4263. *Propagation and culture.* The plants must be raised and forwarded in a hot-bed, under glass, from about the vernal equinox till May. Sow in any general hot-bed about the end of March, or beginning or middle of April; and as to quantity of seed, one ounce will produce sixty plants. As soon as the plants are about two inches high, if they are immediately pricked into another hot-bed, or into that where raised, singly into small pots placed in the hot-bed, they will grow more stocky, and can be more successfully transplanted. About the middle or end of May, transplant them, each with a ball of earth, into a south border, to have the full sun, that the fruit may ripen in perfection. Some may be planted close to a south wall, if vacant spaces can be had; but as they draw the ground exceedingly, do not set them near choice fruit-trees. Give water. During the first week or fortnight, if the nights be cold, defend them with hand-glasses, or by whelming a large garden-pot over each plant; or transplant upon holes of hot dung, earthed to six inches depth, and cover with hand-glasses. When they begin to run, train them to stakes, or, when planted near a wall or pales, nail up the branches.

4264. *Wilmot* plants at the foot of a bed sloping steeply to the south, and trains the runners on it by pegging them down. They frequently strike root at the joints; he "tops them as soon as their branches meet, clears off all the lateral shoots, and thins the leaves by which the fruit is exposed and well ripened. In the fine season of 1818, each plant so treated produced, on an average, twenty pounds' weight of fruit." (*Hort. Trans.* iii. 346.) The fruit begins to ripen in August; gathered in October, and hung up in bunches in any dry apartment, it will continue good for use in November.

4265. *To save seed.* "Gather some of the best ripe fruit in autumn; clear out the seed; wash and cleanse it from the pulp, and dry it thoroughly; then put it up in papers or bags, for use next spring." (*Abercrombie*.)

SUBJECT. 2. *Egg-Plant.* — *Solanum Melongena*, L. (*Pluk. Phyt.* 226. f. 2.) *Pent.* Monog. L. and *Solanaceæ*, B. P. *Melongène*, Fr.; *Tollapfel*, Ger.; and *Melanzana*, Ital.

4266. *The egg-plant* is a tender or green-house annual, a native of Africa, introduced in 1597. The plant rises about two feet high, with reclining branches; the flowers appear in June and July, of a pale-violet color, followed by a very large berry, generally of an oval shape, and white color, much resembling a hen's egg; and in large specimens, that of a swan.

4267. *Use.* In French and Italian cookery, it is used in stews and soups, and for the general purposes of the love-apple.

4268. *The varieties are —*

The oval-shaped white | The globular-shaped white | The purple, or violet-colored, of both forms.

4269. *Culture.* The plants are raised from seed, which may be sown in March or April, in a hot-bed, in light rich earth. After they have shown two or three proper leaves, they may either be pricked out in another hot-bed, or planted in small pots, to be shifted in rotation, till in size No. 16, in which they will produce their fruit. If the plants, instead of being shifted into fruiting-pots, are planted against a wall, or in a warm border in June, they will fruit in the open air, if the season is not unusually wet and cold.

4270. *To save seed.* Gather one or two ripe berries of each sort, large and well formed, and preserve them entire, till the seed is wanted for sowing.

SUBJECT. 3. *Capsicum.* — *Capsicum*, L. *Pent. Monog.* L. and *Solanaceæ*, B. P. *Piment*, Fr.; *Spanischer Pfeffer*, Ger.; and *Peberone*, Ital.

4271. Of the *capsicum* there are three species in cultivation.

4272. *The annual capsicum, or Guinea-pepper*, is the *C. annuum*, L. (*Knorr. Thess.* 2. t. C. 6.), an annual plant, which, though a native of India, endures the open air in this country during summer. It was introduced in 1548, and was cultivated in Gerrard's time. It rises about two feet high, producing long, linear, dark-green leaves, on a branchy stem. The flowers are white, and appear in June and July, succeeded by berries, varying in shape and color, and either long-podded, red and yellow; short-podded, red and yellow; round short-podded, red and yellow; or heart-shaped, red and yellow.

4273. *The cherry-pepper (C. cerasiforme)*, (*Hort. Kew.*), is an annual plant, a native of the West Indies, which also stands our summer. It was introduced in 1759, has the same general character of foliage as the Guinea pepper, and flowers from June to September. It is characterised by its small cherry-shaped fruit, which is sometimes heart-shaped, bell-shaped, or angular, and in color red or yellow.

4274. *The bell-pepper (C. grossum)*, (*Besl. Eyst. Aut.* 1. t. 11. f. 1.), is a stove biennial, a native of India, and introduced in 1759. It is of humble growth, flowers in July, and produces large red or yellow berries. It will endure the open air in summer, but requires a place in the stove during the winter and spring months.

4275. *Use.* The green pods, or inflated berries, of all these varieties, are used for pickling. They are sometimes also used in their ripe state, when they form a spice of the hottest quality, known by the name of Cayenne pepper. The berries of the last named species are deemed better for pickling than the others, the skin being thick, pulpy, and tender.

4276. *Culture.* All the three species, with their varieties, are raised from seed; a small parcel, or the produce of two pods, will be a sufficient quantity of each or of any one variety for ordinary supply. Sow all the annual sorts at the end of March, "or beginning or middle of April, in a moderate hot-bed, under a frame. Cover the seed a quarter of an inch deep. When the plants are two or three inches in growth, prick some into a new slender hot-bed, to forward them for final transplanting; or in default of this, prick them into a bed of natural earth, at the beginning of May, if fine, settled, warm weather; defend them with a frame, or awning of mats, at night and in cold vicissitudes. Give water lightly at planting, and occasionally afterwards in moderate supplies, to assist their fresh rooting and subsequent growth. At the beginning of June, when the weather is settled warm, transplant them into the open garden, in beds of light rich earth, from twelve to eighteen inches apart, giving water. They will thus advance freely, flower in July or August, and produce plenty of pods from August till the end of September. Under the deficiency of a hot-bed or stove, or for succession, annual capsicums may be raised in a bed of light rich earth, under a hand-glass; but the sowing must be deferred to fine warm weather in May. Give the plants air in the day, but cover them close at night, till danger from frost is over. At the close of June, transplant as above. The perennial species must be wintered in the stove." (*Abercrombie.*)

4277. *To save seed.* Leave one or two of the largest and handsomest shaped pods to ripen in autumn; after gathering them, the best way is to hang them up in a dry place, and not take out the seed till wanted for sowing in spring.

SUBJECT. 4. *Samphire, three Species of different Orders and Genera.*

4278. *Common samphire* is the *Crithmum Maritimum*, L. (*Eng. Bot.* 819.); *Pent. Dig.* L. and *Umbelliferae*, J. *Perce-pierre*, or *Saint Pierre*, Fr.; *Meerfenchel*, Ger.; and *Finocchio marino*, Ital. (*fig.* 475. a) It is a perennial plant, a native of Britain, and found on rocky cliffs by the sea, and in dry stone walls. The root-leaves are triternate, those of the stem lanceolate and fleshy; the flowers appear on a stem of about eighteen inches high in August, and are of a yellow color. The name samphire is a corruption of *sampier*, and this again a corruption of the French name *Saint Pierre*.

4279. *Use.* Samphire forms an excellent pickle, and a frequent addition to salads. In taste, it is crisp and aromatic, and constitutes a light and wholesome condiment. It is generally gathered in places where it is found native; and the allusion to the practice by Shakspeare, in his description of Dover cliff, is well known. The plant is also used medicinally.

4280. *Culture*. It is propagated by parting the roots, or by sowing the seed in April; but is rather difficult of cultivation. Marshall says, "it likes a cool situation; but yet prefers a sandy or a gravelly soil, and plenty of water. Some," he adds, "have found it to do best in pots, set for the morning sun only." Braddick placed it in a sheltered dry situation, screened from the morning sun; protected it by litter during winter, and in spring sprinkled the soil with a little powdered barilla: "This I do," he says, "to furnish the plant with a supply of soda, since in its native place of growth, it possesses the power of decomposing sea-water, from which it takes the fossil alkali, and rejects the muriatic acid. With this treatment it has continued to flourish at Thames Ditton for some years, producing an ample supply of shoots, which are cut twice in the season." (*Hort. Trans.* ii. 232.)

4281. *Golden samphire* is the *Inula Crithmifolia*, L. (*Eng. Bot.* 68.) *Syng. Polyg. Super. L.* and *Compositæ*, J. *L'Inule perce-pierre*, Fr.; *Goldene Meerfenchel*, Ger. (*fig.* 475. b) It is a perennial plant, found on sea-shores, generally within salt-water mark. It is occasionally gathered and brought to Covent Garden market, under the name of golden samphire; but has not, we believe, been introduced in the garden. It is used for the same purposes as the common samphire.

4282. *Marsh-samphire* is the *Salicornia Herbacea*, L. (*Eng. Bot.* t. 415.) *Dian. Monog. L.* and *Chenopodææ*, B. P. *Salicorne*, Fr.; *Glasschmalz*, Ger.; and *Erbacali*, Ital. (*fig.* 475. c.) It is an annual plant, a native of Britain, and not uncommon in salt-marshes, and other aits and islets of low land overflowed by the sea. It is occasionally gathered and brought to market; and is used for pickling, and in salads, like the two plants above described. This and the former species might be cultivated in the garden, by imitating a small portion of salt-marsh.

SECT. XII. *Edible Wild Plants, neglected, or not in Cultivation.*

4283. *The subject of edible wild plants* is introduced as highly deserving the study of the horticulturist; partly to increase his resources, partly to induce such as have leisure to try how far these plants may be susceptible of improvement by cultivation; but principally to enable the gentleman's gardener to point out resources to the poor in his neighborhood, in seasons of scarcity. All vegetables not absolutely poisonous may be rendered edible by proper preparation. Many sorts, for example, are disagreeable from their acrid and bitter taste; but this might be, in a great degree, removed by maceration, either in cold or hot water. The vegetable matter once reduced to a state of insipidity, it is easy to give it taste and flavor, by adding salt of some sort, which is an article never scarce through the influence of bad seasons; or by vinegar, or oils, or fats; by the addition of other vegetables of agreeable tastes and flavors, as of thyme, mint, celery-seed, onions, &c.; or by the addition of torrefied vegetable matter; as of the powder of roasted carrot, parsnep, potatoe, or dandelion-roots, or of beans, peas, or wheat; or, if it can be had, of toasted bread, which will render almost any thing palatable, and prolong the pleasure of eating many of the best things.

4284. *Gooseberry, birch, beech, willow, and other leaves*, we are told, were formerly eaten as salads; and there can be little doubt that aboriginal man would eat any green thing that came in his way, till he began to improve. It may be worth while for man in his present multiplied and highly civilised state, to reflect on these things, with a view to resources in times of famine, or in travelling or voyaging, or touching at or settling in new or uncultivated countries. (*Parry's Voyage to the Polar Regions*, 4to. 1821.) Edible wild plants may be classed as greens and pot-herbs, roots, legumes, salads, teas, and plants applied to miscellaneous domestic purposes.

SUBJECT. 1. *Greens and Pot-herbs from Wild Plants.*

4285. *Black bryony*. *Tamus communis*, L. (*Eng. Bot.* 91.) *Diæc. Her. L.* and *Smilacææ*, J. A twining perennial, growing in hedges, and commonly considered a poisonous plant; but the young leaves and tops are boiled and eaten by the country people in spring.

4286. *Burdock*. *Arctium lappa*, L. (*Eng. Bot.* 1228.) *Syng. Pol. Æq. L.* and *Compositæ*, J. A well known perennial, the tender stalks of which many people eat boiled as asparagus. (*Bryant*.)

4287. *Charlock*. *Sinapis arvensis*, L. (*Eng. Bot.* 1748.) *Tetrad. Siliq. L.* and *Cruciferaæ*, J. A common annual weed in corn-fields. The young plant is eaten in the spring as turnip-tops, and is considered not inferior to that vegetable. The seeds of this have sometimes been sold for feeding birds instead of rape; but being hot in its nature, it often renders them diseased.

4288. *Chickweed*. *Alsine media*, L. *Stellaria media*, E. B. (*Eng. Bot.* 537.) *Decan. Trig. L.* and *Caryophyllææ*, J. This common garden-weed is said to be a remarkably good pot-herb, boiled in the spring.

4289. *Shepherd's purse*. *Thlaspi bursa pastoris*, L. (*Eng. Bot.* 1485.) *Tetrad. Silic. L.* and *Cruciferaæ*, J. An esculent plant in Philadelphia, brought to market in large quantities in the early season. The taste, when boiled, approaches that of the cabbage, but is softer and milder. This plant varies wonderfully in size and succulence of leaves, according to the nature and state of the soil where it grows. Those from the gardens and highly cultivated spots near Philadelphia, come to a size and succulence of leaf scarcely to be believed without seeing them. They may be easily blanched by the common method, and certainly, in that state, would be a valuable addition to the list of delicate culinary vegetables. (*Correa de Serra*, in *Hort. Trans.* vol. iv. 445.)

4290. *Fat hen*. *Chenopodium urbicum*, (*Eng. Bot.* 717.) and *C. album*, (*Eng. Bot.* 1723.) *Pent. Dig. L.* and *Chenopodææ*, J. Both these plants are annuals, common among rubbish of buildings, dunghills, &c. Boiled, and eaten as spinach, they are by no means inferior to that vegetable. Several other native, but less common species of this genus, may be applied to the same use.

4291. *Ox-tongue*. *Picris hieracioides*, L. (Eng. Bot. 972.) Syn. Pol. Æq. L. and *Compositæ*, J. This annual, common in clayey pastures and wastes, when boiled, affords a good green. In France and Italy, a species named *P. vulgare*, and probably the same as the above, is grown and used as a salad, and is said to resemble succory. (Bon Jard. 1820. p. 170.)

4292. *Sauce alone*, or *Jack by the hedge*, is the *Erysimum Alliaria*, L. (Eng. Bot. 796.) *Tetrad. Siliq. L.* and *Cruciferae*, J. (fig. 475. d) A biennial plant; found by hedges where the soil is dry and rich. The stem rises two or three feet high, with heart-shaped leaves of a yellowish-green color; the flowers are white, and appear in May. The whole plant, as the trivial name imports, scents strongly of garlic. It is occasionally used as a salad; boiled as a pot-herb, or introduced in sauces. Neill observes, that, "when gathered as it approaches the flowering state, boiled separately, and then eaten to boiled mutton, it certainly forms a most desirable pot-herb; and to any kind of salted meat, an excellent green."

4293. *Sea-orache*. *Atriplex littoralis*, L. (Eng. Bot. 708.) *Poly. Monac. L.* and *Chenopodææ*, B. P. This is an annual, and is eaten in the same manner as the chenopodium, as greens or spinach.

4294. *Sea-beet*. *Beta maritima*, L. (Eng. Bot. 285.) *Pent. Dig. L.* and *Chenopodææ*, J. This biennial is common on various sea-shores, and is also used like the orache, fat hen, and white beet.

4295. *Spotted hawkweed*. *Hypochaeris maculata*, L. (Eng. Bot. 225.) *Syng. Pol. Æq. L.* and *Compositæ*, J. The leaves of this perennial are eaten as salad, and also boiled as greens.

4296. *Stinging nettle*. *Urtica dioica*, L. (Eng. Bot. 1750.) *Monac. Pent. L.* and *Urticææ*, J. This perennial, found in dry rubbishy soils and in hedges; is but seldom seen in places where the hand of man has not been at work, and may therefore be considered a sort of domestic plant. Early in February, the tops will be found to have pushed three or four inches, furnished with tender leaves; in Scotland, Poland, and Germany, these are gathered as a pot-herb for soups, or for dishes like spinach; and their peculiar flavor is by many much esteemed. No plant is better adapted for forcing; and in severe winters, when most of the brassica tribe have been destroyed, it forms an excellent resource. Collect the creeping roots, and plant them either on a hot-bed, or in pots to be placed in a forcing-house, and they will soon send up abundance of tender tops: these, if desired, may be blanched, by covering with other pots. We have known the nettle forced by being planted close to the flue in a vinery, so as to produce excellent nettle-kale and nettle-spinage in the last week of January.

4297. *Wild rocket* is the *Sisymbrium officinale*, (Eng. Bot. 725.) *Tetrad. Siliq. L.* and *Cruciferae*, J. A common annual, of a yellowish hue, from two to three feet high, with the leaves runcinated, and the seed-pods inclined upwards, close to the stalk. It is sometimes used as a pot-herb; and the tender young leaves, in salading, greatly resembling mustard in its taste and flavor.

4298. *Willow-herb*. *Epilobium angustifolium*, L. (Eng. Bot. 1947.) *Oct. Monog. L.* and *Onagrarieæ*, J. The young and tender shoots are eaten as asparagus, and the leaves are a wholesome green.

4299. *Sow-thistle* is the *Sonchus oleraceus*, (Eng. Bot. 843.) *Syng. Polyg. Æqu. L.* and *Compositæ*, J. A hardy annual, and a well known weed in rich garden and field soils. There is a prickly and a smooth variety, both abounding in a milky bitter juice. The tender tops of the smooth variety are in some countries boiled and used as greens, or mashed as spinach: hence the origin of the Linnæan trivial name *oleraceus*.

SUBJECT. 2. Roots of Wild Plants edible.

4300. *Arrowhead*. *Sagittaria sagittifolia*, L. (Eng. Bot. 84.) *Monac. Polyan. I.* and *Alismaceæ*, B. P. The roots of this aquatic perennial are said to be very similar to those of the West India arrow-root (*Maranta Arundinacea*, L.). They are sometimes dried and pounded, but are reported to have an acrid unpleasant taste; though this might, it is believed, be got rid of by washing the powder in water.

4301. *Common arum*. *Arum maculatum*, L. (Eng. Bot. 1293.) *Monac. Polyan. L.* and *Aroideæ*, B. P. This plant is very common in hedges and woods in loamy soils; in the isle of Portland it is very abundant, and there the roots are dug up by the country people, macerated, steeped, and the powder so obtained is dried, and sent to London, and sold under the name of Portland sago.

4302. *Bitter vetch*, or *mouse peas*. *Orobus tuberosus*, L. (Eng. Bot. 1153.) *Diad. Decan. L.* and *Leguminosæ*, J. The tubers are said to be chewed by the Scottish Highlander as a substitute for tobacco. Boiled till a fork will pass through them, and dried slightly and roasted, they are served up in Holland and Flanders in the manner of chestnuts, which they resemble in flavor. Dickson (*Hort. Trans.* ii. 359.) recommends cultivating them in a bed or border of light rich soil, paved at the depth of twenty inches, to prevent their roots from running down. Plant the tubers six inches apart, and three inches below the surface; the second year some will be fit to gather, and by taking only the largest, the bed will continue productive for several years, adding some fresh compost every year.

4303. *Earth-nut*. *Bunium bulbocastanum*, L. (Eng. Bot. 988.) *Pent. Dig. L.* and *Umbelliferae*, J. The roots of this bulbous perennial are eaten raw, and are by some considered a delicacy here, but thought much more of in Sweden, where they are an article of trade: they are eaten also stewed as chestnuts.

4304. *Meadow-sweet*. *Spiræa Filipendula*, L. (Eng. Bot. 284.) *Icos. Di-Pentag. L.* and *Rosaceæ*, J. The tubers of this perennial, common in most meadows where the soil is inclined to peat, or boggy, are ground and made into bread in Sweden.

4305. *Pilewort*. *Ranunculus ficaria*, L. (Eng. Bot. 584.) *Polyan. Polyg. L.* and *Ranunculaceæ*, J. The young leaves, in spring, are boiled by the common people in Sweden, and eaten as greens. The roots are sometimes washed bare by the rains, so that the tubercles appear above ground; and in this state have induced the ignorant, in superstitious times, to fancy that it has rained wheat, which these tubercles somewhat resemble. (*Derham's Physico-Theology*.)

4306. *Sago*. *Orchis Morio*, L. (Eng. Bot. 2059.) *Gynan. Monan. L.* and *Orchideæ*, B. P. The powder of the roots is used in forming the beverage called saloop. Though imported chiefly from Turkey, yet the roots of this country, either gathered wild, or cultivated for use, might answer the same purpose. This plant is particularly abundant in the vale of Gloucester.

4307. *Silver-weed*. *Potentilla Anserina*, L. (Eng. Bot. 861.) *Icos. Polyan. L.* and *Rosaceæ*, J. The roots of this plant taste like parsneps, and are frequently eaten in Scotland either roasted or boiled. In the islands of Jura and Col they are much esteemed, as answering in some measure, the purposes of bread, they having been known to support the inhabitants for months together during a scarcity of other provisions. They often tear up their pasture-grounds with a view to get the roots for their use; and as they abound most in barren and impoverished soils, and in seasons when other crops fail, they afford a most seasonable relief to the inhabitants in times of the greatest scarcity. (*Lightfoot's Fl. Scot.*)

4308. *Solomon's seal*. *Polygonatum vulgare*, D. (Eng. Bot. 280.) The roots are dried, ground, and made into bread; and the young shoots are boiled and eaten as greens.

SUBJECT. 3. *Leguminous Wild Plants Edible.*

4309. *Sea-peas. Pisum maritimum*, L. (Eng. Bot. 1046.) *Diad. Decan. L. and Leguminosæ, J.* (fig. 476.) These peas have a bitterish disagreeable taste, and are therefore rejected when more pleasant food is to be got. In the year 1555, however, when there was a great famine in England, the seeds of this plant were used as food, by which, according to Turner, thousands of families were preserved. The bitter of these seeds might in all probability be removed by steeping and kiln-drying, as in preparing for the mill peas which are to be split.

4310. *Wild vetches. Lathyrus, Vicia, and Ervum, L. Diad. Decan. L. and Leguminosæ, J.* The seeds of all the British species of these genera may be used as peas. They are found in hedges, woods, and corn-fields, and are most prolific in dry seasons.

SUBJECT. 4. *Salads from Wild Plants.*

4311. *Ladies' smock. Cardamine pratensis*, L. (Eng. Bot. 776.) *Tetrad. Siliq. L. and Cruciferae, J.* The leaves of this plant afford an agreeable acrid salad, greatly resembling the American cress.

4312. *Stone-crop, or orpine. Sedum Telephium*, L. (Eng. Bot. 1319.) *Decan. Pentag. L. and Semper-vivæ, J. Trique Madam, Fr.* The leaves are eaten in salads like those of purslane, to which, by the French, it is considered equal.

4313. *Sea-bindweed. Convolvulus Soldanella*, L. (Eng. Bot. 314.) *Pent. Monog. L. and Convolvulaceæ, B. P.* This plant abounds on sea-coasts, where the inhabitants gather the tender stalks, and pickle them. It is considered to have rather a cathartic quality.

4314. *Sweet Cicely. Scandix odorata*, L. (Eng. Bot. 697.) *Pentan. Dig. L. and Umbelliferae, J.* The leaves of this plant used to be employed like those of chervil. The green seeds ground small, and used with lettuce or other cold salads, give them a warm agreeable taste. The smell of the plant attracts bees, and the insides of empty hives are often rubbed with it before placing them over newly-cast swarms to induce them to enter.

4315. *Buckhorn-plantain, or star of the earth. Plantago coronopus*, L. (Eng. Bot. 892.) *Tetrand. Monog. L. Plantagineæ, B. P. Corne de Cerf, Fr.; Krahenfuss, Ger.; and Coronopo, Ital.* This is a hardy annual, a native of Britain, found in sandy soils. It is a low spreading plant, with linear pinnated leaves, and round stalk: producing short spikes of starry flowers from May to August. It was formerly cultivated as a salad herb, and used like the common cress; but is now neglected in English gardens, perhaps on account of its rank and disagreeable smell. It is still, however, regularly sown in French gardens. It is raised by seed, which may be sown the first week in March; and after the plants have come up, they should be thinned so as each may occupy from five to nine square inches. To ensure a succession of tender leaves, cut off the flowers as they appear.

4316. *Ox-eye daisy. Chrysanthemum leucanthemum*, L. (Eng. Bot. 601.) *Syng. Polyg. Super. L. and Compositæ, J. Marguerite grande, Fr.; Grosse Wucherblume, Ger.; and Leucanterno, Ital.* This is a perennial plant, common in dry pastures. The leaves, which spring immediately from the root, are obovate with foot-stalks; from these a stem arises from two to three feet high, furnished with oblong, embracing pinnatifid leaves. The flowers are large, with yellow disks and white rays, and appear in June and July. The young leaves were much used in Italy in salads in Bauhin's time; and they are mentioned by Dr. Withering as being fit for this purpose. The plant is easily propagated by dividing the roots after the flowering season. To produce succulent tender leaves, it should be placed in soft, rich, moist earth.

SUBJECT. 5. *Substitutes for Chinese Teas from Wild Plants.*

4317. *Speedwell. Veronica spicata*, L. (Eng. Bot. 2.) *Dian. Monog. L. and Scrophularineæ, B. P.* This plant is sometimes used as a substitute for tea; and is said to possess a somewhat astringent taste like green tea (*Camellia viridis*).

4318. *Spring grass. Anthoxanthum odoratum*, L. (Eng. Bot. 647.) *Dian. Dig. L. and Gramineæ, B. P. (fig. 477.)* This is a highly odoriferous grass, a decoction of which is said to bear a considerable resemblance to tea.

4319. *Other substitutes.* The leaves of the black currant afford a very good substitute for green tea; and those of *Saxifraga crassifolia* are said, by Tooke (Russ. Emp.), to be used as tea in Siberia. *Ectonica officinalis* (Eng. Bot. 1142.) is said to have the taste and all the good qualities of foreign tea without the bad ones.

SUBJECT. 6. *Wild Plants applied to various Domestic Purposes.*

4320. *Butterwort. Pinguicula vulgaris*, L. (Eng. Bot. 70.) *Diand. Monog. L. and Lentibulariæ, B. P.* The inhabitants of Lapland and the north of Sweden give to milk the consistence of cream by pouring it warm from the cow upon the leaves of this plant, and then instantly straining it, and laying it aside for two or three days till it

acquires a degree of acidity. This milk they are extremely fond of; and once made, they need not repeat the use of the leaves as above, for a spoonful or less of it will coagulate another quantity of warm milk, and make it like the first, and so on, as often as they please to renew their food. (*Lightfoot's Flor. Scot.* p. 77.)

4321. *Cow-parsnep. Heracleum Sphondylium*, L. (*Eng. Bot.* 939.) *Pent. Dig. L.* and *Umbellifera*, J. The inhabitants of Kamschatka, about the beginning of July, collect the foot-stalks of the radical leaves of this plant, and, after peeling off the rind, dry them separately in the sun; and then tying them in bundles, they lay them up carefully in the shade. In a short time afterwards these dried stalks are covered over with a yellow saccharine efflorescence, tasting like licorice, and in this state they are eaten as a delicacy. The Russians, not content with eating the stalks thus prepared, contrive to get a very intoxicating spirit from them, by first fermenting them in water with the greater bilberry (*Vaccinium uliginosum*), and then distilling the liquor to what degree of strength they please; which Gmelin says, is more agreeable to the taste than spirits made from corn. (*Lightfoot's Fl. Scot.*)

4322. *Heath. Erica Vulgaris*, L. (*Eng. Bot.* 1013.) *Octan. Monog. L.* and *Ericace*, J. Formerly the young tops are said to have been used alone to brew a kind of ale; and even now, the inhabitants of Isla and Jura continue to brew a very potable liquor, by mixing two thirds of the tops of the heath with one of malt. (*Lightfoot's Fl. Scot.*)

4323. *Substitutes for capers.* The flower-buds of the marsh-marigold (*Caltha palustris*, L.) form a safe substitute for capers; and likewise the young seed-pods of the common radish; and the unripe seeds of the nasturtium, or Indian cress. A species of spurge, common in gardens, (*Euphorbia Lathyris*), is vulgarly called caper-bush, from the resemblance of its fruit to capers; and though acrid and poisonous, like the other plants of this genus, its seeds are sometimes substituted by the Parisian *restaurateurs* for the pods of the true capers. For more minute details respecting the plants enumerated in this section, and various others which might be used as food, or in domestic economy, see Bryant's *Flora Dietetica*, and Lightfoot's *Flora Scotica*, Hudson's *Flora Anglica*, and the local floras of all parts of Europe.

SUBJECT. 7. Poisonous native Plants to be avoided in searching for edible Wild Plants.

4324. *The principal poisonous plants, natives or growing in Britain, are the following: those marked thus (*) are also the most valuable plants in the native materia medica: the whole, for obvious reasons, ought to be known at sight by every gardener:—*

Bitter Poisons, for which acids, astringents, wines, spirits, and spices are the correctives. Chelidonium majus, Clcuta virosa*, Colchicum autumnale*, Onanthe crocata, Prunus Laurocerasus.

Acrid Poisons, which should be counteracted by powerful astringents, as bark, and afterwards the stomach restored by soft mucilaginous matters, as milk,

fat broth, &c. Aconitum Napellus, and Lycocotum, Actæa spicata, Rhus Toxicodendron.

Stupifying Poisons, to be counteracted by vegetable acids and emetics. Æthusa cynapium, Atropa Belladonna, Datura Stramonium*, Hyoscyamus niger, Lactuca virosa, Solanum dulcamara*, and nigrum.

Fetid Poisons, to be attacked by ether,

wine, or acids. Conium maculatum*, Digitalis purpurea*, Heileborus fatidus, Juniperus Sabina, Scrophularia, aquatica.

Drastic Poisons, to be corrected by acids alkalies, and astringents. Asclepias syriaca, Bryonia dioica, Euphorbia Lathyris and amygdaloides, Mercurialis perennis and annua, Periploca græca, Veratrum album.

4325. *The poisonous fungi will be found in a succeeding section.*

SECT. XIII. Foreign hardy herbaceous culinary Vegetables, little used as such in Britain.

4326. *The culinary plants of other countries are in general the same as our own; but a few may be mentioned which are more commonly cultivated in France, Germany, and America, than in England, but which would thrive in the latter country.*

4327. *The Claytonia perfoliata* (Pentan. Monog. L. and Portulacæ, J.) is a hardy annual, a native of America, of the easiest possible culture in any soil. Sown in autumn, it endures the winter, and flowers in April and May. Its perfoliate foliage is not very abundant, but it is exceedingly succulent, and not inferior to common spinach in flavor. It has no pretensions to supersede, or even to be generally cultivated as a spinach plant; but in very poor soils, under trees, or in other peculiar circumstances, it may be found a useful resource.

4328. *The Basella alba and rubra* (Pentan. Trig. L. and Chenopodæ, J.) are stove-biennials, raised on hot-beds near Paris, and transplanted into warm borders, where they furnish a summer spinach equal to that of the orache. (*Hort. Tour*, 489.) They are also grown for the same purpose in China. (*Livingstone*, in *Hort. Trans.* v. 54.)

