few of our nursery-I have been surprised to find how few of our nursery-men know how to grow them really well, and how impossible it seems to be to obtain a really fine plant from any professional gardener. Even in Curtis' time the growing of Hellebores appears to have been a difficulty, for he says that the Helle-borus niger does not thrive near London. On read-ing his cultural directions I think you get a clue to the reason, and probably the same exists still a with gardeners generally. Curtis says, "I'l towes situation moderately moist, and a soil unmanured." Now a moist soil if well drained will be quite favore. Now a moist soil if well drained will be quite favour-able, but the plant certainly requires most liberal treatment. So great a wealth of flower and foliage as a flourishing Christmas Rose has to bear annually, certainly requires a corresponding amount of suitable plant food. In its native habitat, growing in woods, plant tood. In its native habitat, growing in woods, it gets a top-dressing of leaves every autumn, and these decay and feed the plant the following season. Our Cheshire Hellebore farmers give their plants a top-dressing of old sawdust stable-manure every autumn, just as the flower-buds are setting. This autum, just as the flower-buds are setting. This manure is very rich in ammonia, and this seems to be the food the plant requires. Mr. Archer Hind uses soot in the same way, and I believe this material is also rich in ammonia. There are three things to be observed in successfully growing Christmas Roses, viz.:—I. A deep rich soil well drained, but moist; 2. Complete shelter from all cold and drying winds; 3. Liberal top-dressing with suitable manure and leaf-mould each autumn, so as to feed the plant in its bearing season—the manure to be due into the ground bearing season—the manure to be dug into the ground lightly in spring. Perhaps some one acquainted with the management of H. n. altifolius will tell us if its requirements are similar. Wm. Brockbank, Brockhurst, Didsbury, Jan. 5.

Sr. Brigid's Christmas Rose (Helleborus NIGER VAR.).—Quite a protracted controversy has been going on for some time in the London gardening journals with regard to the Christmas Rose (Helle-borus niger), its varieties and their identification. This we do not pretend or presume to go into; but This we do not pretend or presume to go into; but we have no hesitation in pronouncing an opinion as to what we regard the peculiar aspect and peerless beauty of that grand variety which, in compliment to the enthusiastic florist in whose garden at Howth he first saw it, and was so impressed with its merits and distinctness that Mr. Burbidge suggested it deserved a name, and should be known in future as "St. Brigid's Christmas Rose." Leaving this matter others to discuss and settle, what we have now to do it to recommend any who care to have at Christmas. Brigia's Christinas Rose.

The acting in the control of the contro boder and dividing with his hands the curtain of greenery which completely concealed them, and at the same time effectually prevented their defilement from rain or otherwise, a revelation of floral beauty took place which made one stare and stop long to took place which made one stare and stop long to admire. This revelation took the shape of a nest of flowers of spotless white, numbering some dozens, and individually measuring more than 2 inches across. The way in which this variety so effectually conceals its nestlings from sight and preserves them from deflement is not among the least of its recommendations. Irish Farmers' Gazette.

ORCHID CULTIVATION FOR AMATEURS,-III.

In my last I alluded to "slow firing" as only being practicable when boiler-power and piping are amply sufficient to produce under pressure a much higher temperature than that actually required. Moderate fires and abundant moisture on floors, bare wall surfaces, and staging, give us the "genial" temperatures grateful to Orchids as to all other growing vegetation. An Orchid-house in which plants are growing should smell like a flowery meadow during that sudden burst of sunshine which sometimes comes after a summer shower. There must be cleanliness everywhere-floors, walls, pots, and staging alike. No dust in odd corners, no cobwebs, no dry rubbish under the stages and near the pipes, where wood-lice and cockroaches may breed and revel to their heart's delight. This they assuredly will do, if odd corners and empty pots or crocks lie out of sight; and if so, then will come your reward! You may grow your plants fairly well, but good-bye to the plump, succulent flower-spike almost as soon as it peers from its sheath, and the fresh green root tips of Aerides, Vandas, and other similar plants will become the natural prey of these "unbidden guests," every one as hungry as a jungle

If literary "asides" are permissible, I should like to observe that the enthusiastic amateur is just a little impatient; he likes "bone," and even now is quite anxious for me to "get on to the potting and watering chapters," all of which, however, shall come in due course. I now want to remind the E. A. (enthusiastic amateur) of what I have already said, and to add that if he will express his own particular desire for information to the Editor, I shall do my

best to oblige

r. In my first paper I said that specially built Orchid-houses, however convenient, were not absolutely essential to good Orchid culture.

2. That all Orchid cultivators must continually exercise their powers of observance, and have some sympathy with the plants they wish to grow well.

3. That although some Orchids require a high temperature (=60° F. minimum) to grow them well; and although others will grow equally well under "cool treatment" (= 40° minimum), yet that by far the greatest number of all the Orchids now in cultivation may be grown in a light, airy house (preferably a span-roof not over 9 feet high) in which a "medium temperature" is maintained (=50° F. minimum).

4. It will now plainly appear that all known Orchids may be successfully grown in one or other of these three temperatures, and that amateurs who wish for a general representative collection of the best, i.e., most floriferous and showy species, may grow such a collection in almost any kind of low house where a minimum

temperature of 50° can be ensured.

Now, if we go into almost any one of the hundreds of private places, or to many of the nurseries where Orchids are grown, what do we find? Cattleyas and Lælias from Brazil, Odontoglossums from Mexico and the Western Andes. Angræcums from Madagascar and the West Coast, Dendrobiums from the plains of Burmah, as also from the Khasia Hills, from Ceylon, and Australia-Vandas from Java and Borneo, growing along with those from India, Lycastes from Guatemala, Coelogynes from Nepaul, and Cypripediums from east and west alike. Here you may find evergreen and deciduous Calanthes, and so also Coologynes evergreen and deciduous, Pleiones, all in the same house and side by side. In a word, a little thought about elevations and native habitats in an average well-stocked Orchid-house will reveal some curious and highly interesting facts. Here, in the space of a few score feet (superficial), you have plants from nearly all tropical and intertropical lands, from plain and mountain alike, from sea level to a height of at least 7000 or 8000 feet. shall not draw any moral, if such be wanted it will be found in my first paper, on which I hope this third one has thrown a little additional light.

What I now do want to say, however, is a little more anent temperatures-I mean maximum temperatures. Now, my advice is, do not let maximum temperature trouble you. If a little thin scrim or linen canvas shading is over the glass no sunheat in the British islands will give your temperate Orchids too high a maximum temperature during the summer months. Note well that I am not now alluding in any way to "cool Orchids" of the Odontoglossum and Masdevallia types: for these, indeed, a maximum of over 65° is absolutely injurious, far more so than a low minimum, provided such minimum is above the freezing line. As a matter of fact, I have seen hoar-frost or rime on the sphagnum surfacing of Odontoglossum Alexandræ, O. Rossi majus, some Masdevallias, and of Disa, and although the plants survived the freezing it was not evident that they were improved thereby. I said above the freezing line, because I do not believe that even native plants, hardy in our climate (say a Thistle or a Dandelion), are benefited by actual frost.

For "cool Orchids" 40° to 45° is a safe minimum, and 65° a safe maximum, and for the rank and file or "temperate-house" collection take 50° as a minimum perfectly sale and sufficient, and with free ventilation do not mind how high sun-heat raises your maximum.

NOTES ON VEGETABLES.

A NEW CELERY: THE WHITE PLUME,-If I mistake not, this will open an entirely new phase in Celery culture. It sported in the vicinity of Newark, N.J., some three years ago, from what is known as the half dwarf variety, showing a variegation of creamy-white, mainly confined, however, to the centre stalk and leaves of the plant, looking as if Nature were meeting Art half way; for as we know in all other Celeries, this whitening of the centre, so as to make it fit to eat, is only obtained by the slow and troublesome process of banking or earthing up, while in the White Plume Celery no work is necessary other than hoeiog or ploughing sufficient earth to the rows, so as to straighten it. Another advantage in this new variety is that not only the stalks are white and fit for use, but the leaves also, giving it somewhat the appearance of a bunch of white feathers, and hence the name given to it of White Plume. This ornamental feature will be of great value, as it is well known that Celery at our best hotels is nearly as much valued for an ornament for the table as for use, and in this we have the rare combination of these qualities. only one drawback to this valuable new Celery. natural tendency to white prevents it keeping late into winter, and it usually would not be safe to keep it later than the middle or end of January in such sections of the country where it has to be preserved by putting it away in the trenches. But as the greatest quantity of Celery is generally used in early winter and during the holidays for this purpose no other variety is at all so valuable as White Plume, and when it is known that at least three-fourths of the labour saved in growing it, it may well be believed what a boon it will be to all cultivators of this vegetable. To the greater number of amateurs heretofore the great labour entailed in growing Celery has prevented the attempt, but when it is known that it can be now grown as easily as Cabbage or Lettuce, there is but little doubt the area of Celery culture will be greatly extended. Peter Henderson, New York City, in American "Gardeners' Monthly,"

PARSLEY .- This is far better sown in beds of about 4 feet in breadth, instead of in lines round the quarters, for in the latter way it forms capital hiding places for slugs, and is as bad in some gardens as Box edging for harbouring these pests, and with less reason for its existence in such parts of the garden. If put in the bed form it can be easily covered with frames or even hoops, and can be matted over at night, and in the day, time, too, in the event of hard weather. If it can be so managed that the alleys can be thrown out to the depth of 18 inches or more, and warm manure be put into the trenches, a mild warmth could be maintained sufficient to cause the plants to grow slowly all through the cold months, and all the better if they have frame protection, with plentry of air in mild weather.

ENDIVE BLANCHING .- This is found to be best blanched, not by tying it up, as is usually done, but by placing a piece of heavy slate or tile over it, and by pressing it down slightly. In doing this a fringe of the tips of the longest leaves must be left projecting beyond the edge of the tile. The reason this is to afford the plant some means of existence till the blanching is completed. The tile is better than a pot or flower-saucer, for while it perfectly excludes the light it confines no damp air about the plant to cause decay, and at the same time the plant is safe from lrost and rain, which is not the case with tied plants; in fact, these latter are really traps to catch every drop of rain or dew that falls. The smaller sorts of Endive, when they are blanched with a piece of material only a trifle less in diameter than themselves, when pressed flat, have a very appetising look with the slight fringe of crisped green round the creamy white centre.

EARLY FRAME CARROTS.—One of the best varieties to follow the early French Horn so as to form a succession is the Early Nantes. The form of the latter will be preferred by many, as the tapering and almost uselessly small tapering end is missing from it, the root being of a pretty cylindrical form, scarcely tapering at all. It can be sown on the same day as the French Horn, and will come into use about ten or twelve days later.

FRAME RADISHES.-These are very often spoiled by the young men sowing them too thickly, broadcast-which was the common old-fashioned mode of doing it oadly-or in drills, as is the general way now; either the one or the other plan is bad in the limited space of a frame, for the want of air and light for each individual plant will be materially lessened by this reckless thick sowing, and the formation of an edible root be greatly rendered abortive. It is a far better practice to take two seeds between the finger and thumb and press them slightly into the surface of the soil, that should have been previously made tolerably firm. The seeds are best put in lines running from the back to the front of the frame, and should be distant from each other about 4 inches each way. Merely drawing the soil over the bed with the back of a rake or with a smooth lath will cover them sufficiently. M.

ECONOMIC PLANTS IN COORG.

IN a very interesting report on the past season in Coorg, which is dated Mercara, July 25 last, and which was read at a recent meeting of the Agri-Horticultural Society of Madras, some facts are recorded on the vegetation of the district.

COFFEE.—After noticing the failure of the Coffee crop in 1882, the writer says:—"The flowering season of the Coffee trees is always a critical event, and anxiety, mixed with hope and fear, pre-dominates till the verdict is passed, 'The blossom has well set.' The normal condition of a good blossom appears to be early showers in March to invigorate the flow of sap in the trees, and to form well developed flower-buds; during the ensuing blossom, which lasts but two or three days, sunshine after a foggy, steamy morning, and a few light showers soon after the blossom has passed away. But sometimes the rain falls too early, and brings out a January or February blossom, which may set well, provided the succeeding months are not too dry. On the Mercara plateau and the Sampaji valley rain generally keeps off, and a late blossom is the rule, often exposed to heavy showers, and the question arises as to how far these affect an efficient fructification. Some planters say in such a case the pollen has all been washed off, and there is no crop to be expected; others prognosticate failure from stunted flowers, where for want of sufficient rain the petals of the corolla are small, and of a yellowish colour. Most planters naturally expect from a perfect flower the best results, and yet I have heard a practical and most successful planter utter the paradoxical dictum, 'The finest blossom, the worst crop. How are these adverse opinions to be reconciled? Perhaps by laying not too much stress on the appearance of the blossom, but by taking into principal consideration the natural condition of the trees as affected by cultivation apart from the weather. For my own satisfaction I bave ascertained that in a well developed flower-bud fructification may take place in the state of æstivation, or just before expansion into the full blown flower. The experiment is easily made by removing the stamens just before the flower-bud opens and marking the bud for after observation," The rainfall of 1882 was 83 inches, and for the average of the previous five years and the consequent vigour of the trees should have shaken off the borer pest, but it maintained its destructive sway with the usual severity. writer says he has observed whenever dense shade of the right kind (plants of species of Ficus and Cedrela) have long been established on a highly cultivated estate the damage from borer has been least.

CINCHONA.—The next important article of culture in Coorg is Cinchona, and all the best or newest varie-

ties are eagerly sought after by planters. "It is strange," the writer of the report says, "that an industry so liberally undertaken by; the Madras Government and so profitably worked and retained when successful, should have taken so long in gaining ground in Coore."

CARDAMONS.—The systematic cultivation of these fruits in suitable localities has fair prospects of success, and men of pluck and energy are setting to work to redeem lost fortune. Mr. Graham Anderson's example of success in Cardamon cultivation in the Numzuabad district is highly encouraging, and with the established fame of the Coorg or Malabar Cardamons in the home market, even a moderate crop will pay, and the prospects of the presnte year are favourable.

RUBBER cultivation is still in its infancy, but Ceara trees (Manibot Glaziovi) are already bearing fruit in South Coorg. Of the Silky Oak of Australia (Grevillea robusta), introduced in 1876, one of the trees, nearly 50 feet high, blossomed for the first time at the end of May, but it was feared that the mousoon would interfere with the ripening of the seed. The Oil Palm (Elais guiocensis), and the Raia tree (Pithecolobum Saman), are in a flourishing condition, but a nursery of the former proved a failure.

THE AMARYLLIS.

(Concluded from p. 59.)

SPEAKING generally, perhaps those plants which have not been "sat upon" "by a special society have given, I think, the most charming varieties. What has the Auricula Society done for this plant? I saw some exhibitions of Auriculas, and I was always struck with the idea that this plant was cramped within certain artificial rules by prizes and encouragement of certain restricted characters. I am not aware whether a Fuchsia Society is in existence, but judging from the many charming varieties of this graceful plant I should say not. Now that the Amaryllis is becoming popular, it is hoped that its cultivation may not be cramped by hard and fast rules, such as "so many inches of length and breadth of petal;" "the funnel is to be extinguished," &c. Every point encouraged should have some 'good reason, and not be dependent on the mere fancy of an iodividual. I should say, for instance, as to

Form. - The flower should be so expanded as to show as much of each petal as possible without ceasing to form a continuous whorl-that is, the petals should not cease to overlap somewhat, in order that the maximum of display should be given to the detail of each petal. Then, with the above conditions, the broader and longer the petals are the more of the flower there will be to see and admire. It is doubtful, however, whether a plate-shaped Amaryllis would be as beautiful as a Convolvulus-shaped one, other things being equal. I would not say that the Lilium candidum is more levely than the L. auratum, but that both are very beautiful. One of my hybrids, which I named Carina, has a narrow tube, and a limb only 4 inches across, but looking at it from the front it is a little It 'is symmetrical all round; the colour is a shade lighter than Turkey-red, and it displays in the centre a perfect white star, with all its points and rays. In this case the tube is not seen at all from the front, as it is of a greenish-white, and merges into the star. Speaking generally, and with more reference to the Amaryllis in a wild state, I should say the narrower the tube the less of beauty is there in it to display, and that the wider and more expanded the tube the finer its interior is. In the former the tube is out of the race, and the attraction to insects is made by the contrast between the colouring of the throat and the limb. In the latter the tube also enters into competition with the limb and throat. and takes on brilliant colouring and feathering to invite the attention of insects.

Size.—As a rule large flowers, ceeteris paribus, are more striking to the mind than small ones, provided the eye can take in the whole flower at one view.

Substance.—Flowers with substantial petals are very desirable. They last longer, look more self-supporting, and stand wind and dryness of atmosphere better than wafery petals.

Colour.—This depends a great deal on idiosyncracy, and may range from pure white to the intensest erimson, scarlet, carmine, &c., with all their combinations and variegations. For my part I would prefer an intense Pomegranate-red, or the colour of a blood-

red French Poppy, such as would "mesmerise" me and make me look at it almost for ever. Others might prefer other colours.

The smoothness of the petals is a fine thing, but this, with prettily crisped edges, makes a most charming combination. The straightness, curvature, pointedness, or roundness of the petals gives additional character to a fine flower. Sometimes a little twist to the outer or to all the petals, as I have seen, gives piquancy to the outline. I would here remark that some varieties which have not overlapping petals might nevertheless possess an incomparable beauty, Such, in my opinion, is Amaryllis formosissima. If its petals could be made to overlap, like those of an ordinary Amaryllis, it would hardly continue to be called the most charming Amaryllis.

A word about naming varieties of cultivated plants. There is an admitted physiological fact regarding the limit of our memory. This varies in every individual, but I think there is no doubt that, however clastic the memory may be, it is not infinite. Therefore considering the many names civilised man has to remember, not only in one language, but in many, one should be considerate, and give as short a name as is possible. It would appear that the crossing of plants so not the increase, and therefore the varieties requiring names may be infinite. It seems therefore a needless burden and worry to the mind to have to remember a long name, when a short one would do as well. Should be justified, for instance, in calling a plant Amaryllis Vicomtesse Louise de Montmorency pulcherrima when Sappho would do? The former requires the aid of a dictionary to remember it, while the latter can be dealt with in prioting, writing, and talking, with scarcely an effort. In this case a society might exercise a beneficial influence and refuse certificates to plants which have unspeakably long for inappropriatel names. I have some records of crossing of my Amaryllis which may be interesting to students of the Darwioian theory, but these I must leave for some future occasion. In the meantime, if hybridisers would publish now and again records of their work, with their experience of the best way of giving effect to the action of the pollen on the pistil, they might do very useful and interesting service. E. Benavia, M.D., Surgeon-Major, Etawah.

FRUIT NOTES.

FRUIT GROWING .- Having considerable practical experience in fruit growing, I am glad to endorse all that Mr. Gladstone has said on this subject. If it were not that enormous quantities of red and black Currants, also Gooseberries (green and red) are sent to this country, the price of these home-grown fruits would be so high that jam-though sugar is so cheap would be manufactured only at prices prohibitory to a large consumption of the article. Fourteen years ago io Scotland I planted 120 acres with Strawberries, Raspberries, red and black Currants, and Gooseberries, the result of my experience being that there the climate had much to do with the success or nonsuccess of the undertaking. In Aberdeeo, as Mr. Gladstone says, the climate is the most ungenial in these isles, yet that district is the home of the Strawberry, and the fruit grown there has an acidity of flavour and a firmness unknown to those grown Partly from the foregoing reason I near London. found this fruit paid better than any of the other kinds; red Currants and Raspberries coming next. Black Currants and Gooseberries I found to be so uncertain that I discontinued them. The failure of the Gooseberry crop arises from the frequent frosts in May, when the flower is forming or the fruit begins to swell, reducing the crop in such years to one ton as compared with 20 tons in a good The success of a fruit garden depends on its not being too large, so that the fruit can be pulled when ripe, a sheltered situation, and plenty of labour at hand. The farmers within 50 miles radius of London would find Strawberries, Raspberries, and red Currants more profitable crops than grain or roots; but three years ago I brought the matter before them prominently without success. There is one point which I would desire to refer to-that though the population when Mr. Gladstone was young consumed only 15 lb, of sugar per head as compared with 65 lb. at the present day, that does not necessarily mean or show that the population use four times more sugar than in times when it was so dear. The great bulk of this increase is accounted for by the enormous export of confections, jams, and marmalade to foreign countries, where, notwithstanding there are duties levied on them of from ro to 35 per cent., these English preparations more than hold their own. As

one of some experience I would say that the quantity of jams and marmalade exported annually exceeds 12,000,000 lb. weight, about three-fourths of which consists of sugar. "Al" in the "Daily News."

EFFECTS OF GRAFTING. — What may be called physiological differences between plants demand on the part of the cultivator at least as much attention as those which are more obvious at first sight. Thus "Allen's Everlasting" Apple, a seedling from Sturmer Pippin, and so like it that it is difficult to distinguish it, will nevertheless grow on stocks whereon the parent plant refuses to live.

GOLDEN SPIRE APPLE may be recommended, not only for its shapely pyramidal fruit, but also as an ornamental tree for shrubberies. It seems likely to supplant Manx Codlin in some places.

The Poultry Yard.

DUCKS.—I have just been reading "J. A. C.'s" experiences, in the Gardeners' Chronicle of last week, on poultry keeping, and will send you mine as to ducks. I have a mill pond at Valebridge, on the west side of the Brighton line, 2 miles north of the Burgess Hill Station, and a garden, osicr beds, and the mill stream, and small piece of water in connection with it on the east side. I keep eight brood ducks and three drakes with a trace of wild in them, varying the breed from time to time by an exhange of drakes. There is no yard or artificial shelter of any kind for them, but there is a protection in a duck island with Rhododendrons and other plants and shrubs, and in a shrubbery at the foot of the garden, as well as in the osier beds. The young ducks are never shut up to fatten, but all are fed by my gardener and his wife with whole Maize, and thus the young ones are made fit for table. They do everything for themselves, except that, when they are first hatched, the gardener's wife puts the mother and the young ones under a coop for about a fortnight, especially if it is cold, and gives the little ones some ground Oats. They then go back to the water, and there they remain until they are killed. My average quantity for the table is 100; one year it was 120; last year ninety-two, owing to the late cold weather.

What the value of them is per couple I cannot tell, as not one of them was ever sold, but my friends and my poulterer, who sometimes trusses them, say they are excellent ducks, and speaking from my own table I can certainly say it is so.

I have swans in the millpond, and the old birds come up in the early spring to the duck island and build their nest, which my gardener feoces off with wire netting, so as not to interfere with the sitting ducks, and they all live as a happy family until the cygnets are hatched, and then the swan tribe is remitted to the millpond.

I fattened two of the cygnets in a small stew close to the duck island at the end of 1883 in the same way, and one on my own table was pronounced bymyfriends to be most tender and beautiful eating. The other I sent to a friend, an M.P. in a higher grade of the legal profession than myself, and he and his friends gave the same verdict as to the cygnet, and he sent me a most beautiful haunch of home-fed mutton to boot. I scarcely ever lose a young duck by rats or other natural enemies. There used to be some of the common rats about, and plenty of water-rats, but the latter are in oo way carnivorous; and I have a wonderful cat, which will take to the water like a dog, and sometimes bring up a couple of rats in a day to the gardener's cottage. Somers Clarke, 57, Regency Square, Brighton.

PTERIS UMBROSA.—For cool conservatory decoration this Australian Fern is well worth growing, When planted out it forms fine masses of bright glossy green fronds, sometimes nearly a yard in height. The strong erect bright reddish-brown stipes are from 18 inches to 2 feet in height; the frond measures from 12 to 24 inches in length by from 6 to 12 inches in breadth. P. umbrosa is a near ally of the widely distributed P. cretica, but is altogether a larger plant. Like it the fronds are pinnate, the lower pinnæ being themselves pinnate. Some years ago a plant of P. umbrosa kept alive in a sheltered position in the open air for a couple of winters. As seen planted out in the borders in the Temperate-house at Kew it forms a very handsome object.

SEQUOIA SEMPERVIRENS.—It may be interesting to your readers to know that io noe of the gardens of Messrs, Chas. Huber & Co., Hyères, there is a tree of Sequoia sempervirens, planted forty years ago by Mr. Chas. Huber, which has now attained the height of 18 metres (more than 54 feet), and in girth 2½ metres (7½ feet). Eighteen years ago it was the same height as now, but it has gained in girth 1½ foot; the diameter of breadth of foliage is 8 metres 10 centimetres (24 feet 4 inches or more). On the same piece of ground there are some extaordinary specimens of Abies Piosapo and Encalyptus globulus; the latter, which is the largest in Hyères, is thirty-five years old. H. Renton Min (of Stuart & Mein, Kelso), 17, Boulevard National, Hyères.

TSUGA SIEBOLDI. — In this the typical species of a genus not numerically large, we have a beautiful tree for the lawn or pleasure ground. Possibly it may be better recognised in gardens under the name Abies Tsuga, just as T. canadensis and T. Albertiana are. The graceful pendulous habit of the two latter

trees may be seen by the margin of water both in the arboretum and other parts of the gardens at Kew.

Golden and other Catalpas, — Mr. Culver-well's experience with the golden variety of Catalpas syringiflora will be found to tally with that of most persons who have attempted the culture of it or other varieties in the less warm parts of this country. There is not a handsomer tree, nor one that grows freet, or which suffers less from wet soil, for it will grow with its roots in water; but it is necessary to its well-being that the wood should become well ripened. When that is not the case slight frosts will cause injury to it, but when the growth is thoroughly ripe it will stand 20° below zero without injury. The warmest spots in the garden are the proper places for it; it should not be planted at all in clayey soils, and it should have the benefit of the fullest exposure to suoshine. Mr.

SCIADOPITYS VERTICILLATA, — M. Carrière, in a recent number of the Revue Horticole, figures a proliferous cone of this plant produced in the nursery of M. Moser, at Versailles, similar to that figured in Veitch's Manual of Conifers, reproduced in our columns, vol. xviia, p. 112. The plant also fruited at Kew this season, and we believe has fruited in some of the nurseries, as at Combe Wood. M. Carrière also figures some curious branched leaves of

FIG. 14.—PACKING PEACHES POR MARKET. (SEE P. 81.)

are well known, and sometimes designated by gardeners as weeping Spruces. The species under notice shares this character more or less according to size, but is apparently of slower growth and smaller dimensions. The most distinctive feature moreover, is its dense and leafy branchlets, which almost or completely hide the stem. These leaves are linear and emarginate, of a deep glossy green above, with two broad silvery lines beneath, arranged somewhat distichously, but really in many rows of unequal sizes (the smaller ooes being on the upper side). Several fine specimens in the Kew arboretum are conspicuous for their dense habit as stated, and the lively green foliage.

ALNUS CORDIFOLIA, — Deciduous trees are not without interest even in winter, but on the other hand, especially when old and harmonising with their surroundings, seem to convey an impression of beauty or characteristic individuality that is often less recognisable when in full leafage. This species of Alder suits our climate well, and rapidly attains a considerable height, preserving at the same time a beautifully pyramidal form, well furnished with slender spreading or ascending branches. The heart-shaped leaves are dark green, deusely clothing the tree in summer, and renders it even more effective and desirable for the margins of ornamental water than the common A. glutinosa. Even now the trees are attractive by the numerous young cylindrical male catkins, and the oval

this plant, which is of very great interest, but planters in this country would be glad to see it grow faster.

The Apiany.

THE DURATION OF LIFE IN HONEY-BEES.—
Will you kindly tell me what is the average length of life of a honey-bee? C. M. (Shuckard, in his British Bees, states that "Humble-bees are reputed to have a longer life than of one year, and hive-bees are said to survive several years—a duration of existence inconsistent with analogy, and which has been repeatedly and stroogly denied." Hunter, in A Manual of Beekephee is determined by the amount of work it does, and the introduction of Ligorian queens at various seasons enables us to determine this question with almost certainty. After the introduction of a fertile Ligurian queen to a colony of black workers in May, if we examine the hive two months subsequently we shalf find very few black bees remain, they having died and been replaced with Ligurians; and as probably at the time the strange queen commenced her reign some eggs or young larves of her predecessor remained, we may conclude that six weeks is the limit of time a worker-bee will live in summer. Should the new queen be introduced in October, not until April foling will the same state of affairs be found; it is thus evident that the quietude and rest of winter prolongs the bee's life fourfold." ED.]

Notices of Books.

Traité de la Culture Fruitière Commerciale et Bourgeoise, Par Charles Baltet, Paris : Masson. ("Fruit Growing for Market and for Private Consumption," &c.)

There are many reasons just now why this book should receive respectful consideration. In the first place, in view of the unremunerative nature of corn growing in this country, men's minds are exercised on the question-What to grow as a substitute, and how to grow it? The subject has been recently mooted by no less a financial authority than the Premier himself. Again, when the prodigious quantities of fruit imported from France and from America are considered, it is natural to inquire whether our cultivators could not produce more fruit themselves, and divert some at least of the money that now goes to foreign competitors into their own pockets. For various reasons, elsewhere considered, we do not think the British farmer is likely to benefit by fruit culture to anything like the extent which his kind advisers in the daily papers imagine. No doubt under certain circumstances fruit cultivation is a profitable business, and its extension is to be desired, but to advocate its adoption by farcitizen." In the preface M. Baltet tells us how waste lands, deserted farms, roadsides, railway banks, and such-like situations are turned to account; and he goes on to show how the work is to be done, what sorts are to be grown (dwelling especially on those whose hardihood was proof against that fearful winter of 1879-80), and how their culture may be made profitable. He also indicates to the housewife the best sorts to grow for preserving.

The information is arranged alphabetically. One example will suffice to show the mode of treating the subject. Thus, speaking of the Apricot, we have first a paragraph relating to the soil most suitable for its culture, the aspects most favuorable to it, a description of the several varieties arranged according to their season of ripening, plantations for market purposes (in France the Apricot is grown as a standard), the mode of cultivation, of pruning, of gathering and packing the fruit, the method of preserving the fruit, and other details. A similar plan is followed with the several kinds of fruit of all varieties capable of outdoor culture being treated of. Of course the English reader would have to bear in mind the different conditions under which fruit is grown in this country, and make the necessary allowances. Peach growing necessarily occupies a large share of attention, and those of us in

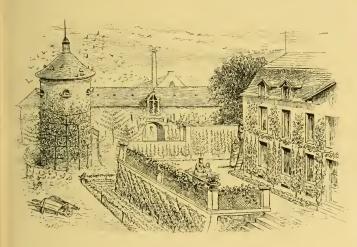

FIG. 15 .- FRUIT-GROWING IN FRANCE.

mers on a large scale, and without heed to local circumstances, is to give bad advice indeed. Those who propose to go into this business on a large scale have only to turn to our annual reports of the fruit crops throughout the country, now continued for several years, to see with what a capricious and uncertain crop they have to deal. Nevertheless, it is certain that we might do more than we do, and that with judicious limitations, according to circumstances, fruit-culture might be adopted to prevent that process of putting all the eggs into one basket which has been so disastrous to British farmers. It is, therefore, useful to see what our friends across the Channel do in the matter of fruit-culture. The climate of the North of France and Belgium, at any rate, is no better than our own on the whole, and the general quality of the fruit grown (barring exceptions) is certainly not equal to our own.

M. Baltet's book comes before us as the work of an accomplished practitioner, with whom fruit-growing is an hereditary instinct, and hence it is specially worthy of attention by those to whom the language in which it is written offers no obstacle. The key-note to the volume is struck in a quotation which may be found on the title-page, and which may be thus freely translated :—"To promote fruit culture, to increase fruit gardens and orchards is to contribute to the prosperity, the wealth, the peace of one's native land—it is the work of a useful man and of a good

this country who lament over the uncertainty of open-air Peach culture, and have heard, as most have, of the extensive cultivation of this fruit at Montreuil, and abused our climate at the expense of the French, may feel some sort of satisfaction at bearing that the losses during the "grand winter" of 1879-80 were estimated at 2,500,000 francs (£100,000)! Nevertheless, by replanting and grafting or inarching where possible, the prosperity of the Peach grower will return. There are at Montreuil 300 hectares (2.4 acres) devoted to Peach culture, or 600,000 metres of wall space, which at 22-25 Peaches per metre yield an annual average of 12,000,000 of Peaches. The earliest Peaches fetch 2-3 francs each; the later ones, which come in after the competition of Southern grown fruits is over, fetch even more. Our illustration (fig. 14), for which we are indebted to the publisher, shows the preparation and packing of the Peaches for the Paris market. The Peaches, when gathered, are laid upon a Vine leaf in a flat basket, and brought to the packing shed; there the fruits are sorted out and brushed. Those engaged in brushing the Peaches have to protect their neck from the down of the fruit, which otherwise causes irritation to the skin. The larger fruits are placed in straw puncets (semelles), eight in each, on Vine leaves; the smaller fruits are packed in baskets holding forty-eight or ninety-six; these are covered over with a cloth. The punnets and baskets are then placed on a tray

(clayon) covered with moss, the whole heing covered with a cloth. These trays are then placed in a large hamper with three partitions or shelves, one above another, and on which the punnets and baskets are placed, the spaces between them being filled in with straw to prevent displacement. Special care is given to fruit of special excellence, but the method of packing such fruit does not seem to have any advantage over our own. The illustration, fig. 15, shows how the walls of farmhouses and cottages might be utilised, and, indeed, are so in France to a much larger extent than here, for no good reason that we know of. How roadsides may be made available is shown in fig. 12, p. 76, where the trees on the one side are Apples, on the other Pears. The reader who may have travelled by diligence in parts of France, Germany, Savoy, and even Switzerland, will recal many such a road. our experience the trees in such situations are often grievously neglected, which looks as if the results did not compensate for the expenses, for unless the ground be well prepared beforehand, the trees staked and tended, suitable sorts planted, the results are not likely to be encouraging. All this, however, demands outlay and Experience alone can show if these can he labour. recouped. The loss from marauding boys is of itself hardly worth considering. The comfort to the traveller is great, but whether the road-surveyor is equally pleased is another matter, for the cost of maintenance of roads so planted must needs be larger than in the case of roads not so planted.

Our last illustration (fig. 13, p. 77) is one which will be familiar to many who find their way to Paris. I represents fruit culture in the swampy marshes near Amiens. Vegetables are chiefly grown in those places, but fruit is also cultivated—principally bush-fruit. Funts here come into requisition both for cultivators' purposes and for collecting the fruit and taking it to market.

The section relating to diseases and insect enemies strikes us as being rather weak. We find no mention of a disease which is very prevalent in Plums and Cherries, and in which the skin separates from the pulp of the leaf, giving the latter a silvery appearance, while "canker" is dismissed in four lines; nevertheless, the book as a whole is comprehensive, full of sound practical information, and free from that diffuseness which renders so many French books tiresome reading.

DORYANTHES EXCELSA.

Last year we recorded in these columns the flowering, for the first time in Europe, of Doryanthes Palmeri at Kew (see p. 409, vol. xvii.) In a short time the only other member of this noble genus of Amaryllidacex—viz., D. excelsa—will also be blooming in the same establishment. Unlike its congener, D. excelsa has not an elongated inflorescence, but a terminal almost spherical cluster of crimson flowers emerging from great half-sheathing crimson bracts. The first flower of this species produced in this country was developed on a portion of a stem, without roots, which had been cut many months before in Australia, and it was principally from this solitary flower that Correa was enabled to found the genus. Some time afterwards a properly developed inflorescence was produced in the greenhouse of the Right Hon. Charles Long, at Bromley Hill, in Kent, probably for the first time in Europe.

This plant was figured in the Botanical Magazine, vol. xli., t. 1685, and a glance at that figure will be sufficient to prove the truth of Salisbury's expression of admiration—"One of the most splendid plants we have yet received from New Holland." That author, in his report-"On the Cultivation of New and Rare Plants," in the first volume of the Horticultural Society's Transactions, says "It will live in a greenhouse, and possibly in the open ground near the sea; but vegetates so slowly that I have recommended all my friends to give it more warmth; for, like the Agaves, it does not flower till it has made a considerable number of leaves. It should have light rich soil in a pot exceedingly well drained; several young plants of it having lately been rotted by having been kept too wet." In a wild state D. excelsa throws up a flowering-stem of from 10 to 20 feet in height, and bears attential cluster, 12 to 14 inches in diameter,

of crimson flowers.

Dr. Bennett, in Australasia, says that it is found in the greatest perfection in the Illawarra district, and attains its full magnitude and beauty about the mountain ranges of that beautiful district of New South Wales. In the "North" Gallery at Kew D. Palmeri is represented in pictures Nos. 600 and 627.

Orchid Potes and Cleanings.

ODONTOGLOSSUM ROSSII MAJUS AND O. CERVANTESII are two of our prettiest dwarf Orchids, and two which not only will stand cold but revel in it, the growths becoming stout and the flowers very fine in a temperature of 45° to 50° in winter. Experiments prove that both these plants will stand frost, and instances are known of them living for years in houses in which no provision had been made for heating by artificial means, and in which they were frequently fozen hard. It is also well understood that they soon die in anything like a hothouse. Notwithstanding these facts, those who strike the happy medium are the most successful. From a house of the temperature mentioned Mr. Cypher sends a massive wax-like bloom of O. Rossii majus, 3 inches across, with a lip 1½ inch across; and also a grand bloom of O. Cervantesii.

DENDROBIUM BIGIBBUM.—A spike about a foot in length and bearing seventeen pretty dark rose-coloured flowers, naturally arranged on it, so as to need but the addition of a little Maidenhair Fern in order to make it a perfect spray for dress ornament, comes from Mr. J. Cypher, of Cheltenham, who grows this plant well and easily, while so many atterly fail with it. According to Mr. Cypher, it needs but to be grown near the glass in full light in a warm and moist but airy house, to have copious supplies of rainwater when growing, and a place in an airy intermediate-house, when its growths are fully made up. D. bigibbum, like many other Orchids, is very difficult to grow until one finds a place to suit it, and then it grows very freely.

EPIDENDRUM SCEPTRUM, Lin.II.— By-the bye some Epidendra have gained general favour, such, for instance, as enemidophorum, Wallisii, syringothyrsus Frederici Guilielmi. There is one that proved very attractive at the late Consul Schiller's, M. Linden's fine discovery, Epidendrum sceptrum. It has pseudobulby, and the general habit of Epidendrum variegatum, but the inflorescence is richer, longer, and the flowers much brighter. Both sepals and petals are orange, with purple-brown spots. The fine rhombic lip is white, with bluish-purple spots, and all the anterior parts are of the same colour, which makes a most curious contrast. Numerous inflorescences in my herbarium are all very florid. The plant would appear not to grow under 6000 feet of height, in New Grenada. II. G. Rehb. f.

STEVENS' ROOMS. - The first special sale of Orchids in flower of the season took place at Mr. J. C. S:evens' rooms, on Wednesday last, and there was a good attendance of Orchid fanciers to do honour to the very fine display of plants brought together on that occasion. The entire available space in the rooms was tilled with fine specimens of most of the popular lavourites which bloom at this time of year, prominent among them being Odontoglossum Alexandræ, in many varieties; Odontoglossum Roezlii; fine masses, well bloomed, of Lælia anceps, L. autumnalis, and its variety, atrorubens; L. albida; Lycaste Skinneri; Cattleya Trianæ, C. Percivaliana, which seems rapidly going up in price; fine pans of Coelogyne cristata, &c. Among the rare plants offered may be noted a distinct-looking, gigantic-flowered Ladia, from Messrs. Backhouse, of York, and which was correctly described in the catalogue as being like L. furfuracea in form and colour, but much The finest form of Lycaste Skinneri alba fetched 12 guineas; Lælia Crawshayana, 4 guineas; Phalænopsis amabilis Dayana, 6 guineas; a fine form of Cattleya Trianæ, 6 guineas; Odontoglossum Edwardii, £7; O. Andersonianum, 9 guineas; a fair plant of Cypripedium villosum, 9 guineas; a fine pan of Cselogyne cristata, 61 guineas; and a good Lælia autumnalis, 61 guineas.

CATLEVA PERCIVALIANA.—The most flattering testimonial that could possibly be given in favour of a new plant, was accorded to this handsome Cattleya on Friday week at Messrs. Protheroe & Morris' Rooms, when Messrs. Veitch & Sons paid 100 guineas for an imported piece that has not yet flowered in this country. This is the highest price that has ever been given under the hammer for an imported piece of

Cattleya, but we are bound to admit that the specimen was an extraordinary mass, and we know now what the variety is like. At Stevens' Rooms, on Thursday, a plant of the white variety, that would weigh about 2 oz. out of the pot, was bought by Baron Schreeder for 19 guineas—something more than its weight in gold!

CATTLEVA GASKELLIANA, another of Mr. Sander's introductions, was also offered at Protheroe & Morris' sale, and a specimen with a hundred red bulbs and leaves fell to Baron Schröeder's bid of 16 guineas. The same grower also gave 20 guineas for a plant of Saccolabium illustre.

ONCIDIUM CHEIROPHORUM,-The flowers of this Orchid are rather small, but they are produced on slender branching panicles, and the bright yellow colour of the curious labellum, together with the contiguity of the numerous individual blooms, render it attractive, and worth the attention of cultivators. Add to this that it is possessed of an odour by no means disagreeable, and we have a subject of some merit for the flower basket. The sepals and petals are slightly tinged with green, but being small and reflexed give all the more prominence to the labellum.

The ordinary divisions of this with the lobes of the crest or callosity, give rise to the fancied resemblance of a hand as expressed in the specific name. One of these lobes projects upwards and backwards in close proximity to the gland of the anther, which is borne on an unusually elongated caudicle. These modifion an unusually elongated caudicle. These modifi-cations doubtless bear direct relationship to the process of fertilisation.

A HYERID ODONTOGLOSSUM.—An extraordinary variety, apparently intermediate between O. maculatum and O. Rossii majus, with the yellow of O. maculatum suffusing a flower of the same shape as those of O. Rossii majus, was acquired by Mr. Lee, at Stevens' rooms, on Thursday.

FRUITS UNDER GLASS.

STRAWBERRIES .- The old method of wintering these, by placing them on their sides in tiers until they formed a stack, is now but little followed. it is well that it is so, for a practice that oftentimes caused plants so treated to remain for weeks together with the soil about their roots dust dry could not possibly be a safe one, and the wonder is it ever became generally adopted. Cold frames are the best places in which to keep Strawberries when at rest; here they can be protected from the injurious effects of the weather when severe, and exposed to its influence when favourable, as well as be conveniently attended to with regard to watering. Failing convenience of this kind they may be safely plunged in beds of ashes or cocoa-nut fibre out-of-doors, provided care is taken to protect their pots from severe frosts by adequate coverings of straw or Bracken. ever mode is adopted, they should not be allowed to suffer from drought. At this early stage forcing by artificial heat should be pursued only in a mild form, and its part may be accomplished principally in the daytime by the valves being opened sufficiently in the morning to cause a circulation through the pipes and closed again in the evening if a night heat of 50° can thus be obtained. What is wanted is bright sunshine, and when this appears allow it to run up the temperature and economise its heat by closing early and syringing the plants overhead. Damp the walls and floors of pits on clear days, but guard against excessive moisture when the weather is dull. When the plants come into blossom keep up a circulation of warm air, and discontinue overhead syringing, and attend to watering in the early part of the day, and about noon go over the flowers with a camel-hair pencil to distribute the pollen. After giving the mode of starting Strawherries early by plunging their pots in bottom-heat repeated trials, and failing to find any advantage therefrom, we have discontinued it. The course we follow instead is this—a number of Melon pits that are not required for early crops are filled with leaves, and over these temporary stages are fixed, upon which the plants are arranged and allowed to remain until they come into blossom; the warmth from the leaves dispenses with much fire-heat, and a humidity is obtained which gathers on the foliage during the night, and under these conditions the plants make early growth.

PEACHES AND NECTABINES -If the trees in the early house have made good progress they will now be coming into blossom; syringing overhead must therefore be discontinued until the fruits are set, but still follow up the damping of walls and borders with tepid water, as anything like parched air would cause a serious check. Insure a buoyant atmosphere by keeping the ventilators a little open night and day so long as the weather remains mild, and keep the night temperature by fire-heat at 55°, with 5° more in the day, or 10° to 15° more from sun-heat, with additional air. About mid-day, when the blossoms are dry, assist fertilisation by passing a camel's hair brush over those that have burst their pollen vessels. A house for succession should now be closed. If it has an external border a covering of fermenting leaves and shutters will prove beneficial, by preventing fluctuations of temperature and encouraging root action. The buds in late houses are becoming exceedingly prominent for the season-dangerously so in those that are unheated-and every available means should be taken to retard their progress; keep the ventilators and doors wide open, and if the internal borders are dry, apply cold water. The severe frosts which we experienced last March, when many expanded blossoms in houses of this description perished, will not readily be forgotten; and should we have a repetition at the same time this year, the chances are it will prove even more disastrous. Proceed with cleaning and tying without delay, for with the buds in their advanced cannot be accomplished too soon; remove inert soil from the surface of the border, and replace it with moderately heavy loam, mixed with old mortar, which should be made firm by treading.

PINES.-Autumn rooted suckers should be in a fit state to repot next month, and the present is a good time to prepare soil for the purpose; the kind most suitable is a light loam full of fibre and roots of grasses, &c., such as is commonly to be met with on hilly sheep-walks, where the finer grasses abound. If turves were procured ten or twelve months ago, and properly stacked, they will now be fit for use, and should be got in readiness by having the loose soil first beaten from them, and then torn in pieces, the necessary quantity thus obtained being placed ridgewise in an airy shed and turned occasionally in order to get it thoroughly dry and sweet. Previous to potting mix with a barrow-load of this soil about half a gallon of soot, and the same quantity of crushed bones. Excellent fruits cap, however, be produced without the aid of either of these fertilisers if guanowater or other similar agent is skilfully employed. A house or pit, as the case may be, should be cleansed for the reception of the plants, the glass being washed both inside and out, the plunging material, tan or leaves, turned and mixed with the necessary additions, and the heat so regulated that the temperature of the bed can be depended upon to keep at about 90°. Our beds are formed of Oak leaves, and have some hotwater pipes under them. In turning over and making additions of leaves to fill up the space caused by decomposition we avoid freshly gathered leaves, preferring those that have done one season's service in pits under Potatos and Melons, as we thereby lessen the risk of violent heating,

VINES .- Now that the shoots in the early house are considerably advanced, and the thermometer outside still ranges unseasonably high, it is well to be able to command an internal temperature correspondingly high-a degree of warmth which it would be hazardous to employ with adverse external conditions. So long as the weather remains dull, and prevents the foliage from assuming its natural dark colour, the atmosphere should not be unduly charged with moisture, especially where the bunches show a tendency to run to tendrils. An error not unfrequently committed is to use water injuriously plentiful in this way, and too sparingly in the borders; the latter should be periodically examined and well soaked with tepid water when necessary, for the Vine enjoys copious supplies at its roots; but the frequency of its application depends entirely upon the state of the Vines, the nature of their horders, and their drainage. As the shoots extend to the limit of their allotted space they should be stopped at as many joints beyond the bunches as space allows without crowding; proceed cautiously in tying these, being content with keeping the leaves clear of the glass until they get a firm hold of the spurs or rods, when they can safely be brought by degrees to the trellis. Stop sublaterals beyond the first joint, and

pick out superfluous bunches, leaving those which are best placed and which should be assisted to fertilise when they come into blossom with the help of a camel's-hair brush. The little trouble this incurs is more than compensated by a more regular size in the berries which it is instrumental in produciog, even with such free-setting varieties as the Black Hamburgh. Where fermenting material is used over outside borders, the desired heat should be maintained by the addition of heated leaves. We formerly followed this plan, and were well satisfied with its results; but our early Vines are now confined to inside borders. Continue to syringe, two or three times daily, the Vines in the house which was closed early this month. If a bed of fermenting leaves is used inside, turn them frequently to allow moisture and heat to escape, this will induce a timely start in the present state of the weather without the aid of fire-heat. A Muscathouse should now be closed, in order to have these in a welt finished state early in the autumn, Thos. Coomber, Hendre Gardens, Monmouth.

PLANTING CABBAGES AND CAULIFLOWERS.—If the present mild weather continues it will be advisable to make a planting of Cabbages from the nursery-beds next week in a warm situation, which will supplement the supply from the autumn-planted ones drawn from the same seed-bed. At the same time a small planting of Cauliflowers should be made in a sunny aspect in drills 3 inches deep and about 24 inches asunder. Plants turned out of 3-ioch pots, inasmuch as they will experience little, if any, check in being transplanted, will be the most suitable for early plantings. The Cabbage plants should be planted in the same way as the Cauliflowers, but need not be so far apart as the latter. A few hundles of Spruce boughs should be provided with which to protect the plants in the event of frosts or cutting winds ensuing, as a little timely forethought and judicious management in this direction invariably leads to good results.

ARREARS OF WORK.—See that all arrears of such work as the wheeling of manure on to vacant pieces of ground and the trenching or digging of the same are proceeded with as opportunity occurs, and do not postpone until a later and busier time work that time and other circumstances will with ultimate advantage allow of being done now. See that the stocks of Onions, Shalots, &c., are looked over occasionally, and that any bad ones that may happen to be amongst them be removed forthwith, and that all green crops, such as Broccoli, Spinach, autumn-sown Onions, and Cabbages, and garden walks be kept free from weeds, and the walks, if necessary, gravelled and rolled at short intervals so as to present a clean and firm surface.

FRAME GROUND.—The subjects in this department should have an abundance of air in the absence of frost and snow—I mean the young Lettuce and Cauliflower plants for spring planting—to insure sturdy growth. Look over the established plants of Lettuce and Endive in this department, and remove therefrom any decayed leaves, and destroy forthwith any slugs that may be found in the frames.

SEED SOWING.—As soon as the condition of the ground will permit of its being done a small sowing of Early Nantes Horn Carrot should be made on a south border. Before drawing the drills, which should be about 1 inch deep, and 1 foot apart, the ground should be dusted over with some new soot, not nnly as a means of fertilising the soil, but also of keeping the roots free from the attacks of wireworm. A small sowing in the same manner and situation should also be made of Early Purple-top Munich and Snowball Turnips, and the Queen or Early White Naples Onion—the latter for drawing young.

FORCING DEPARTMENT.—A good supply of warm during and leaves (about three parts of the latter to one of the former) should be kept in readiness for making the linings of hotbeds on which Potatos, Carrots, &c., are grawing, as a means of maintaining a gentle heat therein, also with which to make fresh beds for similar purposes where necessary. Another batch of Potato sets (in quantity according to the extent of bed or pits to be planted) should be put

in 3-inch pots or boxes in leaf-mould, and placed in an early vinery or Peach-house to start them into growth, and when they have made shoots 2 inches loog they should be planted on the bed in rows 12 or 15 inches upart, and 7 or 8 inches in the row. In making fresh hotbeds, when the frames are placed upon the beds it will be necessary to put a little dung and leaves inside them, so that there may be a corresponding depth in the back and front of the frames, and over this a couple of inches of rotten dung should be put, then 9 or 10 inches in thickness of light garden soil and leaf-mould (about three parts of the former to one of the latter), making the bed of soil as near to the glass as will admit of the respective crops completing their growth without coming in contact with it, and this should be in the frame a few days previously, so as to become slightly warmed before planting the Potatos. In some cases the Potatos will have made so much growth on the shelves in the Potato-house as to render their being set in pots or boxes prior to planting unnecessary. Previously to sowing the Carrot seed the soil should be trodden over, and a few shovelfuls of new dry soot scattered over the surface of the bed, and scratched in with the rake when levelling the soil. Early Nantes Horn Carrot is the best variety for early work, and may be sown in rows at from 9 inches to I foot apart, and where suitable space for early sowings are scarce, a row of Wood's Frame Radish may be sown between the rows of Carrots, covered with half an inch of sifted mould, and patted with the back of the spade to compress the soil. At the outset these frames will require special attention in the way of airing them, and in order to prevent anything like steam arising and becoming pent-up in the frames it will be advisable to leave a little air on them day and night for the present, and subsequently give sufficient air to prevent the occupants of each frame from making a weakly growth. Where Seakale is not forced in the Mushroom-house, another batch of crowns should be covered with pots or boxes, and then with about 3 feet thick of fermenting leaves from the leaf-heap. A batch of Rhubarb crowns may be treated in a like manner. No time should now be lost in making a sowing on a hothed or in boxes, to be placed in heat, of Early London Cauliflower, Brussels Sprouts, and Cabbages, including a pinch of Red Dutch; also a small sowing of Cos and Cabbage Lettuces, and a pan of the most approved sorts of Celery and Leek for early use, and as soon as the plants appear through the soil they should be placed near the glass and in a less warm temperature, where they can have a little air to prevent their making a weakly growth. Keep a supply of good soil in the potting-shed out of the reach of inclement weather, wherein to raise French Beans, and subsequently with which to top-dress them. H. W. Ward, Longford Castle, Wills.

Plants and thein Cultune.

PALMS FOR DECORATIVE PURPOSES .- The cultivation of these Princes of the Vegetable Kingdom in a small state has rapidly risen in favour of late years, and the demand for them seems even to be on the increase. This is especially the case with those varieties that have proved themselves to be of an enduring character when grown under adverse circumstances, and with others which are utilised in the embellish-ment of apartments. Their stately, yet graceful and well-proportioned outline causes them to be in great request for this latter purpose, and when approriately used no other plants can excel them in effect. Where much indoor plant decoration has to be carried out, it is indispensable for the health of the general stock of such plants that a gnodly number should be grown; this is essential also in order to afford a greater diversity in the arrangements and groupings. The complaint is oftentimes made that plants are so frequently spoiled by being used in the house. This in most cases is brought about by a too limited supply for the purpose being kept in reserve. In such cases the plants have to be left beyond reasonable time in situations where it cannot be expected that they will thrive. When plants that have been grown in light glasshouses are transferred to dark rooms the surroundings are so different, the atmosphere so arid, and the exposure to cold currents of air so frequent,

and that too from an open window, sometimes with the outside temperature below the freezing-point, Under these conditions, it is no wonder that complaints are made, which by judicious management might be avoided. To ensure the best possible success, a good reserve stock of plants is indispensable, together with a batch of younger stock coming on to fill their places. Taking this precaution, and a systematic changing of the plants, say at least three times a week, will much reduce the chances of failure. It is also necessary to keep a close watch on all such plants with respect to the watering; on no account should they be allowed to suffer from dryness at the roots, as this, combined with the dry atmosphere of the rooms, will soon cause sickly, yellow foliage, and impaired health. No plants that have been recently potted should be used again till they are well established. Irreparable injury will be caused when this point is overlooked, in the case of young and tender species in particular. The frequent sponging of the soliage is also an essential point in good culture, and improves the appearance of the plants. This need only be done with a weak solution of an insecticide. if there are no mealy-bug or white scale present. Palms in particular are somewhat disposed to attacks from the latter insect, and a form of scale nearly as troublesome, but not so readily recognised by reason of its brownish colour. For these a stronger solution will be necessary in order to dislodge them. Bottomheat for all decorative plants must also be avoided whilst they are liable to be called upon to do duty, from reasons obvious to every practical cultivator.

The present would be a very good time to recruit the stock of Palms for such purposes as we have dwelt upon in these remarks. The immense numbers that are annually raised from seed in this country, and by importations from the Continent, have brought the more popular and the kinds best adapted within the reach of most cultivators. Ifalf dozens and dozens can now be obtained for the price that only a few years back had to be paid for a pair of plants. glance into the houses devoted to their culture by our nurserymen will at once give an idea of the varieties in the greatest request. In the very front rank are the Kentias, chiefly K. Forsteriana and K. australis, for decorative work; these Palms are not surpassed by any others in cultivation. The hardihood of these by any others in cultivation. The hardthood of these plants, combined with the deep green colour of their foliage and compact growth, render them of the greatest value. Seaforthia elegans, Latania (Livistonia) borbonica, Euerpe edulis, Corypha australis, Areca (Kentia) sapida, Phoenix reclinata, P. temis, Area (Kentia) sapida, Phoenix reclinata, P. temis, and P. rupicola are all tolerably hardy kinds, whilst the well-known Cocos (Leopoldinia) Weddelliana, Areca lutescens, and A. Verschaffeltii, which require ordinary stove treatment, should be included in every collection of bothouse plants. Of other good hardy collection of bothouse plants. ordinary stove treatment, snould be included in every collection of hothouse plants. Of other good hardy room plants, Aralia Sieboldii and its variegated form room plants, Aralia Sieboldii and its variegated form are both valuable; so is Aspidistra Iurida variegata and Dracena congesta and D. rubra. For larger vases the Phormiums are all fine objects, and where tall plants can be used the Phorniums. plants can be used the Rhopalas give us a distinct type.

There are many more genera from which selections may be made for use under this heading, but those we have named are among the best for all-round purposes. A good selection of decurative foliage plants is a great boon to those who from necessity rather than choice have much room-decoration to perform, relieving the monottony of and toning down the colours of flowering plants, besides being also a saving in the use of the latter, which are not so well calculated for the purpose, especially where gas is burnt. Any additions that are made to the stock, either by propagation or otherwise at this season of the year, can have good attention given them before greater pressure is brought to bear on the general routine from other departments.

FORCING PLANTS.—Fresh additions to these should be made according to the supply and demand, bearing in mind that a lew plants of any given subject introduced into heat at the time is much better than a greater numberal longer intervals. Azalea mollis and the hardy Rhododendrons may now be started in a gentle heat, whilst Andromeda floribunda, if given the protection of a cold house even, will develope its beautiful spikes to perfection. Lilacs and Deutzias, with the beforementioned plants, will all be benefited by being plunged in a slight hotbed of leaves, the moisture arising from which greatly helps to develope the flower-buds. Lily of the Valley and Hoteia (Spirea) ajapanica should be started now in a brisk heat; a slight covering of each with cocca refuse at the commencement will give the spikes a start in advance of the otherwise rapid formation of foliage. The most advanced of the Hyacirubs, Tulips, and Narcissis should be chosen and accorded a position near the glass, putting in small quantities at frequent intervals. James Hudeon, Gunnersbury House, Acton.

WITH Wheat at 40s per quarter after a harvest barely up to average, and with only a feeble speck on the agricultural horizon to give a gleam of hope for any substantial improvement of prices in years to come, the question which naturally forces itself upon every one at all conversant with rural affairs is, What is to become of the broad acres of England?-at all events, so far as concerns no inconsiderable portion of them. Within a moderate distance by road of large towns, where the straw, which at present prices makes nearly as much per acre as the corn, can be carted to market, and manure in the shape of backcarriage can be had for a nominal price, or where sufficiently near a railway by which the straw can be sent and manure in return be had at a low cost, then there is some chance of corn growing still being made to pay. But there is much more land that has been so far devoted to corn growing that is outside the range of the above-named advantages than is within it, at any rate so far as being within a reachable distance in the matter of manure, even if the supply of this essential commodity were sufficient to meet an extended demand. As usual when any particular industry goes wrong, there is no lack of advice forthcoming-some sound, with much that is impracticable. Grow less corn, and set to work to produce more milk and butter; grow more vegetables and more fruit. advice under certain conditions, and kept within due limits; but it is well to remind those who seem to consider that if the course they suggest were followed the effects of the low corn prices would be set to rights, that this is more imaginary than real. Thousands of acres of heavy thinskinned land that will grow corn will yield little milk and less butter, unless the cows get a good deal besides the grass and hay which such land produces. And here again it is only within a limited distance of towns, or railways connected with the towns, that the principal article, milk, can find a profitable outlet.

With regard to an increase of culinary vegetable growing, so far as to have any appreciable influence on the position of the cultivators of the land throughout the kingdom, the advice can only have been given in ignorance of the subject. In the neighbourhood of towns supply and demand will, as hitherto, find their correct level. If an additional acre in each parish throughout the rural districts of the kingdom were devoted to vegetable culture, leaving Potatos out of consideration, the price obtained for the produce would not cover the cost of production.

Respecting fruit, the subject requires to be considered in a two-fold aspect, as between soft kinds that perish quickly, and others that will keep more or less. Soft kinds. under which head may be included Strawberries, Raspberries, Currants, and Gooseberries, that are not gathered green, must be gathered without delay as they come due or they are useless; and they must be used quickly afterwards or they are wasted; and to attempt their further cultivation to an extent worth naming could only be done in the vicinity of towns, or large villages, away from which the hands to gather them could not be found. As regards the principal fruits-Apples, Pears, Plums, and Cherries-all these take a considerable time in coming to a bearing state; standard trees are mainly to be reckoned on for planting on a

large scale, and something like eight or ten years may be counted on before much return from them can be expected. Beyond this the land over a large extent of the kingdom, where until recent years corn could be profitably grown, will not answer for fruit culture.

With land that cannot longer be let for the cultivation of corn, and which, either from its nature or situation, will not admit of being profitably employed in the production of any of the commodities which are now so glibly talked about as the means by which all the difficulties that beset the question are to be set right, it is no wonder that proprietors who thus find themselves placed are weighing the question whether it would not be well to plant more or less of such land with a view to the growth of timber, and are further meditating about what to plant. It is a subject deserving of consideration.

There can be little doubt, from the evidence of those whose conclusions are drawn from reliable sources, that the supply of foreign timber, which during the present century has reached the country in unlimited quantities, is not likely to be kept up, neither in regard to quantity nor to quality. This is most apparent from the source whence we have so far had the greatest quantities-North America. Compare the thin, sappy deals that now form the bulk of what we get from that country with those that used to come. A similar state of matters is represented as to the condition of the forests in the Old World, where waste, coupled with consumption, effect a clearance much faster than the growth going on can keep pace with, all pointing in one direction-that higher prices at no very distant date will rule. The question as regards the requirements in time to come in the matter of timber is very different to what it was when the commerce of the world was afloat in wooden walls. The best of the hard woods-Oak, Ash, and Elm-will always be wanted in more or less quantities; but the softer, faster growing kinds, such as Poplar, Willow, and Pine, coming sooner to a useful size, not only give quicker returns in the thinnings, but also in the mature growth, which more than counterbalance the difference in price. The demand for these kinds of timber is more likely to increase than otherwise, from the fact of their being used for purposes that in times past did not exist. As regards the Pine, there can be little question that the Corsican Pine (P. Laricio) should hold the first place, growing faster than any of its congeners; forming smaller branches than other kinds it concentrates its strength in the trunk, which stretches out apace, gaining substance in proportion.

Amongst hard woods, Sycamore now heads the list in demand in many parts of the kingdom, with a probability of its still further taking the lead. It thrives anywhere in the kingdom, where not too much elevated, and the soil not too wet. There are few, if any, trees more worthy of the attention of planters in this country at the present time. Sycamore, with the above-named Pine, Willows, and Poplars, selected to suit soils and situations, seem to hold out the best prospects of a remunerative

THE WEEK.—The annual meeting of the Gardeners' Royal Benevolent Institution, which was being held as we went to press last week, and of which a necessarily brief report only could then be given, is likely to be a memorable one in the aonals of the Iostitution. In the first place, the voting was the highest that has ever been recorded. For the first elected candidate, Mrs. LARISSEY, 2931 votes were giveo, or 466 more than the candidate highest on the list last year obtained; while the lowest on the successful list, JAMES HUTCHESON, obtained 1196, or 319 more than were required last year to carry the eleventh candidate; the total number of votes recorded this year for the eleven successful candidates being 19,774, or 4286 more than the same number received

last year; and the total number polled for the nineteen candidates was this year 24,210. The second special feature was a statement made by the Secretary. to the effect that a gentleman, whose name he was not at liberty to give, had authorised him to say that if the sum of £1750 can be raised and added to the reserve fund during the current year, he will give the (500 that will then be required to make the reserve fund up to £20,000, when the pensions can be raised £4 each.—At the forthcoming annual meeting of the Royal Horticultural Society it is proposed that Viscount ENFIELD, Professor MICHAEL FOSTER, and F. CANE GODMAN, Esq., he elected members of the Council in place of the retiring members, James McIntosh, Esq., SirCharles Strickland, and H. WEBB, Esq. The proposed names will, we expect, be hailed with approbation, though we regret to have to lose such tried friends of the Society as those mentioned. No change is proposed to the officers. The annual meeting will take place on February 12.—A new journal, entitled the Scottish Fancier, and devoted to the breeding and management of dogs, poultry, pigeons, &c., has just been commenced. posed to be published monthly at Id.—Mr. GLAD-STONE'S speech to his tenants at Hawarden, in which he mentioned the subject of fruit growing by farmers, has attracted much attention. Mr. GLADSTONE seems to have been misinformed as to the extent to which fruit culture is already practised, which is much greater than he was aware of. Foreign competition, agaio, does not so seriously affect the British fruit grower as he stated, for it deals with a class of fruit which cannot be profitably grown in this country at an early season, such as that at which the foreign fruit comes into the market. Moreover, by far the greater part of the jam consumed in the country is made in this country, and not imported. The argument that farmers, though they may know how to manage a farm, are ignorant of fruit trees and their culture, may be true, but if it once be brought home to them that there is "money in it," we do not doubt they will soon acquire the necessary knowledge if the locality and the tenure upon which they occupy their land be satisfactory, and they be not burdened, as they are in some counties, with "extraordinary tithes" and prohibitive railway rates. - The alteration in the constitution of the Floral Committee, to which we alluded in our last, is received with approval by several of our correspondents, who see in it "a feeble step towards better things."-We have received the programme of the "International Health Exhibition," an awkward title for the exhibition which is destined to "lollow the fish" at South Kensington. The objects at South Kensington. specially mentioned are illustrations of food, dress, the dwelling, the school and the workshop, and appliances relating thereto. It is clear that gardening and garden products, though not specially mentioned, have a potent influence on health. Class I includes specimens illustrative of upprepared vegetable substances used as food; class 8, drawings and models of vegetable parasites. We could have wished to have seen some special attention given to school play-grounds, school gardens, soldiers' gardens, town squares, and recreation grounds, all of which come fairly within the scope of the programme. Perhaps it is not too late to make a special class for plans and other things connected with them.

—— BEAUTY OF APPROPRIATENESS. — Most of the mistakes made in decorative gardening are trace-able to the use of good materials in the wrong place, or for improper purposes. It is desirable and agreeable to make representations of birds, butterflies, coats of arms, heraldic devices, and the like, hut it is a mistake to do so with flowers and coloured leaves. The increase of taste has well-nigh haoished the monstrosities in Berlin wool work, in which our grandmothers delighted. We see now how ludicrously inappropriate such things are, and we shall not be long before we realise that mosaic beds of the character indicated are as great an outrage on good taste. It does not follow that we are not to have cakes and ale any more, only the cake will be better cooked, and the ale more wholesome.

— A New Chinese Rhododendron.—In the number of the Fournal of Botany for this month is a full description of "a very fine new Rhododendron," allied to R. arboreum, and discovered in the mountains of Lo-fau-shan, by the Rev. B. C. Henry. Dr. Hance, who describes the plant, says that a constant cloud-like mist fills and rises from the gorge

FIG. 16.-HELLEBORUS NIGER, VAR. ANGUSTIFOLIUS: FLOWERS PURE WHITE. (SEE P. 77.)

where the plant grows. Dr. HANCE says that the mountains in question, which are about 40 miles north-east of Canton, form a series of plateaux whence arise peaks, some of them attaining a height of 3500 feet, furnish by far the richest and most interesting botanising ground within accessible distance of Canton, and feels sure that its careful exploration would lead to the discovery of a large number of valuable and ornamental trees and shrubs, as well as betbaceous plants, and trusts that the Kew authorities will endeavour to arrange for the systematic investigation of the locality by Mr. FORD, of the Hong Kong Botanic Garden. We should think it a desirable field for a nurseryman's collector also, provided the state of the country permit.

- THE IRISH SEED POTATO FUND. - The report of the committee of the fund promoted by the Society of Friends for Supplying Seed Potatos to the Distressed Peasantry in co. Donegal has been issued, and from this it appears that altogether about 276 tons were distributed, and the committee having set out with the determination of giving only one bag, containing 2 cwt., to each family, the number of recipients was very considerable. The supply of fresh seed was looked upon as a great boon, and very thankfully received; so much so that instances are known of people walking ten miles each way, several times, with the hope of receiving a bag, and the committee have great satisfaction in believing that a very small percentage indeed was used otherwise than for seed, seeing that the distribution was effected just in the most favourable time for planting. There are thousands of acres of waste land in the country which might possibly be properly cultivated. The accounts show a balance of £105 6s. 3d. in hand, which the committee will endeavour to expend judiciously, and in accordance with the object for which it was contributed. In conclusion, the committee are glad to say they have had reports from various parts of Donegal stating that there is an excellent and abundant return from the seed supplied.

→ Mr. Thomas Hewitt has sold the nursery and seed business carried on by him at Solihull and Birmingham to Messis. C. W. Falcon and J. F. L. Evans, by whom the business will be carried on under the title of Thomas Hewitt & Co.

- THE SEASON'S IRREGULARITIES. - A correspondent writes :- "Amongst the striking evidences of the open mild nature of the midwinter months, none is to me so remarkable as the sweet singing of the birds. It is not at all unusual to hear a lark singing high up in the air just as though it were the month of May, and its mate were nestling its eggs in the bosom of Mother Earth. But even from New Year's Morning till now, without exception, a beautiful thrush has been singing gloriously in a near Oak tree; where, perched on the topmost branches, it carols forth in rich and powerful note its orisons to the rising sun. How many millions of town dwellers are there who would delight to possess the privilege I now have of hearing the song of this bird every morn-Birds seldom trouble the fruit in ing when I wake. this locality; but if they did it must be a selfish soul indeed who would grudge to this beautiful throstle and his mate a little of the food so abundantly provided for man. And why not for the birds also

- AMERICAN CUT FLOWERS. - Some New Yorkers are perhaps a little given to exaggerate. If, however, they fail to plead guilty to that literary vice, then must some New York flower-baskets be remarkably large or the flowers remarkably small. When we are told that a retail dealer in cut flowers orders from the salesman 200 Camellia blooms, 200 Carnations, and some 200 of other flowers, and that these hardly cover the bottom of the retailer's basket, we may be excused for thinking that there is a little stretching somewhere. Two hundred Camellia blooms, each 21 inches over, would cover at least a square yard of surface, and the other 400 flowers would certainly cover as much again; so that it must have been a monster basket indeed that had not its bottom filled! It may be that such a lot of flowers was not dear at the price given-viz., £16-for after an examination of the whole: ale price-list from Covent Garden it is doubtful whether such flowers, if good, could be purchased more cheaply here. No doubt the present winter, so far, has been unusually favourable for forcing, because the external temperature has been

high, and the atmosphere fairly dry. The heavy fogs which prevailed about Christmas were exceedingly trying, but forced plants just then seemed more in need of artificial light rather than of additional heat. That dull dark period would have proved a capital time to have tested the value of the electric light in plant forcing. The metropolitan fogs have left us, in mensoriam, a dirty deposit of soot, rendering glasswahing oeedful. In all other respects, however, the winter, so far, has been on the side of the market florist, but native modesty prevents that hoasting which marks some Transatlantic growers.

- HOYA CARNOSA AS A WALL PLANT, -Curious examples of an admirable method of utilising the back walls of heated greenhouses may be seen at the Royal Nursery, Feltham, where Mr. ROBERTS has converted Hoya carnosa into a pure wall plant by cutting out holes in the wall at intervals of 4 feet, and about 2 feet from the rafters, and placing into these plants turned out of small pots. The holes are small -scarcely large enough, indeed, to get both of a man's hands into comfortably-and yet in these mere crevices the Hoyas have rooted and made remarkable growth; in fact, there are shoots 14 feet in length, and the upper portion of the wall is being fast covered. A small orifice is left on the upper side of each hole, into which water is occasionally poured, but the plants really depend for their moisture chiefly upon atmospheric vapour and syringing. They bloom most freely, and in their curiously restricted root-space thrive admirably.

FIGUS ELASTICA.—Standard Indiarubber plants, perhaps, are not common, but a few growing planted out in a centre bed in one of the span-houses at the above nursery show what noble plants these would make in any roomy conservatory, were they trained up to a tall stem and thee broken to throw out a number of branches to be slightly arched, like to the growth of a Weeping Ash. Mr. ROBERTS' plants show magnificent growth, having shoots that of necessity have been tied to the rafters quite S feet in length, and carrying splendid foliage. As a single-stemmed plant this Figus soon assumes a gawky aspect, but grown as a standard the result is very noble.

——SENECIO MIKANIOIDES.—From Italy we have received specimens of this plant under the name of "Nice Ivy," which proclaim it to be a very ornamental species. It is one of the South African climbing species, with stalked, Ivy.like, 5-7 angled leaves, of a bright green colour; and axillary and terminal, small dense corymbs of 10—12 flowered discoid heads, of a bright yellow colour; usually several of the small corymbs are crowded together at the ends of the branches, and make a very effective display. In the island of St. Ilelena, where it has been introduced, it is known by the name of "Ground Ivy." In this country this showy species must of course he treated as a greenhouse climber, like its congener the handsome S. macroglossus.

- THE SAWBRIDGEWORTH NURSERIES .eighth anniversary in connection with the sick fund attached to the Sawbridgeworth Nursery was celebrated in a very pleasant manner on the evening of January 3. At half-past 5 between fifty and sixty of the Messrs. RIVERS' employe's sat down, in one of the large glass-houses in the part of the nursery known as Miseman's, to an excellent dinner of "old English Christmas fare," which was followed by a series of toasts, which included "The Health and Prosperity of the Messrs. RIVERS," and "The Chairman," the firm's able manager, Mr. CAMP, who in reply gave some interesting particulars relating to the sick fund. including details of the receipts and expenditure. He was pleased to say that the institution was in a flourishing condition, notwithstanding the drain upon their resources, for there had been more than usual sickness last year, and consequently additional claims, beyond what had been known for a long time past. But he was thankful to be able to report that, after all demands had been met, there was still an increase of the balance in the Post-office Savings Bank. This must be very gratifying to them all, and certainly the prospects of the fund-which was doing an excellent work-were very promising. An adjoining greenhouse was set apart for smoking and a general gossip while the "banquetting room" was cleared for a concert, to

which neighbours and friends were invited to the number of about 350, and who thoroughly enjoyed the entertainment.

THE "BOTANICAL MAGAZINE" for December contains an illustration of Eremurus robustus, the finest of the genus, having long close spikes of star-shaped pinkish flowers like those of an Asphodel; it is a native of Ceotral Asia; Gentiana Moorcoftiana, Aërides Emeria, Papaver Hookeri, differing from P. Rheas in its great size, as it forms a bushy herb 4 feet in height; Medinilla Curtisii, the representation of which gives the impression of a twining plant with pendulous branches—the specimen shown at Kensington from which our figure p. 108, vol. xx., was taken, was, however, quite erect.

— DECAISNEA INSIGNIS, Bot. Mag., t. 6731, is a most remarkable plant, originally figured in Sir J. HOONER'S Illustrations of Illumalayan Plants. It is a glabrous, creet, little branched shrub, with unequally pinnate leaves, leaflets ovate lancealte acuminate; flowers polygamous, green, bell-shaped, in long racemes each about \(\frac{3}{2} \) inch long, 6-parted in the male flower; the andrescium is columnar below, dividiog above into six stameos, anthers prolonged into a long pointed appendage; in the female flower the stamens are imperfect and surround three cylindrical recurved many-seeded carpels which ripen into golden-yellow, tuberculate follicles filled with white sweet pulp in which the seeds are embedded. It is included in the tribe Lardizabaleæ of Berberidaecæ, It flowered at Kew.

PRIMULA FROLIFERA, Wall., Bot. Mag., t. 6732, better known as P. imperialis, has been recently received from the mountains of Sikkim, where it was gathered at an elevation of 10,000 to 16,000 feet, having previously been known only from the Khasia hills, at about 4000 to 6000 feet; and from the mountains of Java at 8000 to 9000 feet. The foliage is by far the largest of any Primula, the feaves attaining 18 inches in length and 5 inches in breadth. The flowers are yellow, in whorls placed one above another.

LOTUS FELIORHYNCUS, Bot. Mag., t. 6733, is a very remarkable Leguminous plant, from Tenerific which flowered at Kew last spring. It is a small, much-hranched shrub, covered with silky pubescence. The branches are very slender, thickly best with spreading fillform leaves; flowers 1½ inch long, loosely crowded on short axillary stalks, calyx bell-shaped, irregularly five-toothed. Corolla papilionaccous, twice the length of the calyx, dull crimson, with narrow-pointed standard and wings. Staminal tube long, dividing into nine slender filaments, five looger than the rest; a tenth stamen is free.

— MORINA COULTERIANA, Bot. Mag., t. 6734, is a handsome herbaceous plant, more or less covered with pubescence; leaves linear, spiny at the margins; flowers, greenish-yellow, in dense terminal spikes. A Dipsad, native of Alghanistan, but not so handsome as M. longifolia. Sir Joseph Hooker notes M. betonicoides and M. polyphylla from Sikkim, as worthy of introduction, Phacelia campanularia, t. 6735, is closely allied to Whitlavia grandiflora, and is an annual that, from its deep blue bell-shaped flowers, is sure to be a favourite. It was introduced from South California by Mr. THOMYSON, of Ipswitch.