4329. *The Virginian poke* (Phytolacca decandra, Decan. Pentag. L. and Chenopodæ, J.) is a hardy perennial with large ramose roots, shoots half an inch in diameter, and five or six feet high; the leaves five inches long and two and a half inches broad, smooth and of a deep green. It grows vigorously in a good deep soil, and furnishes ample supplies of young shoots, which in America and the West Indies are boiled and eaten as spinach. (*Miller's Dict.* art. Phytolacca; *Correa de Serra*, in *Hort. Trans.* iv. 446.)

4330. *The White cabbage of China* (Chinensis), used both as a pot-herb and a salad (*Barrow; Abel*), and the wild cabbage of America (*B. washitana*, Muhi), used as a pot-herb, might be grown for similar purposes in this country. The procumbent cabbage of China is mentioned by Livingstone (*Hort. Trans.* v. 55.), as being a hardy plant, supplying leaves the whole of winter.

4331. *The Shawanese salad* (Hydrophyllum virginicum, L. Pentan. Monog. L. and Boraginæ, J.) is a hardy perennial, very prolific in lobed lucid green leaves which hold water (whence the name), and are used by the Indians both raw and boiled.

4332. *The Apios tuberosa*, Ph. (Diadelph. Decan. L. and Leguminosæ, J.) is a hardy tuberous-rooted perennial, a native of North America, the tubers of which are used by the Indians.

4333. *The bread-root* (Psoralea esculenta, L. Diadelph. Decan. L. and Leguminosæ, J.) is a hardy perennial, a native of Missouri, and used there as potatoes are in this country.

4334. *The Quamash* (Scilla esculenta, L. Hexan. Monog. L. and Asphodeleæ, J.) is a native of North America, and there used as food.

4335. *Other hardy esculents.* The Indian corn (*Zea mays*) is grown in some parts as a garden-plant, the ears being gathered green or partially ripe, and boiled or roasted. The common millet is grown on the continent as a garden-plant for its seeds, to be used as a substitute for rice: the Polish millet (*Digitaria sanguinalis*) is grown for this purpose in the cottage gardens in Poland; as is the carnation poppy (*Papaver somniferum*), for its seeds, which form a seasoning to buck-wheat porridge. Nigella sativa and arvensis, hardy annuals, are cultivated in Flanders for their seeds, which are used as celery-seeds are in this country, in soups and also in puddings. The Pekin mustard (*Sinapis Pekimensis*) is a hardy annual, and the most extensively used herbaceous plant in China, being, as Livingstone informs us (*Hort. Trans.* v. 54.), carried about the streets of Canton and other towns in the boiled state. The amaranthus polygamus, a hardy annual, grown in China as a spinach plant, and a number of others belonging to the Cruciferae, Chenopodæ, Portulacæ, &c., might be mentioned. (See Forster's *Plant. Esculent. Austr.*; Bryant's *Flora Dietetica*; *Le Bon Jardinier*; *Modern Books of Travels*, &c.)

SECT. XIV. *Edible Fungi.*

4336. Only one species of *edible fungi* has yet been introduced to the garden, though there can be no doubt the whole would submit to, and probably be improved by, cultivation. All of them are natives of Britain, and may be gathered wild at certain seasons, so that though they do not enter into the plot of the cottager, they are, or may be, enjoyed by him. In Poland and Russia, there are above thirty edible sorts of fungi in common use among the peasantry. They are gathered in all the different stages of their growth, and used in various ways: raw, boiled, stewed, roasted; and being hung up and dried in their stoves or chimneys, form a part of their winter stock of provisions. Fungi, however, are not equally abundant in Britain, owing to the general cultivation of the soil; and therefore the good sorts being little familiar to the cottager, most of them are passed over as deleterious. Indeed the greatest caution is requisite in selecting any species of this tribe for food; and though we have given a catalogue both of the good and bad sorts of mushrooms, we can advise none but the botanist to search after any but the common sort (*Agaricus campestris*) as food.

SUBJECT. 1. *Cultivated Mushroom.*—*Agaricus campestris*, L. and Sowerby; *A. edulis* of Bulliard. (*Eng. Bot. Fungi*, t. 1.) *Cryptogamia Fungi*, L. and of the natural order of *Fungi Gymnocarpi*, Persoon. *Champignon Comestible*, Fr.; *Essbare Blätterschamme*, Ger.; and *Pratajuolo*, Ital. (fig. 478.)

4337. *The mushroom* is a well known native vegetable, springing up in open pastures in August and September. It is most readily distinguished, when of middle size, by its fine pink or flesh-colored gills, and pleasant smell; in a more advanced stage, the gills become of a chocolate color, and it is then more apt to be confounded with other kinds of dubious quality; but that species which most nearly resembles it, is slimy to the touch, and destitute of the fine odor, having rather a disagreeable smell: further, the noxious kind grows in woods or on the margins of woods, while the true mushroom springs up chiefly in open pastures, and should be gathered only in such places.

4338. *Use.* The garden-mushroom is eaten fresh, either stewed or boiled; and preserved as a pickle, or in powder, or dried whole. The sauce commonly called *ketchup* (supposed, by Martyn, from the Japanese, *kit-jap*.) is, or ought to be, made from its juice, with salt and spices. Wild mushrooms, from old pastures, are generally considered as more delicate in flavor, and more tender in flesh, than those raised in artificial beds. But the young, or button mushrooms, of the cultivated sort, are firmer and better for pickling; and in using cultivated mushrooms, there is evidently much less risk of deleterious kinds being employed. (*Neill and Martyn*.)

4339. *Species.* The following catalogue of edible and poisonous mushrooms is taken from Sowerby's splendid work on English fungi.

Edible Sorts.			
<i>Agaricus campestris</i> . Common field, or cultivated mushroom	<i>A. pratensis</i> . Champignon	<i>A. orcadæ</i> . Fairy ring, or Scotch bonnets.	<i>A. piperatus</i> . Pepper
<i>A. violaceus</i> . Violet, or blue	<i>A. aurantiacus</i> . Orange		<i>A. campanulatus</i> . Bell
<i>A. cinnamomeus</i> . Cinnamon	<i>A. solitarius</i> . Solitary	Dangerous Sorts.	<i>A. muscarius</i> . Nipple
<i>A. lactifluis</i> . Milky	<i>A. procerus</i> . The grisette of the French, or Tall	<i>A. campestris</i> , var. Dangerous variety of cultivated mushroom	<i>A. aurantiacus</i> , var. Dangerous variety of orange mushroom
<i>A. chantarelus</i> . Chantarelle	<i>A. deliciosus</i> . Sweet mushroom	<i>A. cybeatus</i> . Long-stalked	<i>A. necator</i>
	<i>A. virgineus</i> . Mausseron mushroom	<i>A. muscarius</i> . Reddish	<i>A. virosus</i> . Poisonous, or toad-stool.

4340. *General criteria of wholesome and deleterious fungi.* Unwholesome fungi will sometimes spring up even on artificial beds in gardens; thus, when the spawn begins to run, a spurious brood are often found to precede a crop of genuine mushrooms. The baneful quality of the toad-stool (*A. virosus*) is, in general, indicated by a sickly nauseous smell, though some hurtful sorts are so far without any thing disagreeable in the smell, as to make any criterion, drawn from that alone, very unsafe. The wholesome kinds, however, invariably emit a grateful rich scent.

4341. *Antidote to poisonous sorts.* All fungi should be used with great caution, for even the *champignon*, and edible garden-mushrooms possess deleterious qualities when grown in certain places. All the edible species should be thoroughly masticated, before taken into the stomach, as this greatly lessens the effects of poisons. When accidents of this sort happen, vomiting should be immediately excited, and then the vegetable acids should be given, either vinegar, lemon-juice, or that of apples; after which, give ether and antispasmodic remedies, to stop the excessive bilious vomiting. Infusions of gall-nut, oak-bark, and Peruvian bark are recommended as capable of neutralising the poisonous principle of mushrooms. It is, however, the safest way not to eat any of the good but less common sorts, until they have been soaked in vinegar Spirit of wine and vinegar

extract some part of their poison; and tannin matter decomposes the greatest part of it. (*Botanist's Companion*, vol. ii. p. 145.)

4342. *Culture*. For the culture of the common mushroom, see Chap. VII. Sect. XIV. (3404.) With respect to the other edible sorts, as already observed, they are seldom gathered for use in Britain, excepting by experienced botanists; and none of them, as far as we know, have yet been brought under cultivation. We think, however, that some of them, as the *A. aurantiacus*, *A. deliciosus*, and *A. pratensis*, might very readily, and without danger, be introduced to the garden; treating them like the garden-mushroom, or imitating the climate of the season of the year in which they are found in perfection, and the soil, situation, and exposure, &c. where they are found in greatest abundance, and of the best quality. In the first instance, it would, perhaps, be preferable to propagate from seed, in order to make sure of the species. In the present improved state of horticulture, if this branch of culture were once attempted, it would soon be rendered available by every gardener who can cultivate the common mushroom.

SUBJECT. 2. *Morel*. — *Phallus esculentus*, L.; *Helvella esculenta* of Sowerby (tab. 51.); and *Morchella esculenta* of Persoon. *Cryptogamia Fungi*, L. and *Gymnocarpi*, Persoon. In French, German, and Italian, not distinguished from the *Chamignon* by any popular name. (fig. 479.)

4343. *The morel* is distinguished by its cylindrical, solid, or hollow stem, white and smooth; the cap is hollow within, and adhering to the stem by its base, and latticed on the surface with irregular sinuses. The height is about four inches. It rises in the spring months, in wet banks, in woods, and in moist pastures. It is in perfection in May and June, and should not be gathered when wet with dew, or soon after rain. Gathered dry, they will keep several months.

4344. *Use*. Morels are used, either fresh or dried, as an ingredient to heighten the flavor of gravies, ragouts, &c.

4345. *Culture*. Though this vegetable has not yet been introduced in garden-culture, like the mushroom, there can be no doubt of the attempt being attended with success. The spawn should be collected in June, and planted in beds or ridges, differently composed, and some laid up for use in dry and moist envelopements, in order, by experiment, to come to the best mode of cultivation. Lightfoot says, he has raised the phallus from seed.

SUBJECT. 3. *Truffle*, or *Subterraneous Puff-ball*. — *Tuber Cibarium*, Sowerby. (tab. 309.) *Cryptogamia Fungi*, L. and *Angiocarpi*, Per. *Truffe*, Fr.; *Trüffel*, Ger.; and *Tartufo nero*, Ital. (fig. 480.)

4346. *The truffle* is a subterraneous fungus, growing naturally some inches below the surface in different parts of Britain; and very common in the downs of Wiltshire, Hampshire, and Kent, where dogs are trained to scent it out. The dogs point out the spot by scraping and barking; and the truffles, which are generally found in clusters, are dug up with a spade. The truffle is globular, seldom the size of a hen's egg, without any root, and of a dark color, approaching to blackness. The surface is uneven and rough; the flesh firm, white while young, but when old, it becomes black, with whitish veins.

4347. *Use*. They are used, like the mushroom, in stuffings, gravies, and other high-seasoned culinary preparations. They are generally procured from Covent Garden market, as they bear carriage to any distance.

4348. *Culture*. "No attempt," Neill observes, "it is believed, has hitherto been made to cultivate truffles; but of the practicability of the thing there seems no reason to doubt. In their habits of growth, indeed, they differ essentially from the mushroom; but it is certainly possible to accommodate the soil and other circumstances to the peculiar nature of the fungus. It has been said, that the tubercles on the surface of truffles are analogous to the eyes or buds of potatoes, and that they have been propagated, like potatoes, by means of cuts furnished with tubercles; it may however be suspected, that the pieces thus planted contained ripe seeds. Truffles, we may add, seem to delight in a mixture of clay and sand; and a moderate degree of bottom heat, such as is afforded by a spent hot-bed, might probably forward their vegetation." (*Ed. Encyc.*)

SECT. XV. *Edible Fuci*. — *Cryptogamia Algæ*, L. and *Fucaceæ*, Lamouroux. *Varec*, Fr.; *Meergress*, Ger.; and *Fuco*, Ital.

4349. *The edible British fuci* may be shortly enumerated, because some of them are occasionally used as condiments by families living near the sea-coast; and because they furnish articles of resource for the local poor, especially in seasons of scarcity. There are numerous species; all of which, in common with every other class of sea-weeds and zoophytes, are employed in gardening as manures; and in general economy for making kelp or alkali. The following are the principal of the British species, which are considered edible by the inhabitants of sea-shores.

4350. *Fucus saccharinus*. Sweet fucus, or sea-belt. (fig. 431. a) Lightfoot mentions, that the common people on the coast of England sometimes boil this species as a pot-herb. Anderson says, the Icelanders boil it in milk to the consistence of pottage, and eat it with a spoon. They are also said to soak it in fresh water, dry it in the sun, and then lay it up in wooden vessels; it soon becomes covered with a white efflorescence of salt, which has a sweetish taste, and in this state they eat it with butter. They also feed their cattle with this species.

4351. *F. palmatus*, L. Dulse. (fig. 431. b) Both the tender stalks and young fronds are eaten recent from the sea, commonly without any preparation; they are sometimes considered as forming a salad, but more generally are used as a whet. Dulse formerly was frequently fried and brought to table. It is said, that the inhabitants of the Greek islands are fond of this species, adding it to ragouts and olives, to which it communicates a red color, and at the same time imparts some of its rich and gelatinous qualities. The dried leaves, infused in water, exhale an odor somewhat resembling that of sweet violets, and they communicate that flavor to vegetables with which they are mixed. Lightfoot mentions, that in the Isle of Skye, in Scotland, it is sometimes used in fevers, to promote perspiration, being boiled in water, with the addition of a little butter. It grows not uncommonly on rocks which are barely uncovered at the ebb of the tide; but is more frequent as a parasite on *F. nodosus*; and it occurs also on the stems of *F. digitatus*, attaining in this situation a considerable size, perhaps twelve or fifteen inches long, while, in general, it is only about six or eight inches. It is soft and limber, and does not become rigid by drying, being of a more loose texture than many other sea-weeds.

4352. *F. edulis*, L. red dulse (fig. 431. c), is by many preferred to the *F. palmatus*, especially for roasting in the frying-pan. Like that species, its smell somewhat resembles sweet violets. It is of a deep, opaque, red color, giving out a purple dye.

4353. *F. esculentus*, L. Badderlocks, or henware. (fig. 482. a) The mid-rib, stripped of its membrane, is the part chiefly eaten. In Orkney, the *pinnae* are also eaten, under the name of *mickles*.

4354. *F. ciliatus*, L. ciliated dulse, and *F. digitatus*, fingered dulse, sea-girdle, and hangers (figs. 482. b), are sometimes gathered and eaten like *F. edulis*, *palmatus*, and other species.

4355. *F. digitatus*. In Scotland, the stem of this species is used for making handles to pruning-knives. A pretty thick stem is selected, and cut into pieces about four inches long. Into these, while fresh, the blades are stuck, and as the stem dries, it contracts and hardens, closely and firmly embracing the hilt of the blade; when these handles have become hard and shrivelled, and tipt with metal, they are hardly to be distinguished from harts-horn.

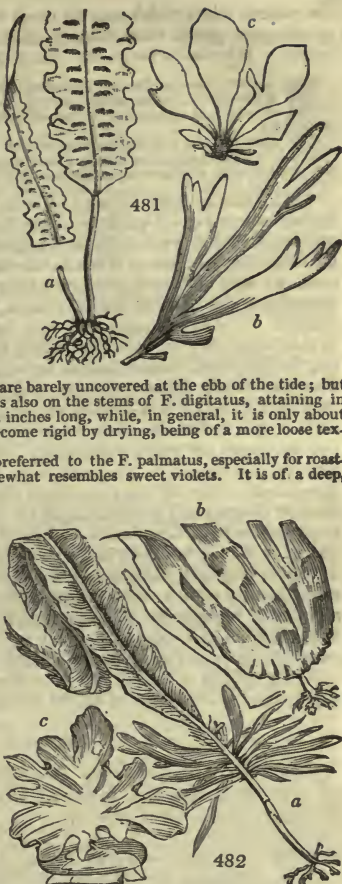

4356. *F. pinnatifidus*, L. Pepper dulse. In Scotland, it is eaten along with the *F. palmatus*, and in Iceland it is used instead of spice. This species is common to Scotland, Iceland, the Red Sea, and the shores of Egypt.

4357. *F. natans*, L. Floating fucus. The succulent fronds, Turner mentions, are selected and pickled like samphire; and the young shoots are eaten as a salad, seasoned with juice of lemons, pepper, and vinegar.

4358. *Ulva lactuca*, L. (fig. 482. c) Lettuce-leaves, or oyster-green. The thin, green, pellucid membranes of which this vegetable is composed are eaten raw, as a salad, and esteemed a great delicacy by such as have been accustomed to the use of marine vegetables.

4359. *Supplies*. No submarine production has hitherto been cultivated in the garden; though it might be worth while to try what could be done by a stone cistern of salt-water, and other contrivances. In the mean time, families in any part of Britain or Ireland, desirous of enjoying these vegetables, might have them regularly forwarded from the sea-shores, especially from such as are rocky. There are very few species known to be absolutely poisonous.

4360. *Edible nests*. We may add, as matter of curiosity, that the transparent edible nests of the East Indian swallows, so much in repute at the luxurious tables of the rich, in China and the East, are now generally believed to be almost entirely composed of gelatinous fuci; and more especially of the *F. lichénoides*. (Turner, t. 113.) The plant is also in high estimation for the table in India.

CHAP. IX.

Horticultural Catalogue. — Hardy Fruit-trees, Shrubs, and Plants.

4361. *The hardy fruits* of a country may be considered in reference to the vegetable appendages of the table, as next in utility to bread, corn, and culinary esculents. The excellent meats which they afford to the second course, and their contributions to the dessert, give them a peculiar value in the domestic economy of all those whose condition in life rises above the care of mere subsistence; and there are some sorts, as the gooseberry and apple, which, happily, either are or may be within the reach of the most humble occupier of a cottage and garden. Many fruits are as wholesome as they are pleasant; and some greatly assist the cure of particular diseases. Cider, perry, and

the various wines which may be made from the juices of fruits, are acceptable offerings to the social circle, when made in the best manner, and form important articles of commerce. We shall arrange the *Hardy Fruits* as—

4362. *Kernel-Fruits* or *Pomes*; including the apple, pear, quince, medlar, service.

4363. *Stone-Fruits*; as the peach, nectarine, almond, apricot, plum, and cherry.

4364. *Berries*; as the mulberry, barberry, elderberry, gooseberry, currant, raspberry, cranberry, and strawberry.

4365. *Nuts*; as the walnut, chestnut, filbert.

4366. *Native and neglected Hardy Fruits*, deserving cultivation, or useful in domestic economy, as the sloe, bird-cherry, wild service, mountain ash, bilberry, &c.

4367. *The varieties of most of these fruits* are so numerous, and each described as having so many good qualities, that the inexperienced selector may well be puzzled in making a choice, even from the comparatively limited lists which we have prepared for the following sections. When to all the names in these lists, and those of the nurserymen, we add the numerous new names annually brought forward by the Horticultural Societies of this country and of France, the difficulty of selection seems insuperably increased. The experienced and well informed gardener will be able to find out his way in this labyrinth; but what are others to do? We would say, as a prudent mode, consult the selections recommended by eminent practical men; as Abercrombie, M'Phail, Forsyth, Nicol, Macdonald, &c. which we have given in this chapter, and also in those on planting the kitchen-garden and orchard. (2498. and 2527.) There are probably not half so many distinct sorts, as there are names in use; and of that half, most likely two thirds are not worth cultivating. Of most of the sorts originated from seed, sufficient time has not elapsed to judge of their merits; they are all described as good; but unquestionably many of them are worth little in comparison with the best old sorts. Some of the new cherries and peaches might be adduced as examples; and the Poonah grape, lately imported from the East Indies, and stated to be "a valuable addition to our gardens" (*Hort. Trans.* iv. 517.), has been in the country (in the Brompton Nursery, for example), for an unknown length of time, under a different name. It is one of the worst descriptions of raisin grapes, with a small elliptical berry, having little flesh, juice, or flavor. — We make these remarks not to discourage from originating or importing new fruits; nor to dissuade from choosing new sorts; but to guard the inexperienced against being led away by names and appearances. The Horticultural Society are doing much to illustrate the subject of fruits, and in a few years they will no doubt settle a nomenclature, and determine the merits of all the fruits now in Europe, or perhaps the world.

SECT. I. *Kernel-Fruits.*

4368. *The principal hardy kernel-fruits* are the apple and pear, too well known for their important uses to require any eulogium. In this section are also included the quince, medlar, and service.

SUBSECT. 1. *Apple*. — *Pyrus Malus*, L. (*Eng. Bot.* 179.) *Icos. Di-Pentag.* L. and *Rosaceæ*, J. *Pomme*, Fr.; *Apfel*, Ger.; and *Pomo* or *Melo*, Ital.

4369. *The apple* is a spreading tree with the branches more horizontal than in the pear-tree; the leaves ovate; the flowers in terminating umbels, produced from the wood of the former year; but more generally from very short shoots or spurs from wood of two years' growth. The fruit is roundish, umbilicate at the base, and of an acid flavor. In its wild state, it is termed the crab, and is then armed with thorns, with smaller leaves, flowers, and fruit, and the pulp of the latter extremely acid. It is a native of most countries of Europe in its wild state; and the improved varieties form an important branch of culture in Britain, France, Germany, and America, for the kitchen, the table, and for the manufacture of cider. From whence we at first received the cultivated apple is unknown; but in all probability it was introduced by the Romans, to whom twenty-two varieties were known in Pliny's time (52.), and afterwards the stock of varieties greatly increased at the Norman conquest. According to Stow, carp and pepins were brought into England by Mascal, who wrote on fruit-trees in 1572. The apple-tree is supposed by some to attain a great age. Haller mentions some trees in Herefordshire that attained a thousand years, and were highly prolific; but Knight considers two hundred years as the ordinary duration of a healthy tree, grafted on a crab-stock, and planted in a strong tenacious soil. Speechly (*Hints*, 58.) mentions a tree in an orchard at Burton-joyce, near Nottingham, of about sixty years old, with branches extending from seven to nine yards round the bole, which, in 1792, produced upwards of 100 pecks of apples. Of all the different fruits which are produced in Britain, none can be brought to so high a degree of perfection, with so little trouble; and of no other are there so many excellent varieties in general cultivation, calculated for almost every soil, situation, and climate, which our island affords. Very good apples are grown in the Highlands and Orkneys, and even in the Shetland Isles, (*Caled. Hort. Mem.* vol. ii.) as well as in Devonshire and Cornwall; some sorts are ripe in the be-

ginning of July, and others, which ripen later, will keep till June. Unlike other fruits, those which ripen latest are the best.

4370. *Use.* For pies, tarts, sauces, and the dessert, the use of the apple is familiar to every one. Dudit, of Mazeres, has found that one-third of boiled apple-pulp, baked with two thirds of flour, having been properly fermented with yeast for twelve hours, makes a very excellent bread, full of eyes, and extremely palatable and light. (*New Month. Mag.* June 1821.) The fermented juice forms cider, a substitute both for grape-wine and malt liquor. In confectionary, it is used for comfits, *compotes*, marmalades, jellies, pastes, tarts, &c. In medicine, verjuice, or the juice of crabs, is used for sprains, and as an astringent and repellent: and, with a proper addition of sugar, Withering thinks a very grateful liquor might be made with it, little inferior to Rhenish wine. Lightfoot affirms that the crab mixed with cultivated apples, or even alone, if thoroughly ripe, will make a sound, masculine wine. The apple, when ripe, is laxative; the juice is excellent in dysentery: boiled or roasted apples fortify a weak stomach. Scopol recovered from a weakness of the stomach and indigestion from using them; and they are equally efficacious in putrid and malignant fevers with the juice of lemons or currants. In perfumery, the pulp of apples, beat up with lard, forms pomatum: and Bosc observes (*N. Cours d' Agriculture*, &c. in loco), that the prolonged stratification of apples with elder-flowers, in a close vessel, gives the former an odor of musk extremely agreeable. In dyeing, the bark produces a yellow color; and, in general economy, the wood of the tree is used for turning, and various purposes, where hardness, compactness, and variegation of color, are objects.

4371. *Criterion of a good apple.* Apples for the table are characterised by a firm juicy pulp, elevated poignant flavor, regular form, and beautiful coloring; those, for kitchen use, by the property of falling, as it is technically termed, or forming in general a pulpy mass of equal consistency, when baked or boiled, and by a large size. Some sorts of apples have the property of falling when green, as the Keswick, Carlisle, Hawthornden, and other codlins; and some only after being ripe, as the russet tribes. Those which have this property when green, are particularly valuable for affording sauces to geese early in the season, and for succeeding the gooseberry in tarts. For cider, an apple must possess a considerable degree of astringency, with or without firmness of pulp, or richness of juice. The best kinds, Knight observes, are often tough, dry, and fibrous; and the Siberian Harvey, which he recommends as one of the very best cider-apples, is unfit either for culinary purposes or the table. Knight has found that the specific gravity of the juice of any apple recently expressed, indicates, with very considerable accuracy, the strength of the future cider. Considering the various uses of the apple, we agree with Speechly in regarding it as a fruit "of more use and benefit to the public in general, than all the other fruits, the produce of this island, united."

4372. *Varieties.* Tusser, in 1573, mentions in his list of fruits, "apples of all sorts." Parkinson, in 1629, enumerates fifty-seven sorts. Evelyn, about thirty years afterwards, says (*Pomona*, pref.), "It was through the plain industry of one Harris, a fruiterer to Henry VIII., that the fields and environs of about thirty towns in Kent only, were planted with fruit from Flanders, to the universal benefit and general improvement of the county." Gibson (*Churches of Dove and Homelacy*.) mentions that Lord Scudamore, ambassador to the court of France, in the time of Charles I., collected in Normandy scions of cider-apple-trees, and when he returned to England, encouraged the grafting them throughout the county of Hereford. Hartlib, in 1650, speaks of "one who had two hundred sorts of apples," and "verily believes there are nearly 500 sorts in this island." Ray, in 1688, selected from the information of the most skilful gardeners about London, a list of 78 sorts. Succeeding writers have been enabled greatly to increase the list, partly from the almost continual accession of sorts received from the continent during intervals of peace, but principally from the great numbers raised from seeds. A variety of apple, like those of most other plants, is supposed by some to have only a limited duration; and hence on taking a retrospective view of the lists of sorts, given by Parkinson, Evelyn, and other authors, many of them are not now to be found, or are so degenerated or diseased, as no longer to deserve the attention of the planter. "The moil," Knight observes, "and its successful rival, the red-streak, with the musts and golden-pippin, are in the last stage of decay, and the stire and foxwhelp are hastening rapidly after them." After making a great variety of experiments for several years, and after many attempts to propagate every old variety of the apple, this author observes (*Tr. on Apple and Pear*, 15.), "I think I am justified in the conclusion, that all plants of this species, however propagated from the same stock, partake in some degree of the same life, and will attend the progress of that life, in the habits of its youth, its maturity, and its decay; though they will not be in any way affected by any incidental injuries the parent tree may sustain after they are detached from it."

4373. Knight next directed his attention to raising new varieties from seeds, and has, by crossing one sort with another, and by having constantly several thousands of seedlings rearing, from which, as they show fruit, to select the best sorts, succeeded in producing several new varieties of apples, much esteemed for the table and the press. Of several of these sorts, and how obtained, accounts will be found in the work above quoted, and in the *Horticultural Transactions*, and a compend of their history and properties will be found in our table (*next page*). Several eminent horticulturists, in different districts, are now engaged in a similar manner; and there can be little doubt a valuable accession will, in a few years, be made to this class of fruits. Some, however, as Williamson (*Hort. Trans.* iii. 291.) and Speechly (*Hints*, 188.), consider that the deterioration of the apple and other fruits may be owing to the climate, and that the return of genial summers would restore to us from old trees as good fruit as heretofore. Such also is our opinion, and Knight's doctrine appears to us contrary to general analogy in vegetable life. It is unquestionably true that all varieties have a tendency to degenerate into the primitive character of the species; but to us it appears equally true, that any variety may be perpetuated with all its excellencies by proper culture, and more especially varieties of trees. However unsuccessful Knight may have been in continuing the moil, redstreak, and golden pippin, we cannot alter our conviction, that by grafting from these sorts they may be continued, such as they are, or were when the scions were taken from the trees, to the end of time. As to plants propagated by extension, "partaking in some degree of the same period of life as the parent," we cannot admit the idea as at all probable. Vines, olives, poplars, and willows have been propagated by extension for ages, and are still, as far as can be ascertained, as vigorous as they were in the time of Noah or Pliny.

4374. *A numerous list of varieties may be considered as puzzling to inexperienced persons who have to select for a garden or an orchard.* Sabine (*Hort. Trans.* iii. 263.) justly observes, that the stock of apples requires reduction rather than increase; and adds, that one of the chief objects to which the attention of the Horticultural Society is at present directed, is to make a judicious selection.

4375. *A great variety of apple-trees in a bearing state may be seen in different nurseries both in Britain and Ireland, but especially near London;* from these in the autumn, the fruit may be tasted from the trees, and either young plants newly worked, or plants in a state of bearing, fixed on and marked, to be taken up at the proper season. The advantages of this mode, especially to such as possess but a small garden, are too obvious to require comment.

4376. *No well arranged catalogue of apples has yet been published,* because, in general, only a limited number of sorts fall under the eye and experience of one individual. Such a work seems more likely to be accomplished by public bodies, and is worthy of their attention. In the mean time, we present the best arrangement in our power of sorts readily procured from British nurseries, including most of the newly originated varieties, of which accounts have been published, and grafts distributed, among the commercial gardeners.

4977. A DESCRIPTIVE CATALOGUE OF APPLES propagated in most BRITISH NURSERY GARDENS, arranged as DESSERT, and KITCHEN, KITCHEN and CIDER FRUITS.

1. DESSERT APPLES. — PIPPINS. *Pippin* or Seedlings. — Common Character of this Tribe: middle size or under; round, often flattened; prevailing colors when ripe, yellow and green; not early ripe, but good for keeping. Tree less hardy and less prolific than many other sorts. In general it may be observed, that the form of the fruit and the color of the skin is less removed from that of a handsome and large crab, than the fruit of many of the other tribes. The sorts are here placed in the order of their keeping.

No.	Name.	Synonym.	How, when, and where originated, procured, or abounding.	Where figured.	Described.	Size.	Figure.	Color.	Ripe in	Last till	Consistence and flavor.	Bearer.	Character of the tree, and general reputation of the fruit.
1.	Old golden	-	An old decaying variety	Lang. Pom. t. 74.	Forsyth, 62.	Small	Roundish	Golden yellow	Oct.	Feb.	Firm flesh, and sweet	Mid.	One of the most ancient & excel. Brit., fit for dessert and cider
2.	Franklin's golden	-	A subvariety of golden	1780	Forsyth, 48.	Med.	Roundish	Gold and dark spots	Nov.	March	Firm, highly aromatic	Mid.	Excellent fruit; tree delicate
3.	Hughes' new gold.	-	A French apple	1803	Neill, En. H. 108.	Small	Flat	Yellow	Oct.	March	Firm, aromatic	Mid.	Ditto fruit; ranks next golden pippin for dessert and cider
4.	* Downton	-	Seedling by Knight	1804	Hort. Tr. i. 145.	Small	Round	Yellow	Oct.	March	Firm, sweet	Great	Good for dessert and cider
5.	Elton	-	Knight's golden p.	-	Salah, Or. 130.	Med.	Round	Gold with spots	Oct.	Feb.	Firm, sweet	Mid.	Excellent fruit
6.	Barnley	-	Estimated Scotch apple	-	Neill, En. H. 108.	Med.	Round	Yellow and green	Oct.	Feb.	Firm, aromatic	Mid.	Excellent fruit
7.	Borsdorf	-	German p. queen's	-	Hort. Tr. i. 123.	Large	Conical	Yellow and red	Oct.	Feb.	Firm and sweet	Mid.	Luxuriant table fruit
8.	Kentish	-	Old Kentish apple	-	Forsyth, 148.	Large	Conical	V. spotted white & red	Oct.	Mid. May	Firm, juicy, sweet	Mid.	Luxuriant tree
9.	Newtown	-	Reinette de Canada	-	Forsyth, 120.	Med.	Round	Orange	Oct.	March	Firm and sweet	Indif.	Weakly tree
10.	New red	-	New scarlet	-	Forsyth, 134.	Med.	Conical	Dark-red and yellow	Oct.	March	Firm and aromatic	Indif.	Tree, weak and drooping.
11.	French	-	Pigeonnette de Rou	-	Forsyth, 51.	Small	Flat	Scarlet and yellow	Oct.	Feb.	Firm, juicy	Indif.	Fruit resembles Orleans plum
12.	Orleans	-	Of French origin	-	Forsyth, 133.	Med.	Conical	Gold and red	Oct.	March	Firm, juicy, and sweet	Mid.	Slender tree
13.	Fears	-	A vigorous variety	-	Hort. Tr. ii. 104.	Med.	Round	Gold and pale-red	Oct.	March	Firm, juicy, and aromatic	Mid.	Very showy at table, large tree
14.	Orange	-	Seedling	-	Forsyth, 97.	Med.	Conical	Red and reddish-yellow	Nov.	March	Firm, juicy	Good	Excellent fruit, vigorous tree
15.	North's new seal.	-	Seedling	-	Forsyth, 84.	Large	Conical	Gold streaked with red	Nov.	March	Firm, juicy	Good	Good fruit, large tree
16.	King of the pipp.	-	A Scotch apple	-	Forsyth, 117.	Med.	Flat	Red and green	Oct.	Jan.	Firm, sweet	Good	Small tree, but hardy
17.	Paradise	-	Cracked pippin	-	Lang. Pom. t. 74.	Med.	Conical	Yellowish-green	Oct.	Jan.	Firm, juicy	Mid.	Small tree; fruit grows mealy
18.	Queen's	-	An American apple	-	Forsyth, 148.	Small	Round	Green and brown	Jan.	May	Firm, aromatic	Good	Large vigorous tree
19.	New England	-	Seedling by Knight	-	Forsyth, 102.	Large	Oval	Golden-yellow	Oct.	March	Firm and juicy	Good	Vigorous tree
20.	Lemon	-	Seedling by Knight	-	Hort. Tr. i. 69.	2 to 31	Oval	Prickly and freckled	Sept.	Feb.	Richly perfumed	Good	Hardy tree; excellent fruit
21.	Padley's	-	Seedling by Knight	-	Forsyth, 188.	Small	Round	Reddish green	Sept.	March	Firm, sweet	Good	Hardy tree
22.	Brinewood	-	Seedling of Knight	-	Hort. Tr. i. 227.	Med.	Round	Strik' white, red & yell.	Nov.	May	Firm, sweet	Good	Luxuriant tree
23.	Yellow pear	-	Seedling of Knight	-	Hort. Tr. i. 227.	Med.	Round	Yellow	Oct.	Feb.	Firm, juicy	Good	Large handsome tree
24.	Red ingersie	-	Seedling of Knight	-	Hort. Tr. i. 229.	Small	Conical	Yellow and red	Oct.	Feb.	Firm, juicy	Good	Vigorous tree
25.	Wormsley	-	From seed of the golden at Huntingdon	-	Hort. Tr. ii. 103.	Small	Flat	Green and yellow	Oct.	Feb.	Firm, juicy	Great	Hardy tree and valuable fruit
26.	Wood's new trans-	-	-	-	-	-	-	Russet white, red, and yellow	Oct.	April	Firm and sweet	Mid.	Tree of low growth
27.	Cockle	-	-	-	-	-	-	-	-	-	-	-	-

DESSERT APPLES. — PEARMAINS. — Common Character: full at the footstalk, in general larger than Pippins.

31.	Summer	-	-	-	Forsyth, 165.	Med.	Conical	Green-striped with red	Aug.	Oct.	Soft, juicy, and sweet	Good	Hardy tree; fruit soon mealy
32.	Golden	-	-	-	Knoop Pom. t. 76	Large	Conical	Deep-red and yellow	Aug.	Oct.	Soft and sweet	Good	Ditto, not large; esteemed fruit
33.	Kernel	-	-	-	Forsyth, 48.	Small	Oval	Streaked white, red	Jan.	May	Firm and juicy	Mid.	Rather a tender tree

241.	Yellow Siberian	-	From the Siberian crab and Loai's pearmain, by Knight	Pom. Her. t. 10.	Kn. Tr. 175.	Very s.	Round	Very yellow	Jan.	Firm and austere	Great	

4378. *Propagation.* The apple, like most other hardy trees, may be propagated by seeds, cuttings, suckers, layers, or engrafting: by seeds, for obtaining new varieties, and by the other modes for continuing such as are in esteem.

4379. *By seeds.* The first business here is, the choice of the seeds; which should be taken from fruits, having the properties it is desired to perpetuate or improve in the greatest degree. The sorts of apples proper for crossing or reciprocal impregnation, appear to be those which have a great many qualities in common, and some different qualities. Thus the golden pippin has been crossed by other pippins or rennets, and not by calvils or codlings. A small-sized apple, crossed by a large sort, will be more certain of producing a new variety than the above mode; but will be almost equally certain of producing a variety destitute of valuable qualities; the qualities of parents of so opposite natures being, as it were, crudely jumbled together in the offspring.

4380. *Knight's mode* of cutting out the stamens of the blossom to be impregnated, and afterwards, when the stigma is mature, introducing the pollen of the other parent, is unquestionably the most scientific mode of performing the operation. In this way he produced those excellent apples, the Downton, red and yellow Ingestrie, and Grange pippins, from the same parents; viz., the seed of the orange pippin, and the pollen of the golden pippin. The Brindwood pippin he produced from golden pippin blossoms (divested of their stamens) dusted with the pollen of the golden harvey apple. The seeds may be sown in autumn, in light earth, covered an inch, and either in pots or beds. The end of the first year they should be transplanted into nursery rows, from six inches to a foot apart every way. Afterwards they should be removed to where they are to produce fruit; and for this purpose the greater the distance between the plants the better. It should not be less than six or eight feet every way. The quickest way to bring them into a bearing state, Williams, of Pitmaston, considers, (*Hort. Trans.* vol. i. 333.) is to let the plants be furnished with lateral shoots from the ground upwards; so disposed as that the leaves of the upper shoots may not shade those situated underneath, pruning away only trifling shoots. This mode of treatment occurred to him on reflecting on Knight's *Theory of the Circulation of the Sap*. Observing the change in the appearance of the leaves of his seedling plants as the trees advanced in growth, he thought it might be possible to hasten the progress of the plants, and procure that peculiar organisation of the leaf, necessary to the formation of blossom-buds, at a much earlier age. He in consequence adopted the mode above described, and succeeded in procuring fruit from seedling apples at four, five, and six years of age, instead of waiting eight, ten, and even fifteen years, which must be the case by the usual mode of planting close, and pruning to naked stems.

4381. *Macdonald*, an eminent Scotch horticulturist, has also succeeded in obtaining fruit from seedlings at an early period by grafting, already stated (2014.) as one of the uses of that mode of propagation. In 1808, he selected some blossoms of the nonpareil, which he impregnated with the pollen of the golden pippin and of the Newton pippin. When the apples were fully ripe, he selected some of the best, from which he took the seeds, and sowed them in pots, which he placed in a frame. He had eight or nine seedlings, which he transplanted into the open ground, in spring 1809. In 1811, he picked out a few of the strongest plants, and put them singly into pots. In spring 1812, he observed one of the plants showing fruit-buds. He took a few of the twigs, and grafted them on a healthy stock on a wall; and in 1813 he had a few apples. This year (1816) his seedling yielded several dozens, and also his grafts; and he mentions, that the apples from the grafts are the largest. He is of opinion that in giving names to seedlings, raised in Scotland, the word "Scotch" should be mentioned.

4382. *A very common practice among those who raise fruit-trees from seed*, is, in the second or third season, to select such plants only as have broad and roundish leaves, throwing away the rest; experience having taught, that the former more frequently produce fruit of improved qualities, or at least larger, than those plants which have narrow-pointed leaves. The width and thickness of the leaf, Knight observes, "generally indicates the size of the future apple; but will by no means convey any correct idea of the merits of the future fruit. Where these have the character of high cultivation, the qualities of the fruit will be far removed from those of the native species; but the apple may be insipid or highly flavored, green, or deeply colored, and of course well or ill calculated to answer the purposes of the planter. An early blossom in the spring, and an early change of color in the autumnal leaf, would naturally be supposed to indicate a fruit of early maturity; but I have never been able to discover any criterion of this kind on which the smallest dependence may be placed. The leaves of some varieties will become yellow and fall off, leaving the fruit green and immature; and the leaves in other kinds will retain their verdure long after the fruit has perished. The plants whose buds in the annual wood are full and prominent, are usually more productive than those whose buds are small and shrunk in the bark; but their future produce will depend much on the power the blossoms possess of bearing the cold, and this power varies in the different varieties, and can only be known from experience. Those which produce their leaves and blossoms rather early in the spring are generally to be preferred, for though they are more exposed to injury from frost, they less frequently suffer from the attacks of insects; the more common cause of failure. The disposition to vegetate early or late in the spring, is like almost every other quality in the apple-tree, transferred in different degrees to its offspring; and the planter must therefore seek those qualities in the parent tree which he wishes to find in the future seedling plants. The most effective method I have been able to discover of obtaining such fruits as vegetate very early in the spring, has been by introducing the farina of the Siberian crab into the blossom of a rich and early apple, and by transferring in the same manner the farina of the apple to the blossom of the Siberian crab. The leaf and the habit of many of the plants, that I have thus obtained, possess much of the character of the apple, whilst they vegetate as early in the spring as the crab of Siberia, and possess, at least, an equal power of bearing cold; and I possess two plants of this family, which are quite as hardy as the most austere crab of our woods."

4383. *Abercrombie* observes that, "as the codling is a sort found to change very little from seed, or not for the worse, new plants of it are sometimes raised by sowing the kernels, not by way of experiment for a new uncertain variety, but with some dependence on having a good sort resembling the parent."

4384. *By cuttings.* Every variety of apple may be grown from cuttings; though some with much greater facility than others. All those of the burknot and codling tribes grow as well this way as by any other, and some allege, that the trees so raised are not liable to canker (*Hort. Trans.* vol. i. p. 120.), which is supposed to be owing to their "putting out no tap-root, but spreading their numerous fibres from the knot or burr horizontally." Even the golden pippin may be continued in this way, and the trees have remained seven years in perfect health, when grafts taken not only from the same tree, but from the very branch, part of which was divided into cuttings, cankered in two or three years. "All apple-trees raised in this way," Biggs observes, "from healthy one-year-old branches, with blossom-buds upon them, will continue to go on bearing the finest fruit, in a small compass, for many years. Such trees are peculiarly proper for forcing, and not liable to canker." (*Hort. Trans.* vol. i. p. 65.) The cuttings are to be chosen from the young wood of horizontal or oblique branches, rather than from upright ones; from six to eight inches or more in length, with a small portion of old wood at

the lower end. Cut off the tip of the shoot, and all the buds, excepting two or three next the tip or upper extremity; then smooth the sections at the lower end, and insert them three or four inches in sandy loam, pressing the earth firmly to them, watering, and covering with a hand-glass. The proper time for this operation is early in February, and the glass should not be touched, excepting to give water, till the shoots have sprung an inch or two. Shade during the mid-day sun, and begin to harden by giving air in July; finally remove the glass in August; and in October transplant to nursery rows, or in pots, according to future intention. With the burknott tribe, all that is necessary is to plant the cuttings in a shady border, and treat them like those of the gooseberry or currant.

4385. *By layers.* The success of this mode of propagation may be considered as certain; as it has nothing peculiar in its application to the apple, we need only refer to general directions (1993.) for performing the operation. The after treatment of the plants is the same with that for those originated by the foregoing or following modes.

4386. *By suckers.* This mode is generally confined to the paradise and creeping apple for stocks.

4387. *By grafting and inoculation.* This may be said to be the universal practice in propagating the apple. The first consideration is the choice of stocks; of these, there are five sorts in common use: — *Seedling apples*, used for full standards, and riders or wall standards; *seedling crabs*, for standards and half standards; *codling apples*, from layers or cuttings, for dwarfs and espaliers; *paradise apples*, or *doucins*, from layers or cuttings, for low dwarfs and trained; and *creeping apples*, from layers or cuttings, for the best dwarfs or bushes. Dubreuil, gardener at Rouen, recommends the doucin for clayey and light soils, and a free stock for such as are chalky and siliceous. (*Hort. Trans.* iv. 566.)

4388. *Stocks of seedling apples.* The seeds should be selected from the fruit of vigorous growing young or middle-aged healthy trees; but when wanted in large quantities, they are procured from cider makers; private propagators will adopt the first mode. The sowing and after treatment is the same as for seedling crabs.

4389. *Seedling crabs.* “A preference,” Knight observes, “has generally and justly been given to apple-stocks raised from the seeds of the native kind, or crab, as being more hardy and durable than those produced from the apple. The offspring of some varieties of the crab, particularly of those introduced from Siberia, vegetate much earlier in the spring than the other trees of the same species; and thence the inexperienced planter will probably be led to suppose, that such stocks would accelerate the vegetation of other varieties in the spring, and tend to produce an early maturity of the fruit in autumn. In this, however, he will be disappointed. The office of the stock is, in every sense of the word, subservient; and it acts only in obedience to the impulse it receives from the branches: the only qualities, therefore, which are wanting to form a perfect stock, are vigor and hardness.”

4390. *Seeds, sowing, and culture.* In recollecting the seeds to sow, it must be remembered, that the habits as well as the diseases of plants are often hereditary, and attention should be paid to the state of the tree from which the seeds are taken; it should be large and of free growth, and rather in a growing state than one of maturity or decay. The crab-trees, which stand in cultivated grounds, generally grow more freely and attain a larger stature than those in the woods, and therefore appear to claim a preference. The seeds should be taken from the fruit before it is ground for vinegar, and sown in beds of good mould an inch deep. From these the plants should be removed in the following autumn to the nursery, and planted in rows at three feet distance from each other, and eighteen inches between each plant. Being here properly protected from cattle and hares, they may remain till they become large enough to be planted out; the ground being regularly worked and kept free from weeds.

4391. *Codling stocks* are raised chiefly from layers, which, at the end of the season, are taken off, and planted in nursery rows two feet between the rows, and one foot plant from plant.

4392. *Paradise*, or as they are called by the French, *doucin stocks*, are raised either from layers or suckers; and stocks from *creeping apples* (so named from their aptitude to throw up suckers), or the *Dutch paradise*, chiefly from the latter mode. They may be planted in nursery rows somewhat closer than the codling stocks.

4393. *All stocks* require to stand in the nursery till they are from half an inch to an inch thick, at the height at which they are to be grafted; such as are intended for full standards or riders will, in general, require to grow three or four years before being fit for this operation; those for half standards two years, and those for dwarfs one year. The ground between them must be kept clear of weeds, and stirred every winter; the side shoots of the plants, at least to the height at which they are intended to be grafted, rubbed off as they appear, and all suckers carefully removed. Where budding is adopted, the stocks may be worked at nearly half the diameter of stem requisite for grafting; and stocks for dwarfs planted in autumn or spring may be inoculated the succeeding summer. No great advantage, however, is gained in this practice, as such plants require to stand at least another year, before they have produced their bud-shoots.

4394. *Soil and situation of the nursery.* “A difference of opinion appears always to have prevailed respecting the quality of the soil proper for a nursery; some have preferred a very poor, and others a very rich soil; and both perhaps are almost equally wrong. The advocates for a poor soil appear to me to have been misled by transferring the feelings of animals to plants, and inferring that a change from want to abundance must be agreeable and beneficial to both. But plants in a very poor soil become stunted and unhealthy, and do not readily acquire habits of vigorous growth, when removed from it. In a soil which has been highly manured, the growth of young apple-trees is extremely rapid; and their appearance, during two or three years, generally indicates the utmost exuberance of health and vigor. These are, however, usually the forerunners of disease, and the ‘canker’s desolating tooth’ blasts the hopes of the planter. In choosing the situation for a nursery, too much shelter, or exposure, should be equally avoided; and a soil, nearly similar to that in which the trees are afterwards to grow, should be selected, where it can be obtained. Pasture ground, or unmanured meadow, should be preferred to old tillage, and a loam of moderate strength and of considerable depth to all other soils.” (*Tr. on App. and Pear.*)

4395. *Grafting.* The first business is to select the scions, the principles of which have been already noticed (2043). At whatever season scions are to be inserted, Knight observes, “the branches, which are to form them, should be taken from the parent stock during the winter, and not later than the end of the preceding year: for if the buds have begun to vegetate in the smallest degree, and they begin with the increasing influence of

the sun, the vigor of the shoots, during the first season, will be diminished, and the grafts will not succeed with equal certainty; though a graft of the apple-tree very rarely fails, unless by accidental injury, or great want of skill in the operator. The amputated branches must be kept alive till wanted, by having the end of each planted in the ground, a few inches deep in a shady situation."

4396. *Stocks destined to form standard trees*, may either be grafted at the usual height at which the lateral branches are allowed to diverge, which is commonly six feet, or they may be grafted near the ground, and a single shoot trained from the graft, so as to form the stem of the tree. The propriety of grafting near the ground, or at the height of six or seven feet, will depend on the kind of fruit to be propagated, whether it be quite new and just beginning to bear, or a middle-aged variety. In new and luxuriant varieties, and these only should be propagated, it will be advantageous to graft when the stocks are three years old, as the growth of such will be more rapid, smooth, and upright than that of the crab, and there will be no danger of these being injured by beginning to bear too early. Middle-aged varieties will be most successfully propagated by planting stocks of six or seven foot high, and letting them remain ungrafted till they become firmly rooted in the places in which the trees are to stand. One graft only should be inserted in each stock; for when more are used, they are apt to divide when loaded with fruit, and to cleave the stock, having no natural bond or connection with each other. When the stocks are too large for a single scion, I would recommend that the grafts be inserted in the branches, and not in the principal stem. This practice is not uncommon in various parts of England; and is general in Germany, with free stocks, where, however, they often neglect to graft the trees; and thus, as Neill observes, produce an endless variety of sorts, some good, but most of them little better than crabs.

4397. *Stocks, intended to form half standards*, are grafted at three or four feet from the ground; and those for *dwarfs* at eight or ten inches, or lower. Miller and Knight agree in recommending to graft near the ground where lasting and vigorous trees are wanted; but the practice of the continental gardeners, and the opinions of some in this country, are in favor of leaving a stem below the graft of not less than a foot in length.

4398. *The kind of grafting generally adopted* for moderate-sized stocks is the *whip* or *tongue* method (2038.), or the new mode of saddle-grafting (2033.) adopted by Knight; and the general time for the apple is the end of February and greater part of March. Much depends on the season and situation; the guiding principle is, to make choice of the time when the sap of the stock is in full motion; while that of the scions, from having been previously cut off and placed in the shade, is less so.

4399. *The common season for budding the apple* is July; as there is nothing peculiar to this tree in performing that operation, we refer to the general directions. (2050.)

4400. *Transplanting grafted trees in the nursery*. "It has been recommended," Knight observes, "to remove grafted trees once or twice during the time they remain in the nursery, under the idea of increasing the number of their roots; but I think this practice only eligible with trees which do not readily grow when transplanted. I have always found the growth of young apple-trees to be much retarded, and a premature disposition to blossom to be brought on by it; and I could not afterwards observe that those trees, which had been twice removed, grew better than others. It has also been supposed that many small roots, proceeding immediately from the trunk, are, in the future growth of the tree, to be preferred to a few which are large; but as the large roots of necessity branch into small, which consequently extend to a greater distance, the advantages of more transplantations than from the seed-bed to the nursery, and thence to the garden or orchard, may reasonably be questioned."

4401. *The choice of sorts* depends on the object in view. The first thing an inexperienced gardener has to do is to consider the various domestic uses of the apple, and then determine what is wanted, according to the family or market to be supplied; the next thing is to consider how those wants may be supplied in his given soil, situation, and circumstances; and the last thing is to study the catalogue of sorts, and select accordingly. In every garden and private orchard, apples for ten different purposes are desirable:—

4402. For summer culinary use, as the

Codlings, while not fully grown or imperfectly ripe, which are fit for using in June, July, and August.

4403. For summer eating or table use, as the

Jennetting, pomroy, &c. which ripen in the end of June or in July	Margaret summer pearmain, &c. which ripen in July	Kentish fill-basket, Hawthorndean, &c. which ripen in August.
---	---	---

4404. For autumn baking, as the

Codlings and Burknott's, red streaks, Eve apple, courtpendu, nonsuch, &c. which ripen in September	Piles's russet, Carlisle codling, cat's head, embroidered, &c. which ripen in October	Wormsley pippin, golden Harvey, queen-ing, golden russet, which ripen in November.
--	---	--

4405. For autumn table use, as the

Kirton and Dalmahoy pippins, Loan's pearmain, colville, Kent, godolphin, &c. which ripen in September	Orange and ribstone pippins, grey rennet, fauseuse, violet, &c. which ripen in October	Franklin's golden, and Borsdorf pippins, Dredge's russet, margil, &c. which ripen in November.
---	--	--

4406. For winter culinary use, as the

Minier's dumpling, Burknott, John apple, Mansfield tart, &c. which are fit to use in December	Hall-door, royal pearmain, Dutch queen-ing, Aclam's russet, which are fit to use in January	Brindgwood pippin, cockagee, tanker-ton, box-apple, &c. which are fit to use in February.
---	---	---

4407. For winter table use, as the

Golden and Kentish pippins, golden and Canadian rennets, brandy, &c. which are fit to eat in December	The Norfolk storing, Hubbard's, Syke-house, white courtpendu, &c. which are fit to eat in January	Dredge's Queen Charlotte, Fearn's, Skern's kernel, and Dalmahoy pippins, royal pearmain, &c. which are fit to eat in February.
---	---	--

4408. For spring culinary use, as the

Quince, white colville, Lord Camden's rennet, winter pearmain, which keep till the end of March	Spencer pippin, Trevolder rennet, Macdonald's Scotch nonpareil, Spanlard, &c. which keep till the end of April	Norfolk paradise, Loan's pearmain, English rennet, &c. which keep till the end of May.
---	--	--

4409. For spring table use, as the

Hollow-eyed, Cornwall rennet, Hughes's new golden pippin, &c. which keep till the end of March

Cockle and Whitmore pippins, golden and Piles's russet, Wheeler's extreme, &c. which keep till the end of April

Stone and spencer pippins, Royal George, Ward, &c. which keep till the end of May.

4410. For summer culinary use, till the apple season returns, as the

Lord Cheney's green, Baxter's pearmain, stoup, codling, &c. which keep till the end of June

Norfolk beaufin, Norfolk storing, French crab, which keep till the end of July.

4411. For summer table use, till the apple season returns, as the

Dredge's fame, oaken peg, carnation, &c. which keep till the end of June

Nonpareil, Yorkshire greening, Norfolk colman, which keep till the end of July.

4412. *Other sources of choice.* Another source of choice, under each of the above heads, may respect the soil, situation, and climate of the garden, or orchard, in which they are to be planted, or the character, whether of dwarfs, espaliers, or wall-trees, which they are to assume there. The winter and spring table apples may require a south wall in one district, while in another they may attain equal maturity as standards or espaliers. Where there is ample room, a selection of large sorts, as the Alexander and Baltimore apples, or of such as are the most beautifully colored, as the violet, carnation, &c. may be made to gratify the eye; where room is wanting, useful sorts and great bearers are to be preferred, as the golden and ribstone pippin, summer pearmain, codlings, grey russet, summer and winter colvilles, &c. In general, small-sized fruit, as the Harveys and Granges, are to be preferred for standards, as less likely to break down the branches of the trees, or be shaken down by winds; middling sorts for walls and dwarfs, and the largest of all for espaliers. In respect to a soil liable to produce canker, sorts raised from cuttings may be desirable, as the Burknott and codling tribe; and where an occupier of a garden has only a short interest therein, such as come into immediate bearing, as the Burknotts, and others from cuttings, and the Hawthorndean, Apius's apple, and other short-lived dwarf-sorts on Paradise or creeping stocks, may deserve the preference. (On the contrary, where a plantation is made on freehold property, or with a view to posterity, new varieties on crab or free stocks, should always be chosen, as the Grange, Ingestrie, Harvey, &c. Some excellent sorts will grow and produce crops every where, as the Hawthorndean, codling, and Ribston pippin; the latter of which, Nicol says, will grow at John o'Groat's house, and may be planted in Cornwall; others are shy bearers in cold situations, as the Newtown pippin of America, and most of the newly imported French sorts.

4413. *Choice of plants and planting.* This depends in some degree on the object in view, the richness of the soil, and the shelter; young trees are more likely to succeed in exposed sites and poor soils, but the apple will bear transplanting at a greater age than any other fruit-tree. It may be planted in any open weather from November till February.

4414. *Soil and site for permanent planting.* Any common soil, neither extremely sandy, gravelly, nor clayey, on a dry sub-soil, and with a free exposure, will suit this tree. On wet, hilly sub-soils, it will do no good, but after being planted a few years will become cankered, and get covered with moss. Where fruit-trees must be planted on such soils, they should first be rendered as dry as possible by under-draining; next, provision made for carrying off the rain-water by surface gutters; and, lastly, the ground should not be trenched above a foot deep, and the trees planted rather in hillocks of earth, above the surface, than in pits dug into it. There is no point of more importance than shallow trenching and shallow planting in cold wet soils, in which deep pits and deep pulverisation only serve to aggravate their natural evils of moisture and cold. (*Sang, in Caled. Hort. Mem. iv. 140.*)

4415. *Knight* observes, that "the apple-tree attains its largest stature in a deep strong loam or marly clay; but it will thrive in all rich soils, which are neither very sandy nor wet at bottom. It succeeds best," he adds, "in situations which are neither high nor remarkably low. In the former its blossoms are frequently injured by cold winds, and in the latter by spring frosts, particularly when the trees are planted in the lowest part of a confined valley. A south, or south-east aspect is generally preferred, on account of the turbulence of the west, and the coldness of north winds; but orchards succeed well in all aspects; and where the violence of the west wind is broken by an intervening rise of ground, a south-west aspect will be found equal to any."

4416. *Abercrombie* says, "all the sorts of apple-tree may be planted in any good common soil, with a free exposure, whether that of a garden, orchard, or field; so that the ground be neither very low nor excessively wet, nor subject to inundation in winter. Avoid, as far as possible, very strong clayey and gravelly soils."

4417. *Mode of bearing.* "In all the varieties of the common apple, the mode of bearing is upon small terminal and lateral spurs, or short robust shoots, from half an inch to two inches long, which spring from the younger branches of two or more years' growth, appearing first at the extremity, and extending gradually down the side: the same bearing-branches and fruit-spurs continue many years fruitful" (*Abercrombie.*)

4418. *Pruning.* "As, from the mode of bearing, apple-trees do not admit of shortening in the general bearers, it should only be practised occasionally: first, where any extend out of limits, or grow irregular and deformed; and secondly, a good shoot contiguous to a vacant space is shortened to a few eyes, to obtain an additional supply of young wood from the lower buds of the shoot for filling up the vacancy. But to shorten without such a motive, is not merely the cutting away of the first and the principal bearing part of the branches, but also occasions their putting forth many strong useless wood-shoots where fruit-spurs would otherwise arise; and both effects greatly tend to retard the trees in bearing; whereas the fertile branches being cultivated to their natural length, shoot moderately, and have fruit-spurs quite to the extremity." (*Abercrombie.*)

4419. *Espaliers and wall-trees* require a summer and winter pruning.

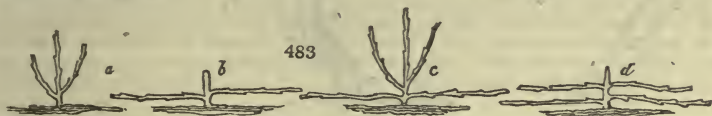

4420. *The summer pruning.* Train in the young shoots of the same year, which are likely to be wanted in the figure, and retrain them where ill placed or too numerous; for as the trees continue bearing many years on the same branches, they only require occasional supplies of young wood; therefore, begin in May or June to pinch off or cut out close all fore-right, ill placed, and superfluous shoots; retaining only some of the promising laterals in the more vacant parts, with a leader to each branch; train in these between the mother branches, at their full length, all summer; or, where any vacancy occurs, some strong conti-

guous shoot may be shortened in June to a few eyes, to furnish several laterals the same season. Keep the shoots in all parts closely trained, both to preserve the regularity of the espalier, and to admit the air and sun to the advancing fruit.

4421. *The winter pruning* may be performed from November till the beginning of April. This comprehends the regulation of the wood-branches, the bearers, and of the young shoots. First, examine the new shoots trained in the preceding summer; and if too abundant, retain only a competency of well placed and promising laterals, to furnish vacant parts, with a leading shoot to each parent branch. Continue these mostly at full length, as far as there is room. Cut out close the superabundant and irregular young shoots; and where any of the elder branches appear unfruitful, cankered, or decayed, cut them either clean out, or prune short to some good lateral, as may seem expedient. Also prune into order any branches which are very irregular, or too extended. Carefully preserve all the eligible natural fruit-spurs; but remove all unfruitful stumps and snags, and large projecting rugged spurs; cutting close to the old wood. As each espalier is pruned, let the old and new branches be laid in at convenient distances, according to the size of the fruit, four, five, or six inches asunder, and neatly tied or nailed to the wall or trellis. (*Abercrombie.*)

4422. *Training espaliers.* The following mode, as described by Mearns, is the most general, and by using stakes, which do not answer so well for any other species of espalier-tree as for apples, is also the most economical:—In the first stage of training, the stakes require to stand as close together as twelve or fourteen inches, and to be arranged in regular order to the full height of five feet, with a rail slightly fastened on the top of them for neatness sake, as well as to steady them. If stakes of small ash, Spanish chestnut, or the like, from coppices or thinnings of young plantations, be used, they will last for three or four years, provided they are from one inch and a half to two inches in diameter, at a foot from the bottom. They need not be extended further in the first instance than the distance to be considered probable the trees may reach in three years' growth; at that period, or the following season, they will all require to be renewed, and the new ones may be placed on each side, to the extent that the trees may be thought to require while these stakes last, finishing the top as before, with a rail. As the trees extend their horizontal branches, and acquire substance, the two stakes on each side of the one that supports the centre leader of the tree, can be spared, and removed to any of the extremities where wanted. And as the tree extends further, and acquires more substance, every other stake will be found sufficient; and the centre stake can be spared also, after the leader has reached its destined height, and is of a sufficient substance to support itself erect. When such a form of training is completed, and the branches of sufficient magnitude, about six, eight, or twelve stakes will be sufficient for the support of the horizontal branches, even when they have the burden of a full crop of fruit. At any other time, about six stakes to each tree will be all that are necessary.