- LICUALA GRANDIS = PRITCHARDIA GRANDIS. -This comparatively recent introduction presents a handsome appearance in all stages of growth, and is destined as it gets dissemintaed to become more popular than its less favoured congeners. Although thirty species or thereabouts are known to science few have been introduced to cultivation. Generally they are of a low shrubby habit, but the present one, from the appearance of a fine specimen in the Palm-house at Kew, bids fair to attain more tree-like dimensions. The Palm in question has several feet of a stem, and has been flowering for some time. It was added to the Kew collection about eighteen months ago under the name of Pritchardia grandis, a provisional name given to it in Mr. Bull's nursery, and under which it is figured in the Gardeners' Chronicle, n. s., vol. i., fig. 89. The bold and striking habit is here shown off to advantage, but much smaller plants, or even seedlings of no great age are very effective for decorative purposes, and are finding their way into many private collections.

- CLIVIA NOBILIS .- In many private establishments plants of this class are more often treated with neglect than given the treatment they deserve. leathery deep green leaves and masses of pendulous flowers of C. nobilis will always recommend it where well grown. Possibly flower-scapes are less frequently produced in this than in the other species known, but the flowers in an individual umbel are far more numerous, and of an orange-scarlet colour, without the green tips to the perianth-segments so characteristic of C. Gardeni. Imantophyllum miniatum, referred here by the Genera Plantarum, doubtless surpasses it in the intense colour of several garden varieties, but the difference exhibited in the direction of the flowers of the two would warrant the desirability of cultivating both, and improving their respective merits. Imantophyllum Aitoni, figured in the Botanical Magazine, t. 2856, is synonymous with C. nobilis. In No. 5 house at Kew, where it generally flowers about this time, it receives no special treatment.

CRASSULA LACTEA.—This thoroughly useful species for winter flowering was sent to this country from the Cape of Good Hope by MASSON more than a century ago. It is a plant of the easiest cultivation, simply requiring a perfectly well-drained soil — old brick rubbish and loam do very well—and a not too plentful supply of water. Its shortly-stalked somewhat pyramidal panicles of white flowers are freely horne by plants in comparatively small pots during the dull winter months. Good specimens in flower are to be seen in the Succulent-house at Kew. C. lactea was figured in the Botanical Magazine, vol. xilii., t. 1771.

—— IONOSIDIUM ACAULE. — A few years ago Mr. BARRON made excellent use of this little Crucifer at Chiswick. When grown in pots it may be had in bloom almost at any time, and all it requires is a place near the glass in a cool house or cold frame. It was at the Horticultural Society that the species was first raised in this country, and the figure in the Botanical Register, vol. xxxii., t. 51, was prepared from a plant flowered at Chiswick. In the rockwork this tiny annual makes itself at home in damp places, and under favourable conditions reproduces itself freely from seeds. The flowers open white, and afterwards turn a clear lilac colour, and are borne above the small delicate green leaves. Ionopsidium acaule is only found in Portugal, and a nearly allied species, I. albiflorum, is found in Sicily.

- THE BOTANIC GARDEN AT DIJON, - This garden is turned to account, not only for purely botanical purposes, but as a trial-ground for ornamental plants. It thus confers a service on hortiwhile the gardener, finding his interests culture. served, looks all the more tolerantly on those depart-ments in which he is less immediately interested. Thus we find in this garden, not only illustrations of hotanical rarities, or illustrations for the use of the professor and his students, but long lines of plants bedded-out with a view to show what each plant can do, and what are its capabilities for garden purposes. Herbaceous plants and alpine plants, bedding plants in the restricted sense of the word, all are treated in the same fashion. The same plan is carried out with reference to trees, shruhs, and flowers suitable for growth in towns. Among these our attention was drawn to Morus Kæmpferi, a species with lanceolate shining leaves. The gardener has thus an opportunity of seeing what plants are at his disposal, and thus of avoiding, if he choose, that unintelligent monotony which is unfortunately the characteristic feature of so many gardens. The botanic gardens show that there is no poverty of material, the defect lies in routine imitation of others, and want of appreciation and enterprise. In this garden was once, as we have already had occasion to mention, a very complete collection of one thousand varieties of Vine, which must have been very instructive till the Vines were destroyed by the Vine-louse. Another instance of the practical spirit manifest in this garden is shown in the practice of grafting Sweet Chestnuts on the Oak. The Chestnut does not thrive on the limestone district around Dijon, preferring a saudy soil, but by grafting it upon the Oak it may be made to succeed. Of the large Black Poplar we have already spoken, but it may be useful to repeat that there is documentary evidence to show that it is 500 years old. It has a height of 40 metres, a circumference at the base of 12 metres, and of 8 metres at 2 metres above the soil. (A metre may be taken as about 11 yard.) The houses are

small, but contain good collections of succulents, Bromeliads, New Holland plants, Ferns, &c. Caladiums and Gloxinias are planted out in well-drained beds on the stages in the end of May, and are lifted in September. Treated in this manner, the growth and flowering are very satisfactory. The whole establishment, though only an unpretending provincial garden, and suffering from scanty funds, and from the effects of recent severe winters, shows on all sides signs of intelligent management, and of a practical spirit capable of providing for the requirements of science and the wants of horticulture and agriculture. M. Where, who has the superintendence of the garden, is also entrusted with the management of the town squares, the park, and a fruit tree nursery at some distance from the town.

STROBILANTHES ISOPHYLLUS .- As a useful winter-flowering plant this one can be utilised for cut flowers, or for the decoration of either stove or greenhouse, and flowers freely and regularly during great part of the winter. The old plants, if well cut back after flowering, will break evenly and flower abundantly for a number of seasons, and young well-flowered specimens can be obtained in one season from cuttings. Its appropriateness in this respect is shown by the great quantity to be seen during the winter months in the conservatory and several other of the houses at Kew. There is a figure of the species in the Botanical Magazine, 4363. Concerning the fertilisation of the flower, we are informed that there is an interesting phenomenon in connection with the stigma. When the anthers are about to shed their pollen the stigma becomes remarkably irritable, so that if touched by an insect entering the corolla it immediately bends downwards, and huries itself in a cushion of hairs on the lower side of the tube. Crossfertilisation is hereby effected, as the insect can now make its exit without dusting the stigma with pollen of the same flower.

— THE CRYSTAL PALACE COMPANY announce that a series of six horticultural exhibitions will be held at the Palace this year, the first of which—an exhibition of spring flowers—will take place on April 4 and 5. The first summer show will be held on May 23 and 24, and a Rose show on July 5. A grand Harvest Festival, with which will be incorporated the International Potato Exhibition, is fixed for October 7 to 11 inclusive; and on November 14 and 15 a show of Chrysanthemums and hardy decorative shrubs will complete the series.

— THE WEATHER,—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending Jan. 14, 1884, issued by the Meteorological Office, London :—The weather has continued cloudy or dult in nearly all parts of the kingdom, though for brief intervals the clouds have dispersed. Rain has been much less prevalent than during last week. The temperature has again heen above the mean in all districts, the excess varying from 2° in the north of Scotland to as much as 6° over the east and west of Scotland, and north-east and central England. The maxima, which was high for the time of year, were generally registered on the 9th, and ranged from 50° in "Scotland, N.," to 55° in "England, N.E.," "Scotland, W.," and "Ireland, S. The minima were recorded at most stations on the 12th or 13th, and varied from 37° in the "Channel Islands," The rainfall has been about equal to the mean in "Scotland, N.," to 37° in the "Channel Islands," and "Scotland, E.," but considerably less in nearly all other districts. Eright sunshine has been more general than for some weeks past, although the percentages of possible duration are still small in most places; in the "Channel Islands," and "Scotland, E.," het percentages of possible duration are still small in most places; in the "Channel Islands," and "Scotland, E.," bet considerably less in nearly all other districts. Eright sunshine has been more general than for some weeks past, although the percentages of possible duration are still small in most places; in the "Channel Islands," and "Scotland, E.," the percentages of possible duration are still small in most places; in the "Channel Islands," and "Scotland, and over Scandinavia, and a few subsidiary disturbances over the United Kingdom. The wind has consequently varied between S.W. and N.W. over the whole country, and at all our northern and western stations has been fresh or strong in force.

— GARDENING APPOINTMENTS. — Mr. ALEX. TAIT, for many years Gardener to Lord TORPHICHEN, Calder House, Midlothian, as Gardener to General FEILDEN, C.M.G., M.P., Witton Park, Blackburn, Lancashire.—Mr. R. Bass, for the last five years Foreman at Knypersley, as successor to Mr. DOLBY, Gardener to R. HEATH, Esq., Biddulph Grange, Congleton.

NOTES ON NYMPHÆAS.

DURING the past summer the large collection of Nymphæas at Kew afforded a good opportunity for an attempt at hybridising some of them, with a view of raising some new forms, and if possible of infusing same of the colours of the tropical species into our hardy ones. So far as we know at present the results of the experiments are satisfactory, a good number of those flowers which were operated upon having produced good seeds, some of which have already germinated. Whether we have succeeded in crossing any of the kinds remains to be proved. The habit of closing their flowers during a portion of each day is a well known characteristic of Nymphæas, but it does not appear that any attention has been paid to this peculiarity as one of some importance in enabling us to classify the species and varieties of cultivated Nymphæas. So far as my observations enable me to judge there is a striking regularity in the opening and closing times of the flowers, and a wide difference in regard to the time this occurs in some of the species. It is a well known fact that N. alba, our native Water Lily, closes its flowers in the evening, and unfolds them again on the following morning. Precisely the same thing occurs with N albo-rosea, sometimes called N. sphærocarpa. N. odorata and N. tuberosa, both North American plants, are also night-closing species, opening their flowers again at sunrise the next morning. N. flava, the pretty yellow species, also a North American plant, N. flava, the exhibits the same peculiarity, and an experiment made with a view to testing whether light affected the opening of the flowers of this species, proved sufficiently reliable in its results to show that such was not the case. To this I shall refer again presently. The Old World species, N. Lotus, and its many varieties, open their flowers in the evening at dusk, and remain fully expanded during the whole night, closing again about noon on the following day. following are the details noted during a fortnight's observation of these plants, commencing Sept. 16:-

	6 A.M.	11 A.M.	2.30 P.M.	7 P. M.	11 30 P M.
N. Lotus var.	Open	Open	Closed	Closed	Орец
"", devoniensis.	11	Clos€ d	.,,	Open	19

ana	11	**	29	Open	**
,, ,, ,, rubra	"	Closed	19	71	>>

It is here shown that, so far at least as the time of opening their flowers is concerned, the whole of the above are related to each other. The age of some of the flowers of several of hose observed no doubt had something to do with the slight difference as to time of opening.

The stellata group bears some resemblance to our

The stellata group bears some resemblance to our native species and the North American ones in the time of opening and closing their flowers. Of those in flower at the time of observation the following table shows the result:

	6 A M.	II A. M.	2 30 P.M.	7 F.M.	11 30 P M.

lea ,, ,, ,, × Dau-	Open		н	32	
benyana.	Closed	Closed	"	12	**

To this list might be added the Australian species, N. gigantea, which invariably opened its flowers in the morning, and closed them again at dusk.

It appeared to me that by gathering flowers of several of each group and reversing the conditions of light, some modification in the closing and opening of each might be the result. This, however, was not the case; flowers which under normal conditions opened in the evening remained closed all day when kept in total darkness, and expanded most beautifully at the usual time, even when exposed to brilliant gaslight. The same indifference to a change of light was exhibited by those of the stellata group, the flowers

remaining perfectly closed all night in a well-lighted room, and opening in the morning when kept in total darkness.

Whatever may be the purpose for which this closing and expanding of the flowers of Nymphæsa is intended, it appears very remarkable that while some should have this purpose served by opening in the daytime, others would appear to expand only during the night. So strange a modification of habit must be supposed to be due to a great alteration of conditions, and if the agency of insects or birds be requisite for the fertilisation of the flowers—which appears to me very likely—such a change in the expanding time must have been brought about by the absence of the proper agency in one circumstances, which resulted in earlier or later closing hours, whichever might be necessary to eatch the right customers for the honeyed liquid secreted in the cup of the flower.

The floral organs of Nymphæas appear to be constructed specially with a view to cross-fertilisation. When a new flower first opens, the stigmatic surface which lies in the cup formed by the surrounding petals and sepals is covered with nectar, which is clear like water and sweet to the taste. On the second day this has almost wholly evaporated, all that remains being a sticky substance about the stigmas, which is evidently intended to hold the pollen grains. The pollen of this flower is, however, not yet ripe, the anthers being closed, so that pollen from the same flower is apparently prevented from performing its functions. Meanwhile the stigma has become fertilised with pollen from another flower, and when the petals close in a second time several rows of abortive stamens bend over so as to completely cover and seal up the stigma. These stamens remain curved downwards until the flower decays. In one or two in-stances I noticed that pollen was ripe hefore the abortive stamens had covered over the stigma, so that self-fertilisation was possible; but the rule appears to be an arrangement for cross-fertilisation, is above stated. I was unable to fertilise several flowers of N. zanzibarensis, owing to there being no ripe pollen at the time the stigma was prepared to receive it. By saving pollen until a second flower opened, this difficulty was overcome.

As it seemed possible that when the flowers sank below the surface of the water—as most of them do soon after closing—the pollen might be lifted from the stigma, and float to the surface, I tried some pollen in a tub of water to test its sinking capacity. It immediately sank to the bottom, and remained there. Here we have a remarkable arrangement, which prevents currents of water, in which the plants might be growing, from interfering with the process of fertilisation.

fertilisation.

In watching the germination of some seeds of Nymphæa sown a month ago I was struck by the unsual process of development, which appears to be wholly unlike that of any other dicotyledonous plant, resembling, on the contrary, very closely, some of the monocotyledons. I have sketched several germinating seeds, to show the development of the embryo, and the very singular arrangement of the cotyledons, or, as it appears to be, cotyledon. In turning to Dr. Lindley's observations on Nymphæaceæl find that the germination of Nymphæas has been referred to by some authors as evidence of their proper position being with endogens rather than exogens. The accompanying figures (fig. 17, p. 89), show a structure decidedly analogous to that of germinatiog seeds of exogens. Further observation will be necessary before we can come to any conclusion with regard to the question, as to whether the characters of the seedlings of Nymphæa are those of a monocotyledon, rather than of a dicotyledon, as generally supposed. [This question is pretty well settled; see Henfrey's Elementary Course, ed. 3 (1878), p. 202. Ed.]. W. Watson, Kew.

BOWENIA SPECTABILIS.—A female plant of this beautiful Cycad, as well as several others, may be seen in cone in the Palm-house, Kew. Although of considerable interest this fruiting condition adds no material ornament to a plant already sufficiently handsome to merit a place in any collection of stove plants. The broad bipinnate leaves is a feature altogether unique in this order, and more resembles a Fern than a Cycad. Generically it is closely allied to the Zamias, and those genera bearing two seeds on the underside pelitate scales of the female cone. The style-like prolongation of the micropyle is here rather prominent a character more or less conspicuous in the Cycads, inducing some authorities to consider the seeds enclosed in an ovary, whereas they are naked. There is a figure of the plant in the Botanical Magazine, t. 5398, and in the same work, t. 6008, is another figure of the seed-bearing form.

Home Correspondence.

Anemones and Christmas Roses,—These go well together, as they are of the same general form and appearance, and the Anemones help to show off the Hellehore flowers by their brightness and rich variety of colour. Christmas Roses are usually plentiful at this season, as it is their natural time of blooming, and Anemones might be had at the same period if seed were only sown annually on some warm sunny border, where, if the soil be light and dry, they flower freely all through the autumn and winter when the weather is mild, and though checked, they seem little affected by frost, as last year we had blooms uninjured peeping up through the snow, and the same plants are now full of buds and blossom again. The way we manage is to dig and enrich the soil by working in a good dressing of decayed leaves and dung, and after raking the surface the seed is sown in drills a foot or so apart, where it is dropped in patches about the same distance asunder, and when the young plants are up they are thinned out, and only two or three left standing in a place, after which they grow rapidly, and soon spread and begin to show flower. The time to sow is about the middle or ead of March, but if the ground is not then in good order it is better to wait, as the seed may lie wet and rot. Jr. S.

Iris rectulata var, cyanea,—This variety (see p. 57) was first described by Dr. E. Regel in the Gartenflora, 1874 (vol. xxiv. p. 162, tab. 797). from specimens sent from my establishment. These were received there by the kindness of M. Boissier as Iris histrio. These two forms are to be considered as synonyms, and if there is a difference between the specimens cultivated, the reason of it may be found in the raising of seedlings. As to the earliness of the different forms of reticulata, it seems to be difficult to give a rule, and it depends probably upon difference of treatment, and upon the origin of the planted bulbs. Dr. Regel (l. c.) states that all flowers of I. reticulata open about the same time, and I suppose this is quite true if they are found in the same conditions, especially in the wild state. Bulbs introduced from the South flower much earlier the first year than subsequently, when they are cultivated on the open ground. J. H. Krelage, Haarlem, Jan. 14.

The Floral Committee—In the leader (p. 52) on the Floral Committee, and its division into two sections, you mention my being "President of the whole;" will you allow me space to say that I had oo hand in the division? George F. Wilson, Heather Bank, Weybridge Heath, Jan. 12.

Rose Stocks.—At p. 51 your correspondent, "T.S. C.," witting of Rose stocks, says of Manetti cuttings: "Cat them into lengths of 9 inches, taking care to remove all the buds on the lower half," We raise many thousands of Manetti stocks here annually, and have tried both ways. We, however, find that the cuttings root much more freely when planted without any of the buds being removed, that is the experience of other growers? Charles Daniels, Town Close Nurseries, Norveich, Jan. 14.

Early Potting of Lilies.—Reading early in the winter of advice to pot up auratum bulbs in the autumn rather than keeping them in the old dry soil and potting in the spring, I so shifted a seedling bulb that bloomed for the first time last year, transferring it with its fleshy tootlets from a 48 into a 24. The pot with its bulb was kept in a cool house, and the soil fairly moist. Curious to discover whether, whilst in its apparently dormant condition it had been making roots, after having been several weeks potted, I the other day turned the soil out and found that roots had been made freely, and these had already a length of from 2 to 3 inches, following the conformation of the pot, thus showing that they were really made since the potting. This fact may not be new to some cultivators of Lilies, but it is to many, and it strikingly proves the value of autumn potting of the bulbs. It is further a fact that although no evidence of upward growth is to be seen, the bulb has materially enlarged since it was reported. E. [The fact of Lilies making root growth under the conditions described by "E." is well known to experienced Lily growers, but every one does not know that the best time to repot Lilies is within a week or two of the stems having completely died down. Ed.]

Pears Doyenné d'Alençon and Easter Beurré, —I can endorse Mr. Bunyard's remarks respecting the distinctness of these Pears. While employed under my father, the late Mr. John Powell, at Frogmore, I grafted several trees that were headed down, amongst them some Easter Beurrés (the fruits of which nearly always cracked) with Doyenné d'Alençon, which did

well and formed fruit-huds on the young growth, bearing a good crop of fruit the next season, and I believe the trees are still hearing well. I consider the Doyenné d'Alençon one of the best late Pears in cultivation. J. H. Powell, Woodgate, Farnham Royal.

Late Flowering Chrysanthemums.—Your correspondent, Mr. Rust, asks (p. 23) for the names of any good January Chrysanthemums besides those he mentions, I enclose blossoms of Peter the Great and Empress Eugleoie grown out-of-doors in a sheltered position against a wall. C. M. Owen, Knockmullen, Gorey, Ireland.

Bromeliads are not much grown in England, but are much appreciated in Belgium, France, and Germany. In many respects they resemble Orchids-namely, in being epiphytes, like most of the Orchids, and requiring the same treatment; the flowers of a great many of them are splendidly coloured, and last, but not least, the plants are very easily cultivated. Here we have a lot of them hung up near the glass, where they feel quite at home; another lot is standing on a beach oear the glass, which are as good as can be; and for want of room we were compelled to put another lot beneath the bench, and these, too, are all right. Last year I put a Bromeliad on a place where the condensed water from the glass roof dropped down, and in consequence the plant was throughout the winter soaked with water, but it always looked as fresh and healthy as the others. I do not advise treatment of this kind; I mention it only to show that Eromeliads are by no means particular as to treatment. For want of room we have but a small collection, about sixty different species, but we are never without flowers. When one ceases another starts flowering, and this keeps on throughout the year. At present we have about half a dozen flowering, and some more showing bloom. Amongst those flowering and some more showing bloom, amongst those flowering are Bilbergia nutans, Baraquini, and Windix. These are not so showy as, for instance, Bilbergia splendida, A'Echmea Weilbachi, Tillandsia Lindeni, and others, but very interesting, as Bilbergia Windix is one of the first hybrid Bromeliads raised in gardens. Bilbergia nutans and Baraquini are its parents, so that we have a whole family in flower—father, mother, and offspring. The leaves and general habit of B. Windi is that of Baraquini, while the flowers more resemble those of nutans. C. Wissenbach, Royal Gardens, Wilhelmshöhe, mear Cassel, Germany.

Old Kinds of Peas.—Would not "Diss" have been more correct had he inquired whether Knight's Dwarf Marrow Pea is in existence in any shape rather than to have assumed that some one was making it perform an act of trade deceit. I cannot answer for other seed lists, but in that of Messrs. James Carter & Co. I note that both Knight's Dwarf White and Green Marrows are offered with over too other kinds, so that it is evident that bouse finds new and distinct kinds sufficiently abundant without renaming old sorts as novelties, New and distinct Peas crop upas fast as do new kinds of Potatos, and in the race old ones die out. Old gardeners naturally cling to the favourites of their youth, younger men swear by the novelties. It is just as well in this small matter, as well as in greater ones, to remember that there is always as good fish in the sea as ever came out of it. A. D.

Sweet William Fungus.—The Puccinia infecting Sweet William Is by no means uncommon. I have specimens from Hertfordshire, and it has occurred near here in two localities during the past year. It is a true Leptopuccinia. The teleutospores germinate as soon as they are mature, and like those of P. buxi and P. malvacearum, are unaccompanied by zecido or uredospores. P. dianthi is remarkahle, however, as being exceptional in the fact that its promyceilal spores do not bore through the eticle of its host plant, but enter through the stomata. De Bary gives three figures of them doing this. Sown on the totyledons and healthy leaves of Dianthus barbatus on June 21, De Bary found in the experiment that the perfect Puccinia was produced by olly 7. He also found these bodies, when placed upon Silene inflata and Lychnis diurna, produced no effect. This seems to indicate that the Puccinia on Dianthus barbatus, although so closely resembling the Funcinia upon Lychois and Silene, is specifically distinct, although Winter groups them all under the oam P. arenarie. It is very remarkable that the germ-tube of the promycelial spores of this fungus should be the only known exception to the rule that the promycelial spores of this fungus should be the only known exception to the rule that the promycelial germ tube bores its way through the cuticle; but Deary is quite certain upon this point, and 1 do not venture to differ from him, although from some observations I made in 1852 and 1853 I certainly thought I saw one or two instances of penetration. Respecting the infection of young seedling with P. malvacearum, I last year tried to see this. I planted in a pot plunged in the ground out-of-doors seeds of

^{*} De Bary, Champignons Parasites, Annales des Sciences Naturelles, 4 series, vol. xx., pl. 12, fig 7.

Malva sylvestris, and also of Hollyhock, most of which were badly affected with the Puccinia. Healthy seedlings only came up, and it was not until they had grown into good-sized pots 3 or 4 inches high that they became affected with the disease. No doubt in the instance alluded to in last week's Cardeners' Chronicle, if the first diseased seedlings had been pulled up and burnt the rest would have escaped the disease. Charles B. Plowright. 7, King Street, King's Lynn, Yan. 14.

Crocus Imperatonius.—Amongst hardy bulbous plants that will bloom at this time of the year naturally in a cool greenhouse or frame few are more pleasing than is this Crocus. Corms need to get so well established in 48-sized pots that there shall be a good bunch of stems to produce flowers. I have just been blooming a couple of such pots, each producing

it has had to give way to such sorts as Duchess of Oldenburg, Warner's King, and Golden Nugget. The Eve Apple is still to the fore, and although small, as your correspondent says, it possesses a flavour which, so far as I know, is unique, and which renders it so tempting as to have given it the name which it bears, to remind us of our common ancestor's weakness for the fruit. Speaking about permanent labels, I see copper wire recommended for hanging zinc labels to the trees. Thin tar twine is much better, as the copper-wire sets up a galvanic action with the zinc, and very rapidly eats its way through the label. A. H. Pearson, Chilwell, Notts.

Jasminum nudiflorum.—This wioter-flowering plant is generally seen trained up the sides of houses or tled to pillars, but just lately I have met with it put to quite a fresh use, as at a place I passed the

Fig. 17.—GERMINATION OF NYMPH.EA: 1, 2, 3, N. STELLATA; 4, N. LOTUS.

a dozen blooms, all so charming and, as compared with the common forms of Crocus, so refined and pleasing. When neither Snowdrops nor Siberian Squills, the earliest of our outdoor bulbs, are yet in flower, it is something to be proud of to have this lovely Crocus flowering so beautifully, and with absolutely no trouble. Every good gardener should get a dozen pots of this bulb for the delight of his employers. Nothing could give less trouble, as the roots seem impatient of shifting, and will do well if kept from the worms, and provided with a slight top-dressing for two or three years in the same pots. A. D.

The American Summering Apple,—Your correspondent, Mr. Woodford, writing about this Apple, calls it a table Apple. I am inclined to think that the variety be knows can hardly be the same as the old American Summering, which has been grown here for fifty years, and which, although a useful early Apple, is only fit for cooking; even in that capacity

other day I saw fine specimens of it in the shrubbery borders, where it was supported by having old pollard heads to grow on, which the Jasminum had clothed completely, and was in full beauty. Planted, and left to itself, a more showy or elegant object could not well he imagined, as there was no stiffness, for every twiggy shoot was flowing out, and hanging down in the most natural and graceful manner, which quite arrested attention. Except on redbricked houses, the blossoms of this Jasmine do not show off to advantage, but in the borders referred to, with dark-leaved evergreens to back the plants up, the numerous flowers looked particularly bright, and were conspicuous from quite a long distance. 3. Sheppard.

Phylloxera Laws in the Netherlands, — The laws and regulations which are the result of the adhesion of the Government of the Netherlands to the Berne Phylloxera Convention of 1851 have been published and brought into execution. The adhesion was sanc-

tioned by the King of the Netherlands on December 6 last, and was published on December 21, 1883, in the Dutch Mackibdal, No. 178, and in the Dutch Staats and was published on December 21, 1883, No. 300. In the same number is to be found the law which authorises the execution by Royal decree, which was also published in the Staatsblad, No. 181, of the same date. The Royal decree setting forth the modeof execution of the law was executed by the King of the Netherlands on December 24 last, and was published on December 29 in the Staatsblad, No. 248, and in the Staats Courant of the same date, No. 306. The terms of this Royal decree are in general those of the Convention of Berne itself. In article 2 is set forth what can be sent free into and through the Netherlands without special formalities from those who sent them out—among them cut flowers, vegetables (fresh and dried), flower roots, seeds, and fruits of all kinds. By article 3 the introduction and transit of Vines is forbidden from countries where Phyllovera exists. Vines from countries not infested may be introduced by special permission of the Minister of Commerce and Industry. In article 5 the frontier offices through which living plants, &c., other than Vines, can be introduced under the proscribed formalities are stated to be:—Amsterdam, Rotterdam, Dordrecht, Flushing, and Harlingen, as well as sundry specified towns in the interior, with the railways at all the depôts. The method of packing and the necessary documents are those prescribed by the Convention, and which are not covered by the prescribed declarations, must be inspected by some of the experts designated by the Minister, at the cost of the receiver. Article 7 says that if the goods presented at the frontiers are not treated conformably to the foregoing article they will be destroyed. The experts have been appointed by the Minister, and everything is now done in this country to found infested by Phylloxera they will be destroyed. The experts have been appointed by the Minister, and everythin

Growing Hyacinths in Glasses — A New Method.—If anything can be said to be cruel in the vegetable world, it is to expect a spleodid sweet-scented Ityacinths-spike when the roots have to live on nothing but pure water. It is unnatural, and the surprise is the custom has existed so long. This year I resolved to try a different plan. I filled the Hyacinth glasses with drift sand, which contained a small fraction of vegetable refuse, but not enough either to decompose or produce any disagreeable odour. I poured on just as much cooled boiled water as the sand and some vegetable fibre could retain, leaving room for the bulb at the top. Boiling the water is necessary, as it renders it pure; and the glass not being porous, there is no evaporation, and no further water will be required for a long time. So far the result has astonished me. Instead of a puny delicate spike, long drooping foliage, and a flower-stalk unable to support the head, the blooms promise to be monsters, and to be at least second class again next year, and splendidly vigorous. W. T. Murphy, Clonmel.

wigorous. W. 7. Murphy, Clonmel.

Mr. Smith's Experiments on the Filtering Power of Sand.—I congratulate Mr. Smith upon having taken the trouble to put this matter to the test of actual experiment, for there is nothing so convincing as the logic of fact; but I cannot help feeling that if he will only continue his observations he will become before he has done with this subject as firm a believer in the value of Mr. Jensen's system of high-moulding as I am. Mr. Smith has prepared the proper apparatus for observing the faculty damp sand has of retaining the spores contained in water that is allowed to percolate through it, but he has fallen into an error in manipulation which has led him to form an incorrect conclusion. If, however, he will repeat his filtration experiment with the same glass cylinder, but instead of pouring the fluid a few drops at a time, he will find that with much less than 6 inches of sand every one of the spores will be retained in it. The best way to test the spore-retaining power of this column of sand is, after the tube has had the requisite quantity of sand placed in it, to pour a small quantity of water in first, and allow this to run through before the experiment is commenced. By doing this the uniform distribution of the sand is ensured for one thing, and the water which subsequently passes through drops out at the bottom clear and free from any muddiness for another. The intention of the experiment is to simulate what actually happens in a state of Nature, where it is obvious the first shower of rain consolidates the surface of the soil after it has been broken up by the spade of the gardener. This settling or consolidation of the land invariably takes

place in the Potato field, and therefore if we wish to produce the same effect in our experiment we must make some allowance for it. The important point, however, is to pour into the filter the water we are using slowly drop by drop, just as the rain falls. The quantity of water charged with Ustilago spores used by Mr. Smith was a teaspoonful. Of course teaspoons vary quantity of water charged with Ustilago spores used by Mr. Smith was a teaspoonful. Of course teaspoons vary in size, but it is generally considered that a teaspoon ful of water contains 60 minims. I find, however, that the average teaspoon holds double this quantity, namely, 120 minims ; 120 minims of water poured into a glass tube half an inch in diameter forms a column of water ruther more than 2 inches bigh, or about one-third the bulk of the filter-bed of sand employed by Mr. Smith in his experiment, which ran employed by Mr. Smith in his experiment, which ran employed by Mr. Smith in his experiment, which ran employed by Mr. Smith in his experiment, which ran alarge volume of water is poured upon such a comparatively small quantity of sand it is obvious that the tube would contain a pretty uniform mixture of sand, spores, and water. In Nature we never practically meet with such a circumstance—rain does not fall in sheets 2 inches thick, unless from a water-spout. On the contrary, it must be an extraordinarily heavy shower in which 1 inch of rain falls in an hour, so that to obtain a correct idea of what happens in Nature we must pour the water into our tube a few drops at a time just as the rain falls. One minim per minute ted fall into a half-inch tube evices 14 inch in the hour we must pour the water into our tube a few drops at a time just as the rain falls. One minim per minute let fall into a half-inch tube gives 1½ inch io the hour—an unprecedented rainfall, but one which is totally insufficient to wash Ustilago spores through 3 inches of sand; at least, so I find upon experiment. It may be suggested that water falling at this rate—a drop per minute—each drop will soak away as it falls upon the sand, and so have no chance of washing the spores through; but then it must be remembered the object of our experiment is, not to see if we can wash the through; but then it must be remembered the object of our experiment is, not to see if we can wash the spores through so much sand, but to represent what takes place in Nature. Mr. Smith suggests that while some of the spores may have been retained in the sand in his experiment they would only be there waiting for the next shower to wash them further down. But what happens to spores laid in damp situations? They certainly in the course of a few hours germinate, and as certainly verified for want of a more riddus to and as certainly perish for want of a proper pidus to grow in. Charles B. Plowright, 7, King Street, King's Lynn, Jan. 14.

Chrysanthemum Meg Merrilies. - My obchrysanthemum Meg Merrines, — My objections to this and certain other large loose flowered Japanese Chrysanthemums, made just at the end of the year, were so clearly meant to apply to them solely as show flowers, that I marvel that "Wild Rose" or any one else should assume that they were directed against them as ordinary winter flowers. There is no connection between the two things, There is no connection between the two things, because flowers grown for exhibition not only have a short existence, but have absolutely no fitness for long winter keeping; indeed for this latter purpose it is well to remove all the earlier, and of course stronger buds, and leave only the smaller and later ones to produce bloom at and after Christmas. Not only is Meg Merrilles good for this purpose, but so are Fair Maid of Guernsey, Ethel, Baronne de Prailly, and some others that are not of the first-class on the show table. Probably it is the general experience that the looser and least densely petalled flowers endure longest when grown for late blooming. X.

Bramble Shoots,-Lithospermum purpureo-Bramble Shoots,—Lithospermum purpureo-cecruleum,—We Cheshire farmers know only too well the habit the common Bramble has of root-ing at the ends of its long shoots, and that in shady damp places these roots begin to grow before the shoot touches the ground. If a brambley hedge is neglected for several years, a Blackberry copse, extending several yards into the field, is formed along it by this habit of the plant. But I am writing to draw attention to a precisely similar habit in a rare British herbaceous plant, I thespergrup purpurse consulern which is found on Lithospermum purpure-occurileum, which is found on heigh. This plant makes purjuh shoots of 2 feet or more in height, with thick terminal tufts of leaves, which in autumn form roots beneath them, even which in attumn form roots beneath them, even before the stalk bends over sufficiently for them to touch the ground, when they at once establish a new plant. The old herbaceous base lives, and grows up pagain, but the connecting stalk dies, and does not root from the leaf axils, it laid, as many stalks do. Somewhat analogous is the viviparous habit of Cardamine pratensis, which makes new plants from the shed lobes of the leaves. L. purpureo-corruleum is well worth cultivating if it can be persuaded to flower freely, the flowers being produced in large bunches, in colour darker than, but nearly as rich as those of the better known L. prostratum. I find it best to cut down the stalks at the end of summer, before the shoots root. C. Wolley Ded, Llandudno, Jan. 14.

Mildness of the Season .- As numerous in stances of the mildness of this remarkable winter are being recorded, perhaps the enclosed buds of Pears and blossom, taken from a standard tree in the gardens here, of Summer Franc Real, with spray of Laburnum in flower and leaf in the middle of January, Ladurium in Hower and leat in the middle of January, may be considered worthy of notice also. In taking a retrospective view of the season, it seems marvellous to think that Christmas has come and gone, and that we are in the middle of January with perpetual and other Roses still flowering on a continuation of last year's growth. It is much to be desired that a change to cold weather may set in soon,

obstruct that a change to cold weather may set in soon, otherwise hardy fruit blossom will stand a poor chance to set their fruits for the present year's crop. John Webster, Gordon Castle, Jan. 14.

—The Roses sent speak for themselves as to the mildness of the winter, even at this bracing place. Arthur Booky, Rose Villa Nurseries, High Harrosate, Jan. 14. [They were very sweet and nice. ED.]

Origin of the British Queen Pea.—I note the enquiry at p. 61 as to the above. The facts of the case are as follows:—About the year 1845 a gentleman in Jersey received a box of Ooions from Spalin, and amongst them were a few Peas scattered about in be box. Being exceptionally large he sawed them, and gave my grandfather (the late Mr. B. J. Saunders, of Jersey), the result of his first sowing. My grandfather thought very highly of the Pea, and grew it on until he had a fair stock, when he sold a quantity to Messrs. Lawson, of Edinburgh, and Messrs. Cormack, of New Cross, London, under the name of St. Peter's Marrow. Both these firms, however, sent the Pea out again under different names—Messrs. Lawson calling it Saunders' St. Helier's Marrow, and Messrs. Cormack selling it as British Queen, by which name it has since been best known. There is no doubt, however, that it has several names even now, and, like it has since been best known. There is no doubt, however, that it has several names even now, and, like many other really good things, it has been christened a good many times. Edmund A. Saunders, The Old Nurseries, Abergavenny. [The Messrs. Lawson, in the supplement to their Agriculturis' Manual, published 1842, mention St. Helier's Wrinkled Marrow as a new variety then, and no doubt it is the same variety as Mr. Saunders meotions. Ed.

Colonel Clarke's Celery.—If your correspondent, J. S.," will procure some seed of the Leicester Red "J. S.," will procure some seed of the Leicester Reed Celery (true), and will send me his address, I will send him a pinch of ours. He will find that they are not the same. How they became confused would eotail a curious story, which I do not choose to rake up. R. T. Clarke, Walton Place, Daventry. The varieties in question are frequently quoted as synonymous, on the strength of a trial at Chiswick a few years ago, and if this is erroneous it would be well if the matter were cleared up. Ed.]

Peports of Societies.

Edinburgh Botanical: Jan. 10.—William B. Boyd, President, in the chair. The Society met at 5. St. Andrew's Square. The following communications

Boyd, President, in the chair. The Society met at 5, St. Andrew's Square. The following communications were read:—

I. "Obituary Notice of the late Professor Oswald Heer, Honorary Fellow," by Andrew Taylor.

II. "On the Common Lupin as a Fodder Plant in Orkney," by William Traill, Esq., M.D., of Woodwick, St. Andrew's. Mr. Taylor read the following letter from Dr. Traill:—

"When taking a walk last September, about a mile to the eastward of the Manse of Sandwick, in the west mainland of Orkney, I was a good deal surprised to come upon a large quantity of the common blue Lupin of our gardens—Lupinus perennis, I believe; about 3 acres of ground were thickly covered with it, but scattered plants extended to a much greater distance; the plants were 2 or 3 feet high, and most of them were covered with ripe seeds; the soil they grew in appeared a thin yellowish loam, mixed with small angular pieces of flagstone, and partially covered with tufts of Heather. On inquiry I found that it was known that the plant had secaped from a garden in the neighbourhood a good many years ago. I observed that in parts where it had been long growing, the tufts of Heather had disappeared, and were replaced by a thin covering of grass. I understand that cattle are partial to this plant, and I observed a cow eagerly cropping it while I was there. I believe this is not the only instance of the Lupin becoming naturalised in Scotland, but it appeared to me to be sufficiently interesting to bring to the notice of the Society, more especially as it seems to be a useful kind of fodder to introduce on waste ground, where hardly anything else will grow."

else will grow,"

III. "Report on Temperature and Vegetation in the
Garden of the Royal Botanic Institution of Glasgow,
from August to December, 1883," by Mr. Robert Bullen,

Curator, August—The highest readings of the thermometer in the shade were 68° on the 3d and 25th respectively. The night temperature varied from 4° to 55° . The fine weather experienced during the early part of the month caused active growth amongst outdoor plants generally. Herbaccous plants, which up to this time were from two to three weeks behind their usual blooming season, now rapidly developed bloom. Heavy rains began to fall

about the middle of the month, and the weather continued more or less broken to the end,

tinued more or less broken to the end.

September.—The highest day temperature was 67°, on
the 3d; the lowest night temperature 32°, on the 30th.
The lowest reading for September last year was 31°,
during the night of the 29th. This month may be characterised as having been most unfavourable for outdoor
operations; rain fell heavily on fourteen days, and although
the average temperature compares favourably with the same
month last year, the excessive moisture and consequent
dull weather presented the timening of many annual and

the average temperature compares favourably with the same month hast year, the excessive moisture and consequent dull weather prevented the ripening of many annual and other seeds which are usually gathered in the garden. The blooming season of both herbaceous plants and annuals was a prolonged on the processing the month were 32°, on the ment were 32°, on the garden. The lowest temperature registered during the month were 32°, on the 2nd; the highest 63°, on the contract of the month; this, taken together with the dull, moist weather which prevailed, prolonged the fall of the leaf considerably, and in some cases caused a second or primitive growth; this was especially so with Rhododendrous which had falled to set bloom-buds. The season is open and favourable for transplanting operations. November.—The highest day temperatures recorded during the month were 49° on the 1st, 2d, and 4th, and 52° on the 3d, and 47°, 48°, and 50° on the 28th, and 24°, or 8° of frost, on the night of the 1st hand 13th, or 11° of frost each night, and 24°, or 8° of frost, on the night of the 1st hand to the 1st hand to the contract of the first week of the month until within the last four or five days the weather has been exceedingly unsettled, and transplanting operations had to be entirely suspended.

teen times, and the total of frost recorded 53\(^2\), or 8\(^2\) less than the total for November last year, when the frost was more continuous, but never below \(^2\) at any time. Since the first week of the month until within the last four or five days the weather has been exceedingly unsettled, and transplanting operations had to be entirely suspended, owing to the frequent and shed vote in dry or slightly frosty weather if due care be taken when filling in the soil to keep the frozen portions on the surface. The dense fog which enveloped this district on the 12th and 13th proved fatal to a number of immature buds of various tender flowering plants.

December—The May-like weather which was experienced showed its effects on most of the hardy and early forms of vegetation, causing the buds of decidious shrubs to swell and premature & the surface of the form of the form of the hardy and early forms of vegetation, causing the buds of decidious shrubs to swell and premature & the surface of the form of the hardy and early forms of vegetation, causing the buds of decidious shrubs to swell and premature & the surface of the hardy and early forms of vegetation, easing the buds of decidious shrubs to swell and premature & the surface of the hardy and early to the surface of the

Notwithstanding the extreme mildness of the season none of the spring flowering plants, whose dates of flowering are annually recorded to this Society are yet in bloom, with the exception of Tussilago fragrans, which opened on December 26 this season, and on January 15 last season; and Dondia epipacits, which began to flower on December 29 this season, and on Pebruary 6 last season; both of these plants, however, are somewhat erratic in their time of flowering, and ought to be struck off the list of spring flowering plants. The Snowdrop, the winter Aconite and Crocus are fast pushing up above ground; but it will be some time, even should the present favourable weather continue, before they are in flower. The Snowdrop opened on January 25 last season, and the winter Aconite on the 27th. To all appearance they will be no earlier this essason. Daphne Mezerceum and Rbododendron attravirens have frequently been in flower by the end of the Notwithstanding the extreme mildness of the season

year; this season they are only in bud. What we have in a remarkable degree this season is a large number of summer and autumn blooming plants with theher they for flowering profitoes of the midness of the season are very conspicuous in the case of the Bay Laurel, which have flower-buds already advanced, the usual time of flowering being April and May; also Ribes sanguineum with much swollen leaf-buds; Roses with young shoots 2 to 4 inches in length. Amongst herbaceous plants, Ferulas, Heracleum, Orobus, and Sisyrinchium are well stard into growth.

The severe storm of wind of December 11 and 12.

Interaction, Olious, and issyntantial and 12, which did so much damage throughout the country, passed over fortunately without doing the slightest damage in the garden.

On the rock garden eight species came into flower duning the month of December, viz., Andromeda floribunda, Helleborns niger angustifolius, H. abschasicus, H. purpurascens, Dondia epipacuis, Hepatica angulosa, Primula denticulata, P. platypetala, making a total for the past year of 905 species and well-marked varieties. Since the New Year came in the thermometer has been ntwo mornings below the freezing point: on the 1st, 1° of frost, and on the 4th, 9°. The following fitty-three species of plants in flower were gathered out-of-doors in the garden to-day, viz.:—

Alnus glutinosa Alchemilla conjuncta Alchemilla conjuocta Arabis procurreos Aster Reevesii Aubrietia deltoidea Calluoa vulgaris varieties Capsella bursa-pastoris Cheiranthus Cheiri Chrysaothemum sincose Corylus Avellana Erica herbacea alba n, hyberoica Garrya elliptica Geum aureum n, coccioeum

Nepenthes, as compared with that in the admit plant, VI. Miscellaneous communications: ——

1. Mr. Patrick Geddes, on behalf of A. G. More, Esq., Dublin, exhibited and presented to the Royal Botanic Garden a living plant of Selaginella lepidophylla.

2. Mr. George L. Brown exhibited a flower of Tritleia uniflora, obtained that day from his garden, Millburn House, Morningeide.

3. Mr. A. B. Heert sent a living plant of a fine dark form of Primula scaulis.

Manchester Horticultural Improvement: Manchester Horticultural Improvement: 7an. 10.—At the fortnightly meeting, beld in the Old Town Hall, on the above date, Mr. Eruce Findlay in the chair, Mr. F. Robinson read a paper on the Tulip. After alluding to the well-known history of the plant, and the enormous prices formerly paid for them, Mr. Robinson said that as late as the year 1854 Mr. Groom, of Clapham, catalogued show Tulips at enormous prices; Duchess of Cambridge, Princes Mary of Cambridge, and Miss Eliza Seymour, were sold at 100 guiness each; others at fifty, twenty-one, and ten

Mary of Cambridge, and Miss Eliza Seymour, were soid at rog guineas each; others at fifty, twenty-one, and ten guineas per bulb. In the following year, 1855, the whole of Mr. Groom's collection, which consisted of over 200,000 bulbs, was sold by auction, as they stood in the rows, at very low prices, and from this time the Tulip, as a show flower, declined in the public favour at a rapid

rate. Mr. Robinson described the different sections of the late or show-blooming varieties, viz., bizarres, byblemens, roses, and breeders, the three first being again divided into the feathered and flamed forms. The soil needed, the planting time, and the treatment were fully and clearly stated; and he next passed on to the early blooming the planting time, and the treatment were fully and clearly stated; and he next passed on to the early blooming sorts—those mostly used for the decoration of our greenhouses and conservatories, as well to the broad stretches of beds to be seen in the spring in public parks and private gardens, where they are grown in masses in the flower beds. An approximate estimate of the numbers sent from Helland approximate for the therefore services the conditions of the leading services. vate gardens, where they are grown in masses in the flower beds. An approximate estimate of the numbers sent from Holland annually of a few of the leading sorts would be about as follows:—Scarlet Due van Thol, 800,000; White Pottebakker, 300,000; Golden Prince, 500,000; White Queen Victoria, 500,000; and Thomas Moore, 100,000. The total number of flowering bulbs of the Tulip yearly exported by the Datch florists amounts to over a thorogonal to a warrier of vallet of the training of the training only about one-tenth the value of a new Hyacinth. The reason for this difference is that it would take fifty years to get up a stock large enough to send out; while with a Hyacinth, which multiplies rapidly, the same results could be produced in ten years.

In the discussion which followed much light was thrown upon the manner in which the new bulbs were reproduced. For in planting the bulbs in autumn and growth taking place in the spring the flower-stem is plainly observed rising from the centre of the bulb, but when the bulbs are taken up after flower the flower-stem is on the outside of the one taken from the ground. A process has gone on all through the growing season by

which the nutriment first taken up by the roots and passed through the leaves, and receiving fresh naterial from the air, is again passed down the leaves and deposited at the base of the flower-stem, and gradually built up into a new flowering bulb for the following season. Mr. G. Lunt, Mr. Astley, Mr. Tait, Mr. Findlay, and the Hon. Secretary (Mr. W. Swan) took part in the discussion.

It was announced that Mr. B. Findlay would give his paper on the next meeting night, January 24; subject, "A plant: what is it?"

Scottish Hortlcultural Association. Scottish Hortleultural Association. — The ordinary monthly meeting of this Association was held in the Hall, 5, St. Andrew's Square, on Tuesday, the 8th inst., Mr. R. Munro, President, in the chair. Dr. J. M. Macfariane, of the Royal Botanic Garden, lectured on "The changes occurring in the ovule after pollination." His remarks were illustrated by a series of diagrams. Mr. Adam Renton, Lees, Coldstream, exhibited Renton's Monarch Leek, Meesrs, Dicksons & Co. exhibited a plant in flower of Saxifraga Burserian major; and Mr. T. S. Ware, London, eshibited flowers of Narcissus monophyllus and Lachenalia pendula.

London: Atmospheric Pressure.—During the week ending January 12, the reading of the barometer at the level of the sea decreased from 29.87 inches at the beginning of the week to 29.80 inches by 3 P.M. on the 6th, increased to 29.95 inches by 9 P.M. on the 7th, decreased to 39.97 inches by 3 P.M. on the 8th, decreased to 39.97 inches by 3 P.M. on the same day, increased to 30.43 inches by 3 P.M. and decreased to 30.42 inches by 9 M.M. on the 11th, decreased to 30.42 inches by 9 A.M. on the 11th, decreased to 30.42 inches by 9 A.M. on the 11th, and was 30.46 inches by the end of the week.

The mean reading of the barometer for the week was 30.18 inches, being the same as last week, and 0.27 inch above the average of the week.

Temperature. - The highest temperature in the shade in the week was 51°,3, on the roth; the highest reached on the 12th was 42°,5. The mean of the seven high day temperatures was 47°,7. The lowest temperature was 35°, on the 12th; on the 6th the lowest temperature was 45°. The

on the 6th the lowest temperature was 45°. The mean of the seven low night temperature was 39°.7.

The greatest range of temperature in one day was 9.5°, on January 8°; and the smallest was 5°.5 on the 7th. The mean of the seven daily ranges the 7th.

was 8°.

The mean temperatures were — on January 6, 48°; on the 7th, 43°.6; on the 8th, 41°.5; on the 9th, 46°.6; on the 10th, 46°.6; on the 11th, 41°.6; and on the 12th, 38°.6; and these were all above their averages by 11°.6, 7°.3, 5°.3, 10°.4, 10°.3, 5°.3, and 2°.2, respectively.

The mean temperature was 43°.8, being 2°.8 higher than last week, and 7°.5 above the average of the week.

The highest reading of a thermometer with

blackened hulb in vacuo placed in the full rays of the sun was 74° , on the 11th. The mean of the seven readings was $62^{\circ}.4$.

The lowest reading of a minimum thermometer placed on grass and fully exposed to the sky was 28°, on January 12. The mean of the seven readings was

Rain .- Rain fell on three days to the amount of

ENGLAND : Temperature, - During the week ending ENGLAND: Temperature,—During the week ending January 12 the highest temperatures were 56° at Truto, 54° at Plymouth and Leeds; the highest at Brighton was 50°.3; and at Bristol and Leicester 51°. The general mean was 52°.4.

The lowest temperatures in the week were 33°.2 at Wolverhampton, 34° at Prighton, 34°.8 at Cambridge; the lowest at Truto was 42°, at Plymouth 38°.8, and at Liverpool, 38°.5. The general mean was 36°.1.

The greatest ranges in the week were 18°.7 at Wolverhampton, 18° at Sheffield, Leeds, and Sunderland; the smallest ranges were 13°.5 at Preston, 14° at Liverpool, and 15°.2 at Plymouth. The general mean was 16°.3.

mean was 16°.3.

The mean of the seven high day temperatures was

highest at Truro, 52°.7, at Plymouth 51°.5, at Leeds 49°.9; and was lowest at Bolton, 46°.3, at Brighton 47°, and at Leicester 47°.2. The general mean was

48°.8. The mean of the seven low night temperatures was highest at Truro, 45°.4, at Plymouth, 43°.5, at Liverpool 42°.8; and was lowest at Wolverhampton, 38°.1, at Brighton 39°.2, and at Sunderland 39°.4. The general mean was 41°.1. The mean daily range of temperature was highest at Wolverhampton, 10°.7, at Sunderland 9°.3, at Scheffield 8°.8; and was least at Liverpool, 5°.6, and at Bolton and Preston 6°.2. The general mean was 2°.7.

was 7°.7.

The mean temperature was highest at Truro, 48°.8,

The mean temperature was highest at Truro, 48°.8, at Plymouth 47°.3, at Leeds 45°.9; and was lowest at Erighton, 43°.9, at Bolton 43°, and at Wolverhampton 43°.2. The general mean was 44°.8. Rain.—The largest fall was 1.09 inch at Bolton, 0.62 inch at Preston, 0.53 inch at Plymouth; the smallest falls were 0.04 inch at Truro, 0.13 inch at Leicester, and 0.14 inch at Cambridge. The general mean fall was 0.36 inch.

SCOTLAND: Temperature,—During the week ending January 12, the highest temperature was \$4\cap21\$, at Leith; at Paisley the highest in the week was \$4\cap3\$. The general mean was \$2\cap2\$. The general mean was \$2\cap2\$. The week was 32\cap3\$, at Edinburgh and Perth; at Glasgow the lowest temperature was 36\cap3\$. The general mean was 33\cap3\$. The general mean was 33\cap3\$. The mean temperature was highest at Glasgow, 44\cap3\$, and lowest at Perth, 42\cap3\$. The general mean sas 33\cap3\$.

Kain.—The largest fall was 2.17 inches, at Greenock; and the smallest fall was 0.20 inch, at Dundee. The general mean fall was 0.8\cap3\$ inch.

JAMES GLAISHER, F.R.S.

JAMES GLAISHER, F.R.S.

Obituary.

An inquest was held at Carshalton, on the 9th inst., on the body of JAMES SLOPER, aged fifty-seven, who had been head gardener to the Rev. Dr. Barrett, D.D., Carshalton House School, for the last twenty-six years. Between three and four years ago he became subject to delusions, and his conduct became so alarming that at last a certificate was obtained from two medical men that he was insane, with a view to having him removed to a lunatic asylum; but, the Rector of the parish refusing to sign the certificate, it could not be acted upon. On Saturday morning he was missing when wanted, and a search being instituted his body was found hanging in an Apple-room, his feet being about 2 inches from the floor. The jury returned a verdict that "The deceased committed suicide while in a fit of temporary insanity."

Variorum.

THE PHYLLONERA LAWS .- While we are suffering THE PHYLLONERA LAWS.—While we are suffering from Cabbage worms. Pea weevils, Codling moths, and what not, imported from the Old World, it is strange that the old folks should kick up like this—and so absurdly too. The Phylloxera is already in Europe, in myriad millions, and far more likely to spread by intercourse among each other, than by anything they may get from us. And England too, a party to this farce! A country which has Phylloxera in almost every Grape border—which raises "hothouse Vines" in almost every nursery—and which hopes, of course, to do a good deal of "shopping" with her associates. America could live and prosper without any of these countries, and might very well afford to shut out all importations of every well afford to shut out all importations of every

description from abroad. It could afford to retaliate by just such a regulation. But she has the good sense to know that she cannot get any good at all without the risk of some attendant evil, and is perfectly willing to take the evil with the good, and trust to human knowledge and human progress to improve the good and conquer the bad. It is to be hoped, for the sake of common sense in human nature chiefly, that the contracting parties will see soon how silly they have acted. Common senses, however, does not seem to be a very common article among the rulers of the Old World. Republics make mistakes sometimes, but these asinine exhibits of the Old-World folks must be a source of comfort to those who have faith in popular self-rule. American Garwho have faith in popular self-rule. American Gardeners' Monthly.

Answers to Correspondents.

APPLES: IV. M. Seedling No. 1: fruit large, hand-some; deserving of further trial. Seedling No. 2 resembles Bedfordshire Foundling; very distinct from the Ribston Pippin. The Cat's-head is a well known useful sort.

ARGENTINE REPUBLIC: R. O. Apply to the Minister in London, Dr. Don Manuel R. Garcia, 15A, Clifford Street, Bond Street, W.

tGNONIA RADICANS: F. This is propagated in the nurseries by grafting on root-cuttings of Catalpa. BIGNONIA RADICANS: F.

CAVIES AS FOOD: H. E. W. Not quite suitable to

Our columns.

ERGOT ON GRASSES: G. C. Y. If Ergot is sown with Grass seed the Grass produced is not likely to injure animals unless ergotted; but the strong probabilities are that if the two are sown together the Grass will be ergotted. Whether planted with Grass seed or kept in hay, the Ergots are capable of producing new Ergots in the following summer. Ergots do not rot in the soil, but rest in a hibernating living state all through the winter and spring. At the time when Grasses are in flower in the following summer the Ergots burst on the ground and produce a fungus, and this fungus bears spores or seeds; the spores blow on to the Grass flowers, and at once produce new Ergots. It is obvious, therefore, that a good plan for the prevention of Ergot in notoriously ergotted districts is to flowering; the spores will then have no Grass flowers to light on. W. G. S.

to light on. W. G. S.
FLAS IN COTTAGE: 7, C. We think if the place
could be treated with burning sulphur, at twice, with
an interval of two or three days, so as to allow of the
eggs, which will not be destroyed by it, to hatch out,
the insects secreted in walls, ceilings, &c., might be
got rid of. If the carpets, bedding, &c., could be
beaten in the open air, and such things as would not
be injured by the fumes of sulphur might also undergo
the process of disinfection. Floors and other woodwork in the building could be washed with a strong solution of Gishnert Compound, or with water and paraffin,
several times at intervals. Pyrethrum (Persian Insectpowder) could be used in bedding, and the like, until
the insects were exterminated.

Fungi: J. J. & S. The Agaries sent appear to belong to Agarieus rachodes; considered edible when fresh, but not so when in the last stages of putridity.

IFSh, Dik HORSAL: "A. Y. Yours is not the scarce edition, and is worth, perhaps, a sovereign. You can send it to us at that price.

KILLARNEY FERN: A. M. If 2 feet in diameter, and well grown, it should be worth about 7 guineas.

well grown, it should be worth about 7 guineas.

MYRTLE: William Foster. The ternate growth of foliage is obtained by stooling old plants, as the Willow is treated when grown for basket Osiera. The plants are best cut over in early spring; got to break in an intermediate-house, and pushed on by liberal treatment, so as to get a rapid elongated growth of shoots from 1 foot to 2½ feet in length. As soon as it is seen which are likely to be the best of these, the weaker one must be cut away. The plants will make good stout growth out-of-doors during July, August, and part of September. In October they are required to be ready. Under this treatment most of the shoots produce ternate leaves, although not all. Such shoots as the Jews will not by come in useful for wreaths and bonquet work in winter.

SEEDS.

LONDON: Jan, 16 .- There is now a fair demand for farm seeds. French and American red Clover seed is held at full rates; samples of new home-grown come forward pretty freely; for choice qualities there is a steady sale, but indifferent parcels are neglected. Alsike and white keep firm. There is not much doing at present in either perennial or Italian Rye-grasses. More money is asked for Tares. Some wrinkled Peas are now offering at exceptionally low rates. Canary seed is steady. In Hemp seed the tendency is downwards. Feeding Linseed is without change. Some fine new Haricot Beans are obtainable at very reasonable figures. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, B.C.

CORN.

At Mark Lane on Monday English Wheat showed fully 1s, per quarter decline on the limited business effected. Foreign Wheat was offered freely at the reduction, but in some cases a larger decline was accepted to effect sales. Flour was quoted 6d, to 1s. lower on the week. Barley was firm, and rather dearer; Beans and Peas in limited demand, and rather cheaper. Maize with a slow sale was quoted 3d. under Monday se'noight. Oats moved off slowly without appreciable change in value.—On Wednesday Wheat and flour found flat markets, with an adverse tendency in prices. For Maize markets, with an adverse tendency in prices. For Maize the demand was slack. Earley was steady, but not active. Beans and Peas remained unaltered, and Oats steady, but with slow sales—Average prices of corn for the week ending Jan. 12:—Wheat, 38s. 9d.; Barley, 32s. 1d.; Oats, 19s. 4d. For the corresponding period last year:—Wheat, 40s.; Barley, 32s. 3d.; Oats, 2d. 2d.

CATTLE.

At the Metropolitan Market on Monday the cattle supplies were fully adequate to the demand, which was slow. The number of sheep was large, and from their prime condition the weight of mutton was more considerable. The trade was extremely dull, and prices ruled] lower. Prime calves were scarce and pigs met little demand. Quotations:—Beasts, 4.4d. to 54. 54., and 55. 8d. to 66.; calves, 55. to 55. 8d.; sheep, 55. 4d., on 75. mad 5. 4d. to 55. to 75. ad 75

HAY.

Tuesday's Whitechapel Market report states that supplies were large and trade dull, especially for meadow hay. Quotations: — Prime old Clover, 95s. to 108s.; inferior, 60s. to 75s.; prime second cut, 90s. to 105s.; best meadow hay, 80s. to 86s.; inferior, 40s. to 65s.; and straw, 28s. to 36s. per load.—On Thursday there was a fair supply. The trade was queet, without alteration. — Cumberland Market quotations: — Superior meadow hay, 78s. to 9ss.; inferior, 60s. to 7ss.; superior Clover, 10s. to 11ss.; inferior, 7ss. to 88s.; and straw, 33s. to 38s. per load.

POTATOS.

The Borough and Spitalfields Markets reports state that a large supply was on offer. The trade was slow, at the following quotations:—Magnum Bonums, 90: to 100:, Regents, 80:. to 100:, Champions, 60:, to 80:; Victorias, 80:, to 90:, per ton; German Reds, 3:. to 4:, per bag.

COALS.

The following are the prices current at market during the week:—Walls End—Hetton, 175.; Hetton Lyons, 15s. 6d.; Lambton, 16s. 6d.; Wenr, 15s. 6d.; Hulam, 16s.; East Hardepool, 16s. 3d.; South Hardlepool, 15s. 9d.; Thornley, 16s. 3d.

Government Stock.—Consols closed on Monday, Tuesday, and Wednesday at 101½ to 101½ for delivery, and 101½ to 101½ for the account.—Thursday's final quo-tations were as on the other days for delivery, but at 101½ to 101½ for the account.

Special Trade Offer.

FAST LOTHIAN STOCK.—Purple, White, Scarlet, and Crimson. Very select. Saved in East Lothian. Price per ounce on application. WILLIAM HIGLIS, General Seed Merchant, Kelso, N.B.

TILLUM HARRISI.—A pure white Lily, of the style of Lilium loogiflorum, but perfectly distinct from that species. In length it equals and in refinement surpasses the true Lilium eximium. The exceptional beauty of its form recalls Lilium Wilsoni, but it infinitely exceeds that variety in its tractability under cultivation, extraordinary vitality, and freedom of propagation. Its foliage recalls a Dracena, and in this respect it diverges widely from the family of Lilium longiflorum. We have no bestiation in calling this the QUEEN OF LILIES.

QUEEN OF LILIES.

As a pot plant we regard it as the most valuable introduction of late years, and we may safely predict that it is destined to a popularity at least equal to that of Lilium auratum. It is a grand acquisition for trade growers, as it propagates itself with great freedom and rapidity, and the times builts will generally bloom. We offer good builts of the true variety at The Trade supplied on special terms.

THE AMERICAN GARDEN

IS A RICHLY ILLUSTRATED, ELEGANTLY PRINTED, AND CAREFULLY GOTTEN-UP MONTHLY PUB-LICATION DEVOTED TO THE GARDEN-ING INTERESTS OF AMERICA.

EDITED BY DR. F. M. HEXAMER. To any one who owns a Flower-Pot, a Garden, or a Farm, It is Indispensable,

because it gives all the latest and best information about every-thing pertaining to the culture of Flowers, Fruits, Vegetables, the care and alwige-out of Lawns and Pleasure Grounds, Window Gardening, Rural Improvements, and all kindred subjects. Its Reliable, because its Editor and Contributors are all experienced Horti-culturists, who write from actual experience and can prove the correctness of their teachings.

culturists, who write from actual experience and can prove the correctness of their teachings.

It is always Seasonable, because it forestalls its readers' wants by giving in every issue practical seasonable hints for the work of the month, which alone are worth more than the price of the paper.

It is Clean and Pure, because an opper is more carefully scrutinised before it meets the eyes of its readers, and because all objectionable and quack medicine advertisements, as well as everything that could in the least offend the most repending the country scrutined.

From times a proper season of the properties of the properties of the properties a beautiful coloured floral picture, and may take his choice of any one of the many valuable articles offered in our Premium List-either Seeds, Plants, Books, or Implements.

Sold at 1s. 19st. and 2s. 9st. per box.

HOLLOWAY'S PILLS — Liver Complaints and Disorders of the Bowels—It is impossible to exaggerate the extraordinary virtue of this medicine in the treatment of all affections of the Liver or irregularities of the Esowels. In cases of depraved or superabundant Bile, these Pills taken freely have never been known to fail. In Bowel complaints they are equally efficacious, though they should then be taken rather more sparingly, for every medicine in the form of an aperient requires caution when the bowels are disordered, and aperient requires caution when the bowels are disordered, these Pills, in moderate doses, has never yet been discovered. If taken according to the printed instructions, they not only cure the complaint, but improve the whole system.

L beginest sincerely to thank all those Members of and Subscribers to the above lositime, who so kindly RECORDED STATES IN MY FAVOUR AT THE LAST ELECTION, thereby enabling me to be placed on the Pennion List, which will ever be gratefully remembered by their obedient servant,

their obedient servant,

Thomas Pierpoint, Deceased,
Parsuant to an Act of Parliament, 2nd and 32d Vic, cap, 35, intituled "An Act to further amend the Law of Property and to Relieve Trustees,"

NOTICE IS HEREBY GIVEN, that all CREDITORS and other PERSONS baving any CLAIMS or DEMAND'S against the Estate of THOMAS PIERPOINT, late of Stockness and the Estate of THOMAS PIERPOINT, late of Stockness Street, Warrington, in the County of Lancaster, Seedsman and Bread-baker, deceased (who died on October 19, 1893, and Administration of whose Personal Estate and Effects was on December 3, 1893, granted by the District Registry at Chester, attached to the Southern County of Lancaster, Seedsman, a Creditor of the Deceased, are hereby required to send the Particulars in Writing of their County of Lancaster, Seedsman, a Creditor of the Deceased, are hereby required to send the Particulars in Writing of their Chims or Demands to us, the undersigned, the Solicitors for the add Administration on or before of the Solicitors for the Assets of the said Deceased among the persons entitled thereto, having regard only to the Claims and Demands of the Assets of the said Deceased or any part theor Demands be also person han drotte, and he will not be Labbe for the Assets of the said Deceased, or any part theor of Demands be also person han drotte.—Dated January, 1844.

Warrington, Solicitors HAMED AND KIRKCONNEL, Warrington, Solicitors the Administrator.

solihull, 1st January, 1884.

Gentlemen,

I beg leave to inform you that I have this day Sold the Business of a Nurseryman and Seedsman hitherto carried on by me at Solihull and Birmingham to

Messrs. C. W. FALCON & J. F. L. EVANS, by whom the Business will in future be carried on, under the Firm of

"THOMAS HEWITT & CO."

The new Firm have authority to receive on my behalf all Debts due to me to date. Yours obediently,

THOMAS HEWITT.

LILIUM HARRISII.—A pure white Lily, of the style of Lilium longiflorum, but perfectly distinct from that species. It length it equals and in refinement surform recells Islaim Wilson's but it infinitely exceeds that variety in its tractability under cultivation, extraordinary vitality, and freedom of propagation. Its foliage recalls a Dracana, and in this respect it diverges widely from the family of Lilium longiflorum. We have no hesitation in calling this the QUEEN OF LILIES.

As a pot plant we regard it as the most valuable introduction of late years, and we may safety for the control of the years, and we may safety for the propagates itself with great freedom and rapidity, and the tiniest bulbs will generally bloom. We offer good bulbs of the true variety at 2s. each, 15s. per dozen, 12s0. per 10s.

SCHOOL GARDENS.

A MONG the various plans proposed by which the youth of our country districts might be induced to take an efficient interest in the cultivation and raising of fruit trees, that of getting the village schoolmasters to teach them the various arts and practices of fruit-culture deserves particular notice on the part of those interested in country pursuits, and who by their social position can initiate and give support to any efforts tending in the direction indicated. The main difficulty will be to find the necessary amount of knowledge and manual skill in the teacher, another will consist, in towns certainly, in the acquisition of a piece of suitable ground in which the various practices of the art can be carried on with living plants. There will be no want of aptness or of interest in the scholars for the appropriateness and usefulness of the matter taught will appeal far more forcibly to the mind of the average schoolboy born and bred in the country than will lessons in parsing or masses of chronological dates and other equally, for him, useless instruction. In those points in which the schoolmaster might find himself deficient in the knowledge required to be imparted, he might generally rely on the assistance of some good neighbouring gardener or nurseryman for lessons himself, and for occasional help in the work of instructing the scholars also.

There seems to be a great desire to make our country, in the matter of fruit production, as independent of the foreign grower as the nature of our climate and the vicissitudes of the seasons will allow, so that if at the present time any impetus to this end could be given, it would meet with cheerful response from nearly all classes of the community.

We have frequently questioned country folk as to the reason so few fruits are to be met with in cottage gardens and fields, and the reply has nearly always been in substance the insecurity or uncertainty of the tenure, and consequently the disinclination to be at any expense to plant fruit trees for others probably to gather the fruits. This, it will be seen, implies the supposed necessity for purchasing trees from the nurseryman; but were the men acquainted with the various methods of raising from seed the Crab, Pear, Cherry, and Plum, and the Quince from layers, and the Doucin or Paradise, or even the Codlins, from cuttings, on which to graft or bud, this objection to plant on the score of the expense would fall away, and planting having become common, the householder or cotter would find fruit trees in every garden to which he might remove.

Although in some cases no doubt people would like to raise their own stocks, or would find them in woods and open spaces, the demand that would arise for such items would be sure to be met by persons making a special business of stock growing, and who would be able to raise them in great numbers and sell them in small ones at a cheap price. Still, the teacher should instruct the boy how to raise such things for themselves, so that whether they stay at home or emigrate to our colonies, they would know how to set to work with a few ounces or pounds of fruit tree seeds and kernels. Instruction should also be imparted by the master in the art of making cuttings and layers of Gooseberries, Currants, Figs, and Filberts, the latter method being inculcated as the only one by which success is assured in all cases. These operations should always take place at the proper season, this alone forming a most essential part of the matter taught. A knowledge of good sorts of fruits, and of the correct way of spelling their names, would be quite as useful as lists of the Jewish Kings, and could be just as easily acquired, it short and judiciously selected, with reference to locality and usefulness in their several classes of culinary and dessert, preference being given to those that are good for

The stock in trade, so to speak, of the schoolmaster, need not necessarily be extensive. A few dozen fruit-tree stocks of the right agegrafts that can be had from the leading gardens of the locality, and cuttings of bush fruit that are obtainable almost everywhere, would include almost all of it. Of course, if a garden is already in existence, there will be fewer hindrances to making a good start at any time, and presumably the means at hand for every purpose. This is a matter we have often urged upon the attention of managers of local horticultural shows, who, by organising instruction of this character in the cultivation of fruits and vegetables, diffusing a knowledge of the sorts best adapted for particular localities and the like, would do more real good than by exhibitions at remote intervals, though obviously the two plans might well be worked in concert. With our rising generation of country lads in possession of some such useful rural knowledge and deftness in manipulation, there would be small reason to complain of the scarcity of fruits in any part of the country in a few years. The propagation of sorts and proper ways of planting are the main things that demand attention; training, pruning, &c., could be acquired later, either with the aid of peripatetic lecturers, as is done in Germany, France, and Belgium, or through cheap pamphlets, like Paxton's Calendar, treating of these and other rural subjects.

COUNT RUMFORD. - In the north - easterly environs of Munich a wild neglected region of forest and marsh, which had formerly been the hunting ground of the Elector, was converted by Thomp-son (afterwards Count Rumford) into an "English garden." Pleasure grounds, parks, and fields were laid out, and surrounded by a drive 6 miles long; walks, promenades, grottos, a Chinese pagoda, a racecourse, and other attractions were introduced; a lake was formed, and a mound raised, while a refreshment saloon, handsomely furnished, provided for the creature comforts of the visitors. Here during Thompson's absence in England in 1795, and without his knowledge, a monument was raised to commemorate his beneficent achievements. It stands within the garden, and is composed of Bavarian freestone and marble. It is quadrangular, its two opposite fronts being ornamented with bassorelievos, and hearing inscriptions. The wanderer on one side is exhorted to halt while thankfulness strengthens his enjoyment. "A creative hint from Carl Theodore, seized upon with spirit, feeling, and love, by the friend of man, Rumford, has ennobled into what thou now seest around thee, this once desert region." On the other side of the monument is a dedication to "Him who eradicated the most scandalous of public evils, Idleness and Mendicity; who gave the poor help, occupation, and morals, and to the youth of the Fatherland so many schools of culture. Go wanderer! try to emulate him in thought and deed, and us in gratitude." From Professor Tyndall's Lecture on Count Rumford before the Royal Institution.

NATURE-PRINTED POTTERY.

MESSRS, DOULTON & Co. have recently introduced a variety of their well-known art stoneware, in which the method of nature-printing forms the chief decoration. The ware is designated "Doulton Repousée-ware," and is produced in the following manner:—The vase, flower-pot, or other article, is formed on the potter's wheel in the usual way, and sent to the designer in the soft state. It is at this time so plastic that the slightest pressure produces an indentation, and the most delicate lines can be impressed upon its surface. The designer, placing the soft vase upon a suitable stand, proceeds to impress upon its exterior the fresh leaves or blossoms which he has before him, according to his taste. The condition of the clay causes the leaves to adhere closely to the form in whatever position they are placed. The artist next covers the whole surface of the vase with a thin coating of some coloured clay, which can be varied at pleasure. As soon as the surface is slightly hardened the leaves can be removed, leaving their most delicate markings faithfully reproduced on the vase itself. While the vase is still soft the designer, putting his tool or finger within its mouth, pushes out the walls of the

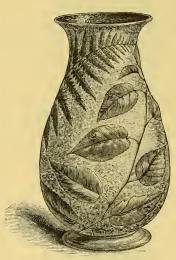

FIG. 18.-THE NATURE-PRINTED VASE.

vase in such a way as to emphasise the forms of the various leaves, and thus add to their artistic effect. Being first allowed to dry thoroughly, the various articles thus decorated are ext coloured by hand in a suitable manner, and lastly fired in the manner peculiar to the special ware which has of late years become connected with the name of Messrs. Doulton. It will be seen at once that by this method of decoration the most accurate representation of natural leaves and flowers can be produced, while endless variation is obtained, no two pieces being quite alike. Moreover, the extreme hardness of the ware in which the articles are produced make the results imperishable. In fact, they remind one of the fossil impressions in coal-beds and other geological strata, and will probably prove as enduring.

CANARINA CAMPANULA. — This Bell - flower, atthough long ago introduced to British gardens, and certaioly worth growingsas greenhouse plant, and which produces its large pendent reddish flowers at a time when flowers are anything but abundant, is but comparatively rarely met with. No difficulty need be experienced in doing it well, as it scarcely requires more care than a Pelargonium. Several good plants are now in bloom in different cool-houses at Kew. A painting of the flower, too, may be seen in picture No. 36 in the "North" Gallery.

FRENCH APRICOTS.

ACCORDING to M. Baltet, whose work on fruit culture we noticed last week, there are three great centres of Apricot production in France-that of Lyons, that of Clermont in Auvergae, where the fruit is preserved in various ways; and that of Avignon. To these may be added the country round Paris and Bordeaux, and the Burgundy district. From one village alone-Bennecourt-in the Paris district, with a population of 850, Apricots were sold to the amount of 200,000 fr. (£8000) in the year 1881, the price ranging from 1 to 1.20 fr. the kilogramme. variety grown, the method of culture, and the mode of disposal of the crop, vary in different cases. At Bennecourt and its neighbourhood the trees are grown on the steep slopes of the hills and in disused quarries, together with Cherries, black Currants, Asparagus, and Peas. The variety principally grown is the "Royal," which is found to be hardier and more productive than others. Its fruit is early and of good quality, and therefore preferred for a dessert fruit to the Triel variety, which is not so good-looking, and which is used for preserving purposes.

Some 8000 to 10,000 trees are grown at Bennecourt grafted on the Almond. The tree is grown in bush or half-standard form, and such is its productiveness that one cultivator is mentioned as having gathered five large basketfuls from one branch. When the Iruit is ripe, about the middle of July, the merchants assemble and make offers for it. They weigh and pack the fruit and despatch it to Paris or to the scaport towns for exportation. The price, of course, varies—a difference of four-and-twenty hours in the period of ripeoing may cause a difference in price of 1 fr. per kilogramme.

Our illustration (fig. 19), for which we have to thank the publisher, shows the sale—quite an official ceremony—the wighing, and packing of the Apricots at Bennecourt, where this industry, originally undertaken on a small scale, has become one of the chief sources of wealth in the district.

New Handen Plants.

ANTHURIUM SPLENDIDUM, Bull.*

HAVING received a good flowering specimen of this distinct and beautiful species from Mr. Bull, who introduced it successfully into cultivation and put it into commerce last year, I am enabled to give a more complete description of the plant than has yet been sublished.