4423. *In selecting trees for the usual horizontal training*, look out for those which have three fine shoots. Or it is better to plant them one year where they are to remain to get their roots well established, and then to head them down to within eight or nine inches of the ground, and to encourage three shoots from the top of each stool (*fig. 483. a*), so that the first and lowermost horizontal shoots may be tied down within ten inches of the ground.

4424. In the pruning season cut down the middle shoot of the three, reserving what is left as an upright leader, its length being about twelve inches from the base of the other two, and train these in a horizontal position (*b*), fixing the middle shoot, which was cut down perpendicularly to the stake it is planted against. But if it is against a wall or pales, it may be better to zigzag the upright leader, for the more regular distribution of the sap, and when that is intended, the leader should be left a little longer, to allow of its being bent. In espalier training this zigzagging is not so readily done, nor is it necessary where the trees are not intended to rise high. It is always necessary, in the course of training the young wood across the stakes, in summer, to have large osier, or similar rods, to tie them to, in order to guide the shoots of the year in a proper direction. The proper ties are small osier twigs.

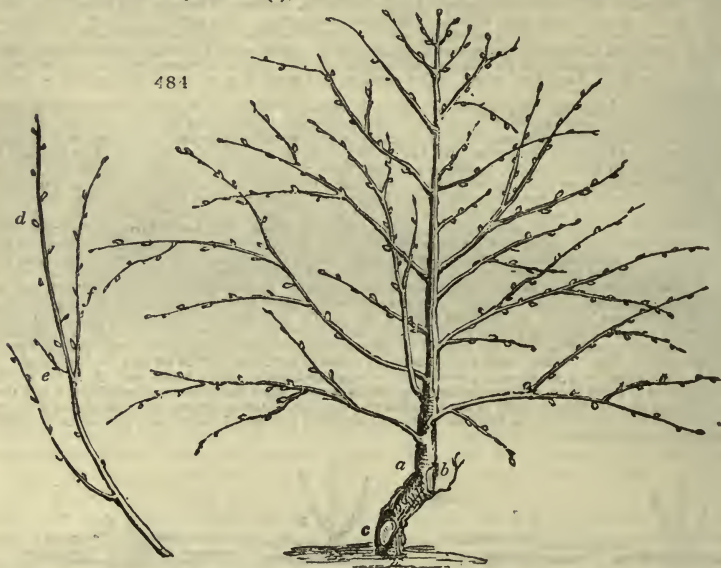

4425. *The following summer* encourage three other shoots in the same way as the season before (*c*), then cut off the middle shoot at ten, twelve, or fifteen inches above the base of the other two, and train these last as in the former season (*d*); and so continue training, year after year, till the trees have reached their destined height. (*Mearns, in Hort. Trans. v. 46.*) An improvement on this mode consists in cutting down the leading shoot during summer, in the manner practised by Harrison, of Wortley Hall, as described in the succeeding paragraphs.

4426. *Training against a wall.* The horizontal mode is unquestionably to be preferred for so vigorous a growing tree as the apple; and Harrison's mode of conducting the process (*Tr. on Fruit-Trees, 1823. ch. xx.*) appears to us much the best. The peculiarity of his method is, that instead of training the leading shoot in a serpentine or zigzag manner with Hitt or Mearns, to make it send out side shoots, he adopts the much more simple and effectual mode of cutting down the current year's shoots in June; by which means he gains annually a year, as side shoots are produced on the young wood of that year, as well as on last year's wood which it sprang from.

4427. *The tree being a maiden plant* is the first year headed down to seven buds. Every bud pushing, two of the shoots, the third and fourth, counting upwards, must be rubbed off when they are three inches in length; the uppermost shoot must be trained straight up the wall for a leading stem, and the remaining four horizontally along the wall. The leading shoot having attained about fifteen inches in length, cut it down to eleven inches. * From the shoots that will thus be produced select three, one to be trained as a leader, and two as side branches. Proceeding in this way for seven years, the tree will have reached the top of a wall twelve feet high. With weak trees, or trees in very cold late situations, this practice will not be advisable, as the wood produced would be too weak, or would not ripen; but in all ordinary situations, it is obviously a superior mode to any that has been hitherto described in books. In pruning the spurs of apple and other trees, Harrison differs from many gardeners in keeping them short, never allowing one spur to have more than three or four fruit-buds, and in cutting off the spurs entirely, or cutting them down for renewal every fourth or fifth year. Every practical gardener, desirous of excelling in the training and spurring of fruit-trees, ought to possess Harrison's treatise.

4428. *Heading down apple-trees* that are much cankered, is strongly recommended by Forsyth, who gives an example of one (*fig. 484.*), after it had been headed down four years, which bore plenty of fine fruit. The point at which it was headed down (*a*) was within eighteen inches of the soil; and under it, on the stump, were two large wounds (*b*)

and (c), made by cutting out the canker part, and which being covered with the composition were soon nearly filled up with sound wood. Very little pruning is at first given to trees so cut, but afterwards a regular succession of bearing wood is kept up by removing such as have borne for three or four years: Thus, one branch (d), which has done bearing, is cut off, and succeeded by another (f), and when that is tired also, it is cut off, and replaced by a third (e), and so on.

4429. *Grafting old apple-trees of different sorts with superior varieties*, is an obvious and long-tried improvement. In this case, if the tree is a standard, it is only headed down to standard height; in old subjects, most commonly the branches only are cut over within a foot or two of the trunk, and then grafted in the crown or cleft manner.

4430. *Injuries, insects, &c.* "The mistletoe (*Viscum album*) is frequently, through negligence, suffered to injure trees in orchards, and different species of mosses and lichens those in gardens. "Moss," Knight observes, "appears to constitute a symptomatic, rather than a primary, disease in fruit-trees: it is often brought on by a damp or uncultivated soil, by the age of the variety of fruit, and by the want of air and light in closely planted unpruned orchards. In these cases it can only be destroyed by removing the cause to which it owes its existence."

4431. *Blights.* Whatever deranges and destroys the organisation of the blossom, and prevents the setting of the fruit, is in general termed a blight; whether produced by insects, parasitical plants, or an excess of heat or cold, drought, or moisture. One of the most injurious insects with which the apple-tree has been visited for the last twenty years, is the *Aphis lanigera*, L., the *Eriosoma mali* of Leach; woolly aphis, apple-bug, or American blight. "The eriosomata," Leach observes, "form what are called improperly galls on the stalks of trees, near their joints and knobs, which are in fact excrescences, caused by the efforts of nature, to repair the damage done to the old trees by the perforation of those insects whose bodies are covered with down." (*Sam. Ent.*) Salisbury has given an engraving of the eriosoma (fig. 485.) as he found it appear under a magnifying glass, when attacking the roots (a) and the branches (b), as well as a still more highly magnified figure of one of the bugs without wings (c) and winged (d). The latter he considers likely to be the male insect. Thoroughly cleaning with a brush and

water, together with amputation when it has been some time at work, is the only means of destroying this insect; but even this will not do, unless resorted to at an early stage of its progress. The caterpillars of many species of butterfly and moth, and the larvæ of various other genera of the *hemiptera* and *lepidoptera*, &c. as *Scarabeus*, *Curculi*, &c. attack the apple-tree in common with other fruit-trees; and on a large scale it is difficult, if not impracticable, to avoid their injurious effects. Burning straw or other materials under the trees has been long recommended; but the principal thing to be relied on, in our opinion, is regimen; that is, judicious sub-soil and surface soil, culture, and pruning.

4432. *Other points of culture* have been already given. See Chap. II. and III. and for gathering and storing the crops, see Chap. IV. Sect. X. and Chap. V. Sect. III.

SUBJECT. 2. *Pear*. — *Pyrus Communis*, L. (*Eng. Bot.* 1784.) *Icos. Di-Pentag.* L. and *Rosaceæ*, J. *Poirier*, Fr.; *Birnbaum*, Ger; and *Pero*, Ital.

4433. *The pear-tree*, in its wild state, is a thorny tree, with upright branches, tending to the pyramidal form, in which it differs materially from the apple-tree. The twigs or spray hang down; the leaves are elliptical, obtuse, serrate; the flowers in terminating villose corymbs, produced from wood of the preceding year, or from buds gradually formed on that of several years' growth, on the extremities of very short protruding shoots called, technically, spurs. It is found in a wild state in England, and abundantly in France and Germany, as well as other parts of Europe, not excepting Russia, as far north as lat. 51. It grows in almost any soil. The cultivated tree differs from the apple, not only in having a tendency to the pyramidal form, but also in being more apt to send out tap-roots; in being, as a seedling plant, longer (generally from fifteen to eighteen years) of coming into bearing; and when on its own root, or grafted on a wild pear-stock, of being much longer lived. In a dry soil it will exist for centuries, and still keep its health, productiveness, and vigor. "The period at which the teinton squash first sprang from the seed, Knight observes, probably, cannot now be at all ascertained; but I suspect, from its present diseased and worn-out state, that it existed at least as early as the beginning of the sixteenth century: for another kind, the barland, which was much cultivated in the early part of the seventeenth century, still retains a large share of health and vigor; and the identical trees which supplied the inhabitants of Herefordshire in the seventeenth century with liquor, are likely to do the same good office to those of the nineteenth." Our remarks on the history of the apple will apply almost without exception to the pear. The Romans, in Pliny's time, possessed thirty-six varieties, and the fruit is still more valued, both in Italy and France, than the apple.

4434. *Use*. As a dessert fruit the pear is much esteemed, and generally preferred to the apple. It is also used for baking, *compotes*, marmalade, &c. Pared and dried in the oven, the fruit will keep several years, either with or without sugar. This mode of preparing the pear is about as common in France as the making of apple-pies is in this country; and what is favorable to the practice is, that bad eating sorts answer best for drying. Bosc (*Nouveau Cours d'Agric.* in loco) describes two methods of drying pears for preservation; and adds, that he has tried them after three years' keeping, and found them still very good. Perry, the *poiré* of the French, is made from the fermented juice, in the manner of cider, and the best sorts are said by Withering to be little inferior to wine. The wood of the pear-tree is light, smooth, and compact, and is used by turners, and to make joiners' tools, picture-frames to be dyed black, &c. The leaves will produce a yellow dye, and may be used to give a green to blue cloths.

4435. *Criterion of a good pear*. *Dessert pears* are characterised by a sugary aromatic juice, with the pulp soft and sub-liquid, or melting, as in the *beurrés*, or butter-pears; or of a firm and crisp consistence, or *breaking*, as in the winter bergamots. *Kitchen pears* should be of large size, with the flesh firm, neither breaking nor melting, and rather austere than sweet, as the wardens. *Perry pears* may be either large or small; but the more austere the taste, the better will be the liquor. Excellent perry is made from the wild pear.

4436. *Varieties*. Tusser, in 1573, in his list of fruits, mentions "peeres of all sorts." Parkinson enumerates sixty-four varieties; Mortimer, in 1708, has many sorts; and Miller has selected eighty sorts, and described them from Tournefort. In France, the varieties of the pear are much more numerous than even the varieties of the apple. The catalogue of the Luxemburg nursery at Paris contains 189 select sorts. The British nursery lists at the present time contain from two to three hundred names, among which, it may be observed, the number of good sorts are fewer in proportion than in the apple lists. In the present very imperfect state of the nomenclature of fruits, all we can do is to make a selection from names which have some descriptive particulars attached. We shall arrange them into dessert, kitchen, and perry pears, and each tribe shall be set down in the order of their ripening.

A DESCRIPTIVE CATALOGUE OF PEARS — continued.

DESSERT PEARS. — *Autumn Fruit*, placed in the order of their ripening — continued.

No.	Name.	Synonym.	How, when, and where originated, procured, or abounding.	Where figured.	Described.	Size.	Figure.	Color.	Ripe in	Ladle fill	Consistence and flavor.	Bearer.	Character of the tree, and general reputation of the fruit.
39.	Williams's bon-chretien	-	-	Hort. Tr. ii. 250.	Forsyth, n. 73.	3 to 4 lo, 2 to 3 br.	Pyramidal	Pale green and russet	Sept.	October	Very juicy	Great	Succeeds Windsor pear & jar-gonelle; bears well on stand
40.	Royal orange berg.	-	-	-	Forsyth, p. 142.	Large	Oblong	Yellow and faint red	Mid. Sep.	-	Melting and musky	Great	Hardy, upright tree, excel. fr.
41.	Green Yair	-	-	-	Forsyth, p. 142.	Med.	-	Green	Mid. Sep.	-	Sweet, juicy, melting	Great	Very aw. like rose-wa.
42.	Revalier	-	-	-	Forsyth, n. 21.	Med.	-	Red, yell. and whitish	Mid. Sep.	-	Tender, sug. perfum.	Great	Very aw. like rose-wa.
43.	Callot's roset	-	-	Duh. n. 21.	Forsyth, n. 23.	-	Skin rough	Brown	End Sep.	-	Tender, agreeable	Great	Hardy, standard-tree
44.	Summer rousset	-	-	Duh. p. 177	Forsyth, n. 23.	-	-	-	End Sep.	-	Melting and perfum.	Great	Hardy, stand-tree; esteem. fr.
45.	Great mouthwater	-	-	Duh. n. 73.	Forsyth, n. 27.	Large	-	-	End Sep.	-	Very juicy, rich, perf.	Great	Fresh gathered; one of the very best sort of butter pears
46.	Princes	-	-	Duh. n. 118.	Forsyth, n. 28.	-	-	-	End Sep.	-	Melting, cold juice	Great	-

A DESCRIPTIVE CATALOGUE OF PEARS — continued.

DESSERT PEARS. — *Winter Fruit*, arranged in the order of their ripening — continued.

No.	Name.	Synonym.	How, when, and where introduced, or abounding.	Where figured.	Described.	Size.	Figure.	Color.	Ripens in	Leaf to till	Consistence and flavor.	Beaver.	Character of the tree, and general reputation of the fruit.
77.	St. Austin				Forsyth, n. 54.	-	-	-	End Dec.	End July	Tender; juicy sharp	-	A good fruit on dwarfs or standards; after wall St. Germain
78.	Brown St. Germain				Forsyth, n. 86.	-	-	-	December	End Mar.	High flavored	-	Without exception, the best of all winter pears
79.	Pear d'Auch	Resembles Calmar			Forsyth, n. 69.	-	-	-	Christmas	April	Flesh yellow	-	Delicate tree; shy bearer
80.	Spanish bonchrét.	Aut. bonchrétien			Forsyth, n. 55.	Large	-	-	January	-	Breaking, sweet	Great	A good fruit
81.	Wilding of Cassoy	Small wint. butter			Forsyth, n. 56.	Small	-	-	January	-	Melt. juice very rich	-	
82.	Martin sire	Ronville	Introduced by the Duke of Northumberland in 1780	Lang. P. t. 70.	Forsyth, n. 57.	-	-	-	January	-	Breaking, juicy, sweet, and perfumed	-	
83.	Winter roussetet				Forsyth, n. 58.	-	-	-	End Jan.	-	Buttery, melting, sw.	-	
84.	Brown beurée				Forsyth, n. 60.	-	-	-	End Jan.	April	Melting & rich in juice	-	Justly esteemed, an excel. pear
85.	Holland bergamot	Angel. Cherer's			Forsyth, n. 61.	-	-	-	February	May	Buttery, tender, juicy	-	A very good pear
86.	Black cat	Mus d'Alençaise			Forsyth, n. 62.	-	-	-	March	-	Buttery, melting, sw.	-	An excellent pear
87.	Pear of Naples	Easter St. Germain			Forsyth, n. 63.	-	-	-	March	June	Half break, sweet	-	An excellent pear
88.	Bonchrétien				Forsyth, n. 64.	Very la.	-	-	March	-	Break, tend & sugared	-	
89.	La pastorale				Lang. P. t. 68.	-	-	-	March	-	Tender, buttery, sweet	-	
90.	St. Martial	Angelique			Duh. n. 100.	-	-	-	March	-	Buttery, tender, sweet	-	
91.	Chauumontelle	Winter beurée			Duh. n. 88.	-	-	-	March	-	Melt. rich, & perfumed	-	
92.	Swan's-egg				Hook. P. t. 11.	Med.	Egg-like	Green and brown	January	-	Melting and musky	-	Healthy tree, and bears well either as standards or dwarfs
93.	Bergamotte d'Espagne	Berg. Bugt. Terling, Paddington			Forsyth, n. 71.	Large	-	-	April	June	Makes a very handsome appearance at table	-	A very excellent winter fruit
94.	Faigue winter				Forsyth, n. 142.	-	-	-	-	-	Hardy tree, bears well as standard	Good	Answers well on stand. or wall
95.	Muirfowl egg	A Clydesdale fruit			Cal. Mem. i. 94.	Large	-	-	-	-	Good	-	
96.	Longueville	An esteemed Scotch fruit			Cal. Mem. i. 91.	Med.	-	-	-	-	Good	-	
97.	John Montezath	An old Scotch variety			Cal. Mem. ii. 106.	-	-	-	-	-	Good	-	
KITCHEN PEARS. — Arranged in the order of their ripening.													
98.	Swan's egg	See No. 91.			Forsyth, p. 142.	Med.	-	-	-	-	-	-	Handsome, upright tree strong shoots
99.	Le Bœy d'Hery		The wilding of the forest of Huri in Bretagne.	Duh. n. 23.	Forsyth, p. 142.	-	-	-	-	-	Austere	-	A beautiful fruit
100.	Unicorn				Forsyth, p. 142.	-	-	-	-	-	Rather austere	-	Excellent to preserve, taking a fine red color from the fire
101.	Round winter	See No. 94.			Forsyth, p. 142.	Large	-	-	-	-	-	-	Excellent for stewing
102.	Double fleur	Double flowering			Forsyth, p. 143.	-	-	-	-	-	-	-	Free-growing, upright tree
103.	Bloody	Partinson's war-			Knop. P. 67.	-	-	-	-	-	-	-	Hardy standard tree
104.	Black Worcester	den, pound			Lang. P. t. 71.	-	-	-	-	-	-	-	Hardy upright tree; cat bearer
105.	Catillac				Forsyth, p. 143.	-	-	-	-	-	-	-	
106.	Span. red warden	Uvedale's St. Germain			Forsyth, p. 144.	-	-	-	-	-	-	-

PERRY PEARS. — Arranged in the order of their ripening.													
110.	Barland				Forsyth, p. 143.	-	-	-	-	-	-	-	Hardy upright tree
111.	Holmore				Pom. Her. t. 27.	-	-	-	-	-	Very austere	-	Upright tree
112.	Widened				Pom. Her. t. 28.	-	-	-	-	-	Austere	-	Large, hardy tree
113.	Outcap				Pom. Her. t. 21.	-	-	-	-	-	-	-	Large tree
114.	Rough cap				Pom. Her. t. 11.	-	-	-	-	-	Very austere	-	Hardy free-growing tree
115.	Squash Teinton				Pom. Her. t. 13.	-	-	-	-	-	Very austere	-	Hardy upright tree; cat bearer

4438. *Propagation.* The pear may be propagated by layers or suckers, but not easily by cuttings. These modes, however, are productive of very indifferent plants, and are justly rejected in favor of raising from seed, and grafting or budding.

4439. *From seed.* This mode is adopted either for the purpose of obtaining new varieties, or for producing pear-stocks. In the former case, the same principles of selection or crossing are to be followed which we have stated in treating of raising seedling apple-trees, between which and the pear-tree, the chief difference is, that the latter requires a longer period, nearly double, to come into bearing, and that the proportion of good sorts to bad, so originated, is but very small. Professor Van Mons, proprietor of the *Pépinière de la Fidélité*, at Brussels, has upwards of 800 approved sorts of new pears, raised from seed by himself and M. Duquesne, of Mons, in the course of fifteen or sixteen years, and selected from, probably, 8000 new seedling fruits. Van Mons observed to Neill, that "he seldom failed in procuring valuable apples from the seed; for those which were not adapted to the garden as dessert fruit, were probably suited for the orchard, and fit for baking or cider-making. With pears the case was different, many proving so bad as to be unfit for any purpose." (*Horticult. Tour*, &c. 309.) Whenever a seedling indicates, by the blunt shape, thickness, and woolliness of its leaves, or by the softness of its bark and fulness of its buds, the promise of future good qualities, as a fruit-bearing tree, Van Mons takes a graft from it, and places it on a well established stock: the value of its fruit is thus much sooner ascertained. (*Horticult. Tour*, &c. 310.) At Brussels, seedlings yield fruit in four or five years, in Britain seldom before seven or ten years have elapsed. The fruit of the first year of bearing is always inferior to that of the second and third years. If a pear or an apple possess a white and heavy pulp, with juice of rather pungent acidity, it may be expected in the second, third, and subsequent years, greatly to improve in size and flavor. New varieties of pears, and indeed, of all fruits, are more likely to be obtained from the seeds of new than of old sorts. (*Horticult. Tour*, &c. 308, 309.)

4440. *In raising pears for stock*, the seeds from perry-makers are generally made use of; but the most proper are those from the wild pear, as likely to produce plants more hardy and durable. There is, however, less difference between free pear-stocks, for those raised from the cultivated fruit, and wild pear-stocks, than there is between free apple and crab-stocks. The seeds being procured, may be sown, and afterwards treated as directed for seedling crab, or apple-tree stocks.

4441. *Grafting and budding.* The most common stocks for grafting the pear are the common pear and wilding; but as the apple is dwarfed, and brought more early into a bearing state by grafting on the paradise or creeper, so is the pear by grafting on the quince or whitethorn. The pear will also succeed very well on the whitebeam, medlar, service, or apple; but the wilding and quince are in most general use. Pears on free stocks grow luxuriantly in good soil on a dry bottom; those on wildings grow less rapidly, but are deemed more durable, and they will thrive on the poorest soil, if a hardy variety, and not over-pruned. "On the quince," Miller observes, "breaking pears are rendered gritty and stony; but the melting sorts are much improved: trees on these stocks may be planted in a moist soil with more success than those on wildings or thorns." On the thorn, pears come very early into bearing, continue prolific, and, in respect to soil, will thrive well on a strong clay, which is unsuitable both to those on quinces and wildings; but they are supposed to have an unfavorable influence on the fruit, in rendering it smaller and hard; and the grafts or buds require to be inserted very low, that the moisture of the earth may tend to favor the swelling or enlargement of the diameter of the stock, which does not increase proportionally to, nor ever attains the same size as the stem of the pear. Dubreuil, a French gardener, recommends the quince-stock for clayey and light soils, and the free stock for chalky and siliceous soils. (*Horticult. Trans.* iv. 566.) The free and wilding pear-stocks are to be planted in nursery rows, at the same distance as recommended for free and wilding apples; and the quince and thorn at the same distance as the paradise and creeper apples; in other respects, the management is the same as for the apple.

4442. *Choice of sorts.* (See Ch. II. and III. on *Planting the Orchard and Küchen-Garden.*) The following is a list of table-pears for use in succession, from July to July again, as furnished for the table of the Duke of Buccleugh from the Dalkeith garden. The letters mark the aspect of the walls against which they are trained.

(W.) Jargonelle	(W.) Autumn bergamot	(S.) Grey achan	(W.) Grey beurée
(S.) Longueville	(W.) Gansel's bergamot	(W.) Green chisel	(W.) Winter boncretien
(S.) Summer bergamot	(S. and W.) Green sugar	(W.) St. Germain	(W.) Swan's egg
(S.) Orange bergamot	(W.) Early primitive	(W.) Cressane	(W.) Chaumontelle
(W.) Summer boncretien	(S.) Muirfowl egg	(W.) Brown beurée	(W.) Colmar.

(*Macdonald*, in *Sir John Sinclair's Gen. Rep. of Scotland*, iv. 433.)

4443. *Choice of plants.* Abercrombie takes trees at one year from the graft, and thence to the sixth year, or older. Forsyth says, "I would advise those who intend to plant pear-trees, instead of choosing young ones, to look out for the oldest that they can find in the nursery, and with strong stems."

4444. *Soil and site.* "A dry, deep loam," Abercrombie observes, "is accounted the best soil for the pear-tree when the stock is of its own species; on a quince-stock it wants a moist soil, without which it will not prosper. Gravel is a good sub-soil, where the incumbent mould is suitable. Cold clay is a bad sub-soil: to prevent fruit-trees from striking into it, slates may be laid just under the roots. For wall-trees, the soil should be made good to the depth of three feet; for orchard-trees, eighteen inches may do. Pear-trees, on their own stocks, will thrive on land where apples will not even live; supposing the plants to be hardy varieties, little removed from wildings, and to have room to grow freely as standards. To the more choice of the early autumn and prime winter pears, assign south, east, or west walls. Knight and M'Phail recommend a strong, deep, loamy soil, and the latter a high wall for training the better sorts."

4445. *Planting finally* is performed any time, in mild weather, from October to March; standards are placed from twenty-five to forty feet apart every way; half standards, from twenty to thirty; and dwarf standards, in borders from fifteen to twenty feet from stem to stem. Wall and espalier trees are planted from fifteen to thirty feet apart, according as they may have been planted on pear or quince-stocks.

4446. *Mode of bearing*, as in the apple-tree. "The pear-tree," M'Phail says, "does not produce blossoms on the former year's wood, as several other sorts of trees do. Its blossom-buds are formed upon spurs growing out of wood not younger than one year old, and consequently, projecting spurs all over the tree must be left for that purpose." "In some pears," Knight observes, "the fruit grows only on the inside of those branches which are exposed to the sun and air; in others it occupies every part of the tree."

4447. *Pruning and training standards.* "Permit these to extend on all sides freely. Several years may elapse before any cross-placed, very irregular, or crowded branches, dead and worn out bearers, require pruning, which give in winter or spring. Keep the head moderately open in the middle." "Pruning," Knight observes, "is not often wanted in the culture of the pear-tree, which is rarely much encumbered with superfluous branches; but in some kinds, whose form of growth resembles the apple-tree, it will sometimes be found beneficial."

4448. *Pruning and training wall-trees.* As a wall-tree or espalier, the pear is always trained in the horizontal manner on account of its luxuriant growth. Harrison trains most pear-trees in this way, and proceeds exactly as he does in training the apple-tree. (4427) But, "when it occurs that a tree trained after this method still continues unfruitful for several years after planting, the branches must be trained in a pendulous manner, and more or less so, according to the luxuriance of the tree, but always commence the training in the horizontal method, and afterwards change the direction of the branches as required." (*Tr. on Fruit Trees*, 144.) The ordinary distance at which he trains the side shoots is nine or ten inches, but the jargonelle he lays in at twelve inches, so as to have room for laying in side shoots from the spurs, for one or more years. This he finds checks the luxuriance of the tree, and keeps it in full bearing. (*Tr. on Fruit Trees*, 159.)

4449. *Forsyth*, in training a young pear-tree, shortens the leading shoot in March, and when the shoots it produces are very strong, he says, "I cut the leading shoot twice in one season; by this method I get two sets of side shoots in one year, which enables me the sooner to cover the wall. The second cutting is performed about the middle of June." (*Tr. on Fruit Trees*, 193.)

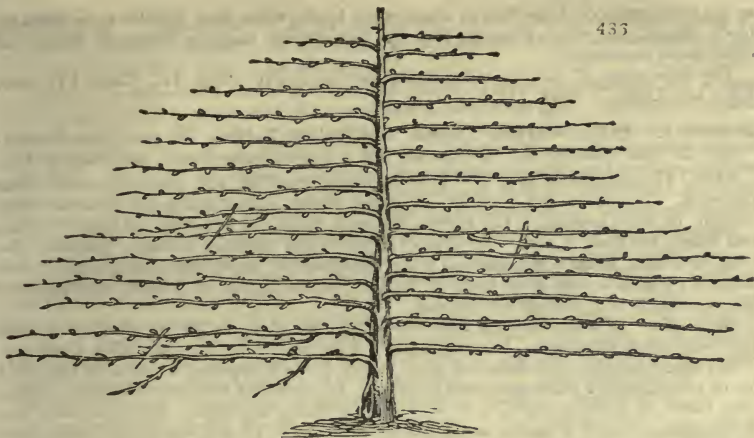

4450. *Established wall-trees and espaliers* will require a summer and winter pruning, and the following are Abercrombie's directions:—

4451. *Summer pruning.* While the spray is young and soft, but not until the wood-shoots can be distinguished from spurs, rub off the fore-right, the disorderly, spongy, and superfluous shoots of the year, rather than let them grow woody, so as to require the knife. Retain some of the most promising, well placed, lateral, and terminal shoots, always keeping a leader to each main branch, where the space will permit. Leave the greater number on young trees not fully supplied with branches. Train in these at their full length, all summer, in order to have a choice of young wood in the winter pruning. Occasionally on old trees, or others, where any considerable vacancy occurs, some principal contiguous shoot may be shortened in June to a few eyes, for a supply of several new shoots the same season.

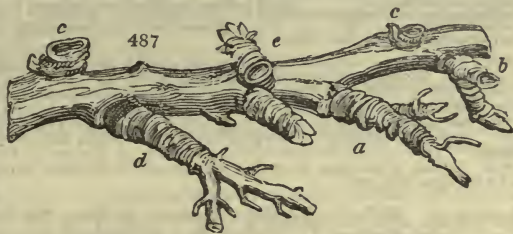

The *winter pruning* may be performed any time from the beginning of November until the beginning of April. If on young trees, or others, a further increase of branches is necessary to fill up either the prescribed space, or any casual vacuity, retain some principal shoots of last summer, to be trained for that purpose. As, however, many young shoots will have arisen on the wood-branches and bearers, of which a great part are redundant and disorderly, but which have received some regulation in the summer pruning, we must now cut these out close to the mother branches, while we are preserving the best in the more open parts. Examine the parent branches, and if any are very irregular, or defective in growth, either cut them out close, or prune them to some eligible lateral to supply the place; or if any branches be over-extended, they may be pruned in to such a lateral, or to a good fruit-bud. Cut out the least regular of the too crowded; also any casually declined bearers; with decayed, cankered, and dead wood. The retained supply of laterals and terminals should be laid as much at length as the limits allow, in order to furnish a more abundant quantity of fruit-buds. During both courses of pruning, be particularly careful to preserve all the orderly fruit-spurs emitted at the sides and ends of the bearers: if, however, any large, rugged, projecting spurs, and woody barren stumps or snags occur, cut them clean away close to the branches, which will render the bearers more productive of fruit-buds, and regular in appearance. As each tree is pruned, nail or tie the branches and shoots to the wall or trellis. If afterwards, in consequence of either pruning out improper or decayed wood, or of former insufficient training, there are any material vacancies or irregularities in the arrangement, un-nail the misplaced and contiguous branches, and lay them in order.