Stem very short and stout. Petioles 4-12 inches long, 3-4 lines thick, terete, with 10-14 membranous wings, which are more or less crisped, especially on the geniculus, olive-green. Lamina cordate, II-16 inches long, 8-I2½ inches broad, bullaterugose, of a rich and brilliant sea-green colour, rather darker along the course of the midrib and veins, apex acute, basal lobes rounded, overlapping or separated 1 inch or more, sinus 2½-4 inches deep, the leaf is 7-nerved at base, the lowermost pair are denuded in the sinus, and give off 2-3 branches, the midrib has 8-to primary lateral ascending slightly curved nerves on each side, all are acute above, and have several narrow wings beneath, partly continued up from the petiole, the edges of the wings and edges of the network veins are mioutely deoticulate; intramarginal vein about 2 lines distant from the margio, continuous or nearly so. Peduncle pale green, 10-12 inches long, $2\frac{1}{2}$ lines thick, narrowly 5 (or more?) winged-angulate. Spathe reflexed, $4\frac{1}{2}$ inches long, I inch broad, lanceolate, gradually tapering from the obliquely inserted amplexicaul base to a fine point, 5-nerved, white, with a delicate pink tinge. Spadix sessile, 4-41 inches long, 3 lines thick at base, tapering, golden-yellow. A native of tropical South America; locality unknown to me. This is unquestionably one of the most strikingly distinct, and at the same time one of the most handsome species of Anthurium in cultivation; not that it can compare with A. Scherzerianum and A. Andreanum for vividness of colour as to its spathes, but the foliage is bold and handsome, and the colour unique so far as my memory serves me, for I do not remember ever to

Bull, Catalogue, 1883, p. 11, f. 3; Gard. Chron. 1883, xix. p. 381, f. 58; Florist and Pomologist, 1883, p. 53.

have seen a green like it in any plant; it is a green that is much heightened by the bullate-rugose surface, and must be seen to be appreciated; the delicately tinted spathe and yellow spadix also make a very effective contrast with it. N. E. Brown.

Lælia Amesiana, n. hybr. Hort., Cattleya maxima (pollen) × Lælia crispa.

"As regards the growth of the plant, it partakes more of Lælia crispa. The longest bulbs are 7 inches, the leaves 11½ inches long by 2½ wide. The bulb is sheathed, like that of Cattleya maxima. We have another plant in bud with three flowers on a truss." These are the ipsissima verba of Mr. Harry Veitch, who sends this freshest novelty, no doubt a Sedenian one. I have a fine peduncle nearly a span long with two flowers, equalling those of a rather good Cattleya maxima, a leaf and a sheath. The flower has sepals and petals nearly as in Lælia crispa -narrow sepals; broad, rhomboid, very wavy petals, all white, but with a delightful lightish rosy hue. The lip has the general shape of that organ in Cattleya maxima, but the colours are more those of Lælia crispa. Of course it is three-lobed, but the side lobes are blunt angled, and with a light mauve-purple border. The wavy, nearly open, broad central lacinia is of the best mauve-purple. Dark veins such as are seen in Lælia crispa I cannot find,

Kefersteiniana grows, the other cousin, Pleurothallis Schiedei, being Mexican. This time it comes from Sir N. de Rothschild, Bart. What a good thing it will be for Orchidology if these little dwarfs, the Stellds and Pleurothalidds, have won the heart of this mighty protector. I had the specimen in hand when another appeared from Mr. Day, but who had not grown it himself, as he states. H. G. Rohb. f.

THE NEW FRUITS OF 1883.

THE year 1883 will long be remembered as the "Apple year;" never on record has there been anything approaching to the extraordinary crop of this important and most useful fruit as that of 1883; never a season in which Apples have appeared in such variety, or in which so much attention has been directed or importance attached to the hetter cultivation and improvement of this chief of English fruits. If the list of novelties introduced-which it is our province here to notice-is not a very lengthy one, it is assuredly a good one. No second-rate fruit was at all admissible during the past season, amongst so much and such varied excellence. If we take those first that were honoured at the National Apple Congress, we have certainly some of the very highest merit. In Grenadier, which is a large conical-shaped fruit, of the Codlin class, with a pale yellow skin,

FIG. 19.—APRICOT SALE BY BEAT OF DRUM. (SEE P. 108.)

The mid-line between the side-lobes is purple to beyond the mid-lobe, the whole remaining part light yellow; border white; column rather thick, white, with a few small purple spots over the base of front side. Pollen masses unequal, finely colouring. Sipes normal. I consider the plant a fine thing. It is named in honour of Mr. F. L. Ames, an enthusiastic lover and collector of Orchids in New England. H. G. Rchb. f.

PLEUROTHALLIS ELACHOPUS, n. sp.*

This neat little gem has short stems, cuneate oblong acute leaves, and a very thin long peduncle, bearing at its end a very few-flowered zigzag raceme ol bivalved light brown flowers, spreading, as in Pleurothallis hians, Lindl., and adorned with numerous brown markings. The lateral sepals are connate upwards near the top, the tepals are rhombic, and the lip is ligulate, with a trulliform anterior lobe.

My first acquaintance with this plant was made in the Hamburg Botanic Garden, where it flowered ten years ago, baving been obtained from the late excellent Wilson Saunders, who believed it came from Venezuela, where the very similar Pleurothallis

* Pleurothallit elachopus, n. sp.—Aff. P. flexuose. Pūpp.
Endl. Carspitosa micropus; folio cuneato oblogo acuto; pedinaculo capillari folium paulo superante vel acquante, apice racemoso
flexuoso; ovariis pedicellatis bracteas parvulas longe superanubus; floribus pendulis seu porrectis coriaceis; sepalis divergenti-bliabiatis; sepalo impari lineari-ligulato fornicato apice
replicato; sepalo pari oblogo gligulato apice didatato bidentato;
tepalis obtusangulo-rhombeis multo brevioribus; labello ante
unguem trullaformi, regione basilari ligulata brevissime sagiitata; columna trigona, apice trifida seu triloba. H. G. R.chb., f.

and extremely handsome, we have an Apple that will, if we mistake not, he largely cultivated. Bramley's Seedling is a variety that has for some time enjoyed a high local repute in Nottinghamshire as a winter culinary fruit, and it is in all respects deserving of its high character. Greatly resembling this last in the appearance of the fruit is Warner's Seedling, from Mr. Warner, of Chelmsford, an altogether first-class variety. Mr. Penny's seedling, the Sandringham, is a large conical green-skinned culinary variety, of great excellence; and from Mr. Tyler, Hereford, we receive Tyler's Kernel, one of the most handsome of Apples, large, conical, highly coloured, and of good cooking quality. Grantonian (Mann) is another cooking Apple that has received honours, although it is in our opinion only second-rate. As an early dessert Apple of the highest excellence Mr. Gladstone has this season secured the "premier" place, thanks to Messrs, Lane and others. variety, although not exactly new, has never had its merits thoroughly recognised. It is decidedly the earliest, if not the best, and withal one of the highest coloured and prettiest of early Apples. Of other prominent sorts special mention must be made of Golden Spire, a truly beautiful pale yellow conical fruit for mid-season kitchen use. Messrs. Cranston also introduce us to the Herefordshire Beaufin, a dark red, medium-sized, flat Apple, stated to possess the merit of not decaying when bruised. Two local Cambridgeshire Apples deserve notice, viz., Histon Favourite and Murfitt's Seedling, the latter a large pale green mid-season fruit, and stated to be an extraordinary cropper. Mr. Moss' seedling, Gospatrick, and Mr.

Iones' (Frogmore) are each possessed of considerable merit. A very distinct variety named Akero, from Mr. Loney, of Gothenburg, attracted our notice, the skin a beautiful peach colour, the flesh white, sweet, and tender. In the Revue Horticole the following sorts are noticed, viz., Double Bon Rammier and Calville Madame Lessans, but not having been tested in this country we cannot speak as to their suitability for this climate.

Of Pears, there is little to be said during the past year, the season being specially unfavourable for them. In the Revue Horticole a variety of the Duchesse d'Angoulême type, named Fondante Thirriot, is noticed as being good in the November season. Plums were equally scarce, the only one of merit coming under our notice being Rivers' Monarch, a variety of the Orleans type, of good quality. In Peaches we have a new French variety, named Belle Henri Pinant, a strong seed-ling of the Grosse Mignonne section, stated to be very excellent; and Alexander, an American variety, as early as the Princess Beatrice, and of superior quality. A decided acquisition for Straw-berries, the Duchess of Edinburgh (Brown), will be found of considerable merit, being large, of fine quality, and a great cropper. Several varieties of Continental origin also claim attention. Raspberry Lord Beaconsfield is a very fine variety, well worthy of introduction. Melons, usually very plentiful, do not give us so much novelty. The Hollanden Favourite of Mr. Goldsmith will be found of high quality, and a good useful sort, and to those who aspire to monster and sensational examples we commend Mr. Rutland's introduction, "The Goodwood," the fruits of which weigh from 20 to 30 lb., and which are, moreover, moderately good in quality. Amongst Filberts, Mr. Cooper's Duke of Edinburgh is a very large and fine variety, and is considered to be a genuine acquisition.

Amongst Grapes, which usually occupy the most prominent position, we can only notify the appearance of a variety named Winter King, from Mr. B. S. Williams. This, which has an ovate-shaped berry, not unlike the Black Alicante in appearance, but of superior quality, is stated to be a graft-hybrid, the result of grafting Gros Colmar on the Raisin de Calabre. Whether this will retain the character assumed, and prove permanently distinct, will require

yet some time to properly determine.

THE NEW VEGETABLES OF 1883.

THE amount of positive novelty attainable amongst vegetables is at all times limited; gradual improvement and progression is, however, generally well manifested, and this has been the case during the past year. It is pleasant to put on record that the year 1883 has been equal to any of its predecessors. Potatos naturally occupy the first place, being at once the most important product of Mother Earth that come within the sphere of the gardeners' art in the vegetable department. That Potatos have been vastly improved during the past ten years or so is a fact that must be patent to every one taking the slightest trouble to think about it. True, we have the old Regent and the old Ashleaf with us still, and which in their way are sometimes unsurpassable, but what of others?-what of the Ashleaf, indeed, as compared with the recent introductions of Mr. Dean? His Midsummer Kidney is earlier than that variety, much larger, yields a better crop, is of better quality, and, above all its other merits, retains its good quality till late in the season; second to this comes his Cosmopolitan. Mr. Ross' Welford Park Kidney is a very handsome white kidney, mid-season, a great cropper, and of excellent quality. Messrs. Perkins' Snowdrop is similar in appearance to Snowflake-the most beautiful of all the American Potatos -but quite distinct, and very superior in quality. Clarke's Maincrop is of the well known Magnum Bonum type—good and trustworthy. Desideratum of Smith is a faintly coloured pink kidney of good quality that promises well; and Mr. Hugh's Beauty of Eydon may be pronounced, as it actually proved, the best quality Potato of the season. It is a broad white kidney-shaped variety and a great cropper. Many other excellent varieties might be noted, but we have here confined ourselves to those which took first honours.

Amongst Lettuces we would direct attention to the Green Unctuous (Verte grasse) submitted by Messrs. Veitch, a close-hearted deep green Cabbage variety; also to Messrs. Vilmorin's white Chauvigny, another

Cabbage variety with large heart, and extra good

quality, standing the summer well.

In Peas there is not so much perhaps to chronicle as usual, still those there are are good. In Mr. Eckford's Duke of Connaught will be found a variety of the Champion of England type of some merit, and from amongst Mr. Laxton's very numerous crosses the Walton Ilero may be considered an acquisition. It is a tall growing deep green Marrow. Other varieties attracting notice and deserving trial are Bliss Abundance and the Stourbridge Marrow.

Amongst Broad Beans, Laxton's John Harrison is a grand variety, having extra large pods; fine for exhibition purposes. And amongst Kidney Beans exhibition purposes. Haricot, Flageolet, Chevrier, having the seeds green, and which remain green after being cooked, are worthy

Amongst Onions the White Globe of Vilmorin, albeit totally distinct from the ordinary White Globe Onion, attracted some notice. The bulbs being of a very regular spherical shape, with a pure white skin, and remarkably firm and solid, were exceedingly handsome. In quality they proved somewhat coarse, and they are found not to keep so well as desirable.

Amongst Turnips the Extra Early Milan Strap-leaf has proved to be several days earlier than the Purpletop Munich, and is, therefore, a welcome and important addition. The Spinach Monstrueuse de Viroflay is a very large-leaved sort, and will be found to yield a much heavier crop than the ordinary variety.

Amongst Vegetable Marrows Muir's Hybrid Marrow, pertaining to the Custard section, is of great merit, being distinct, of fine quality, and an extraordinary cropper. Amongst Cucumbers we have Cardiff Castle, a wonderfully prolific winter sort; Sutton's Purley Park Hero and others; and amongst Tomatos the number of new varieties-all good, if nnt distinct—are simply perplexing. The following may be relied on, viz., Bowerbank's Prolific, a largefruited prolific sort, resembling Trophy; Chiswick Red, a selection from Trophy, but of an entirely different character, the fruits medium-sized, oblong, deep red, and borne in great abundance. A very handsome variety, Henderson's Improved Orange, is a very distinct and beautiful sort, the fruits smooth, round, bright orange, and of excellent quality. What of Tomatos twenty years ago in comparison with Tomatos of the present !

IRIS RETICULATA CYANEA.

Si pacem vis, bellum para—"If you want to be brief take care to be long." [Free translation!] My former note was very short, and by its brevity has misled Mr. Krelage, so I must apologise to him, and

tell a longer story.

Last spring I spent some very pleasant hours in visiting the interesting garden of my friend, the Rev. II. Ewbank, of Ryde, who pointed out to me an Iris (at that season long past flowering) which he had received from Messrs. Haage & Schmidt under the name of I. reticulata cyanea. Being not wholly ignorant of the nomenclature of Irises, I said at once, "I suppose that that is I. histrio?" "No," he replied, "quite different from histrio-a real reticulata, and a very beautiful thing." The result was, that in the autumn I purchased a few bulbs from Messrs. Haage & Schmidt, and now I see them in flower I regret that my knowledge of Indian synonymy preventing my purchasing them the year before has deprived me of a year's pleasure, for the flower is really very charming. I can assure Mr. Krelage that it is not I. histrio, but, as I said in my former note, in form a characteristic I. reticulata Krelagei, with sky-blue standards and stigmas, and when Mr. Krelage sees it I think he will say that it is worthy and fit to hear the name Krelagei. The additional word cyanea is misleading; the shade of blue is not cyanic, using that word even in the German sense; a more appropriate though lengthy name would be I. reticulata Krelagei cœrulea.

Since I wrote my former note I have learnt from my friend Dr. Raddé, of Tiflis, that he has a skyblue (hellblan) I. reticulata growing there. Now, the I. reticulata which grows round Tiflis and in the Caucasus generally is of the Krelagei form; hence most probably the Iris of which we are speaking has been inported from that district. I have been led to understand that the lamented Mr. Nelson raised a sky-blue seedling I. reticulata; but I also understand that he worked only with the typical I. reticulata; so

that when his seedling is distributed (as I trust it will be after a while) we shall have sky-blue varieties both of the typical form and of the Krelagei variety.

The sentence io my former note about the earliness, with me, of the Krelagei variety was intended as a feeler. What Mr. Krelage says about the early flowering of imported bulbs which have been thoroughly well ripened under a warmer and steadier sun than ours is perfectly true; I have often had experience of it. But that hardly explains the case in point. have grown I. reticulata for several years, and have flowering seedlings of my own raising; in all these I have repeatedly observed a tendency for the Krelagei variety to be early with me, under very various conditions of soil, situation, &c. The reason why I call attention to this circumstance is this :- The Krelagei variety finds itself much more at home with me than does the typical form, or 1. histrio (which is in reality a strongly marked variety of reticulata). I have to take trouble to keep the typical I. reticulata and I. histrio in good condition; the variety Krelagei takes care of itself. And while, on my bleak hill, the two former bloom later than in many other places, my Krelagei is frequently ahead of plants growing in places which in other respects are horticultural paradises compared to my desolate patch. And in the case of other plants I have made the same observation. The few flowers which do well with me, all tend to flower early. Conversely the plants which do not like my soil and situation, if they flower at all flower late. For instance, I cannot grow Lilium auratum or L. speciosum. If I put them in the sun they are dried up or blown to pieces. If I put them where they will best get damp and shelter, the autumn frosts cut them down before their buds are fully grown. am inclined to think this earliness of plants which "find themselves at home" is not confined to my own garden, though possibly the fact is more striking with me than elsewhere, because I have a greater choice of adverse conditions to serve as a good background for "throwing up" a success. A misprint in the last word of my former note takes away all the point from a poor little joke; for "Iridophils" read "Leucophils." M. Foster, Shelford.

HEATHERBANK, WEYBRIDGE.

In his pretty home garden, and in its several extensive dependencies, Mr. G. F. Wilson has done much to extend the culture of hardy plants, and the results of the bold experiments which he is now carrying out on so large a scale, and most of which bid fair to be successful, are being looked forward to by many, and will, no doubt, be productive of much useful information on their peculiarities, likes and dislikes. The Heatherbank garden is not used as an experimental ground, but is arranged in the ordinary neat manner with smoothly kept lawn, trim beds, fine specimens of rare coniferous and other hardy shrubs, Lilies everywhere, conservatory and other plant houses, some of which are devoted to Orchids. These by their vigour and general good health proclaim that they are quite at home, and that they do not want a trained cultivator to look after them. A glance at the beautiful specimen arranged in Mr. Wilson's flowering Orchid-house just now offers a good argument for the cultivation of Orchids even on a small scale. The plants are stated to receive ralatively little attention, and the wealth of lovely flowers which is generally to be found there gives abundant

interest for the pains taken.

Many fine paos of Coelogyne cristata are there, the foliage partially hidden by the snowy blooms. Many Odontoglossum Alexandræ of the best forms, one having two spikes of a dozen and a-half flowers each, and several having from ten to sixteen fine blooms of the best shape, size, and substance. A grand form of Odontoglossum Andersonianum is also in bloom, with one long unbranched and another very much branched spike; it is a pretty variety, having nicely spotted flowers, with lemon-yellow margins. Others well in bloom are Odontoglossum pulchellum, O. Karwinskii, O. odoratum, O. Pescatorei, O. triumphans, O. Rossi majus, O. Cervantesii, O. Halli, Coelogyne Rossi majus, flaccida, C. Gardneriana, Ada aurantiaca, Pilumna fragraus, Cypripediums, Masdevallias, &c. On a shelf in a shady corner of an intermediate-house Odontoglossum Phalænopsis is doing much better than it is usually seen, and promises well for flower, and some fine pots of Eucharis candida (one with ten flower-spikes) and Lachenalias do not seem at all out of place among the Orchids. It would also not be

fair to turn from Heatherbank without noticing its famed garden cat, Fat Tommy, whose portrait has been given in the Gardeners' Chronicle, but he has become so much fatter that he has outgrown his portrait.

Near at hand is the cottage garden, devoted to the culture of vegetables, fruits, and hardy flowers, and in it are some substantial orchard-houses filled with fruit trees in pots, all of them being in fine health and good bearing order, notwithstanding that many of them are from twenty to thirty years old; they are, of course, rarely potted, but annually top-dressed, and liberally fed with liquid manure while making their wood. In the borders of the cottage garden there is, even now, no lack of bright flowers, the fine strain of coloured Primroses, many of them of a violet hue, and others of a fine velvety crimson, furnishing them in profusion, and the bed of Winter Aconites presenting a sheet of bright yellow. The Snowdrops, Crocuses, Hellebores, Wallflowers, and other spring flowers seem to have settled it that we are not to have much hard weather, and have decked themselves in their gay clothing accordingly. At the out-skirt of the garden proper a fresh extension has been devoted to dwarf-growing but rambling plants, such as Vinca minor, some Saxifrages, Aubrietias, dwarf Hypericums, &c., and these are each allotted a separate mound about 6 feet across. They all seem to appreciate their allotments, and many of them have already covered the space devoted to them, and presented themselves in quite a new aspect. Further on is a rootery, which displays to advantage the proper use of such material in making a raised garden. Instead of being planted with mixed plants, as is usual, it is furnished with Skimmias, Andromedas, Sedums, Pernettyas, &c., most of which are evergreen, and thus the beauty is maintained all the year round. Beyond is a bed of Pernettyas with scarcely a berry on them, in consequence of their being planted under trees which excludes the light from them; at least, that is the inference, for the large bed of them planted in a more open place in the Wisley garden is beautifully berried-a circumstance which proves that even the situation in which a plant is placed in the same garden often involves a question of success or failure.

On the pond still floats the Wilson raft with its living freight of Iris, Bog Myrtle, and other marsh plants, and near by is a grand mass of Lygodium palmatum in good leafage, and without the slightest protection. In this garden Mr. Wilson has arranged a cheap house for Lilies in pots in what he considers the best way to insure success in their culture. It is merely a pit dug out with a sloping path cut down to it, and one of those stout span-roofed frames which are now so easily to be got placed over the pit. The plants are stood on boards in the bottom of the pit, and Mr. Wilson considers that the shade and cool thus secured in summer give the great elements for successful Lily culture in pots. Such a house could be easily made with old garden lights, and Todeas and many cold Orchids would no doubt thrive in it if constructed in a sheltered spot and properly managed.

OAKWOOD, WISLEY .- Four miles as the crow flies from Heatherbank, through woods of Pine and Oak with undergrowth of Heather and Bracken and open spaces covered with Gorse and forming excellent lungs for Mr. Wilson's gardens-is the Lily El Dorado and Garden io a Wood. It is very happily constituted, the soil in many parts being composed of the rich vegetable deposit of ages, while in other parts loam, peat, gravel, or any other soil that can be desired is found. This condition of things permits Mr. Wilson to make use to the fullest extent of his extensive knowledge of the requirements of different classes of plants-a privilege of which he has been most skilful in availing himself. Under the shade of the trees, and further protected by the shelter of the Rhododendrons, which seed and come up freely all around, are planted large patches of Lilies, over 100,000 of which luxuriate in this natural garden, the remaining old flower-stems showing plainly how well they thriven, and promising a grand spectacle for the coming season. All the varieties are represented in quantity, but it is needless to say that L. auratum and its varieties predominate. To such perfection does this variety attain that Mr. Wilson has had as many as five flower-spikes from one bulb.

At the entrance Jasminum nudiflorum gives masses of bloom, and in the front border Primula denticulata, P. acaulis and its varieties, Omphalodes verna, Crocus Imperati, Snowdrops, &c., give plenty of bright blooms, and lead up to the new Fern rockery, in which a giant form of Polystichum Ionchitis (Holly

Fern), Asplenium viride, A. Adiantum nigrum variegatum, Allosorus crispus, and other generally called "miffy" plants are doing well. With respect to the last-named (the Parsley Fern), Mr. Wilson finds it succeeds best with a piece of sandstone placed on its crown; this protects it, and it comes out with renewed vigour beyond. At the edge of the wood many greenhouse plants are being tried planted out and merely protected by hurdles or screens of Gorse. Shelter No. 1 contains a complete set of vigorous Sikkim Rhododendrous and Lapageria alba; No. 2 an immeose well-budded Camellia Marchioness of Exeter, 10 feet across and 10 feet in height-this is backed by a glass screen, and merely protected on the two sides by Gorse; No. 3 has Indian Azaleas; No. 4 Epacris, in fine health, and many of them in bloom; No. 5 small Camellias; and No. 6 Azaleas. All these show signs of increased vigour since planting, and promise interesting results.

In the bog garden the Sedums, Andromedas, Vacciniums, Gaultherias, Lingæa borealis (both the American and small-leaved Scotch varieties). Pernettyas, &c., are growing wild, the latter being covered with their variously tinted berries. The Mexican bulbs, which have puzzled so many, are heing well handled by Mr. Wilson, who has prepared beds for them and protected them with Heather. The tuberous Begonias are succeeding well on a mound sheltered by an immense spreading Rhododendron. In the lake, which is spanned by a rustic bridge, Aponogeton distachyon has become a beautiful weed, and at its margin large clumps of Cypripedium spectabile, Sarracenia purpurea, Darlingtonia californica, seem to give a hearty approval of their quarters; while on the higher ground the Gentians, Saxifrages, and other plants of a like nature thrive equally well. The order of the day with Mr. Wilson seems to be "A place for everything, and everything in its place," and thus the patches of Goodyera repens, G. japonica, Epigæa repens, and other allied plants, which have made such sound patches in the wood, would probably but have dwindled if placed in exposed situations.

A great feature in this garden, too, is the extensive space of nursery and trial ground on the hill-side, made up of scores of separate cribs burdled off, and in which the Meconopsis and scores of other reputed delicate plants are doing as well as they could in their native homes. Among the innumerable subjects, which are in grand health, too, in Mr. Wilson's interesting garden, and of which many will like to hear, are Convolvulus Cneorum, all the Abelias, Azalea amena, Cyclamens, Kniphofa caulesceos, Phormium tenax, and an immense Eryngium pandanifolium. Mr. Wilson is doing good work by making bold experiments with impunity by reason of his having to work the matters out on sound pricciples beforehand. It must be pleasant to him to know that his son, who is assiduously studying botany and ornithology, is as great a lover of the garden as he is himself.

NOTES ON VEGETABLES.

EARLY POTATOS .- Whilst to those who have large quantities of Potatos in store a hard winter naturally has its terrors, a soft one is not without its difficulties, because then the earlier kinds refuse to remain at rest. Were it possible to devise some form of Potato store wherein the temperature should range from 33° to 36°, the tubers would remain dormant for a very lengtheded period, but it is just possible that so regularly low a temperature might in time be productive of deterioration. Huge stores, or deep vast cellars, may furnish a temperature that is fairly equable, but to the mass of Potato-holders such giant stores are impossible. The best must be made of whatsoever places may be at disposal, be they fruitrooms, sheds, or outhouses, and conditions must, as far as possible, be made adaptable to seasons. The present open winter very severely tests the staying powers of early Potatos; and those who secured stocks for planting have been wise, as in such case they can easily keep their limited quantities in sound form and from undue forcing. For this reason it is wise on the part of purchasers of early sorts of Potatos to procure their stocks in the autumn-say during the month of November-and then, if the sets be placed in shallow boxes, and well exposed to the air, they will in March or April be in the very best possible condition for planting. There is ofttimes a half-expressed fear that if seed-tubers be purchased early some danger is incurred of getting partly diseased ones. As most of the early kinds are lifted in

August there remains three months prior to November during which the disease can operate, and if not then evident, it is fair to assume that the tubers are permanently good. In many cases where early kinds lie in bulk they push growth if the winter be mild, and thus much is lost to the purchaser, as these shoots will certainly be removed ere the tubers are sent out.

SANDER'S AUTUMN MAMMOTH BROCCOLI. — I send you four heads of this Broccoli, which I can safely say is one of the best varieties for winter use that can be grown. I have been cutting from eight 13 sixteen dozen per week since the 1st of October, and have to-day cut ten dozen, of which those I send you are a sample. C. F. Pranguell, Kensington and Chelica District Schoolt, Banstead. [The heads received were of good size, compact, very white, and very delicate when cooked. Et.].

MAJOR CLARKE'S CELERY.—I have no doubt our garden committee, judging from the general appearance, considered the two Celeries too near to be classed as distinct sorts, but alter a careful trial of them, side by side, in my own garden, I found they were certainly not so. Whether my view is right or not, the public will choose the best, whichever it may he, and I do not care to say anything more on the subject. Our sort is to be had pure from several firms, so the two kinds may be compared this season by those who desire it. R. T. Clarke.

ORCHID CULTIVATION FOR AMATEURS.—IV.

An amateur Orchid grower writes :- " It is most difficult for the inexperienced to divide Orchids in relation to heat and ventilation, and with the growing interest now felt in Orchids I am sure rudimentary instructions of a practical kind would be most acceptable. For example, if we knew what difference of treatment should be adopted with regard to the Odontoglossums (of various kinds), the Dendrobiums, Oncidiums, &c., such information would much encourage myself and other amateur cultivators." Now this communication seems to assume that the species of different genera of Orchids will succeed equally well under the same treatment. This, however, is not so, for of all genera some at least require some difference of treatment, but the difference necessary is in detail rather than in broad or general treatment, For example, you may build say a Cattleya-house, but all the species of Cattleya will not flourish in it equally well. C. Dowiana, C. aurea, C. amethystoglossa, and others, will require a little more heat than the rank and file of the species; and then C. citrina and Lælia majalis, L. autumnalis, L. fursuracea, &c., will require a cooler and more airy house. Cattleya or intermediate-house proper may have a minimum of 50°, and any reasonable maximum if raised by sun-heat only.

Then, of Odontoglossums and Masdevallias, a cool house (40° minimum to 65° maximum), with much moisture, will grow most of the kinds well, but we have a few exceptions—Odontoglossum grande, O. Iusleayi and its varieties leopardinum and Schleiperianum, O. Krameri, O. citrosmum, O. hastilabium, O. leve, O. Rozeili, O. vexillarium, &c., will grow best in a house having 50° minimum. They will do in the "Cattleya-house," with the difference that when growing they require much more moisture at the roots than is good for Cattleyas.

As to watering Orchids we shall say more in detail, and especially with reference to the manner of potting, for it is not so much the amount of water poured on to the surface of the compost as the amount of water retained by the compost that deserves notice. Most of the cooler growing of mountain Orchids (such as Odontoglots and Masdevallias) like the compost always moist; the same is true of such epiphytal Orchids as have no pseudobulbs (such as Cypripedium, Phalænopsis, Acrides, Vanda, and Angræcum). and Lælias are not so impatient of water as many suppose if properly potted or arranged in baskets. they like especially is sunshine partially broken during summer, and plenty of air, and very little compost, that little to be of the very best, and arranged on a well drained base of crocks and charcoal. A close, hot and "stuffy" atmosphere is death to Cattleyas; they must have air, and if the compost is firm or dense and sweet they like root moisture in plenty during the annual period of their growth. After Cat-tleyas have "mide up" their growth—that is, when

the growths have attained their fullest length, and the pseudobulbs have plumped themselves out firm and strong—allow the compost to dry up a little, and let the plants enjoy a few weeks of rest. Some growers do not do this, and even boast of their Cattleyrs making two growths during the year, but one good strong growth is enough, and better than the two made under the excitement of constant moisture.

In speaking of "resting" Orchids we must be a little precise. We may rest our pseudobulhous Orchids in various ways:-1. By allowing the compost to become comparatively dry (but not so much as to induce shrivelling) after the season's growth is completely made up. 2. By removing such plants for a time to a cooler and more airy atmosphere. Thus some few Orchids of the cool-house class might be rested in a cold frame, or even out-of-doors, since Mr. Smee tells us that Odontoglossum Alexandræ and O. Rossii withstood 8° and 11° of frost respectively in his garden at Wallington. 3. By cutting th showers as soon as, or soon after, they have attained their full beauty. The old plan of growing Orchids in a hot and shady tunnel during daytime, at d if firing up" during night, is, I hope, now exploded, and with it the "resting" necessitated by such an unnatural course of culture—a combination of "roasting and baking," alike wrong in practice and in principle. Because Nature does sometimes shrivel up her Orchids in exposed positions in the tropics during the dry monsoon, it does not follow that the plants even there (under other conditions natural to them). are benefited by the vagaries of climate. Indeed they are not so benefited any more than are English meadows by a dry and scorching summer-time, or than are our native Daisies and Buttercups by a frost below zero. Let us ask ourselves, What is a pseudobulb after all? A storehouse—a savings bank in fact of acquired capital, no doubt in the first instance developed from the petioles or leaf-stalks, to enable the plant to exist under wide extremes of temperature and moisture. Here is Nature herself supplying the Orchid with a compensation clause, or in other words she enables many of them by means of these stores, or savings banks-masses of cellular tissic filled with potential food, to prepare for and guard against a bad time. As we before said, although Nature shrivelled up her Orchids and their pseudohulbs, such shrivelling is an actual loss of the capital originally intended to enable the plant to meet calls on its energy at flowering or seeding time, or to live on through occasional periods when climate and seasons get a little awry.

There is no "royal road" to Orchid culture except the long one of observation and experience, and it is along this route alone that the goal of an amateur's hopes are to be most surely reached. There is in Orchid culture no chance of a short cut, unless, indeed, as now and then happens wealth is added to intellagence. Some amateurs manage to get "over the garden wall," as it were, in this way, but after all there is a quiet enjoyment and a modera'e success to be had without purse rivalry, by all amateurs who are so minded.

Now, in reference to heat, I made a few general remarks in my second paper; as to ventilation, care. fully note what Dr. Paterson says, and do not be afraid of giving air when the outside temperature is at or over 50° Fahr. En fassant, I may say that our method of ventilating all plant-houses is a little cruce and faulty. Side sashes which open are an especi: I nuisance unless the entire openings are covered with perforated zinc or canvas tightly strained. So al o when ventilation is given by the opening of outer doors, the influx of a draughty body of cold air should be prevented by a light framework, on which coarse hempen or paperhangers' canvas is tightly strained. Instead of a few large openings at intervals being made in the brickwork of Orchid-houses near to the ground level, it would be better to make such openings smaller, and as nearly continuous as possible, carrying them around both sides and ends of the houses. Such openings should be at least a few inches below the hot-water pipes, and should be covered with perforated zinc inside, and wooden slides outside, in the usual way. F. IV. B.

GARRYA ELLIFTICA.—The elegant tassels of this hardy shrub were noticed in full bloom a few days ago at Kew. It is one of the most charming and distinct of hardy shrubs, but too tately seen. The female plant is still rarer, but its flowers are less conspicuous.

HOWICK HALL, NORTHUMBER-

THIS fine estate and princely mansion, the residence of Earl Grey, is situated on the coast of the North Sea, from which the residence itself is distant about a mile. The house, which is of a fine warmcoloured sandstone, dates back to the first years of this century, and lies embosomed in woods, chiefly Beech, of growth older than itself, and on the edge of a moderate declivity. To the south the view is partially open, stretching over a wooded park to a wild piece of rising ground about a mile distant. Owing to the prevailing level nature of the land close to the site, views of any great extent from the house or its vicinity are an impossibility, and the sea view, which would be the finest, was purposely planted out, perhaps with the intention of getting shelter from the fierce blasts that blow from east and north-east, so that personal comfort and the well-being of the choicer plants and trees and gardening generally were obtained at the sacrifice of the only extensive prospect available. This is a matter that we find is very often wilfully ignored by some of the landscape gardeners of the present, detracting thereby considerably from the enjoyableness of gardens and pleasure-grounds, rendering the growth of many things impossible, and

conducing to the well-being of none.

Immediately in front of the mansion looking south the ground slopes away gently to a babbling burn, coursing over its rocky bed; thence on the opposite side of the stream it rises easily, till the level plateau of the park is reached. The fall of the ground in this portion of the garden perhaps suggested the idea of a terrace garden being constructed at this point; at any rate, advantage was taken of it to make a terrace garden of two levels. This was done about forty years ago, and remains intact in its principal features to the present day. The terrace that is attached to the house is of a width of perhaps 15 paces, and the the house is of a width of perhaps is places, and the length of the main building. Steps carry the visitor from either end and from the centre down to the level of the first flower parterre. The garden here may be divided into three main divisions, i.e., a flower-plot on the above-named level, at each end of the terrace, consisting of rather intricate beds edged with Box on gravel, the surrounding margin of turf having a goodsized bed at each of the four corners of the parallelogram. Bedding plants of the usual kinds fill all the beds on the gravel, and some perennials those at the corners, such as Roses, Madame Despres, Fellemberg Noisette, Fuchsia globosa, and Aloysia citriodora. The lower platean, which is also the larger, consists mainly of turf, divided into two equal portions by a water basin and fountain, and the cross walk. The middle portion of each half is arranged as a flower plot, with beds of a simple form, which are annually filled with bedding plants. Formerly these beds were margined with broad belts of Campanula pulla, C. pulla alba, Gentiana acaulis, Fairy Roses, and Hepaticas; but these have now made way for the more formal, although less pleasing, edging of tender plants. At the outskirts of this plateau, which usually looks particularly showy when the summer is favourable to bedding-out gardening in this notoriously rough climate, are planted groups of Rhododendrons and Roses.

Immediately under the terrace wall is a narrow border of beds edged with Box, in the Greek key pattern. These were filled with a variety of bedding plants, of a character rather too large for such narrow, confined beds; then a strip of gravel, and next a narrow margin of turf to the broad gravel road.

On two sides of the mansion are small old-fashioned gardens, planted with a very heterogeneous collection of perennials, and some summer bedders, the latter being happily in the minority-Gladioli, hardy Heaths, Aubrietias, Kalmias, Lilies, Phloxes, Anemone japonica, Pyrus coccinea, Roses, and such like hardy things, the general effect of these being quite unique. These gardens were probably in existeace when the more pretentious terrace-gardens were constructed, and have remained with but little alteration ever since. A good opportunity was lost of constructing a pretty natural garden scene in the hollow, where the terrace gardens now stand. Everything was there-undulating ground, running water, good shelter, and fine trees.

The conservatory, a building standing on the east side of the mansion, and being really the connecting corridor with the stables, is a rather heavy building of

thick stone walls covered with a lofty iron roof. The approach from the outside is through one of those before-mentioned old-fashioned gardens. It contains a nice collection of Camellias, planted out; some Palms, Citrons, Rhododendrons, large Fuchsias, and is well supplied with flowering plants of the popular

On the north side of the mansion, facing the carriage portal, is an enormous group of Rhododendrons, which occupies the middle part of about an acre of gravel. The sorts are chiefly R. ponticum and its hybrids, and must make a fine display in the flowering season.

The kitchen gardens lie to the north-west from the Hall, several hundred yards distant, and are completely screened from observation in that direction by tall trees and a large undergrowth of Portugal Laurel, Rhododendrous, and other shrubs. To reach these gardens another and an older flower garden is entered,

such places. An especially pleasing feature was the unstudied negligence in which all kinds of creepers were allowed to grow about these houses.

The vineries were filled with good vigorous can that were bearing more than a good crop of Gros Colmar, Alicante, and Black Hamburgh Grapes. The earliest crops of Grapes are grown in low pits, in which they are planted in narrow borders, and under which management they produce very fair crops. When these early Vines show signs of exhaustion they are replaced with other fruiting canes. Many other similar pits were filled with Melous, Cucumbers, and small plants for a variety of purposes.

The kitchen gardens consist of about 3 acres within walls 14 feet high, and a partially walled-in piece of half that extent. These gardens have long been celebrated for their culinary produce, and are still as good as formerly. The south border is a very fine one, of about 130 yards long by 14 yards wide, exclusive

FIG. 20.—CEPHALOTAXUS PEDUNCULATA, VAR. FASTIGIATA: THE LOWER FIGURE SHOWS A SPORTING BRANCH IN WHICH THE LEAVES WERE 2-RANKED. (SEE P. 113.)

with an area of about r1 acre. A border of big shrubs bounds this on two of its sides, a range of glasshouses, behind which is the forcing ground, bounds it on the north, and the high wall of the kitchen garden on the west side. The most noticeable features in this part were a very large rectangular mass of Fuchsia Riccartoni, which occupies the middle of the garden—in splendid bloom at the time of our visit and inside of a tall Rose arcade; and the great borders for herbaceous plants, which must be several hundred yards in total length. These borders were filled with a choice collection of hardy perennials, as well as with tenderer plants. Phloxes, Dahlias of all kinds, Salvias, Lilies, were at their best at the time of our visit, and made a wonderfully fine effect. The rest of this garden consists of two large grass plots, on which are a few shrubs, and a fine example of Juniperus lycia, growing, it is said, in about 2 feet of loam overlying the whinstone rock. The tree is about 40 feet in height, and of a beautifully graceful

The plant-stove and cool greenhouse contain a very well managed collection of the usual occupants of

of the hreadth reserved for the roots of the Peach and other trees. This border has a considerable slope, and is famous for raising early crops of the best quality. The whole garden is of oblong shape, and is divided into four quarters by the intersecting roads—a road running round it, but at less distance from the other walls than from the north one. Much espalier and hush fruit is grown, and the walls are very well covered with trees in bearing condition. Pears do exceedingly well on the walls, and but rarely away from them. The north wall, which is flued, produces capital Peaches, Nectarioes, and Figs; the largest trei of the Brown Turkey variety, and is now about 20 yards long by a yards high. Apricots are also grown, but Mr. Ingliss told me they are the least satisfactory of his wall fruits. On the other south wall in the partially walled—in piece the best kinds of Pears are grown, and on a ha-ha wall were several kinds of Apples. and is famous for raising early crops of the best quality. The whole garden is of oblong shape, and is

Pears are grown, and on a na-ha wall were several kinds of Apples.

During Mr. Ingliss' time much has been done to modernise and improve the houses and adjuncts to the gardens, such as fruit-rooms, Mushroom-house, glass-houses, vineries, and beating; all and everything have been overhauled and much improved under his intelligent management. M.

The Arboretum.

CEPHALOTAXUS, —This is a genus of Conifers which, from the fleshy seed, resembling those of Yews, and the aggregation of the female flowers into stalked heads, has received the name above quoted. The resemblance to Yews is great in the foliage, but that of the seed is fallacious. In the Yew the fleshy cup surrounding the seed is a sort of disc that grows up around the seed. In Cephalotaxus the coat of the seed itself becomes fleshy, as in Cycas—indeed, the genus, like Giogko, forms a link between Conifere and Cycadeæ. Most people—and very naturally—would call the seed a fruit or a berry, of which it has all the external appearance; but a fruit and a berry are developments of the ovary, and contain the seed: here, as in other Conifers, the seed is never enclosed within any ovary. The fleshy seed here corresponds to the winged seed of Pious, though so different in appearance, and although not protected by a woody scale, as in most other Conifers.

In British gardeas the species of Cephalotaxus form a small group of hardy evergreen shrubs or low trees, of which C. Fortunei is the best adapted to our climate, and is really a handsome plumose looking tree. The erect form (var. fastigiata) of C. pedunculata, too, may be used wherey the Irish Yew is employed, and is, indeed, bolder in character, while in a small state it does well for window-boxes or winter bedding.

In the last complete systematic revision of Coniferæ by Parlatore, in De Candolle's Prodromus, xvi., p. 503 (1868), a description of three species is given as fully as the material at hand permitted, and two others are mentioned as doubtful. The three better known species are the following :- 1, C. pedunculata of Siebold and Zuccarini, of which the male plant only has been hitherto described; 2, C. Fortunei of Hooker, a native of China, of which both male and so-called female plants are described; and 3, C. drupacea of Siebold and Zuccarini, a native of Japan of which both sexes are described. Parlatore adds little or nothing to what his predecessors had published, and repeats the description of the two species of Siebold given, with excellent illustrations, in Siebold and Zuccarini's Flora Japonica, vol. ii, tab. 130, 131, 133. The male plant of C. Fortunei, collected in Northern China by Fortune, was named and figured by the late Sir William Hooker in the Botanical Magazine, t. 4499. Subsequent writers have for the most part simply transcribed from these original authorities, and have added no fresh information.

There is some doubt as to whether C. drupacea and C. pedunculata may not be forms of one and the same species, as in native specimens in herbaria the two forms undoubtedly do run one into the other, but for garden purposes they may be kept distinct, as they may generally be readily recognised. Considerable doubt also exists as to whether the female plant of the true C. Fortunei (though existing in herbaria), is really in cultivation, the plant usually so-called belonging apparently to C. pedunculata. Latterly, too, another female plant has been brought to light in the garden of the Rev. J. Goring, which differs from any previously described, particularly in the seed. As a rough and ready means of distinguishing the cultivated plants we may call attention to the differences in the leaves, the buds and the berry-like seed. The main differences as to the leaves may be thus expressed:—

Leaves, $1-1\frac{1}{2}$ inch long drupacea. Leaves, $1\frac{1}{2}-2$ inches long . . . pedunculata. Leaves, 2-4 inches long . . . Fortunei

C. DRUPACEA in Eritish gardens is the dwarfest form, forming a low bush with greenish-yellow shoots and leaves. The latter are very generally upturned, and this not only when the flowers are being produced, but also on the sterile branches, so that the two rows of leaves thus form a trough along the upper side of the branches. The individual leaves do not greatly exceed 1 inch in length, and are about \(\frac{1}{2} \) inch in width, almost perfectly linear and straight-sided, rarely falcate, abruptly pointed at the tip, rounded at the base, with a very short petiole. The male catkins are stalked, each stalk immediately after its origin in the axil of the leaf being abruptly bent downwards out of the way of the leaves. The stalk of the male catkins is about \(\frac{1}{2} \) in the long, about the same length as the minute globose catkins them-

selves, and covered with overlapping ovate acute bracts which pass into the scales of the catkin. The scales of the terminal leaf-bud of the shoot are almost all distinctly acuminate. The seed-bearing peduncles in the native specimens are approximate, and the

FIG. 21.—CEPHALOTAXUS FORTUNEI, LEADER-SHOOT WITH

FIG. 22.—SEED-BEARING SHOOT OF CEPHALOTAXUS PEDUNCULATA. SEEDS OLIVE COLOURED.

berry-like seed itself ovoid. We have a rough sketch of the seed of this plant, derived probably from the garden of the late Sir Frederick Pollock, at Hounslow. Is is ovoid, and rather pointed at both ends, smaller than in pedunculata proper. In Japan, where it is often cultivated, it is said to form a spreading tree of small stature. No Chinese specimens are in the Kew Herbarium; but Messrs. Veitch, in their Manual, mention it as having been discovered in North China

by Mr. Fortune in 1849, but Fortune does not mention it in his communications on the subject in this journal, and we suspect Fortune's plant may have been the true C. pedanculata.

C. PEDUNCULATA (S. & Z.) is in gardens a larger growing form than the preceding, with greenish shoots, dark green subsessile leaves, spreading horizontally, each about 11 to 2 inches long, 1 inch wide, flat or slightly recurved, straight or slightly falcate, ovate-acute at the tip, scarcely acuminate, rounded, or scarcely tapering, at the base. The termical leaf-bud has oblong scales, the lower ones sometimes distinctly acuminate, the upper ones obtuse, or scarcely at all acuminate. The stalks of the male catkins are inch long, longer than the top-shaped catkins, and much less markedly reflexed than in C. drupacea, and the catkins themselves are also larger. The female plant is not described by Siebold and Zuccarini, nor by Parlatore; but, so far as I have seen, all the female plants referred to C. Fortunei, except one to be hereafter mentioned, belong here. The stalks are about 1 inch long, deflexed, remote, or approximate, the seeds themselves ovoid, obtuse at both ends, and rather longer than the stalks, fawn-coloured (see fig. 22). It is the Taxus Harringtoni of the Pinetum Woburnense, t. 65 (leaves only), and the Cephalotaxus Fortunei of the Fournal of Horticulture, Sept. 13,

Presuming that the C. Fortunei Q of gardens is really the female of the present species, or of C. drupacea, it may be mentioned that Messrs. Paul & Son, Cheshunt, recorded the fruitiog of this plant in these columns in November, 1863. Thuse gentlemen remarked that the plant stood 5 yards away from the male plant, but that no male flowers had been produced; hence they considered it possible that the female had been fertilised by the pollen of the golden or of the common Yew. It would have been interesting had they been able to raise a cross between these plants. They describe the fruit as brown, longish, about the size of a linuet's egg, with a thick, tough skin and a gummy pulp. They mention that it had fruited at Orleans. Fortune, in the following number, November 28, p. 1134, alluding to this communication, says that he doubted whether the female plant that was produced from seed sent home by him was really C. Fortunei-a conclusion we had arrived at from the examination of specimens in gardens before we became aware of the existence of Fortune's note. above referred to. On his second visit to China he ascertained that this female was quite distinct from Fortunei, and appeared new to science. If we are right in referring this to pedunculata, then China must be given as a habitat for this plant in addition to Japan; but there is no evidence of this in the

Var. Jastigiata.—This is a curious variety, in which the shoots are upright, like those of the Irish Yew, and the leaves, in place of being in two ranks, are scattered spirally round the stem. The leaves are like those of pedunculata, but darker, and the scales of the terminal leaf-buds are all markedly acuminate—circumstances which would rather lead to the inference that this was a form of C. Fortunei rather than of C. pedunculata. Carrière and Veitch, however, both include it under this species, and both cite instances of sports in which C. fastigiata had developed shoots of C. pedunculata (Veitch, Namual, p. 309). We have ourselves seen a similar sport in the Arboretum at Kew (see fig. 20, p. 112), and, moreover, have seen the converse change of C. pedunculata, sporting into the fastigiate variety. This fastigiate variety is the Podocarpus korainous and the Taxus japonica of gardens, and the Cephalotaxus Buergerio of Miquel!

Var.spheralis, Mast.* (see fig. 23, p. 117).—We have now to mention a form which was originally shown at one of the meetings of the Scientific Committee, from the garden of the Rev. J. Goring, of Steyning, Sussex, by Sir Joseph Holoker. The specimens were obligingly put into the hands of the present writer for examination, and Mr. Goring was good enough to furnish the artist with further specimens from which the figure was taken. The plant seems to differ from peduculata principally in the globular, berry-like seeds, unlike anything yet described in the genus. The shoots, moreover, have a brownish-chestnut

colour. As the foliage is so like that of C. pedunculata we have felt some hesitation in making this the type of a new species, preferring to consider it as a variety merely. In the future, when further information becomes available, this judgment can be revised as may be necessary. In the meantime we think it very probable that this is the female plant above referred to, which Fortune met with on his second journey (Gard. Chron. 1863, p. 1134), and which appeared to him to be "new to science." Be this as it may Mr. Goring obtained both trees (pedunculata true), and the present one (pedunculata spheralis), from Bagshot in 1855 or 1866, under the name of C. Fortunei, but certainly neither of them seems cutilted to that appellation.

Even in the mild climate of Worthing these plants

Even in the mild climate of Worthing these plants do not grow well. Mr. Lindsay, of the Edinburgh Botanic Garden, has been good enough to send us specimens of C. pedunculata, and Mr. F. Moore has also had the kindness to send specimens of pedunculata and of drupacea from Glasnevin, but neither of those gentlemen is aware of the ripening of the seed in those localities. At first sight it might be thought that the absence of the male flowers at the right time might naturally account for the non-production of the seed, but, as in the case of Cycads, we have examined several specimens in which, while the outer fleshy covering, the shell and the periperm were fully developed, there was no embryo plant to be seen.

C. FORTUNEI.—There is no difficulty in recognising this, the handsomet species, and apparently the ore best suited to our climate. The comparatively robust habit, the purplish shoots, and very long black-green falcate leaves, paler beneath, and recurved at the triangular acute points, render this species easy to trecognise, at least so far as the male plant is concerned. The terminal bud of the shoots have markedly accumiants escales. The seed is ovoid. The male plant is well figured in the Botanical Magazine, the 499, and specimens of both the male and fenne plants exist in the Herbarium from Amoy (Swinhoe I), Shanghai and Chusan (Fortune!), Kin Kiang (Shearer!, Maries!), end others.

The female plant grown in gardens under this name has comparatively little resemblance to this species, and, as we have seen, was not recognised as such by Fortune himself. Carrière figures and describes a monoccious variety of C. Fortunei, in which the seeds are ovoid (Revue Horticole, 1878, p. 117). M. T. M.

PIESA PUNCENS AND ARIES DOUGLASII.—I enclose some slips of the side branches of a Sprue Fir, the produce of seeds which I bought some years since under the name of "Abies Parlatere;" the plants are now 12 and 18 inches high. They appear to me to be identical with A. Engelmanni, while the glaucous varieties correspond with Miss Bird's "Blue Spruce of the Rocky Mountains"—the Pieca pungens figured and described by you in your number for December 8, 1833. 'You will see that the specimens sent vary in habit and especially in colour. I also send a cone and end of branchlet of an Abies which I found last August on the Porcupine IIills, some 40 miles west of Fort M'Leod in the Northwest Territory of the Dominion of Canada, evidently A. Douglasii. The hill-sides and summits are clothed with a dense forest of these trees. In their mature state they differed so much from the young plants with which we are familiar in England, that I did not recognise them until I obtained a cone. They had lost much of their pyrsmidal habit, the leaves were short and much recurved, and the cones very small; there were acres of young seedlings which were in all respects similar to those in our nursery gardens. I measured, by spanning, many of the mature trees, 22 feet in circumference, and one of 15; the soil in which the latter grew was of a peaty character with large granite boulders cropping out here and there. None were of any great height, not more than 80, or at most 100 feet, I should say. At the foot of the range Sir A. Galt's saw-mill was at work day and angle to the production of the production of the production of the conclusion that two or three so-called species, conference when when you feet he so-called species, concerning which so much confusion has arisen, are merely forms of one and the same. We shall have more to say on the matter when we have been enabled to compare the specimens with others. The small-leaved and small-coned form of the Douglas is, we believe, in cultivation at Kew. Ed.]

THE VINE LOUSE.—The Duchess of Fitzjames has reissued her pamphlets on the subject of counteracting the effects of the Phylloxera by grafting on the American stocks. The work may be had of Delahaye & Lecrosmer, Paris.

Notices of Books.

The Rosarian's Year Book for 188. By the Rev. H. II. D'Ombrain, (Eemrose & Son.)

This useful little annual has for its frontispiece an excellent photograph of Mr. McIntosh, Vice-President of the National Rose Society, and a sympathetic notice of one who, by his disinterested interest in horticulture, and his unbounded kindness and goodwill towards those with whom he comes in contact, has will towards those with whom he comes in contact, has secured universal respect. Mr. Whitwell discusses the "Rose election," which we imagine to be more useful indirectly than directly. Mr. Brown, writing from Reigate, extols "own-root" Roses for their freedom of bloom; while Mr. Fish, writing from Bury St. Edmunds, warmly advocates the seedling. Brier. His remarks on the selection of well-formed buds from flowering shoots rather than from growing ones, raise a question of very great importance, and one to which the observation of intelligent amateurs, as national Rosarians necessarily are, might very profitably be directed. Mr. Julius Sladden strikes a correct note in advocating the claims of old-fashioned Roses. It is certain that, in spite of the keen excitement of the exhibition tent, a far greater and wholesomer source of pleasure is derived from "garden Roses" by persons who never go near an exhibition tent, and would hardly wish to go a second time if they went once. Such persons are far more numerous than either "exhibitors" and exhibition haunters, so that we fully sympathise with the writer when he declares the Rose Society never more thoroughly justified its title "National" than when it undertook to publish a catalogue of garden Roses. Mr. Hall discourses of Roses in Cheshire, Mr. Gray gives his impres-Mr. Hall discourses sions on Rose shows north and south of the Tweed, Mr. Hinton sums up the result of the Rose election; as garden Roses Gloire de Dijon heads the list, as a matter of course, immediately followed by La France, which is surprising to those who try to grow it on cold clay soil; while Charles Lefebvre and Charles Lawson are astonishingly low down in the list. Last on the list of papers comes Mr. Mawley's report on the weather of the past Rose year, a report which year after year of itself justifies the production of *The Rosarian's Year-Book*, as giving within the space and limitations assigned the best account for garden purposes of the weather and the crops that is to be had anywhere.

Tree Pruning. By A. Des Cars.

Messrs, Rider & Son have issued in a cheap form the translation of M. A. Des Cars' treatise on pruning forest and ornamental trees, originally published under the editorship of Professor Sargent in America, Where proper oversight is maintained there ought to be little necessity for pruning, and bad pruning is usually worse in its effects than none at all. Necessary and judicious pruning is quite another matter-it depends on the natural habit of the tree, the purposes for which it is grown, the peculiar circumstances under which the operation has become necessary. The diagrams given illustrative of the "correct form of trees at various ages require, as the author properly says, to be considered not as absolute indications, and in following out his practice the forester must use considerable judgment in the application of the rules laid down. Especially must he study the natural habit of the tree and the mode of development of its buds, else by the pruning and shortening processes here recommended, so far from doing good he may be adding to his yearly toil, or if he neglect it rendering matters worse than if he had never touched the tree,

— A new part of Hooker's Icones Plantarum has just been issued, containing descriptions and illustrations of twenty-five plants, principally of exclusively botanical interest, and some illustrative of genera described in the Genera Plantarum. Gentana Lodeii is a prostrate form, with broadly ovate leaves and large funnel-shaped blue flowers, with fringed scales in the throat. It may be useful to state that four species of Gentiana here figured—namely, G. robusta, from Tibet; G. Loderi, from Kashmir; G. borneensis, from Kina-Balao; G. tibetica, from Tioet, and Swertia Kinglii, from Sikkim—do not find a place in the recently issued part (10) of the Flora of British India, having been received at Kew since the publication of that part.

Archid Notes and Hleanings.

ORCHIDS NEAR STIRLING,-When on a visit to Scotland during the last week in December, 1883, I went on the 27th to Brentham Park, the residence of James Smith, Esq., and was agreeably surprised to find such a fine collection of Orchids. The Odontoglossums were very fine; O. Pescatorei, which was in flower in quantity, looked grand; Cattleyas were looking well, many of them newly bought in; one good plant of C. superba was in flower; Lycastes, Cypripediums, and many others were in flower. The whole place bore evidence of a master hand, and reflects great credit on Mr. MacLeod, the gardener. On the 31st I went to see Dr. Paterson's plants, which I had heard so much about, and where I expected to find a large collection; but for the benefit of readers of the Gardeners' Chronicle I would say the collection is not large, but the examples are quite up to what has been written about them. On the morning of my visit there were 10° of frost, and although entering the houses from the cold air I was much struck to find them so cold, viz., 43°. Now, what would some of our Orchid growers say to that temperature for Cattleyas, Lælias, Vandas, The plants were pictures of health. fine flowers were open which have already been described in the Gardeners' Chronicle, I say with "F, W, B.," at p. 14, that the Doctor is a cultivator of the first water. But I would like to say, in correction of a misapprehension on the part of "F. W. B." that Dr. Paterson employs a gardener, and one who is thoroughly practical, in fact conversant with every subject under his care. Dr. Paterson may give his orders, and in due course they are carried out, but let it be known, at least, that an experienced hand helps. I have neither seen in imported or home-grown plants such luxurious foliage as some of his specimens present, The compost is good, and plenty of it, there is no starving such as may be seen in some places where the poor plants are made to live on a few crocks and charcoal, and with a bit of sphagnum for a surfacedressing. Thrumpton.

"THE ORCHID ALBUM."-Recent numbers of this useful publication contain coloured figures of Lælia harpophylla, t. 117, a species remarkable for its orange-scarlet flowers; Mr. Cookson's variety of Odontoglossum crispum, t. 118, a form with fine flowers, with very large brown blotches; Cypripedium Spicerianum, t. 119, a native of Assam, and remarkable for the white dorsal sepal, traversed by a central narrow band of deep violet; Dendrobium Dearei, t. 120, with racemes of white flowers : Cattleya labiata pallida, t. 121, a form remarkable for its violet lip, golden-yellow thrnat, with radiating lines, the disc marked with a large blotch of deep magenta, and edged with creamy-white; Cypripedium Curtisii, t. 122, a native of the Sunda Isles, has the dorsal sepal green, with purple lines, the side petals oblong lanceolate, thickly spotted with violet, and with black hairs along the edge—the lip is broad, bucket-shaped, shining purplish-brown; Lælia grandis, t. 123, a species from Brazil, with linear lanceolate wavy segments, of a yellow-fawn colour and a white lip, convolute at the base, expanding into an ovate acute cream-coloured disc, marked with violet lines; Vanda Sanderiana, t. 124, a native of the Philippines, "the most wonderful Orchid that has been introduced for many years," and of which we gave an illustration last autumn, vol. xx., p. 440, figs. 67

MASDEVALLIA HARRYANA.—M. Roezl narrates, in the Orchidophile, how he found this plant in the mountains near Ocaña at a height of 1100 to 1200 feet. It was growing by hundreds of thousands on a slope amid low shrubs—Vacciniums, Thibaudias, Melastomacere, &c. The variation in colour was extreme—some were nearly yellow, others striped with fiery-red, others deeper coloured still, and with great variation in size also. Six thousand plants were collected and sent to Europe to perish at St. Nazire, where they arrived at the outbreak of the Franco-German war. M. Roezl goes on to say that the air is pure where the plant grows, the wind strong, the moisture constant but not stagnant, wet moss grows around the toots. For the greater part of the year

fogs cover the mountains; it requires, therefore, shade in the morning, followed by exposure to the sun at mid-day,

CYPRIPEDIUM LAWRENCIANUM.—I send with this a stalk with two flowers on it of Cypripedium Lawrencianum. I know it is not altogether uncommon in C. barbatum, but I never heard of it in Lawrencianum before; I do not know if others have. W. Vanner, Chisichurst. [We have not seen a case like it in this species before, ED.]

CATTLEVA TRIANÆ RUSSELLIANA.—This is certainly the king in the Trianœ section, indeed it is doubtful whether its equal in beauty and grandeur can be found in any other species of Cattleya. At The Dell, Baron Schridder's specimen is just now in perfection, some twelve flowers being fully expanded. It is difficult to describe the colour of the lip, but crimson-plum may be the nearest approach to it. The lip has the form of Mendelii, being full, open, and flat at the side edge; the latter is not fringed but waved. The deep colour enters almost the throat and covers the lip fully; the side wings of the lip right up to the base of the petals is bright purple; sepals broad, the upper one standing upright, and not bending back, which is so rare in Triawe; petals very broad, deep lilac-rose, with heavy light purple veins. A. B.

THE exceedingly mild winter, as well as the unusual dryness of the weather during the last fortnight, has caused the spring garden to already assume a somewhat flowery and gay appearance. Hellebores, Aconites, Snowdrops, Primroses, Polyanthuses, Violets, Crocuses, and Violas are already in bloom, and in some instances form quite a cheerful and brilliant display. How disastrous and distressing will be the effect if severe weather should now ensue, and how quickly will this brightness disappear. Let every means of protection he ready at hand for immediate use should a change occur. For temporary protection at this season there is nothing so useful and efficient, either for protection against frost or cold cutting winds, as short evergreen branches stuck in at intervals between the plants sufficiently close to effectually screen them. They can be easily removed as soon as the danger is past. Should severe weather be likely to continue a mulching of light dry leaf-mould should likewise be placed between the plants as an additional protection; by these means not only tender plants but the blooms may often he preserved when the frost is not of long duration.

THE HEREACEOUS BORDER should now receive attention, and where the necessary divisions and transplanting were not effected in the autumn the mild weather affords an excellent opportunity for the performance of this work, and as many of the plants are now showing signs of growth this can be accomplished very easily, taking care to mulch them immediately the work is performed either with leaf-mould or half decayed manure in a rather dry condition. In rearranging old borders or in forming new ones care should be taken to graduate the plank according to their heights and habits of growth where the mixed method of planting is adopted, also to avoid, as far as possible, the introduction of too many kinds of plants, or too many colours into a limited space; a far more pleasing and effective display is insured by planting in sufficiently large patches or masses a few really good and judiciously selected sorts. But the proper and really natural method of treating this class of plants is undoubtedly by planting in such positions and in such a manner as to cause them to form the connecting link between the wild or woodland garden and the well kept lawn or parterre. Some of them, indeed, are only suited for close association with the usual occupants of the wild garden, where planted in masses or in isolated specimeos they show to great advantage. Those of more medium growths should also be massed in the same manner, not, however, in a formal or stiff way, but in irregular groups or clumps, and in sufficient masses of one kind and colour to produce a decided effect, taking especial care not to permit one particular colour to preponder-

ate so as to destroy the effect of those colours less showy or effective. This method of planting is not only best suited to these plants, but it admits of great variety and creates the greatest possible charm and brightness in that part of the grounds which is usually cheerless and uninteresting. Isolated trees and shrubs, as well as groups of the same, may also be introduced if they do not already exist where required, for the purpose of giving relief to the eye, as well as to afford the necessary shelter either from winds, sun, or frost, which some of these plants require so as to enable them to develope their full beauty. On no account, however, should they be employed—as unfortunately they sometimes are—as edgings or margins to clumps of shrubs, and even specimen trees, where they are not only out of place, but where, in consequence of the encroachments of roots into the borders and branches overhead, they soon present an unhealthy and miserable appearance. As their heauty and effectiveness depends on the full development of both growth and flowers, not only should suitable soil be provided for their peculiar requirements, but the most suitable positions should likewise be carefully chosen. Planted in such a manner and in such situations herbaceous plants and hardy bulbs are perfectly at home, give but comparatively little trouble, and afford a successive and ever varying charm, which cannot fail to please even the most critical eye; nor are they when so placed any longer open to those objections sometimes forcibly used

THE SHRUBBERIES should at this time undergo thorough inspection, carefully thinning and pruning out all dead shoots and irregular growths caused by accident, or indiscriminate or improper planting. In performing this operation endeavour to preserve as nearly as possible that natural form peculiar to the particular shrub or tree, and at the same time be careful by timely thinning to prevent undue crowding, as from this cause alone is the greatest mischief to be feared in the management of specimens, as well as groups of shrubs and trees. One season's neglect of this important operation often causes irreparable mischief. After pruning the clumps should be cleared of all rubbish, except leaves, which should be allowed to remain, and by simply loosening the surface with a steel fork (not digging) they will quickly disappear by the action of the weather and the operations of worms. Near the edges, where greater neatness is desirable, either rake them off or cover them with a small quantity of fresh soil. As we usually experience rough winds at this time every tree or shrub requiring a stake should be secured. Deciduous and ever-green hedges may be pruned during mild weather, but cease this work on the first approach of frost,

The Hardy Hruit Barden.

FROM the fact that the Apricol comes into bloom first of all our fruit trees it necessarily claims our earliest attention in pruning and nailing. It is well to keep the trees in shape, and the spurs moderately short, so as to bring the fruit under the warm influence of the wall; but in pruning be careful not to cut away the fruit-bearing spurs. It often happens that bloom, appearing as it does so early, suffers greatly by inclement weather, therefore make some provision for protecting it when it opens, Glass protectors projecting 2 or 3 feet are best; or a hoard similarly placed will also do, and from which curtains or nets can be suspended during sunny days only, to retard the blooming to the latest date. The curtains should also be used constantly at night, when there is danger from frost during the setting period. The pruning of Pears on walls ought now to be pushed forward, the unusually mild weather enabling the nailing to be proceeded with. For Pears trained as they usually are, on the horizontal plan, we much prefer gal-vanised studs with eyes being driven into every third course of the wall, if of brick, and two feet apart, to which the branches can be tied; common clout nails heated red-hot and thrown into linseed oil to prevent their rusting form good permanent fastenings used in the same way, the branches being tied with small rope-yaro. When pruning the Pears, be careful in distinguishing the fruit-buds from the woodNo time should be lost in getting the Filberts pruned, and in doing so be most careful to leave sufficient catkins or male blooms to perfect the fertilisation; and if this should require more wood to be left than is desirable it can be cut out after the crop is set. At the base of such trees a quantity of suckers are usually produced; these should not be cut off with a knife, but be removed with a sharp spade or suckering iron, so as to reduce the crop of these the current year. These suckers make neat stakes for training small plants, and should be saved for that purpose.

The young wood of Peaches and Nectarines should be loosened from the wall, to retard the blooming period as much as possible, and the loosening will make it easier to prune the trees. Any which are infested by scale should be dressed with Gishurst Compound, at the rate of 6 oz. to the gallon, applied with a painter's brush; care must be taken not to brush downwards, and so rub off the buds. A very grave mistake is often made in pruning orchard trees at this time of the year in using the knife too freely; the branches should simply be thinned out, more especially those which cross each other, but not shortened, as a shoot that is well ripened will much sooner develope into bearing than when the same is severely pruned. If the wood is insufficiently ripened, that is usually caused by want of drainage or too shady a position, and if the tree grows too strongly when of mature age it is from not having been root pruned.

it is from not having been root-pruned.

Where it is desired to form the trees into pyramids the knife must be more freely used, but even then severe pinching of the shoots is preferable. On no account should old orchard trees be severely pruned; simply cut out the inside shoots, which would other-wise not receive sufficient light. Raspberries, if not pruned, must now receive due attention; alter cutting out the old bearing wood of last year and the small shoots tie up the strongest for bearing this year, but for years we have not shortened the shoots till This makes them somewhat later in break-March. ing, and more likely to escape damage from frost; but never, under any circumstances, dig hetween the rows with a spade-it is simply ruinous to the plantation-but simply point the ground slightly over, and it will be better if a good mulchiog of dung, leafmould, or even spent tan, be given, and the ground left undisturbed. The autumn-bearing red and yellow kiads must be cut off close to the ground, as it is on this year's shoots that fruit appears, and as it is in September and October when the fruit of these two kinds ripens the situation should be sunny and fully exposed. It may happen that the locality does not suit certain trees in the orchard, and it will then be desirable to graft them with kinds which have been proved to do well in the neighbourhood. Where that is intended no time should be lost in heading back the trees to the proper place; the grafting of them we shall speak of in a subsequent Calendar. F. Rust, Eridge Castle, Sussex.

The Orchard House.

We have in our new garden a different form of house to the old one at Loxford, and have also adopted a different system of management. of the trees are planted out and trained to trelliswork, and others are grown in pots. The trees in pots are still out-of-doors, but we are now cleaning the house, and turning out the numerous pots of Chrysaothemums. This generally affords a good opportunity to clean the trees, as well as the house and glass. Brown-scale is rather troublesome if it once gets a good foothold; but we had it on a few trees, and that to a limited extent only; now we have entirely destroyed it, merely by looking over the trees carefully as they were taken into the house, and washing the scale off with strong soft-soapy water. Syringing and fumigating does not touch scale. We fumigate two or three times before the blossoms open, and that precaution keeps the trees free from the Peach aphis. If this is not done we are likely to be pestered with it all the season. The plants will now be placed in their positions, and the border where the trees have been planted out will be surface-dressed. In the forcing compartment, where surface-dressed. In the forcing compartment, where the trees were started before Christmas, the temperature must not be very high as yet. See that the trees are all right at the roots; provide also a circulation of air—even at night a little air ought to be admitted. This precaution is necessary to prevent the blossom-buds from dropping off. J. Douglas, Great Gearies, Ilford.

APPOINTMENTS FOR THE ENSUING WEEK.

MDNDAY,

Jan. 26

Sale of Lilies and Other Bulbs, at Stevens'
Security of the Stevens' Security of Sec

THE letter of Mr. EWING in a recent number on the necessity or otherwise of ventilation in plant-houses, and on the sources of carbon-dioxide, opens up some very important questions. It is universally admitted that the carbon which plants contain is derived from the atmosphere in the form of carbon-dioxide, alias carbonic acid gas. To effect the introduction, or at any rate to make it of any use, the presence of green colouring matter, and the action of sunlight are absolutely necessary. By their means the carbon is fixed, and the oxygen is dissipated. The prevalent opinion among physicists is that the roots take no part in the absorption of carbon-dioxide as such, but in some combination, as in the form of soluble carbonates, the plants may take up carbon, and if so then one of Mr. EWING'S questions would be answered, for there would probably be a sufficient supply of available carbon, even in the most hermetically sealed house. In any case the carbon of the soil does exert a very powerful influence for good on the plant. Humus, wihch we do not hear so much about now as we used to do, contains, in addition to nitrogen and other matters, about half its weight of carbon. But besides this, humus may take up and retain at least its own weight of water, and even more; and this water is almost sure to contain carbon-dioxide. The humus itself owes its origin to the gradual decomposition of vegetable matter - roots, leaves, &c., in the soil. The value of pottingsoil, peat, and leaf-mould is largely dependent

on the presence of this substance. M. DEHÉRAIN has lately called attention to the experiments of BOUSSINGAULT and others, which show that much larger quantities of humus are contained in meadow land than in arable land. In seeking for the cause of this DEHÉRAIN points out that the tillage of the arable land-the ploughing, the harrowing, the fallowing even, tend to increase oxidation, and to destroy, or as chemists say, burn away the humus, which, on the contrary, accumulates in the undisturbed meadow land, and oxidises much more slowly. A Vine border, or even an ordinary pot-plant, then presents a nearer approach to the condition of the meadow than to that of the ploughed field, and the accumulation of humus is less interfered with, to say nothing of the fresh supplies yielded by manure, The lloss of humus from arable land may be checked by a proper rotation, as by growing Clover after Wheat. The gradual loss of humus is then due to oxidation, rendered manifest by the quantity of carbon-dioxide in the soil, Till recently this process of oxidation would have been considered as a purely chemical phenomenon, but of late years we have come to look upon the soil, not always as a dead mass, but as teeming with life in the shape of the most minute organisms. We have on a former occasion alluded to the influence of these ferment-agents in the formation of nitrates in the soil, and now it appears certain, from the researches of German French chemists, that these bacteria or "germs," or whatever they are to be called, also play a most important part in the oxidation of organic matters. A soil, the humus of which is destroyed by this agency, gradually becomes sterile, and as M. DEHÉRAIN shows, becomes incapable of resisting drought. In Algeria, where the land is becoming sterile, or rather,

where it has been so for centuries, the mischief is rendered worse by the destruction of the forests. The soil of the forest is rich in humus, but this is soon used up, and the state of that land becomes worse than before. The leaves radiate heat freely, and in consequence there is a large deposit of water in the form of dew on the leaves, but with the destruction of the forests by the axe, or by the goats, this precious deposit ceases and the land is left to become utterly barren, with all the goodness scorched by a torrid sun and burnt out of it.

The course of destruction in such countries is as follows :- The soil is tilled annually, air penetrates it, the humus is burnt up, the nitrogen forms nitrates which are washed away by the rain when it does come, the organic matter disappears and with it the ability of the soil to resist prolonged drought. When rain does fall the water runs away and is not stored up, and the soil, no longer able to sustain vegetable life, becomes a desert. Then comes the destruction of the forests as above stated, and the ruin is complete. M. DEHÉRAIN concludes the lecture, from which we have quoted these remarks, by showing that the exhaustion of the soil under the circumstances he mentions is not due to the lack of phosphates, nor of potash, but to that of humus, which carries with it that of nitrogen and water.

The remedy for this state of things is easy in theory if not in practice. It consists in restoring the conditions of the meadow by allowing the gradual accumulation of humus, and this is to be effected by keeping the soil supplied with water by means of irrigation, by replanting the forests, and by a proper system of forest conservancy and inspection—by doing, in fact so far as circumstances permit, just what the gardener does in his stoves under more fortunate conditions.

— CHATSWORTH. — We understand that Mr. THOMAS BANNERMAN, Gardener to Lord BAGOT, Blithfield, Rugely, has been engaged by the Duke of DEVONSHIRE to succeed the late Mr. SPEED as Gardener at Chatsworth.

ITALIAN BOTANIC GARDENS. — Professor PIROTTA has been appointed Professor of Botany and Director of the Botanic Garden at Rome. At Turin, Professor GIBELLI; at Modena, Dr. Mori; at Pavia, Professor BRIOSI; and at Naples, Professor PASQUALB, have been respectively appointed.;

— NEFENTHES RAJAH. — Mr. COURT, whose skill is known to all visitors to Messrs. VEITCH'S nurseries, being dissatisfied with the results of the ordinary stewing treatment which this plant receives, has now adopted a cool treatment for it. The plants are grown in a cool-house facing north, and kept wet by sphagnum, like the Cephalotus. The progress, though slow, is satisfactory, the foliage being firm and well coloured.

- THE WEATHER IN AMERICA .- From Messrs. TATTEN & SCHAFER, Saratoga Springs, we have received a note on the severe weather experienced in the State of New York hetween December 26 and January 9. New Year's Day was warm and cloudy; the 2d was cloudy, with wind and snow in the afternoon; and the 3d was colder, about 12° above zero, and the wind travelling at the rate of 50 miles an hour in the evening. On the 4th it was much colder, about zero, and the weather clearing; the 5th was colder still, 10° below zero; the 6th very cold, 24° below zero-in some places as low as 34° below, wind N.W.; the 7th, a very severe morning, 24° below zero again; the 8th, about 16° below zero: and on the 9th a great change to rain, with snow and strong wind in the afternoon, thermometer 14° above freezing point,

— VIOLET LADY HUME CAMPBELL.—What is this? We saw a quantity of fine plants a few days since growing in a cold frame in the gardeos of Harefield Court, Rickmansworth, and were much struck with the size and vigour of the plants, for they were represented by specimens fully, 18 inches in diameter, finely grown, and full of buds; they were planted out, and appeared to like the situation exceedingly well. It is regarded locally as a superior variety of the Neapolitan, being much more robust in growth. It was brought from ahroad some years ago by Lady Hume Campbell. to her residence, High Grove, Watford, and Mr. Brush, the gardener, noticed among some of the plants a darker coloured free-blooming form, and its superiority to the old Neapolitan was soon made manifest. About five years ago Mr. C. Turner hought the stock of it, but it does not appear in the list of sweet Violets found in his catalogue. We were able to compare it with the Neapolitan, and found it to be superior in every way. It may be that its advent anticipated one of the newer forms since introduced from Italy, but we fail to find it in any list of sweet Violets.

— NARCISSUS MONOPHYLLUS VAR. ALBUS.—
MESSUS. COLLINS BROTHERS & GARRIEL have
favoured us with some fine blooms of this chastely
beautiful flower, grown out-of-doors at Kiogston with
the protection of a hand-light during had weather.
The bulbs were collected last autumn, and as they
are flowering so well now, under the conditions we
have named, this is clearly a plant that should be
looked after by those who have to provide choice cut
flowers. For bouquets it is just the thing, resembling
as it does a miniature Eucharis.

GREENHOUSE RHODODENDRONS. — Messrs. VEITCH have adopted a plan of growing these plants which is quite charming. The tops of the shoots are taken off wheo of a length of 3 or 4 inches, and when the bloom-bud is commencing to form. These cuttings are struck in cutting-pots, and when the flowers are about to unfold the pot is placed in a small pan filled with moss and hung up close to the glass. In this situation the flowers expand and form delightful ornaments to the house.

- WALLFLOWERS. - Messrs. CANNELL have sent us bunches of dark coloured and yellow Wallflowers, both very good, and the former especially The Wallflowers as a class of sweet-smelling ever favourite flowers, whether in mid-winter or in other and pleasanter seasons, are not so much grown in pots for conservatory or greenhouse embellishment as they should be. Nothing can be easier than the pot cultivation of these old favourites, for by sowing the seeds in gentle warmth in February, and hardening off when the true leaves appear, stocky plants are soon in readiness to prick off. Every effort should be made to keep the little plants stocky and hardy. They can be grown in good soil in the open till August, when they must be taken up with as much earth as will adhere, and potted in large 32's, afterwards standing them behind a north wall for ten days till rooted, when they must get the sunniest place out-of-doors till October, or later still if there frost. A cold, or, better still, a dwarf light house, with plenty of room between the plants, so as to preserve their lower foliage, will suit them till they come into flower. The soil for pot plants should be rich loam, with not over much crocking, and requires to be very firm.

— International Potato Exhibition.— The Royal Horticultural Society, having granted facilities for the trial, culture, and cooking of new varieties of Potatos entered in competition for the International Certificate of Merit, the following regulations must be observed by competitors :- Not more than eight varieties will be received from any one person, and in every case six sample tubers must be sent, carriage paid, to Mr. A. F. BARRON, Horticultural Gardens, Chiswick, near London. Senders of samples to Chiswick are desired to send a list of the names or numbers of the sorts, and, if possible, pedi-grees and characters, to the Honorary Secretary of Thames Street, London, E.C. The authoritative announcement made in our columns last week that the International Potato Exhibition of the present year would he held at the Crystal Palace during the second week in October, instead of in the month of September, will no doubt prove very acceptable to many Northern growers, and no doubt will help to swell the already enormous competition in the various classes. The days on which the show will be held have not yet been settled by the Executive Committee, but it is anticipated that, for various reasons, and

FIG. 23,-CEPHALOFAXUS PEDUNCULATA, VAR. SPHÆRALIS. (SEE P. 113.)

specially because of the effort to be made by the Palace directors to popularise the exhibition the more largely by associating the show with a grand harvest festival, that it may extend to three days. The spirit shown in the management of the Potato Exhibition indicates that it is yet full of interest and vigour. Should there be associated with the Potato an exhibition of other roots, fruits, and also of vegetables, there can be little doubt but that this particular show would prove to gardeners one of the most attractive of the whole season. It is possible, and, indeed, it is desirable, that some changes should be made in the prize list of the Potato show to enable small growers to compete independently of those champion growers whose very names mean prizes. It is right that the

best should win, but open classes and liberal prizes will always bring the first quality in plenty. What is rather needed is to furnish encouragement to the small amateur and gardener whose means are limited, and who yet in many cases develope into first-class growers, if not too heavily handicapped at the outset.

— JASMINUM NUDIFLORUM IN COMBINATION WITH IVY.—A few days ago we saw a harmonious and striking effect produced by this widely grown and deservedly popular plant in combination with the common Irish Ivy. Both had been planted at the same time and allowed to scramble at will overa heap of stones and old roots; the Jasmine certainly seemed quite able to hold its own, and its long leafless shoots, studded with yellow starry flowers, seemed to be more

beautiful contrasted with the groundwork of the dark green leaves of the Ivy. In Sion House grounds a large mass of Jasminum budiflorum forms a circular bed on a lawn; no stakes are used, and the plants are allowed to grow naturally. At the present time this clump presents a charming appearance.

— THE GRRAT AUTUMN SHOW AT DUNDER.

—We have received a copy of the schedule of prizes offered for competition at the Great Horticultural Exhibition to be held in Dundee next September, and with which will be incorporated the annual exhibition of the East of Scotland Honey Society. The schedule includes 219 classes for fruits, flowers, and vegetables, and twenty-three for honey. In the fruit section the highest prizes offered are £20, £15, and

\$10, for a collection of sixteen sorts; \$15, \$10, and £5, for a collection of twelve sorts; £10, £6, and £4, for a collection of eight sorts; £15, £10, and £5, for eight varieties of Grapes; £8, £5, and £3, for six varieties of Grapes; and £5, £3, and £2, for a collection of eight sorts of hardy fruits. In the plant classes the same liberality prevails; thus in a section devoted to nurserymen sums of £20, £15, £10, are offered for a table of plants 20 feet by 8 feet; £10, £6, and £4, for eight Orchids in bloom; and £10, £7, and £3, for twelve stove or greenhouse plants introduced since 1880. For amateurs and gardeners only a loog list of classes includes the following: - 6,20, 615, £10, for twelve stove or greenhouse plants; £10, £7, £3 for six stove or green-house plants; £10, £6, £4, for a table of plants 15 feet by 8 feet. Vegetables, we are sorry to observe, are somewhat meanly treated in the two main classes, only the sums of £4, £3, and £2 being offered for a collection of fifteen kinds; and £2 10s. and £1 10s. for ten kinds, exclusive of Tomatos and Cucumbers. In comparison with these offers the tos, given as a Ist prize in classes for two Cabbages, two Beet, and so on, seems out of all proportion.

- PARROTIA PERSICA. - Conspicuous enough at the present moment amongst the deciduous trees at Kew is a fine specimen of Parrotia persica, the terminal and lateral clusters of crowded flowers, with their scarlet anthers, lending a distinct appearance and no little beauty to the naked brown twigs. When figured in the Botanical Magazine, in 1868 (tab. 5744), it was stated to be one of the rarest trees in cultivation; now, however, owing to layers having been distributed from Kew, the Parrotia is better known, although still very far from being common. Nearly fifty years ago two plants in pots were received from the Botanic Gardens at St. Petershurg, one of these is trained against a west wall, the other, which is now less than 15 feet high, stands in the open ground not far from the grand entrance. In 1868, when it was figured for the first time, this tree flowered in March, this year it is in flower in the middle of January. The great beauty of the Parrotia consists in the magnificent colouring of the foliage in late autumn, when the leaves usually turn of a brilliant orange and golden-yellow and scarlet, and hang upon the plant until late in winter. As the protection of a wall generally ensures more brilliant colouring, and keeps the foliage from falling long after trees in the open have become leafless, such a protection should, where available, be afforded to the The wood is said to be extremely hard Parrotia. and durable, hence its Persian name, "iron-wood." Only one other species of Parrotia is known, viz., P. Jacquemontiana, a native of the Cashmir Himalaya, not yet introduced to cultivation. The subject of our previous remarks is from the Transcaucasian provinces of Russia and Northern Persia.

- THE INVERNESS NURSERIES. - The Northern Chronicle of January 16, in a communication on the Silva of Inverness-shire, states that the first nursery established in the North for the systematic production of forest trees was at Muirtown, and was carried on by two brothers of the name of FRASER. This was about sixty-five years ago. They were succeeded by the DICKSONS (JAMES and GEORGE), who took a lease of suitable ground at Millburn, and carried on a large business successfully for a considerable period. About half a century ago, at the time when the demand for forest trees was just beginning to make itself felt in the North, Mr. CHARLES LAWSON, late Lord Provost of Edinburgh, and nurseryman and seedsman to the Highland and Agricultural Society, re-established the nursery business at Muirtown, where it is still carried on. He was succeeded by the Messrs. Howden Bro-THERS. Under them, and subsequently under Messrs. HOWDEN & COMPANY, the business was extended, as increased facilities for the transmission of trees were established. Messrs. Howden & Company now hold about 30 acres of the best land in Sir ALEXANDER MATHESON'S Inverness property, and this extent is yearly being found more and more insufficient for the requirements of the trade.

THE LATE HERMANN MUELLER.—We had occasion some time since to allude to the English translation of the work which caused its lamenta author so much labour and research. We regret to learn that by his death his widow and daughters are left but poorly provided for. He died at fifty-four, after three days' illness, of inflammation

of the lungs, caught on one of his "Alpeu-Blumen" excursions. He had carned his living as teacher in the gymnasium at Lippstadt, for twenty-eight years, adding to his income by private lessons. He published a mass of laborious work. His emoluments were so small that he was unable to provide adequately for his widow and two unmarried daughters, one of whom is an invalid. The idea of a German committee formed for the purpose is to provide some help for the widow, and if possible to connect Hermann Mueller's name with a sort of natural science studentship or bursary, to be founded at Lippstadt alter the death of the widow. Subscriptions are now received by Professor Percenal. Wright, Trinity College, Dublin; and by F. Darnin, Esq., So, Huntingdon Road, Cambridge.

- JAPANESE VINES .- A correspondent calls attention to an article in the Bulletin of the National Agricultural Society of France, in which Dr. MAGET, a French naval surgeon, makes known the existence in the mountains of Japan of wild Vines. They grow at altitudes as high as 1800 metres, and produce very sweet and pleasant flavoured Grapes. The climate is mild and moist, like that of Brittany or Ireland. In the Island of Vesso, and particularly along the river Tchikari, this traveller found no fewer than eleven species of Vine. It is to be hoped that fuller information will be forthcoming as to these plants. Io the meantime it may be mentioned that the ordinary Vine is cultivated in Japan, and is mentioned by Franchet and Savatier as naturalised, quasi spontanea, in copses.

- ILLUSTRATED SEED LISTS. - There can be no doubt but that our trade seed lists show a very decided advance in taste and truthfulness of delineation upon those of several years since. Good seed lists-or, to put it more correctly, lists sent out by good seed houses-are now not only illustrated, but generally got up in a style that would do credit to any branch of trade or commerce. Even the wood engravings show elegance and finish that may well compare with those found in any publication, and there is not only less exaggeration, but more evidence of original drawing from good examples. Coloured plates are not always so successful, though perhaps the artists' efforts may in some cases suffer from the defects of the printer; but still the errors are less found in form and general outline of the objects than in too glaring or impossible hues, or in attempts to depict in florists' flowers certain features that such flowers never have possessed. In one very admirably illustrated list we noted a black and white picture of a supposed first-class Gold-laced Polyauthus every pip of which had seven petals and fourteen The artist, in striving to show the merits of the strain of seed offered, somewhat overdid his duty, and exhibited a slight ignorance of the structure of what should be a well known flower that ordinary observation might easily have corrected. Few good Gold-laced Polyanthus flowers have more than five petals and ten lobes, though twelve lobes are occasionally visible. This is one of those minor errors found in catalogue illustrations, but amidst so much really excellent work it may pass. No doubt catalogue illustrating is a costly business, but we must hope that it pays. Seedsmen may be trusted to know their own business best. Certainly the illustrations in the main being truthful are instructive, and the pictures are, as a rule, far better than are those found on seed-packets; indeed, a good illustrated list renders these latter of little moment.

- MARKET VEGETABLES. - The season, so far, has been most favourable to market growers, not only in the constant growth seen in the hardy crops, but also in the admirable manner in which the ground works, and has favoured its cleaning and turning throughout the winter. Already considerable breadths of early Peas and Broad Beans are being sown, and should the weather continue dry as in the past, we may expect to find unusually large breadths of Peas sown this season-not least, perhaps, that seed is fairly abundant. Peas are a popular crop, not only because always profitable and certain, but also because they are soon cleared off. The haulm, well harvested, is useful for winter fodder, and the ground can be recropped immediately. All kinds of greenhave made continuous growth, never having received a day's check. Such an experience, even in past mild winters, is most unwonted, but frost, rain, and wind alike, have all remained quiescent, and the

winter, so far, has been little other than a pleasant The dry condition of the soil and the mild autumn. weather have proved favourable to pruning, and that work has been greatly advanced. Specially valuable has the dryness of the weather been for foul soils, as forking and cleaning have been done largely; indeed, we have never seen so much activity in the market gardens during the winter months as in the present season. Thus not only have the poor been spared much suffering and pinching, but work has been un-Let what may he said as to the usually abundant. profitableness or otherwise of fruit culture, and of spade labour in particular, at least market gardens, if in the hands of capable men, come into any locality as a blessing to the labouring classes, finding them ample work at good wages, and generally diffusing the sweets of abundance all around.

- VACCINIUM VITIS-IDÆA. - At Chiswick we recently saw a singularly beautiful variegated form of this charming little native shrub, the copious creamy white markings contrasting well with the dark glossy green. Either as a pot-plant, or grown as a border to dwarf plants in the "American Garden," or as an isolated patch on the rockery, this pretty variety is be appreciated. The type itself, with its almost black-green Box-like leaves, its pretty pale pink flowers, and its blood-red berries which remain on the plant for a considerable period, is an object of no little beauty. LOUDON says:—"The berries are scarcely to be eaten raw, but they are made into pies in Derbyshire, and in Sweden a rob or jelly is made from them which is eaten with all kinds of roast meat. In Sweden this preserve is also considered an excellent medicine in colds, sore throats, and all irritations of the mouth or fauces. In Siberia the berries are macerated during the autumn and part of the winter, in water, and after they are eaten in a raw state, and fermented along with Barley or Rye, and a spirit distilled from them; or with honey, and a wine pro-duced. Sweetments are also made of them with honey or sugar, which in 1814 we found in frequent use at Moscow at balls and masquerades, In Sweden and Norway the plant is said to be used in gardens for edgiogs, as Box is in Central Europe; and in British gardens it is sometimes so applied to American beds and borders, and in other cases where the soil is peat. From its smooth shining foliage, and the beauty of its flowers and fruit, the latter being retained on the plant for several months, it forms a more beautiful and varied edging than Box, provided clip-ping can be dispensed with." At one time, as appears from TUSSER'S Five Hundred Points of Good Husbandry, published in 1573, Hurtill-berries were grown in British gardens. Hurtleberries, according to Sir JOSEPH BANKS, are the fruit of Vaccinium Vitis-Idea, although in BRITTEN and HOLLAND's Dictionary of English Plant Names they are said to be V. myrtillus. Sir Joseph Banks, in a paper published in the Horticultural Society's Transactions says, "Hurtleberries, the fruit of Vaccinium Vitis-Idæa, though no longer cultivated in our gardens, are still esteemed and served up at the tables of the opulent people in the countries that produce them naturally; they are every year brought to London from the rocky country near Leith Tower, in Surrey, where they meet with so ready a sale among the middle classes of the people that the richer classes scarcely know where they are to be bought.'

- THE TUBER-BEARING SPECIES OF SOLA-NUM .- At the Linnean Society's meeting held on January 17 a paper on this subject was read by Mr. I. G. BAKER. In 1882 there were grown in Great Britain 541,000 acres of Potatos. Taking the average yield at 7 toos an acre, and adding to this the quantity imported, which in 1882 was 200,000 tons, this gives us 4,000,000 tons as our average annual consumption, which at 5s. per hundredweight amounts to As they stand at present in £20,000,000 sterling. As they stand at 1 DE CANDOLLE'S Prodromus and other books the tuber-yielding Solanums are estimated as twenty distinct species. Mr. BAKER thinks that not more than six of these are really distinct species in any broad sense, these six being :—I, S. tuberosum, a native of the dry regions of the Andes from Chili northwards, reappearing in Mexico and the Rocky Mountains; 2, S. Maglia, a native of the damp low regions of Chili near the coast as far south as 44°-45° 3, S. Commersoni, a low-level plant of Uruguay and South Brazil, lately published as a novelty under the name of S, Ohrondii ; 4, S, cardiophyllum, a native of the highlands of Central Mexico; 5, S. Jamesii, a native of New Mexico and Arizona; and 6, S. oxycarpun, a little known plant from the Mexican bighlands. Of the two last the tubers are very small. All our cultivated Potatos belong to forms of S. tuberosum, but the species gathered by DARWIN in the Chonos Archipelago and that experimentised upon by SABINE at Chiswick, are both Solanum Maglia. The author attributes the deterioration of the Potato plant partly to its being grown in too humid climates, and partly to the tuber having been unduly stimulated at the expense of the other organs of the plant. There are many hundred species of Solanum known, which do not possess any tubers at all, but which maintain their ground in the world by means of their seeds alone. He urges then, in order to extend the power of climatic adaptation of the Potato, that species 3 and 4, both of which have been fully proved to yield a large supply of eatable tubers, should be brought into cultivation and tried, both as oure specific types, and as hybridised with the innumerable forms of tuberosum.

- GLUCOSE, OR GRAPE SUGAR .- Regarding the manufacture of glucose, or Grape-sugar, which has occupied so much attention of late in America, it is stated in a recent report that, owing to the unwillinguess of manufacturers to impart information, it is difficult to obtain trustworthy statistics in regard to the aggregate quantity produced. Latterly, however, prices of refined sugar have fallen so low in America that its adulteration with the corn product has ceased tn be as profitable as heretofore. The cultivation of Sorghum, and the production of sugar therefrom, is still in an experimental stage. The Maple sugar industry continues to be of considerable importance in some of the Eastern and a few of the Western States, but there appear to be no reliable data on which to found an estimate of the quantity produced. The State of Vermont is perhaps the largest producer, the quantity now manufactured being estimated at 15,000 tons, the other States producing altogether about 5000 tons.

— TECOMA AUSTRALIS.—Although not nearly so handsome a plant as many of its near allies, this species is worth a place on the rafter of the cool greenhouse. The dark green glossy pinnated leaves form a pleasing contrast with the numerous small somewhat trumpet-shaped flowers, which are yellowishwhite, tinged inside with purple. A good specimen in full flower may now be seen in the conservatory (No. 4) at Kew. Under the name of Eignonia Pandone it was very many years ago figured in the Botanical Magazine, tah. 865. The species is found in a wild state widely distributed over the Australian continent.

— Irsea speciosa.—There is now represented in flower in the Kew Orchid collection a terrestrial Orchid which is but rarely seen in this country, and perhaps at present exists in no other establishment in the British Isles. It is a handsome species with the general habit of a Bletia, the flowers being produced on scapes I foot or more in height before the solitary leaves appear. I no clour the flowers, which measure about 2 inches or 2½ inches in diameter, are a golden-yellow, with faint reddish lines on the disc of the lip. The Kew plants were sent from Ceylon. Some years ago a good figure of tpsea speciosa appeared in the Botanical Magazine, tab. 5701.

- HENEGUEN OR SISAL HEMP .- In a recently issued Government report on the trade and commerce of Mexico the following appears:—"Heneguen, known in England as Sisal, or Sisal Hemp, and so called from the name of a port whence large shipments of it used to be made, is the product of a plant of the Agave family, and is grown almost exclusively in the Yucatan. Its uses for the manufacture peninsula of of cords and ropes were known to the ancient inhabitants of Mexico, but it is only within comparatively recent times that its value has been recognised in other countries, and it has come to be an important item of export. It is said that cables of Heneguen are superior to those made of Hemp, in that they retain their flexibility unaltered by cold or wet; but in spite of this and of the great and growing demand for it, especially in the United States, the price is always considerably below that of a similar class of Manila. Ixile is the fibre of another species of Agave, which flourishes principally in the States of Tamaulipas, San Luis de Potosi, and Vera Cruz, and is of some-what finer texture than the Heneguen. Up to quite recently no apparatus has been found that will satisfactorily separate the fibre from the pulp, and it is probably due to this that the price of it is so much higher than that of Heneguen, which can be treated by machinery." To show the enormous development of these industries in the past fifteen years it is stated that "the United States, which takes on an average 80 per cent, of the gross amount of fibre produced in Mexico, imported in 1867, under the head of Hemp and Jute, 975 tons of these materials, whereas in 1881 the imports under the same head amounted to 17,454 tons." The writer of this report has made some confusion in the trade names of the fibres, as well as in their botani-cal classification, referring them to the genus Aloe. The Sisal Hemp of commerce is furnished by Agave Ixtli, KARWINSKI, var. Sisalana, ENGEL., and plant is called "Sosquil" in Mexico, and " Cabulta 1 in Central America. To extract this fibre the fleshy leaves are scraped with a long wooden implement, having three sharp edges; by this process, it is said, all the Sisal Hemp brought to market, as well as the infinitely larger quantity used by the natives themselves, is slowly and laboriously extracted, the produce being only from 5 lb. to 6 lb. per day. report refers the Sisal Hemp to plants belonging to the Aloe family, instead of which, as is well known to our readers, the species of the genus Agave helonging to the Amaryllidaceæ.

- ASTRAP.EA WALLICHII .- The large leaves and drooping heads of bright red flowers, as large as those of some Rhododendrons, give to this plant a peculiar appearance. It has long been in cultivation in this country, but is rarely met with except in large establishments or botanic gardens. Perhaps this is because of the space required in order that the plant may develope itself sufficiently to exhibit all its beauties. ELLIS, in his Visits to Madagascar, speaks in eloquent terms of the strikingly beautiful effects produced by the large foliage and the long-stalked pendulous flower-heads, when seen from beneath, as he was conveyed in a boat upon the streams along the banks of which large-sized trees of this handsome Byttneriaceous plant were growing. The species was first sent to Kew by Dr. WALLICH from Calcutta, whither it had been introduced from Madagascar. A figure appeared in the Botanical Magazine, t. 2503. In the Palm-house at Kew a good specimen is now bearing a number of its showy flower-heads.

- THE WEATHER, -General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending Jan. 21, 1884, issued by the Meteorological Office, London :- The weather has continued very dull and gloomy in almost all parts of the kingdom, though, except in the extreme west of Scotland, dom, though, except in the extreme west of Scotland, there has been very little rain. The temperature has again been very high for the time of year, the excess in "Scotland, E." being 9°, in "Scotland, W." and "England, N.E." 7°, and in most other districts 4° to 6°. The maxima were recorded either on the 4 to 0. The maxima were recorded either on the 15th, 20th, or 21st, and ranged from 51° in "Scotland, N.," "England, E.," "England, S.W.," and the "Channel Islands" to 54° in Irelaod, and 55° in "Scotland, E." The minima, which were registered on different days in the various districts, ranged from 30° in "England, E.," and 31° in "Scotland, E.," to 40° in "Ireland, S."
The rainfall has been a little more than the mean in "Scotland, W.," but less in all other districts. Over the greater part of England scarcely any has fallen. Bright sunshine has been generally ficient. In "Scotland, E." 37 per cent. of the possible duration was recorded, but in other parts of the sible duration was recorded, but in other parts of the kingdom the percentages were much lower, varying from 4 in the "Midland Couoties," and 5 in "England, N.W." and "Ireland, S.," to 21 in the Channel Islands, while in "England, S.W." the weather was quite sunless. Depressions observed.—During the whole of this period an anticyclone, in which barometric readings were an anticyclone, in which caronic retainings we above 30.6 inches, lay over France, or the southern parts of our islands. No depressions of importance approached our coasts until near the end of the week, when (late on the 19th) an exceedingly deep and rapidly moving disturbance reached our extrem northern coasts from the west ward, causing very violent south-westerly gales in the north of Scotland, and fresh or strong gales in the west and north generally. As this depression passed away over Scandinavia it was succeeded by another, which on the evening of the arst was shown off our north-western coasts, occasioning a rapid decrease of pressure over Ireland and Scotland, and strong winds or gales on all our coasts,

COLONIAL NOTES.

CINCHONA .- One fact becomes more and more apparent that although Cinchona cultivation is still increasing in different parts of the world, especially in Ceylon and Jamaica, considerable uncertainty exists as to the exact species that are being grown. It is evident that until this confusion is cleared up the commercial cultivation of the plants can only be carried on by rule of thumb, and the assistance the chemist would be capable of rendering to the cultivator will be minimised through the shortcomings of the botanist. Nevertheless some interesting facts have been placed on record, and one or two of these point to the probability that when the botanist has done his work he will only have made it still more evident that the cultivator must always look to the chemist to help him to decide under what conditions of growth any species or variety of Cinchona may be made to produce the most favourable yield of alkaloid. In the first place Dr. Trimen has reported some experience with what were believed to be succirubra plants all raised from one kind of seed, which seems to show that elevation has a great influence on the development of alkaloids, nearly twice as much alkaloid found in the bark grown at a height of 5500 feet as in the bark grown at 1500 feet, whilst the alkaloid in the former case was mainly lævorotatory (quinine and cinchonidine) and in the latter case principally dextrorotatory (cinchonioe and quinidine). Analyses made by the late Mr. J. E. Howard of barks from different elevations in Jamaica and in Ceylon appeared to confirm this inference, and it is worth mentioning that in all the cases the bark grown at the lower elevation, though considered to have the best appearance, was poorest in alkaloid. Mr. D. Howard has recorded the observation, that whilst in renewed bark produced on trees after strip-ping according to Mr. McIvor's plan, in which alternate strips are removed down to the cambium, the proportion of quinine is higher than in the original bark, the reverse is the case in renewed bark produced after the "shaving" process, in which the bark is usually removed uniformly and superficially, the tendency being then to develope cincbonidine at the expense of quinine. He also states, as evidence of the field there is for skill in the selection of Cinchonas for cultivation, that he has met with original "Red Bark" yielding 4 or 5 per cent. of quinine, whilst Calisaya bark from individual trees, grown in Ceylon under apparently similar conditions, varied from 3 to 9 per cent. in their yield of quinine. Such a result is perplexing; nevertheless, the general results seem to show that, other things being equal, the plants yieldiog the most valuable barks grow in the richest soil, which is quite in accord with what might be expected, and also with the experience of Mr. Broughton, published a dozen years ago. A similar lesson as to the relative effect of the depth to which the bark is removed appears to be taught by some analyses made by Mr. J. Hodgkin of different pieces of Ceylon succirubra quill-bark taken from the same consignment, some being natural, some renewed, and some partially natural and partially renewed on the same piece. In the renewed portion of the natural-renewed quill, where the shaving removed would necessarily be decreasingly thin, the quantity of quinine was less than in the entirely natural quills, while the cinchonidine was more than double. The entirely renewed bark showed an increase of quinine equal to 75 per cent, which more than outstripped the in-crease in cinchonidine. The cinchonine did not show much variation, but there appeared a consider-able diminution of alkaloid in the natural bark in juxtaposition to the renewed bark, Pharmaceutical

SHARK'S BAY.—Baron F, von Mueller has published a list of the plaots indigenous in the neighbourhood of Shark's Bay, West Australia, prefaced by a few historical remarks. The plants upon which the list is based were collected by the Hon. John Forrest. The herbage is varied, and in some respects excellent, the species of Gastrolobium and Oxylobium, which are deleterious to sheep, not being represented. Many tropical species extend into this part of Australia, and various southern forms are seen to extend northwards. Two new Verticordias are described, their presence in a sub-tropical region being very interesting. Proteaceæ are well represented, but Epacridaceæ, Candolleaceæ, Ferns and Orchids, are wanting

Home Correspondence.

Hardy Primroses.—I send you herewith a box of Primrose flowers in many colours, not to show the "mildness of the season," that has been amply demonstrated already, but rather to exhibit the purity and freshness of colour found in the blooms this season. Here, growing in a horribly stiff unkind clay, without a particle of shelter, the Primroses exhibit exceeding beauty such as at this usually inclement season of the year might well cause us to wonder whether May has not fallen into the arms of January. The flowers may not be equal to Orchids in rareases or elegance, but I think there are few households, how-soever rich and fasticious the residents, in which a duplicate lot of flowers would not be welcomed. The little bunch of one kind shows how near we are getting to really blue flowers. A. Dean, Bedfont. [A charming bouquet, Ed.]

Camellia Donckelaari.—This old and not often grown variety is quite worthy of all the favour in which many cultivators still hold it. It was formerly more generally met with, and old plants are to direct from Japan, were carefully cultivated under glass, and immediately they were up in the seed pans were all attacked and destroyed. In a case like this it really does not matter whether the fungus is a Leptopuccinia, an Uromyces, or an Euromyces (to quote the elegant phraseology now being grafted on to the subject), or whether De Bary pot his spores to germinate or whether he did not, for there are no spores in the question, either Uredo spores, teleutospores, Æcidiospores, promycelium spores, or any other spores, big or little. The simple fact is, the seeds were probably saturated with the disease plasma of the fungus, exactly in the same way as the Celery seeds were in the instance described by Dr. Cooke. In that case, seeds taken from clean plants produced a crop of Celery free from Puccinia, and seeds from diseased plants produced plants every one badly infested with P. Apii; and although the plants were grown near each other in the same garden, one row of Celery keep free from disease, and the other row was destroyed by the fungus, which it doubtlessly inherited from its parents through the seeds. Just in the same way as hereditary disease is handed down from the parents in the ovum in animals, so disease is often carried on from one generation to another in the seeds of plants. No one can see the germs (say of phthisis) in an ovum; why should disease germs be visible

nearly all in this district originated, were brought from Leicestershire by the wife of our late vicar. A. D. Webster, Llandegai, Bangor.

An Old Pear Tree made Fruitful,—Reference having been made in the columns of the Gardeners' Chronicle to a Beurré Rance Pear tree on a south wall during the past year, carrying a crop of thirty dozen fruit, allow me to say that, on having the erop gathered last autumn, I had the fruit weighed, and they gave an average of 12 oz. each. This Pear tree was tap-root pruned three years ago, and fresh soil given after the operation. It has matured sixty dozen of fine fruit since the root-pruning. No good fruit had been taken from this for many years before. I send a few fruit for your inspection. Robert Smith, Kenward Gardens, Yalding.

Natural Layering, —In proportion to the frequency we observe it, or the commonness of its occurrence, so the less will our curiosity be excited, or our attention drawn to the many and wonderful contrivances Nature has recourse to for the multiplication of plant life. When individuals are increased by specially modified structures, as the runners of Strawberries and of some species of Potentilla, or the stoloniferous stems of some Hawkweeds, or the

FIG. 24.-FRUIT OF CAMELLIA DONCKELAARI.

be found growing in borders or tubs that are wonders of floriferous beauty in their season. It is a moderate grower, and sets its bloom-buds freely—so much so that a timely thinning-out of these is advantageous, four or more often making their appearance on the tips of the shoots. It is also a variety that produces seed almost as abundantly as single forms of the Camellia, and which, on plants kept under glass the whole year through, will be ripe during late autumn or winter (see fig. 24); these are as useful for stock rearing as those of C. simplex, and reproduce the variety with some degree of constancy. The plant from which the drawing of the bloom (fig. 25) was taken grew at Spring Grove, Bewdley, the residence of J. D. Clarke, Esq. The plant was 10 feet in height and 6 feet in diameter, and the flower sent measured 13 inches in circumference—a fine example of the variety.

Sweet William Fungus,—I think Mr. C. B. Plowright, in adverting to this subject on p. 88, has completely overlooked the meaning of the instructive letter on the Sweet William fungus that you published on p. 57. Of course it is very interesting to hear what my esteemed friend has to say about the fungus being "a true Leptopuccinia," and curious to hear that he considers it may be a distinct species peculiar to Dianthus simply because De Bary's effort to make it grow artificially on Lychnis and Silene (where it grows naturally in profusion) had "no effect." The really instructive part of the original letter is this:—Your correspondent's Sweet William seeds came

in all tissues? The subject is an important one, and this case has a distinct bearing on the allied fungus of corn mildew, Puccinia graminis, which no one doubts is carried on from one generation to another in the seeds. This being the case, and nearly every grain of corn being probably saturated with the poisonous plasma of corn mildew, the statements regarding the production of mildew on corn from the contact of spores from a Barberry bush (the corn, it must be remembered, being almost invariably infested with breeditary disease) should be received with very great caution. W. G. Smith.

The Stinking Hellebore (H. fætidus).—When in full flower this is both a distinct and beautiful plant, as may at present be seen in some of the woods here, where it frequently attains the height of over 2 teet, and with from forty to fifty flowers on a stem. I believe it to be wild here, indeed its occurrence in one or two ont-of-the-way places at once dispels the idea of its having been introduced. After reading Mr. Brockbank's excellent article on "Helleborus niger and its varieties," I am inclined to believe that most of the plants grown by cottagers in this neighbourhood are none other than the Brockhurst variety for on examining those in several gardens about, I find them to exactly agree with his description of that form—the stalks being green, and with scarcely a trace of purple mottling, and which Mr. Brockbank describes as the great difference between his and Miss Hope's variety. The original plants, from which

Willow-herbs, we conclude it is natural; and so it is. But when ordinary stems are made to serve the purpose of increase our attention is diverted to it at once, as correspondents testify at pp. 56 and 90 of the present volume. Forsythia suspensa and Jasminum nudiforum, belonging to two closely allied yet distinct natural orders, annually produce long, flexible, cord-like shoots that emit roots freely at their tips on coming in contact with the soil. They seem even to possess the power of burrowing or inserting themselves to some depth in the soil, and forming a sharp angle, or knee, when the main axis is continued beyond the point where roots are emitted. If grown near to, or fastened to, a wall which is not too solid or dry, young shoots will often insert themselves into the crevices, and continue to grow and flower freely, although severed from the parent plant. In a state of Nature this habit could not fail to be of service in rambling over or amongst rocks, bushes, or other of Nature this habit could not fail to be of service in the sharp of the state of the growns eason is at all a moist one roots will be readily produced where the branches rest on the ground, much to the inconvenience of the cultivator. Among other exotic plants coming under the care of the gardener, and requiring hothouse treatment, analogous instances occur in subjects more or less widely related and dissimilar in appearance. Russelia juncea, and several

or most of the other species, root freely and form young plants if the twigs are allowed to come in contact with the soil in which they are growing, or damp ashes or gravel on which the pots are stood. The lower shoots of Barleria flava proceed for some distance in almost a horizontal direction, then suddenly turn upwards, forming a right angle with the older part. From the lower side of this knee great fleshy roots are produced, although in no way touching the soil. In Mariea gracilis we have a remarkable instance, not of a stem, but a flower-stalk becoming proliferous. After flowering young plants originate inside the spathes whence the flowers emanated. As these plantlets increase in size the stalks bearing them hang down, affording them an opportunity of rooting into the soil. If by any chance they have failed to root they will nevertheless remain fresh for a year, at least, and produce flower-stalks while yet in active connection with, and supported by, the parent plant, Z.

Potato Disease,—It does not seem to be so well known as it should be that Potato tubers are fre-

December 1, 1883, p. 698) is generally mere sun burning, or natural autumnal fading, and no evidence either of ill health or the presence of the Peronospora. With this I send you evidence (but not for publication) of the correctness of the above remarks, W. G. S.

Watering Plants,—Simple though the watering of plants may appear, it is one of the most important operations in gardening, and requires great skill and knowledge, as so much depends on the way it is carried out, for however good and suitable the soil may be for the particular subjects it is used for it may soon be spoiled by the indiscriminate application of water, which, if administered in too great quantities, or at the wrong time, clogs the soil, and quickly renders it close, sour, and inert. Many, thinking perhaps to avoid these evils, are in the habit of giving water in driblets, which is as great a mistake as giving too much and too often, as by adopting the first course the balls of the plants are never properly soaked, and though they may appear sufficiently moist above it frequently occurs, and would be seen if they were examined, that they are dust-dry below. For Heaths

activity and vigour of the freshly formed roots. J. Sheppard.

Jasminum nudiflorum,—This fine winter blooming climber is so beautiful on the cottages in this locality just now, and, indeed, has been so for some time, the fine open weather favouring the flowers to the utmost, that one marvels not to find it amongst forced market plants. It blooms so freely, even near to the ground and upon every piece of wood, that were small well wooded plants specially prepared for pot culture, as Deutzias and similar things are, the result should be very successful. A plant that blooms naturally at Christmas would, of course, need little forcing, and though it is common enough in the country, it is not so in towns. For these reasons this Jasmine should make a popular winter pot plant. A. D.

Senecio mikanioides.—This plant, mentioned on p. 86, has not been turned to much use in England, and though it has been in very good hands it has failed to make an impression. I have had it for at

Fig. 25.—Camellia donckelaari. (see p. 120.)

quently badly permeated with disease when there is no sign whatever of its presence on the skin of the Potato. Potatos are harvested apparently sound, and the keenest eye can detect no discoloration of the skin. On cutting such Potatos in pieces the interior mass, and that only, is often brown with the disease, and this does not reach the skin. During the winter this brown stain at length travels to the skin from the linside, and then bursts through and produces the Peronospora. It is evident that in instances of this class (which are perfectly well known to practical men) the disease cannot have reached the tuber through the skin from the outside, but must have traversed the stem. In other instances tubers are sometimes badly diseased when the plant above-ground has shown no outward trace of the perfect Peronospora. In fact the Peronospora sometimes confines its growth entirely to the interior of the plant, and does not burst through the organs of transpiration at all. The presence of the Peronospora within is manifested only by a peculiar faint putrid odour, and the much deeper green tint of the foliage. The presence of the Peronospora within its manifested only by a peculiar faint putrid odour, and the much deeper green tint of the foliage. The presence of the Peronospora within the tissues causes an abnormal production of chlorophyl), and the dark green colour of the leaves is a certain sign of disease within. The "yellowish tinge" referred to as a sign of ill health in a recent lecture (Gardeners' Chronicle,

and Azaleas to get in this condition is very injurious, as their hair-like roots must perish, and the only way to prevent this is to give thorough soakings when they require water, and then leave the plants to themselves till they need the same attention again. The experienced cultivator knows when this time has arrived by giving a single glance at the soil, but there are other indexes to go by, such as touching the surface of it or sounding the pots by a rap from the knuckle, when, as the balls shrink from the sides if dry, and the soil becomes full of air, the pots will ring, but if the balls be wet there will be little or no sound beyond a dull thud, which proves that the soil is full of moisture, and should have no more till the greater portion of what is in has evaporated or has been taken up by the plant. The great thing is to find out and fix on the happy moment when the drink is wanted, which time, careful observation, and a little practice will soon teach, as to the watchful eye plants soon show their requirements by their distressed or satisfied look. During winter, except where there is much artificial heat kept up, very little water is needed, and by keeping plants rather on the dry side when they are not growing or flowering they get a rest, and the soil becomes aerated and sweetened, the highly beneficial effects of which are seen in the spring by the improved health given through the increased

least ten years, though I cannot tell how it came into my garden. It was used for trailing from baskets, but though it makes much longer shoots than the Ivy-leaved Pelargoniums, which it imitates, it is very inferior to them in neatness of growth, and I have never seen it flower out-of-doors. I have given it to some of the best gardeners in my neighbourhood, who were struck by its very vigorous growth, but I have within the last two years discarded it as a useless plant for outdoor decoration. C. W. Dod, Llandudno, Jan. 21.

Filtering Fungus Spores through Sand,—The position my friend Mr. Plowright takes in regard to this subject reminds me of the chief character in the Barbier de Séville—wheo I think I have "cornered" him in one direction he suddeally appears in a wholly unexpected position. My friend now says my glass tube experiments were imperfect, and that the imitation of rainfall was incomplete. There was nothing then left for me but to patiently await a real shower of rain, so I told my people here to be on the look out for one. Just as I was going to bed on Sunday night, my maid told me a few drops of rain were falling, so in a trice I whipped out a clean flower-pot, \$\frac{1}{2}\$ inches wide and the same deep, covered the hole ioside with calico, filled the pot with sand and #2-urated the sand

with water; when the water had drained out I put the pot in a perfectly clean white plate and placed a few oats diseased with the smut fungus on the top of the sand. Before I went to bed the moon had risen and all seemed to bid fair for a fine clear night. Many times during the night I got out of bed and made meteorological observations at the open window, but although there might have been a slight fall of rain during the night, I saw the stars every time, and could detect onthing on my naked arm but a little dew. At the break of day I rushed to my flower-pot with a heavy heart, and on taking it from the plate one or two drops of water had percolated through the sand and calico and rested under the hole at the bottom of the pot. My microscope was ready, and a \(\frac{1}{2}\)-inch object glass ready screwed in. With a clean camel's hair brush I transferred the drops of moisture to a clean gase plate, and on examining them under the microscope they were charged with Ustilago spores. As overy little moisture had fallen I did not expect to see any. I do not doubt any of my friend's facts—far from it; I esteem his facts highly, and carefully catalogue them. I only doubt some of the deductions he (as I respectfully think) perhaps too hastily draws from his facts. W. G. Smith.

Glass v. Wood: Cordon Pear Trees, Tree Glass v. Wood: Cordon Pear Trees, Irree.
Labels, &c.—Perhaps there are few gardeners of the
present day who are not convinced that the more
glass and the less timber there is in horticultural
buildings, the better they are adapted for plant, and
especially for fruit, growing. But it is one thing to
the convinced in one's own mind that such is the case. be convinced in one's own mind that such is the case, and another to put one's own idea to the test of practice. As no one would like to see his house fall, either before or after it is finished, I confess I have felt my way up, and I also confess that I was some-what afraid before I finished my last effort, that it might be a failure; but as it has in every way been a might be a failure; but as it has in every way been a success, I will describe the house in the hope that it may be of use to some who would be glad to reduce the wood. It is a small house, in two divisions, 34 feet long and 12 feet wide, and the back wall 12 feet 6 inches high; 9 feet 6 inches of brick and 2 feet 9 inches of glass, in which are the ventilating libble, on gives consigning by the sural elbow because lights on pivots opening by the usual elbow bearers. The front wall is 2 feet from the ioside border, 1 foot Ine front wan is 2 feet from the losted border, I loof brickwork and I foot of wood, in which there is a 6-inch board opening in the usual way. The astragals (for there are no rafters) are 16 feet 3 inches long, and before being worked were 2 × 1½ in., (now a little less), and the rabbet, ½ in., under the glass is well bevelledoff. Italf way up the sashbars, and screwed to each, runs a purline of 14 angle and to each runs a division are two supports of 14 in, from barrel, and from their junction with the purline are carried horizontals of the same size to and let into the back wall. This makes the whole structure as rigid as if times the amount of timber and iron was used. front plate, which is bevelled outside and in, is covered with lead trimmed into the O G gutter projecting in over inside, no water can lodge on the plate. The glass does not project over the plate in the usual way, but pitches on to the lead which carries the water into the gutter. All plates, &c., are bevelled on the inside up to the glass, the size of the panes of which is 16 × 27 inches. This will show that there are but few sashbars in such a house; the simplicity and little building there is are in themselves a recommendation, but the light is the desideratum. The whole thing looks as frail as a spider's web, but it stands the pressure of the wind, to which it is much exposed, better than any house on the place. It was built for an early Peach-bouse, to supply fruit for the London season, and planted with Waterloo, Alexander, Hale's Early, and Early Beatrice; but I have done with houses in England, and hope in a have done with nouses in England, and hope in a few weeks to be where they are not required. I intend about the end of the present month to go to Queensland—not to give up Peach growing, but to add to it the cultivation of Sugar, Pines, Bananas, Sc. Before I stop writing may I trespass a name farther on your space to enter a plea for oblique cordons on walls? Three years ago next March I planted a wall 75 yards long with Pears and Plums in about equal numbers and at 18 inches apart. Some of the Plums are now 13 feet long. They were all maidens. Not an inch was cut off any of them, but the points were bent down, and they broke from tip to the points were bent down, and they broke from tip to bud. Some recommend cutting them back to cause them to break regularly, but it is a waste of time. Owing to the cold and bad soil here Pears in the open quarters do badly, the fruits being small, spotted, cracked, and of no flavour; but the cordon wall has shown us its advantages. True it has glass coping projecting 28 inches, with glass partitions projecting 24 inches at every 10 yards, and the result has been most satisfactory. Bearré Diel, for example, which was, perhaps, the worst of all in the open, has on the wall given us a heavy crop of fruit; and other sorts in proportion. The coping of fruit; and other sorts in proportion. The coping is light T and angle-iron, glass 28 × 24 inches, and removable (it is all out now), but the partitions are permanent. I have heard cordon Pears objected to

because they do not stand pinching well. I never pinch them, but after the second or third leaf has been made I keep the rest picked off. The shoots grow weaker, and soon harden, when they are cut half-way back; they soon break again, and the same process of picking goes on. In this way the permanent leaves are large and healthy, and surround fine healthy flower-buds, not one of which burst into wood in the past season. Plums stand any amount of pinching. Let me allude to yet another hobby, a short time ago in the Gardeners' Chronicle the subject of labels was wisely and very necessarily mentioned. Well, there are labels and labels, but those manufactured by Mr. Smith, Stratford-on-Avon, either for nailing or hanging or placing in the ground, I think are as yet the best. Should a few Queensland notes be of any interest to readers of the Gardeners' Chronicle, I shall be glad to supply them, and if I can but show that there is a better field there than here, the information may be of advantage to many, for when one sees in the gardening papers how many nurserymen there are who can advertise a stock of hands and brains at almost any price down to starvation point, I think it would be real philanthropy to try to ease the market. D. Buchanars, Shevwood, Tunbridge Wells. [We heartily wish our old and valued correspondent a pleasant voyage out, and good bealth and prosperity in his new home. The honest opinion of such an experienced man as Mr. Buchanan, on Queensland as a field of enterprise for British gardeners, would be of the greatest value, and we need scarcely add how glad we shall be to bear from him. Ed.]

FORESTRY.

INTERNATIONAL FORESTRY EXHIBITION. - The new lists of patrons and general committee of the above have lately been issued. The project has been warmly taken up in this country by such competent and influential authorities, in addition to those already announced, as the Commissioners of Woods and Forests, the Director of the Royal Gardens, Kew, the Secretary of State for War, the Institution of Surveyors, England; the Royal Society of Edinburgh, &c. ; while the names of the Senior Woods and Forests Commissioner for England, the Governor of South Australia, the Surveyor-General of Forests, New Brunswick; the Commissioner of Agriculture, Washington; and the Principal of the University of Edinburgh, have been added to the general com-The guarantee fund has been raised by the subscriptions of the Dukes of Devonshire and Westminster, the Marquis of Bute, Sir Samuel Wilson, and others, to considerably over £6000. But when the project is more immediately placed before the landed proprietors of Great Britain, whose interests it is intended greatly to promote, this sum should be largely augmented. Applications for space come in daily, and there is hardly a country in the world which will not be represented in one of the various sections. The outside collection in the way of foresters' huts, pavilions, fences of various kinds, &c., promises to be a large and interesting feature of the Exhibition. At a meeting of the Executive Committee, held recently, the Marquis of Lothian presiding, a letter was read from Dr. J. Crombie Brown, Haddington, offering to deliver lectures in the Exhibition on subjects connected with the forestry of different countries, and also offering to prepare handbooks of a popular nature on the same subject for sale during the Exhibition. The letter was remitted to the Committee on Essays and Reports. In view of several offers of special prizes having been intimated to the committee, a motion (of which previous notice had been given) came up for consideration, to the effect that special prizes be not accepted. An amendment empowering the committee to accept such prizes, was, however, agreed to by a large A communication was read from Iler Majesty's forester at Balmoral submitting plans of a Swiss châlet, which Her Majesty proposes to exhibit, along with sections of Scots Fir-wood from the Ballochbuie forest. The committee, it need hardly be said, very cordially accepted the offer. The proposed châlet will occupy a considerable extent of space, and, covered with bark, will present a rustic exterior. The sections of Scots Fir-wood will be shown both in and around the building, and, altogether, the display will form an interesting feature of the Exhibition. The question of the proposed site for the Exhibition came up for further consideration, and though the matter has not been definitely settled yet, the committee hope to be able shortly to announce the completion of the negotiations which are being made in this direction. The Committee on Applications for Space met afterwards, and disposed of a number of communications addressed to them. These applications, we believe, are coming in freely from various countries.

At a meeting of the Executive Committee held on January 16, it was reported that arrangements for a very eligible site for the Exhibition were all but completed, and the committee hoped to be able to announce at the next meeting all details and arrangements connected therewith. Applications for space were submitted to the meeting from various foreign Governments and numerous private individuals, all of which were conditionally accepted; and it was announced that the Prince of Wales, and various other members of the Royal Family, intend to exhibit several extensive and valuable collections of a suitable and interesting nature.

CARPETS FOR TREES .- During the dreary, naked, cold season of winter, when most trees are stripped of their foliage, it is not only a beautiful but refresh-ing sight to behold our woodlands carpeted with such dwarf shrubs as are suitable for growing beneath the shade and drip of our larger trees. Carpet plants, in contradistinction to general underwood, may be classed as evergreens, which, from their low, procumbent mode of growth, are hardly in the true sense of the word suited for game coverts. To clearly define the difference would, however, be no easy matter, and even were it possible to do so, would in the end be productive of but little good, as the habits of different plants vary so much that what is used io one place for carpeting purposes might in another and more favourable situation be equally valuable for game covert. A good example of this will be found in our covert. A good example of this will be found in our common St. John's Wort (Hypericum calycinum), which, when planted out and allowed to ramble at will amongst Bramble, Privet, &c., forms a capital covert, whereas when used in open, airy situationssuch as alongside shrubbery walks, or beneath our large woodland trees-soon forms a dense evergreen carpet, of so compact a growth as to be almost impenetrable even to ground game.

There are but few plants, comparatively speaking, of a low, trailing habit, that can be advantageously employed for planting in shady positions, the following being a list of those generally in use :- St. John's Wort, Periwinkles (Vinca major and V. minor), Gaultheria Shallon and G. procumbens, Euonymus japonicommon British Ivy (Hedera helix). The St. John's Wort, as a low, spreading shrub, is unsurpassed, and thrives best in a light sandy or peaty soil. It is readily propagated by division of the roots, and when planted out in small patches. when planted out in small patches, a foot or two apart, the creeping stems soon cover a considerable surface of ground, and form a dense evergreen mass, covered in summer with hright golden flowers. For covering the base of walls where, from the dryness of the soil, few other plants could exist, the St. John's Wort is invaluable; indeed, in this respect it is perhaps not excelled by any evergreen plant in cultivation.

A very pleasing effect is produced by having mixed patches of Periwinkle and St. John's Wort, as when in bloom the contrast of commingled yellow and blue is very beautiful. Both these plants are in flower here at present, which shows the extreme mildness of the weather, their usual flowering period being from May to July. The St. John's Wort is supposed by many to be injurious to the trees under which it is growing, and several iostances have occurred here in which Horse Chestnuts surrounded by this plant have gradually become unhealthy, and ultimately died out.

Gaultheria Shallon, another plant of creeping habit, is not withstanding its many good qualities, seldom planted to any extent in our woodlands; but this may, to some extent at least, be accounted for by the high price of the plants, as well as the small size of those purchasable from our nurserymen. Like most other North American plants the Gaultheria prefers a rather damp peaty soil, and is one of the few shrubs found to thrive in Pine plantations. The ornamental berries, which are borne in great abundance, are greedily devoured by pheasants, and, in their native country, are not unfrequently used as food. Johnston, in his Chemistry of Common Life, when treating of the "odours we enjoy" mentions that in the State of New Jersey, North America, the Partridge-berry Tea-berry, or Winter Green (Gaultheria procumbens), grows abundantly in the woods and drier swamps.

It is a dwarf evergreen, fragrant, heath plant, and possesses an agreeable aromatic odour, resembling that of the Sweet Birch. It has long been gathered and distilled, like other fragrant plants, for the sake of the volatile oil which in this way may be extracted from it. This natural essence is largely imported into Europe as a perfume, and is known in commerce as "Oil of Winter Green."

The Ivy which mantles over the old ruins, or climbs to the highest bough of the Oak, though in some cases not desirable, is better adapted for carpeting our woodland trees than most other plants. The extreme hardiness of this plant, combined with its ease of culture and dark evergreen foliage, renders the Ivy a particular favourite with most people. A damp climate and maritime situation seem to foster the growth of Ivy, and here, I am sorry to say, it has become quite a nuisance, and necessitated the expenditure of a great amount of labour in trying to eradicate it from young plantations. As an ornamental plant for carpeting the edges of woodland walks, or covering any unsightly garden object, it has no equal, and it will succeed in almost any soil or situation.

Several species of Euonymus and Cotoneaster are well fitted for ornamenting walks; the small leaved dwarf forms of the latter are especially valuable, and present us, when other trees are stripped of their foliage, always something on which the eye can rest, and on which is may be refreshed. Beneath clumps of trees, or even single specimens on the lawn, where the taller growing evergreens would have an unsightly appearance, any or all of the above plants may be successfully introduced as a carpet, in which positions they will be found to succeed even better than in the open. A. Webster, Penrhyn Castle, North Wales.

floqists' flowers.

THE NEW FLOWERS OF THE YEAR .- In the Scandinavian mythology we are told that when Thor and his companions arrived at Utgard he was told that "Nobody is permitted to remain here unless he understands some art, and excel in it all other men; and, says R. W. Emerson, "the same question is still put to the posterity of Thor," And the same writer remarks that the capacity of an Englishman is shown by his setting his shoulder to the wheel in order to advance his business, pursuing it with a wonderful heat, and working at it with a pertinacity that must accomplish worthy results. In some such persistent way the florist works and achieves. some it is given to combine in a new form all the good qualities of two others that had with them some alloy of imperfection. Others may be said to receive bountiful gifts from Nature, as unexpected as they are welcome. And it can be noted with real pleasure that there abounds a great activity in the production of new forms of flowers and plants, and some of the more prominent achievements of the past year are set forth in the following columns.

New AMARYLLISES have been in astonishing force during the past year, a greater number receiving distinguishing awards than in any previous year. Such an occurrence indicates the energy that is being thrown into the production of new varieties. Messrs. Veitch & Sons bave as usual come to the front, and such fine forms as Achilles, A. F. Barron, Adolphus Kent, Henry Little, Tennyson, and Wordsworth, are splendid additions to a numerous and very showy class, and they greatly enrich the extensive collection at Chelsea. There are evidences that an extended culture of these striking stove plants is one result of the activity of product :

Further proofs of the Rev. Mr. Horner's and Mr. J. Douglas' efforts to improve the Auricula were seen at the meeting of the National Auricula Society at South Kensington in April last. Mr. Horner has a fine new green-edge in Ajax, a flower of excellent properties throughout, and a valuable addition to a class needing to be strengthened. But this is one out of some thirty new varieties that Mr. Horner had raised, and the question is being asked, When will any of these new flowers find their way into general cultivation? Their sole possession by Mr. Horner places him at a great advantage as an exhibitor, for the Auricula is a flower that wins only on the point of quality in the pips, and

some of the newer varieties have this in a remarkable degree. Conservative (Douglas) is a fine addition to the white-edged varieties, and it will make a fine subject for the exhibition table. Mr. Douglas has a new green-edge in Mabel, which promises to be very useful. Conservative is to be distributed by Mr. Turner. The last-named has a wonderful break of alpine Auriculas. They are characterised by splendid pips, deep golden centres, rich body colours, with shadings or edgings as well defined as they are in the best laced varieties. During the past three years the alpine Auricula has taken a surprising leap forwards, and the credit of this is almost entirely due to Mr. Turner. It seems difficult to advance upon such varieties as A. Lloyd, Resplendens, Roysterer, and others; but who can forecast or limit the possidevelopment in any flower apparently capable of such expansion as the alpine Auricula? The double varieties increase slowly; but in Delicata (Dean), a large, firmly-formed primrose-yellow variety, we get an excellent companion to the deep purple Purpurea. A few other fine forms are likely to be seen next spring.

AZALEAS, now a very numerous class, were last season reinforced by a few fine varieties brought home from Ghent by the visitors to the International Exhibition - Antigone (double), white streaked and spotted with purple; Baron Nathaniel de Rothschild (double), rich purplish-crimson-very fine; Deutsche Perle (double), pure white - very fine in quality; and Princess Louise (double), salmon-pink, are among the best, and promise to make equally fine exhibition and decorative plants. Todman's Duchess of Albany is a hybrid variety, bearing medium-sized pure white flowers of good form, and produced with great freedom. It was certificated simply as a deco-

rative variety.

And what shall be said of TUBEROUS-ROOTED BEGONIAS? Their name is legion. It is interesting to note what an extraordinary accession was made to the double flowered varieties during the past year, not less than fifteen varieties having been awarded Certificates of Merit. Messrs. J. Laing & Co., as usual, lead the way with very fine double and some single varieties of superb quality. Mr. W. Bealby has also come to the fore during the year as an exhibitor of fine double varieties. The flowers of the latter are becoming much appreciated by dealers in cut flowers, as they can be wired and used in many ways.

Testimony must be borne to the great industry

shown by E. S. Dodwell in the production of new CARNATIONS AND PICOTEES. He has been eminently successful, and the high qualities of a few of his new flowers were recognised at the meeting of the National Carnation and Picotee Society in August last and elsewhere. C.B. Samuel Barlow, P. and P.B. Mr. Anstiss, S.F. Henry Cannell, P.F. Squire Whitbourn, and R.F. Dorothy, are all flowers of firstclass excellence. Mr. Turner's Rob Roy, S.F., is also a flower of first quality of the Clove type; Mrs. Keen, deep maroon, almost black, and Royal Purple, both from Messrs. Veitch & Sons, are decided additions to this latter class.

Of new CHRYSANTHEMUMS, the past season saw numerous additions to the Japanese class, and more than a dozen of these received awards at various places. The greater part were of Continental origin. George Stevens, Jeanne d'Arc, M. Astorg, Mons, Dufour, and roseum superbum, are very fine additions to the already largely-represented Japanese section. Bendigo is a finely incurved pale yellow sport from Mr. Heale; and Lord Alcester, a pale creamy-yellow sport from Golden Empress of India. Madame d'Arnaud is a very pretty rosy-purple pom-pon, shown by Messrs. J. Laing & Co.; and there are several Continental introductions in the class that were seen last year, which are entitled to the attention of English growers.

CINERARIAS had a good share of attention last season, and Mr. James secured over a dozen certificates. He has a strain remarkable for a dwarf and compact, yet vigorous growth, and large, stout, richlymarked flowers. As the Cineraria has pretty well ceased to be an exhibition flower, it may be assumed that these awards are intended to indicate only decorative value. Victory (Cannell) is a fine purplishcrimson variety, but with flowers inclining to coarseness, a defect common to some of Mr. James' varieties. One new double variety must be mentioned-A. F. Barron (Cannell), with large double rosy-purple flowers; but this class appears to be declining in popular favour.

New CLEMATISES are much less numerously produced than they were a few years ago; but Mr. Noble obtained three certificates last year, Jackmanni alba will give growers what was really wanted - a good white, summer blooming variety. John Brown, rich purplish-blue, and Krao, deep purplish-violet, are fine varieties of the lanuginosa

The COLEUS seems doomed to become to a considerable extent a neglected plant, though Mr. King, who is well known as a raiser, received certificates for Ellen Terry and Henry Irving, two varieties conspicuous for the beauty of their foliage. Canary Bird (Laing) has a prominent leaf-colouring which suggested

Mr. Henry Little, whose name has for so long been associated with the successful culture of the CYCLAMEN, produced three fine varieties last year, viz., Amethyst, a very rich purplish-violet; Mr. H. Little, the nearest approach to a crimson yet seen; and Mr. H. Veitch, a fine white variety of the giganteum type-all having been awarded Certificates of Merit. In the two former Mr. Little has reached shades of crimson and purple of astonishing depth and brilliancy.

It is long since so few new DAHLIAS put in an appearance as during the past year, and, indeed, but two certificates were awarded in London, viz, to Mr. Hurst, subsequently named Mr. W. E. Gladstone, a beautiful delicate show variety, and Duchess of Connaught, a distinct fancy sport from Old Gaiety. But it is rumoured that some fine show flowers that could not be exhibited in the autumn will be forthcoming in the spring. The single varieties increase with amazing rapidity, and they are now nearly as numerous as the Gouble flowers. Nor do they appear to have lost their hold on the popular favour. difficulty was experienced in making selections for certificates, and some of these went to a smallflowered section as being better adapted for general decorative purposes. One feature deserves notice, their adaptability for exhibition when set up in the form of bunches backed by their own foliage.

As usual Messrs, Kelway & Son were to the fore with new varieties of GLADIOLI, taking a dozen or so certificates for flowers of splendid quality. It seems invidious to make a selection where all are so good. Two new French varieties shown by Messrs. morin & Co., both of surpassing merit, received similar awards. It is said this flower is declining in the popular estimation, but if so, it does not appear to check in the least degree the enterprise of

A large number of new HYACINTHS were produced by Messrs. Veitch & Sons, and so fine have been the additions made during the past ten years, that it is only flowers of marked individuality that can now win certificates. Empress of India, rich deep crimson; Pink Perfection, delicate pale pink, and Souvenir de J. H. Veen, rich dark blue, are decided acquisitions.

The pretty crimson-maroon LOBELIA, Prima Donna, shown by Messrs. Carter & Co., with its dwarf-tufted growth and singular freedom of bloom, gives what is likely to prove a very useful bedding plant. As seen growing at their St. Osyth seed grounds it was winning in the extreme.

The rich crimson large flowered MIMULUS, Brilliant, shown by Mr. R. Dean, will prove of value as a decorative plant for pot culture; and the large hose in hose variety, named Novelty, though not new, is worthy of attention as being something more than a floral curiosity.

PELARGONIUMS of all sections are undoubtedly losing their hold on the public esteem, and perhaps one illustration of this is found in the dissolution of the Pelargonium Society. Mrs. H. Little is a charming pure white addition to the show class; it is of fine quality and very free. In the decorative section, Mr. Turner's Dresden China is singularly novel, having white flowers flaked and splashed with crimson and pale rose. Messrs. Pearson & Son produced some very fine new zonals; and Eckford's White Perfection pale rose. is an excellent pure white variety. Erl King and La Cygne, both new double forms in the zonal class, the first with salmon-scarlet, the second with pure white flowers, are both likely to prove extremely useful. Some good additions to the Ivy-leaved section have also been made-Dr. Masters and Future Fame, both raised by Mr. George, being of high

New forms of PRIMULA SINENSIS are plentifully produced, but the fine varieties raised by Messrs.

Sutton & Sons, Mr. G. Tomkins, and others, do not find their way to London. Careful selection is doing more probably than fertilisation to augment the num. ber of distinct new varieties; and the new blue forms, of which Holhorn Gem is a conspicuous type, arc being increased with added quality.

Every year sees fine additions of the new HYBRID RHODODENDRONS of the Javanese section produced by Messrs. Veitch & Sons. The individual flowers and trusses are becoming larger, bolder, and of richer colours. Such new varieties as Brilliant, Diadem, Scarlet Crowo, and Triumphans, among others, are

forms of great excellence.

In touching on new Roses it is satisfactory to note that English raisers now have a monopoly of those flowers which are distinguished by awards. Mr. Hose nowers without actusting under the Augustian H. Bennett has been very successful with his pedigree Roses, his Tea varieties being very promising. Merveille de Lyon, White Baroness, and Violette Bouyer, if quite distinct, are invaluable as additions to our white Roses. Anna Maria de Montravel and Mignonette are two charming additions to the Polyautha section, with their attractive clusters of flowers.

The useful group of SWEET PEAS is now engaging more attention than It did a few years ago, and Mr. Eckford is to be commended for his patient crossings. Five Certificates of Merit in one year to new varieties of Sweet Peas is a remarkable incident; one or two of these, though not strictly new, have hitherto been

but little known.

The group of TYDÆAS grown by Mr. Barron at Chiswick during the past season brought into notice the new additions that have been made by Continental raisers, and several Certificates of Merit were awarded.

A collection of VERBENAS grown in the open ground at Chiswick furnished several fine but not new varieties for bedding purposes. Mr. W. H. Stacey took honours with Delicata, Fantastic, Mabel, and Miss Maynard, all varieties with finely-rounded pips and distinct colours.

Of new plants coming under a MISCELLANEOUS heading it may be recorded that Messrs. R. B. Laird & Sons are sending out a batch of new Delphiniums, which will, no doubt, be looked for with some interest. Iberis Empress, a fine new annual Candytust, is identical with Dolbie's new Spiral Candytuft, and was first distributed under the last name. It is a very fine addition to the annual varieties. Some pretty new Gloxinias were shown by Messrs. Veitch & Sons, and others, Alabaster (Bennett) being one of the finest white varieties yet produced. Iberis gibraltarica hybrida is a most useful biennial, especially well adapted for pot culture. [Messrs. Carter & Co.'s deep blue-flowered form of Nemophila atomaria is a fine addition to this class of hardy anouals. Tropæolum Lustrous is an excellent crimson-flowered addition to the compactum class; and the excellent white Violet Comte de Brazzi is being warmly welcomed by all admirers of these sweetscented flowers.

The foregoing record, while not altogether exhaustive, is a worthy one, and characteristic of the sons of Thor who make floriculture their study; and what they have done in the past is but an earnest of what will be accomplished in the year into which we have but so recently entered. R. D.

Reports of Societies.

The Royal Botanical and Horticultural of Manchester,—Jan. 22.—The fifty-sixth annual meeting of this Society was held in the Mayor's Parlour of the Town Hall, Albert Square, Dr. John Watts, President of the Council, in the chair. The annual report having been taken as read, the Chairman, in moving its adoption, said he thought the members would find the report a very satisfactory document, but they would scarcely learn from it what a hard-working and anxions year the Society had passed through. Two years ago they had to rebuild the long range of plant-houses, enlarge the lawn by putting the houses further back, and remove the old Palm-house. They left off at the end of 1832 with a debt of Lagoo, which was an addition of 1832 with a debt of Lagoo, which was an addition of 1200 was caused by the rebuilding of the long range of plant-houses, and that he thought was a very satisfactory work. When that work was finished the Council thought they would have a little breathing the Council thought they would have a little breathing the council thought they would have a little breathing the council thought they would have a little breathing the council thought they would have a little breathing the council thought they would have a little breathing the council thought they would have a little breathing the same of the same part of the same part of the large exhibition house was had been of repairs. A year ago, when they asked a gentleman to look at it with a The Royal Botanical and Horticultural of

view to having it repaired, they could get no one to go on the roof, and they were solemnly told that if they ventured to keep it up they might have some of it coming down on the heads of the company beneath it. If anything had happened they would have had the moral responsibility, at any rate, and they came to the conclusion that the house must be pulled down. They had an early Whitsuntide coming upon them, and no possible plan of carrying out their ordinary large exhibition unless by a renewal of the house, but this they found was impossible, owing to its unsound condition. They had to do their best, and they determined not only to rebuild but to enlarge the house, so as to have more space for future exhibitions. They set to work in earnest, and when Whitsuntide came they were ready. They were not ready a moment too soon, for a more magnificent exhibition than the Whit-week exhibition of last year he though it would be impossible to conceive. The cost of the new exhibition-house and its heating apparatus was nearly Zooo. That was a very heavy sum for a small Society to raise in addition to its ordinary annual outlay. By the course adopted, however, that sum was raised, and they finished the year owing £330 less than any began it. He looked upon that eat as good cause in good dainy that money was in good hands they proved the set of the search of the year had been quite as well done as usual, if not even better than usual. In the autumn they had a grand they finished when year well had been quite as well done as usual, if not even better than usual. In the autumn they had a grand chibition of Apples, an exhibition of which, he ventured to say, Manchester never saw the like before. The Council though the Society was becoming increasingly useful in direct educational effort. They had established a series of lectures by Mr. Leo Grindon during the summer, and these lectures were becoming more popular year by year. They received an annual subscription from the Scientific Students' Association to admit their members received a third subscription from the Medical School at Owens College for the admission of their students. That was a line upon which the Society was prepared to enlarge. It cost them nothing, it was an opening for a very large amount of good, and would help the medical men of the tuture to become better acquarted with the various features of medical plants are usually continued to the found that the fact in the state of the found that the fact is the found that the the received. He did not think that was 60 medical plants are the found that the fact received. He did not think that was 60 medical plants are the found that the fact received. He did not think that was 60 medical plants are the found that the continued, and, he boped, improved. The Rose show, falling in the wet month of July, was as usual a loss to continued, and, he boped, improved. The Rose show, falling in the wet month of July, was as usual a loss to the Society. It cost the Society fize more than they received. The cottagers show, he was sorry to say, cost them £49 more than they received. He had hoped, and still hoped, that they might, by the introduction of new features, make that show useful. It would, however, be a matter of serious consideration by the Conneil how to get better results from the cottagers show. Turning again to the Apple show, he found that the Society received a balance from that of £57, which was a very satisfactory result. Then the calico garden party furnished them with £113, which was not so much as in the year before, for the reason that they gave a larger proportion of the receipts to the promoters for the other institutions. The Whitsuntide show, favoured by the weather, gave them the largest sum they had ever cleared at Whitsuntide, the result of that showbeing that the Society owed £6332, and on December 31 last they more than the was found to the donors of plants am they had a per a way in stimulating the pursuit of horticulture and floriculture about £5500 in extraordinary expenditure, and they were now owing

The National (late Borough of Hackney) Chrysanthemum.—The annual general meeting of this Society took place at the "Four Swans," Bishopsgate Chrysanthemum,—The annual general meeting of this Society took place at the "Four Swans," Bishopsgate Street, on the 17th inst., E. Sanderson, Esq., President, in the chair, there being a large attendance of members. This was the thirty-seventh annual gathering, the Society being the original Stoke Newington Chrysanthemum; it is the oldest Chrysanthemum Society extant holding a show in the metropolis, and the report, which was of a highly satisfactory character, stated that the members increased forty per cent. during 1883, and that the sum of £155 2s. was paid in prize money as awarded at the Royal Aquanium. The growth of the Society was shown in a statement made by Mr. William Holmes, the indefatigable Secretary, who said that when he took this office eight years ago there were but fifty-two members; but with the candidates to be elected that evening they had a membership of over 200 persons. The change of title has led to some modifications in the government of the Society, and instead of the comparatively small committee which has hitherto sufficed for the government of the Society, and instead of the comparatively small committee which has hold, and she per increased to thirty members with power to add to their number, who will meet at stated times as

arranged, and there will be at least two general meetings during the year. Provision is also made for the appointment of a succession of the state of the appointment of a succession of the state of the appointment of a succession of the state of the state of the state of the appointment of the state of

Obituary.

REV. C. FIRMINGER .- We regret to hear of the rather sudden death of the Rev. T. A. C. Firminger, M. A. Cantab, Honorary Member of the Agri-Horticultural Societies of India and of the Punjab. He was author of a Manual of Gardening for Bengal and Upper India, of which a second edition was published in 1869. He was for some time a member of the Scientific Committee of the Royal Horticultural Society, and died on January 18, at Warren Lodge, Edmonton, aged seventy-two.

Fine; dull day and night.
Fine; very dull day and night.
Fine; dull day. The sky clear at night occasionally.
Fine and beitter

19.—rice; timi ay. Ine say clear at ingut occasionally.
20.—Fine and bright during part of morning. Slight rain at 9 F.M. Strong wind afterwards.
21.—Fine morning. Bright dull afteraoco. Fine night.
22.—Very rough day and night. Heavy gale. The minimum reading of the barometer was 29.1 inches; turning to fise at about 9 F.M., and was 29.28 inches by midoight.

LONDON: Atmospheric Pressure.—During the week ending Jaouary 19, the reading of the barometer at the level of the sea increased from 30.46 inches at the beginning of the week to 30.50 inches by 9 A.M., decreased to 30.45 inches by 3 P.M., and increased to 30.46 inches by midnight on the 13th, decreased to 30.40 inches by 3 P.M. on the 14th, increased to 30.40 inches by 3 P.M. on the 14th, increased to 30.58 inches by 9 A.M. on the 16th, decreased to 30.58 inches by midnight on the 17th, increased to 30.51 inches by 9 A.M. on the 18th, and decreased to 30.57 inches by 3 P.M. on the 18th, increased to 30.62 inches by 3 P.M. on the 19th, and was 30.57 inches by the endof the week.

The mean reading of the barometer for the week at the level of the sea was 30.56 inches, being 0 39 inch higher than last week, and 0.65 inch above

inch higher than last week, and 0.65 inch above the average of the week.

Temperature. — The highest temperature in the shade in the week was 50% on the 15th; the highest reached on the 17th was 43°. The mean of the seven high day temperatures was 46°.4.

The lowest temperature was 35°.2, on the 13th; on the 15th the lowest temperature was 42°. The mean of the seven low night temperatures was 38°.5.

The greatest range of temperature in one day was 10°, on the 14th; the smallest was 5°.5, on the 17th. The mean of the seven daily ranges was 7°.9.

The mean temperatures were — on January 13, 4°.9; on the 14th, 45°, on the 15th, 46°.3; on the 16th, 40°.7; on the 17th, 40°.7; on the 18th,

42°.4; and on the 19th, 42°.6; and these were all above by 5°.3, 8°.5, 9°.8, 4°, 3°.9, 5°.5, and 5°.6, respectively.

The mean temperature was 42°.8, being 1° lower than last week, and 6°.1 above the average of the

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 68°, on the 14th. The mean of the seven readings was 51°.2.

The lowest reading of a thermometer with its bulb placed on short grass was 27°, on the 13th. The mean of the seven readings was 31°.7.

Rain.—Rain fell on the 16th to the amount of 0.01

ENGLAND: Temperature,—During the week ending January 19 the highest temperatures were 52° at Turo and Bristol, and 51°.1 at Liverpool; the highest at Bolton was 47°.3, at Preston 48°, and at Bradford 49°.8. The general mean was 50°.1.

The lowest temperatures in the week were 31°.8 at Cambridge, 32°.7 at Nottingham, 34° at Wolverhampton, Sheffield, and Sunderland; the lowest at Preston was 40°, at Bristol 38°, and at Liverpool 37°.2. The general mean was 35°.7.

The greatest ranges in the week were 18°.3 at Cambridge, 17°.3 at Nottingham, 16°.1 at Wolverhampton; the smallest ranges were 8° at Preston, 10°.8 at Bolton, and 12°.8 at Bradford. The general mean was 44°.4.

mean was 14°.4.

The mean of the seven high day temperatures was

The mean of the seven high day temperatures was 49°, at Truco, 48°.6 at Plymouth; and was lowest at Bolton, 45°.1, at Wolverhampton 45°.5; and at Nottingham 45°.9. The general mean was 47°.

The mean of the seven low night temperatures was highest at Preston, 43°.1, at Truco 42°.3, at Liverpool and Bradford 41°.8; and was lowest at Cambridge, 36°.7, at Wolverhampton 37°.2, and at Nottingham 37°.5. The general mean was 30°.9.

The mean daily range of temperature was greatest at Cambridge, 9°.5, at Brighton 8°.5, at Nottingham and Sunderland 8°.4; and was least at Preston, 2°.9, at Liverpool 5°.1, and at Bradford 5°.3. The general mean was 7°.1.

The mean temperature was highest at Truco. 45°.8.

The mean temperature was highest at Truro, 45°.8,

The mean temperature was highest at Truco, 45°.8, at Plymouth and Preston 44°.4; and was lowest at Wolverhampton, 41°.1, at Cambridge 41°.3, and at Nottingham 41°.5. The general mean was 43°.3. Rain.—The largest fall was 0.19 inch at Bolton, 0.09 inch at Truco, and 0.06 inch at Preston; the smallest fall was 0.01 inch at Plymouth, Brighton, Blackheath, Nottingham, and Liverpool The general mean fall was 0.03 inch. No rain fell at Bristol, Leicester, Cambridge, Wolverhampton, Bradford, Leeds, or Sunderland.

SCOTLAND: Temperature. - During the week end-SCOTLAND: Temperature.—During the week ending January 19, the highest temperature was \$4^{\circ}.4,
at Aberdeen; at Greenock the highest in the week
was 49^{\circ.2}. The general mean was 50^{\circ.9},
The lowest temperature in the week was 32^{\circ.5}, at
Aberdeen; at Leit the lowest temperature was 43^{\circ.2}.
The general mean was 38^{\circ.7},

The mean temperature was highest at Leith, 47°.5; and lowest at Aherdeen, 44°.4. The general mean

and nowest at Anterdetin, 44, 44.

Was 45.5.

Rain.—The largest fall was 0.87 inch, at Greenock, and 0.15 inch at Dundee; the smallest fall was 0.07 inch, at Leith, and 0.05 inch at Paisley. The general mean fall was 0.16 inch.

No rain fell at Edinburgh or Aberdeen.

JAMES GLAISHER, F.R.S.

OILERS: S. L. 1. Most of the manufacturers and dealers in boilers and hot-water pipes, &c., publish illustrated catalogues. 2. Because the hot water is the lightest, and the higher the rise in the pipes the quicker is the circulation.

CACTUSES: G. W. Uhink. There is the subject in the Eoglish language. There is no good book on

CLIMATAL INFORMATION: America. We will attend to your suggestions as far as possible, but such things cannot be bespoke to order.

GOING ABROAD: R. S. Having no practical experience of either country we do not feel justified in advising you in such a momentous matter, Had we to make the choice ourselves we should prefer Australia or New Zealand, and to go direct to either Sydney or Christ-Zeanand, and to go urrect to enter Sydney or Unist-church, as the case may be. A gardener, in good health, who knows bis business, and is not afraid to rough it at first, should be able to do well in either country. A tropical climate, like that of Queensland, or an arctic one, like that of Canada, must obviously have grave disadvantages.