4452. *Knight's mode of training the pear-tree* is as follows: "A young pear-stock, which had two lateral branches upon each side, and was about six feet high, was planted against a wall early in the spring of 1810; and it was grafted in each of its lateral branches, two of which sprang out of the stem, about four feet from the ground, and the other at its summit in the following year. The shoots these grafts produced, when about a foot long, were trained downwards, the undermost nearly perpendicularly, and the uppermost just below the horizontal line, placing them at such distances that the leaves of one shoot did not at all shade those of another. In the next year, the same mode of training was continued, and in the year following I obtained an abundant crop of fruit. An old St. Germain pear-tree, of the spurious kind, had been trained in the fan-form, against a north-west wall in my garden, and the central branches, as usually happens in old trees thus trained, had long reached the top of the wall, and had become wholly unproductive. The other branches afforded but very little fruit, and that never acquiring maturity, was consequently of no value; so that it was necessary to change the variety, as well as to render the tree productive. To attain these purposes, every branch which did not want at least twenty degrees of being perpendicular, was taken out at its base; and the spurs upon every other branch, which I intended to retain, were taken off closely with the saw and chisel. Into these branches, at their subdivisions, grafts were inserted at different distances from the root, and some so near the extremities of the branches, that the tree extended as widely in the autumn, after it was grafted, as it did in the preceding year. The grafts were also so disposed, that every part of the space the tree previously covered, was equally well supplied with young wood. As soon, in the succeeding summer, as the young shoots had attained sufficient length, they were trained almost perpendicularly downwards, between the larger branches and the wall to which they were nailed. The most perpendicular remaining branch, upon each side, was grafted about four feet below the top of the wall, which is twelve feet high; and the young shoots, which the grafts upon these afforded, were trained inwards, and bent down to occupy the space from which the old central branches had been taken away; and therefore very little vacant space any where remained in the end of the first autumn. A few blossoms, but not any fruit, were produced by several of the grafts in the succeeding spring; but in the following year, and subsequently, I have had abundant crops, equally dispersed over every part of the tree."

4453. *Heading down and pruning old pear-trees.* "The method of pruning pear-trees," *Forsyth* observes, "is very different from that practised for apple-trees in general. The constant practice has been to have great spurs, as big as a man's arm, standing out from the walls, from a foot to eighteen inches or upwards." The constant cutting of these spurs, he says, brings on the canker, and the fruit produced is small, spotted, and kernelly. *Forsyth's* practice with such trees was to cut them down, and renew the soil at their roots, and he refers to beurré pear (*fig.* 486.), restored from an inch and a half of bark, which, in 1796, bore four hundred and fifty fine large pears, &c.

4454. *Harrison*, and various other gardeners, adopt the mode of keeping only short spurs, by which much larger fruit is produced. According to this plan, each spur (*fig. 487. a*) bears only once, when it is cut out, and succeeded by an embryo-bud (*d*) at its base. This bud at the end of the first season, is no more than a leaf-bud (*c*); but at the end of the second summer, it has become a blossom-bud (*b*), and bears the third summer (*a*). Some useful observations on the management of pear-trees, in correspondence with *Harrison's* practice, will be found in different parts of the *Caledonian Hort. Memoirs*, vol. i.

4455. *Forsyth* says, "The constant practice has been to leave great spurs as big as a man's arm, standing out from the walls, from one foot to eighteen inches and upwards. The constant pruning of these brings on the canker; and by the spurs standing out so far from the wall, the blossom and fruit are liable to be much injured by the frost and blighting winds, and thus the sap will not have a free circulation all over the tree. The sap will always find its way first to the extremities of the shoots; and the spurs will only receive it in a small proportion, as it returns from the ends of the branches." (*Tr. on Fruit Trees*, 187.)

4456. *Settling the fruit*. In a very curious paper on this subject, by the Rev. G. Swayne, he informs us of a pear-tree, which had for twenty years never borne fruit, but which he induced to bear by cutting off all the blossoms of each corymbus of flowers, excepting the lower three, on the same principle as gardeners top beans. This succeeded to a certain extent on one tree, but not on another; the selected blossoms of the other he rendered fruitful by cross-impregnation. He says, "I fancied likewise that the point was fit for impregnation before the anthers were ripe, and even before the petals expanded; and from the peculiarly slender and delicate make of the latter, as it struck me, I supposed, that it ceased to be in a proper state as soon as it became exposed to the sun and air; I therefore concluded, that there might possibly be a chance of obtaining fruit, by depriving the blossoms of their petals before they expanded, and enclosing with each floret in this state, within a paper envelope (as is my mode of effecting artificial impregnation), a riper blossom, viz. one that had just begun to diffuse its farina, either one of its own, or, preferably, of some other variety of pear." (*Hort. Trans.* v. 210.) He tied up twenty-seven envelopes on the 27th of March, and took off the papers on the 15th of April; a number succeeded, and produced ripe fruit, specimens of which were sent to the Horticultural Society, and found unusually large and handsome. The Rev. Experimenter concludes his paper, by observing, "whether the result of the above-detailed experiments be such as to authorise an expectation that artificial assistance in vegetable fecundation, will hereafter become of so much importance to gardeners, in the instance just alluded to, as in those at present recognised, of the cucumber, the melon, the early bean, and the hautbois strawberry, must be left to futurity to ascertain." (*Hort. Trans.* v. 212.)

4457. *Harrison* appears to have adopted a similar practice, he says, "It is very general to see healthy pear-trees, which produce an abundance of bloom but set a very small proportion of fruit; this is more particularly the case with the tenderest kinds. The reason of such barrenness is in some cases from the stamina being destitute of farina, and in others from the farina having been dispersed before the pistillum had arrived at a proper state for its reception. To remedy such defects, I adopt the following practice. As soon as the florets have expanded and the pistillum is in a proper state of maturity, I impregnate six upon each corymb of blossom. The florets which I choose for this operation are those situated nearest the origin of the spur, for when pears set naturally, it is very generally such florets. The time I choose for this operation is calm dry days, and if possible when the sun is not very hot upon the trees. Immediately after performance, I give each tree about eighteen gallons of manure water, or soft pond water, at the roots. The trees should never be washed over the tops for a considerable time after this impregnation has been effected." (*Tr. on Fruit Trees*.)

4458. *Insects, diseases, &c.* The pear-tree is liable to the attacks of the same insects

as the apple-tree ; and the fruit of the summer kinds, when ripe, is liable to be eaten by birds, wasps, &c. which must be kept off by shooting, hanging bottles of water, and other usual preventives.

For other points of culture, and gathering and storing, see Chap. II., Chap. IV. Sect. IX., and Chap. V. Sect. III.

SUBJECT. 3. Quince.—*Pyrus Cydonia*, L. ; *Cydonia Vulgaris*, W. en. *Icos. Di-Pentag. L.* and *Rosaceæ*, J. *Coignassier*, Fr. ; *Quittenbaum*, Ger. ; and *Cotogno*, Ital.

4459. The quince-tree is of low growth, much branched, and generally crooked and distorted. The leaves are roundish or ovate, entire, above dusky-green, underneath whitish, on short petioles. The flowers are large, white, or pale-red, and appear in May and June ; the fruit, a pome, varying in shape in the different varieties, globular, oblong, or ovate ; it has a peculiar and rather disagreeable smell and austere taste. It is a native of Austria and other parts of Europe ; is mentioned by Tusser, in 1753 ; but has never been very generally cultivated.

4460. *Use.* The fruit is not eaten raw ; but stewed, or in pies or tarts, along with apples, is much esteemed. In confectionary, it forms an excellent marmalade and syrup. When apples are flat, and have lost their flavor, Forsyth observes, a quince or two, in a pie or pudding, will add a quickness to them. In medicine, the expressed juice, repeatedly taken in small quantities, is said to be cooling, astringent, and stomachic, &c. A mucilage prepared from the seeds was formerly much in use, but is now supplanted by the simple gums. In nursery-gardening, the plants are much used as stocks for the pear.

4461. *Varieties.* Miller enumerates —

The oblong, or pear-quince ; with oblong ovate leaves, and an oblong fruit lengthened at the base.

The apple-quince ; with ovate leaves and a rounder fruit.

The Portugal quince (*Lang. Pom. t. 73.*) ;

with obovate leaves, and an oblong fruit, which is more juicy and less harsh than the others, and therefore the most valuable. It is rather a shy bearer, but is highly esteemed

for marmalade, as the pulp has the property of assuming a fine purple tint in the course of being prepared. The mild or eatable quince ; less austere and astringent than the others.

4462. *Propagation.* Generally by layers, but also by cuttings, and approved sorts may be perpetuated by grafting. In propagating for stocks, nothing more is necessary than removing the lower shoots from the larger, so as to preserve a clean stem as high as the graft ; but for fruit-bearing trees, it is necessary to train the stem to a rod, till it has attained four or five feet in height, and can support itself upright.

4463. *Soil and site.* The quince prefers a soft moist soil, and rather shady, or, at least, sheltered situation. It is seldom planted but as a standard in the orchard, and a very few trees are sufficient for any family.

4464. *The time of planting, the mode of bearing,* and all the other particulars of culture, are the same as for the apple and pear.

SUBJECT. 4. Medlar.—*Mespilus Germanica*, L. (*Eng. Bot.* 1523.) *Icos. Di-Pentag. L.* and *Rosaceæ*, J. *Nestier*, Fr. ; *Mispelbaum*, Ger. ; and *Nespolo*, Ital.

4465. The medlar is a small or middle-sized branching tree ; the branches woolly, and covered with an ash-colored bark, and, in a wild state, armed with stiff spines. Leaves oval-lanceolate, serrate, towards the point somewhat woolly, on very short channelled petioles. Flowers produced on small natural spurs, at the ends and sides of the branches. Bracte as long as the corolla ; calyxes terminating, fleshy ; petals, white ; fruit, a turbinate berry, crowned with five calycine leaflets ; pulp thick, mixed with callose granules, and containing five gibbous wrinkled stones. The tree flowers in June and July, and the fruit is ripe in November. It is a native of the south of Europe ; but appears to be naturalised in some parts of England, where it has been sown in copses by binds.

4466. *Use.* The fruit is eaten raw in a state of incipient decay ; its taste and flavor are peculiar, and by some much esteemed.

4467. *Varieties.* Those in common cultivation are —

The Dutch medlar (*Pom. Franc. 2. p. 45. t. 2, 3.*) ; a crooked, deformed, low tree with very large leaves, entire, and downy on the under side. The flowers and fruit are very large ; the

latter approaching to the shape of an apple.

The Nottingham medlar ; with fruit of a quicker and more poignant taste.

The wild medlar ; a smaller tree, with smaller leaves, flowers, and fruit than any of the former sorts, and the fruit is pear-shaped.

4468. *Propagation.* By seeds, by layers, and cuttings, or by grafting on seedlings of their own species, or on any other species of *mespilus*, or of *cydonia*, or *cratægus*. Miller observes, that if the stones are taken out of the fruit as soon as it is ripe, and immediately planted, they will come up next spring, and make good plants in two years. He prefers raising from seed to grafting on the *cratægus*. Forsyth says, "Those who wish to keep the sorts true, should propagate them by grafting on their own stocks." The plant is rather difficult to strike by cuttings.

4469. *Soil.* The soil in which the medlar thrives best is a loamy rich earth, rather moist than dry ; but not on a wet bottom.

4470. *Final planting.* The medlar, like the quince, is usually grown as a standard or espalier ; the former may be planted from twenty to thirty, and the latter from fifteen to twenty feet apart.

4471. *Mode of bearing.* On small spurs at the ends and sides of the branches.

4472. *Pruning.* Forsyth recommends the same sort of treatment as for the quince. Cut out all the dead and cankered wood, and keep the tree thin of branches when it is desired to have large fruit. Care is requisite to train standards with tall stems. Espaliers will require a summer and winter pruning, as in the apple-tree.

For other details of culture, see the *Apple* and *Pear*.

SUBSECT. 5. *True-Service*. — *Sorbus Domestica*, L. (*Pyrus Domestica*, Eng. Bot. 350.) *Icosan. Di-Pentag. L.* and *Rosaceæ*, J. *Alizier*, Fr.; *Elsbeerbaum*, Ger.; and *Loto*, or *Bagolaro*, Ital. (fig. 488.)

4473. *The true-service-tree* is of the middle size, not unlike the mountain-ash, of a very low growth, and not flowering till it arrives at a very great age. The leaves are compound, alternate, with ovate or oval leaflets. The flowers are produced on terminating panicles issuing from spurs of two or more years' growth; the petals are cream-colored; the fruit, according to Gærtner, is a pome, pear-shaped, reddish, and spotted, extremely austere, and not eatable till it is quite mellowed by frost or time, when it becomes brown and very soft. It flowers in May, and the fruit ripens in November; the tree, according to Krocke, does not come into full bearing before it is sixty years old. It is a native of the warmer parts of Europe, and has also been found wild in Cornwall, Worcestershire, and Hertfordshire, from whence the fruit is brought to London in autumn in large quantities. Miller says, "There was one tree in the garden of John Tradescant, of South Lambeth, near forty feet high, which produced a great quantity of fruit annually, shaped like pears. Some trees of middling growth, in the garden of Henry Marsh, Esq. at Hammersmith, produced fruit of the apple-shape. From these many trees were raised in the nurseries near London, but the fruit was small compared with that of Tradescant." Great numbers of large service-trees grow wild about Aubigny in France; from the seeds of which one of the dukes of Richmond raised a great many trees at Goodwood in Sussex. It is a very common fruit-tree at St. Germain's en Laye, where it is cultivated along with *Pyrus Americana*.

4474. *Use*. The fruit has a peculiar acid flavor, and is eaten, when mellowed, like that of the medlar, to which it is deemed inferior. It is common in Italy, and ripens at Genoa in September, where it is esteemed good in dysentery and fluxes. The wood, which is very hard, is held in repute for making mathematical rulers, and excisemen's gauging-sticks.

4475. *Varieties*. In Italy they have many varieties obtained from seeds; but those generally known here are only three: the pear-shaped, apple-shaped, and berry-shaped.

4476. *Propagation*. By seeds, cuttings, or layers; or, which is preferable for plants intended to form good-sized and early-bearing trees, by grafting on seedlings of their own species. It may also be grafted on the *pyrus*, *mespilus*, or *cratægus*.

4477. *Soil*. The best is a strong clayey loam.

4478. *Culture*. The tree is recommended by Forsyth and Abercrombie to be grown as a standard at twenty or thirty feet distance, and to be pruned and otherwise treated like the apple and pear. Choice sorts, Abercrombie observes, are sometimes trained as dwarf standards, or espaliers.

4479. *Gathering the crop*. It is late in autumn before this operation can be performed. Wipe the fruit dry, and lay it on dry wheat-straw, spread on the open shelves of the fruit-room. In about a month it will become mellow and fit for use. See Chap. IV. Sect. X. and Chap. V. Sect. III.

SECT. II. Stone-Fruits.

4480. *Of stone-fruits* the most esteemed is the peach tribe, and next the apricot; both the trees natives of Persia, but acclimated in Britain, and remarkable for the lively colors and early appearance of their blossoms. The peach is one of the most delicious of summer fruits. Besides the peach, nectarine, and apricot; the almond, plum, and cherry, are comprehended in this section.

SUBSECT. 1. *Peach*. — *Amygdalus Persica*, L. (*Black. t. 101.*) *Icos. Monog. L.* and *Rosaceæ*, J. *Malus Persica* of the Romans. *Pêcher*, Fr.; *Pfirsichbaum*, Ger.; and *Persico*, Ital.

4481. *The peach-tree* in its natural state is under the middle size, with spreading branches, lanceolate, smooth, and serrated leaves. The flowers are sessile, with reddish calyces, and bell-shaped, pale or dark-red corollas, often bordered with purple; the fruit a roundish drupe, generally pointed, and with a longitudinal groove; pulp, large, fleshy or succulent, white or yellowish, sometimes reddish, abounding with a grateful, sweet, acid juice; stone, hard, irregularly furrowed; kernel, bitter. The tree of quick growth, and not of long duration; blossoms in April, and ripens its fruit in August and September. Sickler considers Persia as the original country of the peach, which, in Media, is deemed unwholesome; but, when planted in Egypt, becomes pulpy, delicious, and salubrious. The peach also, according to Columella, when first brought from Persia into the Roman empire, possessed deleterious qualities; which Knight concludes to have arisen from those peaches being only swollen almonds (the *tuberes* of Pliny), or im-

perfect peaches; and which are known to contain the Prussic acid which operates unfavorably in many constitutions. The tree has been cultivated time immemorial in most parts of Asia; when it was introduced into Greece is uncertain: the Romans seem to have brought it direct from Persia, during the reign of the emperor Claudius. It is first mentioned by Columella, and afterwards described by Pliny. The best peaches in Europe are at present grown in Italy on standards; and next may be cited those of Montreuil, near Paris, trained on lime-whited walls. (*Mozard, sur l'Education des arbres à Fruits, et principalement du Pêcher, &c.* 1814.) We visited these gardens in May, 1819, and examined more particularly those of Jean Pierre Savard, the principal *propriétaire cultivateur*. His trees were that season covered with aphides, and the principal part of treatment in which he seemed expert was that of varying the position of the branches of the tree every year, by elevating to a greater angle the weak, depressing the strong, and cutting out the old, naked, or twigless shoots; thus presenting at all times a well balanced tree. The stems of these trees, when first planted, and for one or two years afterwards, are hooked to the wall, to prevent their being stolen! Mozard's garden was visited by the Caledonian Horticultural deputation in 1817, who found wholesome management, but nothing new. In England, there are but few sorts of peaches that come to tolerable perfection in the open air, in ordinary seasons. The best adapted for this purpose are the free stones; but all the sorts ripen well by the aid of a hot-wall or glass, and may be forced so as to ripen in May or June. The tree is generally an abundant bearer; one of the noblesse kind, at Yoxfield, in Suffolk, which covers above six hundred square feet of trellis under a glass case, without flues, ripens annually from sixty to seventy dozen of peaches. (*Hort. Trans.* iii. 17.)

4482. *Use.* It is a dessert fruit, of the first order, and makes a delicious preserve. In Maryland and Virginia a brandy is made from this fruit. "The manufacture of this liquor, and the feeding of pigs, being," as Braddick observes (*Hort. Tr.* ii. 205.), "the principal uses to which the peach is applied in those countries." The leaves, steeped in gin or whiskey, communicate a flavor resembling that of noyau.

4483. *Criterion of a good peach.* A good peach, Miller observes, possesses these qualities: the flesh is firm; the skin is thin, of a deep or bright red color next the sun, and of a yellowish-green next the wall; the pulp is of a yellowish color, full of high-flavored juice; the fleshy part thick, and the stone small.

4484. *Varieties.* Linnæus divides the *A. Persica* into two varieties; that with downy fruit or the peach, and that with smooth fruit or the nectarine. There are various instances on record (*Hort. Trans.* vol. i. p. 103.) of both fruits growing on the same tree, even on the same branch; and one case has occurred of a single fruit partaking of the nature of both. The French consider them as one fruit, arranging them in four divisions: the *pêches*, or free stone peaches, the flesh of whose fruit separates readily from the skin and the stone; the *pêches lisses*, or free stone nectarines, or free stone smooth peaches; the *pavies*, or cling-stone peaches, whose flesh is firm and adheres both to the skin and stone; and the *brugnons*, or nectarines, or cling-stone smooth peaches. Knight (*Hort. Tr.* iii. 1.), Robertson (*Hort. Tr.* iii. 382.), and various botanists, consider the peach and almond as one species.

4485. *The flat peach of China* (*Hort. Trans.* vol. iv. pl. 19.) is a curious flattened fruit (*fig.* 489.), sweet and juicy, and with a little noyau flavor. Knight has fruited it, and considers that from the early habits of the tree it will prove a valuable acquisition. He has "found excitability of habit to be hereditary in the seedling offspring of plants, and to be transferable by the pollen;" and, therefore, imagines "there will be no difficulty in obtaining from the flat peach other varieties of similar habits, free from the deformity which has recommended it to the Chinese." (*Hort. Trans.* v. 272.)

4486. *There are many fine varieties of the peach:* Tusser, in 1573, mentions peaches, white and red; Parkinson, in 1629, enumerates twenty-one; and Miller, in 1750, thirty-one varieties. In the garden of the Luxemburg, at Paris, are seventy varieties; and above double that number of names are to be found in the catalogues of our nurseries. Three distinguished and ingenious attempts have been made to class the varieties of peaches and nectarines, by the leaf and flower as well as the fruit: the first is by Poiteau, in the *Bon Jardinier*; the next by Count Lelieur, in his *Pomone Française*; and the third by Robertson, nurseryman, of Kilkenny, whose arrangement is founded on the glands of the leaves. But as these systems are not yet sufficiently perfected to render them available for this work, all we can do is to submit the following table:—

FREE STONES. — Arranged in the order of their ripening. The Free Stones ripen more kindly in most parts of Britain than Cling-Stones.

No.	Name.	Synonyms and resemblances.	Hon., when, and where originated, procured, or abundant.	Where figured.	Where described.	Size.	Form.	Color.	Ripens	Pulp and flavor.	Remarks.	Characteristics of the tree and general reputation of the fruit.
1.	White nutmeg	L'avant pêche blanche	-	Duh. n. 1. t. 2.	Forsyth, 1.	Small	Round	White	End July	Juice sugary and musky	-	Only esteemed for being the first sort ripe
2.	Red nutmeg	L'avant pêche de Troye	-	Duh. n. 3. t. 3.	Forsyth, 2.	Large	Round	Bright vermilion and yellowish-red	Begin. Aug.	Pulp white, red at the stone; rich, musky	Great	Valued for its early maturity
3.	Avant	-	-	-	Forsyth, 3.	Large	-	Red	Begin. Aug.	Very fine	-	Fruit apt to be stringy
4.	Superb royal	-	-	-	Forsyth, 27.	Large	-	-	Mid. Aug.	-	-	-
5.	Early purple	Pourprée hâtive	-	Duh. n. 8. t. 12.	Forsyth, 10.	Large	Round	Fine deep red	Mid. Aug.	Pulp white, red at stone; juice rich and vinous	-	An excellent fruit
6.	Neal's early purple	-	-	Hook. P. t. 25.	Forsyth, 39.	-	-	-	-	-	-	-
7.	Early Anne	-	-	Lang. P. t. 27.	Forsyth, 5.	Medium	Round	Fine deep red	Mid. Aug.	Pulp white, red at stone	-	One of the best peaches, and so tender as to require grading on a peach or apricot stock
8.	Great mignonne	Grosse mignonne	-	Duh. n. 14. t. 10.	Forsyth, 11.	Large	Round	Rose-colored and greenish-yellow	Mid. Aug.	Pulp white; sugary, high-flavored	-	-
9.	Small mignonne	Early mignonne, double de Troye, or mignonnette	-	Duh. n. 3. t. 4.	Forsyth, 11.	Medium	Round	Dark red and pale yellow	Begin. Aug.	Pulp white, red at stone; vinous, sugary	-	-
10.	Belle chevreuse	-	-	-	-	-	-	-	-	-	-	-
11.	Smith's Newington	Early Newington, resembling le Pavie blanc	-	Duh. n. 17. t. 13.	Forsyth, 13.	Medium	Oblong	Red and yellow	End Aug.	Pulp yellow; juice rich and sugary	Good	Good fruit
12.	Early admirable	-	-	Duh. n. 9.	Forsyth, 15.	Medium	-	Fine red	End Aug.	Pulp white and firm, very red at stone; of a pretty good flavor	-	-
13.	Chancellor	-	-	Duh. n. 29.	Forsyth, 26.	Large	Round	-	End Aug.	Pulp white, red at stone; high vinous flavor	-	-
14.	Montauban	-	-	Duh. n. 19.	Forsyth, 20.	Medium	Oval	Fine red	End Aug.	Pulp white, and melting; high vinous flavor	-	-

A DESCRIPTIVE CATALOGUE OF PEACHES—continued.

FREE STONES.—Arranged in the order of their ripening—continued.

No.	Name.	Synonyms and resemblances.	How, when, and where originated, procured, or abounding.	Where figured.	Where described.	Size.	Form.	Color.	Ripens.	Pulp and flavor.	Remarks.	Characteristics of the tree, and general reputation of the fruit.
30.	Rambouillet	Rumbouillon	-	Lang. P. t. 33.	Forsyth, 34.	Medium	Roundish deep fur.	Fine red and bri. yellow	Begin. Sept.	Deep red at stone; rich and vinous	-	-
31.	Royal George	La Royale; Grosse mignonne	-	Hook. P. t. 41.	Forsyth, 6.	Large, often warty	Round	-	Begin. Sept.	White, melting, rich	Great	Fruit sets with less air than most peaches
32.	Grimwood's Royal George	Millet's mignonne	-	-	Forsyth, 36.	Large, often warty	Round	-	Begin. Sept.	White, melting, rich	-	Tree apt to mildew
33.	Royal Kensington	Resembles the old George	Sent to Kensington royal gardens in 1780	Duh. n. 37.	Forsyth, 7.	-	-	High red and yellow	Begin. Sept.	Rich juice	Great	One of the best peaches we have, not liable to the blight
34.	Incomparable	Royal George	-	-	Forsyth, p. 38.	Very large	Roundish	Bri. red and pale yellow	Mid. Sept.	Greenish yell. red at stone; full of rich juice	-	Fine fruit
35.	Nivette	Pavie admirable	-	-	Forsyth, 30.	Large	Round	Red all over	Mid. Sept.	White and fine, red at stone; rich and vinous	-	-
36.	Vineuse	-	-	-	-	Medium	Round	Pale red	Mid. Sept.	Juicy, rich	Good	-
37.	Noblesse	-	-	Hook. P. t. 2.	Forsyth, 18.	Very large	Round	Red and very white	Mid. Sept.	Rich, juicy, and sweet	Good	Tree not apt to mildew or gum
38.	Acton Scott	-	Origin. at Downton Castle by Knight, fr. noblesse & nutmeg-peaches in 1814	Hort. Tr. ii. t. 10.	Hort. Tr. ii. 140.	Medium	Round	Dark red and bright yell.	Mid. Sept.	Firm but melting; of excellent flavor	Good	Succeeds best on an apricot stock
39.	Spring grove	-	Origin. by Knight, at Downton, from large seedling, fr. nutmeg-peaches in 1814	-	Hort. Tr. ii. 48.	Medium	Round	Dark red and yellow	End Sept.	White and melting, deep red at stone; sw. & high if firm, white, red at stone; juicy and h. fl. pleasant	-	-
40.	Late purple	La pourpre	-	Duh. n. 13.	Forsyth, 29.	Large	Round	Fine red	-	White, melt. red at stone; rich and sugary	Shy	-
41.	Pesique	-	-	Duh. n. 35.	Abercrom. 290.	Large	Oblong	Faint red, and straw-col.	End Sept.	-	-	-
42.	Teton de Venus	-	-	-	Forsyth, 28.	Med. with a breast-like protuberance.	-	Purplish and orange	End Sept.	Melting, musky, and juicy	Good	Requires much heat & fav. seasons to attain full perfection
43.	Braddick's American	-	-	Hort. Tr. ii. t. 13.	Hort. Tr. ii. 205.	Large	Irregular globose	Deep red	End Sept.	Deep red	-	Requires artificial heat, otherwise fruit is watery
44.	Bloody	Sanguinole	-	Duh. n. 41.	Forsyth, 36.	-	-	Red and whitish wax co.	Begin. Oct.	Melting and tolerable	-	A beautiful fruit, resembling in color the pomme d'apius
45.	Cherry peach	Pêche-cerise	-	Duh. n. 21.	Forsyth, 35.	Small	Globular	Bright yellow	-	Like the apricot in color and flavor	-	An excellent peach; large, yellow, and apricot-flavored
46.	Yellow admirable	Apricot peach	-	Dun. n. 30.	Forsyth, 41.	-	-	-	-	-	-	-
CLING-STONES.—Arranged in the order of their ripening.												
47.	Late admirable	-	-	-	Abercrom. 290.	Rather lar.	Round	Bright marbled red	Mid. Sept.	Greenish wh. veined with red at the stone; rich and vinous	-	-
48.	Bellis	La belle de vitry, late admirable	-	Duh. n. 34.	Forsyth, 26.	Medium	Round	Pale red	Mid. Sept.	White, red at stone; juice very rich and vinous	-	-
49.	Golden	Orange	-	-	Abercrom. 290.	Ab. med.	Round	Crim. or rich purple with gold	End Sept.	Deep yellow, crimson at stone; superior	-	-
50.	Old Newington	-	-	Lang. P. 104.	Forsyth, 19.	Large	-	Fine red	End Sept.	White, deep red at stone; excellent	-	-
51.	Portugal	-	-	-	Forsyth, 27.	Large	-	Beautiful red and spotted	End Sept.	Firm, white, red at stone; rich and sugary	-	Stone small, and deeply furrowed
52.	Catherine	-	-	Lang. P. t. 33.	Forsyth, 52.	Large	Round	Dark red	Begin. Oct.	Firm, white, red at stone; rich and pleasant	Good	Excellent for forcing; or under cold glass
53.	Monstrous pavie	Partie rouge de pomponne, royal pavie	-	Duh. n. 35.	Forsyth, 31.	Exceed. lar.	Round	Fine red & greenish wh.	End Oct.	White, melting, deep red at stone; pretty juicy, vinous	-	An excellent fruit

4488. *Selection of sorts.* Abercrombie says, "Except the situation be completely favorable as to climate, aspect, and shelter, forbear to plant very early or extreme late fruit; the frost will almost inevitably cut off the former when blossoming and setting; and the latter will hardly ripen under the declining heat of autumn."

4489. *The peaches proper for a small garden, according to Forsyth, are —*

The early avant
Small mignonne
Anne

Royal George
Royal Kensington
Noblesse

Early Newington
Gallande
Early purple Chancellor

Nivette
Catherine
Late Newington.

4490. *The peaches in the Dalkeith garden, and which ripen in the order in which they are placed are as follows; those marked (H.) being planted against hot-walls:*

(W.) Early nutmeg
(W.) Early Anne
(W.) Red Magdalen
(W.) Royal George

(W.) Grimwood's Royal George
(W.) Noblesse
(H.) Gallande

(H.) Bellegard
(H.) Montaubon
(H.) Millet's mignonne

(W.) Smith's early Newington
(H.) Chancellor
(W.) White Magdalen

The best varieties for forcing, according to Oldacre, are, the violet, native, mignonne, and Marlborough.