HAILSTORMS: Charles Colebrook. You can insure your glass in the Royal Farmers' and General Insurance Company, 3, Norfolk Street, Strand.

HEREFORD SHOW: Observer. We are much obliged for the corrections, which, however, would have been more valuable if sent when the errors appeared. You have not complied with our rules by sending your name and address.

JOHNSON'S "GARDENERS' DICTIONARY:" C. G. Published by G. Bell & Sons, York Street, Covent Garden,

LæLia Crawshayana.—Mr. De B. Crawshay requests us to correct an error in our last issue: —"Lælia Crawshayana was not sold at £4 st, it was bought in "—a fact, we presume, which was-only known at the material content of the automorphism of the material content."

the time to the authoneer and ne owner.

LAPAGERIA ALBA: John Neal. Your plant seems to be suffering from over-much watering, too big a border, and perhaps a soured state of the soil. Three feet in depth is excessive; such wide borders are best made up piecemeal as a plant grows and its roots extend. By giving manure-water before the plant bad exhausted the fertility of the soil you have made matters worse. Reduce the quantity of soil round the plant, and give water with caution until the plant gets healthy again. See that the drainage is good.

LAVENDER: Leader. See the article on "Lavender Culture at Mitcham," in Mr. C. W. Shaw's The London Market Gardens (Garden Office).

NAMES OF FRUIT: G. Wall. Your Pear is named Vicar of Winkfield. — IV. C. S. Apple: Cat's-head.

Vicar of Winkfield, — IV. C. S. Apple: Cat's-head.

NAMES OF PLANTS: Amateur. We decline to waste any time in attempting to identify such a specimen.—

H. J. Ross. Onychinm auratum. — J. E. Brassavola nodosa, a poor variety of Udontoglossum crispum, and Adiantum concinnum.—R. A. B. 1, Acacia Drummondii; 2, A. armata; 3, send again when in flower; 4 and 5, Ccelogyne cristata; 6, no specimen; 7, Peristrophe speciosa.—J. V. J. Next week.

ORCHIO SEEDS: X. asks if seeds of Zygopetalum Mackayii and Dendrobium aureum are scarce, as he has some of last year's growth. [Why, certainly, At what rate per ounce can "X." offer it?]

POULTRY: A Nanice. Hens law fertile eyes when thou

what rate per ounce can "X." offer it?]

POULTRY: A Novica. Hens lay fertile eggs when they bave plenty of grit, healthy runs, food that is not overfattening, as Matze is when given frequently. There should not be more than eighteen birds to one cock. The best sitters are those that lay a certain number of eggs in the spring and early summer, and then show a desire to sit, such as the Darkings and Sussex, and other breeds with five toes. Cochin Chinas, Brahmas, and black Langshans, are good layers in winter, and will hatch out then. Most early hatched birds will lay in autumn and winter, but the eggs are small. The continual layers, that are seldom "broody," are Black Spanish, Polish, Hamburghs, and Houdan breeds.

Spanish, Folish, Hamburghs, and Houdan breeds.

SALSAFY, POINSETTIAS, AND TURNIPS: S. P. The
first you can sow about the beginning of May, in rows,
a foot apart. It is cultivated like the Carrot, and
lifted at the same time and stored in damp sand in a
cool place, where no frost can enter. The Poinsettia
is gradually dried off after the foliage has obtained its
full development, and stored away in a dry place tilt
year's shoots may be cut back to an eye or two. Cuttings or eyes made from these shoots make nice plants
in one season. Cut them to 6 inches in length, if for
cuttings, and insert them in sandy soil, and place in a
gentle heat; they will soon make root. Eyes are
made in shorter pieces with one bud on each; place
them on sandy soil, covering them so that only the
bud is visible, and treat as cuttings. Turnips may be
sown thinly in a france, on a mild bottom-heat (from
leaves only), in February, and later at intervals of fourteen days. The later sowings need not be under
glass, but under any simple contrivance to ward off
late frosts and cold winds. Thin early, give plenty of
air when it is mild, and water with warm water.
Choose early kinds. Choose early kinds.

SAP: The subject has been so often treated of that we scruple in justice to old subscribers to repeat it till we have something fresh to say. Read *Plant Life*.

LUGS: G. C. D. It is Testacella Maugei, an intro-duced species of a genus of Mollusca, now often found in gardens, and easily recognised by the small shell on its back. It has been several times illustrated in our columns.

SUGGESTIONS: Stitch is thanked for his communication tion. If the number were small and the time ample, it might be done; as it is, the condition are unpro-

TESTIMONIALS: B. H. S. E. If the testimonials were written for and received by the employer, the gardener has clearly no claim to them.

* * All communications intended for publication should be addressed to the "Editor," and not to the Publisher or to any member of the staff personally. The Editor would also be obliged by such communications being written on one side only of the paper and sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

INTELLIGENT READERS, PLEASE NOTE: — Letters re-lating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the Publisher, and NOT to the Editor.

FOREIGN SUBSCRIBERS sending Post-Office Orders are requested to send them to the Publisher of this journal, 41, Wellington Street, Covent Garden, and to make them payable to William Richards, at the Post Office, Drury Lane, London, W.C.

SEEDS.

SEEDS.

London: Jan. 23.—There is now an increasingly active demand for farm seeds. Choice samples of home-grown Clover seed are getting scarcer, and are realising rather more money. Of American red the stock in London is, for the time of year, exceedingly moderate. White Clover is firm at the recent advance. There is not much passing in Alsike. Fine Trefoil continues scarce. Rye-grasses are cheaper. Spring Tares keep dear. Very low rates prevail for Timothy. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

CORN.

At Mark Lane on Monday the Wheat trade was exceedingly dull. Both English and foreign Wheat written 11. per quarter lower on the week, but prices were very irregular, and in some cases the decline was heavier for interior qualities. Flour followed the same course as Wheat, and was quoted 6d. to 15. lower for the week, the largest decline being on American. No alteration was, however, made in the official top price of town flour. In Barley good qualities were not a large proportion. Malting grades were firm, and grinding descriptions steady. Peas have receded 11. per quarter from the previous Monday's rates, and Canadian were quoted 35t, to 36s. Beans were without quotable alteration. New Odessa Maize was 6d. lower on the week, and next after lower figure, but the current market was not quoted at any decline.—On Wednesday next to nothing was done in Wheat, and quotations were nominal, but the tone depressed. For flour the market was in the ame condition. Barley showed steady value, and met a moderate demand. Beans and Peas moved off in retail quantities at Monday's currency. Maize was barely supported.—Average prices of corn for the week ending January 19:—Wheat, 38s. de, 1 Barley, 32s. 3d.; Oats, 19s. 3d. For the corresponding period last year:

— Wheat, 40s.; Barley, 32s. 6d.; Oats, 20s. 2d.

CATTLE.

At the Metropolitan Market on Monday there was a small supply of cattle, but good selections. The general trade was rather better for first quality cattle, Sheep supplies were good as to number and quality, but mostly prime heavy weights. Trade slow, with drooping prices. Our top quotation is for sheep weighing not less than 10 stone. Calves nominally lower; pig trade very dull. Quotations: —Peasts, 45, 64, to 55, 64, and 55, 64, to 55, 64, and 65, 64 to 75; pigs, 45, to 64. 64. Thursday's trade was quiet, Beasts were held with a shade more firmness, but sheep were difficult to move, even at a reduction. Calves and pigs sold slowly.

Tuesday's Whitechapel Market report states that supplies were not quite so large, but trade was very quiet, at the following quotations: F-rime old Clover, 95* to 105**s.; inferior, 60**s. to 75**s.; prime second cut, 90**s. to 10**s.; best meadow hay, 80**s. to 86**s.; inferior, 40**s. to 55**s.; and straw, 28**s. to 55**s. per load,—On Thursday there was a moderate supply of hay and straw on offer. The trade was quiet, except for straw, which was somewhat dearer. — Cumberland Market quotations:—Superior meadow hay, 80**s. to 12**s.; inferior, 70**s. to 75**s.; superior Clover, 98**s. to 12**s.; inferior, 70**s. to 80**s.; and straw, 33**s. to 37**s. per load.

POTATOS.

The Borough and Spitalfields Markets reports state that good supplies were on offer, and met a slow demand as follows:—Magnum Bonums, 8os. to roos.; Regents, 7os. to 9os.; Champions, 5os. to 7os.; and Victorias, 8os. to 100., per ton.—The imports into London last week consisted of 203 bags from Boulogne and 2 packages from Havre. packages from Havre.

COALS.

The following are the prices current at market during the week:—Bebside West Hartley, 145. 9d.; Walls End —Hetton, 165.; Hetton Lyons, 144. 6d.; Lambton, 151. 6d.; Wear, 145. 6d.; Thornley, 155. 3d.; Tees, 16s, ; Caradoc, 16s.

Government Stock.—Consols closed on Monday at 101½ to 101½ for delivery, and 101½ to 101½ for the account. The prices of Tuesday and Wednesday were as on Monday for delivery, and 101½ to 101½ for the account. On Thursday Consols closed at 101½ to 101½ for delivery, and 101½ for 101½ for the account.

FLOWERS.

LOBELIA Prima Donna

OBELIIA TIMB DONNA.

Awarded First-class Certificate Royal Horticultural Society. No modern introduction to the world of Flora has received a bearine welcome than was accorded to Committee of the Royal Horticultural Society. In habit it is very compact and dwarf, whilst the rich velvety crimson-marcon flowers—equal in size to those of Lorentz and the committee of the Royal Horticultural Society. In habit, we have a size of the Royal Horticultural Society. In habit, we have been a second flowers—equal in size to those of Lorentz habit, which was a size of the Royal Royal

NEMOPHILA atomaria atro-

Gorulea. Awarded First-class Certificate, Royal Horticultural Society. After years of anxious care and selection we have succeeded in fixing the beautiful rich purplish-blue in this charming novelty. The colour of the flower is a deep ultramarine, pure white centre, with a zone of black purple.

Price, in sealed packets, 11.6d., 21.6d., and 31.6d., post-free.

SWEET PEA Adonis.

The hright rosy-carmine blossoms of this distinct novelty contrasts most pleasingly with the pure white, scarlet and other decided colours already in cultivation Price, in sealed packets, 1s. 6d. and 2s. 6d., post-free.

NEW PRIMULAS. CARTERS' HOLBORN GROUP.

AWIERS' HOLBORN GROUP.

Awarded Bronze Banksian Medal Royal Horticultural Society. We have lately raised a section of compactness of habit, and substance, and size of flower. The better to distinguish our new strains from the ordinary ones in general cultivation we have formed them into a section designated "The Holhors," and the group will hereafter be identified with that appellation.

CARTERS' HOLBORN BLUE.

Awarded a First-class Certificate, Royal Horticul-tural Society. The first Blue Primula ever offered— and still the best.

W. R. Robinson, Esq., Gloucester, writes:—"Carters' Holborn Gem Primula is a great success, and gives satisfaction to all who have seen them."

W. WING, Esq., Oakham, writes:—"The Holborn Gem Prinula is now in flower, and there is no mistake about its being exactly as depicted in your Catalogue." Price, in sealed packets, 3s. 6d., 5s., and 10s. 6d. per packet, post-free.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone.
(Registered Trade Mark)

This VARNISH is an eacellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the Advertisers, and its genuine good quality, notwithstanding a host of unprincipled initiators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardees, and at the seats of many hundreds of the Nobility and Gentry, from whom the most Sold is Casks of all the seater received.

Sold is Casks of all the seater seaters, at it, 6d, per gallon at the Manufactory, or it. 8d, per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL.

"Fiercefield Park, June at, 1876.—Sirg.—I have this day forwarded from Chepstow to your address a black varnish cask, to be filled and returned with as good Varnish as the last we have the filled and returned with as good Varnish as the last we varnish clerchfield. Park, Chepstow.—I am, Sirk, Jours tespectfully, Win. Cox."

Varnish to Piercefield Park, Chepstow.—I am, Sirk, Jours tespectfully, Win. Cox."

CAUTION.—Hit. & Suttri would particularly warn their Customers against the various cheap Varnishes now so much adventice. You will be a supported to the large estates in the kingdom for upwards of thirty years and their constantly increasing trade in it, and the numers and their constantly increasing trade in it, and the numer and the standard of the constantly increasing trade in it, and the numer are traded with their name and Registered Trade Mark as above, without which once is genuine. Every cask is legibly marked with their name and Registered Trade Mark as above, without which once is genuine. HiLL and SMITH, Brierley Hill Ironworks, Staffordshire; 118, Queen Victoria Street, London, E.C.; and 1706. St. Vincent Street, Glasgow.

THE AMERICAN GARDEN

IT A RICHLY ILLUSTRATED, ELEGANTLY PRINTED,
AND CAREFULLY GOTTEN-UP MONTHLY PUBLICATION DEVOTED TO THE GARDENING INTERESTS OF AMERICA.
EDITED BY DR. P. M. HEXAMER.
To any cane who owns a Flower-Pot, a Garden, or a Farm, It is Indispensable,

because it gives all the latest and best information about everything pertaining to the culture of Flowers, Fruits, Vegetables,
the care and laying-cutof Lawas and Pleasure Grounds, Window
Gardening, Rural Improvements, and all kindred subjects.

It is Reliable,
because its Editor and Contributors are all experienced Horticulturists, who write from actual experience and can prove
the correctness of their teachings.
It is always Seasonable,

It is always Seasonable, breause it forestalls its readers' wants by giving in every issue practical seasonable hints for the work of the month, which alone are worth more than the price of the paper, because no paper is more carefully scrutinised before it meets the eyes of its readers, and because all objectionable and quack medicine advertisements, as well as everything that could in the least offend the most refined tastes, are scrupulously excluded from its nases.

least offend the most refined tastes, are scrupulously excluded from its pages. Premiums.

In addition to all these good things, every yearly subscriber receives a beautiful coloured floral picture, and may take his choice of any one of the many valuable articles offered in our Premium List—either Seeds, Plants, Books, or Implements.

Subscription Price, 5: per year, including forcigin postage. Sample Copy Free. Remit by Post-office Order on New-York or London.

WATER

Cao be heightened or lowered, or made to suit any requirements. They stand complete in themselves, and require no building work, being wholly water-jackted and thus entirely free from risk by fire. They can be had all sizes, to heat from, say, a few feet up to 8000 feet of 4-inch pipe each: are now in all parts of the world, and are univalled as being the best, most powerful, and most economical Het-water Bolders in use.

Specimen Extracts from Testimonials:

From W. Morgan Robbins, Eag. Architect, Ilfracombe,
Softember 9, 1836.

"I am delighted with your Boiler; it answers admirably, and
the directors are satisfied that it is one of the best £25 worth

ever put in the hotel."

From Q. C. CHALMBIS, Gardens of James Mudie, Esq., From Q. C. CHALMBIS, Gardens of James Mudie, Esq., "Your Boiler beats all my expectations; at 1830.

"Your Boiler beats all my expectations; at 1830.

From ISAAC HOLDEN, Esq., Oakworth House, Keighley, Vorkabley, 1831.

From Your Boiler beats nearly Soc feet of sinch pipe.)

From Wal. Frank, Kipfer Gardens, Dunning, Perthshre, December 6, 1832.

"I consider your Boiler most efficient; as for economy, it is the acme of perfection."

From Rev. James Cardwell, Military Academy, Highlands, Fersey, December 31, 1881.

"Nothing could be better than the Boiler you sent me; it burns all sorts of rubbish, and gives an excellent heat."

From ARTHUR BOOTY, E.Q., Rese Villa Nurseries, High Harvogale, March 22, 1832.

'Your Boiler has exceeded all my expectations; it will pay for itself as a fuel saver in a short time. It beats 2000 feet of 4-inch pipe."

SEEDS.

JAMES VEITCH & SONS, ROYAL EXOTIC NURSERY, CHELSEA, LONDON, S.W.

NEW CYCLAMEN GIGANTEUM,
Charming Bride.

First-class Certificate, Read Herticultural Society.
This super hew and silicontary sy of compact, robust, free-flowering habit, and remarkable for the immense substance, perfect form, and pure ivory whiteness of its flowers, which are without any tinge of colour at the base. It is the largest and best pure white variety extant. Per fruchelf, 5s.

IMPATIENS SULTANI
THE FINEST FLORAL NOVELTY OF 1884.
Awarded last scann Two First-class Certificates by the Reyal Horticultural and Reyal Belancia Societies.
This most distinct and beautiful plant commences to bloom freely when only a few inches high, and is remarkable for its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effective engagements of its lowers, which are of a brilliant and effectively engagements.

Per packet, 1s. 6d. und 2s. 6d.

GIGANTEUM.

NEW CYCLAMEN

AMARYLLIS, VEITOH'S HYBRID.
Saved from our magnificent collection grown at our Chelsen
Nursery, from which so many exceedingly beautiful varieties o
rich colour and improved shape have been selected by the Roya.
Horticulumal Society for First class Certificates. Per packet, 2s. 6d.

ACROCLINIUM ROSEUM flore-pleno.

A new perfectly double form of this pretty Everlasting, of a charming rosy hue. Per packet, Is.

ASTER, Dwarf Perfection, Pure White (New).

A new pure white and compact form of the Pæony Perfection type, of dwarf growth, erect habit, and extremely floriferous; flowers of large size, very double, and of good form; excellent for edgings, beds, or pot culture.

Per Packet, 1s. 6d.

BALSAM, VEITCH'S SUPERB STRAIN. This unique strain has again been specially selected by us from an immense collection while in bloom, and cannot be sur-passed in doubleness, variety and brilliancy of colour, form and size of flowers, or habit of growth.

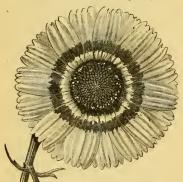

Finest Mixed Colours, per packet, 2s. 6d.

BEGONIA, Choicest Hybrid.

Carefully hybridised and saved from our celebrated collection.

Per packet, 1s. 6d. and 2s. 6d.

CHRYSANTHEMUM SEGETUM. Bright Golden-Yellow. Per packet, 6d.

CHRYSANTHEMUMS, Single. Remarkably showy and effective plants; now extensively rown for Covent Garden Market. They are perfectly hardy, f rapid growth, very profuse and continuous blooming, and last long time decorative.

Collection of 8 fine varieties, 2s. 6d.

CALCEOLARIA, International Prize.

Saved from plants which have carried off the leading prizes at the chief Metropolitan Exhibitions. The flowers are exceedingly rich and varied in colour, beautifully spoted and blotched, and of remarkably fine form and substance.

Per packet, 2s. 6d.

CELOSIA PYRAMIDALIS.

licautiful decorative plants for the conservatory during the autumn months; they vary considerably in colour, embracing various shades of scarlet, crimson, yellow, orange, and orange-scarlet.

Per packet, 1s.

CINERARIA, Veitch's Superb Strain.

Bernares the richest and brightest coloured selfs, as also the most varied, showy, and attractive varieties, with clearly defined and elegant margins and rings of various shades.

Per packet, 2s. 6d.

CYCLAMEN PERSICUM.

Saved from the finest varieties, and cannot fail to produce flowers of the finest substance, and of the most charming and diversified shades of colour.

Per packet, 2s. 6d.

Cyclamen giganteum magnificum. Cyclamen giganteum roseum compactum.

First-class Certificates, Royal Horticultural Society.

Magnificent varieties, with flowers of immense size, beautiful colours, and massive substance.

Each, per packet, 3s. 6d.

PRIMULA OBCONICA First-class Certificate Royal Horticultural Society, A. First-class Certificate Royal Horticultural Society, A. Ilaces bade of colour, flowering continuously and profusely from spring till autumn. Per packet, 2s. 6d.

GLOXINIA, Veitch's Superb Strain.

Our magnificent collection of this lovely decorative plant is well known. The seed now offered has been saved from the inest varieties, specially selected for that purpose, and will renduce flowers of the finest quality, embracing all the diversified tints of colour to be found to the genus.

Per packet, 2s. 6d.

DAHLIA, Single; Mixed Colours.
Saved from a very extensive and varied collection, embracing ill the newest and best hybrid varieties of this most beautiful and highly decorative class of plants.

Per packet, 1s.

MARIGOLD, Veitch's Superb Striped. A fine selected strain of this favourite flower. Per packet, 1s. 6d.

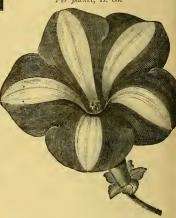

MIGNONETTE, CRIMSON KING.

This new arisety proved in our trials one of the finest and most destrable for pot culture. It is of dwarf, vigorous, pyraolidal, short-branched habit, and throws up numerous strut flower-stalks, terminated by extremely broad spikes of delightully scented bright red flowers.

Per packet, 1s. 6d.

MYOSOTIS DISSITIFLORA ALBA.

A true pure white form of the lovely M. dissitiflora. A most desirable acquisition for early spring gardening. Per packet, 1s. 6d.

PETUNIA, Veitch's Superb Striped. Selected for many years with great care; very consproduces beautifully striped flowers.

Per packet, 1s.

PRIMULAS, Veitch's Superb Strains.
FINEST FRINGED, Red, White, and Mixed.
These are the finest in cultivation, and were awarded a First-class Certificate by the Royal Horticultural Society for superior quality.

Each, per packet, 2s. 6d.

SUNFLOWER, ARGOPHYLLUS.

Of dwarf neat habit, with small silvery-woolly foliage, bearing an abundance of small, single, bright golden-yellow flowers with a black disc; very decorative, and highly useful for cutting. Per packet, 6d.

TROPÆOLUM LOBBIANUM FULGENS. A distinct and brilliant shade of scarlet-crimson, with dark-coloured foliage, and of medium growth; a splendid new variety selected at our seed farm; highly recommended. Per packet, 6d.

VIOLA, SNOWFLAKE.

A very dwarf pure white variety, of compact habit, perfectly hardy, and comes into bloom very early in spring, its snow-white flowers making a fine display during the spring and summer mooths.

Per packet, 1s.

WALLFLOWER, Veitch's Dwarf Dark Red A new and very superior selection, of rich dark colour, dwarf growth and bushy habit, fine for spring gardening.

Per packet, 1s.

SATURDAY, FEBRUARY 2, 1884.

PLANTING.

I N such exceptional seasons as that we are now passing through, with the mean temperature so far above the average, and with an absence of the autumn frosts that generally exercise so beneficial a check on growth, those who have planting to do not unusually congratulate themselves on the chance they have of getting on with the work, keeping on continuously, even with the removal of evergreens, as if there were a certainty, or even a probability, of such weather enduring throughout. Yet it is well to point to the risky character of such proceedings, or, rather, to the failures which the planters thus court, even when the plants they deal with are in suitable condition for moving. There is an old saying that "Winter is never lost," and it almost invariably happens that when we get a continuance of unusually mild weather at the latter end of the old year and beginning of the new, we have a cold, cutting, unseasonable spring. March, above all months, is the planter's dread, and when it comes so as to deserve its proverbial character, with dry, biting easterly winds and bright sunny days, its slaughtering effects are partially seen at once in the drooping, shrivelled leaves of such things as Hollies, Portugal and other Laurels, Laurustinus, Arbutus, and others of like nature; but with the coniferous and taxaceous plants the destruction is not so apparent until later on in

The temptation offered by fine open weather in winter to get on with and finish such work in place of letting it hang on hand, is often so strong that it is acted on, instead of adopting the more reasonable course of deferring, until well on in the spring, the planting of such evergreens as could not be moved early enough in autumn to ensure their rooting freely. The loss of evergreens that die outright, through unseasonable removal, is by no means the whole of the mischief, many that do not absolutely succumb are years before they take to growing freely, getting into a stunted state which they do not readily come out of. The cause of such mistaken work is often traceable to a want of forethought in beginning early enough in the latter end of summer. It frequently happens that those who have new work, or alterations which entail a large amount of labour, do not make their minds up soon enough, often only beginning when they ought to have finished, and they are afterwards impatient of any delay-a course that is frequently costly in its result.

Where work of considerable extent has to be done, entailing the removal of evergreen shrubs, there is nothing like doing whatever draining is necessary, with the trenching and other preparation in the summer; then the planting can be carried out during the later part of August, and up to the third week in October, which is by far the best and safest time for moving evergreen shrubs, not only from the little loss that follows planting during this period, but in the saving of labour in the watering that is unavoidable after spring planting. When planting of this kind cannot be completed within the

THE QUEEN'S SEEDSMEN, READING.

time above-named, it is meeting failure more than half way to do it before spring, at which time the period when such work is admissible is in the most favourable seasons short. In such springs as that of last year, when we had piercing March weather up to the middle of May, no great amount of such work can be got through satisfactorily.

As regards deciduous trees and shrubs, the old saying that in planting before Christmas they grow of their own accord, whereas when moved afterwards you have to make them grow, is expressive and correct. The difference in the result of planting in the periods named is not so noticeable in the proportion of those that die after the latter time of removal, as in those that make much less progress in the first and second summer afterwards. This is most apparent in the case of trees that have got above the ordinary planting size, and are not in the best condition for moving through having stood too long without being transplanted. In the case of such, if fairly taken up, properly planted, and well staked as soon as the leaves have fallen in autumn, they will often do as well as others in better condition for moving that are planted late in winter.

The gist of what has been said will be seen to point to the mistake of being lured to planting evergreens too late after the right season in autumn is past and too soon in spring before there is a certainty of the roots beginning to act immediately the plants are put in, and to the equal importance of getting on without delay in completing the planting of all kinds of deciduous trees and shrubs, which in this exceptional season will push their buds earlier than usual. During the past autumn root-action has been prolonged later than ordinary: a quantity of Hollies and other evergreens we were obliged to take up in the last two or three days of October were heeled in, and they are now as full of young white roots, made since they were taken up as would usually be found present with plants moved a month earlier. The cause of this is, no doubt, the uninterrupted mild weather, further influenced by the more than usual amount of warmth still present in the soil through the absence of snow and the unusually light rainfall.

L.ELIA ELEGANS PICTA, n. var.*

I HAD this nearly a quarter of a century ago from Mr. S. Low, and now it is at hand from Mr. Harvey, 12, Riversdale Road, Aigburth, Liverpool. It bas light 12, Riversdale Road, Algourth, Liverpool. It has light lose sepals and petals, with greyish zones, and numerous small spots of darker purple. The fine lip has rather sharp side lacinize, nearly equal to the midlacinize, and a cuneate dilatate emarginate body. This and the tips of the side lacinize and the central area of the disc are fine purple, the remaining part, major part, of side laciniæ fine yellow. It is very good. H. G. Rehb. f.

Cypripedium Leeanum, n. hybr.

Messrs, Veitch have surprised the orchidist world with the flowers of this fine Sedenian mule between new Spicerianum and old insigne var. Maulei. upper sepal, the best of the flower, is very broad, expanded, nearly flat, retuse, not replicate at the borders, white, with two central batches of mauve spots, and smaller, broken narrow lines of mauve on the low green base. The lateral sepals have an oblong, acute, whitish body, shorter than the lip. The tepals are ligulate, blunt, acute, very wavy, dark brown, with two even darker longitudinal lines, and a light yellowish border. The lip's basilar part is light ochre with numerous sepia lines. The anterior part is of good cinnamon with a honey coloured narrow margin, and very short angles. Stamioode rhom-boid, but emarginate at superior base, light ochre with an orange knob in front. Ovary nearly mauve-purple. Stamioode rhomPeduncle brown. Bract much shorter than ovary, green, with a few purple lines. The plant being quite young we may expect its improvement next year. The lovely novelty is dedicated to the excellent collector, Mr. W. Lee, Downside, Leatherhead. H. G. Rohb. f.

VRIESIA HELICONIOIDES,*

This was one of the most striking plants exhibited at the Ghent Quinquennial last spring, under the name of V. bellula. It turns out, however, to be the V. heliconioides of Lindley. In any case it forms a most desirable plant for amateurs with small space at command, for the plant is of relatively small dimensions-less than a foot in diameter each way. It has the tufted habit so characteristic of Bromeliads, with arching, ligulate-lanceolate green leaves, of a violet colour on the under-surface, each about 10-12 inches long. The inflorescence is a simple erect spike, rising from the centre of the tuft of leaves to a height of 4-5 inches, and bearing two rows of spreading, boat-shaped bracts, overlapping each other at the base, and of a

WALLFLOWERS.

THROUGHOUT the market gardens of West Middlesex Wallflowers are so green and vigorous, and have been blooming so richly throughout the winter, that it would indeed he a disaster were any severe weather to intervene to their injury. The fine quality of the true market strain may be seen in breadths of several acres in extent in which almost every plant is of the same height, and size, and has the same rich-coloured flowers. The best strains are not so very dwarf, averaging perhaps where not drawn some 12 to 14 inches in height, but then the seed is sown in February probably, and the plants in good soil are far bigger than are those seen in private gardens; indeed, in most cases a bushel basket would not cover them. Rather dwarfer selections, specially fitted for bedding, are not difficult to obtain, but these do not give such good spikes of bloom for cutting as do stronger-growing plants. We may take it

FIG. 26.-VRIESIA HELICONIOIDES.

brilliant rose-pink colour, the free end being green. brillant rose-pick colour, the free end being green. The tubular curved flowers, of which only the unexpanded buds are shown in our illustration, greatly exceed the bract in length, and are of a pure white. The plant grows on trees in the valley of the Magdalena. For our illustration (fig. 26) we are indebted to the Compagnie Contineotale d'Horticulture, by whom the plant was introduced to commerce.

CHRYSANTHEMUM CERES. - We bave received a flower from Messrs, Cannell & Sons, Swanley, under the above name. It is of a pleasing light flesh colour, resembling the Rose La France, and illustrates forcibly how near we are getting to a race of varieties that will overlap the flowering time of the summer bloomers. The specimens sent showed great sturdiness of growth, fine foliage, and were fair sized flowers. The strain is evidently hybrid Japanese, as seen in the broad, convoluted, and loog petals. Under special culture this would possibly develope into a good flower.

for granted that crimson kinds of single Wallflowers, let them be under what name they may, are generally identical with the London market strain, one which it is difficult to excel.

It need hardly be said that market growers do not sow their pounds of seed in warmth even in February. A dry piece of ground and a dry day is all that is needed, and the seed being fresh and good will germinate freely, and give tens of thousands of plants to go out in May and June. The grower invariably marks for his own seeding a dozen or two plants that are early to bloom, are of a deep rich hue, and, not least, those which exhibit a good habit in the production of flowerspikes. There is nothing like a plant that gives up its spikes all at once, so that one cutting clears it off. The same habit is best in bedding strains, and those who want to see a rich mass of colour in the winter and spring can hardly do better than sow seed of a first-rate deep red Wallflower early; plant out as the market growers do, and then transplant with big balls of soil and roots into the bed in October, using not a wheelbarrow but a handbarrow to carry the plants from one place to another. Whilst, however, there

V. heliconioides, Lindley, ex E. Morren in Illustr. Horti-cole, t. 490; V. bellula, hort. Linden; V. Falkenbergii, hort. Augl.

may be said to be but one really good kind of dark coloured single Wallflower, there are several good yellow kinds; indeed we can name five that exhibit distinctness, and perchance there may be others. The strongest of all perhaps is found in Graham's Yellow Perfection. It is a strong grower, the spikes long, and the pips large, but in many the petals hang somewhat loosely; the colour is a rich bright yellow. As a rule it is somewhat less compact in habit than the blood-red market kind. Very closely allied to this is the somewhat misnamed Golden Tom Thumb, which in bloom grows to a height of 18 inches, and is of somewhat irregular habit; still it is a fine yellow for cutting, and we marvel that, with a fashionable taste for yellow flowers, such a beautiful kind has never been grown for market.

Whether the public would purchase or not does not seem to have been fairly tested, but when middlemen or dealers decline the public must submit. The best of any good yellow strain is seen in the fact that from first to last the colour does not vary. On the other hand the deep red flowers will fade as the season grows, until a few warm days will turn the finest colours to a yellowish-brown. That means consider-

average height of full grown plants is 6 inches. It makes for these reasons a beautiful pot plant, but, of course, it is best employed as a bedder or edging plant. A good breadth shows remarkable evencess in habit, and presents the dwarfest true Wallflower extant. Such a strain of the Blood-Red kind would be most valuable.

SAXIFRAGA BURSERIANA VAR. MAJOR.

THIS is one of the dwarf-growing species, forming little tutts of closely-packed, three-sided, sharply-pointed, ciliated leaves, from amid which the flower-stalks, about 2 inches high, arise, each bearing a solitary pure white flower with rounded petals. It is a native of the Austrian Alps, extending into Transsilvania and the Banat. It is one of the earliest of the Saxifrages to bloom, flowering on the rockery as early as February, on which account alone it is worthy a place in all gardens. Like most plauts it is subject to considerable variation, and the collector is, of course, ever on the alert to pick out what he thinks

FIG. 27 .- SAXIFRAGA BURSERIANA VAR. MAJOR: FLOWERS WHITE,

able depreciation in market value. From out of this Continental yellow strain, which is called Golden Tom Thumb, has been selected a very fine flowered but much more compact habited strain, named Bedfont Yellow. The first kind has distinct pale green leafage and flower-buds; the latter bas leafage like almost to that of the Blood-Red, and rather darker flower-buds; its average height is 12 inches, and the flowers have fine flat stout petals of a rich orange-yellow hue. It is very early, and will make a grand bedding kind, or to edge a mass of the taller deep Blood-Red kind. Then we have a well-known bedding kind in the Belvoir Yellow, but it is a little later than any other. Its average height is 9 to 10 inches, it carries dense heads of bloom, but the petals are small, and of a pale yellow hue, as a rule. This kind may always be distinguished by its peculiar habit and pale green flower buds. It is best sown early in April, as the seedling plants are not quite so hardy as are those of the Market Red. For cutting purposes it is of little value, but in April and May it makes a very striking mass of yellow.

Still another, and dwarfest of all, is Yellow Dwarf. This is a very distinctive babited kind from Belvoir Yellow, though a selection from it. Strong plants, prior to blooming, average 3 to 4 inches in height, and are of a dense bushy babit. When in bloom the

the best. In this case there will not be much difference of opinion as to the superior merits of the var. major, which we are enabled to figure (fig. 27) from a specimen kindly forwarded by Messrs. Backhouse, of York.

FORESTRY.

PINUS LARICIO.—About sixteen years ago, having occasion to clear and plant several acres of land in Cheshire, I determined to try all the leading kinds of coniferous trees, hardly any of which were growing in the neighbourhood. I will speak oow of the Corsican Pine, P. Laricio, about which I have lately observed several notices in the Gardeners' Chronicle. My attention was especially directed to this Pine by having frequently noticed the fine specimen of it in the Royal Gardens at Kew, which grows about 100 yards from the Kew Green entrance to the gardens, on the left-hand side of the path; and of this specimen I will say more presently. Having obtained 2000 or 3000 two-year-old seedlings, and planted them in a nursery, I bought a hundred trees of 2 feet high to plant out at once. Nearly all of these were dead in a few mooths, and so were a second and a

third lot of the same size. I then discovered that, if P. Laricio has been growing two years or more without transplanting, it will not stand having the roots bared and being sent a journey. Meanwhile I was every autumn transferring those in my oursery to permanent places, and of them I lost hardly one. I planted them, some on wet boggy soil, some on rather stiff clay, some on sand. Those on the wet soil did worst, not nearly as well as Scotch Firs planted at the same time. Those on the clay grew very fast, many of them as much as 3 feet a year for several years after they were established, till they became from 15 to 20 feet high, and then nearly all of them became top-heavy, and were blown down, not by one violent gale, but a few at a time. The soil was so strong that the roots had not to travel to find food, and so confined themselves within a very small radius from the stem, and afforded insufficient hold. Where the soil was sandy the growth was perhaps one-third slower, and as the roots are more spreading the tendency to blow down is not so great. Still, as compared with Scotch Fir, the tree is more top-heavy and less stable.

Where I made mixed plantations of several kinds of Conifers, the Corsicans always presented themselves as trees to be taken out in the process of thinning, becoming untidy at an early age as compared with Larch, Douglas Fir, Silver Fir, and Wellingtonia, so that I have probably not more than 200 or 300 Corsicans left. It is remarkable how easily they are cut down at the age of ten or twelve years, being much softer in the wood than Scotch Fir of the same size; in fact, up to that age they seem to be nearly all sap-wood. The tallest amongst my trees at fifteen years old are from 25 to 30 feet, and their girth near the ground from 28 to 30 inches. Up to this time they have beaten Scotch Firs planted with them, but the annual growth of the Corsicans is fast diminishing, and the Scotch are gaining upon them. The same is happening a few miles away on the range of hills at the end of which Beeston Castle stands; where a large tract of sandy hill-side was planted in 1865 with Larch, Corsican, and Scotch Fir. Few of the Corsicans are there more than 25 feet high, and some of the Scotch are nearly as tall: but both look healthy.

The late Mr. William Menzies, head forester of Wiodsor Park, told me a few years ago that he believed the Corsciean Pine was proving a failure, and it has certainly been planted long enough in many parts of the country for us to know more than we do about it, if it is successful. The following abstract of its history has been collected partly from the books on forest trees edited by Gregor, Selby, and Brown, but mostly from the very full account given in Loudon's Arboretum Britannicum, published in 1838.

The Corsican Pine is a native of many parts of the South of Europe, Spain, the Morea, Mount Etna, the coasts of France, and also the Caucasus, and parts of Asia Minor, but grows to the largest size in Corsica, where it is often found from 120 to 140 feet high, attaining its full size at the age of seventy or eighty years, and being used as good timber at the age of thirty. The first planted in England is said to have been brought in 1759, and is probably the very tree mentioned already as growing at Kew. which is now therefore about 124 years old. Loudon figures this tree as it was in 1838, when it was about 85 feet high. It was then branched to within a few feet of the ground. Selby, whose Forest Trees was published four years later, speaks of the same tree as being 90 feet high. It is now, perhaps, 120 feet high, and the trunk is bare to within a few feet of the top, and as straight as a ship's mast. The next tree of which the progress is recorded was planted in the Jardin des Plantes at Paris in 1774. Loudon speaks of this tree as being 80 feet high in 1838. It would be interesting to know whether it is still standing. About the time that the latter tree was planted the quality of the timber, which had long been used in the French Navy, became the subject of investigation. left uncertain whether the timber of Scotch Fir from the Baltic or Corsican Pine from Corsica was the better; but it was recommended by the French Government that the tree should be cultivated in France. However, the cones were so difficult to obtain that those of P. maritima (Pinaster), a closely allied species, were fraudulently sold as those of P. Laricio. In 1822, owing to the continued difficulty of obtaining genuine seeds, many thousand Corsican Pines were grafted on Scotch Fir in France, and planted in the Royal forests; but about that time M.

Vilmorin, who had planted the tree extensively at Barres, in Brittany, supplied the market with seed, and continued to do so for many years.

Loudon tells us that in his time the tree had been planted for ornament in many parts of England and Scotland, and that its growth had been very rapid. The trees mentioned by him must, many of them, be from sixty to seventy years old, and have attained their full maturity. The most remarkable charactertheir full maturity. The most remarkable characteristic of the tree is its rapidity of growth; it has been mentioned that in its native country it makes a timber tree in thirty years, and that it ceases to grow at the age of seventy or eighty; while the Scotch Fir will continue to grow up to the age of 200 years, and remain standing sound up to 300. Still we have the fact stated, that the cultivation of the tree was recommended, and in some instances commenced, in Great Britain more than fifty years ago, and it is not known that any timber worth recording has yet been produced by it. It is probable that any soil suitable for Corsican Pine would also grow good Larch, and that the latter tree would give more profit in the same time. In the young trees which I have cut, or which have been blown down, the amount of sap is so great, and the wood so soft, that they are of no use for fence rails or even for firewood. I accidentally heard within a few days that on Lord Belper's estate in Nottinghamshire, where the soil is heavy, the Corsican Pines planted from thirty to forty years ago have all been blown down.

Pinus Laricio was first introduced to England by the name of P. maritima, which it still retained at Kew when Loudon's work was published. C. Wolley Dod. Llandudino.

P.S.—I must plead guilty to having made a mis-statement about Lord Belper's trees. The Firs which were blown down in the recent gales were, I am informed, Pinus austriaca, not P. Laricio. These two kinds of Fir were planted together about thirty-five or forty years ago on Lord Belper's estate in the south of Nottinghamshire, where the soil is clay. The P. Laricio are now from 50 to 60 feet high, and seem likely to make good timber, whilst the P. austriaca, which are not more than 40 feet high, have been blown down. This is certainly the opposite of what has happened here. I planted some hundreds of P. austriaca with the P. Laricio, and half of the latter have been blown down, but not one of the former. The P. Laricio are at least half as tall again as the P. austriaca, which never can make a timber tree from its bushy habit, though for ornament as well as for shelter I consider it superior to P. Laricio. C. Wolley Dod, Jan. 29.

FOREST WORK FOR FEBRUARY: PLANTING .-Owing to the lengthened continuance of fine dry weather, planting operations should now be near a close, unless in such wet unfavourable situations as it was deemed necessary to leave over till spring. Where transplanting is carried on at the present season great care is necessary to avoid keeping the plants out of the ground longer than is absolutely necessary. Where trenching and pitting were carried out in autumn or early winter there will be but little difficulty in obtaining a finely comminuted soil for the reception of the young plants. Unless urgently required it will be better to leave unprepared ground over for planting next autumn. Attend to newly planted ground, and see that none of the plants are rocking with the wind, which proves fatal to many, especially during a dry spring and summer.

NURSERY. - In the nursery transplant layers of Elm and Lime, plant cuttings of all kinds, and prepare beds for the reception of coniferous seeds. Cones may still be collected, especially those of the Austrian and Corsican Pines; but we cannot too strongly insist upon the necessity of selecting those of the best quality, and from healthy, vigorous, middle-aged trees. Sow seeds from the rot-heap, and during dry weather Sycamore, Ash, Maple, Beech and Elm may also be sown in previously prepared beds. Always select fine dry weather for nursery work, and the results will be far more satisfactory than when pursued when the ground is in a damp wet state. transplanting young stock avoid overcrowding, as nothing is more injurious, and give each plant ample room to furnish its side branches, and so produce bushy well-rooted trees, that are not likely to be upset by the wind when planted out permanently. Trench or ridge up such plots as are not to be re-filled with trees, at the same time clear them of all

weeds, and add a liberal supply of manure if found necessary.

THINNING. — Continue the general thinning of plantations, Oak excepted, removing the hardwoods first, and leaving Pine and Fir till the last. This is, however, only practicable where each wood is composed of but one class of timber, and cannot be pursued with advantage in mixed plantations. Plantations that have been neglected till they have formed a dense thicket must be thinned gradually, for if thinned at once those left would not only be injured by the sudden exposure, but many would be blown over during the first storm. Thinning should be commenced in due time, carried on gradually, and proportionately to the exposure of the plantation.

Hedges or trees intended for removal this season should be cut at once, so as not to interfere with farming operations.

Unless in the removal of broken or dead branches, pruning should now be discontinued, especially on such trees as are given to excessive bleeding.

FENCING.—All fences ought now to be put in thorough repair, as during severe weather, and with a scarcity of food, sheep and cattle are difficult to keep in bounds. Examine tree-guards, rabbit-proof fences, and look frequently to the staking and tying of recent transplants. Where game abounds it will be found beceficial, for preventing their attacks on newly planted trees and shrubs, to strew fresh branches about for these pests to feed upon. Hares are especially mischievous to recently planted trees, and frequently cut the leader and side branches over, and that during mild open weather, and with a plentiful supply of tood within easy access.

HEDGING.—There will be but little work in this department at present—at least, if previous instructions have been acted upon; where trimming and plashing of hedges is allowed to remain until late in spring the succeeding growth is weak and feeble. Even the planting of Quicks and formation of hedges, if not already finished, should be speedily brought to a close. Ivy is very pernicious to live fences; indeed, in some damp maritime situations it is a regular nuisance, and necessitates great expenditure in its extermination.

ROADS AND WALKS. — The main requisites of a well-kept road are a smooth, firm, and dry surface; and to produce as well as maintain this a great amount of care in the construction and after-management is necessary. Carriage drives, and all walks within the policy grounds, should receive special attention, so that a clean smooth surface may at all times be maintained, few things being more disagreable to foot or other passengers than dirty uneven roads. Roads that have recently been metalled should receive a coating of screenings, and have a roller passed over their surface, which will greatly help to consolidate them, especially if the latter operation is performed after a night's rain.

GENERAL WORK.—Groundwork improvements of all kinds may be prosecuted during favourable weather, and the shrubberies pruned of all dead, twisted, or overgrown branches. Woodland ditches should receive attention during the winter months, and have all obstructions immediately removed from their course. The mouths of closed drains and culverts will also require frequent inspection, neglect of which often produces serious consequences, and the outlay of time and expense to rectify. A. D. Webster, Penrhyn Castle, North Wales.

WINTER BEDDING AT HALTON.

With the arrival of the cold season, in normal winters, we usually see the flower-beds bereft of all their floral beauty, although, as in the present one, the foliage may remain on the hardiest species. But this will have become ragged and torn by wind and rain, and the plants having made no growth their appearance goes from bad to worse.

Still we prefer these remnants of the past, shabby though they be, to the trimmest of bare beds, as almost anything of a green colour, if kept in order, is to be preferred to bare earth, and that perhaps immediately in front of the windows. One of some of the makebelieve modes of filling our winter flower beds that deserves universal condemnation on the score of downingth tugliness, and as a waste of means to an end, is

that of filling the beds with slips and branches of evergreen plants. No amount of care will make these appear anything other than what they are—rootless bits, which in all weathers have a frozen-out, flaccid look about them, and which get loose, and twisted with every wind that blows. Sedums and Saxifages, if the gardener has them in numbers sufficient to clothe the soil well, will make fairly good substitutes for the faded bedders of the previous summer. They have the fault of possessing too little variety in growth and colouring, and they labour under the disadvantage of similarity of height. They are therefore not the best of subjects to be employed, without assistance from other plants.

The surfaces are, if varied in colour, too flat to be altogether pleasing, and in large beds especially something is wanted to break up the uniformity of outline and surface flatness. Among the plants generally employed now for this purpose are the smaller growing evergreens, and small specimens of plants that when of mature age, under good culture, become of a large size, but which, under a system of removal in spring and autumn, keep fairly dwaff for

many years.

A still better mode of filling the beds is that of sing evergreens altogether, or in conjunction with bulbs and some good carpeting Sedum to cover the ground in which the latter are planted; by this mixing of the different species of plants very pleasing beds can be furnished that will give a cheerful, warm look to the otherwise bare flower parterres, and which in spring will be gay with Dutch bulbs and other spring flowering plants. A good example of this mixed system of planting with evergreens, bulbs, and Sedums, is to be seen this season at Halton, near Tring, the new residence of Mr. Alfred de Rothschild. These extensive pleasure grounds and gardens, covering twenty-five acres of ground, have only been lately laid out by Messrs. Veitch & Sons, of Chelsea. The style adopted is the natural or English; still, in the parts near the mansion the arrangements partake of the formal character of adjacent objects. A terrace with a balustrade and several flights of steps surrounds the house on the north or garden front proper, the cast and south-east sides. This terrace has at its base a broad margin of turf, on which are a series of beds of simple forms—the circle, the oblong, with semicircular projections from the sides, and a combination of four circles, are the principal figures. These adapt themselves admirably to a style of planting with evergreen shrubs and miniature Conifers, which are the principal subjects made use of. In one bed that stood at the conservatory end of the terrace were the following plants :- Two rows outside of Retinospora plumosa aurea, then came a quantity of Osmanthus ilicifolius variegatus, then another row of Erica vagaos, the centre being Hedera Regneriana lutea, with an edging of Euonymus japonicus. A quadrilateral figure, with semicircular projection, was very prettily planted with an edging of Sedum acre aureum, next to which was a row of Erica mediterranea rosea, then Osmanthus ilicifolius variegatus, a circle in the centre being planted with a golden-leaved Ivy and Retinos-Another bed at the base of the terrace was filled with silver variegated Yew as the centre patch; then came three rows of Mahonia Aquifolium, next to which was a variety of Erica carnea, the outermost line being formed of variegated Box. In other of these terrace beds, Cryptomeria elegans, Retinospora argentea, Thuia borealis, variegated forms of Euonymus, and various species and varieties of hardy Heaths, formed the chief furnishing plants, the flowering section consisting of broad bands of Crocuses in three distinct colours, representing 2s nearly as possible those of the house of Rothschild, On the spacious lawn, which descends from the mansion towards the north, and from which is seen a beautiful panorama of the rich Vale of Aylesbury, the beds are now filled with evergreen and other plants, giving a warm and well-furnished appearance to a garden scene that is, from its complete newness, bare of large trees, although immeose efforts were made to give an appearance of age to it by the planting of comparatively large Coulfers, Ifollies, and deciduous subjects of all kinds. A broad walk leads from the terrace to a water basin of 50 feet in diameter. Right and left from this walk is arranged a row of large-sized beds, and in the centre of each half of the lawn, that is thus divided by the beforementioned walk, is a very large bed, square in genera form, but having circular beds let into the sides. We noticed the planting of these two centre beds was

quite similar, the middle plant being a neat specimen of Picea nigra surrounded by Aucuba japonica, round which was Mahonia Aquifolium; this formed altogether a circle in the middle of the bed; then, right and left, were circles filled with Golden Yew as the centre plant, then Thuia Vervaeneana, and green Euonymus edged with Retinospora plumosa argentea. other circles in the same bed were planted with Golden Yew as the centre plant, round which were dwarf Rhododendrons, and an edge of Retinospora squarrosa. The space between these circles was planted with a scarlet Tulip, and carpeted with a Sedum. One long parallelogram was filled with Golden Euonymus, Portugal Laurel, Cupressus Lawsoniana, and Skimmia japonica covered with berries. Veronica Traversi. Mahonia, Erica mediterranea alba, Menziesia polifolia fol. rubris, Taxus japonica, Cupressus Lawsoniana erecta viridis, Euonymus radicans, make up the major portion of the materials employed in this most extensive series of beds, which are very tastefully arranged. Very few of the plants exceed r foot in height, many of the naturally dwarf ones being much less; and although the arrangements are pleasing now under their purely winter aspects, they will appear much finer when the immense quantities of Tulips and Crocuses with which most are planted come into bloom. M.

AMARYLLIS.—We are now in the bustle of repot-ting the bulbs. This is done once a year, and the usual time is just before they start into growth. For three months previous to this they ought to have been quite at rest by being kept dry at the roots and in a cool greenhouse temperature. We do not let them get so dusty-dry that the rather fleshy roots become In repotting the bulbs it is best to shake all the old compost from the roots, and any offsets that will part readily from the parent bulbs should be removed. Pot the smaller bulbs in large and small 60's, and the larger ones in large and small 48's. We use four sizes of pots for the flowering bulbs, viz., 5, 6, 7, and 8 inch; and for potting soil two parts good turfy loam to one of peat, with a fifth part of rotten stable manure, and sufficient sand to keep the material open. It will not be necessary to water them for two or three weeks after they are potted, especially if the pots are plunged, as they ought to be, in a gentle bottom-heat; also avoid a high minimum temperature, which is not only unnecessary but injurious.

AZALEAS .- As an exhibition plant for the large summer exhibitions the Azalea always holds a promineot position. During the months of May and June the plants are at their greatest beauty. The pyramid form of training is not so fashionable now as it used to be. It is an unnatural form, not only for the Azalea, but for any other plant. Even the round formal heads, which in some instances have taken their place, may be made almost as unnatural looking as the pyramids by the use of plenty of strings. Azalea takes naturally the form of an irregular bush, and most of the named varieties have an awkward habit of growing out of all form, by one or two leading shoots pushing away from the twiggy bud-furnished branches. This habit must be restrained by pinching these vigorous growths during the late summer months I have previously alluded to thinning out the buds; this is an important part of their culture, as a mass of flowers so much crowded together that they cannot open, is not a pleasant sight either in the greenhouse or conservatory, far less on the exhibition stage, well bloomed specimen Azalea is a strong point in a collection of stove or greenhouse plants in July. Late flowering varieties should be selected for this, and can be retarded by being placed either in a cool part of the greenhouse, or in a cool house with a north

CINERARIAS. — Few persons now grow named varieties, at least not into the form of exhibitors specimens of large size. I have observed that, not only in London but at the large provincial exhibitions, all the plants are seedlings merely, with no attempt at training. This primitive method of managing the business is not to be commended. Propagated plants of named or selected varieties are

as easily grown as seedlings, and they make equally good specimens. We have propagated plants now, including the variety "March Past," in 8-inch pots, that will be between 2 and 3 fect across. They are propagated in the autumn, and potted on as they require it, the centre being pinched out as soon as it can be done. Keep the plants now close to the glass; give them sufficient air. High winds, even if they are not frosty winds, are injurious. Give weak liquid-manure water occasionally when the pots are pretty well filled with roots.

CHEYSANTHEMUMS.—We were rather later this year in getting the cuttings put in, but have now done so. It is best to plant each cutting carefully in a small pot, and plunge the pots in some moist material in a cold frame, keeping the lights close for a few weeks. If a hotbed with a gentle bottomheat is at hand, it may be as well to place them in there, but they will form roots in a cold frame, though more slowly. Young plants propagated early to form specimens should be placed on a shelf in the greenhouse; they need no more artificial heat than enough to keep the frost from them, but they must be grown on freely without any check. If the Chrysanthenum has to be well grown it must be looked after all the year round, and be kept growing steadily, free from insect pests. The specimen plants at least must be kept growing until all danger of frost is over.

CALCEOLARIAS .- The culture of these and that of Cinerarias is very much alike. Propagating named varieties is not quite so satisfactory as in the case of Cinerarias, and perhaps it is best to trust entirely to seedlings of a good dwarf strain, as the principal seedsmen vie with each other to produce the best article; good seeds can now be obtained from all the seedsmen. This plant is rather more hardy than the Cineraria-it will almost stand a touch of frost-but they are more liable to be injured by greenfly; it is of the very first importance that they should be kept clean. Gardeners and amateurs are not alive to the importance of keeping their plants clean rather than destroying the fly after it has done considerable injury.

PELARGONIUMS.—With the increasing light, and the plants under favourable conditions—that is, near the glass in an airy greenhouse—the leaves will be deep green, and rather brittle; care is therefore necessary in tying out the stems, in case these snap off or the leaves get broken. The over-crowded growths ought to have been thinned out before this time; but if it has not been done, do so without any delay. The latest flowering plants may not yet be potted, but it will be best to see that they are done at once. The plants ought to be potted rather firmly, and those that were potted in October are now pretty full of roots. During the last six weeks they have been kept rather dry, each plant ought, therefore, to have a thorough good watering, to moisten all the roots, 7. Douglas, Great Gearies, Hord.

THE PROPAGATOR.

THE CULTURE AND PROPAGATION OF GLOX-INIAS .- The Gloxinia is one of the finest of summer flowering bulbs. Its flowers are of brilliant and rich colours, and for window decoration it lends an iovaluable aid. In conservatories it stands prominent for its rich beauty and graceful appearance; when tastefully arranged in baskets with Feros it can scarcely be surpassed for beauty and good effect. Few other plants equal it when combined with Ferns for drawing-room or other indoor decorations. Custom has long used the flower of the Gloxinia with success and profit for bouquets when intermingled with Ferns. It is hardly necessary to say that, when arranging a bouquet of Gloxinias, the erect varieties should be placed in the centre, and the drooping ones on the outer side. We propose now to make a few observations on the propagation and culture of Gloxinias, adding a lew remarks about the seed-time, and of the way to keep them in a state of health and beauty. There are many varieties of plants which are most easily propagated, but the delicate operations in the propagation of the Gloxinia must be performed with the greatest skill and care if we would be successful.

Gloxinias may be produced—1, from cuttings; 2, from whole leaves; 3, from pieces of leaves; 4, from seeds

I. FROM CUTTINGS .- Having selected a number of growing Gloxinias for cuttings, cut each plant down, only leaving the first pair of eyes directly above the bulb, in order that the old plant may grow and shoot out like a new bulb. The top of the plant that bas been severed from the bulb has now to be made into cuttings, and care must be taken to see that they are made as follows: - Beginning at the top, or smallest part of the stem, cut it off immediately below the first pair of eyes, i.e., below the first pair of leaves, but not so as to cut the leaves in any way. The next section must be made differently to the first cutting, about an inch below the next pair of eyes. This and the subsequent cuttings must be cut longitudinally, so as to make single eyes-or two cuttings out of one; and continue so to do until the plant has been used up. These cuttings, the eyes of which are only just covered with soil, must be potted each in a thumb pot, with a small stick to support them. If there is any difficulty in keeping the top cutting in the pot, it would be advisable to make a hooked peg, and thus make it secure in the soil over the leaf-stalks. are now ready for the cutting frame, in which they must be put on a gentle heat. They must, however, be well ventilated for an hour in the morning and in the evening, or if the house is a very close one it would be better to remove the covers from off the frames during the whole of the night.

2. FROM WHOLE LEAVES. - Although propagation by the leaves is a somewhat delicate operation, the gardener who is gifted with common sense and intelligence, and who strictly follows the remarks given below, must command success. nature of the success of the propagation of Gloxinias from leaves must depend upon the first step that is taken in making the cuttings. The first step is to gather your leaves together; they must be fully developed and ripe ones, or, to write in the terms of a propagator, "hard" leaves. If young and tender leaves are selected, potted and put in a frame, they will only rot. The footstalks of the leaf cuttings must be severed close to the leaf itself; the midrib of each leaf must be notched, with a sharp knife, in four or five places; and the veins branching out from the midrib in one place only. If the midrib or vein be cut through, the abundance of sap will waste and thus weaken or limit the number of plants it would otherwise produce. A few well drained pans, filled with a sandy soil sifted through a 4-inch-sized sieve, are now required. The leaves must be spread upon and pegged loosely to the surface of the soil. The pans must now be placed in a cutting frame. When young plants have formed on the leaf-cuttings and begin to send out shoots, pot them into thumb pots and put them in a damp but warm place; either upon a gentle bottom-heat or upon a warm shelf. As the plants increase in size they must be put into larger pots, and on no account must they be allowed to become "pot bound." There is, however, another method of forming strong bulbs in a shorter time. If flowering bulbs are required in one season there is no better method of which we know than that given below. Having made the selection of leaves as directed above, put six leaves, if they are large ones, eight if medium, or twelve if small, into a 48-sized pot. When cutting them, an inch of the foot-stalk must be left on the leaf in each case. They must be planted up to the leaf in a cutting-pot, and supported by means of four sticks on the borders of the pots, placed so as to form the corners of a square, and around them on the outside a piece of matting must be tied to make the cuttings secure. They must be placed in a cutting frame until they have rooted, then they can be potted off, or the bulb can be allowed to mature in the cutting-pot if more convenient.

3. FROM PIECES OF LEAVES. — This method of Gloxinia propagation is perhaps the most difficult. It is important to have proper cutting-pans or pots prepared. The best soil is sandy peat sprinkled with loam and sifted through a fine sieve. When filling the cutting-pan or pot press the soil down firmly, and cover it with sand a quarter of an inch in depth. In order to make it with a rose-pot and allow it to settle. Take a hard leaf and spread it upon a deal board. The footstalk must be severed close to the leaf; the midrih of it, if a thick one, must be reduced to one-half its bulk, i.e., a slip must be taken off along the top of it. The leaf must now be divided into two parts with a sharp kolfe through the centre of the midrih longitudicall; ;

these two portions of the leaf must again be divided, crosswise, into small strips, each strip having a vein running through it. If the latter remark is acted upon, not only will the vein help to support the piece of leaf, but also it will help to form a larger bulb. With the aid of a label, or any other flat piece of wood, the cuttings can be placed half an inch deep into the cutting pot. It should be arranged for twelve pieces to form the outer ring, eight the next, and four the centre. The holes made with the labels should be filled up with dry sand. When the cuttings have been watered through a fine rose-pot, put them in a cutting frame. As soon as they begin to send out shoots, pot them into thumb pots, and repot them as often as necessity dictates.

In the culture of Gloxinias, from this time great care must be exercised to prevent the attacks of the rust and the fungi, which cause so much damage. If the plants are kept clean, and in an equable temperature, it is seldom they are attacked by rust If, however, the temperature is allowed to vary from hot to cold, not only does it dwarf the plants, but it weakens them also, and thus renders them doubly liable to the attacks of thrips and red-spider. Should the plants be attacked by these pests, the best means of cleansing them is to sprinkle them lightly with sulphur through a dredger, two or three times. When the plants have been sprinkled with sulphur, under no circumstances must sprinked with surpair, under in chromatoces may be allowed to reach them, because it would burn them. Also the temperature must be kept up to between 65° and 75°. The floor of the house must be well damped, and it is also a good plan to syringe between the pots, but never over the heads of the plants.

Sometimes the Gloxinia is attacked by a small white fungus, which generally spreads itself over the whole root of the plant. The best treatment is to have the plant shaken out, and the roots washed two or three times in a solution of tobacco-water and soap. The proportions of the mixture should be, a quart of tobacco-water added to a piece of soft soap about the size of a Walnut. The soap should be first dissolved in hot water, and mixed with tobacco-water, to which a quart of ordinary water should be added, and the whole mixed well together.

The best time for starting the Gloxinia into growth is in February. The old plants should be shaken out from the large pots they filled, and potted into as small pots as conveoient; the roots of the plant as smart pots as convenient; the roots of the plant being rubbed off first. As soon as they root through they can be potted into 32-sized pots. If specimen plants are required, the strongest ones should be separated from the rest and potted into 16-sized pots. The latter will of course require training. A hoop of wire should be coiled underneath the rim of the pot to which the shoots of the plant should be tied with a piece of matting. The shoots should be trained straight across the pot. It is a good plan to thin out the leaves in the centre of the plant as they grow until about the flower-time. If this is done the plants will be symmetrical, and the flowers will increase incredibly in number and beauty. The best soil for potting the Gloxinia in should be composed of one-half loam, and the other half of peat, leaf-mould and sand in equal proportions.

4. FROM SEEDS .- It is a fruitful and interesting means of increasing Gloxinias to raise them from seed. The seeds should be sown early in January, and in similar soil to that mentioned above, only the leaf-mould must be excluded and the soil passed through a fine sleve. Shallow pans should be filled with the soil, firmly pressed down, and the seed sown with the soil, firmly pressed down, and the seed sown upon the surface. A piece of glass must be placed upon the top of the pan, and the pan must be put upon a warm shelf. When the seedlings apring up prick them off and put them in another pan, each seedling an inch from the other. As these increase in size and strength pot them into thumbs, and repot them into a larger size until a 48-sized pot is reached. In this pot they will flower. During the growth of the seedlings a good growing temperature must be kept up, and the gardener must be careful to see the growth is not checked by a widely varying temperature.

rature.

Of the old varieties for Gloxinia the following are perhaps the best:—Charme de Lutéce, Prince of Wales, Duchess of Teck, Insulaire, Boule de Nêjeç, Coup d'Hébé, Mont Blanc, and Vesuvius.

Messrs. James Veitch & Son, of Chelsea, are noted for fine Gloxinias, and among the best of their new ones are Cordelia, Crimsoo Queen, Radiance, The Car, Daimio, Bayard, Mrs. Atkinson, and Garibaldi. T. O.

BRITISH EPIPHYTAL ORCHIDS.

GROWING here and there in the upland bogs of the British Islands may be found a very small Orchid, having one or two tioy pseudobulbs, not at all unlike those of some tropical species of Dendrobium. So small and inconspicuous is the plant, however, that you may search for it in vain unless you are an experienced collector, or unless some friend is there to show you the peculiar habitat it invariably prefers. The little plant alluded to is popularly called the "Marsh Bog Orchis" (Malaxis paludosa), and it is a species of peculiar interest, only found on trembling sods of bog-moss, or sphagnum, and in positions where one may not always venture with impunity, since, however tempting and secure the cushions of moss may look, they are apt to be as treacherous as they are beautiful; and even when the dainty little Orchid itself is discovered, one can but rarely gather it with dry feet; and perhaps this is Orchids of the epiphytal class now so popular in our gardens. As a matter of fact, we bave many among our native plants which now and then assume epiphytal habits. Some mosses, lichens, and Ferns often do this, and wild Roses, Honeysuckle, and Ivy, occasionally exist in a sub-epiphytal way, but I believe we have no true epiphytes, as distinguished from parasites, among our flowering plants except these two rare little native Orchids. This, if true— and for the present our observations prove this to be

the case—is a very interesting fact.

We have said that the little Malaxis is always epiphytal-epiphytal on living sphagoum moss-and this fact of itself becomes practically interesting and suggestive when we remember how very little progress of a permanent character was made in the culture of tropical Orchids uotil the use of this same sphagnum became general. Even the sphagnum itself is peculiar in its variation as also in geographical distribution, and that it readily adapts itself to the tropical temperature of our Orchid-houses may be

Fig. 28 .- BRITISH EPIPHYTAL ORCHIDS. A, Malaxis paludosa on Sphagnum; B, Liparis Loesellii on Rushes.

one reason why the plant is thought to be rather rare and local in our flora. It has been found in mountain bogs at 1500 feet above the sea level, and is not at all uncommon among the Dublin mountains, where the "lesser Twayblade" (Listera cordata) is also quite at home to the wandering botanist, and where Isoetes lacustris forms a bright green turf near the margins of the gloomy lakes or taros. But just now the little Malaxis is of most interest to us, as being undoubtedly a true epiphyte in its way, growing as it does on the stems of the common bog-moss or sphagnum, instead of emu-lating its relatives, the Dendrobia of the East or the Masdevallia of the West, by growing high up in the branches of a forest tree. Its real relation to tropical Orchids of the epiphytal group is still further shown, inasmuch as its pollen is concrete or wax-like, and not powdery, as is the rule among our native Orchids of the terrestrial group. Although by no means beautiful, this little Orchid and its solitary relative, Liparis Loesellii (epiphytal on rushes in the bogs of Cambridge and Lincolnshire), illustrate for us the most characteristic traits of that large group of tropical

one illustration of its cosmopolitan distribution-or rather the result of that latent strength and vigour which enables it to resist the variable, albeit more temperate climates of both hemispheres. Now-a-days sphagnum moss is such an important factor in the compost, or rooting media, employed in the culture of all tropical epiphytes, whether they are Orchids, Nepenthes, Arolds, Fromeliads, or Ferns, that it becomes even more interesting to find that Nature has been growing our native epiphytal Malaxis for ages on the same material. F. W. Burbidge.

USNEA.

THIS, like its fellow lichens, is an epiphyte, growing upon trees, but is not really parasitic upon them in the sense of deriving nourishment from them. Our illustration (fig. 29) is taken from a photograph representing a scene in a swamp in Florida, where the trees, rising from an undergrowth of dwarf Palms (Palmetto) have their branches wreathed with the pendulous wisps of this grey licben. The profusion of this growth, its length and dull colour, give a peculiarly weird, lustreless aspect to the forests. Like other Lichens, these Usneas afford an example of good-fellowship; at one time thought to be imaginary, but which is now becoming generally accepted—we allude to the association in one plant of a fungus with an Alga. The fungus, destitute of chlorophyll, preys upon the Alga, which has a store of that material,

they may obstruct the ingress and egress of gases and liquids, which go on through the younger bark in the same way as through the leaves. Lichens are usually indicative of a moist atmosphere, but it is remarkable how they infest certain trees and not others. Thus at Osborne, where there is a long avenue of Austrian Pines alternating with Elms, the latter are thickly encrusted with lichen, while the

FIG. 29.-GROWTH OF USNEA ON TREES IN FLORIDA: FROM A PHOTOGRAPH.

and thus makes the Alga do its life-work for it. But as the growth of the Alga continues proportionate to the demands made upon it, the balance is not destroyed, and the two plants jog on comfortably together. The epiphytal habit of lichens makes it a question whether fruit growers need to he so careful to remove the "moss," as they call it, from the stems of their trees as they are. But although the lichens do not prey on the fruit trees they may serve as a harhour for insects, and, in the case of the younger shoots,

Pines are nearly free (Gard. Chron., August 13, 1881, p. 198).

PLANTING IN MAURITIUS.—According to Mr. Home's reports, the planting in the suburbs of Port Louis has been successful in improving the sanitary condition of sites formerly most unbealthy. Eucalypti of various kinds succeed well, and Cedrela Toona is highly spaken of for the rapidity of its growth and the value of its timber.

Prehid Notes and Cleanings.

ERIOPSIS SPRUCEI, Rehb. f.— This interesting species was discovered in 1854, in the neighbourhood of the Rio Negro of Amazona, or Solimoes, by the eminent collector, Dr. Spruce, whose No. 2390 it is. I named and described it in Walper's Annales, vi., 663, and now, after a lapse of nearly thirty years since the discovery, I have it alive. Mr. E. Harvey, 12, Riversdale Road, Aighurth, Liverpool, has kindly sent me bulbs, leaves, and inflorescence, telling me that it came from the Amazon territory. The cylindrical, strong, green bulbs are nearly even, having few linear superficial furrows, and the scars of the leaves are aculeate from the remains of the vascular hundles, as in Lycaste, &c. The long cuneate oblong-ligulate acute leaves are of a thicker substance than those of a common Lycaste and Zygopetalum. The raceme is long, cylindrical; the flowers equal in size to those of Eriopsis biloba, Lindl.; the sepals and petals are lemon coloured, and the petals have red borders. The side lacinize of the lip are nearly circular, the mid-lacinia has broad stalk, and a transverse elliptic blade. Two fleshy retrorse acute horns stand in the middle of the disc, quite an unusual ornament for an Eriopsis, when the nearest ally, Eriopsis sceptrum, has two membranous, triangular, no doubt resupinate blades, standing more towards the base. It is exceedingly distinct in this, not to speak of the different bulbs. The side lacinize are whitish, covered over by innumerable red minute spots. The central part between the side laciniæ, the disc, is white, like the two horns, which have an apiculus below their point in front, and mauve spots at the base. The central lacinia is lemoncoloured, with mauve spots on the base of the stalk. The trigonous curved column is lemon-coloured, and has a few purple spots on the anterior part of the It was an extraordinary satisfaction for me to see this fine plant alive—a pleasure for a botanist to name such distinct species. H. G. Rehb. f.

IPSEA SPECIOSA .- Your correpondent at p. 119 is in error in supposing this attractive species exists only in the Kew collection. It has been regularly grown for the last seven or eight years by me, and is always highly esteemed by visitors as well as amateurs in Orchids for its extremely distinct qualities. In March, 1879, my gardener was awarded a First-class Certificate for it at South Kensington, and the plant was excellently figured in a coloured plate in the Garden, vol. xxii., p. 188 (August 26, 1882). Its cultural requirements are not difficult to satisfy; pot in an equal mixture of peat and loam, with sharp river-sand to keep it open; grow in the warmest house, and keep clear from yellow fly (aphis), which seems to have a special fancy for the tender growths. With me the leaves always appear first, and the flower-scape rises afterwards, exactly the reverse of the statement of your correspondent, who must I think have been misled by what has happened with newly imported plants, and mistaken their conduct for the regular habit of the plant when established and settled to its regular régime. F. A. Philbrick.

ODONTOGLOSSUM ROSSII MAJUS.—With this as with all other Orchids the quality of the variety rules the value of the plants. At Sander's sale at Messrs. Protheroe & Morris' on January 25 a very fine variety of this having very large flowers, the colouring of the sepals being of a yellowish-brown instead of the usual claret-brown, the same colour running almost to the tips of the petals and through the usually white outer half in a very quaint manner, was purchased by Baron Schröder for eleven guineas, plants of the ordinary form only realising as many shillings.

ORCHIDS IN FLOWER AT THE CLAPTON NURSERIES.—Amongst several rarities in bloom here is a beautiful new Saccolabium that bears the name of S. bellinum; it is much in the way of S. higibbum, but the individual flowers are double the size; the ground colour of the sepals and petals is olive-yellow; three-fourths of the surface are covered with large blackish-brown spots; the interior of the sac is pure white spotted with crimson; the lip is quite flat, three-fourths of an inch across; conspicuously fringed, white, with a bright yellow circular blotch in the centre, in which, forming almost a

circle, appears a row of well-defined red spots, which latter, although they stand out distinctly on the yellow blotch, are only reflected, as in reality they are on the back of the lip. Several examples of this really fine Orchid are in flower, differing to some extent in their more or less depth of colour. growth of the plant is like S. lanceolata. In the thousands of plants of Cattleya Triange here that have not before bloomed, and which are now daily opening their first flowers, not a few of them have four or five scapes apiece. There is much interest attached to the unfolding of these first blooms of this most variable of Cattleyas. Some varieties of extraordinary merit have already appeared, one in particular may be mentioned, to which the varietal name of T. Backhouseana superba has been given; it is a flower of large size and great substance in all its parts; the lip is of the most intense deep purple, suffused with an indescribable violet shade, contrasting beautifully with the yellow at the base. The sepals and petals are of the usual soft lilac shade; the petals, which are unusually large, have a distinct feathery stripe of deep purple running from the extremity downwards to about half the depth, half an inch wide at the extremity, tapering at the bottom: this band of deep colour in the petals is the most decided we have seen, and much enhances the beauty of the flowers. Another lovely form of this Cattleya has an unusual amount of the orange-yellow colour running completely across the interior portion of the lip, then comes a broad band of crimson, almost black, whilst the extremity of the lip is violet-purple, much lighter in shade; the sepals and petals are nearly white. Many other fine and distinct forms of this Cattleya are here to be seen, but the above stand out as gems such as rarely make their appearance. A new and distinct looking Phalænopsis is also in flower, something in the way of P. Veitchii. The sepals and petals are white, suffused with mauve; base of lip pale yellow, freckled over with small crimson spots; the lip is unusually long, and of a dark reddish colour. The leaves are like those of P. Veitchii, which also was in flower, and several forms of P. Stuartiana. The immense quantities of P. amabilis and P. Schilleriana are opening a second lot of buds, formed after the first, which, as so often occurs, were destroyed by the fog. Some 6000 recently imported P. grandiflora fill a considerable portion of one of the large houses; they are in excellent condition, the leaves in most cases showing little effects of their trying journey. The rare Calanthe Cecilize is in flower; it may be described as a C. veratrisolia with the lip pale lavender, all the remainder of the flower white, as in C. veratrisolia. number of healthy plants of the miniature white-flowered Angræcum hyaloides are blooming; so free to flower is it that tiny single crown plants not above 2 inches high were bearing three or four spikes each. A new Dendrobe, with the growth of D. luteolum, is flowering; it has short broad sepals and petals, pale primrose-yellowin colour, with pinkishred lines on the lip. Amongst different varieties of D. Lowii is one much superior to the ordinary form, with the usual yellow sepals and petals; the red blotch on the lip is much darker and better defined than general. The singular Trichocentrum albosanguineum is likewise in bloom, with its remarkably marked lip, the white and sanguine-red colours in which are so clearly defined. Among numerous Cypri-pediums were C. Stonei, C. Lowii, C. Harrisonianum, and C. Boxalli. Of this last, which is one of the best winter flowerers, there is an immense number. Of C. Lawrenceanum one of the large houses contains 7000 newly imported plants, that have arrived io surprising condition; a few pags of this handsome variegated plant help to enliven an Orchid-house with its beautiful foliage, independent of its flowers. useful winter-flowering Lycaste Skinneri is represented by some beautiful varieties in bloom; the enormous quantities of this good old plant coming on will soon be a sight in themselves, with their endless variety in shade and colour.

Odontoglossum Warnerianum.—This beautiful epiphytal Orchid is one of the many forms referable to the O. Rossii type, and which have been introduced at various times from Mexico. The present one is far superior in size and colouring to the type, having the sepals heavily blotched with dark chocolate markings on a white ground, thus differing from the type in the absence of the green tinge suffusing the ground colour. The elliptic obtuse petals, with the exception of a few dull purple

blotches at the base, are of the purest white, and the same may be said of the labellum, enlivened at the base with its pale yellow or lemon cup-like crest or tubercle. This form, introduced in 1865, seems to be altogether different from O. Warneri, introduced in 1844, and described as having yellow and crimson flowers borne on a few-flowered raceme; petals smaller than sepals, and a cuneate two-lobed labellum.

CYPRIFEDIUM GODEFROY.E. — This is a new Cypripedium, the native country of which has not been revealed, and the introduction of which has been attended with inconvenience and disaster, the narrative of which, as well as an engraving, are given in the December number of the Orchidophile. It is described as intermediate in character between C. niveum and C. concolor. The lip is like that of the latter species. The flowers are white, spotted with chocolate spots. The plant is reputed to grow on limestone rocks, shaded on the mountain on which it grows during the morning, but is afterwards exposed to the most intense sunlight. The stock has been purchased by Messrs. Veitch.

ORCHIDS AT THE VICTORIA NURSERIES, HOLLO-WAY .-- Here, among the forerunners of a finer display that will follow-for many things show wonderfully well in sheath and bud-we noticed the seldom seen Sophronitis violacea in flower, in a small suspended basket hung near the roof. They are evidently getting to know the wants of this hitherto difficult bloomer hetter, and we may hope to see more of it in collections. The vividly coloured Masdevallia ignea gigantea had several of its flowers open; this will be a conspicuous object when larger than this plant was amongst these fireflies of the Orchid race. There were flanking the doorway in one of the houses two beautiful large plants, just going past their best, of Coologyne cristata, the largest of them about 30 inches in diameter, and carrying between 200 and 300 flowers. Lighting up a bank of flowerless plants was a nice The Vandas are showing piece of Ada aurantiaca. here grandly, so far as bloom-buds at present indicate, but a piece of the Dalkeith variety of V. tricolor had a fully expanded raceme of bloom open which displayed that beautiful densely spotted hybrid form to perfection. The everblooming Odontoglossums were seen in many varieties; O. tripudians, than which few are prettier, had two moderate-sized racemes open, as had O. cristatum and O. maculatum. The charming gold and brown in Oncidium Forbesii was very telling when seen in contrast with the ivory whiteness of the Odontoglots in this house, notwithstanding there was but one spike of it amidst scores of the others. Odontoglossum cariniferum was also in the cool-house in fine bloom; the modest beauties of this easily grown kind, which has the property of lasting in flower for several months in succession, making it a desirable variety. The favourite Odontoglossums, Hallii and gloriosum, had each several spikes of their fine blooms open. O. pulchellum, so desirable for a winter display, was also showing its spikes here and there in this house. Lycastes of various varieties were to be met with in different houses, and were to be seen in flower from the richly coloured L. Skinneri purpurata through varying degrees of brightness in the Skinneri section, to the pale creamy L. lanipes, of which several were in bloom. Cattleya Percivaliana bad withstood the baleful influence of fog better than others of this genus, or had opened some few days later, as it had several fresh-looking blooms open. On a strong plant of Cattleya Trianæ tyrianthina seven sheaths were showing themselves. The pretty miniature Orchid, Comparettia rosea, was in flower in an elevated position; this is another species that may be relied on for late autumn and winter flowering, if not subjected to that deleterious drying off during the resting period. Another useful white flower, and well adapted for most purposes, was seen in Calanthe nivalis, almost, if not quite, the latest bloomer amongst Calanthes. A few early flowers had appeared on Cypripedium villosum, and on two of newer intro-duction, C. Meirax and C. melanophthalmum, and on C. calophyllum; and a few blooms of Dendrobiums rewarded the visitor in D. luteolum (a pale primrose), D. primulinum, and the gold and white blooms of D. thyrsiflora. D. Ainsworthi was also conspicuous by its richness of claret colour among the paler blossoms around it, wanting foliage only to make a perfect setting for its plentiful crop of flowers.

FRUITS UNDER GLASS.

VINES .- Although the weather at present is favourable to early forcing, so far as artificial heating is concerned, on the other hand its almost continual duluess is by no means helpful to the forcing gar-dener. The foliage and wood of Vines forced in sunless weather are always unsatisfactory, showing a great want of robustness, and where they are in this condition careful management in airing and damping must be exercised on the return of sunny days to prevent scalding; but when once they are inured to more sunlight it is surprising how quickly improvement sets in. During the time the Vines in the early house arc in blossom maintain a light, warm temperature, and if the tying and stopping are well forward deler the work on them until they have blossomed. If quality is wisely valued, be careful not to over-crop, and lose no time in commencing to thin the berries after they are large enough to handle. The system of not growing many varieties in the early house is a good one; the Black Hamburgh should be the one principally planted, it being the best for the purpose, as it both sets freely and may be thinned safely at an early stage. Madresfield Court is another black Grape of excellent quality, which sets well under similar culture, and may be grown with it to give variety in the early house. As soon as the first thinning is finished give the inside border a good mulching of cow and horse manure, and in watering, liquid manure should be administered if the Vines need it, but not otherwise. The strength of the shoots and texture of the foliage are generally a safe enough guide in this matter, and, as a rule, they do not require it for the first few years after being planted. Follow on with disbudding as required in successional-houses, and when the ouds are well advanced syringe overhead in bright weather, and then once daily early in the afternoon, and increase the warmth as the shoots lengthen. In the Grape-room look over the bunches and remove decaying berries with regularity, keep the bottles filled with rain-water, and make use of fire-heat when necessary to expel moisture.

MELONS,-Plants intended for the first crop will have been shifted from their seed pots into 32's, and preparations should now be made for planting them in their fruiting quarters; small well-lighted houses or pits provided with adequate means of heating are the best structures for the purpose. Presuming these are at command they should be thoroughly cleansed and at command they should be intologist, or classed and a bottom-heat of 80° to 85°, either from pipes or fermenting leaves, secured. The soil producing the finest fruits is a heavy turfy loam from an old pasture, cut and stacked at the end of last summer, which will now be in a proper condition for Melon growing, and will not require the addition of any other substance. Supposing a turf stack of this sort is at hand, a portion should be cut down, and be coarsely broken up with forks. It should then be placed in the form of a ridge loosely thrown together, under the lower part of the trellis, so as to be the more readily warmed and aërated; and when warmed through it should be made quite firm by ramming, an important point of practice, as then the plants make short-jointed frunful growth, together with great quantities of fibrous roots, and are less liable to canker than when planted in soil that is loose and porous. Before turning the plants from their pots be sure they are moist at their roots, and in planting press the soil firmly around them; arrange them on the centre of the ridge about 21 feet asunder, and see that each is on a mound, so that in watering canker can be guarded against by keeping the soil dry immediately surrounding the stems. Furnish each plant with a stake, and either rub out or nip beyond the first joint all side shoots as they appear before the trellis is reached, but let the main hoots proceed unchecked until they attain the desired length. Keep a night temperature of 65°, with about 10° more in the day-time from fire-heat, and admit air when the suo's heat has raised the temperature to Soo, and allow it to run up to 90° or more, with additional ventilation; close early, and at the same time syringe freely overhead on sunny days. Where Melons are fruited io pots keep them plunged in fermeeting leaves, and on no account let them suffer from want of water at their roots. At intervals of about three weeks sow seeds singly in 3-inch pots for successional crops, using a compost of loam mixed

with leaf soil, and when the plants appear keep them plunged in bottom-heat near the glass.

PEACHES AND NECTARINES .- Continue to fertilise the blossoms of late-flowering sorts, and when the blossoms drop syringe the trees gently over with tepid water twice a day when the weather is favourable; but by no means allow the young fruits to remain continually wet. Endeavour to maintain a growing atmosphere by keeping the surface of the borders, &c., damped; and still keep low night temperatures—55° will be sufficient while mild weather continues, but 50°, or a little lower, should frosty weather ensue. Fumigate immediately greenfly is seen, and should red-spider appear so early, repeatedly syringe the foliage on both sides. vere with disbudding, which is one of the most important operations in Peach culture, and to carry out which properly carefulness and forethought are both necessary. It should at all times be done gradually; the young shoots on the upper and lower surfaces can, as a rule, he all removed first, while those that are intended to form the tree, or to be laid in to carry the succeeding year's crop, should be selected from those that are most suitably placed on the sides of main shoots. Eudeavour to perfect the form of the trees, and to secure an equal distribution of fruitful wood over every part of them, and where there is likely to be a deficiency of foliage form spurs by pinching out the points of shoots. In the successionhouse, that will be following on closely after the first, the buds will be swelling and showing signs of colour even where no artificial heat has been used. Do not neglect to efficiently fumigate trees when in this condition, and treat them as directed for the early house. T. Coomber, Hendre Gardens, Monmouth.

PLANTING AND SOWING .- Peas and Beans which were sown in pots and boxes the first week in January, and subsequently hardened off, will now be ready for planting (weather permitting of the work being done) in a warm border. They should be carefully turned out of the pots-disturbing the balls of soil and roots as little as possible in doing soand planted in rows 4 feet apart (if dwarf-growing varieties), and 9 or 12 inches asunder in the row. A little soil should be drawn up on either side of the rows, after which lime and soot should be strewed on each side of the rows, and some pea-stick spray stuck in to support the haulm. The spray should be put sufficiently close to the Peas to keep them in an upright position, and then some Spruce boughs stuck firmly in the ground on either side the row sufficiently close to protect them from frosts and cutting winds. As the Peas progress in growth and become inured to the weather the boughs should be gradually removed, which will prevent the Peas making a weakly growth. And with this object in view it will be advisable in favourable weather to remove the boughs during the day, replacing them at night when frost is apprehended.

Beans should be transplanted singly in rows 4 feet apart, and from 10 to 12 inches in the row, and have a small stick put to each plant for support. Draw a little soil up to the plants on either side, then a line of lime and soot in the same direction to protect the plants from the attacks of slugs. Another sowing of Peas and Broad Beans of the following or kindred varieties should be made next week—viz., Laxton's Supreme, John Bull, Carter's Telephone, and Carter's Stratagem Peas, and Leviathan and Taylor's Broad Windsor Beans. These - which should be sown thinly in the row, as by so doing better results will be obtained — will be found suitable for all purposes. Should the present open weather continue another planting of Cauliflowers and Cabbages should be made, in the manner described at p. 83. A planting should now be made, I foot apart each way, of young Lettuce plants that were pricked out in the autumo in a warm border, over which a dusting of lime and soot has been previously strewn. For this purpose the plants in every other row in the nursery-bed above referred to should be taken up as required, which will then leave a space of 9 or 12 inches between the remaining rows, which again should be thinned in the rows as the plants are required.

ORDINARY WORK. — Pitted Potatos should now bave attention in the way of sorting and disbudding, and Jerusalem Artichokes should be taken up, where not already done, and be sorted and housed. If not already done, stake autumn-sown Peas, and make the soil firm about the collars of any Cabbage or Broccoli plants that may have been loosened by the wind.

FORCING DEPARTMENT.-Transplant young Lettuce plants, as soon as they are large enough to handle, into a bed containing a gentle bottom-heat; and earth-up Potatos on hotbeds as they require it, with soil of the same temperature as that in which they are growing, and give air freely on all favourable Thin out young Carrots growing on hotbeds to 2 inches apart in the rows, after which they can be thinned as required for use. Tomato plants which are intended for fruiting in pots should be shifted into larger-sized pots as they are found to require more room at the roots, using good loam and well rotted manure, in the proportion of about threeparts of the former to one of the latter, with a sprinkling of charcoal, and again place them near the glass in a forcing house, where the night temperature ranges from 50° to 60°, and by day from 65° to 70° by fire-heat, and 10° higher with heat; and endeavous to obtain a short-jointed consolidated growth. Maintain a good supply of Mint, Tarragon, Mustard and Cress, also French Beans. The latter should be syringed twice a day (more or less frequently, according to circumstances) as a means of keeping the plants free from red-spider, to which they are usually subject when grown in artificial heat. A night temperature of from 50° to 60°, and 10 higher by day with fire-heat, running up 10° or 15 with sun-beat, and plenty of atmospheric moisture at shutting up time, will be congenial to the requirements of the plants. Succession crops of Beans should have the points of the shoots pinched out to make them branch, and be top-dressed with rich soil.

MUSHROOMS.—Collect horse-droppings, and keep them spread out thinly in a dry shed for a few days. With such materials make up succession-beds, as soon as the necessary quantity of droppings for that purpose have been cullected, beating the materials as firmly together as possible. In making-up the bed a dipping thermometer or "test-stick" should be inserted, and when the heat has declined to 75° or 70° it may be spawned, inserting pieces about half the size of a hen's egg under the surface of the beds about 6 inches apart, and then covering with half an inch of such droppings pressed firmly down. The surface of the bed should then be covered with the same thickness of soil consisting of two parts of light loam, one part of garden soil, and one of cow-dung, thoroughly mixed to the consistency of mortar, which should be laid on with a trowel or float, finishing off with a perfectly smooth surface, which effectually cases the bed, thereby preventing the ammonia, which is necessary for the production of a good supply of Mushrooms, from escaping. A rather moist atmosphere, with a temperature of from 50° to 60°, should be maintained in the house, but I need hardly observe that so long as the Mushrooms grow sufficiently fast to meet the demand for them, it will not be necessary to turn the hot-water on in the pipes, or to apply atmospheric moisture in the house, further than damping the surface of the beds with tepid water in the event of their getting dry. As a rule, woodlice are very troublesome and destructive at least and the readlest and at the same time most efficient way of eradicating these pests is to pour boiling water out of a long-spouted watering-can along the sides and cods of the beds, especially between the latter and the walls, where they congregate as soon as daylight is let in upon them, and which is the best time to apply the boiling water. H. W.

Plants and thein Sultune.

GENERAL REMARKS.—It is a good custom thus early in the New Year to thoroughly well consider our plans and arrangements for the coming season. In doing this it is as necessary to reflect on the failures, as it is on the successes, of the past seasons. All of us by close observation have something to learn in the wide field of horticulture, of which plant culture is no exception. It has often struck me that there is but a slight step between success and failure in many instances. Cases in support of this are constantly cropping up, and failures occurring, which at

the moment seemed inexplicable, unless all details of treatment are well thought out and reviewed. mistakes have been made in the past, lessons of experience should have been learnt from which we ought to derive benefit in the future. Nil desperanaum is, we think, a very good motto for a gardener to remember in following his profession. In some few cases our attempts may have been futile, either from want of better accommodation for certain classes of plants, or from undue pressure having been brought to bear on our everyday routine of work. Where any of us have met with success beyond our anticipations, the same should be chronicled for the benefit of less successful cultivators. This used to be the case far more in the past than it is in the present; there are, however, without doubt, many good gardeners who would enlighten us if we could but persuade them to do so.

The requirements of a proper supply of plants for furnishing cut flowers and for decorative uses should be well considered. Certain classes of plants are always indispensable where the demand is great, and may be put down as such. There are also many others which might be brought into prominent notice, say for a few years only, and then be allowed to recede for a time, and some other classes of plants brought forward to replace them. This can easily be done with such plants as are annually raised from cuttings or from seed. We advocate this for the sake of securing a change in some measure from the otherwise too frequent repetition of the same plants season after It is a mistake to overcrowd ourselves with an excess of stock of any given genera. Fewer plants, and those better grown, by reason of having more room to develope themselves, will be by far the best plan in the end, and a saving both in labour and material. It is an error to rely too much on quantity for general effect, when it might be more easily attained and of greater durability, by having due regard to quality instead. If we happen to be fortunate enough to secure a good strike or to raise an extra number of seedlings, it does not follow that all such should be reserved for cultivation. Better consign some of them to the rubbish-heap at once than to grow them for a time and then be compelled to do away with them when crowded out.

SEED SOWING.—Several necessary and most useful kinds of flower seeds should now be sown, such as a pinch of seed from a choice strain of Gloxinias and tuberous-rooted Begonias; both of these will form a good succession to the hulbs of last and previous year's growth. Torenia Fournieri should not be overlooked; it is a valuable and distinct decorative plant, seedlings of which will make nice stuff for the coming summer if raised as soon as possible. Seeds of a good strain of Amaryliis should also be obtained, so that the full benefit of the season may be obtained. Those who grow Aphelandra auranticae. Roezlii or A. nitens will the more readily increase their stock of either from seed, but must look sharp after the same as soon as it is ripe, when the capsules quickly burst and scatter the seed. The comparatively new Impatiens Sultani will now, without doubt, meet with more extended cultivation, as seed can be obtained at a cheap rate. We intend to give it a trial under different conditions this season, and hope to report progress by-and-bye. The stove section of Vincas can easily be raised from seeds; this is the most ready way of securing a stock, and they are well worthy of more extended cultivation. Of foliage plants, the fertilised seeds of Coleus will afford an infinite variety, whilst a packet of seed of Grevillea robusta, if successfully raised, will give a serviceable lot of plants. We find an extra stock of patience is required in raising this plant from seed, as it has often germinated a long time after it has been given up as a failure. Acacia lophantha should also be thought of an early sowing of Mignonette to succeed the autumn stock; in doing so, choose good friable loam and a little mortar rubble with some fowl's dung next the recoks; press the soil, or rather ram it into the pots as firmly as possible, so that the finger will not easily penetrate the soil. A few dozen pots of Rhodanthe maculata and R. m. alba should be sown soon; these will give a good account of themselves when the glut of sprin

and which have been adopted by Baron von

Feb. 8 Sociation of Comments of Comm THURSDAY,

FRIDAY, SATURDAY. NOT greatly inferior in importance to the

MUELLER, are also noted; but for his purposes M. NAUDIN prefers characters taken from the inflorescence, flowers, and fruit. Singularly enough it is not yet ascertained whether fertilisation takes place before or after the fall of the little cap which at first covers over the stamens and styles. If before, then cross-fertilisation would not occur as a rule. M. NAUDIN, however, suspects that the fertilisation takes place after the fall of the cap, and that much of the variation met with is due to crossed impregnation. This would certainly seem the most probable view, though against it we have to set the opinion of Baron VON MUELLER, whose experience is so large that no one would be disposed to question it unless he felt very secure of his facts. So far as the Riviera is concerned, and the few species there grown, the question as to the self or crossfertilisation surely could speedily be settled, even if it were more difficult to prove actual

hybridity.

As to propagation, M. NAUDIN recommends seeds in preference to cuttings, there being no difficulty in raising the seed in seed-pans under glass in a warm greenhouse or propagating pit. As the seeds are very small they should be covered with only the slightest possible covering of earth. It is not so easy, however, to rear the seedlings during the two or three months of their existence, except in the case of those which have been grown in the open air. If they have to be pricked out from the seed-pan the risk of injury is great. This pricking out is best done early, when the plants have only three or four leaves. They should be placed in small pots, in a compost of vegetable mould, sand, and loam, in equal proportions, and should be placed in a shaded position till they have established themselves, when they must be exposed gradually to sun and air. Injudicious watering is the greatest danger likely to befall them. M. NAUDIN points out that they are naturally plants of a very dry climate, with abundance of clear light. As they grow on the plants should be shifted into larger pots with a larger proportion of loam terre franche, and with good drainage : the pots can be protected in winter if necessary, and planted out in the open the next year (M. NAUDIN is writing of the Mediterranean regions).

The site where the Eucalypts are to be planted should be chosen beforehand, for they admit no rival near them and by their rapid growth make large demands on the soil, which should therefore be deep, though there are some dwarf-growing "scrub" species which do well on a shallow rocky soil.

When it is desired to make a plantation the trees should be planted in lines at equal distances, at first thickly, each tree having a space of 4 square metres-that is to say, there should be 2500 trees per hectare (a hectare is rather more than 2 acres). After three or four years clearances should be made by removing alternate lines of the trees, first lengthwise and after an interval in the opposite direction, so as to leave space between the trees as they grow. Pruning should scarcely be required unless in the case of misshapen trees. At the end of the ten years the number of trees per hectare should be by the means above detailed reduced to 400-500.

Felling may commence after about twenty years, according to circumstances, the trees having by that time acquired a height of 20-25 metres, and a girth at I metre above the soil of 2.50-3 metres.

The profit to be obtained, of course, will vary according to local circumstances, but under ordinary conditions a very satisfactory result may be counted on.

For the most part the Eucalypts are trees of warm temperate regions, where the winter is

mild, the spring rainy, the summer hot and dry. Very few of them are found in the tropics. Some of the Tasmanian species, such as amygdalina, coccifera, or some from the Australian alps - E. Gunnii, coriacea, polyanthema-may succeed near the sea in Western Europe. Some species are limited in distribution by soil-characters, some being found on sandstone, some on basalt, granite, or limestone. Incidentally M. NAUDIN speaks of the value of the flowers as food for bees.

The culture of the Eucalyptus in Southern Europe only dates from the last quarter of a century, but the trees are now to be counted by hundreds of thousands. Without pledging himself to any opinion as to any special virtue in Eucalypts, such as has been claimed for them, M. NAUDIN points out how valuable trees are as sanitary agents, and especially in countries like some parts of Italy, Algiers, and Turkey, where the indiscriminate felling of the forests has rendered the country a desert. What a melancholy spectacle for the traveller in these countries, formerly flourishing and deeply populated, to see them now barren, reduced to their rocky skeletons, or with their plains alternately scorched by the sun, or transformed into pestilential swamps. The remedy is now known, and it is not beyond the power of a civilised Government to effect it in time by means of replanting, and a proper system of forest conservancy. The condition of Algeria, which M. NAUDIN has studied for himself, leads him to advocate replanting there on the largest possible scale, in spite of the inevitable cost and difficulty of the proceeding. Various Oaks, Abies Pinsapo, Pinus halepensis, Pistacia atlantica, &c., form the natural timber of the country, but these have been recklessly destroyed, meanwhile timber and firewood are urgently needed by the growing population. M. NAU-DIN shows how the Eucalyptus globulus will supply in the same period of time at least four times as much timber as an Oak.

With these remarks, with which all who have considered the subject must in substance concur, M. NAUDIN prefaces his detailed description of the thirty-one species which he has been enabled to study from the seedling to the fruiting stage. Descriptions of these are given in Latin, as being serviceable all over the world; and, as we have said, the primary distinctions are based upon the inflorescence, the flower being solitary, or cymose, umbellate, or panicled. Afterwards come characters founded upon the number of flowers in each inflorescence, the distribution of the stamens, the form of the

calyx-lid (operculum), &c.

M. NAUDIN has had many other species under observation, but only includes those which he has been enabled to study from the seedling stage to maturity. We may add that there is a collection of several species represented, of course by small specimens only, in

the Temperate-house at Kew.

CARVOPTERIS MASTACHANTHUS, - In the autumn of last year we received from Messrs, VEITCH a flowering spray of this hardy Japanese shrub, from that rich store place of interesting plants, Combe Wood. The illustration from the pencil of Mr. FITCH (p. 149) will serve to give a general idea of the plant, which undoubtedly is one of the best flowering shrubs. It is hardy at Combe Wood, but we would not from that circumstance infer that it would prove equally so in less propitious localities. The plant is a Japanese shrub, with its leaves covered with a hoary tomentum, like Nepeta incana, and with dense whorls of lavenderblue bi-labiate flowers proceeding from the axils of the upper leaves, thus forming a terminal leafy panicled inflorescence. FORTUNE met with the plant in China, and other explorers have sent it home from Japan, where it is said to grow at the margins of fields, and even on the tops of the mountains. Not many young gardeners would, be a member of the Verbena family, but so it is by many young gardeners would, we suspect, guess it to described by SCHAUER in the eleventh volume of DE CANDOLLE'S Prodromus, p. 625 (1847).

introduction of the Cinchona into India and certain of our colonies has been the diffusion of various species of EUCALYPTUS throughout our colonies and in the South of Europe. In this island the species are too tender to be anything more than curiosities, though E. Gunnii survives the unfavourable conditions of a Kew winter, and E. coccifera has formed a good-sized tree at Powderham Castle, Devonshire, and has even flowered (see vol. xiii., p. 395). But it is to our colonies that the cultivation of these trees is a matter of importance, and it may, therefore, be not inappropriate to call the attention of our readers to a valuable memoir on the species of Eucalyptus introduced into the Mediterranean region, recently published by M. NAUDIN in the Annales des Sciences Naturelles. We have frequently had occasion to allude to the splendid monograph in course of publication by Baron VON MUELLER which must serve as the standard of scientific information on these trees for years to come. M. NAUDIN'S object is more restricted; he confines himself to the species introducedinto Europe, and he studies them from a cultivator's point of view, not from dried

specimens or trees in one stage of growth only,

but from the germination to the ripening of the

fruit. The rich collections of the Villa Thuret

and other gardens along the Riviera have

have then in the treatise before us one of those

botano-horticultural memoirs which are of such

afforded him the means of doing this.

special value to cultivators. One of the first points noticed is the variation in the form of the leaf in the same plant, which is so marked a feature in the species best known in this country, E. globulus. M. NAUDIN points out how the seedling plants of various species differ one from another in this particular. If the trees are pollarded, shoots are produced from near the base of the trunk. bearing leaves similar to those of the juvenile plant, and leaves of this form are often produced without any injury to the tree having taken place. This partial reversion to a previous condition is no bar to the production of blossom, as flowers and fruit are produced on these juvenile looking shoots as well as on those of the adult branches. We have, then, in the Eucalypti the same condition that occurs in so many Conifers, Thuias, Junipers, &c., and to which we owe many of the Retinosporas of our gardens. the latter class of plants the disposition of the breathing pores, and the production of the leaves on branches of different character of growth, point to a difference of function, which is not hinted at by M. NAUDIN in the case of the Eucalypts, although he suggests the possibility of the diversity in form having been due to cross or hybrid fertilisation.

M. NAUDIN passes in review the "characters" that have been proposed to distinguish the species, such as the form and nervation of the leaf, the size and habit of the tree, some being small, others furnishing trees which exceed the famous Sequoias of California in height. characters afforded by the bark of the full-grown

Fig. 30.—caryopteris mastachanthus: hardy shrub: flowers lavender-blue. (see p. 148.)

— THE PHYLLONERA LAWS,—The Editor will be obliged if those nurserymen who have suffered loss or inconvenience in exporting plants to the Continent or colonies, owing to the operation of these laws, will communicate with him before Tuesday next.

CHATSWORTH.—Mr. BANNERMAN writes to say that he has not been engaged to go to Chatsworth, and that we have been wrongly informed on the subject.

— INTERNATIONAL POTATO EXHIBITION.—
Through a slip of the pen, the writer of the note
under this head, that appeared last week, made a
mistake as to the number of sets, or sample tubers,
that should be sent for trial at Chiswick. There
must be at least twenty sets or samples of each soit,
and not more than eight sorts will be received from
any one exhibitor.

- THE WEEK .- The horticultural event of the week which has caused the greatest sensation is probably the gale, which blew all over the country on Saturday last. Hitherto, although its force is stated to have been greater than in most similar cases, we have not heard of damage in proportion. Fortunately the branches were not laden with snow or foliage .-We are glad to find that the Nottingham folk are continuing their agitation against the mischievous proposal to convert the allotment gardens of that town into "eligible building land," surrounding a park. The value of open spaces in towns is beginning to be understood, and the value of gardening as a wholesome and profitable recreation might well be studied by our City magnates. The Garden Holder's Asso-ciation of Nottingham, among various proposals, recommend that "the Corporation should make permanent provision for gardening, and set apart as many gardens as possible, including the Hunger Hills, as permanent gardens." They further propose that in those cases where it is requisite to convert the present gardens to other purposes, due notice and adequate compensation should be given.—The Worshipful Companies of the City of London are devoting their energies towards carrying-out in spirit, if not in letter, the designs to fulfil which they were originally We have before us an essay on "profitable founded. fruit-farming" by Mr. CHARLES WHITEHEAD, written for the Worshipful Company of Fruiterers, at the suggestion of the late Lord Mayor. This matter of fruit growing requires to be considered with great care before any large amount of capital is embarked in it, else disaster is only too likely to befal the incautious planter, as has happened in more than one instance to our knowledge.-This reference to fruit trees induces us to allude to the letter of Mr. HARRISON WEIR in another column. Mr. WEIR is jubilant in the belief that he has found the cause of canker, and, moreover, can apply the right remedy in the form of We do not controvert our correspondent's Gishurst, statements, but we are of opinion that we require to know a great deal more on the subject before we can afford to be at all positive on the matter. First, we require an exact definition of what canker is, for to our knowledge gardeners mean different things by the Mr. BERKELEY, whose knowledge same word. on the matter is at once more comprehensive and more exact than that of any one else, refers it to "constitutional depravity," the indications of which may be made appparent by various causes. In support of Mr. WEIR's theory there is, so far as we know, no direct evidence at present-merely vague statements as to the presence of insects, or as to indications of their presence. Such statements are far too vague to be of any real use. The canker of the Ash has been attributed to insects, and especially to the larva of some Tinea, or allied moth of minute dimensions. The canker of Peach trees has been attributed in America to bacteria; but in no case that we know of has it been satisfactorily proved that the insects or the bacteria, which are undoubtedly present, are really the causes of the disease. They may be merely the scavengers. - We are glad to find that exporters of plants are beginning to inquire whether anything can be done about the Phylloxera laws. The outlook is not hopeful, but it will be a comfortto Editors at least-to have it established whether any thing can be done or no.

— Cydonia Japonica.— From Mr. Lowry, The Gardens, Belmont, Mill Hill, we have received a fine spray of this beautiful shrub, showing to what a degree the unusual mildness of the season has

affected its early blooming. It is seldom that in the neighbourhood of London this shrub is to be found in bloom earlier than the month of March. The particular plant from which the flowers were taken is growing on a southern aspect, and is stated to be four weeks earlier in bloom than it has ever been before. The Cydonias are deserving of more extended culture, not forgetting C. vulgaris, the common Quince, than which no finer shrub in flower and leaf is to be found in our gardens. C. japonica and its varieties, C. alba, C. princeps, and C. Maulei, make capital hedges in sunny localities, bearing the shears well, and blooming densely under the treatment, C. japonica being then a veritable fire shrub.

- WEATHER ASPECTS, - The recent stormy weather has sufficed to let us know that with all our congratulations over the mildness of the season we are yet far from being out of the wood. The clerk of the weather has for some time been in an admirable humour, and given us an exceedingly pleasant time; so much so, in fact, that we were in danger of forgetting that functionary's office. We may, therefore, take it for granted that the clerk in the recent boisterous ebullition of wind and rain has just given us a hint that he is still "boss" of the meteorological department, and we his dependents. No doubt the storms have done much mischief, but then coming at a time of the year when Nature is at rest, much less mischief is done than has been seen at some previous outbursts of Boreas. We see no reason, however, to assume that the recent visitation indicates a long spell of bad weather, or a severe close to a so far mild The more violent the outburst, as a rule, the winter. less prolonged are its effects; therefore we hope still for some of that pleasant weather which has left the now departed month of January famous as one of the most pleasant of its name. Foresters, and, indeed, arboriculturists generally, may well discuss the effects of storms upon forest trees, especially at a time when becoming a subject of such exceeding interest. Of course, storms often do great mischief in laying noble trees low, but perhaps the majority of these are safer down than up. What is worth enquiry is to learn whether on robust growing timber the lively action of the limbs, promoted by wind-storms, is beneficial or otherwise.

MR. JACOB ROSE, who for so many years has been gardener to Admiral ECERTON, St. George's Hall, Byfleet, has, we regret to hear, been compelled through illness to resign his position as from March next; and from the same cause he has been compelled to retire from the committee of the Gardeners' Royal Benevolent Institution. Mr. Rose, by his manly, straightforward character, has endeared himself to a great many members of the gardening fraternity, who will be sorry to hear of the misfortune that has overtaken him.

THE INTERNATIONAL FORESTRY EXHIBI-TION-SITE FIXED .- It has now been definitely settled that the forthcoming International Exhibition of Forestry will be held within the grounds of Donaldson's Hospital, Edinburgh. The exhibition building will be erected in the park in front of the hospital, while the outside exhibits will be shown on ground immediately adjoining, which belongs to the Heriot Trust. The Secretary of State for the Colonies has authorised a grant of £100 to the colony of Dominica, to enable it to take part in the exhibition. Sufficient time has not elapsed for answers to be received from all our colonies, and as yet the Governor of South Australia alone has responded from Australasia. Every wish, however, is evinced in all the replies that have been received to have the colonies suitably and amply represented. The committee have received an offer of some models of forestry huts from Denmark, which has been accepted. It is hoped that builders of timber bridges will show specimens of their workmanship, as we understand that much difficulty is experienced by landed proprietors in getting a good, useful, and ornamental bridge at anything like a reasonable cost. The date fixed for the open-ing (July) seems rather late, but it will be better to have everything in order than to open prematurely, as exhibitions of this kind are wont to do.

— EUCHARIS AMAZONICA.—Some very fine specimens of this most useful flowering plant can now be seen at Harefield Grove, near Uxbridge, the residence of GEORGE WEBSTER, Esq. They are in 16-inch pots, and are fed with soot-water, and twenty

or more strong flower-stems can be counted on each. The plants were repotted in June, and allowed to rest until November, when they were pushed into growth, and as soon as they began to put forth new leaves soot-water was given to them, and, as above stated, is being liberally supplied. It is seldom that any one sees such large and vigorous specimens carrying such marvellous heads of bloom. Mr. Goucit, the head gardeoer at Harefield Grove, proceeds upon the principle of giving gentle shifts, not more than an inch or so at a time; and his practice is, as soon as the bulbs touch the side of the pots to give a shift. The Eucharis is largely grown here, as Mr. GOUCH depends on it for cut flowers, and there are many plants in various stages of growth, including a young stock of a highly promising character.

— DISEASES IN THE VEGETABLE KINGDOM was the subject of the paper read by Mr. BRUCE FINDLAY at the last meeting of the Manchester Horticutural Mutual Improvement Society.

THE PIEPUL. — The following interesting details respecting the Peepul (Ficus religiosa) are copied from a letter in a recent issue of the Daily News. From this letter-one of a series entitled " A Journey Round the World," from the travelling correspondent of the Daily News, written from from the travelling Benares, which is not only the holiest, but also the oldest city in India - a vivid idea may be gained by non-travelled readers of certain phases of Indian life "Close by here, too, is a more than usually sacred growth of the Peepul, a patriarchal tree whose once stalwart limbs, drooping under the weight of farspreading boughs, were supported by a block of solid maronry built under them. Being Saturday an everchanging procession of grave elders, matronly women, young men and maidens, were walking round and round the tree, chanting a low strain. Every time they passed a particular point in its circumference threw on it with their hand water taken from the Ganges and carried in their lotas. Some varied their performance by throwing Marigolds or grains of Rice. It seemed a particularly dull game of follow-my-leader, but it is a serious religious function, and good Hindoos would not see Saturday's sun go down till they had walked 108 times round the Peepul tree, laved its trunk with holy water, or cast upon it some offering of food or flower. A goat had discovered the richness of the land, and, climbing up the masonry, browsed upon the flowers, whilst the pigeons coming down in swarms pecked up the Rice, nobody saying them nay," In the "North" Gallery, at Kew, picture No. 282 represents a Nepalese temple and Peepul tree, with blue pigeons, which are sacred to CHRISTNA, bathing in the foreground. No. 329 is another representation of the Peepul tree. The Hindoos hold the Peepul sacred, in the belief that their god VISIINU was born among its branches. From GARDNER's Ceylon we learn that the Peepul is held in great veneration in Ceylon, and in the Cingalese language is called Bogaha, or Tree of Buddha. It is accounted the most sacred of trees, and is held in such estimation in the district of Kandy that the form of its leaves is only allowed to be painted on furniture employed exclusively for the gratification of the king. tailed leaves are skeletonised, varnished, and painted by the Chinese. Specimens so treated may be seen in the No. 1 Museum at Kew; living plants, too, are to be seen in the Palm-house and elsewhere in the same establishment.

- ITEA VIRGINICA is, from a gardening point of view, a very desirable shrub. It is a member of the Saxifrage family, and is worthy of a place even by the side of the showiest shrubs furnished by that order, one which must hold a high place in the estimation of the horticultural world, seeing that it includes such deservedly popular garden plants as the Ribes, Hydrangeas, and Escallonias, &c. Itea virginica has been known for above a century in British gardens, having been cultivated as far back as 1744 by Archibald, Duke of Argyll, to whose merits as a gardener Collinson, a great gardener himself, pays the following tribute :- "The Duke of ARGYLL, on the 15th of April, 1761, died as he sat in his chair, my honoured friend, and great patron of all planters, aged 79, a very hearty man of that age. In the year 1723 4 he took in a part of Hounslow Heath to add to a little farm, and began planting by raising all sorts of trees and shrubs from seeds from our northern colonies, and all other parts of the world. He had the largest collection in England, and happily lived to see what a surprising maturity they had arrived to in thirty-seven or thirty-eight years. Great was his benevolence, for he gave to every one to encourage planting, and raised plants on purpose to oblige the curious at this seat of his called Whitton. He had a fine collection of rare birds and beasts; he was a great chemist, natural philosopher, mechanic, astronomer, and mathematician. He was a wonderful amiable man, plain in his dress, without pride or vain ostentation; his library was scarcely to be equalled. He was forty-one years old when he began to sow seeds for his plantations." The Itea succeeds best in damp peaty soil, grows from 2 to 5 feet in height, and produces a profusion of upright racemes of small white flowers about June or July. This shrub derives its name from the Greek for "Willow," which it somewhat resembles in its mode of growth.

RHODODENDRON ARGENTRUM, - In the Winter Garden, Kew, a large specimen of this magnificent Rhododendrom seems to bid defiance to short days and cloudy sunless skies. The tip of every shoot, with its radiating clusters of leaves, is laden with flowers in various stages of progressive development. In bud these flowers exhibit a rosy lilac hue, but when fully expanded they display an interior that is nearly white, traversed with longitudinal bloodpurple veins. The campanulate corollas are of great size, and more or less numerously produced in a truss, while the orthodox number of stamens (namely, 5-10) that prevails amongst Rhododendrons generally is exceeded in this instance, as well as in several oth Himalayan species. This is ooe of the many noble types collected by Sir J. D. HOOKER in the Sikkim Himalayas. There is a figure of it in HOOKER'S Rhododendrons (9), and a painting (No. 248) in the " North" Gallery at Kew.

—— SEMPERVIVUM HOLOCHRYSUM, —A good many Sempervivums are tolerably well known and pretty largely grown for the summer decoration of the flower garden. S. tabulæforme and others of the Canary Islands and Madeiran species are frequent in gardens; but the shrubby ones, as a rule, are not allowed to develope themselves so as to show anything like their true character. A large group of these interesting plants are always to be seen in the Succulent-house (No. 5) at Kew, and in addition to the differences in leaf form, some are nearly always to be found in bloom. Pyramidal panicles of golden-yellow flowers produced at a dull season are by no means to be despised, and the Sempervivums are very easily grown. The species mentioned at the commencement of this note has been in flower for some time at Kew. The Sempervivums, as some of them grow in their native habitats, are beautifully represented in the "North" Gallery at Kew, in picture No. 34.

— LIVISTONA AUSTRALIS,—In private establishments it is seldom we have the pleasure of witnessing these noble types of vegetation in flower, as number, and not size, is the usual desideratum there. A tree in the Palm-house at Kew has been flowering for weeks, and the flowers are conspicuously more ornamental than those of its congener, L. chinensis, flowering close by. It is, moreover, the tallest tree in the house, and distinctly shows its leaves in the uppermost dome or section of the building. The much branched spadix and flowers are of a bright straw-yellow colour, while the more slender and ultimate branchings hang about in a graceful manner. In a wild state it is one of the tallest of the Australian Palms, and a conspicuous feature of the vegetation where it occurs. There are paintings in the "North" Gallery at Kew (Nos. 549 and 582) showing the habit and general appearance of the tree.

— ORCHID SALES.—At Messrs, PROTHEROE & MORRIS' sale of flowering Orchids on Tuesday there was a large attendance of visitors and buyers, and the competition for some of the specimens was unsually good. The more important lots sold as follows:—Lælia anceps var., £10 10.; Oncidium superbiens var., £18 18s.; Lycaste Skinneri alba, £22 1s.; Odontoglossum crispum Dormanianum, £19 18s. 6.d.; Cypripedium Wallisi, £19 19s.; Odontoglossum Alexandre, £15 15s. At the usual weekly sale on the previous Friday two more large masses, each consisting of one hundred bulbs or more, came under the hammer, and realised respectively £105

and £126. At the same sale Cattleya Trianæ alba was knocked down for 12 gs.

— A GIGANTIC FLOWER. — The remarkable Aroid, Godwinia gigas, is now fast developing its immense flower in Mr. WILLIAM BULL's establishment, King's Road, Chelsea. This extremely rare plant was discovered by the late Dr. SEEMANN when collecting for Mr. BULL, on the Chontale Mountains, Nicaragua. This specimen is quite unique. It flowered once before in this country, in 1872—the bloom or flower spathe them measuring I foot II inches in length, and I foot S inches in width—truly gigantic dimensions for an individual bloom. The plant was illustrated in our volume for 1873, p. 72.

- IRIS STYLOSA. - As another instance of the mildness of the season, attested by numerous correspondents from many parts of the country, it may be mentioned that this winter-blooming Iris has been opening beautiful and fully developed flowers for some time in the ordinary collection at Kew. This occupies a narrow border alongside a wall with an eastern aspect, and no other protection has been There is a figure of this species in DESFON-TAINE'S Flora Atlantica, I., xl., 5. It is recorded in gardening books as having been introduced from the island of Corfu, although an eminent authority is of opinion that it is confined to Algeria alone. blue flowers, enlivened with feathered markings on the lower part of the segments, is very welcome outof-doors, although we frequently see it grown under the protection of a cool frame.

THE NEWCASTLE - UPON - TYNE FLOWER SHOWS are announced to be held on April 23 and 24, and July 23, 24, and 25.

- THE WEATHER, -- General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending Jan. 28, 1884, issued by the Meteorological Office, London :- The weather has been in an extremely unsettled, boisterous, and rainy condition in all parts of our islands. Snow has fallen in all the more northern districts, and in many places some sharp thunderstorms have been experienced. The temperature has been about equal to the mean in "Scotland, W.," and a little below it in "Scotland, E.," and " Ireland, N.," but in all other districts it has continued above its normal value, the excess over central, southern, and eastern England being 4°. maxima were recorded either on the 22d or 23d, when the thermometer rose to 48° in "Scotland, E.," and to between 52° and 55° in most other districts; but in "England, E.," and "Ireland, S.," as high a level as 56° was reached, while in " England, N.W., the maximum was 57°. The minima, which were registered on the 26th or 27th, varied in most districts between 27° and 32°; in "Scotland, E.," however, the temperature fell to 25°, and in "Ireland, N." to 19°. The rainfall has been considerably more than the mean in all districts, Bright sunshioe, though still very deficient, shows a slight increase in duration in most places, the percentages ranged from 12 in "England, S.W." to 25 in "Scotland, E." Depressions observed .- During this period barometric pressure has been subject to very great and remarkable changes, two very deep and important depressions having crossed our islands from the westward. The first of these travelled with great rapidity over the south of Scotland, the North Sea, and Denmark during the 23d, bringing violent gales on all our coasts-from S.W. as it approached, and from W. or N.W. as it moved away. The second disturbance, which travelled in a north-easterly direction across Scotland on the 26th, was very much deeper, and during its passage pressure decreased with excessive rapidity. The centre appears to have passed near Aberdeen, where the barometer at midnight regis-tered the abnormally low reading of 27.40 inches. The depression occasioned south-westerly to westerly gales of very great violence in all parts of our islands, and strong winds or gales over the whole of western

THE BRIGHTON AND HOVE CHRYSANTHE-MUM SOCIETY'S SHOW is fixed for November 11

— GARDENING APPOINTMENTS. — Mr. R. WOODFINE, Hally Foreman at Kilkenny Castle, the seat of the Marquis of Ormonder, as Gardener to C. P. Boyd, Esq., Emsworth House, Hants.

Home Correspondence.

An Iris Garden,—I lately had the pleasure of visiting a really scientific garden, the capital of Irischom; its situation is known to hardy plant growers, but as it is hardly a place for the merely curious visitors I need not name it. The owner is well known for his high scientific attainments: these have obviously reacted on his garden. The natural soil did not seem very favourable, nor the climate, except that the garden being on a hill in a very flat country, it is somewhat above the damp, I went as an ignoramus in Irises. Some species, especially Iris Ræmpfert, grow well in our Oakwood experimental garden, but this is "plan par bonkur gue par sagesse"—we had exactly the right soil and damp situations, and therefore they thrive; other species, mostly owed to the kindness of friends, are, after being watched, and under advice, moved about till they seem happy. But Iris growing at S—is very different from this. There the exact requirements of all species of soil, situation, moisture, and dryness have been studied till they are known, so that any new arrival has a congenial home at once ready for it. Some of the mechanical contrivances are very good; two especially struck me—one a dark frame for seeds in a greenhouse; another a frame made so as to give complete shelter or full open air, with shelter from wind, at will; this last, I think, might be useful in Lily growing. Very few species were in bloom—these beautiful ones; but there was plenty to learn from the growth. In going over a garden like this some thoughts force themselves upon you:—That always growing number of influential amateurs who make hobbies of their gardens will not long be content without a powerful, prosperous, independent Noyal Horticultural Society, with a paid secretary, like the Society of Arts. That gardening seems the natural and most satisfying rest for the highest order of minds: this struck me lately, when a note from my friend, Professor, now Sir Richard Owen, showed that long life had not the least blunde de a thousand pities if al

Nepenthes Rajah,—Mr. Moore was growing this distinct Pitcher-plant very well in the cool Orchid-house at Glasnevin, when I was there in September, It was close to the glass with some of the Masdevallias, Considering its cool habitat in its mountain home in Borneo, where it luxuriates in a humid atmosphere, it was but reasonable to expect that the cool-house would suit it best, "F. Donglas, Great Gearies, Illord.

At Daylesford House, Chipping Norton, the large plant of Rhododendron Nuttalii is again showing between forty and fifty trusses of its magnificent blooms. This is the finest variety I ever saw, the individual flowers being much larger than is usually seen. I understand the plant was imported direct from its native habitat. When in flower it is one of the finest plants for conservatory decoration that it is possible to have, and one that ought to be in every large conservatory, both flowers and foliage being very fine. In the stove I observed a plant of Stephanotis floribunda, in a 16-inch pot, with flourteen of its large egg-shaped fruits, and a quantity of Calanthe Veitchii, the spikes being 42 inches in length, and bearing from forty-five to fifty flowers. I never saw a finer lot, the flowers being so abundant on, comparatively speaking, short flower-spikes. The same remark will apply to the Euphorbia fulgens, in 5-inch pots; the plants averaged 30 inches in height, with wreaths of bloom 18 inches in length. The Poinsettia pulcherrima was equally well done, stiff, sturdy plants, with trusses 18 inches in depth. The Poinsettia pulcherrima was equally well done, stiff, sturdy plants, with trusses 18 inches in depth. The Poinsettia pulcherrima was equally well done, stiff, sturdy plants, with trusses 18 inches in depth. The Poinsettia pulcherrima was equally well done, stiff, sturdy plants, with trusses 18 inches in depth. The Poinsettia pulcherrima was equally well done, stiff, sturdy plants, with trusses 18 inches in depth of the cultural skill and ability displayed by Mr. Otley, the courteous and able gardener at Daylestord. F. K. Fetch.

Ourisia coccinea.—Many complain of the failure of this bright-flowered hardy plant, and I have been amongst the number, having tried it in many varieties of soil and situation with indifferent success. To those who wish to know under what conditions it may thrive, the following extract may be interesting —it is from a letter written to me by the owner of a gardeo near Glasgow, situated on such low ground that the soil is sometimes washed out of the flower-beds by floods:—"I learn with wonder your failure with Ourisia coccinea. Here it grows very freely; and at Kirn, 25 miles down the tea-coast, it flourish;

like a weed; but if an old bell-plass is placed over it there in winter, it doubles the bloom the following summer. The soil there is stiff clay, over which sand has been freely sprinkled yearly." C. Wolley Dod, Edge Hall, 7 gan. 29.

"Beauty of Appropriateness."—Reading the short article with the above heading in the Gardeners' Chronicle of January 19, p. 84, one is inclined to ask, What next? for surely it means far more than appears on the surface. It is a condemnation of the practice on the surface. It is a condemnation of the practice of very many, if not all the gardeners of the present day. It opens up a wide field of contention without giving any specific idea how to remedy the evil compained of. The subject is an important one, for there is no disputing the fact, that much ugliness is recluded thought but the find-man is matching the here is no disputing the fact, that much ugliness is produced through want of judgment in gardening, as well as in all other branches of decorative art. It may be asked, What is appropriate beauty in gardening? Is it to have everything in in its proper place? If so, how many beautiful things must be removed or changed! How often do we see remarks as to the beautiful and interesting rockwork in the Horticultural Gardens at Chiswick. There, then, we have beauty, but the rockwork is inappropriate; yet without the rockwork was to be beautiful flowers growing in the vegetable gardens, and even on the Vine borders: here, again, "beauty of appropriateness" is wanting. Will it be appropriate beauty to have each flower-bed planted of one colour? I had the privilege some years ago to look through I had the privilege some years ago to look through the fine gardens at Enville Hall, Staffordshire; here each flower-bed consisted of but one colour-scarlet, pink, yellow, &c.; I have no hesitation in stating that beauty so inappropriate was never seen—no, not even in the mosaic beds of the present day. We have the righton heart of the reserve the reserve that the second bave the ribbon-border, consisting of five or six rows of plants—red, white, blue, pink, yellow; can anything be more monstrous than to try to can anything be more monstrous than to try to blend the colours of the rainbow with flowers?—
even the sadly maligned mosaic or carpet-bedding is to be preferred before it. Then we have the so-called sub-tropical bedding—some beds wholly filled with ooe kind, say of Cannas, with possibly an edging of some variegated grass. Will it be said filled with one kind, say of Cannas, with possibly an edging of some variegated grass. Will it be said that "beauty of appropriateness" maintains a very honourable position surrounded by so much stiffness? There is still another style of bedding, viz., the mixed, and in which it will be difficult to find beauty of appropriateness" abundant, for here we have a pland or patch of this, that, and the othermany of them beautiful, but ineffective, because of the want of atrapement, and association with unsuitable want of arrangement, and association with unsuitable companions. The increase of taste has but little to do with the banishment of monstrosities in needlework; fashion has transferred it from wool to silk, and cruel imitations are made of flowers and fruit, to say nothing of birds and butterflies, as far removed from "beauty of appropriatenes" as was much of the work of our grandmothers. It is to be hoped that some more able pen than mine will take this subject in hand, and try, if possible, to show gardeners the right place in which to use the good materials. Most gardeners do the best thing they can with the materials at hand, and endeavour if possible to please the taste and satisfy the expectations of their employers and the public, believing that the gardens that afford the want of arrangement, and association with unsuitable companions. The increase of taste has but little to and satisfy the expectations of their employers and the public, believing that the gardens that afford the greatest variety are as a rule the most valuable and magnificent, even if "beauty of appropriateness" be absent from some of their efforts. George Thomson, Knap Hill.

Canker in Fruit Trees,—It is now some time since I first addressed you on this subject. When I last wrote some one replied, saying the canker was caused by frost. My previous letter proved that it was not, so I cared not to notice that letter or to write a rejoinder. For some years I have felt perfectly certain that the so-called canker in the Apple tree was caused by an insect, and did not proceed either from the action of frost or the planting of the trees on wet soil or gravel, which has been so repeatedly stated as the reason. I have said, and I still maintain, that canker has nothing whatever to do with root-action. Observe a piece of the wood that is cankered, where there is a small connecting strip of bark left that swells larger and larger until it is of size sufficient to well supply the branch beyond with all the sap required. If the canker came from disease of the root this would not be the case, for there would be a deficient supply of sap, and therefore no enlargement of the bark he speaks of, is a direct consequence of the supply of water from the root alone? Ed.] Secondly, it could not proceed from frost, because I have found canker on the wood of the year before any frost has taken place. Thirdly, where I have applied Gishurst Compound to a tree I have found that part was un-affected with canker; and, further, when I have found canker just making its appearance I have cout the part, rubbed in some Gishurst Compound, and the place has healed, and in many instances the

bark has grown over. I have taken cankered wood to entomological meetings, shown it, left it for observation, &c., but never yet have I got any information on the subject; and I have invariably found when speaking to gardeners, fruit growers, and others on the subject that not one has entertained my views, and generally I have been answered by a smile of incredulity. This has the more astonished me because, by close observation (to me) it is so apparent that the canker is caused by an insect. I am sorry to say that I have not a microscope (besides which my sight is not so strong as I could wish), so that I have made my observations with a Stanhope lens. With it I have seen clearly that the defects on the branch are the results of the working of an insect; but I have never yet discovered the insect itself. I had hoped that a gentleman of such scientific and microscopical attainments as Mr. Worthington Smith would have carried out, as he is perfectly able to do, such inspection of branches, cuttings, &c., as would not only have proved my assertion beyond a doubt, but that he, with his accurate pencil, would have figured ova, larve, and the perfect insect. I still look for this at his hands. While I have been making these observations for many years another has been doing the same, and in like direction, though quite unknown to myself. This gentleman is that close and accurate observer of Nature, that excellent and truthful naturalist, Mr. Hiam, of The Wren's Nest, Redditch, and to him is due the discovery of the canker insects. This last week I received a newspaper from him, giving an account of a discussion on the subject. I send the newspaper with this. If Mr. Worthington Smith would kindly give his valuable talents and time to the picturing of this scourge to the Apple tree I think he would confer a boon to us all, and finally set at rest that which has been miscalled canker, mis-stated as proceeding from the root, and as wrongly from frost, and all from the lack of tree and kernellu observation. Harrivom Weir

The Late Gale.—The winds of January, 1884, have made their mark in the gardens at Thorpe Perrow. The last hurricane, which took place on the night of the 27th, appears to have been the most disastrous among the good things. In the first Abies Nordmannian that was brought into Europe. This tree was brought from Prince Worozow's garden in the Crimea by one of the Lords Alvanley, and given to the late Lady Augusta Milbank. I think another went to Bicton, the only two plants out of six brought over alive. The tree we have lost was about 50 feet high. It was planted in a good situation, and much sheltered from winds. consequently, a sequall must have done the damage. Some time since in the Gardeners' Chronicle I advocated the practice of weighting the roots of all choice Coniferons plants, and as this tree is one so treated, it makes it the more interesting. The wind had no effect on the roots, but broke the top off about 12 feet above the ground. All the other trees so weighted stood this terrible hurricane without any damage. Abies nobilis, weighted with over five tons of soil, and above 50 feet high, stood well, although it is growing in a very exposed place. Handsome Spruce trees not so weighted were blown down in numbers all over the grounds, some in places where they will be much missed. In addition to this sorrowful tale, several fine old Hollies were blown and knocked down by other large trees falling on them. Twenty-two fine them, such as Box and Vews. One large Oak fell on a Yew with a spread of 18 feet, taking every branch from the stem, and leaving the latter a clean pole. In the woods the damage done is in proportion to what has been and one in the pleasure grounds; two breaks were made in one large plantation of Spruce, which must have been planted hard on 100 years. One is a passage right through the wood, about 20 yards wide; the other is a large space where over 100 trees lie one over the other in a perfect mass, and must have all gone with one gust of wind. One might has ke hat became of all the pi

— The unusually mild weather has been somewhat abruptly altered for the worse during the past eight days—cold showers of sleet and angry gusts of wind prevailing during this period. On Saturday last we experienced one of the most violent storms of wind, accompanied with sleet and rain, ever felt or remembered by the oldest inhabitant here. The morning broke calm and fair, although slight showers intervened towards mid-day, becoming more severe and frequent by mid-day. By four o'clock it had increased to a terrific hurricane, breaking and uprooting large trees in the park, unroofing houses, breaking glass, and carrying wreckage and destruction in its unabating fury, until about eight o'clock when it became calm. Thunder and lightning succeeded, and continued until midnight, when a slight fall of snow covered the hills, which was dispersed by the rays of the sun on Sunday.

The weather still continues stormy and unsettled. P. Davidson, Justine Minster, David

Pea Nelson's Vanguard.—As many of your readers will now be getting in the early crops of Peas I should like, with your permission, to bring to their notice a variety deserving of more extended cultivation by amateur and market gardeners. I have found Nelson's Vanguard a first-rate wrinkled Pea, 3 feet in beight, raised by the late Rev. John Nelson, of Winterton, Norfolk. It is very hardy, and may be sown in January in any soil. It comes into bearing only about a week later than William the First. It is also very prolific when liberally treated, and is of a most delicious flavour. With the late Rev. J. G. Nelson, of Aldborough, Norfolk, who was no mean judge, this Pea maintained its position to the last, as he did not consider it superseded by any later introduction. No one who saw it in his garden in the month of June will forget its magnificent appearance. H. C. Cooke, Aldborough Mill.

The Potato Disease : Sand Filtration,-In the Gardeners' Chronicle of January 12, I see an account of an experiment made by Mr. W. G. Smith regarding the power earth has of retaining the spores of fungi, upon which I beg to make a few remarks. I have proved that sand and different kinds of earth have spore-retaining power to a very high degree as far as the spores of the Potato fungus are concerned. At first Mr. Smith doubted very much, on account of certain theoretical reasons, that my experiments had any reality whatever. I am glad to see that he has now made a considerable advance in so far as he has himself repeated my experiments, not, however, with spores of the Detach purple with the reason of the Detach purple with the reason of seather the contraction. self repeated my experiments, not, however, with spores of the Potato fungus, but with spores of another fungus altogether. He has now convinced himself that there is nothing impossible in such experiments, and I hope that Mr. Murray and other unbelievers are satisfied also upon this point. It has now been proved in Great Britain by direct experiments that I was right in Great Britain by direct experiments that I was right in my assertions:—I. That high-moulding, done high enough and early enough, has the power of affording almost perfect protection to the tubers in the ground against the disease. 2. That when Potatos have been lifted while the Snores are still in active life in been lifted while the spores are still in active life in the leaves, the sound tubers will often be attacked to a very large extent in the very act of lifting them, and by spores falling from the leaves upon them; whereas such an "after-sickness" does not occur when the Potatos an "after-sickuess" does not occur when the Potatos have been left in the ground until two or three weeks after the complete withering of the leaves (as to the English confirmatory experiment, see the Gardeners' Chronicle, September 28, 1882). These are the great practical results of my researches. Other important results I trust will likewise be confirmed. After the publication of my treatise on the Potato disease some publication of my treatise on the Potato disease some old experiments were brought to light, which show that the effect of high-moulding was long ago noticed by a few practical farmers, one instance of this kind even as far back as the year 1846; these practical observations, however, have been almost entirely forgotten, which shows that want of belief in trustworthy facts is as great a cause of error as over-credulity. I hope, however, that the important fact that high-moulding is a powerful means of protecting Potato tubers from the disease has now been so impressed on the mind of the British public that it will never tubers from the disease has now been so impressed on the mind of the British public that it will never again be forgotten. The necessity for late lifting has, however, been much less spoken of than protective moulding, yet it has not only been proved, but also confirmed by communications in the Gardeners' Chronick, that a perfectly sound crop may be in great part destroyed by lifting it too early. I therefore beg to say, "Let this never be forgotten," for it is a fact of the greatest practical importance. 3. Next, it has been shown by Mr. Smith that the experiments on the retention of spores by earth, which at first he conbeen shown by Mr. Smith that the experiments on the retention of spores by earth, which at first he considered as impossible, really can be performed in the manner I have suggested. Such being the case, I think I may lay claim to a little more confidence in the value of my experiments than has hitherto been vouchsafed me by Mr. Smith and his adherents. I do not however by any means thun criticism on voucnsated me by Mr. Smith and his adherents. I do not, however, by any means shue criticism; on the contrary, I am desirous of it, on the basis of really controlling experiments. But on the other hand I am of opinion that unscientific remonstrances are prejudicial to the progress of truth, if not among scientists, at least as far as the general public are conscientists, at least as far as the general public are con-cerned. Let us now examine the experiments of Mr. Smith which tend to disprove what I have stated concerning the retention of Peronospora spores by sand and other soils. Curiously enough Mr. Smith has not experimented with the spores of the Potato fungus, but with those of Ustilago carbo. Why is this? Because spores of the Potato fungus, according this? Because spores of the Potato fungus, according to Mr. Smith, are not readily procurable in sufficient quantity for making satisfactory experiments at this season of the year. If Mr. Smith had known more of the subject he could not have said such a thing, for only starting with, say, ten healthy spores, a hundred millions of spores may be produced in the course of ten or fourteen days. It seems that Mr. Smith made use of a perfectly dry material, and that he has put all the spore-charged water on at once. If so,

this would diminish the spore-retaining power of the sand, but not, I think, do away with it altogether. If, therefore, Mr. Smith has committed no other serious error (and I do not see how this is possible) it must be admitted, I think, that his experiments show that sand and earth have no marked power of retaining spores of Ustilago carbo. This, indeed, is in itself very interesting, but it does not in any way contradict my experiments made with a totally different kind of spores—namely, those of the Potato fungus. After all said, I maintain that the retention of Potato disease spores by sand and earth cannot be reasonably disease spores by sand and earth cannot he reasonably disputed from any standpoint, because it is a well-established fact. The only way of controlling my experiments is to repeat them. If this be done I have no doubt they will receive complete confirmation. If, as Mr. Smith asserts, the spores of Ustilago carbo are not retained by sand and earth, I think the reason must be because, as suggested by Professor M. Forster, they contain fatty matter, which diminishes their adhesion to the material through which the filtration took place. But whether this be so or not, I cannot tell, because I have not myself experimented with these spress. which have nothing to do with the street. with these spores, which have nothing to do with the Potato disease—the sole object of my researches for several years. As I do not think it is generally known in England how to obtain in a short time a large number of spores of the Potato fungus for experimental purposes, I beg to make a few observations upon this subject. I am willing to send Potato slices dipped in spore-charged water to any English upon this subject. I am willing to send Potato slices dipped in spore-charged water to any English mycologist who wishes to repeat my experiments. These slices can be sent in a letter. By placing these slices under a bell-glass, or an inverted wine-glass, for the matter of that, in a room where the temperature is from 17°-18° C. (60°-65° F.), ripe conidia will be produced in about three days; with lower temperature this takes a longer time. To obtain a large quantity of spores, when the slices begin to produce conidia they should be plunged into and well shaken in a small quantity of water—say, in about a teappoonful. In the spore-charged water thus obtained fresh slices of Potato are dipped. The shove quantity of water would be enough for dipping a bundred fresh slices, but, generally speaking, ten to twelve slices will be amply sufficient for the experiments in question. Before putting these slices under wine-glasses they ought to the exposed to the free air for one or two hours, so as to dry a little, otherwise it often happens that the production of conidia is considerably interfered with by "wet rot" attacking the slices; but if these have been dried somewhat after being dipped a large crop of conidia can be generally obtained before the "tweet to "commences" being dipped a large crop of conidia can be generally obtained before the "wet rot" commences. The spores should always be made use of as generally obtained before the "wet rot" commences. The spores should always be made use of as soon as they are ripe, else they will mostly fall off, and "wet rot" will soon appear, by which the crop is spoiled. The details of the experiment itself have been given in the Gardeners' Chronick, December 22, 1883. For preserving the fungus for a long time whole tubers should be dipped in spore-targed water, and for some days placed in a moist position in a warm room. I generally put them in a jar, and cover them with a piece of wet linen. They must not be suffered to dry beforehand, and should be placed in the moist position immediately after being dipped. If the Potatos have not previously been dried, and if the spores are in an active state of vitality—which they always are when taken fresh from dried, and if the spores are in an active state of vitality—which they always are when taken fresh from the slices—the Potatos will nearly all become diseased, even when the skin is undamaged; but if the Potatos are rather dry, it is safer to prick them through the skin with a fork. When it has been ascertained that the Potatos thus treated have become diseased, they should be placed in a cool place. In a warm room the mycelium generally dies in the course of a lew weeks, but in a cold place (2°–5°C–35′—40° Fahr.) the fungus can be preserved all through the winter. When a piece of diseased Potato is placed under a bell-glass it generally produces but few condida if it has been long diseased. The number of these spores is insufficient for the experiment here spoken of, but is insufficient for the experiment here spoken of, but sufficient for producing a large crop of spores if they are put into a little water, in which fresh Potato slices can be dipped, and treated in the manner above described, J. L. Jensen, 141, Rue Perronel, Neuilly-sur-Seine, Jan. 24.

Mr. Smith's Fungus Experiment,—The great defect in the experiment detailed by Mr. W. G. Smith at p. 121 is seen in the fact that he so far departed from what is the normal state of the soil in the summer as to have saturated the sand in his flower-pot with water, so that for sand it was at the moment of carrying out his experiment as loaded with moisture as well could be. Now it should be known to Mr. Smith that sand can absorb only a certain quantity of water, and beyond that all the rest must percolate away if there be drainage; in fact, such is the porous nature of sand that once it is thoroughly saturated all other added moisture will pass through the silicate as fast as through a drain; consequently it needed but an additional drop or two of moisture to fall during the night to run through the sand in the

pot as fast as it liked. In the meantime the moisture arising from the saturated sand in the pot had liberated the spores of the Oat fungus, and with the drop of water or two that fell these would pass through the sand. Really the result was just what might have been expected, having regard to the fact that the sand had been specially prepared to produce it. The soil about Potato plants is of from 4 to 5 inches in thickness, and is never found in the summer in a saturated condition, as Mr. Smith's sand was. Still farther, no kind of soil is so porous, therefore the conditions of Mr. Smith's experiment, and those seen in high-moulding as practised by Mr., lensen, are in no way analogous. 'Tis true, many Potato tubers show disease in the flesh but not in the skin, but how it got there there is as yet no evidence to show. A. D.

Sand and Fungus Spores,—A simple drawing often gives a better idea of an object than pages of description. The accompanying little illustration (fig. 31) shows the relative sizes of grains of sand and spores of the Potato fungus, all enlarged from the actual objects 40 diameters. A represents the extremely fine sand found at Clapton, London; 12 the sand of Gray's Thurrock, Essex—both these sands are so fine and compact that they might be mistaken for brickearth; c is Reigate sand, unusually small; and D is the finest sand known to me, belonging to Croydon.

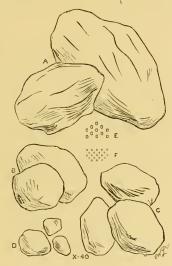

Fig. 31.—Grains of Sand, and the two orders of spores
Belonging to the Potato fungus, drawn to the
Same Scala. X 40.

Mr. Plowright has spoken of "compressed sand" and the interstices between the grains, but there is hardly such a thing as "compressed sand." When Egyptians fix the pegs of their tents in the desert they do not drive them in, as any attempt of that sort would split the pegs to pieces, the sand being non-compressible; the Egyptians, therefore, dig a hole for each peg. Even piles for bridges and other engineering works cannot be forced in sand, the non-compressible sand splits piles and turns the iron points. At E are the redinary Potato fungus spores, and at F the little moving zonspores, which burst out of the ordinary spores and swim about. Mr. Jensen has gravely told us that 3 inches of sand will sift these little spores and prevent them from reaching the tuber of the Potato, whereas fungus spores, when seen mixed with sand, flow about in the little currents of water like tadpoles in the whitpool rapids of Niagara. Wherever water goes the spores go too. Mr. Plowright tadpoles in the whitpool rapids of Niagara. Wherever water goes the spores go too. Mr. Plowright saks, on p. 46, "How many millions upon millions of layers would there be in 4 inches of compressed sand?" Would be be surprised to hear that in common sand, instead of "millions upon millions" there are not many more than a thousand layers? In Croydon sand there would be 1500 layers, and in the finest sand I have ever seen 6000 only. In respectfully sifting the calculations (and the sand) it must be understood that I do not question, and have not questioned, any possible benefits to be derived from high-moulding of Potatos—I hope practical gardeners, to whom we owe so much, will belp to settle this point. W. G. Smith.

American Summering Apple.—I cannot say whether the Apple I knew when a boy at Woodhouse, near Loughborough, as the American Summering is the same as the variety grown by Mr. Pearson, of Chilwell, under that name: but I am still inclined to call it a table Apple. I well remember, when a schoolboy, we used to consider it one of the best eating early Apples we could get. That was forty years ago, and there were large trees of it then, so it is a very old variety. I may add that some twelve or fourteen years ago, when on a visit to Woodhouse in the autumn, I ate one, and thought it as good as I did when a boy. Thes. Woodford, The Nurseries, Atherstone.

Crocus Imperati.—This pretty Crocus thrives and multiplies fast, even over the cold subsoil of my garden, in which delicate bulbs always fail. The difficulty is to ensure its flowering during the "heleyon days" which are due just after the winter solstice. This year it has had a splendid time, and I cannot recollect its flowers on fine or so durable ever before. Mr. Harpur-Crewe used to take up his bulbs of it when ripe, and keep them dry till late in autumn; and it then flowered in spring. Of course a raised hand-light is a very desirable protection to it when flowering out-of-doors at Christmas. I observe that a correspondent on p. 89 writes the name Imperatonius. I think the worthy Italian botanist, after whom it is called, would be the first to protest against such an adjective. Imperati is the modern form of the Latin Imperatus, a good loyal name, similar to Torquatus, Pilatus, Donatus, and a dozen others. The genitive of these must end in "ti." How the possessive adjective formed from them would end there is no certain rule; but either onius or orius would be impossible. Surely if plants are to be named after persons, it is better to use the possessive case than the possessive adjective, the attempt to form which often results in an uncouth barbarism. C. Wolley Dod, Llandualno, 74n. 26.

Helleborus niger.—So much has heen written on this subject that I should not again refer to it were it not to express the satisfaction with which, as an old cultivator of the genus, I have read Mr. Brockbank's recent papers in the Gardeners' Chronicle. He has shown both energy and judgment; and his earnest-ness, having been responded to by the confidence of collectors, he has had submitted to him, and heen enabled to compare specimens from all parts, at home and abroad, in unprecedented variety; and he has, I think, made good use of his opportunities—in fact, exhausted the subject. With regard to H. niger altifolius he may not have proved that it is a distinct species, but we all know now where it is to be found in a wild state. In his more recent essay he brings before us a great variety of forms, not with any suggestion that they are more than varieties of typical niger, but with proof that many of them have been established for a long period, and in widely distant localities, and that the Cheshire plant, with which his name is specially associated, is, in all probability, similar to that which in 1826 was distinguished by Sweet and Don as angustifolius. With reference to the illustration it is beautifully executed, and gives a vivid idea of a large, pure, well-formed flower. T. H. Archer-Hind, South Devon, Fan. 24.

Grapes at Longford Castle. — The Graperoom at this place presents just now an unusually attractive appearance, being filled to its utmost capacity with as fine a representative collection of late varieties as I have ever seen in midwinter, which in berry and clusters are all that one could desire, the latter varying in weight from 1½ lb. 0½ lb. each. The names of the varieties are as follows:—Alicante, Lady Downe's, Muscat of Alexandria, Mrs. Pince, Gros Colmar, and Gros Guillaume; the last-named, although not generally regarded as a favourite, is much esteemed at Longford. The Vines from which the crop was cut were struck from eyes in 1881, fruited the following year, and are now, after having borne a second crop—which in my opinion, was an exceedingly heavy one—full of vigour and promise for the future. From four Vines of Gros Guillaume twelve bunches were cut of an aggregate weight of 89 lb., being respectively three, 27 lb.; three, 24 lb.; three, 20 lb.; and three, 18 lb., the largest individual bunch, as previously mentioned, being 9½ lb. Gros Colmar produced bunches varying in weight from 2½ to 5 lb. The average diameter of fully developed leaves of Gros Guillaume was from 15 to 20 ioches, girth of rods 5 inches, and laterals bearing bunches 2½ inches. I give these particulars by way of recording what may be done (under favourable conditions) with Vines

Trichodesma physaloides, — This is a plant that nurserymen would do well to look after and introduce into cultivation, since, according to collectors' notes, it is a very beautiful plant ("a lovely object"), a statement that is fully borne out by an inspection of the dried specimens. This plant is

one of the Boragineæ, and has large fleshy tubers from which spring up annually a number of stems about a foot in height, sometimes forming patches about a foot in height, sometimes forming patches 2 feet in diameter from one root, well furnished with oblong, acute, glaucous green opposite leaves, and each stem ending in a rather large panicle of pure white flowers of good form an inch in diameter, and having the sepals purple. It is a native of the Transvaal in the neighbourhood of Pretoria and elsewhere; it also grows in other parts of Eastern Tropical Africa. If it were introduced it would no doubt be very easy to cultivate, and if treated in a similar manner to Dahlias would probably succeed well as a summer bedding plant, and would be a very desirable one, since white is not a colour of which there is too lavish a display in summer. The flowers appear to be lasting. N. E. Brown.

Notices of Books.

The English Flower Garden. By W. Robinson. (I vol., 8vo.) Murray: 1883.

The general object of this book, we are told, is to show by what arrangements and with what materials gardens, whether large or small, may be most effectually made to afford rational and lasting pleasure to those who frequent them. The "bedding out" system, which led to the expulsion of hardy herbaceous plants from many English gardens, reached its climax about thirty years ago. The setting-up of the Crystal Palace on Sydenham Hill was the apotheosis of conventional formalism in laying out pleasure grounds, the saoction of a kind of Baal-worship under which all natural beauty in gardens was sacrificed. But those who had a natural taste for flowers soon began to get weary of the tedious sameness of formal rows of scarlet and yellow in the long borders which they recollected full of handsome hardy flowers, and they sighed to have the plants of their childhood back again. These, however, had long ago been burnt on the rubbishheap, and a new generation of gardeners had grown up trained to know and believe in nothing for out-ofdoor gardening but bedding-out plants; so the recovery of gardens to a more healthy condition was slow at first; but in the last few years the reaction has progressed rapidly, and not only have all the oldfashioned hardy plants been restored to honour, but many new flowers of the best types for open-air gardening have been introduced and the demand as well

as the supply is increasing year by year.

In the celebration of Nature's triumph on her restoration to power in English gardens Mr. Robinson deserves to hold a conspicuous place; for no one has done more than he both to make and to meet the de-

mand for it.

The book of which we now speak is divided into two distinct parts; the former part, about 120 pages, deals with the laying-out of the grounds, the making of the beds and borders, and the arrangement of the plants in them. Examples, with illustrative plates, are given and discussed, from the ducal palaces of Treatham and Clumber to the villa of Professor Owen at Richmond, the rectory garden at Eversley, and the cottage of Gilbert White at Selborne. Mr. Robinson is not intolerant or dogmatic in his opinions about gardens; he gives us no ideal models, and his book is thoroughly practical throughout, and he draws tor us a series of pictures from real life, all of which please in different ways. Originality and variety of arrangement, so as turn to the best account the means at our disposal, are always to be commended; but conventional sameness and servile imitations are deservedly condemned. The gorgeous display of flowers made at Trentham and Chatsworth, and their clear fountains, delight us by their splendour; but to try to produce these effects by muddy ponds and illplastered terrace walls in a third class villa is ridiculous: we ask-

" An quodeunque facit Mæcenas, te quoque verum est Tantum dissimilem, et tanto certare minorem?

It is silly to try to make a Lucrine lake out of a duck-

In the arrangement of the flower beds also, and of the flowers in them, no fixed rules must be observed. We should try to follow "Nature in her best aspects." If we study any art in the matter it must be the art of artless arrangement—" Artem colandi artem." A visit to the best gardens in the kingdom, and the descriptions of others in Mr. Robinson's gardening journals, have made him familiar with great varietics of style, for all of which something may be said, and

select examples are given-the late Miss Hope's flower beds and borders as described by herself, Mr. Brockbank's in his villa garden near Manchester, Mr. Frank Miles' in the rectory garden at Bingham, and several others. Mr. Robinson strongly urges planting in groups, especially dwarf and choice plaots, to produce an effect, rather than having them dotted about, and in danger of losing themselves. Those who have seen the mass of Epigæa repens in the wood garden of Mr. Wilson, the colony of Pyrola rotundifolia at Munstead, and Pinguicula grandiflora in the bog garden at Floore, well know the value of this advice. Such subjects as Primula rosea and Gentiana verna not only look best, but may be most successfully treated when so grown.

We are not advised to destroy or lessen our grass lawns, but to make the most of the space devoted to flowers, and to look for tresh opportunities which may be turned to account for growing them. Rustic stone steps, the tops of old walls, waste corners, rough patches of grass which need not be mown till June, even the edges of walks, may all be made gay with flowers at some time of the year. From the Snowdrop of January to the Christmas Rose of December the beds and borders must never be flowerless. Advocates of the bedding-out system boast that the plants employed in it last so long in flower, but Mr. Robinson, with some reason, thinks that this very argument tells against it; we like variety in season as well as in kind, so that every part of each month may have its characteristic flowers-

" Floribus alternis, non tempore, computat annum"

-a true gardener's flowers are as good as an almanac

Tying up and labelling, of course, meet with attention in the preliminary chapters, but when all that is possible has been written and read about them, every one will continue to use his own plan, so we will leave these matters alone; but something like the "reserve garden" planned on pl. 69 we strongly recommend to all gardeners. It consists of a plot of level ground divided by narrow paths into rectangular beds, of such a width that any part of each bed may be reached without stepping on the soil. In these partitions, replenished from time to time with suitable soil, choice florists' flowers may be grown, new plants tested, duplicates for distribution raised; and it may form, as we have seen it at Munstead, a rich treasury of floral

The edging for beds and borders not bounded by grass is an important consideration, as in a large garden it has to be provided by the mile. Mr. Robinson advises the use of small stone slabs placed upright, or of thick pieces of sawn slate, over which dwarf plants may trail; where these materials cannot easily be obtained, Staffordshire blue tiles are good, and never break with any frost. They are rounded on the upper edge, the perpendicular edges being shaped to interlock, and their cost is £7 per 1000, or about £50 per mile. They are best laid with the outside 4 inches out of the walk, while on the inside the soil should come within an inch of the top, so that dwarf plants can easily trail over. Mr. Robinson advises that these plants shall be allowed to encroach a little on the walk so as to break the monotonous line; but, more than this, we find that such dwarfs as wild Thyme and Sandwort crawl over and down the tiles, and leaving the soil establish themselves in the gravel walk, where they feel more at home, and that Erigeron mucronatum, alpine Poppies, and similar free seeders, come up and flower well in the angle at the outer base of the tile, making a pretty row of alpines against the dark blue back.