4491. *Propagating to procure new sorts.* The peach is raised from the stone; and this mode is pursued in America, even for procuring trees for common purposes. In Maryland and Virginia, Neill observes, "peach-trees are propagated from the stones without budding. Every peach-orchard contains of course numerous varieties. Among these, a few are always of superior quality; with the rest of the fruit pigs are fed." The peaches (Nos. 38, 39.) in the table, mentioned as produced by Knight, were thus originated: the parent trees were dwarfs planted in large pots; these being brought into a state of vigorous health, the pistils of the blossom of one sort were impregnated with the pollen of another; only three peaches were suffered to remain on each tree; and from sowing the stones of these, the Acton scott, and spring grove, and other varieties, were produced: the male parent of the latter was the large French mignonne; and the female, the little red nutmeg; which choice is consistent with the general principle, that the most perfect and vigorous offspring will be obtained of plants, as of animals, when the male and female parent are not closely related to each other. (Neill.)

4492. *Knight* has some excellent observations on this subject in various papers published in the *Hort. Trans.*; but especially in *Observations on the Method of producing new and early Fruits, and on some Varieties of the Peach.* (vol. i.) In the latter paper he thus concludes, "I entertain little doubt that the peach-tree might, in successive generations, be so far hardened and naturalised to the climate of England and Ireland, as to succeed well as a standard in favorable situations. The peach does not, like many other species of fruit, much exercise the patience of the gardener, who raises it from the seed; for it may always be made to bear when three years old. I will not venture to decide whether it might not possibly produce fruit even at the end of a single year. In prosecuting such experiments, I would recommend the seedling peach-trees to be retained in pots, and buds from them only to be inserted in older trees; for their rapid and luxuriant growth is extremely troublesome on the wall, and pruning is death to them." He afterwards succeeded in producing blossom-buds the first year: the means used were, leaving on the laterals near the extremities of the shoots, and exposing the leaves as much as possible to the sun, in order to promote the growth, and ripening of the wood.

4493. *Miller* says, the best sorts for sowing, are those whose flesh is firm and cleaves to the stone; and from amongst those, you should choose such as ripen pretty early, and have a rich vinous juice. These stones should be planted in autumn, on a bed of light dry earth, about three inches deep and four inches asunder; and in the winter the beds should be covered to protect them from the frost, which, if permitted to enter deep into the ground, will destroy them. After remaining two years in this bed, they may be transplanted into nursery rows, three feet asunder, and one foot distant, plant from plant, in the rows; mulching the surface, and watering during summer in very dry weather. After being two years in this nursery, transplant them where they are to remain to produce fruit. Plant them as standards till you see their fruit; cut off bruised roots, but give their tops no other pruning than cutting out decayed or very irregular branches.

4494. *Propagation to perpetuate varieties.* The peach is generally budded on damask plum-stocks, and some of the more delicate sorts on apricot-stocks, or old apricot-trees cut down, or on seedling peaches, almonds, or nectarines. Knight recommends growing almond-stocks for the finer kinds of nectarines, and apricots, as likely to prevent the mildew, and as being allied to the peach. He says, "almond-stocks should be raised and retained in the nursery in pots, as they do not transplant well." Dubreuil, already mentioned (4387. 4441.), recommends a plum-stock for a clayey soil, and the almond for such as are light, chalky, or sandy. The same opinion is held by the Montreuil gardeners. "Perform the budding in July or August, in the side of the stock, one bud in each, inserted near the bottom, for principal wall-trees; and at the height of three, four, or five feet, for riders. The bud will shoot the following spring, and attain the length of three or four feet in the summer's growth. After the budded trees have ripened the first year's shoot, they may either be planted where they are to remain, or be trained in the nursery for two, three, or four years, till in a bearing state. Whether the plants be removed into the garden at a year old, or remain longer in the nursery, the first shoots from the budding must be headed down, either early in June the same year, to gain a season, or in the March following, to four, five, or six eyes, to produce lateral shoots, with one upright leader, to begin the formation of the head in a fan-like expansion: the second year's shoots should also be shortened to a few eyes at the return of June or March; and those also of the third year in such degrees as may seem expedient." At Montreuil, almond-stocks are used because the soil is dry; but Mozar prefers plum-stocks where the soil is strong and black. (*Hort. Tour*, &c. 429.) The Flemish nurserymen graft both the peach and nectarine on the Mirabelle plum, a very small cherry-shaped fruit.

4495. *Soil.* A good soil for peach-trees, according to Abercrombie, "is composed of three parts mellow unexhausted loam, and one part drift sand, moderately enriched with vegetable mould, or the cooler dung. If the soil be lean and poor, and at the same time light, have the borders improved with decomposed dung and fertile mellow earth (new top-spit loam, if attainable); if the ground be strong and heavy, add some light earth or dung; if very gravelly, remove the grossest part, excavating to a proper depth; and in the same proportion apply a compost as above. Let the soil be made good to the depth of thirty inches or three feet. The nectarine wants the warmer, richer, and deeper soil, if any difference be made. Bad cold ground, or an exhausted mould, is often the cause of the trees gumming." Forsyth says, "Peaches require a lighter soil than pears and plums, and a light mellow loam is best."

4496. *Choice of plants.* Abercrombie, Forsyth, Nicol, and most authors, agree in recommending the choice of trees, two, three, or four years trained. Forsyth says, "they should be procured in the latter end of October, or beginning of November, as soon as the leaf begins to fall."

4497. *Final planting.* The peach is almost universally planted against walls in Britain; in some few warm situations they have been tried as dwarf standards, and Knight (*Hort. Trans.* vol. ii. p. 219.) "thinks

they may be grown in some cases as low as espaliers, covering with mats in spring to protect the blossom. In a very warm season there can be no doubt the fruit of the hardier sorts so grown, would be higher-colored and of superior flavor, and the trees would be less subject to the red spider. Early autumn planting is best on a dry soil. Spring planting may be successfully performed in February and March; the sooner, so as the weather be favorable, the better; that the trees may take root immediately before the dry warm season commences."

4498. *Mode of bearing.* "All the varieties of the peach and nectarine bear the fruit upon the young wood of a year old; the blossom-buds rising immediately from the eyes of the shoots. The same shoot seldom bears after the first year, except on some casual small spurs on the two years' wood, which is not to be counted upon. Hence, the trees are to be pruned as bearing entirely on the shoots of the preceding year; and a full supply of every year's shoots must be trained in for successional bearers the following season." (*Abercrombie.*) Du Petit Thouars denies the propriety of the distinction usually made of wood-buds and flower-buds in the peach-tree and stalks, and that each leaf produces a bud at its base, which soon becomes triple, the two outer proving flower-buds, and the middle one a leaf or wood bud.

4499. *The summer pruning,* "in May and June, and occasionally in the succeeding months, is to regulate the shoots of the same year, and to prevent improper growths by disbudding. Pinch off fore-right buds or shoots; and pinch off or cut out ill placed, very weakly, spongy, and deformed shoots, and very strong luxuriant growths; retaining a plentiful supply of good lateral shoots in all parts of the tree; and leaving a leader to each branch. Let them mostly be trained in at full length all summer, about three inches asunder, for next year's bearers; and divest them of any lateral twigs, to prevent a thicket-like intricacy, and to promote a healthy fruitful growth in the shoots themselves. In the course of the summer regulation, if any partial vacancy occurs, or should a young tree under training want an additional supply of wood, shorten some convenient-placed strong shoot in June to a few eyes, to furnish a supply of laterals the same season."

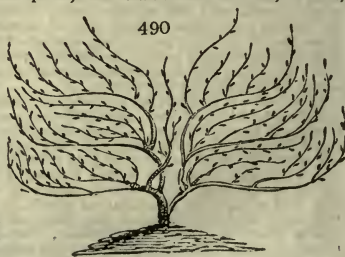

4500. *The winter pruning* "may be performed at the fall of the leaf, and thence, according to some professional writers, at any time in mild weather until spring. It should be completed in February, or early in March, before the blossom-buds are considerably advanced, which are distinguishable by being round, plump, and prominent, while the leaf and shoot buds are oblong and narrow. There is some advantage in pruning when the blossom-buds can be certainly known. Retain, in all parts of the tree, a competent supply of such regular-grown shoots of last year as are apparently fruitful in blossom-buds. Most part of these should be shortened, not indiscriminately, but according to their strength and situation; the very strong shoots should be left longest, being topped about one fourth, or one third; shoots of middling vigor reduce one third or one half; and prune the very weak to two or three buds. Always cut at a shoot-bud, to advance for a leader: sometimes a shoot-bud lies between a twin blossom-bud: cut half an inch above the bud. As many new shoots as will lay from three to six inches asunder may be deemed a competent supply for next year's bearers. Cut out quite close the redundant, irregular, and other improper shoots: remove or reduce some part of the former bearers of the two preceding years, cutting the most naked quite away, and others down to the most eligible younger branch or well placed shoot. Also take out all diseased and dead wood: retaining young, where necessary, to fill a vacancy."

4501. *A mode of pruning adapted to cold and late situations* is recommended by Knight as calculated to obtain fruit-bearing spurs on the peach, and these spurs he finds best calculated in such situations and late seasons, to generate well organised and vigorous blossoms. "Instead of taking off so large a portion of the young shoots, and training in a few only to a considerable length, as is usually done, and as I should myself do to a great extent, in the vicinity of London, and in every favorable situation, I preserve a large number of the young shoots, which are emitted in a proper direction in early spring by the yearling wood, shortening each where necessary, by pinching off the minute succulent points, generally to the length of one or two inches. Spurs which lie close to the wall are thus made, upon which numerous blossom-buds form very early in the ensuing summer; and upon such, after the last most unfavorable season, and in a situation so high and cold that the peach-tree, in the most favorable seasons, had usually produced only a few feeble blossoms; I observed as strong and vigorous blossoms in the present spring, as I have usually seen in the best seasons and situations; and I am quite confident that if the peach-trees, in the gardens round the metropolis had been pruned in the manner above described, in the last season, an abundant and vigorous blossom would have appeared in the present spring. I do not, however, mean to recommend to the gardener to trust wholly, in any situation, for his crop of fruit to the spurs produced by the above-mentioned mode of pruning and training the peach-tree. In every warm and favorable situation, I would advise him to train the larger part of his young wood, according to the ordinary method, and in cold and late situations only, to adopt, to a great extent, the mode of management above suggested. A mixture of both modes, in every situation, will be generally found to multiply the chances of success; and, therefore, neither ought to be exclusively adopted, or wholly rejected in any situation. The spurs must not be shortened in the winter or spring, till it can be ascertained what parts of them are provided with leaf-buds."

4502. *Harrison,* in a very elevated and cold situation, prunes and nails his peach and nectarine trees in December and January, taking away two thirds of the young shoots; and in two hand-dressings in May and July, he leaves the lowest and weakest shoots for a succession in the year following, pinching off the leading and other shoots. J. S. Wortley, Esq. (Harrison's employer) says, "he can hardly do his gardener justice in describing his practice; for he never saw trees so beautifully trained, and upon such good principles. The chief rule which he follows, is never to allow the shoots that are left for bearing fruit, to run to any length from the strong wood; for which reason, when the trees are pruned in autumn the bearing branches for the next year are shortened, taking care not to leave more fruiting-buds than he thinks will come to perfection." (*Hort. Trans.* vol. ii. p. 14; *Harrison's Tr. on Fr. Trees*, ch. xxv.)

4503. *Training.* The peach is almost universally trained in the fan manner, though some allege that it bears better in rich soils when leading branches are trained nearly horizontally, and the bearing shoots trained upwards from those, thus combining horizontal and upright training. Hayward suggests the wavy-fan manner (*fig.* 490.), as likely to answer better than the common mode of fan-training.

4504. *Mozard's mode of training* peach-trees is as follows: in the course of the winter he cuts over the young tree above the graft, leaving four or five buds to produce as many branches. In July following, he cuts out, close

to the main stem, all other branches than those absolutely needed for furnishing the tree. He trains regularly to the right and left; but the weaker branches receive less inclination, or are placed more upright than the stronger ones, that this more favorable position may give them energy, and bring them to an equality of vigor with the stronger branches which are laid in horizontally. At the first regular forming or cutting in, about a year and a half after planting, the branches are reduced to two on each side; and at the next pruning, one branch is removed on each side, leaving the tree to be formed only of two principal branches, and those the most equally balanced as to general form and promise. If the first year's growth do not yield two sufficiently good leading branches, they are sought from the growth of the second year; the best branch of the former year is now, with this view, trained upright as a stem, and two leading branches or arms are derived from it in the succeeding season. In subsequent years the pruning is conducted on similar principles. It is a common rule to leave two secondary arms, of nearly equal strength, and about two feet apart, on each side. In trees managed in the way now described, the sap seems to be equally distributed; at least, the trees exhibit, upon the whole, a great equality of branches, both as to size or strength, and as to furniture of twigs, leaves, and fruit. Continued care is exercised to keep both sides of the tree equally balanced as to vigor. If one principal arm become stronger than the other, a few robbers are allowed to push for a time on the weak arm, with the view of drawing an increase of sap to that side of the tree, till the equilibrium be restored; or, the weak arm is altogether raised a little more towards the vertical, while the stronger is depressed more to the horizontal, and thus an equality is gradually accomplished. The *lambourdes*, or robbers, it may be added, with due management, frequently afford the healthiest and best wood. They are cut down to a foot and a half, leaving one or two buds as near as possible to the trunk of the tree; the resulting shoots are laid in, and form good fruit-bearing wood the next season. The annual shoots are left of different lengths, according to the vigor of the tree, from one foot to three feet. There are two kinds of shoots, such as are the produce both of the early spring and of the summer flow of sap, and such as result from the latter only. The former are preferred, and are called *rameaux*; the latter are distinguished as *ramilles*. When the tree reaches the top of the wall, the cutting in is discontinued, and the pruning extends only to shortening the leading shoots, or, in some cases, bending them till they be confined about two or three inches below the coping of the wall. In this way the equable distribution of the sap in the central parts of the tree is promoted. In the regular course of pruning, all branchlets that show fruit-buds only, or are thought to contain no others, are sacrificed without mercy. This would appear absurd to any one not a horticulturist, but if such branchlets do exist, their excision is quite prudent; for wood-buds or shoots are like pumps, to draw sap towards the branchlets; and if they be wanting, the blossom on the twig commonly fails to set; or if the fruit form, it soon falls off, or at all events, is deficient in size and flavor. From four to eight flower-buds are left on each twig, according to its strength, and a wood-bud at the extremity, when it can be there had, or between two flower-buds near the extremity. When this wood-bud expands into a shoot, the shoot is shortened to an inch or so in length, and this remains as the pump for drawing sap to the four or eight fruit-buds of the twig. Other wood-shoots, as they are called, which may appear below the fruit-buds, or nearer to the main branches, are cut down to one or two eyes. Mozart likewise resorts to disbudbing, although little or no notice is taken of that practice in his work. (*Hort. Tour*, 432.)

4505. *Sieulle*, gardener at Vauz Praslin, adopts, for the first two years, a different mode of training and pruning from that of Mozart. The distinguishing characteristics of Sieulle's method are applicable only to very young peach-trees, in their first and second years. In the first year he does not at all cut or shorten the two original or principal branches, called the *mère* branches. The young tree has only to be fixed to the wall or trellis, requiring no other treatment till the fall of the leaf. By leaving these *mère* branches at full length, and only disbudbing late in the autumn, the vigor of the young tree is greatly promoted. He trains these principal branches to a much wider angle than the Montreuil gardeners, perhaps 60° or 65° instead of 45°. At the approach of winter he practises *l'ébourgeonnement à sec*, leaving only four buds on each branch, and removing the rest neatly with a sharp knife. At Montreuil the *mère* branches are cut in or shortened in the first year, and disbudbing is delayed till the leaves be developed in the following year. By disbudbing at this season the young tree not only suffers an unnecessary check or injury, but the consequence is that the buds left, instead of forming good shoots, develop themselves into numerous *brindilles*. Late in the autumn of the second year, Sieulle cuts in, to the extent of one third, the four lateral branches produced on each of his *mère* branches. In the following year, he disbuds the lateral branches to the extent of one half; and in the future management he practises winter disbudbing greatly in place of pruning, a practice long ago strongly recommended by Nicol in his horticultural writings. By Sieulle's method, Du Petit Thouars remarks, the young tree is more quickly brought to fill its place on the espalier; it is afterwards much more easily kept in regular order: many poorer flower-buds are allowed to unfold themselves, but the necessity of thinning the fruit is thus in a great measure superseded, and the peaches produced are larger and finer. (*Hort. Tour*, 479.)

4506. *Thinning the fruit*. "In favorable seasons, the blossoms often set more fruit than they can support, or than have room to attain full growth; and if all were to remain, it would hurt the trees in their future bearing: therefore they should be timely thinned, when of the size of large peas or half-grown gooseberries. There should be a preparatory thinning before the time of stoning, and a final thinning afterwards, because most plants, especially such as have overborne themselves, drop many fruit at that crisis. Finish the thinning with great regularity, leaving those retained at proper distances, three, four, or five, on strong shoots, two or three on middling, and one or two on the weaker shoots; and never leaving more than one peach at the same eye. The fruit on weakly trees, thin more in proportion." (*Abercrombie*.)

4507. *Renovating old decaying trees*. Head down, and renew the soil from an old upland pasture, and if the bottom of the border is moist, or if the roots have gone more than two feet, or two and a half feet downwards, pave the bottom, or otherwise render it dry and impervious to roots at the depth of twenty inches, or two feet from the surface. This plan will be found almost universally successful in restoring sufficient vigor, to resist insects and diseases, and produce abundance of fruit.

4508. *Protecting blossom*. This may require to be done by some of the various modes already enumerated. (2206. to 2218.) Forsyth recommends old netting as the best covering.

4509. *Harrison* protects his trees from the frost, in the month of January, by branches of broom: these are previously steeped in soap-suds, mixed with one-third of urine, for forty-eight hours, in order to clear them from insects, and when dry, disposed thinly over the whole tree, letting them remain on only until the trees begin to break into leaf. At the time of the blooming and setting of the fruit he applies cold water in the following manner: viz. If upon visiting the trees, before the sun is up, in the morning, after a frosty night, he finds that there is any appearance of frost in the bloom or young fruit, he waters the bloom or young fruit thoroughly with cold water, from the garden-engine; and he affirms, that even

if the blossoms or young fruit are discolored, this operation recovers them, provided it be done before the sun comes upon them. He farther says, that he has sometimes had occasion to water particular parts of the trees more than once in the same morning, before he could get entirely rid of the effects of the frost. Dr. Noehden remarks (*Hort. Trans.* ii.) "that this operation of watering before sunrise, in counteracting the frost, seems to produce its effect in a manner analogous to the application of cold water to a frozen joint or limb, which is injured by the sudden application of warmth." Harrison discovered this method by the following accident: "In planting some cabbage-plants, among the rows of some kidneybeans, very early in the morning, after a frosty night, in spring, before the sun was high enough to come upon the frosted beans, he spilt some of the water upon them which he used in planting the cabbage-plants; and to his surprise, he found that the beans began immediately to recover."

4510. *Ripening peaches on leafless branches.* Whenever the part of the bearing branch, which extends beyond the fruit, is without foliage, the fruit itself rarely acquires maturity, and never its proper flavor and excellence. This Knight conjectured to be owing to the want of the returning sap which would have been furnished by the leaves; and he proved it experimentally, by inarching a small branch immediately above the fruit. The fruit, in consequence, acquired the highest degree of maturity and perfection. (*Hort. Trans.* ii. 25.)

4511. *Insects, diseases, &c.* The leaves of the peach-tree are very liable to the attacks of the acarus, its greatest enemy, and also to be devoured by the *Chermes* (fig. 491. a), *Aphis* (fig. 491. b), and even a much smaller insect, the *Thrips* (fig. 492.),

492 which, in its natural size (c) is hardly perceptible with the naked eye. These are to be kept under by the usual means of watering over the leaves, and fumigation with tobacco-smoke. The honey-dew, mildew, gum, and canker, are chiefly to be kept under by regimen: dusting with sulphur has been found to destroy the mildew (*Robertson, in Hort. Trans.* v. 184.), but the only certain way of removing it is by a renewal of the soil, which will commonly be found old mould long in use and too rich; and by abundance of air. J. Kirk. (*Caled. Hort. Mem.* iv. 159.) has tried renewing the soil for fifty years, and always found it an effectual remedy.

4512. *Black spots or blotches* are very apt to appear and spread on the young wood of the peach-tree, and these Kinmet proved to be produced by over-rich soil. He says, "Some time in the beginning of winter, 1811, I collected together a rich compost-heap (No. 1.), consisting of one third light loam, one sixth strong clay, one twelfth lime, one sixth hot-bed dung, one sixth vegetable mould, and one twelfth pigeon-dung. At the same time, I collected another heap (No. 2.), much less rich, consisting of one half light loam, one fourth strong clay, one eighth earth from scourings of ditches, one sixteenth lime, and one sixteenth hot-bed dung. These heaps I turned over occasionally, in order that they might be well meliorated by the frosts. About the middle of March, 1812, I planted the trees, and applied to the roots of a few of them the rich compost of No. 1.; but the greatest number of them were planted with the compost No. 2. About the latter end of June, I examined the young trees all over: the shoots that they had made were nearly all of the same size; but I was no way disappointed when I found those I had planted with the rich mould, sadly infested with black spots; while those planted with No. 2. remained whole and sound. There being only the few which were planted with No. 1. infested with the black spots. With my knife I cut the blemishes entirely out; and about the latter end of September I found the wounds completely whole. Early in the spring, 1813, I cleared off the rich mould entirely from their roots, and supplied the vacancy with No. 2.; and at the end of last season I had the happiness to see them succeed to the utmost of my wishes, free of black spots." (*Caled. Hort. Mem.* ii. 79, 80.)

4513. *The wasp (Vespa vulgaris), the large fly (Musca vomitoria), the ant (Formica vulgaris), and especially the earwig (Forficula auricularia), are enemies to the ripe peach.* The three first may be excluded by nets, or enticed by honied bottles, and the last caught by the beetle-trap, reeds, or bean-stalks, laid in behind the leaves, and examined every morning.

4514. *The Montreuil peach-growers* water to wash off the aphides; pick off wrinkled, blotched, and mildewed leaves, and cut out canker and gum, and cover the wound with *onguent de St. Fiacre*, i. e. cow-dung and loam, "much in the same way," Neill observes, "as is practised in Scotland."

4515. *Gathering.* Use the peach-gatherer, and gather one day or two before the fruit is to be used, and before it be dead-ripe, laying it on clean paper in a dry airy part of the fruit-room. See Chap. IV. Sec. III. and Chap. V. Sect. X.

4516. *Forcing, and the use of hot-walls.* The peach-tree forces well under glass, (See Chap. VII. Sect. III.) and its ripening may be accelerated in the open air, when planted against a hot-wall, by the application of gentle fires in cold moist weather, in August and September. This will ripen the fruit and wood, but attempts to accelerate the lossoms early in spring are very dangerous, as without the protection of glass they are almost certain of being cut off.

SUBJECT. 2. *Nectarine.* — *Amygdalus Persica*, var. *Nectarina*, L. *Pêche lisse*, Fr.

4517. *The nectarine* is distinguished from the peach by its smooth and rather firmer and more plump fruit. In other respects the general description of the peach equally applies to the nectarine, both, as before observed, being by the continental gardeners considered as one fruit. Forsyth says, "The fruit is called nectarine from nectar, the poetical drink of the gods." Some botanists, considering it as a distinct species, distinguish it by the trivial name of *nuci-persica*, from the similitude of the green fruit in smoothness, color, size, and form to the walnut (*nux*) covered with its outer green shell.

4518. *The varieties are enumerated in the following table: —*

Free Stones arranged in the order of their ripening.

Elruge; first cultivated at Hoxton, by Gurle, in 1680; (*Hook. P. I. & For. 3.*) medium size; dark-red and pale-yellow color; ripens about the middle of August; and is soft and melting

Fairchild's early (*For. 1.*); small size; round figure; beautiful red color; ripens in the middle of August; flavor good

Peterborough, Late Green, Vermash (*For. 10.*)

Scarlet (*For. 4.*); small size; fine scarlet and pale-red color; ripens in the end of August

Violet, Violet Hâtive (*Hook. P. t. 15. For. 11.*); medium size; purple and pale color; vinous flavor

Murphy (*For. 7.*); medium size; dingy red and pale green; ripens in the middle of September

White, Flanders (*Hook. P. t. 30. For. p. 58.*); ripens in the beginning of September.

Cling-stones arranged in the order of their ripening.

Late Newington (*Lang. P. t. 29. For. 2.*); red and yellow color; ripens in the middle of September; excellent rich juice
Brugnon, Italian (*Lang. P. t. 29. For. 5.*); deep-red and pale-yellow color; ripens the beginning of September; rich flavor

Red Roman, Brugnon Musqué (*Duh. n. 26. For. 6.*); large size; dark-red and yellow color; ripens in September; replete with rich juice
Golden (*Lang. p. t. 29. For. 9.*); medium size; soft red and yellow color; ripens in the beginning of October; poignant rich flavor

Early Pavie (*For. 57.*)
Late Genoa (*For. 57.*)
Early Newington (*For. 57.*); above medium size; ripens the end of August; deep-red color; pulp super-excellent; and, according to Miller, one of the best flavored of nectarines, or of any known fruit in the world
Roger's seedling. (*For. 77.*)

4519. *Selection of sorts.* Forsyth recommends for a small garden —

Fairchild's early | Elruge | Scarlet | Newington | Red Roman | Temple's.

4520. *Those in the Dalkeith garden* are as follows; such as are marked (*H.*) being planted against a hot-wall: —

(*H.*) Red Roman | (*H.*) Elruge | (*H.*) Temple | Fairchild's | (*H.*) Clermont
(*H.*) Dutilly's | (*H.*) Brugnon | (*H.*) Murry | (*H.*) Scarlet

4521. *Insects.* "On account of the smoothness of the skin of the nectarine," Forsyth says, "it suffers much more from the wood-louse (*Oniscus asellus*), ear-wigs, &c. than the peach; it will, therefore, be necessary to hang up a greater number of bundles of bean-stalks about these than about any other fruit-trees. Wasps are also very destructive to nectarines, and the trees are very liable to be infested with the red spider."

Culture, &c. This is in all respects the same as the peach.

SUBJECT. 3. *Apricot.* — *Prunus Armeniaca*, L.; *Armeniaca Vulgaris*, P. S. (*Lam. III. t. 431.*) *Icos. Di-Pentag. L.* and *Rosaceæ, J. Malus Armeniaca* of the Ancients. *Abricot*, Fr.; *Abricosenbaum*, Ger.; and *Albicocco*, Ital.

4522. *The apricot* is a low tree, of rather crooked growth, with broad roundish-pointed leaves, glandular, serrated, and the petiole commonly tinged with red. Linnæus remarks, that the vernant leaves are convoluted, that is, not folded flat together, like those of the cherry, but rolling upwards, more or less. The leaves of many apricot-trees have a disposition to this at all times. The flowers are sessile, of a white color, tinged with dusky-red; fruit round, yellow within and without, firmer than plums and most peaches, enclosing a smooth compressed stone, like that of the plum. The flowers appear in April, on the shoots of the preceding year, and on spurs of two or more years' growth, and the fruit ripens in September. From its trivial name, it is generally supposed to have originated in Armenia, but Regnier and Sickler assign it a parallel between the Niger and the Atlas; and Pallas states it to be a native of the whole of the Caucasus, the mountains there, to the top, being covered with it. Thunberg describes it as a very large, spreading, branchy tree in Japan. Grossier says that it covers the barren mountains to the west of Pekin, that the Chinese have a great many varieties of the tree, double-blossomed, which they plant on little mounts for ornament, and dwarfs in pots for their apartments. It appears from Turner's *Herbal*, that the apricot was cultivated here in 1562; and in Hakluyt's *Remembrancer*, 1582, it is affirmed, that the apricot was procured out of Italy by Wolfe, a French priest, gardener to Henry VIII. The fruit seems to have been known in Italy in the time of Dioscorides, under the name of *Præcocia*, probably, as Regnier supposes, from the Arabic, *Berkoch*; whence the Tuscan, *Bacoch* or *Albicocco*; and the English, *Apricock*: or, as Professor Martyn observes, a tree, when first introduced, might have been called a *præcox*, or early fruit; and gardeners taking the article *a* for the first syllable of the word, might easily have corrupted it to *apricocks*. The orthography seems to have been finally changed to *apricot* about the end of the last century; as Justice, in 1764, writes *apricock*; and Kyle, of Moredun in 1782, *apricot*.

4523. *Use.* The fruit is used in a raw state at the dessert, and is esteemed next to the peach; it is also made into marmalades, jellies, and preserved. Grossier says, that lozenges are made by the Chinese, from the clarified juice, which, dissolved in water, yield a cool refreshing beverage: oil may be extracted from the nut, and the young shoots yield a fine golden cinnamon-color to wool.

4524. *Varieties.* Parkinson, in 1629, enumerates six; Rea, 1720, seven; the Luxembourg catalogue, in 1800, fifteen; and the British catalogues enumerate about the same number.

Masculine, Early Red Masculine; an old variety, mentioned by Parkinson in 1629 (*Duh. n. t. 1. & For. 1.*); small size; roundish form; greenish-red color; ripens in the end of July; the pulp tender, with a tart taste; the tree a good bearer, and the fruit esteemed for its earliness and tart taste
Orange; mentioned by Rea in 1702 (*For. 2.*); large size; deep-yellow color; ripens in the end of August; the pulp dry and insipid; fitter for tarts than for the table; excellent for preserving
Alger; mentioned by Rea in 1702 (*For. 3.*); flattened oval form; straw-

color; ripens in the middle of August; the pulp juicy and high-flavored; and, according to Miller, earlier than the orange
Roman; mentioned by Rea in 1702 (*Lang. P. t. 15. and For. 4.*) large size; round form; deep-yellow color; ripens in the middle of August; the pulp not very juicy
Turkey; mentioned by Rea in 1702 (*Lang. P. t. 13. and For. 5.*); large size; globular form; very deep yellow color; ripens in the end of August; the pulp firm and dry
Breda; brought from Africa to Breda, and thence to England in 1702;

(*For. 6.*); large size; round form; deep-yellow color; ripens in the end of August; the pulp soft and juicy; the tree a great bearer; an excellent fruit, especially if grown on standards, to which this sort is particularly adapted
Brussels; mentioned by Rea as brought from Brussels in 1702 (*Pom. Aust. t. 57. and For. 7.*); medium size; inclining to an oval form; red, with dark spots, and greenish-yellow color; ripens in the end of August; the pulp not liable to be mealy, or doughy; brisk flavor; the tree a great bearer; and held in great esteem on account

of its bearing so well in standards, or large dwarfs

Moor Park; Anson's, Temple's, Dunmore's Breda, and Peach Apricot; brought from the Netherlands by Sir Thos. More, say in 1700 (*Hook. P. t. 9. and For. 8.*); ripens in the end of August; fine fruit; according to Nicol, preferable to all other apricots

Peach Apricot; Apricot of Nancy; brought from Paris by the Duke of Northumberland, in 1767 (*Duh.*

n. 10. and For. 9.); very large size; ripens in the end of August; the fruit is the finest and largest of all the apricots, and differs from the Moor Park chiefly in the leaves
Black Peach; introduced by Sir Joseph Banks in 1800 (*Pom. Franc. i. 36. and For. 10.*); black-skinned; ripens in the beginning of August; and of good flavor
Alberge (*Pom. Franc. i. 39. and For. p. 5.*); the only variety whose seeds produce the same fruit as the parent

Angoumois (*Duh. n. 4. t. 3. and For. p. 5.*)

Bloched-leaved (*Pom. Franc. i. 34. and For. p. 5.*)

Breda, Grover's (*For. p. 5.*)

Great (*For. p. 5.*)

Holland (*Duh. 5. t. 4. and For. p. 5.*)

Orange, Royal

Persian

Portugal (*Duh. 6. t. 5. and For. p. 5.*)

Provence (*Duh. 6. t. 4.*)

Transparent

Violet.