We must now say something of the second and larger portion of the book, which consists of a descriptive catalogue of the materials with which the English outdoor garden may be made beautiful. These are arranged in alphabetical order, and extend over 300 pages, upwards of 1500 hotanical names heading as many descriptive paragraphs, which must not be judged from a botanical point of view, but which will be useful for reference, if not for comparison. In many instances a whole genus is included under its single generic name, several species being mentioned in the same paragraph. Thus, such genera as Aconitum, Helleborus, Hypericum, Salvia, Statice, &c., each of which may easily reckon a dozen ornamental species, have their members grouped together under one head. Many good half-hardy plants, easy to save through the winter, are included, as well as the best hardy bulbs and a few choice annuals, and

we probably have upwards of 4000 named varieties described. This is exclusive of florists' flowers, for each of which a code of cultural directions is given, with a list of favourites to be tried. The descripwith a list of lavourites to be tried. The descriptions are interleaved with 137 leaves filled on both sides with engravings of the plants mentioned on the opposite pages; under each figure the botanical name is printed in full, saving the tedious process of a numerical reference. Many of these figures are old acquaintances, somewhat the worse for wear, which we have already seen in the illustrated catalogues of nurserymeo, English or Continental. The absence of any scale of proportion is rather embarrassing at times, as when we find a flower of Ficaria bigger than a plant of Ferula; still they are useful to enable those who do not know the plants to judge of their babit, the size and colour being easily learnt from the letterpress on the adjacent leaf. We may mention that the popular English names are mixed up with the botanical names in the same leading type, each in its own alphabetical order, for convenience of reference. Large as the number of plants included may seem the author truly says that he gives only a selection of the best, and he fairly warns us if anything is of second-rate merit or difficult to manage. Some genera meet with especial favour both in the number of species described in separate paragraphs, and in the fulness of the cultural directions. Campanula is first in numerical force, with forty-four leading species; Saxifraga comes next with thirty-eight, while Primula and Iris have each twenty-six. Still perhaps all growers of large collections may find some favourites slighted; for instance, it may seem hard that such pretty and elegant flowers as Anemone parcissiflora and A. rivularis should be only enumerated and not commended; and that the characteristic Gentiana poeumonanthe, and one of the choicest of rockery ornaments, Hypericum reptans; should be entirely omitted. Still we have not many such omissions to notice, and the catalogue will be found a trustworthy guide to makers of collections, the cultural directions being founded upon the experience of the best gardeners,

We should have liked to have seen a good index of at least the former part of the work, as it is tiresome to have to look through a table of contents to find a passage to which we may wish to refer. The pages, too, might have been numbered with Arabic numerals throughout, instead of using those clumsy anachronisms, Roman numerals, up to 120, and then starting afresh; but these are small details, which detract but little from the general merit of the book.

The Meather.

Jan. 24 — Fine day and night,

25.— Fine bright morning; dull aftergoon; rain at

- 25.- Fine bight morning; dull afteronon; rain at night.

- 26.- A very severe storm. The minimum reading of the barometer took place at 7 30 F.M., when it was 28.35 inches. Lightning at night.

- 27.- Snow from 10. Ab. to 11 A.M., afterwards cleer and cloudy. Lightning at night.

- 28.- Fine day and night.

- 29.- Dense leg in morning; windy afternoon and 30.- Heavy rain at times; very dull day. Dark sky at night.

LONDON : Atmospheric Pressure .- During the week ending January 26, the reading of the barometer at the level of the sea decreased from 30.57 inches at the

beginning of the week to 30.39 inches by midnight on the 20th, increased to 30.54 inches by 3 P.M. on the 21st, decreased to 29.34 inches by 3 P.M. on the 23d, increased to 29.93 inches by 3 P.M. on the 24th, and was 28.71 inches by the end of the week.

The mean reading of the barometer for the week at the level of the sea was 29.88 inches, being o 68 inch lower than last week, and 0.08 inch lower than

the average of the week.

Temperature. — The highest temperature in the shade in the week was 52°, on the 23d; the highest reached on the 24th was 43°.5. The mean of the seven high day temperatures was 48°.8.

The lowest temperature was 36.°5, on the 24th; on the 22d the lowest temperature was 44°.5. mean of the seven low night temperatures was 39°.7.

The greatest range of temperature in one day was 11°.5, on the 26th; the smallest was 6°.5, on the 22d. The mean of the seven daily ranges was 9°.1.

The mean temperatures were-on January 20th, 10 mean temperatures were—on january 20m, 42°,7; on the 21st, 46°,4; on the 22d, 48°,8; on the 23d, 47°,9; on the 24th, 40°; on the 25th, 42°,8; and on the 26th, 42°; and these were all above their averages by 7°,5, 9°,1, 11°,4, 10°, 2°,3, 5°, and 4°.1 respectively.

The mean temperature was 44°.7, being 1°.9

higher than the average, and 7°.1 above the average

the week.

The highest reading of a thermometer with blackened bulb in vacuo placed in the full rays of the sun was 77°, on the 20th. The mean of the seven readings was 62°.2.

The lowest reading of a thermometer with its bulb placed on grass was 30°.5, on the 24th and 26th. The mean of the seven readings was 33°.1.

Rain.—Rain fell on five days to the amount of 0.81

inch, of which 0.40 inch fell on the 26th.

ENGLAND : Temperature, - During the week ending January 26 the highest temperatures were 56³.4 at Cambridge, 55³ at Leeds, 54³.4 at Bristol; the highest at Brighton was 50³, and at Blackheath and Preston 52³. The general mean was 53³.5.

The lowest temperatures in the week were 30°.3 at Wolverhampton, 31° at Hull, 31°.9 at Nottingham; the lowest at Truro was 41°, at Plymouth 38°.5, and at Bristol 38°. The general mean was 34°.4.

at Bristol 38°. The general mean was 34°.4

The greatest ranges were 23°.6 at Wolverhampton, 23° at Hull, 22° at Leeds; the smallest ranges were 13° at Truto, 14°.7 at Brighton, and 15°.5 at Plymouth and Blackheath. The general mean was 10°.

The mean of the seven high day temperatures was highest at Truto, 52°.1, at Plymouth 50°.9, at Cambridge 50°; and was lowest at Bolton, 46°.8, at Brighton 47°.5, and at Preston 48°.1. The general mean was 48°.9.

The mean of the seven low night temperatures was highest at Truto, 43°.7, at Plymouth 42°.4, at Bristol 41°.6; and was lowest at Wolverhampton, 37°, at Hull 37°4, and at Bolton 37°.6. The general mean was 39°.4.

The mean dally range of temperature was greatest

mean was 39°.4.

The mean duly range of temperature was greatest at Cambridge and Wolverhampton, 11°.4, at Nottingham 10°.7; and was least at Bristol 7°.8, at Preston 8°.2, and at Truro 8°.4. The general mean was 9°.5.

The mean temperature was highest at Truro, 47°.7, at Flymouth 46°.5, at Bristol 45°.3; and was lowest at Bolton 42°, at Hull 42°.3, and at Wolverhampton 42°.5. The general mean was 44°.

Kain.—The largest fall was 2.45 inches at Bradford, 2.39 inches at Shefield, and 2.13 inches at Bolton; the smallest fall was 0.67 inch at Cambridge, 0.81 inch at Blackheath, and 0.84 inch at Nottingham. The general mean fall was 1.44 inch. Rain fell on every day in the week at Bolton.

SCOTLAND: Temperature,-During the week ending January 26, the highest temperature was 53°, at Glasgow; at Greenock and Paisley the highest in the week was 50°. The general mean was 51°.5.

The lowest temperature in the week was 25°. at

Perth; at Leith the lowest temperature was 32°. The general mean was 28°.4.

The mean temperature was highest at Glasgow,

42°.1; and lowest at Dundee, 39°.1, The general

mean was 40°.6.

Kain.—The largest fall was 4.39 inches, at Greenock; and the smallest fall was 1.03 inch, at Aberdeen. The general mean fall was 2.07 inch. JAMES GLAISHER, F.R.S.

St. Louis, Mo.—Our climate here is one of extremes. On Jan. 5 the thermometer registered $-23^{\circ}.5$ Fahr., and on the $8th-3^{\circ}$. How our gardens will fare remains to be seen; the Peach crop is almost certainly annihilated, if not the Peach trees themselves, E.

Obituary.

MRS, R. B. DODGSON .- We regret to record the death, on January 19, of the widow of R. B. Dodgson, Esq., of Beardwood, Blackburn, who a few years ago was the possessor of one of the richest collections of Orchids in Laucashire, and whose demise, in June, 1852, was much regretted by a wide circle of Orchid growers. Mrs. Dodgson has, we hear, bequeathed \$\frac{1}{2}\triangle 0.00 to the Blackburn Grammar School; \$\frac{1}{2}\triangle 1.000 to the Blackburn and East Lancashire Infirmary; £10,000 to the Royal Albert Asylum for Idlots and Imbeciles at Lancaster; £5000 to the Manchester Infirmary; £5000 to the Royal National Lifeboat Institution; and \$500 to the Gardeners' Royal Benevolent Institution. She recently signed a deed of gift, transferring to the authorities of the borough of Blackburn a collection of oil paintings and watercolour drawings, valued roughly at £10,000 or £12,000, for the Public Museum.

— Mr. THOMAS BRITTAIN, the Laocashire botanist, died a few days ago, at his house at Urmston. He was a prominent member of the Manchester Field Naturalists' and Archæologists' Society, of the Manchester Mechanics' Institute, and of the Manchester Microscopical Society, of which he was President Society. dent in 1882. He was a great collector of botanical specimens.

Enquiries.

"He that questioneth much shall learn much."- BACON.

DRACENA GOLDIEANA. — Will some of your readers kindly tell me, from their experience, the best way of propagating this Dracena? I have a large plant, and wish to cut it down, but am not sure whether it is easy to root. L. Ye

TUFA STONE.—Will some of your readers kindly tell to where I can obtain Tufa stone for building grottos? 7. IVallace.

Answers to Correspondents.

CELERY, THE WHITE PLUME: H. J. P. B. We do not know if it has reached any of our seedsmen yet. Mr. Peter Henderson, of New York, U.S.A., holds the stock.

COAL-ASHES OAL-ASHES AND TAR FOR PATHS: H. Hawker. These, together with course gravel, make good serviceable paths for foot passengers only. It is essential to good work that the ashes and gravel be sifted, to take out the fine portions, and that the residue be dried thoroughly either over a fire, on iron plates, or in some other efficient manner, before adding the tar—a sufficient quantity to make a thick grout. AND TAR FOR PATHS:

CROCUS INTERATI: "A. Imperati is the proper form, How it came to be called Imperatonius we do not know, at any rate, that epithet should be discarded in favour of the word Imperati, which conforms to the canons of philology, etymology, and botany, and therefore must be right.

DIAMONDS: Uncut. We are unable to give you any advice beyond recommending you to consult one of the leading Glasgow jewellers.

FRENCH BEAN: J. S. Your best plan would be to send a few seeds for trial to Mr. Barron, Royal Horticultural Society's Garden, Chiswick, who will bring them under the notice of the Fruit Committee.

FUNGUS ON SILO: IV. D. C., Hampitead. The name of the fungus which has appeared on the clean cut surface of your silo is Schizophyllum commune. It is widely spread in tropical regions, but of extreme rarity even upon imported foreign timber, in Britain. We should be very much obliged if you would send us some more. IV. G. S.

Some more. W. C. S.

GLADIOLI: Y. F. C. To make a show in the autumn you should plant the Rhododendron beds with Liliums, especially L. auratum, and not with Gladioli, which seldom do better than yours have done in such a position. The Gladioli, of all things, enjoys deep cultivation, and to do them well the ground—a good loam—should be heavily manured and trenched about 2 feet deep in the autumn -say in September.

deep in the autumn—say in September.

GOSSEBERISE: T. d. We should select the following
to grow for exhibition purposes:—Red: Dan's Mistake, London, and Rover. Yellow: Leveller, Mount
Pleasant, and Ringer. Green: Stockwell, Rough
Green, and Village Green. White: Antagonist, Freedom, and Observer. For ordinary good cropping
qualities you should select such sorts as Crown Bob,
Monarch, Red Wartington, and white and yellow
Champagne. Messrs. Salsbury & Sons, Melbourne,
near Derby, grow Gooseberries as a speciality, but any
nurseryman could get them for you.

Grayes: A. In your Muscat-house plant Mrs. Pince's Black Muscat, Alicante, Muscat of Alexandria; at the cool end you could have Black Hamburgh and Lady Downe's. In the Hamburgh house plant this variety, Madresfield Court, Foster's Seedling, and, if you have room, a Grizzly Frontignee.

HELLEBORE POWDER: W. Divers. This is the powdered rhizone of Helleborus niger, and is obtained mainly from Germany and Austria. It is known to be adulterated with the powdered rhizones of H. viridis and H. fordiosa, and also of Actea spicata—the Baneberry.

H. Rettous, and also of Actea spicata—the Baneberry.

NAMES OF PLANTS: Cordillera. We have seen a
furcate Pteris aquilina very much like yours, but of
English origin. The Asplenium appears to be a very
small frond of A. ferulaceum, which was introduced
about ten years since, but has never become common,
notwithstanding its elegant character. E. Kruiff.
The Helleborus niger of English gardens. — 7. Y. Y.
T. Beckea virgata; 2, Juniperus sp.; 3, Ceropegia
Gardneri; 4, Tristania conferta.

Gardneri, I., Irisaina conierta.

PINEMICOPHORIUM SECHELLARUM: E. II', P. This noble Palm is a native of the Seychelles Islands, and, therefore, requires stove treatment. It should be potted in a mixture of two parts of rough peat and one of loam, with enough sand to make it porous, and should not be potted too firmly, as it likes frequent waterings, and, to keep the soil sweet, the water should be able to get away quickly. With root treatment of this character, a moist atmosphere, and high temperature it will make a good growth.

temperature it will make a good growth.

PINLLOXERA: A. M. Rododendrons are not at all likely
to be inlested with Phylloxera which do not feed on
the roots of these plants, though it is of course impossible to deny the possibility of their occurrence in the
soil. Some soil from an infected Vine border might
in some way have been imported, or some of the insects or their eggs transported on the heel of a boot.
We have no doubt whatever, from what you say, that
you may conscientiously certify; but whether the
authorities on the other side will heed your afirmation
is another matter. 2. There is risk in importing Phylloxera with seedling forest trees from France, especially if they come from a Vine-growing district; indeed, we strongly suspect that the insect has been
repeatedly introduced with Roses.

SEEDS.

SEEDS.

London: Jan. 30.—The seed market to-day was thinly attended, and there was not much business doing. For red Clover seed the demand is quiet. As regards English Clover seed, the great majority of the samples offering show only medium quality. American and Continental quotations come firm, and are relatively above those ruling here. Alsike is dearer; fine white continues searce, and commands extreme rates. Trefoil sells slowly on unaltered terms. In Rye-grasses the tendency is downwards. The high prices asked for spring Tares stop business. Canary seed is 1s. per quarter higher. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

Tuesday's Whitechapel Market report states that supplies were rather large, and the trade very quiet. Quotations: —Frime Clover, 95s. to 108s.; inferior, 6os. to 75s.; prime second cut, 9os. to 105s.; best meadow hay, 8os. to 80s.; inferior, 4os. to 65s.; and straw, 28s. to 37s. per load.—On Thursday there was a large supply, and trade was very duit, at late rates.—Cumber-land Market quotations:—Superior meadow hay, 8os. to 90s.; inferior, 6os. to 72s.; superior Clover, 10os. to 110s.; inferior, 65s. to 84s.; and straw, 33s. to 38s. per load.

POTATOS.

The Borough and Spitalfields Markets reports state that good supplies have been on offer, and a fair trade as follows:—Magnum Bonums, 80s. to roos.; Reamplions, 70s. to 90s.; Champions, 50s. to 70s.; and Victorias, 80s. to roos. per ton.—The imports into London last week consisted of 5t bags from Boulogne.

COALS.

The following are the prices current at market during the week:—Bebside West Hartley, 141, 9d.; Walls End —Hetton, 165, 6d.; Hetton Lyons, 155.; Lambton, 165.; Wear, 154.; Caradoc, 165.6d.; Tyne (unscreened), 115.6d.; Wear, 155.; Hulm, 155.

Carters'

STERLING

NOVELTIES

IMPORTANT FACTS.—It is generally admitted that the Vegetable and Floral Novellies introduced of late years by Messrs CARTER nossess sterling qualities to a degree that finds few competitors. J C, & Co have only to refer to the splendid introductions, Stratagem, Telephone, and Pride of the Market Peas, Leviathan Beans, Heartwell Cabbage, Model Gucumber, Dedham Favourite Tomato, &c, to confirm the statement, and it is a notable fact that Messrs. Carters' Novelties, unlike many others, do not Tade from public favour, but are generally recognised as necessary in every garden, whether for Exhibition or for the Table.

CARTERS' SOLID IVORY CELERY.
This remarkable novelty is so very dwarf in habit
as to require no earthing up.
Price, in sealed packets, 1s. and 2s. 6d. per packet, post-free.

CARTERS' TELEPHONE PEA.
First-class Certificate Royal Horticultural Society.
Over 70 1st Prices at country shows. Mr. Mines
says:—"Excellect for exhibition."
Price, in sealed packets, 2s. 6d, per pint.

CARTERS' STRATAGEM PEA.
Two First-class Certificates Royal Horticultural Society,
and over for 1st Prizes at commry shows. Mr. Gilbert
says:—"This is a gem."
Price, in sealed packets, 2s. 6d. per pint.

CARTERS' PRIDE OF THE MARKET
PEA.—First-class Certificate Royal Horticultural Society; if rat Prizes during last year. Mr. HALL
writes:—"They grow without asy sticks."
Price, in sealed packets, 2s. 6d. per pint.

CARTERS' LEVIATHAN BEAN.

The longest-podded and finest Broad Bean in cultivation. Mr. REAVILL writes:—"I grew pods 21 in, long."
Price, in sealed packets, 25. 6d, per pint.

CARTERS' BLENHEIM ORANGE MELON,—The best scarlet-flesh Melon. Recommended in a leading Horticultural Journal as "the best Melon in cultivation."

Price, in sealed packets, 1s. 6d., 2s. 6d., and 3s. 6d. per packet, post-free.

CARTERS' DEDHAM FAVOURITE TOMATO,—The best for exhibition. Mr. RAFFERTY writes:—"It is a grand sort. I shall grow no other." Price, in sealed packets, 2s. per packet, post-free.

CARTERS' MODEL CUCUMBER.
The largest and handsomest grown.
Price. in sealed packets, 2s. 6d. and 3s. 6d., per packet, post-free.

KING'S ACRE, HEREFORD.

NEW EARLY RHUBARB, Charles Kershaw's "Paragon."

This is unquestionably the finest variety of Rhubarb ever offered; in mild seasons it is ready to pull in February. The crows and stalks are produced in such profusion that more than twice the weight can be pulled from this than from any other sort. The colour is a splendid red, flavour excellent, and it has this qualification over all others, IT NEVER SEEDS.

FOR SALE.

SUBJECT TO TRIAL AND APPROVAL,

GROSS-BRED POTATO SEEDS

Each Seed being the starting-point of life of a new variety.

A DVERTISER begs leave to state that, during the last eight years, he has been growing each year 5000 new varieties of the plant, selecting the best, and cross-breeding them under instructions from

"DARWIN,"

from whom he has received upwards of thirty letters on the subject under various dates from January 26, 1876, to January 10, 1882, some extracts from which are subjoined :-

"My Drax Sir,
"..... I cannot but think that the principle on which
you are acting (cross-fertilisation and selection) is right....
The more I reflect on your scheme the more I believe it to be
the one plan for succeeding in obtaining sound varieties...
I admire your indomitable spirit; if any one ever deserved to
succeed, you do so.... I my opinion it would be a national
calamity if your crossed seeds were lost I am delighted
to hear so excellent a report on so immense a scale, and I am
glind to find that we agree upon the control of the control of

"CH. DARWIN."

Premising which, ALVERTISER says :-

That he believes he is now in possession of crossed seeds sufficient to flood the kingdom almost immediately, with eew good varieties, provided only that the owners of the hand could be induced to look personally into their own interests. To these Landowners, therefore, Advertiser now begs leave to offer these seeds for sale, conditionally—that is to say, subject to tit was approval—on movey to be put to five the conditionally—that is one of the conditional conditionally—that is one of the conditional conditionally—that is one of the conditional condit

Advertisers also offers for Sale, under same conditions, 400 or 500 new crossed varieties, and he believes he can show the way easily to double the crop and get rid of the disease.

For terms and information, showing that new varieties shou'd be continually coming forward in multitudes all over the kingdom, please apply to JAMES TORBITT, Belfast.

GRATEFUL-COMFORTING. EPPS'S COCOA.

"By a thorough knowledge of the natural laws which govern the operations of digestion and autrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Ryps has provided our breakfast-tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong en magh to resist every tenorency to disease. Hundreds of subtle maladies are floating may excape many a fatals last by keeping ourselves well fortified with pure blood and a properly nourished frame," Civil Service Gazette.

Made simply with boiling water or milk. Sold only in Packets, labelled thus:
JAMES EPPS & CO., Homeopathic Chemists, London, England.

"This was a control of the breath and Coughs."

DR. LOCOCK'S PULMONIC WAFERS for upwards of thirty-five years, and I have derived more benefit than from any other medicine—J. Kenn, Great Wakering, Essex." Be Bronchitis, Athma. Consumption. Coughs, Colds, Rheumatism, and all His verical and Nervous Complaints they are instant left, a rabid cure, and taste pleasantly. Sold by all Druggists at 15. 1/2d, 21. 91. 42. 6d, and 115. per Box.

HOLLOWAY'S PILLS.—Sudden changes, HOLLOWAY'S PILLS.—Sudden changes, frequent fogs, and pervading dampness sovely impede the vital functions, and conduce to ill health. The remedy for such disorders lies in some puritying medicine, like these chief at its source, and stamp it out, without fretting the nerves, or weakening the system. Holloway's Pills extract from the blood all navious matter, regulate the action of every disordered organ, stimulate the liver and kidneys, and relax the blood has been compaints these Pills are remarkably effective, especially when aided by a free local application of steady, and beneficent progress, and sound bealth will soon be re-established.

THE PRESS SAYS THUS:

"A FEW GOOD THINGS AT SWANLEY."

VISITOR.

"There are many 'good things' in the establishment of Messrs. | at the same time in such great demand at home. This then accounts for Cannell, as nearly all the world knows, for it is certain there are few the multitudinous nature of the stock, for the clients of the establishment civilised countries that have not had their floral collec-

tions enriched from this 'Home of Flowers' in the pretty Kentish valley that has undergone such a remarkable transformation during the past few years. So great, indeed, is the variety of plants, notwithstanding the periodical weedings with the object of making the collection still more choice, that they almost bewilder by their numbers; and that such an assemblage is necessary proves the extraordinary diversity of taste that exists in cultivators of flowers. There appear to be not only local, but national fancies. In one district a mania sets in for Pelargoniums, another for Fuchsias, another for Begonias, and so on; while in the Continental, American, and Australian markets there are 'runs' on plants that are not

Gold Medal awarded at the Great Show at Ghent.

are scattered all round the globe.

"After seeing all that was to be seen, and much more than I can remember, I left Swanley with a feeling of astonishment at the widespread love for plants that now exists, and which must be growing yearly, or how else could such establishments as this be maintained so well? It is truly wonderful, and the more so as all appears to be flourishing and extending. This is a healthy hopeful sign, as it is directly indicative of the public taste-a taste, no doubt, that has been, in a great measure, created by these enterprising florists, who have secured the best varieties that have been raised at home and abroad, and let the world know they possess them," &c.—Yournal of Horticulture, November 1, 1883.

"Royal Hotticultural Society.—Single, Pompon, Fancy, and Show Dahlias were staged in splendid style by Messrs. H. Cannell & Sons, who were awarded a Silver-gilt Medal. The Singles included several navelities of great interest of the Cactus Singles included several navelities of great interest of the Cactus double flower of a bright orange colour, very distinct and effective. Messrs. Cannell & Sons in addition showed a collection of Zinnias, which represented a fine strain of these splendid annuals."

"Speaking of Trowbridge remnds me of one of the competitions there of Trowbridge remnds me of one of the competitions there of the competitions there are not only the competition to the competition of the competit

"Messrs, Cannell & Sons made a pretty little picture in the great hall at the Ghent Exhibition with groups of double purple Cinerarias (Mr. Thomas Lloyd), and Zonal Pelargoniums attracted many admiring eyes, and to a certain number were recognisable on the lostant as productions of the Swanley Nurseties.

Numeries.

"Gardners' Magazine, June 26, 1883.

"Royal Horticultural Society.—Messrs. H. Camell & Soos exhibited a very large collection of cut flowers and a bank of Pelargenniums. The cut flowers included several splendid stands of Verbeaus, comprising about thirty of the finest varieties at present in ealth-utice of the present in ealth-utice and present in ealth-utice and present in ealth-utice.

The Gardeners' Magazine, May 19, 1893.

"Royal Botanic Society's First Summer Show,—Messre.
Cannell & Sons were awarded a large Bronze Medal for a fine collection of Calceolarias."

collection of Calceolaras."

The Gardener's Magazine, April 14, 1883.
"Messrs. Cannell also showed Chrysanthenum segetum fi-pl., a valuable double variety of a fine form and rich golden-yellow, habit dwart and compact, and by judicious management the plants can be flowered all the winter; a collection of Single Anemones, which presented a very attractive appearance, and fully demonstrated their value for garden decoration. The firm was awarded a Bronze Banksian Medal.

The Gardeners' Magazine, June 13, 1883.

"Royal Botanic Society's Second Summer Show.—The magnificent display of cut Pelargoniums and Verbenas from Messrs, Cannell & Sons was awarded a Silver Medal,"

Gardeners' Magazine, July 28, 1883.

"Royal Honticulural Society—Mesars. H. Canaell & Sons exhibited densely flowered, and admirably represented their superb strain of those useful annuals. The flowers are of large size, very double, and effectively coloured."

Gardeners' Magazine, June 26, 1883

"Pelargonium Society —Messrs. Cannell & Sons necupied the first place with a stand, in which the flowers were of the highest quality and admirably set up."

Gardeners' Magazine, July 14 1883.
"'Crystal Palace Rose Show.— Messrs H. Cannell & Sons' collection of Verbeaus, Regal and Zonal Pelaryoniums, and Delphiniums, in the finest condition, and were staged with much taste and judgment,"

"Royal Haticultural Society—Measts. Camad & Syns ex-hibited double Primuls and named Cincerais in selendid condition, and were awarded a Silver Medal. The double Pri-mulas were especially well grown, the plants being of a lorg-size, compact, and bearing a profusion of flowers of superb quality."

"Chinese Primulas from Messrs. Cannell & Soas.—They are surprisinely fine, the light colours being of extra size and stout as parchment, and some of the full-coloured dazzling in their brillancy."

as parament, and some of the indicoloured dazzing in their brilliancy.

"Horticultural Society's Commutees,—Messrs. H. Cannell and Sans staged a very attractive group of Frimulas, amongst which their beautiful variety the Princess of Wales was consciours; this type was awarded a Frast-class Certificate twelve special control of high-coloured strains, was admirably shown; and Swaoley White, which occupies a leading position amongst the white, was admirably shown; and Swaoley White, which occupies a leading position amongst the white, was admirably spread, and the white was admirably spreading the white which occupies a leading position amongst the white, was admirably spreading the white white, was admirably spreading the white was admirably spreading the white was admirably spreading the white was admirably spreading to the white was admirably spreading the white was a superior with the work of the work o

me condition—their new decorative Fuchsia."

The Journal of Horticulture.—Royal Horticultural Society, July 24, Fruit Committee.

"Messrs. Cannell & Sons contributed a collection of double Balsams, the flowers extremely large and full; and a beautiful collection of Ficotees and Carnations, including all the best varieties."

varieties."

The Journal of Horticulture.—Royal Horticultural Society

"Messrs. H. Cannell & Sons contributed largely to the
attractions of the display, several groups of Cinerarias, Primulas,
and other plants being staged. Cuerarias comprised two
magnificent varieties, viz., Victory, a surprisingly handsome
crimson form, which was certificated. March Past flowers are
of wonderful site and substance, rich velvely crimson in colour,
and white at the base, forming a narrow ring; halit strong,
and white at the base, forming a narrow ring; halit strong,
condition. Primulas were extremely good examples of culture,
Alba pleua being most profusely flowered in sinch pots, bearing
twenty large tusses of large double pure white flowers. A
Silver Medal was deservedly awarded the collection.

Pelargonium Show, June 26, 1823.

Pelargonium Show, June 26, 1883,
"Messrs. Cannell & Sons took First Prizz with twenty-four varieties uncommonly fine in size and colour, and also in the thirty-six varieties took the lead with a magnificent collec-

tion."

"Journal of Horticulture, December 6, 1883.

"Messys. Cannell & Sons send us flowers of ther. New Departure single Chrysanthemums, which comprise some pretty and delicately-coloured varieties. These were admired by Horticultural Society at Kensigton, and as single flowers are just now becoming such favourites it may be expected that they will have a large share of popularity. They are light and graceful in appearance, the colours ranging from crimson, to roce, pale pink and white, the central rubbar flyres being certain oppular acturs, actresses, and of view."

Pennal Hartfeelund Society. Secret.

Royal Horticultural Society, September 11, 1853— Solver-gilt Medal was awarded to Messrs. Cannell and Sons, who contibuted a very handsome collection of Dahlia blooms, representing all sections—the Show and Fancy varieties were every fine, blooms of picta formosissima, orange colour, with searlet streaks. Several stands of fine Zinnias were also staged.

also staged."

"Sour nal of Horticulture, December 13, 1883.

"Single Chrysanthemums.—We alluded to this New Departure last week. These single Chrysanthemums, which, we are informed, were first brought into notice by C. L. Tee-dale, Esq., Chichester, through Messrs. H. Cannell & Sons, are not only likely to become popular for vace decoration, for which purpose the ordinary double forms are fully too heavy, but they are naturally late in flowering, which renders them additionally acceptable, and the foliage is usually free from midew. Mr. acceptable, and the foliage is usually free from midew, Mr. in his nursery is now as white as millers, the lewes of the singles are as green as Leeks, and certainly all the examples that have been sent to us were free from the unsightly parasite."

Juny 12, 1883.

July 12, 1883.

have not been to Swanley let them call at once on Messer.

Cannell & Sons, the the flowers in their nursery and the
fruits all round it, they will see sufficient in a few hours to think
about for years.

Cannell & Sons, and with the flowers in their nursery and the funits all round it, they will see sufficient in a few hours to thisk about for years. **Cardener*** Nagazine.**

"At all times and suffering the work the work nurseries are rich in attractions, and afford pleaty to well-known nurseries are rich in attractions, and afford pleaty to well-known with the rangaged in floring that the control of the other the quarters and houses are bright with colour and full of interest, and it is not possible to proceed far without being struck with the rare judgment with which the various college struck with the rare judgment with which the various college struck with the rare judgment with which the various college struck with the rare judgment with the law to the complete collections of lyvleaved Pelargoniums, Tuberous Begonius, Tuberous Begonius, Tuberous Begonius, Which are in the finest condition, and afford a successful successful the successful successfu

The Gar Ien, September 11, 1883.

"Royal Horticultural Society.—Messis, Cannell, & Sons had a fine collection of Show, Single, Pompon, and Cacuss Dahlias, and also Double Zimias, the finest formed flowers we have seen, and very vaited in colour; a Silver-gilk Medal was awarded.

The Garden, July 24, 1883.

"Royal Horticultural Society.—Messrs, Cannell & Sons exhibited a collection of double Balsams; Rowers very large, perfectly double, and of bright and varied colours."

"Viola Countess of Kintore — This is a novel and truly charming kind, and was shown findly the other day by Mr. Cannell. The flowers are large, white in ground, with a big irregular blue blotch in the middle. It is robust, dwarf, and frea should, when abundant and better known, become a universal favourite."

avoutte. The Gorden, June 26, 1882.

"Royal Horticultural Society.—Mesars. Camell & Sons made a bright display of cut flowers and plants A socre of ital spakes of Delphiaiums were a beautiful feature, distinct from anything eise in the show."

The Garden, March 24, 1883.
Primula Princess of Wales, a charming blush-tinted variety, shown in lovely condition by Mr. Cannell."

The Garden, March 3, 1883.

"Where can be seen in the dead of winter such a grand show of Pelargonium blooms, or mure finely grown and bloomed single and double Primulas, than at Swanley?"

The Gorden, April 15, 1883.

"International Honizoltumia Exhibiting Ghent.—A group of the double-flowered Cineraria, Mr. Thomas Lloyd, and same cut trusses of Single 2 and Pelagonium, exhibited by Mesure Cannell & Sons, which won the admiration of every one. A Gold Medal was awarded."

CAUTION.

SEASON 1884.

In again calling the attention of Market Growers, Gardeners, and Amateurs to Clay's Fertiliser, we feel a pride in stating that it has increased in popularity year by year, until it has attained the position of being considered an absolute necessity for the production of Fruit, Flowers, and Vegetables of the highest excellence.

Unfortunately, this success has induced some unprincipled persons to adulterate the Manure, causing great disappointment to users and serious annovance to ourselves. We have therefore decided, after the 1st of January, 1884, to send out all Manure (except 1s. packets) in Sealed Bags; and we trust buyers will, for their own protection, insist on having it in our bags with our Trade Mark and Seal attached, for which alone we shall be responsible.

Gardeners' Chronicle.

SATURDAY, FEBRUARY 9, 1884.

WATER PRESSURE FOR GARDENS.

THERE are few matters connected with gardens of more importance than a plentiful, well-arranged supply of water; and although this is so generally accepted, yet it oftener than not happens that there is either a deficiency of this indispensable element, or that the arrangements for applying it are such as to prevent the full advantages connected with its use being obtainable. Doubtless there are some localities that offer no inconsiderable amount of difficulties in the matter of water, such as in the chalk or limestone districts, where the water is hard and so far affected by the stratum through which it passes as to be unsuited for at least some of the requirements connected with a garden. In such localities there is often no resource available except that of making provision for catching and storing as much of the water obtainable from the roofs of the houses as will suffice for applying to the roots of the various plants that refuse to thrive with lime-impregnated water. But when all that is possible in this direction has been done the supply falls vastly short of what is required in any place of considerable extent, more especially in those parts of the kingdom where the rainfall is light.

No inconsiderable proportion of the failures or partial successes that take place with wall fruit, particularly Peaches and Nectarines, is traceable to a supply of water to the roots, as well as applied overhead, insufficient to keep the foliage in the healthy condition, free from insects, without which it is useless to look for anything above medicirity in either the quantity or quality of the fruit. And the same holds good in respect to Vine culture, about which the necessity for thorough drainage has been so persistently and correctly urged, but along with which the need for an unstinted use of water to the soil should have been simultaneously insisted on as equally indispensable. The frequent soakings required by the roots of Peaches grown under glass, as also by those grown on open walls, in dry summer weather, and by Vine borders, inside and out, through the growing season, necessitate an amount of water such as no storage accommodation we have yet seen would go far enough to meet. Moreover, the constant needs of the thousand and one things in a large garden are such, that when there is a feeling that the supply is limited, everything goes short, with the inevitable result that all suffer. Needless to say wells and pumps furnish the usual supplies in aid of rain-water tanks, where the latter are in existence; but quite as often the former are the only means whence a supply can be obtained, and a good many large gardens have little else to depend on. Tanks and wells and pumps and water-barrows are no doubt very useful in their way, and much may be done with them where there happens to be no stint of labour to do all that is required; but this is just the one important element in many places where the greatest pinch is felt. At the present time the water requirements of gardens collectively throughout the kingdom may safely be set down as double what they were before, owing to the increase in

the numbers of plants grown under glass, although little addition has been made in the matters of water provision or labour.

What is wanted in all gardens of any extent is a sufficiency of water with pressure. Where there is the provision of a plentiful head of water to give the requisite force, so that it can be used without the never ending labour of pumping, carrying, and wheeling, the first essential to successful cultivation, and saving in labour, is present, and without this there is no true economy. With a hose-pipe, and an unstinted supply of water, a man will do as much in the way of washing the trees on a wall in an hour as he will in half a day by the pumping and wheeling process, besides doing the work more effectually than it usually gets done under the slow method. But it is in the root supply that the great saving in labour is effected, as it is needless to say, where the hose can be turned on to Vine and other fruit borders, Strawberry beds, Celery, Peas, &c., little labour is needed; with the still further advantage that the work gets done in a way such as is rarely equalled by direct hand labour.

In many places the first outlay required to make such provision as here suggested is fractional as compared with the after saving. Comparatively few gardens are situated where, within a reasonable distance, a pond, stream, or spring cannot be made to afford a supply that would give the requisite head for pressure; and the price of iron is now so low that the piping needed for conveying the water can be had for little, whilst the laying requires only to be low enough to be out of the reach of frost.

In every department of the garden the advantages of an unlimited quantity of water are felt; in the flower garden, in place of the shortlived blaze of bloom that often occurs in a burning summer, when there is no corresponding growth going on in the plants to yield a sufficient succession of flowers, the autumn effect is frequently poorer than it should be; whereas if the hose-pipe is available all this can be rectified. In such seasons as above alluded to, even in the most suitable and well manured soil, Roses often are white with mildew during August and September instead of giving a succession of bloom during a time when their presence is most accepiable-when, if the beds were now and then properly drenched by moistening the soil down as low as the roots go, a very different state of matters would exist to what occurs where the water-pot has to be depended on. In place of the brown sun-burnt terrace-slopes by no means unusually met with the grass can easily be kept fresh and green by leaving the hose going for a time, with an occasional removal; with like advantage it can be used to the many other thirsty things that have to go short where inadequate provision exists. water supply, such as here briefly sketched is more conducive to successful gardening, combined with economy, than anything else we can think of. T. B.

BORONIA MEOASTIGMA.—To a casual observer this lowly plant bears little outward or superficial resemblance to the Orange tree or other members of the Rutaceous order which furnishes many more or less familiar garden plants. The construction of the floral organs, however, declare its true relationship, and in several minor particulars, as in the compound leaves, evidence of this connection is fully borne out. These leaves are opposite and trifoliate, and together with the slender twiggy stems and nodding flowers remind one of Tremandra verticillata in habit, only the flowers are in this case brown externally, and yellow internally. This species is of comparatively recent introduction, and deserves to be universally grown as a winter flowering greenhouse or conservatory plant for the grateful odour it gives rise to in a house.

MASDEVALLIA PACHYANTIIA, n. sp.*

Titts species stands near Masdevallia affinis of Dr. Lindley, but its flower is far larger, coming nearest that of the Veitchian monopoly, Masdevallia gargantua, yellowish - ochre - coloured, or a green lilacbrownish, with dark nerves on the upper sepal, and less expressed ones on the lateral sepals. The upper sepal is triangular, prolonged into a long thick tail. The lateral sepals are deeply connate, with shorter triangles, and shorter thick tails. Petals ligulate acute. Lip thickish, with two very obscure keels in the middle (perhaps scarcely to be seen in the living state), ligulate, blunt, very dark. It may prove an interesting addition to the collection of Masdevallias, which are, I believe, numerous. I had this a long while ago from Mr. Harry Veitch, for whom it was collected by Mr. Cross. I have now several flowers sent by Mr. Carder along with good living plants, forwarded by Mr. E. Shuttleworth, 191, Park Road, Clapham. Mr. F. C. Lehmaon wrote to me about it long ago. H. G. Rchb. f.

SACCOLABIUM BELLINUM, n. sp. †

A discovery of Mr. Boxall's in Birmah, kindly sent by my invaluable eldest English correspondent, Mr. S. Low, in the form both of wild and garden specimens. To be short, it is an increased and embellished Saccolabium calceolare, Lindl. It is said to grow upright, while my wild calceolare specimens are asceading. The leaves are like those of the last named species. The flowers are two to three times larger than those of the old species. Sepals and petals straw coloured, with very large dark brown blotches. Lip's blade transverse, much serrate, fleshy, rough, with two great cushions of filiform processes at the base. Basilar hollow not so deep as in S. calceolare. Lip and column white, with mauve-purple blotches. It is no grand thing, but one of those elegant little beauties one may delight to look at after being tired of monotonous grandeur. II. G. Rehb. J.

Cyprifedium Bullenianum anophthalmum, n. var.

Mr. W. Bull kindly sends me this variety. It is distinct from the type and from C. oculatum in having no eye-spots on the petals and no deep brown area under the green mouth of the lip. We have had the same variety in the Hamburg Botanic Garden, when we had four plants from Mr. S. Low. They all perished, a "visitor" having tried to take one or two in his pocket. He was stopped, but all the roots having been broken the plants were condemned to death. The moral is, watch well the "visitors." II. G. Reth. J.

LÆLIA BELLA, n. hyb., hort.

This is a Chelsea gain once more, as writes Mr. Harry Veitch, who obtained it from Baron von Schröder, who has flowered it. "It is a cross between Lælia purpurata crossed with the true old autumnal Cattleya labiata. Longest leaf 12 inches by 2½ wide; Iongest bulb 8 inches. In habit intermediate, but partakes more ol Cattleya labiata. Leaf purple underneath." So far Mr. Harry Veitch. The sepals and broad petals are light lilac. Lip with blunt angles, and a broad anterior wavy lobe of a glorious warm purple, as well as the side angles, when the superior margins are very light. There are two oblong ascending zones of light ochre-white at the base, and two smilar spots before the middle, in the way of Cattleya Warscewiczii. The disc is light purple, interrupted by light lines. Column white, with lightest purple on the side. A lovely beauty! H. G. Rehb, f.

GREENFLY.

APHIDES are to be found almost everywhere throughout Britain. Some are hardy enough to thrive on stony heaths of Scotland and Northumberland, whilst others will live almost in the reach of the spray on the sea-shore; terrestrial and aquatic plants are alike subject to their attacks. Some feed on succulent herbs, others on hard timber trees; others again on the roots of flowering plants. Sometimes the white Water Lily (Nymphæa alba) is almost destroyed by the myriads of Rhopalosiphum nymphææ which crowd on its leaves and flowers. certain trees and shrubs appear to be attacked exclusively by their own peculiar aphis other trees give nourishment indiscriminately to numerous species. Thus the Oak is attacked by at least six, the Willow and Birch by eight, and the Conifers by the same number. Some families of plants are free, or almost from them, such as the Gentian and Irid lamilies. But one species of the large group of the Ferns is as yet known to be attacked by them; indeed the Cryptogams are, as a general rule, very free from aphides, but we have known a species of Marsilia to swarm with them.

The migration of the aphides is still involved in some mystery, and we seem to have as yet no certain knowledge of the winter habitats of numerous species which seem to occur only during a few weeks of midsummer, such as Siphonopora millefolii, which may be found from July to September, and then entirely eludes our ootice for the rest of the year.

The peculiar habits of the species opens an immensely interesting subject; some are almost sedentary, others are fairly active; some form receptacles which strangely mimic fruits; some, if disturbed, drop to the ground, others run to the opposite side of a leaf or twig; some throw up their hind legs when alarmed, which action gives a signal to the rest of the colony, which responds by going through the same performance; some assimilate their colours to their food plants, so as to be difficult to perceive. An interesting phenomenon in connection with these insects is their dimorphism. early spring form of Chermes laricis is different from that of all her progeny till the last, and the same is the case with Aphis mali. These variations often relate to size and colour, but often, also, to considerable change in form and modification of parts. The most extraordinary instance occurs in Chaitophorus aceris, the early spring forms of which occasionally are so diverse that they have been described as belonging to not only different genera, but even to distinct families. Thus, Mr. Thornton, the original discoverer of this strange insect, gives it the name of Phyllophorus testudinatus; afterwards Mr. L. Clark called it Chelymorpha testudo, placing it between the Aphididæ and the Coccidæ. But a nearly equally striking example occurs in the dreaded Phylloxera vitis, which has two entirely different habits of life and form. In one it is active and winged, in the other it is anterous and subterranean. . . .

Full details are given in Mr. Buckton's recent work of that troublesome insect, Rhopalosiphum dianthe, the Aphis vastator of Some, which feeds on almost every cultivated plant, often swarming on the Petato, Turnips, Finks, not to mention Hyacinths, Tulips, and Oleanders, but which the author agrees has nothing to do with the production of either the Potato disease or clubbing in Crucifers. Forty-five species of the genus aphis are enumerated, and a very useful analytical table of these is appended in the work cited. No less than seven synonyms are quoted to A. rumicis, Lin., which commits such destruction often on the Bean and Turnip crop, and which is not very particular as to its food plants.

Among the more familiar species we have here the aphis (Pterocallis tiliae) which abounds on the Lime tree, and so bedews it with its sweet secretion; the Beech aphis (Phyllaphis fagi), so well known as often covering the leaves of the Beech tree with its white cottony or rather waxy fuff; the Sallow aphis (Lachnus viminalis), which sometimes swarms on our Willows. The "American blight" (Schizoneura Ianigera) on our Apple trees, is an introduced species, apparently from America. It appears that they descend into the soil in winter and attack the roots of the Apple trees. S. Januginosa is the aphis which produces the wonderful Fig-like galls on the Elm tree. These galls are about the size of small green Figs, with a small opening at their summits, they contain thousands of the plant lice. In 1866 Mr. McLachlan,

Masdevallis pachyantha, m. sp. — Aff. M. affini, Lind.; flore majori latiori; sepalo impari triangulo lato truervi in caudam sublongionem crassam extenso; sepalo pari lantum summo bifido cruribus triangulis, caudis crassis brevibus; tepalis ligulatis acults, centum versus antice augulatis, uninervite, latello longiori ligulato obtuso, basi supra unquem cordato; columos androclimo apice acumiatio. — Periz mium ochreaceum ungue ochracesviolaceo, labello valde obscuro. travelling in the south of France, gathered a number of these galls, which were in extreme profusion-Elm trees 20 feet high being one mass of galls-with the intention of bringing them home; but they made such an awful mess from the viscid liquid in the galls that he was compelled at last to throw them away. Pem-phigus lactucarius is the species found living in little earth cavities in the vicinity of the roots of various plants. If a stump of Lettuce be pulled up in sprinthese "downy flocks" will be very often detected. . If a stump of Lettuce be pulled up in spring,

The Fir aphis (Chermes abietis) is the maker of the curious cone-like galls of the Spruce, and a closely related species is often very destructive to Larch planta-Of the genus Phylloxera two native species are described, and a full account of the Vine aphis (P. vitis) now introduced into our hothouses is also given. In this account we have a very interesting and important communication from that eminent entomologist Jules Lichtenstein, in which he gives a summary of his views on the metamorphoses of the plant lice. From a review of Mr. Buckton's "Monograph of British Aphides" in "Nature."

HEPATICAS.

SOME fine clumps of the double red and the single blue Hepaticas, in pots, and now in full bloom, are so charming as to be of a character to rouse the floral enthusiasm of any one who looks upon them. Potted up in 6-inch pots a year ago, and stood out-of-doors all the summer on a bed of cocoa-fibre with the aspect due north, they filled the pots with roots, and during the summer and autumn they were treated to occasional doses of that friend to the amateur gardener-Clay's Fertiliser. Owing to the mildness of the season the plants began to throw up their flower-buds early, and now they occupy a cold house, the flowers are expanding in large numbers, and sweetly pretty they look, with the promise of spring shown in their bright coloured petals. The two varieties named are probably the commonest of the Hepaticas; when planted in the open ground they do well in a deep moist sandy loam, into which they can root deeply, and, if let alone, as they should be, form quite huge tufts in course of time.

In my harsh soil near London I cannot grow Hepaticas in the open ground, but only in pots. It is death to them to plant them out; they get roasted in summer, or if they escape this they die from rot in winter. Happy is he who has a kindly garden soil in which he can plant-out Hepaticas, and see them flourish. They are among the most acceptable of early spring flowering plants, but unfortunately, because they flower so early, their charms are often sadly disfigured by the cold storms, frosts, and cutting winds which so often accompany retarded springs. I have a few others in pots, such as angulosa, with its large soft pale mauve blossoms; Barlowii, purple-blue, a very pleasing shade, the purple, in which the blue has deepened to purple, and so gives a very distinct hue of colour; the common single red, rosea, with charming pinkish-rose blossoms; and the white-all of which are single-flowered; and last, but not least, the fine rich and somewhat scarce double blue. This is by no means a complete collection, but it is a fairly representative one, and full of interest.

There are no doubt many persons who while they are unable to cultivate the Hepatica in the open ground, could do so in pots. For this purpose they should use "long Toms," or the deepest pots they can procure, for the Hepatica, as before observed roots deeply into the soil. The best compost I can use is one made up of good yellow loam, grit from a gravelled road, or failing this coarse silver sand, some leaf-mould, and a little well-decomposed manure. I use a crock at the bottom of the pot, but dispense with drainage, using instead a layer of cocoa-fibre refuse, which keeps cool and moist, and to my mind answers to the character of the subsoil best fitted for the Hepatica. The crowns at the time of potting are put fairly deep into the soil, but by no means buried, and the soil pressed firmly about them. I find they root quickly nto such a compost, and form stout blooming crowns. The double blue in particular succeeds well when The double one in particular sources for the streated in this way, and developes into strong plants. As a matter of course they must not be neglected during the summer, and while they are kept well watered the close to the stream of the str during the summer, and white they are kept weit watered in drying, hot weather, the plants are twice or thrice during the summer months looked over, the sour surface-soil removed, and replaced by a fresh compost, taking care not to disturb the roots more than is necessary. When stood on a bed of cocoa fibre the roots enter it readily, a decided advantage in hot, drying weather. A slight surface dressing of Clay's Fertiliser is given while the plants are forming new leaves, and ag in when they have matured them.

Can anything be done in the way of producing new varieties of the Hepatica by cross-fertilisation? The single blue and the single white appear to mature seeds, and these might be used as seed-parents. A single tote and the single white appear to mature seeds, and these might be used as seed-parents. A few days since I found several self-sown seedlings round a plant of the single blue, which I carefully removed, and shall hope to see them flower by-and-bye. I presume that some, if not all, of the varieties of the single blue type have been obtained by selection. Do they who, like Mr. G. F. Wilson, grow Hepaticas successfully in the open air, ever find self-sown seedlings among their plants? And if so, have they, when they flowered, betrayed the possession of any distinguishing characteristics? This is a matter of interest, and perhaps some may be able to throw light upon the matter. [The mode of germination would also probably be interesting to observe. Ed.] When clumps of Hepaticas become well established in the open ground it will be observed that they, in course of time, thrust themselves up out of the soil, I will also be found that the roots, as well as being deep down in the soil, are also close to the surface,

deep down in the soil, are also close to the surface, and thickly matted. Some top dressing will be found and thickly matted. Some top-dressing will be tound of great service, but to prevent this being washed away by heavy raios it is necessary to raise the level of the surrounding soil; or, if this cannot be done, to lift the clump and replant it at a greater depth. R. D.

The Arboreium.

CORNELIAN CHERRY (CORNUS MAS). - As an ornamental tree or shrub the Cornelian Cherry is decidedly valuable, not only on account of its early flowering, and the fine display now and then made by the ripe fruit, but because it is particularly suitable for small or suburban gardens, bearing cutting in well, and besides not growing fast, nor occupying too much space. Old trees in thoroughly favoured conditions sometimes attain a height of 20 feet; as a rule, however, the species is generally met with as a more or less compact bush from 6 to 10 feet high. The small yellow flowers are borne in nmbels on the naked brownish-green twigs from February to April, and the beautiful scarlet oblong fruits ripen in October and November. A figure will be found at p. 399 of our volume ix. for 1878. According to Evelyn, "the preserved and pickled Cherries are most refreshing, an excellent condiment, and also do well in tarts. The same author also relates what he justly calls an odd notion. "Though Matthiolus affirms it, upon his own knowledge and experience, that one who has been bitten by a mad dog, if in a year after he handle the wood of this tree till it grow warm relapses again into his former distemper." The name "mas" has been applied to the species since the days of Theophrastus, in all probability because young plants are barren for many years after they show flowers, these flowers being furnished with stamens only. The Cornelian Cherry is widely distributed throughout Europe, and has been cultivated for centuries in Britain, 1596 Gerard wrote, " It groweth not wild in England. but yet there be sundry trees of them growing in the gardens of such as love rare and dainty plants; whereof I have a tree or two in my garden." The form with leaves margined with white (var. variegatus) is one of the best of compact-growing smallleaved deciduous shrubs, and one (var. elegantissima), which originated some years ago in the nursery of Messrs. Charles Lee & Son, is more showy on account of the red and yellow variegation; in fact, this latter variety exhibits foliage as richly coloured as some of the tricolor Pelargoniums which were so highly valued by the gardening world about half a score years ago.

SEQUOIA SEMPERVIRENS (RED WOOD). — This Conifer I have for years highly recommended, and have planted it both on chalk and on other soils. All nave planted it both on chalk and on other soils. All it requires is a north aspect, if possible, and shelter. There are some fine specimens at Weston, near Steyning, also many at Fentillo Castle, Cornwall. I have myself a fine specimen with a girth at 4 feet from the ground of 8 feet 4 inches, which exceeds that of the one at Hyères, mentioned in a recent issue. J. T. B.

SOUTH AFRICA.-The year 1883 was an exceedingly dry one in this part, only 18.26 inches of rain having fallen. In 1882 the rainfall was 23.87 inches, the average about King William's Town being 27 inches. The Leighton, King William's Town.

HAREFIELD GROVE.

TAKING Rickmansworth as a centre, any one desirous of studying practical gardening as carried out in private gardens might devote a week at least in a profitable manner in visiting the many places of interest grouped within a few miles. From Radlett to Uxbridge, and from Harrow to King's Langley, there are districts replete with places of an extremely interesting character. One of these is Harefield Grove, and it is separated from Moor Park by a comparatively narrow strip of land. It can be reached either from Rickmansworth or Uxbridge, but is nearest to the former, being close to the village of Harefield, and there are lodge entrances at Rickmansworth, at Harefield, and towards Uxbridge. Harefield Grove is an estate of some 400 acres; of this at least 30 acres are devoted to pleasure grounds, hardy fruit gardens, and glass—of the latter there is an enormous quantity. T. W. Boord, Esq., M.P., for-merly resided here, and about four years ago the estate passed into the hands of the present owner, George Webster, Esq., who has considerably ex tended the glass structures, and likewise constructed an extensive orchard for hardy fruits.

The superficial area of glass is, indeed, something enormous; there are in all about seventy houses, and though grouped here and there in extensive blocks, the whole extends for a considerable distance, and jooked at from the height from whence it is approached from Harefield, it has the appearance of an extensive nursery. It is a task of considerable extent to go through these houses, and were their structural arrangements and contents noted in detail it would require a considerable space to set them

There is one block of span-roofed houses for forcing purposes, in which are large quantities of Osborn's forcing French Beans, planted out and coming into flower; also Tomatos, which are very largely grown, Melons and Cucumbers. Six houses, from 100 feet to 110 feet in length, are devoted to Cucumbers only. There are vineries of various sizes, some of them very large; one is 100 by 19 and has 14 feet rafters; this is planted with young Vines that are full of promise. Another is 100 by 16, in two divisions; another is 70 by 16, and another 80 by 18, both in two divisions; another 90 by 14, in three divisions. A new one in course of construction is 100 by 18, and is also in three divisions. All the best varieties of Grapes are grown here. The Peach-houses are remarkable structures. One is in two divisions, and is 120 by 23 feet. There is a row of fine standard trees down the middle, and at the sides are excellent trees trained against curvilinear wire trellises. The leading varieties are Bellegarde, Lord Palmerston, Grosse Mignonne, and Sea Eagle. Great crops of fruit are gathered in the season. Another Peach-house is 70 by 24 feet and is similarly planted. There is a Peach-wall covered with glass 105 by 6 feet, and this can also be used as a Strawberry-house. Three of the Cucumberbouses are 100 by 12 feet, the plants on either side trained up to the roof. Two of the houses used for Melons are of the same dimensions. Telegraph is the principal variety of Cucumber grown. The two leading Tomatos are a selection from the Large Red and Vick's Criterion.

Here may be seen a good collection of Orchids, and there are several spacious plant-houses for specimen foliaged and flowering plants, Ferns, &c. Gardenias are seen here in very fine condition, planted out, growing freely and flowering abundantly in the middle of January, in addition to Eucharis and Orchids, among which Calanthe Veitchii was quite striking. There were also Hoteia japonica, double white Primulas, Roman Hyacinths, Gardenias, Cyclamens, Pelargoniums, Bouvardias, Roses, Lilies of the Valley, Cinerarias, &c. Roses are a remarkable feature here; there are it is computed more than 3000 Tea Roses in pots of all the best kinds, coming into flower. An excellent Rose-house has been constructed on the top of a potting shed, and the top of this house is at the back of a vinery; and in addition to being lighted from the roof and front, light is also had from a glass partition which divides the Rose-house from the vinery. The Rosehouse is of considerable length and wide enough to admit of a level stage on either hand, on which are placed the plants in pots. A number of Maréchal Niel Roses are planted against the back wall, in order to flower on the roof, and these are

planted in old bulb cases, which are conveniently arranged and hidden from view by the stage; and the flooring of the house is so constructed that no water can pass down to the potting-shed beneath. There are other houses in which Roses are growing, but this is the principal one. There is one excellent feature about the plant-houses and vineries; closets are formed at the backs of the houses, one, at least, in each division, and here steps, watering-cans, &c., can be stowed away when not in use, instead of being left about under stages to become eyesores.

It is impossible to do more than give a cursory glance at the glass structures. The heating arrangements are on a very extensive scale. There are about 24,000 feet of hot-water piping, and to do the necessary work of heating eight powerful boilers, each capable of heating 5000 feet of piping, are in use. Three of them are Jones' Terminal Saddle boilers, two are the Cornish or tubular boilers, three others are Terminal Saddles by Anderson, and one horizontal tubular 18 feet in length. Rather more than 400 of Messenger's patent valves are in use for the purpose of regulating the heat in the various houses. Some of the houses are 300 feet from the boiler, and double flow and double return pipes are employed. There is a great command of heat, and it is under perfect control in every department.

Strawberry forcing is a great feature at Harefield, and something like 14,000 pots are got into fruiting. New houses are in course of construction, to excend the growth of this fruit. The leading sorts grown are Sir C. Napier, Sir J. Paxton, and Vicomtesse Héri-

cart de Thury.

There is an excellent Mushroom-house, 60 by 18 feet, in which enormous quantities of this esculent are produced. It is constructed with three tiers of heds on either side, and the roof being stuffed with 1 foot of shavings under the slates, and at the bottom, forming the ceiling, a layer of cement, an equable temperature is maintained.

Chrysanthemums are largely grown for autumn and winter blooming, Princess Teck being one of the best varieties. In one of the propagating-houses could be seen thousands of cuttings that had been in about three weeks, and had already rooted.

The new bothies are commodious, lofty, and well constructed, with all conveniences fully provided, and they may be taken as a model after which such places

may be constructed.

Two years ago an extent of rich pasturage, about 15½ acres, was broken up and converted into a hardy fruit orchard. The soil varies a little, but is generally a generous loam on clay, the subsoil being well draiued. In this space about 5,000 trees of various kinds are planted, 6000 being pyramid fruit trees, 3000 of these Plums, and the rest Applies and Pears; the remainder is made up of Gooseberries, and black, white, and red Currants. This orchard is in four huge divisions, and the outer line throughout its extent is planted with Filherts. On the west and south sides is a tall hedge of Thuiopsis borealls, 10 to 12 feet in height, and this lice of shelter is also continued in the pleasure-grounds. In a few years, and with favourable seasons, the produce of this orchard, will be something extraordinary.

and with avoirable seasons, the produce of his orchard will be something extraordinary.

On the south-west side of the mansion a large portion of ground lying beyond the pleasure grounds, but which will now form a continuation of it, has been laid out as a spacious lawn-tennis ground, 250 leet in length by 50 feet in width, exclusive of a handsome terrace and broad gravel walk which surrounds it. Between the teonis-ground and the mansion a Rose garden has been formed, and the boundary line with a hedge of oval-leaved Privet, and at every 7 feet of hedge there has been planted a standard Acer Negundo variegatum. Close by a huge raised circular bed has just been made, and planted with the choicer sorts of Clematis, that will make a fine object in summer; and near it a huge rootery is in course of formation. From this point, and away to the west and north sides of the mansion, the pleasure grounds are much undulated, and the landscape gardener has availed himself of certain natural advantages to work out admitable features and effects. On the west side is a very handsome ornamental

conservatory, Under the management of Mr. John Gough, formerly manager of the Crystal Palace at Sutton Coldfield, who has the entire charge of the gardeos here, various improvements are being carried out, which, when completed, will finish—for the present at least—what will be a truly wonderful garden. The estate is finely timbered—Oak, Beech, Scotch Fit, Horse Chestnut, Limes, &c., being particularly fine.

ON BARYA AURANTIACA

WHILE ergot has been collected on many species of grass in all parts of Britain, the mature Claviceps or "ascophore," of which ergot is the "stroma," has been more rarely met with. Opportunities have therefore

Fig. 32. - Barya Aurantiaca on Ergot, Showing perithecia; also conidiferous hyphae: magn.

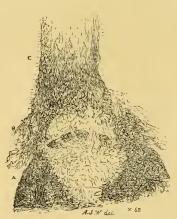

Fig. 33 -- A, Transverse section of Ergot; B, Diffuse base of Ascophore; c, Lower part of Ascophore.

been wanting for observation of C. purpurea growing naturally, and as affected by environing circumstances. But the writers of this paper have found it in several localities in great abundance every year since 1874. The discovery of Tulasne, based upon the results of artificial cultivation, that ergot is the selerotium of a fungus, is thus fully sustained by

observation of the natural growth from this sclerotium of the Claviceps purpurea, Tul.

It has been generally supposed that ergot will germinate only in the season following that on which it is produced. While this supposition is practically true, we have produced a few specimens of the Claviceps from ergots of two years old, but none from those of three years old. It is thus evident that, as in other seeds, a process of devitalisation is going on in the substances of the ergot, suggesting some important considerations. If old ergot is less vital than ergot during the first year, or altogether dead, in which condition are the medical qualities of ergot at their best? And we may ask, have the ergots of the common wild grasses been fully compared in their effects with the ergot of cereal Rye?

It has been chiefly on the ergot of Glyceria fluitans, R. Br., that the Claviceps purpurea has been found growing naturally, as above stated. At the bottom and on the sides of a half dry ditch, where this grass is allowed to grow undisturbed, the ergots fall down in autumn and are covered by the decaying grass. The ditch runs east and west, and the purple Claviceps has been found mostly on the south, or shady side.

The early part of 1882 was very wet, and in July, when the fungus was looked for, very few specimens could be found; but in their place, and upon the same ergot, everywhere appeared white and yellow stipes, about the same height as those of the purple Claviceps. Last year (1883) they appeared agaio, but apparently intermixed with a larger proportion of the purple form. Whether they appeared first in this locality in consequence of climatic peculiarities, or whether they had been previously overlooked, it would not now be safe to say. Their conspicuous appearance is against the alternative that they were overlooked till 1882.

That this yellow ascophore grows upon the same ergot as the purple Claviceps grows upon is beyond doubt—namely, that of Glyceria fluitans. In many cases the pales of the floret, agglutinated to the ergot, remain attached at the time the ascophore is growing; but while it is rare to find both the purple and the yellow forms growing on one individual spur three cases have turned up in which the purple form with its globular hymenium and immersed perithecia occupied one end of the ergot, while the other end was occupied by the yellow form with its club-shaped hymenium and free perithecia. (See fig. 34, I, A. B. C.)

That an ergot should develope two forms of fruit-bearing stems so different in outward appearance is, however, not to be accepted without full evidence. Now the purple Claviceps makes its exit first from a clean dark surface by disrupting the outer substance, the ergot having no epidermis. But this new ascophore arises on a kind of secondary white stroma, which forms patches here and there on the outside or in the cracks of the ergot. The exterior of the ergot consists of a mass of agglutinated stylospores and the short styles on which they grow from the spongy mycelloid axis. And the question is, Does the white stroma arise from a diffuse germination of the stylospores, or does it arise parasitically from the elements of another fungus altogether?

Perhaps nothing can so fully determine this question as the production, or non-production, of ergot from the sporidia of the new perithecia. Experiments with these sporidia have as yet produced only negative results. These sporidia are precisely of the same fillorm character as those of C. purpurea, only they are larger. If a ripe club be taken from a cold to a warm room, and placed under a low power, the perithecian batteries will speedily open in all directions, and the shower of sporidia will be seen flashing across the field. It is evidently the elastic pressure within the perithecian consequent on the continuous growth of younger saci which constitutes the projectile force; for when this pressure is relieved by discharge, the sporidia are expelled more slowly, and may be seen swaying about here and there in the air, and at length falling over on the outside, the force being insufficient to expel them.

Barya aurantiaca, Plowright and Wilson, n. sp. (fig. 32). — Stroma vertical, clavate or subapitate, 10-20 nill. high by T-3 mill. in diameter; when young floccose, white with condidiferous hyphe, and bearing yellow perithecia with orange ostiolia on its upper two-thirds. Conidia elliptico-lanceolate, borne in chains on the ends of branching condidiferous hyphe, $10-12\times 2-3$ mk. Perithecia pyriform, yellow, almost

free, with elongated necks which with the minute ostiola are orange, $250-300 \times 150$ mk. Asci cylindrical, $200-250 \times 30$ mk. Sporidia filiform, flexuous, continuous, as long as the asci,

The base of the stroma springs from a floccose mass of yellowish white mycelium. On Claviceps purpurea on the ergot of Glyicera fluitans. Near Aberdeen. July.

This fungus was at first regarded as a species of Claviceps allied to C. pusilla, Ces.,* and C. setulosa, Quel.,† which species it resembles in colour, but hardly in any other character except its association with ergot. In some points—notably in the form of the stroma and

Wheat, Rye, and Poa trivialis with its mature sporidia to produce a sclerotium, and although we have succeeded in doing so with the spores of C. purpurea we have invariably failed with B. aurantiaca. It is interesting to note that it, like B. parasitica, Fck.* occurs parasitically upon a sphæriaceous host, and that it is accompanied with conidia. It affects the Claviceps at a very early period of its existence, just as Hypocrea alutacea does Clavaria ligula, and Spathularia flavida and Hypomyces viridis (A. and S.) does the Agaries upon which it occurs: in all these instances the host fungus is so altered in appearance

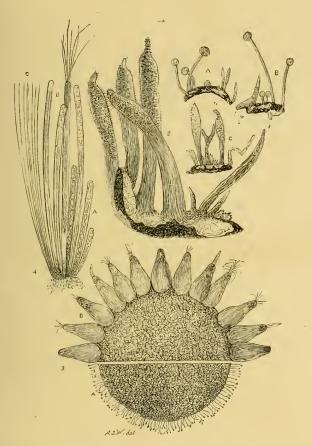

FIG. 34.

REFERENCES:—(1). A, E, C, Claviceps purpurea and Barya aurantiaca on spurs of Ergot: nat. sire. (2). Barya aurantiaca: enlarged. (3). Transverse section of stroma—A, below perithecia = 2, through perithecia: magn. (4). Asci and sporidia in various stages! highly magn.

in having prominent perithecia-it resembles some species of Cordiceps (C. militaris, Linn., for instance), but its sporidia are always continuous and never break up into joints as those of Cordiceps do. Resembling in habit a Hypomyces it differs in its fruit, for the Hypomyces have short, oblong or fusiform normally uniseptate sporidia. Its parasitic nature is shown by its always occurring upon Sclerotium clavus, in company with Claviceps purpurea; sometimes upon the same ergot in company with its host fungus. We have individually attempted by infecting the stigmata of

as to be in the majority of instances quite unrecognisable specifically. C. B. Plowright, A. S. Wilson.

BESSERA ELEGANS. - This is a Mexican (Liliaceous) bulb, succeeding best, according to Mr. Hors-MAN, in the open border. Leaves linear lanceolate, scape slender supporting an umbel of Fuchsia-shaped red flowers, each pendulous from the end of a slender pedicel, the tube elongate, funnel-shaped, the limb equally long and divided, with six oblong acute lobes. Stamens six, connivent, and projecting beyond the perianth, anthers blue. It is figured in the Garden, January 19, 1884.

COLONIAL NOTES.

QUEENSLAND .- Mr. L. A. Bernays, already favourably known for his researches into the botany of Queensland, has added to the obligations under which he has placed the colonist by publishing a work on the cultural industries of Queensland. The object of the author is to place in the hands of the cultivator information relating to economic plants suitable for culture in the colony which he could not readily procure in any other way. The mere introduction and diffusion of useful plants is not sufficient to secure their successful industrial establishment. As Mr. Bernays says, "they are often neglected for want of knowledge of their value, or were subjected to wrong treatment through ignorance of their habits, and of the proper methods of their cultivation and utilisa-This has been generally felt by colonial botanists, as witnessed by the publications of Müeller, Schomburgk, Morris and others. In the present volume we have an alphabetical list of plants adapted for culture in tropical and semi-tropical regions, together with a brief account of the plant, its products, the mode of culture, and the method of manufacture. It is, in fact, a Cyclopædia of economic hotany, compiled from the best and most trustworthy The alphabetical arrangement has, of sources. course, many advantages, but it may be carried out too strictly. For instance, "Coffee" and "Liberian Coffee" are separated by fifty or sixty pages, merely because the name of the West African Coffee begins with an L. We should not have thought of looking for an account of Cinchona under "Quinine tree, But this is a matter of little consequence, as the writer has also supplied an alphabetical index. miss any account of the Kola-nut; a still more striking omission is that of Cotton, for the exclusion of which there must probably he some good reason.

CEYLON,-Dr. Trimen has recently published a little hand-guide to the Royal Botanic Gardens, Peradeniya, Ceylon, which cannot fail to be very useful. "A botanic garden in the tropics is somewhat bewildering to those accustomed to the neatness, order, and regularity of such establishments in temperate countries. The plants to be grown are mainly trees and shrubs suitable to the climate, and planted in the open; we cannot, as at home, produce artificially the conditions necessary for species of other climes by specially regulated houses where the different sorts can be classified, neatly ticketed and arranged for easy examination. Here Nature asserts herself, almost uncontrolled; she gives us grandeur of form, wealth of foliage, exuberance of growth, and splendour of colour -unfading beauties, but of a quite different kind from those of the sweet summer flower-gardens or the well-kept stoves and greenhouses of England," The area of the garden is 150 acres, heautifully undulated, itselevation on the average being 1450 feet. The climate is hot, moist, and equable, the mean annual temperature being 77° Fahr., April and May the hottest, and December the coldest months. Rain falls on about 200 days in the year, the annual rainfall being about 85 inches, pretty evenly distributed throughout the year, but heaviest in October and November, and in The history of the existing garden, of its Tune. predecessors, and of its several superintendents, from the time of Alexander Moon to the retirement of Dr. Thwaites, is given at some legth. We have at various times given illustrations of some of the more remarkable trees in this garden, such as of the Talipot, Corypha umbraculifera, the noblest of all Palms, though in some sense an "annual," for like an annual it produces flowers but once, and then, having accom-plished its mission, dies. The gigantic buttresses of the indiarubber trees (Ficus elastica) have also been figured by Captain Oliver. Dr. Trimen's narrative, strictly didactic though it be, makes "one's mouth water," if the expression may be allowed. Three other gardens in different climatic districts of the island are also under Dr. Trimen's charge,

THE BOTANIC GARDENS, MAURITIUS .- Ninetyfour thousand persons are reported as having visited the gardens in 1882. The rainfall was 75 inches-March, with a fall of 24.88 inches, being the wettest month. The highest temperature recorded was 85°.6 Fahr., on January 21, and the lowest 53°, of June 1—the mean maximum for the year team 77°, the mean minimum 70°. The propagation of the Ceara rubber tree, Manihot Glaziovii, has been proceeded with satisfactorily. Trials are being made of other rubber trees, the great demand for

COCUS WOOD.

WHAT Box-wood is to wond engravers Cocus-wood is to musical instrument makers, at least to the makers of wind irstruments, such as flutes, clarionets, &c. No true substitute has yet been found either for Boxwood or Cocus-wood, the fine close grain of the former, and the metallic ring of the latter being as yet undis covered in any other woods. Like many woods of great commercial importance, the botanical source of Cocus-wood was for some time quite unknown. In Holtzapfel's Descriptive Catalogue of Woods it is referred to under Cocoa or Cocus-wood, and is there said to be "imported from the West Indies in logs from 2 to 8 inches in diameter, sawn in lengths of from 3 to 6 feet, tolerably free from knots, with a thick yellow sap; the heart, which is rarely sound, tines, venow sap; the heart, which is rarely sound, is of a light yellow-brown, streaked when first cut with hazel and darker brown, but it changes to deep brown, sometimes to almost black. Cocca-wood is much used for turnery of all kinds and for flutes; it is excellent for eccentric turning, and in that respect is next to the African Black-wood. An apparent variety of Cocca-wood, from 2 to 6 or 7 inches indiameter, with a leave recording the state of the African Black-wood. in diameter, with a large proportion of hard sap, of the colour of Beech-wood, and heartwood of a chestnut-brown colour, is used for tree-nails and pins for ship work, and purposes similar to Lignum-Vite, to which it bears some resemblance, although it is much smaller, has a rough bark, the sap is more red, and the heart darker and more handsomely coloured when first opened than Lignum-Vitæ; it is intermediate between it and Cocoa-wood. Another, but ioferior wood, exactly agrees with the ordinary Cocoa-wood, but that the heart is in wavy rings, alternately hard and soft."

The above is all that was known of Cocus or Cocoawood when Holtzapfel's little book was published in 13c, and since then we have by no means satisfactorily cleared up this point. The writer of the article quoted above says —"It is really singular that the exact localities and the botanical name of the Cocoanical name of th exact localities and the botanical name of the Cocoawood that is so much used should be uncertain; it
appears to come from a country producing sugar,
being often imported as dunnage, or the stowage upon
which the sugar hogsheads are packed. It is also
known as Brown Ebony, but the Amerimnum Ebenus
of Jamaica seems dissimilar."

The Amerimnum Ebenus of Swartz is now referred
to Brue Ebenus of DC, and the wood of this plant.

The Amerimnum Ebenus of Swartz is now referred to Brya Ebenus of DC., and the wood of this plant, which is known in Jamaica as Green Ebony, is now credited with furnishing the Cocus-wood of commerce. The woods, indeed, upon comparison are almost identical except in colour, the Cocus-wood being somewhat darker, but this may be due to the wood being older, and perhaps selected on account of its deeper colour, for the darker the colour is for flutes the more highly it seems to be valued, its principal competitor in the market for this purpose being a still darker coloured wood known as African Elackwood, the botanical source of which has not yet exemped. wood, the botanical source of which has not yet even been guessed at.

been guessed at.

Another wood, so similar to Cocus-wood that it is difficult, if not impossible, to distinguish it, is furnished by a Euphorbiaceous tree of Northern and Eastern Bengal and Birma, known as Kokra-wood, and furnished by Aporosa dioica, Mull. Arg. (Lepidostachys Roxburphii, Wall.) The similarity of the Bengalese name, Kokra, with the commercial name, Cocus, or Cocoa as it was formerly spelt, is so remarkable that it would seem to point to them as being one and the same thing, and the question then arises whether, instead of Cocus-wood coming from the West Indies it does not in reality come from the arises whether, instead of Cocus-wood coming from the West Indies it does not in reality come from the East, Gamble, indeed, in his Manual of Indian Timbers, says (p. 355):—"This last (Aporosa dioica) has been identified with the tree producing the 'Coco-wood' of commerce, generally supposed to come from the West Indies," Gamble further says:
—"The wood of Aporosa dioica should be carefully examined to prove that the Indian tree gives a timber similar to Coco-wood." A comparison of the two woods contained in the Kew Museum proves their similarity. John R. Jackson, Museum, Kew.

STENANTHIUM OCCIDENTALE is a hardy bulb from the Rocky Mountains of Oregon, with long linear glabrous leaves, from amid which uprises a slender one-sided raceme of long narrow beli-shaped nodding flowers, each about half an inch long, the tubular portion pink, the six recurved linear lobes of the limb green. Gartenflora t, 1132.

Prchid Notes and Hleanings.

CATTLEYA PERCIVALIANA,-First introduced as a new plant by Messrs. F. Sander & Co., of St. Alban's, in 1882, the glowing description which the collector sent with it caused it to be eagerly sought after by most Orchid growers, the more particularly as they had long since despaired of ever again getting a really new and fine large flowered Cattleya. The first bloom, however, which the plants produced under cultivation did not seem to some to bear out the warranty given with it, and consequently a discussion arose as to its merits. On the general question at issue the evidence pro and con seemed about equal, and in the end it was wisely lett to the plant to settle the question itself. This it has done this season in its own favour in a remarkable degree. At its first meeting this year the Floral Committee of the Royal Horticultural Society awarded it a First-class Certificate, and on every side we both see and hear of the wondrous beauty of the good varieties of this Cattleya; while in many instances we have heard of the varieties previously condemned as bad at their last flowering having come good this year, on account of their being better established. If further evidence were wanted for the plant, it can be obtained from the commercial side of the question. Since the commencement of its present flowering season it has rapidly gone up in price, to such an extent that three of the largest masses sold at Protheroe & Morris' Rooms recently realised together 320 guineas—prices hitherto unknown in the history of freshly imported Cattleyas. C. Per-civaliana is said to come from Northern Brazil, where it grows on upright rocks, overhanging streams, at an altitude of from 5000-5500 feet, always exposed to full sunlight, and frequently to very strong currents of air; it will, therefore, be readily understood that it must be liberally treated with regard to both of these elements, in order to make it thrive. In its native habitat its wet season is October and November; but while bearing this fact in mind it will be better to learn from the plants themselves the season in which they want most water, as in this particular their altered condition under cultivation may make a difference, as it does in their time of flowering, which in Brazil is in November, but with us it does not take place until from Christmas, through January and onward. at which season its flowers are more acceptable than at any other time of year. The plant has so often been attempted to be described of late that we herewith furnish an illustration (fig. 35, p. 181), but even with it the beautiful fringe to the labellum and other delicate points cannot be conveyed. The sepals and petals are clear light rose, and the gorgeous labellum, which no words can describe, varies from bright velvety crimson to violet-tinted maroon, generally margined with white or pale lavender, and blotched in the upper half with orange lived and shaded with crimsonbrown, the intensity and richness of the colours in the labellum being so great that they are hardly to be approached by any known Orchid in that respect. Mr. R. P. Percival, who wisely held his peace while the merits of his protege were being discussed, may congratulate himself on having his name attached to such a neat, useful, and lovely plant. The illustration at p. 181 is of a specimen sent us by Messrs. Ireland

CATTLEYA (LABIATA TRIANÆI) MASSANGEANA, Rchb. f. (Gard. Chron., xix., n.s., 18, p. 242, Feb. 24, 1883).-M. Dieudonné Massange de Louvrex has been so kind as to send me a fresh flower of his wonder, which proves identical with what I stated last year, though some details of the stripes stated last year, though some details of the stripes require to be altered. I have altready stated that our friend Mr. Edward Klaboch, when he saw my sketch in water colours began to laugh, saying it was a funny invention; and Mr. Klaboch has seen as many flowers of the labiata type as few other mortals can have done. H. G. Rehb. f.

THE ORCHIDS AT KEW, which improve in vigour every year, at present include in their number many interesting and rare species in Dendrobium tetragonum, with its long, bloom. slender, square pseudobulbs furnished with curious flowers like those of some of the smaller Maxillarias; D. rhodocentrum, with pretty white and lilac blooms; Brassia ocanensis, with small brown and yellow flowers; Oncidium aureum, Lindl., having flowers with vivid yellow labellums; and many rare botanical curiosities being there in flower now. Dodanical Cutosaless being there in lower how.

Among better known things Gomezia planifolia,
Odontoglossum Sanderianum, O. triumphans, O. tripudians, O. Rossii majus, O. constrictum, Ipsea
speciosa, and many lovely Cattleyas, Dendrobes,
Angræcums, and Masdevallias will be found represented by fine well-bloomed plants, while the now rather rare Lælia superbiens may be seen producing an immense spike, which later on will cause wonder and admiration to many of the Gardens' numerous

ORCHIDS AT MESSRS. SHUTTLEWORTH, CARDER & Co.'s .- As the establishment at 191, Park Road. Clapham, is a brisk trading one, continually receiving large importations and sending out great quantities of good things, one does not look to it for the show of flowers which is arranged for in many establishments; but somehow the visitor seldom goes to it without seeing something he could not see elsewhere. This may in a great measure be accounted for by the many marked plants which the collectors send (chiefly those collected by Mr. John Carder himself) and which are proved at home. In such plants—and especially in the very fine hybrid Odonto-glossums of the Wilckeanum, mulus, hebraicum, and Andersonianum sections - Shuttleworth, Carder & Co. have been very lucky, as even their present show of them will prove. Masdevallias are a great feature here, the lovely M. Shuttleworthii being now, as always, in bloom, and good plants of M. Estradæ, M. ignea Massangeana, M. chimæra, well furnished with their bright flowers, while several new species are in bud, and large healthy batches of M. macrura, M. trochilus, and most of the other good Masdevallias appear in the best condition. The great triumph of this firm this season has been the introduction of the lovely orange-scarlet M. racemosa Crossii, which bears long sprays of richly-tinted blooms. This plant, owing to the difficulty every one found in importing it, has got the name of being a very bad grower. Many will be glad to learn that such is not the case, for at Messrs. Shuttleworth's it is growing like a weed, in a very cold moist house. The difficulty is in getting the plant, not in growing it. M. pachyantha is also an introduction of equal importance to the last, the form and size of its flowers are the same as M. Veitchii, the ground colour yellowish, surfaced with various tints, from dark lilac to maroon. It is a sturdy grower, and there appears to be great variety in the blooms. The span Cattleya-house contains large batches of C Mendelii, C. Trianæ, the new Popayan Cattleya, C. Dowiana, &c. Many grand Trianæs are in bloom, one with immense flowers, having the flowers wholly white, faintly shaded with lavender; another having an indescribably vivid magenta-crimson labellum, and a third being snow-white. A good collection of Paphinias—P. rugosa, P. cristata, P. grandis—are in this house, and a large lot of Miltonia Warscewiczii sending up their bloom. The Odontoglossums, Masdevallias, Oncidiums, &c., are accommodated in three roomy span-houses, each over 100 feet in length, the middle one being slightly warmer than the other two, and containing the O. vexillarium, O. Roezlii, Lycastes, &c. Of these last there are many scores of handsome forms in bloom, including one plant of the snow-white variety. The Odontoglossum - house proper contains over 10,000 O. Alexandræ, O. Pescatorei, &c., many in bloom or bud; and the further cool-house contains almost as many more, as well as cool-mouse Contains amoust as many more, as went as some interesting things on trial; the full collection of Bomareas, for which this firm is noted, and a fine lot of O, Rossii majus and O. Cervantesii in bloom. A large span-house at the end contains heat-loving plants, that worthy companion to the Ortchids, the chaste Eucharis candida, supplying plenty of flowers even at this dull season to assist the Dendrobium Wardianum, D. splendidum, D. Ainsworthii, D. Wallichianum, and some Angræcums and Phalenopsis, in giving a show which could not fail to be grateful even to one who did not know a single Orchid by name.

MR, WILSON'S ORCHIDS.—In your article on our gardens at p. 110 there is one slight error, for which I alone am to blame. When saying that I took little charge of our Orchids except buying them, I did not mention that my gardener, who grew Orchids at a former place, did not give them much care and attention. George F. Wilson, Heatherbank,

Notices of Books.

Guide to Methods of Insect Life. By Eleanor A. Ormerod, F.R. Met. Soc. London: Simpkin, Marshall & Co., 1884.

There are few, if any, ladies who can claim such activity and energy in any branch of science as Miss Ormerod in that which she has made entirely her own, namely, the means of preventing insect ravages to farm and garden crops. Her annual reports on injurious insects, which have now become well known, have been increasing, not only in value, but also in bulk year by year till they are now a great deal more than pamphlets; besides these, Miss Ormerod has issued a Manual of Injurious Insects, and Methods of Prevention, and has delivered lectures at Cirencester and South Kensiogton. It is this last course, delivered in December last for the Institute of Agriculture, that Miss Ormerod has published under the title given above. Her aim in these lectures was to place her subject before the minds of her hearers and readers in as plain language as possible, "The book is formed," the authoress says in her preface, "in the hope that it may be taken to the field, or taken up at an odd minute, and give a little information without burdening the reader with a need of looking elsewhere for explanations. I have, therefore, as far as possible throughout used only the words of our own language, and for the explanation of such scientific terms as are used, or for the scientific names of the insects figured, the reader is referred to the Glossary and to the list of insects." Again, in the first lecture, which treats of eggs and caterpillars, Miss Ormerod says, "I would advise with regard to insect know-ledge for farm use, that whenever an English word has a well known meaning and may correctly and properly be used, you should use it rather than the scientific one. If the larvæ of flies are called 'maggots,' or the larvæ of butterflies 'caterpillars, few people in the country will fail to know what is meant; but if we wish to speak of the first stage of flies and butterflies and other insects together, then we must use the scientific word, and speak of them as larvæ, giving careful explanation." The meaning of the terms larva, pupa, and imago is next defined and illustrations given. Subsequent chapters treat of chrysalis, perfect insects, orders, flies, fleas, beetles, sawflies, wasps, and other insects that field and garden crops are too often exposed to. Methods are also given for their prevention and extermination. The book is profusely illustrated with woodcuts of the insects in their various stages, and will, we are sure, be very useful to those for whom it has been written.

— Compendio della Flora Italiana.—This useful publication has now reached the thirty-second number and the ninety-second plate.

— Journal d'Agriculture et d'Horticulture de l'Ouest.—Under this title a jouroal has just been started, dealing with agricultural and horticultural matters in the West of France. It is to appear fortnightly. M. J. Le Corvec is the publisher, Rue Nanteuil, Nantes,

— The Illustration Horticole,—The Directors of the Compagnic Continentale d'Ilorticulture have issued a complete index to the plants described and figured in the first thirty volumes of the Illustration Horticole.

Natural History.

THE KINGFISHER.—I have never noticed the kingfisher so plentiful on the rivers here as during the past season; but I fear that this rare and beautiful bird is doomed to extermination, even though there are but few responses to the following advertisement, which appeared lately in a Yorkshire newspaper:—"Wanted, kingfishers, clean and fresh killed, any quantity." This certainly looks like a wholesale attempt to exterminate, especially as the price offered for each bird is, I am given to understand, very high. No doubt the present searcity of the kingfisher is greatly due to the way in which it is hunted down by idle seoundrels, and the sooner such a foul game is stopped the better. River watchers, or, in fact, any person interested at all in our feathered tribes, on seeing such a heartless

game in practice should for once take the law into their own hands and give the perpetrators a good sound dressing, as a foretaste of what they might expect in the future. A. D. Webster,

The Flower Handen.

THE spring plants are unusually early this season, and had we not been visited with the destructive storms of wind and hail which occurred a fortnight ago the spring gardens would now have been unusually gay. The effect of these storms was not only to destroy the flowers but the foliage of the plants in exposed beds was also torn to shreds. In order to rectify this mischief the beds should now be carefully gone over, so as to remove the dead leaves and flowers, and where the soil is hardened by the heavy rains the surface should be loosened either with fork Where the bulbs are breaking through the ground they should, in the event of frost, be slightly covered either with leaf-mould or cocoa-fibre, otherwise they will suffer severely after the mild weather we have had. Cleanliness and good keeping should now be strictly maintained, as nothing is more essential in order to produce a good and pleasing effect. A few of the early blooming Roses may now be pruned, and as they are now commencing to grow it will be advisable to do this by degrees rather than by pruning close at once, so as to keep the back buds dormant as long as possible, as in the event of severe frosts destroying the forward growths these dormant buds will form a safe reserve to prune to later on in the season. Clematis will this scason require careful management, as they have already made considerable growth. Where trained against walls these can be easily protected either with mats or other safe and convenient covering nailed up in front of them during severe frosts, but where grown in masses in beds this is not so easily accomplished without breaking off the young shoots. The plan I have found best is to hoop over the beds with Hazel-sticks, and then place mats over the hoops; they should, however, be removed immediately the danger is past.

THE PROPAGATION OF THE SUMMER PLANTS should now receive every attention. All the deficiencies should now be worked up as quickly as possible, so as to enable the plants to become well possibly, so as to change the plants to become well established by planting time. All the quick rooting kinds, such as Verbeoas, Lobelias, Heliotropes, Salvias, Tropæolums, and Dahlias can easily be produced in any quantities if the store plants have been prepared according to previous instructions, and if plunged in a strong bottom-heat for a few days. Immediately they are struck they should be removed into cooler quarters to harden off, when they can either be potted singly or in pairs, or planted in frames where frost can be excluded, or else rather thickly into shallow boxes till required for planting. Pelargoniums and all the autumn-struck cuttings will now require to be potted, or planted in pits or frames. as before described. All this kind of work should be completed as soon as possible, so as to obtain good, sturdy, well-hardened plants at the planting

THE BULE STORE should now be examined, and where Gladiolus are showing signs of growth they should be planted, choosing a mild day for the operation. The soil should also be in a comparatively dry Ranunculus, Anemones, Tigridias, Lilies, Tritonias, and all similar bulbs preserved in the store through the winter, should now be planted when the weather is mild and dry. All these bulbs require a deep rich sandy loam, which should be made thoroughly firm at the time of planting; they should also receive protection should severe frosts occur. All of them, except the Lilies, require an open sunny situation; these, however, succeed best where they are partially shaded from the mid-day san. The late storms have unfortunately given plenty of work on the lawn and shrubberies in the removal of timber and branches which should be executed as quickly and with as little injury to the turf or walks as possible, and where planting either of trees or shrubs is required to fill the vacancies made it should be done without delay. T, S, C,

The Handy Hnuit Garden.

THE pruning of Cherries will now require attention in simply thinning out the small branches, and leaving them at their full length, as shortening them would only increase the quantity of wood for next year, and cause much overcrowding. On no account cut off large boughs, as that is almost sure to injure the trees, and produce gumming, which is always a bad sign. Standard trees do best on grass, where it is pastured and fed off with stock. Great care is required in nailing trees that are against a wall, so as not to bruise or in any way injure the branches, and see that nails which touch the bark of stem and branches are removed. Grape Vines may now be pruned, cutting them back to one bud, of course eaving the leading shoots 2 or 3 feet long; Black Cluster and Sweetwater are the only really to be trusted out-of-doors, and that only in favourable localities. On no account touch the Fig trees yet. We may have frost, which would be much more likely to injure them if pruned.

Where there are vacancies in the orchard of any kind they may still be made good by planting. Be careful when transplanting that the roots are as short a time as possible exposed to the air, and see that the trees are firmly and securely staked.

Bush fruits may still be pruned, but we deprecate the too free use of the knife, for if the shoots are left tolerably thick they shelter each other in the case of frost, and the crop will be far heavier, which will induce greater fruitfulness next year, and less wood; and should the crop prove heavier than can be matured it can easily be reduced by gathering the berries while green for the daily supply of the family, and the great secret is not only to get a good crop but to prolong the season of each kind as long as possible by planting early kinds in a sunny place, and late kinds on a north aspect, also where they can be protected from birds. north wall here of considerable length we grow Morello and late dessert Cherries, while the border is planted with Raspberry Carter's Prolific; Currant (black) Prince of Wales, and the new Black Champion; Gooseberry Warrington, and other late kinds; red Currant Victoria, white Currant Transparent, and Straw-berries Victoria, Loxford Itall, and Helen Gloëde, Stout posts are let into the edge of the border and wire netting a yard broad is attached, and from the top of these posts to the top of the wall is Eddy's square mesh netting. It takes but little more netting than if the wall only was covered, and in this way both fruit on the wall and in the border is protected from depredators, and the gathering scason prolonged. If lichens attach themselves to bush fruits a dusting of quicklime over them will clear the noxious growths away, and also in some measure protect the from birds. Dress the bushes with manure and afterwards dig the ground amongst them very shallow with forks. Prune and tie up espalier trees, and if stakes are used tar the pointed ends before driving them into the ground. The best support for espalier trees is strained iron wire with iron standards, but if galvanised wire is used the shoot should not be brought immediately in contact with the iron; make a tie on the wire first, then tie the shoot. The choicer kinds of Apples and Pears do well on the espalier, the large fruit of which would be blown off a standard before they were tipe. J. Rust, Eridge Castle, Sussex.

The Orangery.

The imported Oranges that have come into this neighbourhood are very sour this season, and those who have a few dishes of home-grown fruits will find them very nusful. The Tangterines, which usually ripen in September and October, are over, of course, and if the trees are now in blossom they must be kept in a rather dry temperature of, say, 60° at night. I fancy the fruit sets better in a temperature of 60° or even lower, than at a higher figure. Those trees that have fruit ripening on them should have a night temperature of 65°, and the trees at this season should be quite close to the glass. This is the time to wash the trees, and also to clean the house in which they are growing. Repotting may also be done: it is a good chance to do so when the ripe fruit has been gathered. Use good turfy loam, with a liberal sprinkling of crushed bones and charcoal, 3. Donglas, Great Gearies, 1flord.

APPOINTMENTS FOR THE ENSUING WEEK.

APPOINTMENTS FOR THE ENSUING WEEK.

Monday, Feb. 15 Sale of Lilies and other Roots, at Stevens' Rooms.

Royal Horicultural Society: Meeting of Fruit and Floral Committees, at 17 A.M.; Section of Fruit and Floral Committees, at 17 A.M.; Stevens' Rooms.

Wednesday, Feb. 15 Sale of Roots, Carlotte Societies meet in the Consortation of Province of Montal Auricula and National Carnation and Florete Societies meet in the Consortation of Province of Morris Sale of Imported Orchids, at Stevens' Rooms, Gracechurch Street, by Produce & Morris Sale of Imported Orchids, at Stevens' Rooms, Gracechurch Street, by Produce & Morris Sale of Imported Orchids, at Stevens' Sale of Imported Orchids, at Stevens' Rooms, Gracechurch Street, by Produce & Morris Of Horizon & Morris Of Horizon & Morris Of Horizon & Morris Of Horizon & Sale of Imported Orchids, at Produce & Sale of Imported Orchids, at Produce & Sale of Office of Hardy Plants, Bulbs, &c., at Stevens' Rooms.

A T the instigation of the Nursery and Seed Trade Protection Association a MEETING OF REPRESENTATIVE HORTICULTURISTS interested in the exportation of plants was held in the office of this Journal on the 6th inst. to consider what, if any, steps should be taken with a view to remove or modify the restrictions now put upon British horticultural commerce by reason of the Phylloxera laws as enacted by the revised Convention of Berne, and as carried out by the countries which have given in their adhesion to that Convention. The meeting was attended by Messrs. Backhouse (York), Bull, Cannell, Fisher (Sheffield), Laing, Sander (St. Al-Fisher (Sheffield), Laing, Sander (St. Albans), Turner, Veitch, and Williams, Dr. Masters being in the chair. Mr. Dyer, Assistant Director, Royal Gardens, Kew, was present unofficially, and explained the pro-visions of the treaty of Berne and the means to be adopted to comply with its enactments, including the procuring of the necessary certificates. Mr. McLachlan, one of our most eminent entomologists, also attended the meeting to give the results of his experience in the matter. Letters were read from Messrs. Van Geert (Ghent), Booth (Hamburgh), Krelage (Haarlem), Geo. Paul, F. & A. Dickson & Sons, Jas. Dickson & Sons, Hugh Low & Co., W. Paul, A. Waterer, J. Marriott, Keynes, Williams & Co., H. Bennett, and E. Sawyer.

An exhaustive discussion ensued (1) as to the

advisability or otherwise of requesting our Government to join the Convention of Berne;
(2) of approaching the Government by means of a deputation to the President of the Board of Trade; or (3) of securing a modification and uniformity of procedure in the mode of obtaining the necessary certificates.

It was, however, ultimately agreed, without a dissentient voice, that under existing circumstances, and in view of the facts brought before the meeting, it was not expedient to take any further action, but to let matters take their course, it being generally considered that the balance of advantage lay in enduring the present inconveniences rather than in taking any step which would in all probability be attended with even greater expenditure and annoyance than those to which the trade was now subject.

THE WEEK. - The Sibthorpian Chair of Rural Economy in the University of Oxford is to be held under the new regulations by Dr. GILBERT, so well known in association with Sir John Lawes for wen known in association with 31 John LAWES 107 libs life-long devotion to the science of agriculture. Formerly this chair was held with the then poorly endowed Sherardian Professorship of Botany, first by the late Dr. DAUBENY, and afterwards by Professor LAWSON, but it can hardly be said that the results were satisfactory. By the new regulations the Sibthorpian Professorship is wholly detached from the Botany Chair, and the Professor is to hold his professorship for three years, or for six, at his discretion. His duties will be to give instruction in the principles of agriculture and forestry. We earnestly trust the new arrangements may prove beneficial by securing to the future race of landed proprietors and tenants a knowledge of the principles on which the successful cultivation of plants depends. Certainly no fitter appointment than that of Dr. GIL-BERT could have been made, and as the duties involve

only the delivery of some twelve lectures during the academic year, it is to be hoped that the Doctor's work at the Harpenden experimental farm will not be seriously interfered with by his new duties, but that his sphere of usefulness will only be extended .-We are delighted to find that the opposition to the establishment of a proper laboratory for Dr. BURDON SANDERSON on the part of some anti-vivisectionist members of Convocation has been unavailing. It is quite sad to see such unreasoning and unreasonable hostility, not only on the part of the ignorant and unreflecting, but on the part of educated men, to the progress of physiological research by men no more wanting in their duties to dumb animals than themselves, but infinitely more capable of bettering their condition.—The appointment of Professor FLOWER, of the Royal College of Surgeons, to the Superintendentship of the Natural History Department of the British Museum, in the room of Sir RICHARD OWEN, will give general satisfaction among those who know the competence of the new Superintendent and the requirements of his office. - In the last number of Nature is a further contribution to the history of the flora of ancient Egypt, by Dr. SCHWEINFURTH, many of the illustrative specimens having been forwarded to the Museum of the Royal Gardens, Kew. In addition to the plants already mentioned in this journal Dr. SCHWEINFURTH now mentions leaves of Salix satsaf, and of the Date Palm, flowers of Papaver Rhoeas, Centaurea depressa, and Picris coronopifolia. Barley, Wheat, Beans, Flax, Lentils, tubers of Cyperus esculentus, as well as fruits of the Pomegranate, Doum Palm, Fig, &c., have been found. Cones of Pinus pinea and Juniper berries are stated to indicate commercial relations in those early times between Egypt, Greece, Asia Minor, and Syria. The whole article is one of exceeding value to those interested in the history of cultivated, or the geographical distribution and modifications of wild plants. -Among the publications we have received during the week, and to some of which we may have to refer more at length hereafter, are the Bushberg Catalogue of Vines, which is something more than a trade list, seeing that it contains an article on the classification of the American species of Vine, by Dr. ENGELMANN; abstracts of Professor RILEY's articles on the Phylloxera and other Grape insects; diseases of the Grape, by Dr. Engelmann, together with numerous cultural details, and a full descriptive list of sorts, with illustrations. Mr. Morrest Report on the Agricultural Resources of St. Helena, and the same author's little volume on the Resources and Prospects of British Honduras, can only now be mentioned, their importance de-mands fuller notice hereafter. A like remark applies to M. LAVALLEE's fine Monograph of the Large flowered Species of Clematis, with twenty-two quarto plates. It will create some surprise to learn that Clematis Jackmanni x is here considered not a hybrid, but simply a form of a species found wild in Japan and called C hakonensis. We scarcely think this statement will be allowed to pass without protest, in the face of the circumstantial account given in our columns in 1864, p. 173, by the raiser, and repeated in MOORE and JACK-MANN'S book on the Clematis; but we shall take an early opportunity of giving M. LAVALLÉE'S views on the subject, which in any case deserve respectful consideration.—Evidences of the passage not only of fluids from cell to cell of plants, but of the essential constituent of all plants, the viscid substance known as protoplasm, are multiplying. They will cause us to modify our notions as to the independent life of individual cells, and by showing more clearly than before their joint action by means of the communications in question, throw light on the causes of the movements of various plants or parts of plants vaguely referred to variations in degree of turgescence and consequent tension. In conjunction with the known contractile property of protoplasm these new facts point, not only to a foreshadowing of the muscular tissue of animals, but of the nervous system also. In addition to previous instances brought forward by GARDINER and others Mr. HICKS now figures in the Journal of Botany, and describes cases of a protoplasmic continuity in the Red Sea weeds.

- PARLIAMENTARY NOTES .- At the opening of the session on Tuesday, Sir JOHN LUBBOCK gave notice of his intention to call attention to the state of forestry in this country, and to move a resolution. Mr. INDERWICK gave notice, on the same day, to introduce a bill relating to the extraordinary tithe; and

Mr. HARRINGTON one relating to the planting of trees in Ireland. On Wednesday Dr. Lyons gave notice of a Bill for the re-afforestiog of waste lands in

-- St. Petersburg International Hor-TICULTURAL EXHIBITION .- It will be remembered that the exhibition and botanical congress, postponed from May last on account of the coronation of the Emperor, are to be held from May 17 to 28 next ensuing. Additional prizes are offered. Plants can be sent by sea from England, through the agency of Messrs. WATSON & SCULL, 40, Lower Thames Street. There will be three meetings of the Congress, the preliminary direction of which is entrusted to M. DE MAXIMOWICZ, of the Imperial Botanic Garden. The subject of the geographical distribution of certain plants of different families, wild or cultivated, will be considered in reference to their northern and southern limits respectively. Schedules and further particulars may be had on application to the Editor of this Journal, or direct from M. DE REGEL, Imperial Botanic Garden, St. Petersburg.

- EXCHANGE LISTS .- We have received the Index seminum of the Palermo Botanic Garden, and of the Jardin des Plantes, Paris, respectively. In the latter case all applications for seeds should be made before the end of the current month.

- "THE ENGLISH FLOWER GARDEN."-We are informed that in future issues of this book, noticed by us last week, the ordinary numerals will be followed from end to end, that there will be a full index, notwithstanding that the arrangement is mainly alphabetical; and that every illustration objectionable in any way will be drawn and engraved

- PHÆDRANASSA LEHMANNI.-This is a new species, discovered by LEHMANN on the western side of the Andes of the United States of Columbia, at an elevation of 7000 feet, and described by Dr. REGEL in the Gartenflora, t. 1138. The bulbs are about the size of a goose's egg, the leaves stalked, broadly lanceolate, the scape terete, bearing a few-flowered umbel of nodding, narrow, tubular scarlet flowers, each about 11 inch long, with projecting stamens.

- IMPORTED PRODUCE,-During the week ending, February 2, 23,264 bushels of Onions, and 7855 cwt. of Potatos, were imported into this country.

- ROYAL INSTITUTION .- On Monday last Sir J. D. HOOKER, K.C.S.I., was elected a Manager of this Institution in the place of the late Sir W. SIEMENS.

- HARDY PLANTS IN BLOOM, - Further evidence to the extreme mildness of the season comes to us from Mr. JOHN CLARK, in the form of a list of about four dozen hardy plants in bloom in Mrs. JOAD's garden at Patching House, Worthing, Sussex, among garden at ratening flouse, instanting the more remarkable of which are Tritonia Burchellii, Tritoma uvaria, Schizostylis coccinea, Polemonium coeruleum, Kniphona sarmentosa, Lithospermum cœruleum, Kniphofia sarmentosa, Lithospermum prostratum, Agathea cœlestis, Amphicome Emodi, Lagurus ovatus, and Abelia rupestris.

- JASMINUM NUDIFLORUM.-In a previous issue (p. 117) we referred to the pleasing effects of Jasminum nudiflorum in combination with Ivy: a correspondent now describes a similarly pleasing effect of this well-known Jasmine mixed with Yew. In this case the Yew formed a well clipped hedge from the pavement to the house in a neat and well kept fore-garden in the King's Road, Richmond. The bright yellow flowers of the Jasmine were equally dispersed all over the hedge, the dark green of which made them appear more brilliant than usual. These examples would point to the advisability of using Jasminum nudiflorum more in conjunction with evergreens, the foliage of which supplies what the Jasmine lacks. In our own case we find it very effective, not only against Ivy but also in front of a Pyracantha shrub.

- PANSIES IN POTS .- It is very unlikely that the Pansy will ever be so much grown in pots as it was thirty years ago, but could some idea of the beauty of the flowers in early spring, when grown in this way, be realised, we think not a fee lovers of the Pansy would grow a few plants in pots.

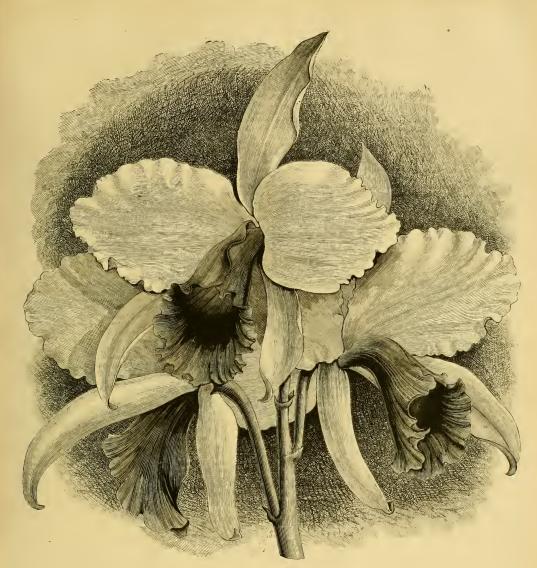

FIG. 35.—CATTLEYA PERCIYALIANA: FLOWER-SEGMENTS ROSY-LILAC: LIP MAGENTA-CRIMSON. (SEE P. 178.)

Plants potted up into small 60-sized pots in September are now full of roots, and require shifting into 48 or 32-sized pots, according to their size and dimensions; and they need rich soil; and if returned to the cold frame they will soon make a display of flower. Some plants in 48-sized pots, kept over from last year because potted late in the summer, and top-dressed a short time ago, are now blooming freely in a cold frame, where the blossoms, being protected, are as perfect and clean as any one can well desire them.

—— STRANGLED HYACINTHS,—This term may be applied to those Hyacinths which, whether grown in glasses or in pots, fail to develope their flowerspike, because the opening through which it ascends is too small to admit of its swelling, and it parts asunder while in the neck of the bud. It is happily not a common occurrence except in the case of

Hyacinths that are being forced into flower early under the pressure of great heat. It is by no means easy to have Hyacinths in bloom at Christmas, and to accomplish this they have to be sent along at a great rate, and we were recently informed that it is not uncommon to lose a large percentage by strangulation. Hyacinths in glasses are more liable to this than in the case of bulbs grown in pots. It would appear that it is traceable to a development of the flower-spike before the orifice at the top of the bulbs formed between the tips of the scaly leaves, is capable of affording it a passage; disappointments, therefore, are incurred in this way, and they have to be horne, for it is seldom that a second flower-spike is thrown up to take the place of the first. Probably the death of the topmost flowers which so often occurs is due to the same cause; the Hyacinth, it will be remembered, frequently expanding its flowers from above downwards, though its

inflorescence is called a "raceme," one characteristic of which is that the flowers expand in order, from below upwards,

— Mr. John Greenshields.—We deem it worthy of record that Mr. John Greenshields, gardener to the Earl of Ducte, completed last week fifty years' service as Head Gardener at Sarsden, Oxon, Mr. Greenshields, a native of Lanarkshire, and came to Eogland when a very young man, his first situation being at Dropmore, Bucks. Though in his eighty-first year he enjoys excellent health, and takes the full management of everything in his department. His well directed activity would put many active young men to the blush. Like most gardeners who have reached advanced years he acts upon the belief that his fruit trees will only yield their abundance after the application of his own knife. A second noteworthy fact is that Mr. Puch, who was Mr.

GREENSHIELDS' immediate predecessor, held the appointment over forty years. Mr. GREENSHIELDS was installed some time before Mr. PUGH'S death, and can still recount the latter's description of the great improvements made at Sarsden in the last decade of last century, soon after the estate had been purchased by Mr. JOHN LANGSTON, M.P., who was succeeded by his son, Mr. JAMES HAUGHTON LANGSTON, M.P., who died in 1863, leaving an only child, the present Countess of DUCIE. We are sure Mr. GREENSHIELDS will have the good wishes of his professional brethreo, that his long and honourable life will yet see many bright days.

- THE FRUIT BUDS .- There is ample evidence that the buds on fruit trees are finding the exciting influences of the mild weather operating to their Whenever a ray of sunshine peeps disturbance. out from behind the heavy clouds the whitened points of the buds, both on Pear and Apple trees, may be seen in abundance, whilst on walls the buds are of a deeper hue, yet showing ample evidence of activity. That the buds should show signs of expansion so early is, however, not a desirable feature. are yet a long way from the margin of the winter wood, and would prefer to he somewhat nearer the desired haven of spring ere we see our fruit trees teeming with their lovely blossoms. A few weeks of cold would prove most serviceable in keeping the trees in check, but should we, on the contrary, have a further spell of soft open weather, the March winds may become exceedingly unwelcome.

—— PRIVA LÆVIS is a hardy, tuberous-rooted perennial, native of Chili, and a member of the Verbena family, having, indeed, much of the habit of our common Vervain (Verbena officinalis), but the flowers are larger and of a rosy-lilac colour. Figured in Gartenflora, t. 1131.

—— GHENT NURSERIES,—In 1816, according to the Illustration Horticole, there were but thirteen nurseries in Ghent, and those on a small scale. The names of DE COCK, SFAE, and VERSCHAFFELT, were among the thirteen.

- COMPTONIA ASPLENIFOLIA is a pretty deciduous shrub, attaining a height of about 3 feet, and with sweet-scented Fern-like leaves. It is a member of the Sweet Gale family, and perfectly bardy in Britain. LOUDON'S name, "the Asplenium-leaved Comp-LOUDON'S name, "the Asplenium-leaved Comptonia," is not one which recommends itself to most people, as it is more cumbrous and somewhat less euphonious than its scientific appellation; "Sweet Fern," the name given in Dr. Asa GRAY's Manual, would be a preferable one, only the plant is by no means a Fern. In a wild state it is found sterile hills from New England, Virginia, to Wisconsin and northwards, The following memorandum occurs in Hortus Collinsonianus:-" Received from JOHN BARTRAM, January 22, 1756, three roots of Gale, with Spleenwort leaves. It makes a fine tea, and gives a good flavour to beer used as Hops," would appear from LOUDON, however, that Comptonia was introduced to this country in 1714. The generic name was given by SOLANDER in honour of IIENRY COMPTON, Bishop of London, the introducer and cultivator of many curious exotic plants, and one of the greatest patrons of botany and gardening of his

- BALANTIUM ANTARCTICUM .- There is now in the Zoological Gardens at Rotterdam a specimen of Balantium antarcticum, the trunk of which measures upwards of 21 feet in height, its girth at 1 foot above the tub heing rather more than 6 feet, whilst the total height from the top of the now but slightly ascending fronds to the bottom of the tub is above 28 feet. Altogether it is one of the largest specimens -if not the largest one-ever imported, and is certainly the largest in Holland. It was hought in 1879, not long after being imported, and ever since has enjoyed good health-in fact, last spring it threw up thirty-nine new fronds, and it is stlll adorned with a good number of a former year's growth. In the same gardens an Alsophila australis attracts much notice. as it has formed six branches, which seem to start from the same point, and are now, with one exception, about I foot long.

--- THE POLLUTION OF THE THAMES.-A deputation representing the inhabitants of Kew and

Richmond recently had an interview with the First Commissioner of Works to complain of the proposed erection of sewage precipitation works at Kew. The speakers contended that the works would do a great deal of injury to Kew Gardens, and would materially affect the welfare of Kew and Richmond. The scheme provides for the pumping into the Thames of 5,000,000 gallons of sewage daily. Ham would undoubtedly be a most fitting place for the erection of such works, because there was not such a large residential population. Mr. SHAW-LEFEVER, in reply, said the only question was whether all the sewage should be pumped in at one place or at three or four different places; but anything likely to injure Kew Gardens would receive his careful consideration.

A MEMORABLE TREE,—During the recent gale one of the most noted trees in Sherwood Forest fell a prey to the wind's violence. It was known as the "Major Oak," and was situated near Edwinstowe. The tree, a grand old Oak, had a girth of 28 feet, and "the circumlerence of the outspread tree at the utmost extent of its branches was 240 feet, It was at one time, says the Daily News, called the Cockspen Tree, because its interior was used formerly as a hen-roost. Latterly many pic-nic parties have gathered in the hollowed-out trunk, and in a history of Worksop the following reference is made to the tree:—"Seven persons at once have been known to partake of a meal in it; while no doubt with a little contrivance it might have accommodated more." Notwitstanding its internal decay, the old Oak (which had existed for more than seven centuries) was one of the noblest trees in the kingdom."

- Undressed Flowers at Exhibitions .-One result of the establishment of a National Chrysanthemum Society has been the reception from not a few lovers of the Chrysanthemum of requests that undressed flowers should be encouraged as far as possible at the Society's exhibition in November. appears a very easy matter to provide classes for these, but how is such a regulation to be applied? How can it be expected that judges should know how much or how little dressing has been applied to a Chrysanthemum bloom? Old Chrysanthemum cultivators say that the request for undressed flowers cropped up years ago, and classes were made for them, but it was lound that the judges always gave the prizes to the best flowers, and trusted to the honour of exhibitors. But no one could undertake to say that a flower placed on the exhibition table had been dressed, or not been dressed. Dressing may be said to consist in so arranging the petals of a flower as to make it appear as symmetrical as possible, and it is obvious that a clever dresser has an advantage over one that is not so expert at this work. Nothing should be added to a flower. but it is lawful to take from it superfluous or damaged petals, and flowers are greatly improved by this pro-Who could venture to say that a flower had been so touched? And in the case of some varieties of Chrysanthemums it is possible to grow them so approximately perfect in shape that little, if anything, in the shape of dressing is required. It would be hard if a judge were to assert that such a flower had been dressed. However much one may desire to encourage as far as possible a mode of exhibiting that dispenses as much as possible with anything in the way of dressing, yet it is not so easy to prohibit the practice as is imagined. Any suggestions that may lead to this desired end are always welcome, if they are practical. It has been remarked that but little dressing is required in the case of the Anemone. flowered section, but we were recently informed by an old grower and exhibitor that there is no class of Chrysanthemums that can be so greatly improved in appearance by dressing as the Anemone-flowered Chrysanthemums,

— FOREST FLORA OF JAPAN.—This, according to Dr. YARONN NAKANURA, may be divided into five zones, according to altitude, as follows:—(1) Zone of Pines, reaching to a height of 1500—1600 feet. In the lower part, Pinus Massoniana, with evergreen Oaks, Quercus glauca, Q. glabra, Buxus sempervirens, &c. Above these Pinus densiflora, Zelkowa Keaki, Gingko biloba, Sophora Japonica, Populus Sieboldi, Ilex crenata, &c. (2) The zone of Cypresses, from 1500—3500 feet. Here occur the Retinosporas obtusa, pisifera, Podocarpus macrophylla, P. Nageia, Sciadopitys verticillata, Torreya nuclifera, &c. (3) The zone of deciduous trees, from 3500—5100 feet,

In this zone occur Magnolia hypoleuca, Alous campestris, A. maritima, Juglans Sieboldiana, Acer palmatum, A. crattegifolium, &c. (4) Zone of Firs, extending from 5100—7200 feet. At the lower part occur Abies firma, A. Tsuga, and Larix leptolepis; while above occur Abies Veitehii, Picea Alcockiana, P. polita, &c. (5) Zone of Alpine Pines, from 7200—8400 feet. In this zone grow Pinus parvifora, Alnus viridis, A. firma, Betula alba, Sorbus aucuparia, &c.

- TOXICOPHLEA THUNBERGII .- Like many more of the Dogbanes this is possessed of a poisonous milky juice, otherwise it is a beautiful free-flowering shrub of some considerable size. The flowers may be likened to those of a Bouvardia in shape, but are very much smaller, pure white, and produced in dense, sub-sessile, axillary clusters, all along the shoots of the previous season. They keep up a succession from February to April, and the delicious odour they diffuse through a house, especially when the sun shines, is alone a sufficient recommendation for admitting the plant to any collection of stove-flowering subjects. It differs from T. spectabilis in the shorter propor tionately broader leaves, and the more elongated branching flower-cymes. T. Thunbergii was intro duced as long ago as 1787, but has flourished under a rather labyrinthine synonymy. Besides the above name it is described or recorded under the names of Cestrum venenetum and Acokanthera veneneta, while the Genera Plantarum adheres to Acokanthera, and limits the genus to three species.

· PINGUICULA LUTEA.-We have recently had sent us to name specimens of this wonderfully pretty species. Nearly seventy years ago it was in cultivation in this country, for a characteristic figure is given in the second volume of the Botanical Register, tab. 126; in all probability, however, the plant was soon after lost to English gardens, and so its re-introduction deserves meation here. P. lutea is undoubtedly one of the handsomest species of a genus which embraces a good many very showy plants; it has deep glossy yellow flowers, from I to II inch across, borne on scapes from 6 inches to I foot in height. The rounded lobes of the corolla, being rather deeply 2 to 4-cleft, give a particularly distinct and striking aspect to the large brightly coloured flower. No more charming companion plant could well be imagined for the Mexican P, caudata, which, with its large deep bright violet-purple flowers caused some little sensation when first exhibited a year or two ago at one of the meetings of the Royal Horticultural Society by Messrs. SANDER & Co. A figure of this species, with the name under which it was exhibited, P. Bakeriana, is given in our columns for 1881, vol. xv., p. 541, and another will be found in the Botanical Magazine, tab. 6624, under the correct name of P. caudata. No doubt the same treatment which proves so successful for P. caudata will do for P. lutea. The gentleman who has re-introduced the latter species writes:—"I found the flower very common in Florida, growing with two other species, wherever there was a patch of marshy ground among the sandy soil, but never in the very wet marshes.

They were in flower from the middle of February to the middle of March, when I left the country. too probable that P. edentula, which was cultivated at Kew in 1823, and is figured in HOOKER's Exotic Flora, tab. 16, has also disappeared from cultivation. This last was sent to Kew from Savannah, and is remarkable for its paler yellow almost regular

- NEW ANNUALS .- In this season's issue of Messrs. VILMORIN-ANDRIBUX ET CIE.'s list a new white Eucharidium is highly recommended for flower garden purposes, and also as a plant for pots. belongs to a very useful class of annuals, which are well adapted to a variety of uses in flower garden and window decoration, especially in those positions where only subjects of quite moderate dimensions are required. Partaking of the general characteristics of the Clarkias, being as abundant flowerers, but smaller in all their parts, and very lasting, they are capital things for spring and early summer beds, as are all the varieties of Clarkia as well, although we do not see them so much grown as they once were. When sown early in September in a cool frame or out-of-doors in a warm position, and then pricked off into pots when large enough, and kept in a cold frame and treated after the manner of Carnations, they will be in good order to plant out in March and April.

Managed in this way the Eucharidiums flower beautifully and last longer in flower than when they are sown in May in the open border, and got to flower in the hottest part of the summer. A double white Eschscholtzia is also to be found in the above mentioned list; this should form a capital contrast with E. Mandarin, if the plant should be found to answer the description giveo of it; and as the genus does well io most parts of the country, it will be an acquisition in hardy border annuals. It is said to be very flotiferous, earrying its blooms in bunches,

TEA CULTIVATION IN AMERICA.-From experiments that have been made in the cultivation of the Tea plant in North America, it seems scarcely to be expected to become a profitable crop : not that the plants do not thrive, but that the Tea itself, as prepared for the market, lacks strength. It seems to have been in the latter part of the year 1879 that the cultivation and manufacture of Tea was taken up in earnest at Summerville, in America, by a thoroughly practical and competent person, who had previously had considerable experience in the Tea plantations in British India. The plants grew well, and in the spring of 1880 the attempt at preparing or manufacturing the Tea was considered encouraging. The make and appearance of the Tea were all that could be desired, but it was found upon testing it that it was very deficient in strength. This, it was thought, might be remedied by special attention being given to the plants, and they were consequently carefully pruned and manured, with a result of a most satisfactory growth and fine crops of leaves. Upon again being tested by experts, the Tea was found equally deficient in strength, so that it is considered that if Tea is to be grown in America the State of Florida must be looked upon as presenting the most favourable conditions. The United States Economist recommends its cultivation as supplemental to other agricultural enterprises, "Each farmer," it says, "may raise enough for his domestic consumption, for ten or twelve trees will furnish enough Tea to meet the wants of a family of eight persons; the labour to cultivate a few Tea plants would only absorb the odds and ends of a farmer's time, which might otherwise go to waste."

— PRIMULA LONGISCAPA, Ledeb., is a species found on the Altai and Ilithal Mountains, having radical tufts of long-stalked, spatulate, entire, glabrous leaves, from the centre of which rises a scape 8—10 inches high, bearing a terminal umbel of small rose-coloured flowers, the petals of which are very deeply two-lobed. It is, according to REGEL, who figures it in the Gartenflova, t. 1132, the same species as that called intermedia in the Bot, Mag., t. 1219.

--- CHAMÆDOREA SCANDENS. -- Throughout this large and varied genus we have a considerable number of types of greater or less value for horticul-tural or ordinary decorative purposes. Generally they are characterised by slender reed-like stems, which often require support after they have attained The most remarkable feature noticeable in this species is the manner in which the leaves hang down as if fractured near the base. A few of the lower ones retain their arching habit, and the young ones before expansion grow erect, so that we have in this one of the many instances of an expedient in Nature by which slender subjects like this can scramble up through forest vegetation, and by the after deflection of their leaves maintain their position. A tall specimen in No. 1 house at Kew, with its branching scarlet spadices and olive-green fruit, is by no means unornamental.

— THE BLACK BEARBERRY (ARCTOSTAPHYLLOS ALFINA).—This rare and interesting native shrub, although not by any means difficult to manage if allowed certain conditions, is not at all frequent in British gardens. At Kew it succeeds very well among stones in a rather dry elevated peat border. It requires an airy position, and is somewhat averse to shelter, being a native of cold or mountainous countries. In Scotland it occurs on dry barren mountainous places from Perth and Forfar northwards; the extra British distribution being Arctic Scandinavia, mountains of Central Europe (just below the snow line), and cold and Arctic Asia and America. Under the old name of Arbutus alpina, Franklin, in his Journey to the Shores of the Polar Sea, says he found an abundance of the fruit to which the natives

gave the name of Magpieberry; the traveller and bis companions found this an agreeable article of food. The plant forms stout woody interlaced patches, with leafy branches and scaly bark; the wrinkled serrated deciduous leaves are much unlike those of the common Bearberry (A. Uva-ursi). The black fruit, about the size of a Sloe, is ripe in September, and has a taste somewhat resembling that of black Currants. The alpine or black Bearberry is the badge of the Clan Ross.

- THE GOLDEN ELDER is, without doubt, one of the best of all "pictorial shruhs." A clump of this form of our common native Elder makes a mass of rich colour not surpassed, or indeed perhaps equalled, by any other hardy deciduous tree. The richest tints are assumed by plants which are annually cut in, and either as a single plant dotted here and there in the pleasure-ground, shrubbery, or planted in a clump for more decided effect, the Golden Elder so treated is unique. In its way it is quite as good as the purple-leaved variety of the common Hazel-nut, which likewise is capable of being used with great effect by the landscape gardener. A cut-leaved form with green leaves is a very ornamental shrub, as is also a white variegated sub-variety; this latter, however, is very subject to revert to the one with green soliage.

READING HORTICULTURAL SOCIETY.—
What is termed the spring show of this Society will take place on Thursday, May 15, and the summer show on Thursday, August 21. The Chrysanthemum show held last year by the Society will be continued this year also, but will be managed by an independent committee. The Reading Society has apparently discovered, in common with other societies, that it can hold two exhibitions and make them pay, but that the addition of a third is too heavy a burden to be borne.

- THE WEATHER .- General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending Feb. 4, 1884, issued by the Meteorological Office, London:—The weather has been very cloudy or dull over the whole kingdom, with a good deal of rain in most places. The temperature has been above the mean in all districts, the excess over central, southern, and eastern England being as great as 4° or 5°. The maxima, which were registered on as 4 or 5. The maxima, which were registered on January 29 or 30, varied from 52° in "Scotland, W.," and the "Channel Islands," and 53° in "Scotland, E.," and "Ireland, N.," to 56° in "England, S.," while in "England, E.," and "Ireland, S.," the thermometer rose to 57°. The minima were recorded on February 3, and were generally rather lower than of late, ranging from 24° in the "Midland Counties" to 29° In "Ireland, W." In the "Channel Islands" the temperature did not fall below 34°. The rainfall has been about equal to the mean in Ireland and the east of England; but more in all other districts. Bright sunshine has been less pre-valent than during last week. In "England, N.E.," there was none at all; but elsewhere the percentages of possible duration ranged from (in "England, S.") to 24 (in "Scotland, E."). Depressions observed :- During the greater part of the period some large and deep depressions passed from west to east, to the northward of Scotland and over Scandinavia, so that the prevailing winds in our islands were south-westerly or westerly. On the morning of the 2d, however, a rather deep depression appeared over the south of Ireland, and in the course of the succeeding twenty-four hours its centre passed in an east-south-easterly direction across the Channel and south of England. During its passage the wind increased to a fresh or strong gale at all except our extreme northerly stations, from north-east or north in the north-west, north, and east; and from south-west, and subsequently north-east, in the south and south-east. As this disturbance passed away from our neighbourhood the barometer rose with great rapidity at the southwestern and southern stations, and by the end of the period an anti-cyclone had been formed over France.

— GARDENING APPOINTMENTS. — Mr. W. SHERWIN, late of Charlwood, Huyton, Liverpool, as Gardener to Sir Andrew B. Walker, Osmaston Manor, near Ashbourne, Derby.

CINCHONA IN THE NILGIRIS.

SITUATED on the south-eastern slope of the Nilgiri Hills at the top of the Auchterlony Valley, and directly overlooking the Wynaad and Mysore districts, are the Government Cinchona plantations at Nedi nultum. These plantations, about 20 miles distant from Ootacamund, have hitherto furnished the principal supply of Cinchona bark exported from southern India. The plantations are three in number, viz., the Nedinultum estate, the Wood estate, and the Hooker estate—the latter named, I believe, in compliment to the present Director of Kew Gardens. The amount allowed by Government for the keeping up of the plantations has of late years been principally expended on the Nedinultum plantation, the two others being at present in a semi-abandoned condition, mainly attributable to the fact that the surface-soil containing the rich vegetable humus so essential to the growth of the Cinchona has been nearly all washed away by the heavy rains of successive seasons, and no regular attempt has been made at improving the soil by applying manure or any fertilising matter.

The Nedinultum plantation consists mainly of the red-bark tree, Cinchona succirubra, but contains likewise a good sprinkling of the crown bark, C. officinalis, and grey bark, C. micrantha, as well as C. pubescens, a well marked hybrid between the two former, and a few C. Calisaya, a group containing such a host of sub-varieties and forms merging more or less into each other as to have formed the basis of a never-ending controversy concerning the proper name due to each particular form; and it is needless, perhaps, to add that the names applied or suggested are almost legion, whilst each fresh one only adds to the existing confusion.

Two well-built bungalows exist on this estate, as well as two of smaller dimensions for the use of the clerks and assistant overseers, the extensive drying sheds being well worthy of a visit. Here the Cinchona bark, after being collected from the living trees by the alternate stripping system, or the Java process of scraping or uprooting, is dried by fire-heat, and securely packed in bales of 100 lb. each, and marked ready for the market. A new system of drying and packing houses is now in course of completion, the main building being filled with bark on the occasion of my visit for the first time. Owing to some defect in the building of the flues generating the dry heat necessary to cure the Cinchona bark, the fires did not draw satisfactorily, and the flues not being properly set, had burst, filling the building with smoke, much to the deterioration of the bark contained therein, the brickwork and woodwork in general having been done by cheap contract labour improperly supervised, leaving much to be required before the buildings approached perfection. Near the drying sheds is erected a long span-roofed propagating-house, heated also by flues; this is used principally for the propagation of C. pubescens and C. Ledgeriana, thy latter taxing the abilities of the officials to the uttermost from its shyness of propagation when in the younger stages of growth.

Fully one-third of this plantation has been uprooted during the last two seasons, and is now being replanted with C. pubescens, a fact which speaks highly for the far-sightedness of the manager in charge, as undoubtedly this will be the Cinchona of the future. At the elevation of 5000 feet-the altitude of the Nedinultum estates-in a plot well sheltered from the south-east monsoons, were to be seen two fine specimens of the "hard Carthagena" Cinchona, C. cordifolia, introduced to the Nilgiris by Mr. R. Cross, in 1880, from South America. These were fine sturdy young plants, upwards of 4 feet in height, the result of eighteen months' growth. It is a matter for regret that no energetic attempts have been made to extend the number of plants of this new kind, or that of its fellow novelty, the Calisaya of Santa Fé, not more than thirty or forty being alive at the present time, although most easy of propagation-private planters, from some unaccountable misunderstanding, being denied plants of these species when they apply to the responsible authorities for them, even though they may possess every appliance for propagating them successfully and extensively. Three or four large nurseries are kept well filled with plants and seedlings for supplying the estate and neighbouring planters who purchase at the very moderate rate of 5 rupees per 1000. W. 7. Kemp.

JAMES GRAY.

WE are indebted to Mr. Alfred Gray or the opportunity of presenting our readers with a portrait of his father, the late Mr. James Gray, of Danvers Street, Chelsea. Mr. Gray, who died in November last, was, it will be remembered, one of the oldest members of the horticultural building trade, and for his many good qualities was very highly respected. Further particulars respecting Mr. Gray's career will be found in our issue for December 1, 1883.

Home Gorrespondence.

Masson's Drawings of South African Plants.—In hunting up some references for certain South African Orchids, I lately came upon the following interesting note in The Yournal of Science and the Arts, 1818, vol. iv., p. 199, relative to some drawings brought by Masson from the Cape:—"Mr. Francis Masson, the late intelligent and industrious collector of plants, while procuring supplies for Kew Gardens, unexpectedly met with, among the Dutch soldiers who guarded that colony, an artist of great skill as a designer of the objects of natural history. Availing himself of this circumstance, he formed a considerable portfolio of coloured drawings of the samples of the more curious objects of his pursuit, and especially of such as he deemed most refractory to exotic transplantation. They have since been added by Sir Joseph Banks to those treasures so long regarded throughout the world, to their possessors and our own country's honour as the best friends of science." Where are these drawings now? The above would seem to imply that they should be in the Banksian collection now in the British Museum, and it would be interesting to know if this is the case. In the volume of the work from which the above is quoted, and in several of the succeeding volumes, are some coloured plates of Cape Orchidis, said to be copies of some of the drawings above alluded to, and probably the plates in Masson's Stapeliae Nova are from the same source. N. E. Bresum.

Ficus australis.—This useful decorative plant is as well worth attention as F. elastica, which it much resembles. The full-grown follage is nearly as large as in that species, but hardly so pendulous, colour and habit being similar. The terminal buds are sheathed in a green envelope, instead of a red one, as in F. elastica. The plant will endure ordinary greenhouse temperature at all seasons, is easily grown, and suffers from no insect pests, so that it is eminently suited for room decoration. M.

Luculia gratissima,—When visiting my neighbour, Mr. Harris, at Alnwick Castle, the other day, I was delighted to see a grand plant of Luculia gratissima in full flower; it had upwards of forty trusses of bloom, which I could compare to nothing else than large trusses of Hydrangea, growing on one of the pillars of the large conservatory, which was very gay with Azaleas and other flowering plants. It was a very pleasing sight indeed. From its profuse flowering Mr. Harris was rather afraid it indicated weakness, but to all appearance the plant showed no signs of unbealthiness. There is much to write about from this fine place, but I will only add in particular that the fine collection of Orchids which has been got together of late years are in the best of health; and under the direction of such an able chief as Mr. Harris we may expect to hear more of it in future. D. Inglis, Howick.

Squirrels and Lime Bark,—For some time past I have been puzzled to account for the white-barked appearance of the branches of Lime trees in the park here, but it is no longer a mystery, for on examinoing the nest of a squirrel to-day I found it almost entirely composed of the bark of this tree torn into shreds, These little animals are also very destructive to the young buds of the Horse Chestnut, and on several occasions we have had to use strenuous measures to stop their depredations, A. D. Webster.

Thrips and Red-spider. — A novel way of getting rid of these pests on Azaleas was adopted some years since by a nurseryman in the neighbour-hood of Brixton. His plants had become, through great neglect, so inlested with these insects that they threatened to cast the whole of their foliage, the loss of which would have been followed in that case with that of the flower-buds; so means had to be found to touch them. Doses of Gishurst Compound and tobacco-water (paraffin was not known then) were syringed on them, they being too big for sousing overhead in a tub; but the effect was nil. Smoking could not be thought of, owing to the fearfully dilapidated condition of the worthy proprietor's houses, so as a

kill-or-cure remedy worthy of the owner, whose idea it was, the whole collection was thoroughly coated with limewash in a dilute form syringed on to them two or three times, always waiting a day or so to let one coat get dry before giving them the next. The remedy was a drastic one, but it was effectual, the plants losing but few more leaves, and no bloom-buds. After remaining on for a fortinght or more the plants were taken out-of-doors and well washed with the aid of an engine whilst lying on their sides, the coating of lime bringing away with it dead insects that had been suffocated, the eggs, and all deposits. M.

Violet Empress Augusta for Forcing. — Amongst the Violets of recent introduction, all of which claim the possession of better qualities than the older ones, I know of none which can rival Empress Augusta in any way. It was exhibited for the first time at the Berlin winter flower show in January, 1852, by Messrs. A. Rathke & Son, of Praust. All who saw it there were surprised at its striking beauty, and, indeed, one can scarcely imagine that any Violet could be so perfect. We have cultivated it since its introduction, and have thrown all the other sorts away. With us it has been flowering since September (of course, in different batches), and

ample justice. With the production of it he had nothing to do, I thought the Pelargonium Society had a rule compelling the exhibitor to affix the raiser's name when showing a new flower. It was not followed in this case. *The Raiser*.

Ivy and Box Propagation.—It is sometimes required to produce Ivy in great numbers for use in the flower garden, such as patches, edgings, and the like. To buy the plants would be an expensive item. Plants of Hedera Helix, dug up in woods, seldom look well the first season, if they live at all, so that propagation from the shoots of plants on walls, &c., alone remains. If a mild hot-bed from leaves, or from old hotbed material mixed with fresh dung, so as to afford a gentle heat, were thrown together, and a frame put over, a good assistance will be obtained with which to begin the work of multiplying stock. Some boxes (Pelargonium boxes) should then be filled with sandy soil, and the Ivy cuttings, cut to 5 or 6 inches loog, dibbled in them. As the boxes are filled put them into the frame, if the rank heat and steam have declined. The frame will require ventilating in the morning between 9 and to o'clock to get rid of the extra amount of moisture that accumulates in the night. Shade must be given when the

THE LATE JAMES GRAY.

it will continue to do so until the plants out-of-doors come in. The flowers, which appear in rich abundance, are thrown up about 2½ or 3 inches above the leaves, all at the same height; they are of a very beautiful dark blue, and of bold habit, the stalks being nearly as robust as those of The Czar, but straighter. Empress Augusta is said to be the result of a cross between V. russica and V. semperflorens, and indeed it possesses the good qualities of its parents, vir., the beautiful flowers and the ability of bearing early forcing of the first and the abundance of flowers of the latter in a much enhanced degree. We have had young plants with more than forty flowers at once in bloom. Frite Lenz, Danzig.

Honour to whom Honour is Due,—As a "Son of Thor" I wish to know why the "hardworkers" in the paths of floriculture do not get the credit of their labours. Your notes on "The new flowers of the year" have led me to ask the question. It is there intimated that "the singularly novel" Pelargonium "Dresden China" is a production of Mr. Turner. As the same statement has frequently occurred, and as precisely the same thing also occurred with another excellent seedling of mine, The Maid of Kent, I suppose it will always be size was non vabis mellificatis apes, but Dresden China was merely sent to Mr. Turner as an old friend, and as one who, I knew, would do it

sun shines between 10 A.M. and 3 P.M., then sprinkle lightly, and close the frame till 6 P.M., when a thin wedge may be placed under each light for the night, and the frame be covered up. If this work is undertaken in February or early in March the plants ought to be potted, hardened off, and ready to make use of late in April. Ivies may be struck in autumn, under the cool treatment, by beginning with the work in September, using the same soil-boxes, e., and putting them into close cool pits or frames till rooted, which may occur any time during the winter. Attention must be given to airing, watering, but shading will most likely be dispensed with. Cutings of Box are also successfully and quickly struck on the cold plan at the same time of year, but heavy sandy loam is the better soil for them, as they must be kept uniformly moist till struck, when they may be at once planted in the open ground. M.

Dracæna Goldieana (see Enquiry, p. 155).

—My experience of propagating the above is as follows: — Two years ago I cut down a plant 3 feet in height, which had lost its lower leaves. The top (about 1 foot long) was put in a 48-poi in the usual way, plunged in bottom-heat of 80 to 90°, and covered with a handglass; the leaves were supported with sticks bent like a hairpin, and care taken as to shading, &c. It rooted in three months, and only lost one of the lower leaves. I

potted it on, and it is now 3 feet 6 inches high, over 2 feet across, with leaves 7 inches in diameter, and it will soon require cutting down again, as it has not thrown out any laterals. I also put in five eyes, and of these three rooted, two of which had two suckers each. T. E.

Asplenium Adiantum nigrum var. caudifolium (Woll.).—This is a new form, uamed by Mr. G. B. Wollaston, but found by the writer in July last in the Dartmoor district, where some yards of a stone though its spores must have been scattered freely, I could not find a single plant of it outside the range of some yards, where it not merely predominated, but, as I have said, quite monopolised the space indicated—a fact which points to some subtle local influence, for which, however, it is difficult to account, the whole dyke being apparently similarly built and circumstanced. Singular to say, I was attracted to the find by seeing a markedly caudate frond belonging to an intermediate and non-depauperate form, which proved to be the sole plant of its kind in the batch.

coral colour, free from the corrugations so remarkable in A. Andreanum." The spathe varies in colour according to age, or perhaps differs somewhat in different individuals, for we note that while the first specimen we saw was described as above, another in the Royal Gardens, Kew, is stated to have had spathes of a peculiar deep red colour, while in the plant from which our illustration (fig. 37) was taken the spathe was of a shining rosy-lilac colour. The spadix is vory-while, flushed with rose. Our illustration was taken from a plant in Messrs. Veitch's nursery.

Mildew or Fungus on Imported Lily Bulbs.
—For several years I have supplemented my homegrown stock of Lilies, by additions from imported Japanese. Almost invariably after being put into the soil the scales, and often the base of the bulbs, get attacked with a species of fungoid rot, often in patches over the scales, sepecially in spots, that seem as if bruised. I take it for granted you have seen it already, otherwise I should forward you some decomposing scales. Now it seems not to be produced by moisture, nor yet by dryness, nor by a high nor a low temperature, for I have tried all. As a rule, I did not lose many, and have to thank the vigilance I used in at once cutting away any diseased part, and immediately dusting it with charcoal or very fine dust. I would strongly recommend in case of pot Lilies, that are accessible, to examine them until started into active growth, once a week. From the fact of homegrown Lilies—I have auratum specially in view—not being thus attacked, I conclude this fungus is not native. What do other observers say? W. T. M., Clonnel. [If our correspondent will plunge his newly-imported bulbs in cocoa-nut fibre out-of-doors, and not pot them until they commence to grow, he will not lose any, presuming that the bulbs are sound. Ed.]

Canker in Fruit Trees.—I have carefully read the remarks on this subject at p. 150, and also Mr. Harrison Weir's letter at p. 152. At p. 150 refer-ence is made to various kinds of fruit trees, but I take the remarks on this subject at p. 150, and also Mr. Harrison Weir's letter at p. 152. At p. 150 reference is made to various kinds of fruit trees, but I take it that Mr. Weir alludes to the Apple tree only. If the question is narrowed down to one kind of fruit tree only, and that the Apple, I I acrog gardeners in that case are only too well acquainted with canker. I'we receive from gardeners at least three different diseases as canker in Apple trees, and believe the term to be very indefinite. Eb.] How it is caused is a question that has often been asked, and the answer has always been, "By the roots getting down into unsuitable soil." In what way does the unsuitable soil." In what way does the unsuitable soil." Is mother question that may be fairly asked. I do not know whether scientific inquiry has gone so far as to answer it; indeed, if Mr. Weir is right in his surmises, further inquiry into the vitating nature of the subsoil would be superfluous. I have always acted on the assumption that the evil lay at the roots, and the question arises again—How is it that cutting the roots running into the subsoil, and adding fresh loam for the new fibres to work into, stops the progress of the canker? I can give many instances of this. When I first took charge of the gardens at Loxford Hall there were many veryold Apple trees, and some younger ones. Now nearly all the young trees were badly cankered, a few of the old ones also; while some old trees were not cankered at all. The young trees had been lone by merely digging a hole large enough for the roots, filling in the same soil again. I am sure many experienced gardeners will hear me out when I say that Apple trees planted in this way amongst old ones seldom do well, and very often canker badly. That it was so in this case there is no doubt. By a different system of managing the soil I found an difficient system of managing the soil I found an difficient system of managing the soil I found an difficient system of managing the soil I found an difficient system of mana ones seldom do well, and very often canker badly. That it was so in this case there is no doubt. By a different system of managing the soil I found no difficulty in preventing canker, with two or three exceptions, to be referred to hereafter. I planted about one hundred Apple trees, both on the Crab and Paradise stock. The first operation was to trench the soil about 18 inches deep, and in doing so a barrowload of soil from an old pasture was put into each trench 9 feet long by 2½ feet wide. Some rotten manure was also mixed with it. When the trees were planted, some fresh loam was placed round the roots. They did remarkably well the next season, making strong clean growths. The following season lagain lifted the whole of the trees, re-trenched the ground, adding the same quantity of loam, and on planting the trees the same quantity of loam, and on planting the trees the same quantity of loam was placed round the roots, and during the twenty years I was there the only cases of canker occurred in two trees of the Wellington (or Dumelow's Seedling), and in a tree of Ribston Pippin; all of the cankers occurred in the canker occurred in the canker of the cone year, and the other side the following season, taking away the old soil and adding fresh to it. The canker was stopped, and the fruit, which had also deteriorated in size and quitty, was greatly improved. If insects are the primary cause of canker, how does it happen that those planted on prepared and recovated soil are free from it,

FIG. 37.—ANTHURIUM FERRIERENSE X: SPADIX VERY PALE ROSE: SPATHE PALE ROSE, OR PINK-CORAL COLOURED.

dyke had been monopolised by it, to the entire exclusion of the normal form, which grew in profusion all over the rest of the dyke. Amongst several hundred plants I have failed to discover a mature frond which does not show at least two or three yellow lobes at the point of greatest depauperation, while the caudate termination is very evident, even in small seedlings. The pinoæ also show a strong tendency to partake of the caudate character of the apex of the frond. From the great number of plants I found, and the fact that amongst them no normal seedlings were discoverable, it would seem that in some way the variety is more vigorous than the normal form, and able to oust it; yet, on the other hand,

It was much handsomer than caudifolium, but under cultivation has reverted altogether to the normal form, while caudifolium proves quite constant. Chas. T. Druery, Fernholme, Forest Gate.

Anthurium ferrierensex. — In March of last year this plant, stated to be a hybrid between A. Ornatum and A. Andreanum, was shown at one of the meetings of the Royal Horticultural Society, when it obtained a First-class Certificate for its raiser, M. Bergmann, of the gardens fat Ferrieres. "The leaf-stalks are terete, with a thickened extremity, bearing large cordate ovate leaves with remote venation, and spathes of a lustrous pink-

while they were badly injured in every case on unpre-pared ground? As soon as trees do become cankered, the ruptured bark becomes a hiding-place for many insect pests, which spread from thence to other parts of the trees. American blight frequently finds a home in the cankered parts, indeed this pest often causes protuberances to arise on the smooth bark of young trees, and this part in time forms an obstacle to the flow of sap, and also forms something very like

young Irees, and this part in time forms an obstacle to the flow of sap, and also forms something very like canker. 7. Dong/ats.

—It will be interesting to learn what the entomologists have to say to Mr. Harrison Weir's theory as to the cause of canker in fruit trees. It is significant that from the same side of the Thames the late Mr. Smee put forth his ingeolous but strangely inexact theory that an insect, the Aphis vastator, was the cause of the Potato disease, and which was about as true as it would be were I to say that earthworms are the cause of the Hotato disease, and which was about as true as it would be were I to say that earthworms are the cause of earthquakes. Nothing in the diagnosis of diseases of all kinds seems to be easier than the mistaking of effect for cause. An old and respectable authority on canker has said that in trees it is allied to ulcerous diseases in man and animals, and arises chiefly from a plethora of crude or unhealthy sap. That may be so or not, but it is certain that very many practical gardeners have attributed canker to that particular cause, produced by the roots getting into soil that was sour or unfit to sustain plant life in a healthy condition. But a few winters since, when the intense boar frosts wrought such havoc amongst our hardy fruit trees, killing whole ones here, and half killing others there, and disseminating canker in all directions, there came a conviction that, after all, cold was the primary cause of the old affection, but that, owing to attributing it to other causes, the right one had been overlooked. That insects produce this diseminating candler in all directions, there came a conviction that, after all, cold was the primary cause of the old affection, but that, owing to attributing it to other causes, the right one had been overlooked. That insects produce this disemption of the cellular tissue of the bark and it is far more probable that the injuries are caused by some disruption of the cellular tissue of the bark by sudden changes of temperature or sharp frosts, or, by suden changes of temperature or sharp frosts, or, after all, it may be that crude immature sap has formed tree ulcers that, having burst, have produced that which we term canker. Z. [Until the matter has been thoroughly investigated from the very beginning, through all its stages, by some competent microscopist, it appears to us that all conjectures are more or less vain. Ed.]

Mildness of the Season in South Wilts. The least observant person who happens to live in the country far away from the noise, bustle, and turmoil of a town life can hardly fail to notice at the present time the advanced state of outdoor vegetation present time the advanced state of outdoor vegetation and of other signs affording evidence of the unusual and abnormal character of the season. Fruit trees are fast swelling their buds, and some kinds, notably Apricots, Peaches, Nectarines, and Pears bid soon to show us the nature and colour of their soon to show us the nature and colour of their petals if the weather continnes in its uninterrupted course much longer; whilst Rose trees and a few other subjects have already young shoots I inch or more in length. Of early spring flowers there is quite a wealth, The undermentioned flowers are to be met with in this locality at the time of writing, many of which are, comparatively speaking, plentiful, viz:—Violetts, Primroses, Polyantus, Snowdrops, Crocus, Ficaria verna, Hepaticas, Helleborus, Wallflowers, Arabis albida, Forget-ment, Isaminum mudiforum, Berberis amifolia, and Helleborus, Wallflowers, Arabis albida, Forget-menot, Jasminum undiflorum, Berberis aquifolia, and Laurustinus. Amongst other signs of the unusual character of the season are the notes of our feathered songsters, and to realise this to its fullest extent one has only to go through the woods and plantations at early dawn. Although one cannot refrain from admiring the joyous songs of these harbingers of spring and the abundance of early flowers, it is perhaps as well to remind the unwary of the fact that there is plenty of time between this and the end of next month for severe weather, and he would do well next month for severe weather, and he would do well not to be over-naxious with regard to planting and seed sowing, but to be on the alert, and fully prepared for any emergency by being able to afford protection whenever it becomes necessary to all such things as require it. J. Horsefield, Heytesbury, Feb. 2.

Flowers In and Out of Season .- Not only do we hear of various kinds of birds nesting and mistaking the season through the mildress of the weather, but many plants are flowering long before their usual time, and to-day (Jan. 24) quite a nosegay might be gathered by taking a short walk outdoors in the garden, where I noted the following:—First, and most welcome, was the Honeysneckle (Lonicera fragrantissima), which, growing on a pier at the end of a southest wall, is quite covered with fresh pure blossoms, so sweet as to perfume the air with their odonr. Near by, occupying the same kind of position, are two plants of Garrya elliptica robed with their elegant drapery of long flowing catkins, which, seen drooping and dangling in the wind, with the dark foliage behind, have a most striking and pleasing effect. On the same wall a bloom of the fine old Magnolia grandiflora has been struggling to open, but in the absence of sum it has had a hard task, and now looks as if it can get no further, so tight and close are the folds of do we hear of various kinds of birds nesting and mis-

its petals. Standing close by M. purpurea is fast swelling its buds, which it usually forms in great quantities, and is one of the first harbingers of spring, as it is always early in unfolding its blossoms. Another plant that seldom fails to reward one for a search at this season is the Chimonanthus fragrans, search at this season is the Chimonanthus fragrans, the flowers of which we have had for some time, and which, though dull in appearance, have a delicious perfume that make them in high favour with all. While on sweet-scented flowers, I must not forget to mention the Tussilago, spikes of which I have just gathered standing up quite naked ont of the ground, where, with their big heads of bloom, they looked very forlorn and conspicuous, and I felt I could easily forgive myself breaking them off and bringing them indoors, where they are rewarding me now with their fragrance, which is almost could to some the same they are rewarding me bringing them indoors, where they are rewarding me now with their fragrance, which is almost equal to that of the Heliotrope; and with this to recommend them the wonder is that the Coltsfoot is not more grown for cutting from, especially as it will succeed almost anywhere in light soil where its roots can get a free run. Jasminum nudiflorum quite forces itself on every one's attention this year, as never before perhaps has it been seen in such beauty, for every shoot is full of its rich yellow bloom, and this without spot or blemish, thanks to the weather, which has all along been in its favour. The way I have witnessed this Jasminum looking best is on tall blocks of wood, round which the plants were tiged to lead them up. this Jasminum looking best is on tall blocks of wood, round which the plants were tied to lead them up, and then left to themselves to grow at their will. The effect of their slender branches drooping down in their own natural manner is charming. Plants also look well trained loosely to wires against a red brick wall, which colour as a background shows up the flowers to the greatest advantage. Lithospermum prostratum is another plant that no one can pass by without stopping to admire the lovely little blooms, so rich and intense are they in the great depth of their blue, and I could gather many sprigs of them to-day that would have given quite a finishing touch to any bouquet. Soon the plants, one of which covers over a yard of ground, will be a mass, and vie with the Gentians, now fast pushing their buds, and with one or two just ready to open, but waiting for sun, which the Gentian must have, or but waiting for sun, which the Gentian must have, or it hides its beauty all the day long. Winter Aconites seem quite indifferent about solar rays, as they are seem quite indifferent about solar rays, as they are through the earth, and make the borders here and there ablaze with the glow of their yellow, but, unfortunately, they do not last long, as, being so near the ground, the blossoms get bespattered by the first heavy rain, and are made shabby at once. Forming a fine contrast with the Aconties, the Scilla sibirica is now coming on, but where it looks best is near Snowdrops, as the pure white of these makes the blue of the Squills appear richer than ever. Hitherto I have made no special note of the time of blooming of Snowdrops, but if my memory serves me, they must be at least a month before their usual season, as with us, clumps are fully in bloom, and Primroses are now be at less a month before the issual season, as with its, clumps are fully in bloom, and Primroses are now becoming quite gay, and making a nice show in some beds. Red and white Daisies surrounding them are also looking bright, as they, too, have a few flowers, and the lovely Myosotis disstititions is trying its best to be in with them too but its bloomer. and the lovely Myosotis, dissilifora is trying its best to be in with them too, but its blossoms at present have a pink hue. Stocks have never ceased flowering, and plenty of them might now be cut, as also Anemone coronaria, a bed or border of which everyone who has a garden should sow, as plants are most valuable for cutting from, for when raised early they yield a supply of flowers nearly the whole of the winter, and come in admirably for dressing with the Christmas Rose, with which they associate well. Violets are fast peeping out of their foliage, and will soon be in great abundance, especially The Czar, which has been yielding a few blooms for the Last month, and the old Russian longer than that. Some perpetual Carnations standing out have a few they can be compared thousers, and Berberis nepalensis and Datwinii are quite gay, the first-named having every shoot terminal with great clusters of blossoms. Petunias.—At one time much trouble was taken in saving plants to propagate by cuttings, and very few varieties were then grown, the greatest favourite as a bedder being Countess of Ellesmere, which had neat, small flowers of a deep rose colour that looked very rich in masses and stood the weather well. Fine as the above-named and a few others were, they are now far surpassed by new strains of a totally different character, the finest and most note worthy perhaps being those of the grandiflora section, which commisses several kinds all modulous blooms worthy pernaps being those of the granditions section, which comprises several kinds, all producing blooms remarkable for their size and splendid markings, some being beautifully striped and others fringed, and the whole particularly striking and showy. For large beds these Petunias are very valuable, but I think they look best in borders, and the way to grow them there is to plant one or more in a patch, and surround in the production of the plant one or more in a patch, and surround in the production of the plant one or more in a patch, and surround in the production of the plant one or more in a patch, and surround in the production of the plant one or more in a patch, and surround in the plant one or more in a patch, and surround in the plant of the plant one or more in a patch, and surround in the plant of t it with a piece of 18-inch wide coarse-meshed wire netting, through which the branches of the plants push and find the support they need; and after a time the wire becomes hidden and clothed with gay blos-