4525. *Choice of sorts.* Those grown in the Dalkeith gardens are —

Moor Park

| Breda, early

| Masculine, early

| Brussels, early

| Orange, early.

4526. Propagation. New varieties are procured from the seed as in the peach, and approved sorts are perpetuated by budding, generally on muscle or plum stocks. The Brussels and Breda, when intended for standards, are budded on the St. Julian plum, which produces a strong clean stem; but for the rest, any stock will do, provided it be free and thriving. Knight (*Hort. Trans. vol. ii. p. 19.*) recommends budding the Moor Park on an apricot-stock, which he has found prevents the trees of this sort from becoming diseased and debilitated, which they generally do on plum-stocks. Budding apricots is generally performed early in the season, from the middle of June to the end of July. For dwarfs, the bud is inserted six or eight inches from the ground; and the sorts are sometimes twice budded, or one variety budded on another, which is said to keep the trees in a more dwarf state. For riders or standards, they are budded on plum-stocks four or five feet high. Miller prefers half standards, budded about three or four feet from the ground; the trees so produced, being less liable to suffer from high winds.

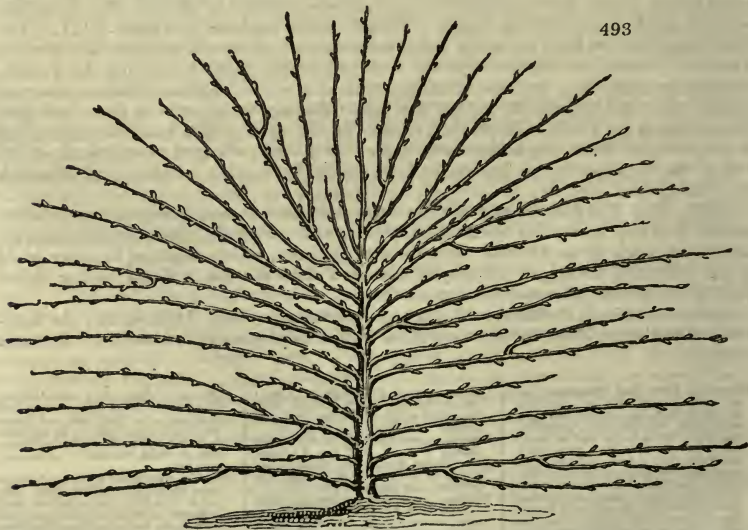

4527. Choice of the plants. Abercrombie prefers trees of two or three years' growth from the bud, and fit for immediate bearing. Forsyth makes choice of those plants which have the strongest and cleanest stems: and if he can such as have been headed down, of two or three years' growth, as they will bear and fill the walls much sooner than those which have not been so treated. He says, "make choice of trees with one stem; or, if they have two, one of them should be cut off; for by planting those with two stems, the middle of the tree is left naked, and, of course, one third of the wall remains uncovered."

4528. Season of planting. Abercrombie says, the best season is from the fall of the leaf until February or March. Forsyth says, the best time is in August, when the leaf begins to fall.

4529. Final planting. The Breda and Brussels are occasionally planted as standards or espaliers in warm situations; and in these states, in fine seasons, produce more highly flavored fruit than on walls. The other varieties are generally planted on walls, which, Miller and Forsyth say, should have an east or west aspect; for, if they are planted full south, the great heat causes them to be mealy before they are eatable. The borders should not be less than six or eight feet wide, and two or two and a half feet deep. The soil a light rich loam, perfectly dry below. Forsyth says, "the borders may be three feet deep." "Standard apricots," Abercrombie observes, "do not come into bearing under a considerable number of years, sometimes ten or twelve; but then the fruit, in a congenial situation, is abundant and of the finest flavor. So, when the prevailing fault of a particular sort is meanness, and yet it cannot be expected to ripen on even a dwarf standard, the medium course of training the plant to a trellis almost touching a south wall, will improve the flavor."

4530. Mode of training. The fan method is very generally adopted with this tree: Forsyth prefers the horizontal manner, and Harrison also trains horizontally, but "so as to let the branches have an elevation to their extremities of 20 degrees, varied, however, according to the luxuriancy or weakness of the tree." With young trees he proceeds to fill the wall by heading down, twice a year, in the same manner as with the apple and pear. The result produces a tree (*fig. 493.*) not essentially different from Forsyth's engraving. (*Tr. on Fr. Tr. chap. xxiv.*)

493

4531. Mode of bearing. The varieties of the apricot, in general, bear chiefly upon the young shoots of last year, and casually upon small spurs rising on the two or three

year-old fruit-branches. The Moor Park bears chiefly on the last year's shoots, and on close spurs formed on the two-year-old wood. The bearing shoots emit the blossom-buds immediately from the eyes along the sides; and the buds have a round and swelling appearance.

4532. *Pruning wall-trees.* The general culture of the wall-apricots comprehends a summer and winter course of regulation by pruning and training.

4533. *Summer pruning.* Begin the summer pruning in May or early in June, and continue it occasionally in July, August, &c. This pruning is principally to regulate the young shoots, of the same year. In the first place, take off close all the fore-right shoots, and others that are ill placed or irregular, or too luxuriant in growth; taking care to retain a competent supply of choice, well placed, moderately growing side shoots, with a good leader to each mother branch. Continue these mostly at their full length all summer, regularly trained in close to the wall, to procure a sufficiency to choose from in the general winter pruning, for new bearers next year. If the summer regulation commence early, while the shoots are quite young, and, as it were, herbaceous, one, two, three, or four inches long, those improper to retain may be detached with the finger and thumb; but when of firmer growth, they must be removed with the knife. If any very strong shoot rise in any casually vacant part, it may be topped in June, which will cause it to produce several laterals the same year of more moderate growth, eligible for training in to supply the vacancy.

4534. *Thinning the fruit.* Sometimes the fruit are much too numerous, often growing in clusters; in which case, thin them in May and the beginning of June, in their young green state; leaving the most promising fruit singly, at three or four inches' distance, or from about two to six on the respective shoots, according to their strength. The apricots so thinned off, and the first principal green fruit, are esteemed very fine for tarts.

4535. *Winter pruning.* This may be performed either at the fall of the leaf, or in mild intervals from that time until the beginning of March. When it is deferred until the buds begin to swell, the promising shoots can be better distinguished. It comprehends a general regulation both of the last year's shoots and the older branches. A general supply of the most regular-placed young shoots must be every where retained, for successional bearers the ensuing year. Cut out some of the most naked part of the two last years' bearers, and naked old branches not furnished with competent supplies of young wood, or with fruit-spurs, either to their origin, or to some well directed lateral, as most expedient, to make room for training a general supply of the new bearers retained; and cut away all decayed wood and old stumps. Generally observe, in this pruning, to retain one leading shoot at the end of each branch; either a naturally placed terminal, or one formed by cutting, where a vacancy is to be furnished, into a proper leader. Let the shoots retained for bearers be moderately shortened: strong shoots reduce in the least proportion, cutting off one fourth or less of their length; from weak shoots take away a third, and sometimes half. This shortening will conduce to the production of a competency of lateral shoots the ensuing summer, from the lower and middle-placed eyes; whereas, without it, the new shoots would proceed mostly from the top, and leave the under part of the mother branches naked, and the lower and middle parts of the tree unfurnished with proper supplies of bearing wood. Never prune below all the blossom-buds, except to provide wood, in which case cut nearer to the origin of the branch. As, in these trees, small fruit-spurs, an inch or two long, often appear on some of the two or three years' branches furnished with blossom-buds; these spurs should generally be retained for bearing; but when any project fore-right far from the wall, cut them in accordingly; for spurs projecting above three inches, though they may set their fruit, seldom ripen it, unless the season and situation are both favorable. The thick clusters of spurs which are apt to form on aged trees, ought also to be thinned. As each tree is pruned, nail it, laying in the branches and shoots from three to six inches' distance, straight and close to the wall.

4536. *Pruning espaliers.* As directed for wall-trees.

4537. *Pruning standards.* Half standards will require only occasional pruning to regulate any branches which are too numerous, too extended, or cross-placed; and to remove any casually unfruitful parts and dead wood. At the same time, the regular branches, forming the head of the tree, should not be generally shortened, but permitted to advance in free growth. (*Abercrombie.*)

4538. *Renovating old decaying trees.* Forsyth had the greatest success in this department of fruit-tree culture, by cutting down to within a foot or eighteen inches, or more, of the ground, and then renewing the soil of the border. He says "it has been the general practice to train apricot-trees on walls in the fan form, which occasions the sap to rise too freely to the top, leaving the lower part almost naked; so that scarcely one quarter of the wall is covered with bearing wood." His remedy for this evil is to "cut down the whole of the tree, as near to the place where it was budded as possible; remembering always to cut it to an eye or joint. If there should be any young shoots on the lower part of the tree, it will be proper to leave them, training them horizontally, which will check the flow of the sap, and thereby render them much more fruitful." (*Tr. on Fr. Tr. ch. i.*) Harrison says, "Apricots are very susceptible of injury from pruning away any strong branches." Instead of heading down old peach, apricot, or plum, or even cherry trees, he generally prefers rooting them out and planting young ones.

4539. *Gathering.* The fruit is apt to become mealy, if left on the tree till over ripe; it should be gathered with the peach-gatherer while moderately firm.

4540. *Insects, diseases, &c.* As the fruit ripens early, it is very liable to be attacked by wasps and large flies, which should be kept off by a net, stretched a foot or more apart from the wall or trellis. The other insects, and the diseases of this tree, are the same as in the peach-tree; but it is not nearly so obnoxious to their attacks, probably owing to the comparatively hard nature of its bark and wood, and coriaceous leaves.

4541. *The apricot does not force well;* but a few are sometimes tried in pots, and placed in the peach-house. See Chap. VII. Sect. III.

SUBJECT. 4. *Almond.* — *Amygdalus*, L. *Icos. Monog. L.* and *Rosaceæ*, J. (*Plenck. Ic. t. 385.*) *Amandier*, Fr.; *Mandelbaum*, Ger.; and *Mandorlo*, Ital.

4542. *The common or sweet almond* is the *A. communis*, L.; and the *bitter almond* is the *A. amara*, L. (*Blackw. t. 195.*) Both will grow to the height of twenty feet, with spreading branches. The leaves resemble those of the peach, but the lower serratures are

glandular, which has given rise to the conjecture that glandular-leaved peaches have sprung more immediately from the almond than such as are without glands, as is generally the case with nectarines. The flowers vary in their color from the fine blush of the apple-blossom to a snowy whiteness. The chief obvious distinction is in the fruit, which is flatter, with a coriaceous covering, instead of the rich pulp of the peach and nectarine, opening spontaneously when the kernel is ripe. It is a native of Barbary, China, and most eastern countries. The *tuberes* of Pliny, Knight considers as swollen almonds, and the same with the *amandier pêcher*, or almond-peach, described by Du Hamel: having raised a similar variety from dusting the stigma of the almond with the pollen of the peach, which produced a tolerably good fruit. (*Hort. Trans.* iii. 4.) The almond is mentioned by Turner in 1548, and, though scarcely worth cultivating in England as a fruit-tree for profit, yet it is a very satisfactory thing to produce almonds of one's own growing at the dessert. The tree forms an important article in the general culture of many parts of France, Italy, and Spain. In a forward spring the blossoms often appear in February, but in this case frost generally destroys them, and they bear little or no fruit; whereas, when the trees do not flower till March, they seldom fail to produce fruit in abundance.

4543. *Use.* The kernel of the stone is the only part used, which is tender, and of a fine flavor. The sweet almond and other varieties are brought to the dessert in a green or imperfectly ripe, and also in a ripe or dried state. They are much used in cookery, confectionary, perfumery, and medicine. "Sweet almonds used in food," Professor Martyn observes, "are difficult of digestion; and afford very little nourishment, unless extremely well comminuted. As medicine, they blunt acrimonious humors; and sometimes give instant relief in the heartburn."

4544. *Varieties and species in cultivation.* Miller enumerates three species, Du Hamel seven; the number of sorts at present grown in the nurseries are as follows:—

Tender-shelled, Sultane (*Duh.* n. 2. and *For.* 1.); small size
Sweet, Common Sweet (*Duh.* n. 5. and *For.* 2.); large size; bitter almonds sometimes found on the same tree
Bitter, Common Bitter (*Pom. Franc.* 1. 67. and *For.* 3.); large size; sweet

almonds sometimes found on the same tree
Sweet Jordan (*Amng. dulcis* of Miller) (*Pom. Franc.* i. 67. and *For.* 4.); tender shell, and large sweet kernel; leaves broad, short, and crenate
Hard-shelled (*For.* 5.)
Dwarf (*Duh.* n. 8. and *For.* 6.)

Peach Almond, *Amandier Pêcher* (*Duh.* n. 2. 1. 4. and *Hort. Trans.* 3. 1.); produces some fruits; pulpy and of tolerable good flavor; and others mere almonds; some partake of both natures
Pistachio, *Amande Pistache* (*Miller*, 4.); very small size.

4545. *Selection of sorts.* The tender-shelled is in the greatest esteem; and next, the sweet and Jordan.
4546. *Propagation.* The almond is propagated, like the peach, by seed, for varieties, or for stocks; and by budding on its own or on plum stocks, for continuing varieties. Plum-stocks are preferred for strong moist soils, and peach or almond stocks for dry situations.

4547. *Final planting.* It is generally planted as standards in shrubberies, and these will sometimes in good seasons ripen their fruit; but when fruit is the object, it should be trained against a west or east wall, like the peach.

4548. *Mode of bearing and pruning.* The almond-tree bears chiefly on the young wood of the previous year, like the apricot and peach; and in part upon small spurs on the two-year-old, three-year-old, and older branches; it is therefore pruned like these trees.

4549. *Gathering and preserving the crop.* A part may be gathered when nearly ripe daily for some weeks before gathering the whole crop. This operation generally falls to be performed in September, when a part may be laid in the fruit-room, and a part thoroughly dried and bedded in sand in the fruit-cellar, for keeping through the winter.

SUBJECT. 5. *Plum.* — *Prunus domestica*, L. (*Eng. Bot.* 1783.) *Icos. Di-Pentag.* L. and *Rosaceæ*, J. *Prune*, Fr.; *Pflaumenbaum*, Ger.; and *Prugno*, Ital.

4550. The plum-tree rises fifteen feet in height, branching into a moderately spreading head; the leaves are ovate, serrated, and on short petioles. Petals white, drupe an oblong spheroid, shell long, ovate, and compressed. The natural color of the plum is generally considered to be black; but the varieties in cultivation are of yellow, red, blue, and green colors, and of different forms and flavors. It is a native, or naturalised in Britain, being frequently found in hedges; but its original country is supposed to be Asia, in Europe: and, according to Pliny, it was brought from Syria into Greece; and thence into Italy.

4551. *Use.* The best varieties are esteemed a delicious dessert fruit; and the others are used in pies, tarts, conserves, and sweetmeats. A wholesome wine is also occasionally made from them, with or without other fruits and ingredients. "Plums," Professor Martyn observes, "when sufficiently ripe, and taken in moderate quantity, are not unwholesome; but in an immature state, they are more liable to produce colicky pains, diarrhœa, or cholera, than any other fruit of this class. Considered medicinally, they are emollient, cooling, and laxative, especially the French prunes, which are peculiarly useful in costive habits. The wood of the plum is used in turnery, cabinet work, and in making musical instruments."

4552. *Varieties.* Tusser enumerates ten; Parkinson, sixty; Miller, only thirty sorts. In the Luxemburg catalogue are sixty-eight; nearly a hundred names are to be found in the catalogues of our nurserymen, of which those in the following table are deemed the best.

4553. A DESCRIPTIVE CATALOGUE OF PLUMS, commonly propagated in BRITISH NURSERIES, arranged as DESSERT and KITCHEN FRUIT.

DESSERT PLUMS. — Arranged in the order of their ripening.

No.	Name.	Synonyms and retentions.	How, when, and where originated, procured, or abounding.	Where figured.	Described.	Size.	Shape.	Color.	Ripens.	Flesh and flavor.	Bearer.	Character of the tree, and general reputation of the fruit.
1.	Jaune ha ve	White primordian	-	Duh. n. 1. t. 61.	Forsyth, 1.	Small	Round	Yellow	End of July	Mealy	-	Chiefly esteemed for its precocity
2.	Early damask	Morocco	-	Lang. P. t. 20.	Forsyth, 2.	Medium	Oval	Red and blue	Aug. of Sept.	Good	-	
3.	Great damask	Tours	-	Duh. n. 4.	Forsyth, 3.	Large	Oval	Bluish	Aug.	Rich	-	
4.	Violet	Blue perdrigon	-	Duh. n. 21.	Forsyth, 4.	-	-	Bluish-red and yellow	End of Aug.	Rich	-	
5.	Little black damask	Red damask	-	Duh. n. 9.	Forsyth, 5.	Large	-	Black	End of Aug.	Rich	-	
6.	White perdrigon	Red damask	-	Duh. n. 20.	Forsyth, 6.	-	-	Black	End of Aug.	Rich	-	
7.	White perdrigon	Red damask	-	Duh. n. 30.	Forsyth, 7.	-	-	Black	End of Aug.	Rich	-	
8.	Robolan	Red damask	-	Duh. n. 46.	Forsyth, 8.	-	-	Black	End of Aug.	Rich	-	
9.	Roche corbon	Red damask	-	Duh. n. 37.	Forsyth, 9.	-	-	Black	End of Aug.	Rich	-	
10.	Wilmore Orleans	Red damask	-	Duh. n. 37.	Forsyth, 10.	-	-	Black	End of Aug.	Rich	-	
11.	Fotheringham	Red damask	-	Duh. n. 37.	Forsyth, 11.	-	-	Black	End of Aug.	Rich	-	
12.	Little Queen Claudia	Red damask	-	Lang. P. t. 20.	Forsyth, 12.	-	-	Black	End of Aug.	Rich	-	
13.	Green gage	Reine Claude	-	Hook. P. t. 131.	Forsyth, 13.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
14.	Isleworth green gage	Reine Claude	-	Hook. P. t. 38.	Forsyth, 14.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
15.	Le rouge	Reine Claude	-	Hook. P. t. 38.	Forsyth, 15.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
16.	De laurier	Cloth of gold	-	Hook. P. t. 47.	Forsyth, 16.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
17.	Cheson	Cloth of gold	-	Duh. n. 30.	Forsyth, 17.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
18.	Saint Catherine	Dauphine gage	-	Lang. P. t. 25.	Forsyth, 18.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
19.	Great Queen Claudia	Dauphine gage	-	Hook. P. t. 24.	Forsyth, 19.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
20.	Apricot	Dauphine gage	-	Duh. n. 25.	Forsyth, 20.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
21.	Maitre Claude	Dauphine gage	-	Lang. P. t. 25.	Forsyth, 21.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
22.	Violet	Dauphine gage	-	Hook. P. t. 4.	Forsyth, 22.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
23.	Coe's golden drop	Dauphine gage	-	Hook. P. t. 4.	Forsyth, 23.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
24.	Damascene	Dauphine gage	-	Lang. P. t. 25.	Forsyth, 24.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
25.	Black damask	Dauphine gage	-	Hook. P. t. 25.	Forsyth, 25.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
26.	Diaper blanc	Dauphine gage	-	Duh. n. 36.	Forsyth, 26.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
27.	Nectarine	Dauphine gage	-	Hook. P. t. 39.	Forsyth, 27.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	
28.	Précoce de Tours	Dauphine gage	-	Hook. P. t. 34.	Forsyth, 28.	Small	Round	Whitish yellow and red	Mid of Sept.	Rich	-	

KITCHEN PLUMS. — Arranged in the order of their ripening.

29.	Mirabelle	Dauphine gage	-	Duh. n. 29.	Forsyth, 29.	Small	Oval	Amber	Reg. of Sept.	Juicy	-	Excellent for sweetmeats
30.	Large white damask	Dauphine gage	-	Duh. n. 7.	Forsyth, 30.	Medium	Oval	Pale yellow	Reg. of Sept.	Firm & well-tast.	-	A useful kitchen-fruit
31.	Prunella	Dauphine gage	-	Duh. n. 7.	Forsyth, 31.	Small	Oval	White	Reg. of Sept.	-	-	Excellent for drying fr. used by the country people, & bear well in hedge.
32.	Bullace	Dauphine gage	-	Duh. n. 32.	Forsyth, 32.	Large	Oval	Green, black and white	Reg. of Sept.	-	-	An excellent baking fruit
33.	Red imperial	Dauphine gage	-	Duh. n. 32.	Forsyth, 33.	Large	Oval	Red	Reg. of Sept.	Rich flavor	-	Tree raised from suckers, or stones, fruit good for bak. or preserv. and in gathering upwards of a month
34.	Damson	Dauphine gage	-	Duh. n. 32.	Forsyth, 34.	Large	Oval	Black	Reg. of Sept.	-	-	
35.	Muscle	Dauphine gage	-	Duh. n. 19.	Forsyth, 35.	Large	Oval	Yellowish	Reg. of Oct.	Too sharp to be eaten raw	-	Excellent for baking
36.	Prune Suisse	Dauphine gage	-	Duh. n. 19.	Forsyth, 36.	Large	Oval	Yellowish	Reg. of Oct.	-	-	Excellent for baking
37.	Wentworth	Dauphine gage	-	Pom. Fr. i. 127.	Forsyth, 37.	Large	Oval	Yellowish	Reg. of Oct.	-	-	An excel. fr. for preserv.; grown on any soil; best on lime-st. or gravel
38.	White imperial	Dauphine gage	-	Duh. n. 41.	Forsyth, 38.	Large	Oval	Yellowish	Reg. of Oct.	-	-	
39.	Monsieur's	Dauphine gage	-	Duh. n. 41.	Forsyth, 39.	Large	Oval	Yellowish	Reg. of Oct.	-	-	
40.	Wine sour	Dauphine gage	-	Duh. n. 41.	Forsyth, 40.	Large	Oval	Yellowish	Reg. of Oct.	-	-	

4554. *Selection of sorts.* The following are recommended by Forsyth for a small garden :—

Jaune hâtive Early damask Orléans	Royal Green gage (different sorts) Drap d'or	Saint Catherine and impera- trice	Magnum bonum; for baking Winesour; for preserving.
---	--	--------------------------------------	---

4555. *The table fruit in the Dalkeith garden* are as under, placed in the order of their ripening, all of them being planted against walls :—

Violet hâtive Early hâtive New Orleans	Early Morocco Green gage Blue gage	Blue perdigon Apricot plum Fotheringham	White magnum bonum Imperial.
--	--	---	---------------------------------

4556. *Propagation.* Most of the varieties are propagated by grafting or budding on the muscle, St. Julian, bonum magnum, or any free-growing plums, raised from seed, or from suckers; but seedlings are preferable stocks for a permanent plantation. The common baking plums, as the damson, bullace, wentworth, &c. are generally propagated by suckers, without being either budded or grafted. Plum-grafting is performed in July or March; budding in July or August. Miller prefers budding, because plums are very apt to gum wherever large wounds are made on them. The myrobalan, a small plum shaped like a cherry, and resembling a May-duke when half ripe, is planted to form hedges about Ghent, and used by the Flemish nurserymen, as stocks for both nectarines and peaches. (Neill, in *Hort. Tour.*)

4557. *New varieties* are procured by propagating from seeds on the general principles already stated. Knight (*Hort. Trans.* iii. 214); in an attempt to combine the bulk of the yellow magnum bonum with the richness and flavor of the green gage, produced a fruit which partook of both parents, but which has not yet been given to the public; but a good variety of the Orléans plum. (*Hort. Trans.* iii. 392.)

4558. *Soil.* Plums, according to Miller, should have a middling soil, neither too wet and heavy, nor over light and dry, in either of which extremes they seldom do well. Abercrombie recommends any mellow fertile garden or orchard ground; and where a soil is to be made, "one half fresh loam, one fourth sharp sand, one sixth road-stuff, and one twelfth vegetable remains, or decomposed dung or animal matter."

4559. *Site.* The plum is cultivated like other indigenous fruit-trees: the hardier sorts, as standards; and the finer varieties against walls. It is sometimes forced; but the blossom, like that of the cherry, is difficult to set, and on the whole, it is a fruit not well adapted for forcing. The finer varieties are almost always planted against walls, which, Miller says, should have an east or south-east aspect, which is more kindly to these fruits than a full south aspect, on which they are subject to shrivel and be very dry; and many sorts will be extremely mealy, if exposed too much to the heat of the sun; but most sorts will ripen extremely well on espaliers, if rightly managed. Some, he adds, plant plums for standards, in which method some of the ordinary sorts will bear very well; but then the fruit will not be near so fair as those produced on espaliers, and will be more in danger of being bruised or blown down by strong winds. Abercrombie says, "have some choice sorts against south walls for earlier and superior fruit; others on east and west walls, and espaliers, to ripen in succession, with full and half standards in the orchard."

4560. *Choice of plants.* Miller recommends trees of not more than one year's growth from the bud; for if they are older, they are very subject to canker; or if they take well to the ground, commonly produce only two or three luxuriant branches. Abercrombie and Nicol take plants from one to five years old. Forsyth chooses "clean straight plants with single stems, and of two or three years' growth."

4561. *Final planting.* Miller says, it is common to see plum-trees planted at the distance of fourteen or sixteen feet, so that the walls are in a few years covered with branches; and then all the shoots are cut and mangled with the knife so as to appear like a stumped hedge, and produce little fruit; therefore the only way to have plum-trees in good order, is to give them room, and extend their branches at full length. Abercrombie directs full and half standards to be planted at forty, thirty, twenty-five, and twenty feet distance; dwarfs generally twenty feet apart, and wall-trees or espaliers fifteen, twenty, or twenty-five feet from stem to stem. Forsyth says, plums and cherries thrive best by themselves; and he prefers a wall for each, placing plums on walls ten feet high, eight yards apart; and at seven yards' distance on twelve-feet walls.

4562. *Mode of bearing.* "All the sorts produce their fruit on small natural spurs, rising at the ends and along the sides of the bearing shoots of one, two, or three years' growth. In most sorts, new fruit-branches are two years old before the spurs bear. The same branches and spurs continue fruitful in proportion to the time which they take to come into bearing."

4563. *Mode of training.* Forsyth and Harrison decidedly prefer the horizontal manner, and both head down the leading upright shoot twice in a year. Forsyth says, "if the leading shoot be very strong, you may top it twice in the summer, as directed for pears, and at the same time that you top them (spring or winter pruning, and June); repeating the same every year till the wall is filled to the top." (*Tr. on Fr. Tr.* ch. ii.)

4564. *Pruning.* After the formation of the head is begun, it takes from two to six years before the different sorts come into bearing. Miller trains horizontally, and is against shortening the branches of plum-trees, since the more these trees are pruned, the more luxuriant they grow, until the strength of them is exhausted, and then they gum and spoil; therefore the safest method to manage these trees is to lay in their shoots horizontally, as they are produced at equal distances, in proportion to the length of their leaves, pinching off the points of young shoots where lateral branches are desired, and displacing fore-right and irregular shoots, or such as shade the fruit. With this carefully going over these trees in the growing season, there will be but little work to do to them in the winter.

4565. *Abercrombie* agrees with Miller in not shortening fruitful branches. Standards, he says, must be allowed to "expand in free growth, occasionally pruning long ramblers, and cross-placed or other irregular branches. Thin crowded parts, cut away worn out bearers, also decayed and cankered wood."

4566. *Forsyth* says, "Never cut the stems of young plum-trees when first planted, but leave them till the buds begin to break; then you may head them down to five or more eyes, always observing to leave an odd one for the leading shoot: remember to cut sloping towards the wall, and as near to an eye as possible; thus managed, the shoots will soon fill the wall with fine wood. If you find that some of the shoots are too luxuriant, you may pinch the tops off with your finger and thumb, about the beginning of June, in the first year after planting; by doing which you will obtain plenty of wood to fill the bottom of the wall. A great deal depends on the first and second year's management of your trees."

4567. *Renovating decaying trees.* Proceed as directed for the peach; but observe that the plum-tree, when cut down, is very apt to run to wood, therefore the new soil must neither be very rich, nor laid on in a very deep stratum.

4568. *Protecting blossom.* This is sometimes done with the tenderer sorts, in the same way as for peaches and apricots.

4569. *Taking the crop.* The different sorts of the plum ripen in succession for about three months in summer and autumn. Some early sorts begin to ripen in July; the main varieties reach full maturity in August and September; late sorts continue ripening till the end of October or beginning of November. Each kind should be brought to table presently after being gathered, as they will not keep long in a natural state.

4570. *Forcing the plum.* Plums may be forced in pots, or otherwise, like other fruit trees. Grange and Aiton, have forced them both ways: the latter thus describes his practice. "The sorts generally preferred for forcing are the following, *Précoce de Tours*, green gage, blue gage, white perdrigon, Orleans, New Orleans, and Morocco. Some others have been tried, as *La Royale*, *simiennes*, and blue perdrigon, but are found objectionable, the two first producing fruit void of flavor, and the latter has a tendency to crack and gum."

4571. *When an early crop is desired*, plums are best forced in large pots or tubs, as this method admits of their removal at pleasure into different degrees of temperature, as occasion may require; but for a general crop to ripen by the end of May, or beginning of June, it is preferable to have the trees planted in the forcing-house, and if they are intended to be forced in the first year, proper trees for the purpose furnished with well branching wood, should be selected and planted early in the autumn, that they may establish themselves before the winter sets in. The soil to be preferred is a moderately rich loam, without mixture of manure.

4572. *For a crop to ripen in the second week in May*, the house must be covered in early in January commencing with a temperature of 42° of Fahrenheit, for the first fortnight, after which the heat may be gradually raised to 52°, at which it may continue until the flowers make their appearance; during this time frequent changes of air must be admitted, to strengthen the bloom, and the crop will be rendered more certain by keeping the trees in blossom as long as possible, by light shading, where necessary; and when the petals begin to fall, gentle dews may be raised from the surface of the mould. As the fruit forms, the thermometer should be raised to 58°; this must be done gradually, as the consequence of a rapid rise may be a casting of the fruit; during the progress of stoning great care must be taken against sudden variations of the temperature, water very sparingly used, and every check by fumigation be given to the various insects which will be particularly active at this period. When the fruit is safely stoned, a moderate dressing of rotten manure may be spread on the surface of the mould; the heat increased to 68°, and a more liberal supply of water given. After the fruit has attained a full size, and approaches maturity, air may be freely admitted, and water should be given in less quantities, and finally discontinued, a few days before gathering.

4573. *Insects, diseases, &c.* See *Peach*. The gum and canker are the most common diseases, and, as in almost every other case, the acarus is the most noxious insect. As a remedy for the former, Abercrombie directs to head down. The insects are destroyed by the common means. The gages, or *reine Claudes*, when nearly ripe, are very apt to be eaten by wasps.

SUBSECT. 6. *Cherry.* — *Prunus Cerasus*, L. (*Eng. Bot.* 706.) *Icos. Di-Pentag.* L. and *Rosaceæ*, J. *Cerisier*, Fr.; *Kirschenbaum*, Ger.; and *Ciriegio*, Ital.

4574. *The cherry* is a middle-sized tree, with ash-colored, shining, roundish branches, ovate serrated leaves, and white flowers, produced in nodding umbels, and succeeded by a red drupe, with an acid pulp. The leaf and flowering buds are distinct, the former terminating, the latter produced from the sides of the two or more years' branches. The cultivated cherry was brought to Italy by the Roman general Lucullus, in 73 A. C. from a town in Pontus in Asia, called *Cerasus*, whence its specific name, and was introduced to Britain 120 years afterwards. Many suppose that the cherries introduced by the Romans into Britain were lost, and that they were re-introduced in the time of Henry VIII. by Richard Haines, the fruiterer to that monarch. But though we have no proof that cherries were in England at the time of the Norman conquest, or for some centuries after it; yet Warton has proved, by a quotation from Lidgate, a poet who wrote about or before 1415, that the hawkers in London were wont to expose cherries for sale, in the same manner as is now done early in the season. The tree is now very generally cultivated both as a wall and standard fruit, and has been forced for upwards of two centuries.

4575. *Use.* It is a refreshing summer fruit, highly grateful at the dessert, and affording pies, tarts, and other useful and elegant preparations in cookery and confectionary. Steeping cherries in brandy qualifies and improves its strength and flavor; a fine wine is made from the juice, and a spirit distilled from the fermented pulp. The gum which exudes from the tree is equal to gum arabic; and Hasselquist relates that more than one hundred men, during a siege, were kept alive for nearly two months, without any other sustenance than a little of this gum taken sometimes into the mouth, and suffered gradually to dissolve. Cherry-wood is hard and tough, and is used by the turner, flute-maker, and cabinet-maker.

4576. *Varieties.* The Romans had eight kinds; red, black, tender-fleshed, hard-fleshed, small bitter-flavored, and a dwarf sort. Tusser, in 1573, mentions cherries red and black. Parkinson mentions thirty-four sorts, Ray twenty-four, and Miller has eighteen sorts, to which he says others are continually adding, differing little from those he has described. The catalogue of the Luxemburg garden contains forty-two sorts, and those of our nurseries exceed that number of names. As usual, we have inserted only those sorts of which we could obtain some authenticated descriptive particulars. The French divide their cherries into *griottes* or tender-fleshed, *bigarreaux* or hard-fleshed, and *guignes*, *geans* or small fruits.

4577. A DESCRIPTIVE CATALOGUE OF CHERRIES, commonly propagated in BRITISH NURSERIES, arranged in the order of their ripening.

No.	Name.	Synonym.	How, when, and where originated, or abounding.	Where figured.	Where described.	Size.	Figure.	Color.	Ripe in	Flesh and flavor.	Bearer.	Characteristics of the tree, and general reputation of the fruit.
1.	Small may	-	-	Lang. P. xvii. 2.	Forsyth, 1.	Small	Round	Red	Beg. of June	Soft and sub-acid	Great	One or two trees sufficient for a large garden; being only esteemed for its precocity.
2.	May duke	-	-	Hook. P. t. 28.	Forsyth, 2.	Med.	Round	Red	Beg. of June	Soft and agreeable acid	Good	Excellent cherry; bears well against a wall, or as a dwarf-standard.
3.	Early black	-	-	-	Hort. T. iii. 212.	Med.	Round and pointed	Black	Beg. of June	Soft, not very juicy,	-	Valuable as being more early than even the May duke.
4.	Late duke	-	-	Duh. xx. t. 15.	Forsyth, 3.	-	-	Blackish red	Mid. of June	Firm, red, very sweet	-	Very good fruit.
5.	Archduke	-	-	Duh. xviii. 13.	Forsyth, 4.	-	-	-	Beg. of July	-	-	Excellent fruit.
6.	Ronald's large black-heart	-	-	Hook. P. 31.	Forsyth, 16.	Large	-	-	Beg. of July	-	-	Valuable for forcing; well worth cultivating.
7.	Fraser's black	-	-	-	Forsyth, 17.	Large	-	Black	Beg. of July	Brisk	Excel.	A fine fruit.
8.	Fraser's white	-	-	-	Forsyth, 18.	-	-	White & trans.	-	Brisk	Excel.	-
9.	Black eagle	-	-	Hort. Tr. ii. 9.	Hort. Tr. ii. 187.	-	Belted & ro.	Dark red	Mid. of July	Firm, sweet, high	Good	Tree very luxuriant and hardy
10.	Kentish	-	-	-	Forsyth, 5.	-	-	Bright red	July	Agreeably acid	Great	A good fruit
11.	Biganeau, several sorts	-	-	Duh. x. 8.	Forsyth, p. 66.	-	-	-	July	-	-	-
12.	Holman's duke	-	-	Hook P. 46.	Forsyth, p. 66.	-	-	-	July	-	-	-
13.	Elton	-	-	Lang. P. xvi. 1.	Forsyth, p. 66.	Large	Heart	-	July	-	-	Tree very luxuriant and hardy
14.	Hartfordshire	-	-	Hook P. 7.	Forsyth, p. 66.	-	-	-	-	-	-	-
15.	Black-heart	-	-	Lang. P. xvii. 4.	Forsyth, 6.	Very la.	Long	Dark red	End of July	Firmer than most here.	-	Valuable as a succession-fruit
16.	Garnet	-	-	Lang. P. xvi. 3.	Forsyth, 7.	Large	Round	Red and white	End of July	Soft, not very sweet	-	A showy fruit
17.	Wenzeloo	-	-	Hort. Tr. ii. 81.	Forsyth, 11.	Large	Conical	Deep red	End of July	Firm, sweet, high	Good	An excellent fruit
18.	Harrison's heart	-	-	-	Forsyth, 8.	-	-	-	July & Aug.	-	-	A fine fruit; trees 100 years old in Kensington-gardens, bear good crops
19.	Black-heart	-	-	Lang. P. t. 18.	Forsyth, 9.	-	-	-	July & Aug.	Firm and stone flat	-	A fine well-known fruit
20.	Grillon	-	-	-	Forsyth, 15.	-	-	-	Beg. of Aug.	-	-	-
21.	Corone	-	-	Lang. P. xvi. 1.	Forsyth, 13.	-	-	-	-	-	-	An excellent fruit
22.	Luteward	-	-	-	Forsyth, 14.	-	Round	-	Beg. of Aug.	Pleasant	Good	A fine fruit
23.	Black geau	-	-	-	Abercrombie	Small	Round	Black	Mid. of Aug.	Firm, peculiar flavor	Good	Tree fit for tin.; from its seeds are raised the black corou, and sm. white cherry
24.	Small black wild	-	-	-	Abercrombie	Small	Round	Black	Mid. of Aug.	Firm, bitterish	Great	Tree lofty & la.; fruit ex for wine & bra.
25.	Small red wild	-	-	-	Abercrombie	Small	Round	Red	Mid. of Aug.	Firm, bitterish	Great	Tree lofty and large; fruit excellent for making wine or qualifying brandy
26.	White Swiss	-	-	-	Abercrombie	Med.	-	White	Mid. of Aug.	-	-	-
27.	Landie geau	-	-	-	Forsyth, 19.	-	-	Black	August	High	-	-
28.	Transparent geau	-	-	-	Forsyth, 20.	Small	-	Red and trans.	August	Delicious	-	-
29.	Cluster	-	-	Lang. P. xvii. 2.	Forsyth, p. 66.	-	-	-	August	-	-	-
30.	Yellow Spanish	-	-	Hort. Tr. ii. 14.	Forsyth, 12.	Med.	Oval	Amber	Aug. & Sep.	Sweet and pleasant	Good	A highly esteemed fruit at Florence
31.	Florence	-	-	Hort. Tr. ii. 14.	Forsyth, 12.	-	Heart	Pale red	September	Firm, white, sweet, and rich	-	-
32.	Amber heart	-	-	-	Forsyth, p. 66.	-	Heart	-	-	-	-	-
33.	Red heart	-	-	Duh. xiv. 11.	Forsyth, p. 66.	-	Heart	-	-	-	-	-
34.	Red heart	-	-	Lang. P. xviii. 3.	Forsyth, p. 67.	-	Heart	-	-	-	-	-
35.	White heart	-	-	Lang. P. xviii. 4.	Forsyth, p. 67.	-	Heart	-	-	-	-	-
36.	Morello	-	-	Lang. P. t. 16.	Forsyth, 10.	Small	Round	Light red	Sep. & Oct.	Soft and acid	Great	A very fine fruit, when kept till October; excellent for preserving and brandy

4578. *Selection of sorts.* Forsyth recommends, for a small garden —

The may-duke	The arch-duke	The Harrison's heart	The Turkey heart
The morello	The black heart	The graffion	The Kensington duke cherry.

4579. *Those in the Dalkeith garden are —*

The early may-duke, two sorts	The black heart	The amber heart
The Harrison's heart	The white heart	The morello; all against walls.

4580. *Miller* says, the best sorts for an orchard are the common red or Kentish, the duke, and the lukeward; all of which are plentiful bearers.

4581. *Propagation.* Varieties of the cherry are continued by grafting or budding on stocks of the black or wild red cherries, which are strong shooters, and of a longer duration than any of the garden kinds. The hearts, which are all ill bearers, are sometimes grafted on bird-cherry stocks, which are said to have the same effect on the cherry, that the paradise-stock has on the apple, that of dwarfing the tree and rendering it more prolific. Some graft on the morello for the same purpose, but the most effectual dwarfing stock is the mahaleb. *Dubreuil* of Rouen recommends the wild cherry for clayey and light soils, and the mahaleb for soils of a light, sandy, or chalky nature. The stones of the cultivated cherry are commonly, but improperly, substituted for those of the wild sort, as being more easily procured. New varieties are procured by propagating from seed, and some valuable fruits will be found in the table, so raised by *Knight*. "The cherry," this gentleman observes (*Hort. Trans.* ii. 138.), "sports more extensively in variety, when propagated from seeds, than any other fruit which I have hitherto subjected to experiment: and this species of fruit is therefore probably capable of acquiring a higher state of perfection than it has ever yet attained. New varieties are also much wanted; for the trees of the best old kinds are every where in a state of decay in the cherry orchards; and I am quite confident, that neither healthy nor productive trees will ever be obtained from grafts or buds of the old and expended varieties of this or any other species of fruit-tree." Cherry-stones, whether for stocks or new varieties, are sown in light sandy earth in autumn; or are preserved in sand till spring, and then sowed. They will come up the same season, and should not be removed till the second autumn after sowing. They may then be planted out in rows three feet apart, and the plants one foot asunder in the row. The succeeding summer they will be fit to bud, if intended for dwarfs; but if for standards, they will require to stand one or more seasons, generally till four years old. They should be budded or grafted near six feet from the ground; the usual way is to bud in summer, and graft those which do not succeed the following spring.

4582. *Soil.* The cherry delights in a dry sandy soil and elevated situation; but some sorts, as the may-duke, will thrive in all soils and aspects, and all the varieties may be planted in any common mellow garden or orchard ground. In Kent, the tree prospers in a deep loam incumbent on rock. *Miller* says, the soil which cherries thrive best in, is a fresh hazel loam; if it be a dry gravel, they will not live many years, and will be perpetually blighted in the spring.

4583. *Site.* To obtain fruit early, some sorts, as the may-duke, are planted against walls; but all the varieties will do well as dwarfs or espaliers in general situations, and most of them as standards. The may-duke, *Nicol* observes, does well as a standard; but against a south wall the fruit becomes considerably larger, and contrary to what happens in other fruits, it seems to acquire a higher flavor. The morello is much improved in flavor when planted against a wall of good aspect. *Abercrombie* says, "Allot to the finest of the early kinds south walls for fruit in May and June; train others against west and east walls, for supplies in succession; and some on north walls for the latest ripeners, particularly the morello, which, so situated, will continue in perfection till September and October: but it is also proper to plant some trees of this sort on south walls, to have the fruit ripen earlier, with improved flavor."

4584. *Final planting.* "Plant full standards from twenty to thirty feet apart; small standards, fifteen, eighteen, or twenty feet. The proper season for planting is from the middle or end of October, or any time in November or December, if open weather, till February or March." *Miller* says, never plant standard or rider cherry-trees over other fruits; for there is no sort of fruit that will prosper well under the drip of cherries. He allows forty feet square for standards in orchards for the same reason.

4585. *Mode of bearing.* "Cherry-trees in general produce the fruit upon small spurs or studs, from half an inch to two inches in length, which proceed from the sides and ends of the two-year, three-year, and older branches; and as new spurs continue shooting from the extreme parts, it is a maxim in pruning both standards and wall-trees, not to shorten the bearing branches where there is room for their regular extension. The morello is in some degree an exception."

4586. *Mode of training.* Forsyth and Harrison train in the horizontal manner, and practise shortening the leading shoots as in the plum, apple, &c. For the morello *Harrison* adopts the horizontal or half-fan method, "the horizontal method when the tree grows very vigorous, and the half-fan method when weaker." (*Tr. on Fr. Tr.* ch. xxiii.)

4587. *Pruning cherry-trees in general. — Standards.* Give only occasional pruning, to reform or remove any casual irregularity from cross-placed or very crowded branches; and take away all cankered and decayed wood.

4588. *Wall-trees.* "A summer pruning, to commence in May or June, is necessary to regulate the shoots of the same year. Disbud the superfluous and fore-right shoots; or if they have been suffered to spring, pinch or cut them off, with such as are disorderly. Retain a competent supply of some of the best well-placed side and terminal shoots, to remain for selection at the winter pruning. Nail or lay in the reserve close to the wall, at their full length, and so train them all summer. The winter pruning may be performed at the fall of the leaf, or at any time in moderate weather till February or March. It comprises a regulation both of the old and young wood. Carefully preserve the sound productive branches and bearers in their full expansion; and reduce or remove such only as are irregular in growth, too crowded, unfruitful, decayed, or cankered. Any branches extending out of bounds, prune in to some good lateral shoot or fruit-bud. According to the time the bearers have already lasted, look to some promising shoots, for successors to those which may first wear out. To fill immediate vacancies, retain select shoots of last year, and the year before, with uniformly a leader to the advancing branch where there is room, and with lateral shoots in any open or unproductive space near the origin of the branch, to be trained as bearers between the main branches. Some cut superfluous fruit-shoots clean away; others leave a sprinkling of short stubs, cut very short if fore-right. The new laterals and terminals are to be trained in at full length, as far as room will permit. They will come into bearing the first and second year. In pruning cherry-trees in general, be careful to preserve the small clustering fruit-spurs, except where in wall-trees any old spurs project considerably, and assume a rugged disorderly appearance; cut such clean out smoothly."

4589. *Pruning the morello.* "The morello cherry bears principally on the shoots of last year, the fruit proceeding immediately from the eyes of the shoots; and bears but casually, and in a small degree on close spurs formed on the two-year-old wood, and scarcely ever on wood of the third year. Therefore, both in the summer and winter pruning, leave a supply of last year's shoots, on all the branches, from the origin

to the extremity of the tree, for next year's bearers; cutting out past bearers to make room. It is plain that the morello ought to have no stubs left with a view to spurs, and all fore-right shoots ought to be disbudded while young. To leave a convenient space for young wood, train the present bearers six inches apart; lay in between each of these one young shoot for bearing next year, which will make the promiscuous distance three inches."

4590. *Underwood* (Caled. Mem. i. 427.) has often observed, when the branches of cherry-trees are laid in too near to one another, or are crossed by branches of the same kind, or by plum-tree branches, as is sometimes the case, that although there be abundance of blossom, yet there is no crop, even in good seasons. On examining the blossom, produced on such crowded shoots, he found, that in fifty flowers, there were not above two styles, of course no fruit could be expected. By not laying in the branches so close, and by removing all superfluous summer shoots, more light and air was admitted, and he had, in consequence, plentiful crops.

4591. *Renovating old or decayed trees.* Proceed as in renovating the plum.

4592. *Protection from birds.* "As cherries, in a ripening state, are frequently attacked by birds, it is advisable to have choice wall-trees or espaliers defended with large nets in due time. Old fishing-nets may also be spread over the branches of dwarf standards. To protect other standard trees, let scarecrows and clap-boards be put up in *terrorem*."

4593. *Gathering the fruit.* Use the hand, taking hold of the fruit-stalk, in gathering from the wall, and the cherry-gatherer, in gathering, from distant branches of high standards.

4594. *Insects, diseases, &c.* Wall cherry-trees are often infested with the red spider, but standards are generally not much injured by insects. Naismith says, "our cherry-trees, both in the open air, and on the natural walls, particularly the tops of the young shoots, are much attacked with a small black insect, provincially called the black beetle. The remedy I have found most effectual for their destruction, is, a mixture of pitch, with one sixteenth part of powdered orpiment, one sixteenth part of sulphur, dissolved over a slow fire in an earthen pipkin, until they be well incorporated; when cold, divide it into small pieces, about the size of a hen's egg, and burn it under the trees with damp straw, directing the smoke as much as possible where the insects are most numerous. In an hour afterwards (if the state of the fruit will admit) give the trees a good washing with the garden-engine, which generally clears off the half-dead beetles, and prevents the spreading of the red spider." (Caled. Mem. ii. 90.)

SECT. III. Berries.

4595. *Of the cultivated berries* the gooseberry is the most useful species in Britain, in which it is grown in far greater perfection than in any other country; next to the gooseberry is the currant, valuable as affording wine; besides these are included the mulberry, raspberry, strawberry, barberry, and elderberry.

SUBSECT. 1. *Black, or Garden Mulberry.* — *Morus nigra*, L. (Blackw. t. 126.) *Monæcia Tetrandria*, L. and *Urticeæ*, J. Mûrier, Fr.; *Maulbeerbaum*, Ger.; and *Moro*, Ital.

4596. *The black mulberry* is a middle-sized tree, with a whitish bark, and broad, sub-quinquelobate, bluntnish, and rugged leaves. It has generally male flowers or catkins, on the same tree with the fruit, which is a turbinate berry. Young trees from seed, Professor Martyn and Knight observe, often show nothing but male flowers for several years, and yet afterwards produce also female flowers, and become fruitful. The fruit of seedling-trees, it is said, is the largest and best flavored. The black mulberry is a native of Persia, and it is supposed was brought to Europe by the Romans, as Pliny mentions two varieties. It will not live in the open air in several parts of Sweden, and is treated as a wall-tree in the north of Germany. It is mentioned by Tusser, in 1573, and was cultivated by Gerarde, in 1596. In some of the old kitchen-gardens near London, there are trees of a very great age, which are very healthy and fruitful. Bradley says, that most of these were planted in the time of James the First, who attempted unsuccessfully to set up a silk manufacture in England; but the species on the leaves of which silk-worms are fed, is the white mulberry (*Morus alba*), whose fruit is not of any value. Forsyth mentions "four large mulberry-trees as still standing on the site of an old kitchen-garden, now part of the pleasure-ground at Sion House, which the late Duke of Northumberland used to say were about three hundred years old." The mulberry is remarkable for putting out its leaves late, so that when they appear, which is generally in May, with the leaves of the common ash-tree, the gardener may take it for granted that all danger from frost is over. There is a curious tree formed by two stems proceeding from a fallen trunk on the site of the garden of the Abbey of St. Augustine at Canterbury, which must at least be 300 years old, probably much older. (Neill, in *Hort. Tour*, &c. p. 13.)

4597. *Use.* The fruit is brought to the dessert, and recommends itself by its highly aromatic flavor, and abundant subacid juice. It is very wholesome, cooling, and rather laxative. Like the strawberry, it does not undergo the acetous fermentation, and therefore may be safely eaten by gouty and rheumatic persons. An agreeable wine is made from the juice; a syrup is obtained from the unripe berries, which is used as a gargle in cases of sore throat; and the bark of the tree is a vermifuge.

4598. *Varieties.* Only one variety of the black is mentioned by Miller, with palmate leaves and smaller fruit.

4599. *Propagation.* By seed, layers, cuttings, or grafting. The first is the least advisable mode, unless for stocks to inarch upon, because, though some affirm the fruit of seedlings to be the largest, yet the plants are very long of coming into bearing.

4600. *By layers.* "These will generally take root sufficiently the first year to bear separating from the parent tree, and should then be planted in a nursery, and trained up with single stems. In four years they will be fit to plant out where they are to remain. They should be planted at a proper distance to admit the

sun and air, as the fruit, when the trees are too close, is very apt to turn mouldy; they should also be sheltered from the east, north, and west winds." Knight lays parts of the bearing branches of old trees, in pots raised to these branches upon poles. Wood of any age will do, and the plants afford fruit the second or third year.

4601. *By cuttings.* In raising mulberries from cuttings, choose the former year's shoots, having one joint of the two years' old wood. Plant them in autumn, if fine weather, or in the month of March, in rows nine inches apart, and at the distance of two inches in the rows, leaving only two or three buds above ground: mulch the ground with leaves or dung well rotted, to keep it moist, and the plants will require little watering. If they succeed well, they may, next season, be transplanted into a nursery, and treated as directed for layers. These young trees, while they remain in the nursery, should be transplanted every three or four years. Miller says, mulberry cuttings will also strike well if planted on a hot-bed in spring.

4602. *Knight* failed in raising cuttings on a hot-bed in spring, but was very successful by the following process. He cut vigorous shoots from the trees in November, and formed them into cuttings of about five inches long, each consisting of about two parts of two years' old wood, and one part of yearling wood. They were intended to be put in pots, and the bottom of each cutting was cut so much aslope, that its surface might be nearly parallel with that of the bottom of the pot in which it was to be placed. "The cuttings were then placed in the common ground, under a south wall, and so deeply immersed in it, that one bud only remained visible above its surface; and in this situation they remained till April. At this period the buds were much swollen, and the upper ends of the cuttings appeared similar to those of branches which had been shortened in the preceding autumn, and become incapable of transmitting any portion of the ascending fluid. The bark at the lower ends had also begun to emit those processes, which usually precede the production of roots. The cuttings were now removed to the pots, to which they had been previously fitted, and placed in a moderate hot-bed, a single bud only of each cutting remaining visible above the mould, and that being partially covered; and in this situation they vegetated with so much vigor, and emitted roots so abundantly, that I do not think one cutting in a hundred would fail with proper attention. The mould I employed was the alluvial and somewhat sandy loam of a meadow, which was sparingly supplied with water; and the plants, till they had become sufficiently rooted, were shaded during bright weather."

4603. *In Spain and India*, as Townsend and Tenant inform us, the white or silk-worm mulberry is always propagated by cuttings, three or four being planted together, so as to grow up into a bush.

4604. *By suckers.* Mulberry-trees, as well as most others so propagated, are longer of coming into bearing, than those raised in any other way but by seed. The plants of this tree, raised from bearing branches, have entire heart-shaped leaves, but those obtained from suckers or seeds present deeply divided or half-winged leaves.

4605. *By grafting.* Knight having planted some young mulberry-trees in pots, raised them to the bearing branches of old trees, and grafted them by approach. The young grafts bore fruit the third year, and continued annually productive. This tree succeeds very ill by the common mode of independent grafting. (*Hort. Trans.* i. 60.)

4606. *Soil.* The tree, Miller observes, delights in a rich light earth, and where there is depth of soil, as in most of the old kitchen-gardens about London. In a very stiff soil, or on shallow ground, whether of clay, chalk, or gravel; the trunk and branches are commonly covered with moss, and the little fruit produced is small, ill tasted, and ripens late. Abercrombie says, the mulberry thrives well in a deep sandy loam, and will succeed in any fertile mellow ground, having a free situation in the full sun.

4607. *Site.* The mulberry is generally grown as a standard or half standard, sometimes as espaliers, dwarfs, or wall-trees. A single young plant does not afford much fruit; but one full-grown and healthy, will afford more than is sufficient for the supply of a large family. Miller recommends planting in a situation defended from the strong south and north-west winds, in order to preserve the fruit from being blown off; but at the same time to keep them at such a distance from trees or buildings, as not to keep off the sun, for where the fruit has not the benefit of his rays to dissipate the morning dews early, it will turn mouldy and rot upon the trees. The nurseries, and especially those at Paris, afford large standard trees of five or six years' growth, which come into bearing the year after removal. Those are in general to be made choice of in preference to raising the tree from cuttings, or inarching. In orchards they may be planted thirty or thirty-five feet from other trees, and twenty feet apart on walls or espaliers; dwarfs may be planted fifteen feet apart, and in each case temporary fruit-trees may be introduced between.

4608. *Forsyth* recommends planting mulberries in grass orchards and pleasure-grounds, because as the finest of the fruit, when ripe, frequently drops, it can be picked up without receiving any injury. Another reason for planting these trees on lawns or in orchards is, that, when full-grown, they are too large for a kitchen-garden. Abercrombie adds, "so nice is the criterion of perfect ripeness, that berries falling without damage are superior to those gathered. Besides, a grass surface harmonises best with trees of magnitude, and increases the beauty of a rural scene."

4609. *Williams* experienced, that the fruit might be much improved in size and flavor by training the trees against a south or west wall. "The standard mulberry," he says, "receives great injury by being planted on grass-plots with the view of preserving the fruit when it falls spontaneously. No tree perhaps receives more benefit from the spade and the dunghill than the mulberry; it ought, therefore, to be frequently dug about the roots, and occasionally assisted with manure. The ground under the tree should be kept free from weeds throughout the summer, particularly when the fruit is ripening, as the reflected light and heat from the bare surface of the soil is thus increased; more especially if the end branches are kept pruned, so as not to bower over too near to, and shade, the ground. The fruit is also very fine if the tree is trained as an espalier, within the reflection of a south wall or other building. If a wooden trellis were constructed with the same inclination as the roof of a forcing-house, fronting the south, and raised about six feet from the ground, leaving the soil with the same inclination as the trellis, a tree trained on it would receive the solar influence to great advantage, and would probably ripen its fruit much better than a standard." (*Hort. Trans.* ii. 92.)

4610. *Knight* concurs with *Williams* as to the advantages of planting the tree against a south wall in cold situations, adding, that "it affords an exception to all, or almost all, other fruits, to which the wall gives increased bulk and beauty, at the expense of richness and flavor." (*Hort. Trans.* iii. 66.)

4611. *Mode of bearing.* "The mulberry produces its fruit chiefly on little shoots of the same year, which arise on last year's wood, and on spurs from the two-year-old wood; in both stages, mostly at the end of the shoots and branches."

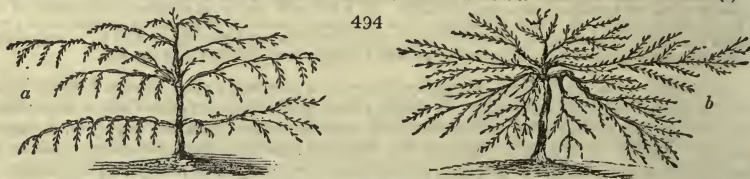

4612. *Pruning.* Miller and *Forsyth* agree in saying there is no occasion to prune standards farther than to thin out irregular crossing branches, and never to shorten the young wood, on which the fruit is produced.

4613. *Pruning wall-trees and espaliers.* "Cut so as to bring in a partial succession of new wood every year, and a complete succession once in two years: taking the old barren wood out, as may be necessary. In the winter pruning, lay in the reserved branches and shoots at six or seven inches' distance."

4614. *Williams* observes, that the trained mulberry requires some nicety in pruning, otherwise it will not bear fruit. "The following method has succeeded in my garden for several years past. All the annual shoots, except the fore-right, are neatly trained to the wall, and these last must be left to grow till towards midsummer, and then be shortened about one third of their growth to admit light to the leaves beneath. By the end of August the fore-right shoots will have advanced again, so as to obstruct the light, and they must then be shortened nearer to the wall than before. In the month of March, or beginning of April, the ends of the terminal shoots should be pruned away down to the first strong bud that does not stand fore-right, and the front shoots which were pruned in August, must also be shortened down to two or three eyes. If trained after this method, the tree will afford fruit the third year; when the management of the fore-right shoots must be somewhat different. These should now be shortened at the end of the month of June or beginning of July, so as to leave one leaf only beyond the fruit, the terminal shoots being nailed to the wall as before, and left without any summer pruning; the fore-rights will not advance any further, as their nutriment will go into the fruit, which, when quite ripe, becomes perfectly black, very large, and highly saccharine."

4615. *Knight* remarks (*Hort. Tr.* iii. 63.), that the mode recommended by *Williams* may suit the extremely fertile soil and climate of Pitmaston. "But in cold situations (and it is chiefly in such that the mulberry-tree will be found to deserve a place on the south wall,) little fruit will be produced, and that will ripen but ill, unless the bearing wood be brought closely into contact with the wall; and the great width of the leaves, and vigorous habit of the tree, present some difficulties to the cultivator, when this mode of training and pruning is adopted. It will be found necessary to diminish the luxuriant growth of the tree, and at the same time to increase its disposition to bear fruit. Such effects may, however, be readily produced by several different means; by destroying a small portion of the bark, in a line extending round the trunk or large branches, or ringing, by tight and long-continued ligatures, or by training the bearing branches almost perpendicularly downwards. I have adopted the last-mentioned method, because it greatly increases the disposition in the tree to bear fruit, without injuring its general health, and because it occasions a proper degree of vigor to be every where almost equally distributed."

4616. *Season for pruning.* "As the blossom-buds of the mulberry-tree cannot be readily distinguished from others in the winter, the best period for pruning is when the blossoms first become visible in the spring. Pinch off every barren shoot which is not wanted to cover the wall, and stop every bearing shoot, under similar circumstances, at the third or fourth leaf. *Williams* has correctly stated, that the bud immediately below the point, at which a bearing or other branch is pinched off, usually affords fruit in the following year." (*Knight*, in *Hort. Trans.* iii. 63.) The mulberry succeeds better than any other tree when trained downwards (*fig.* 494.), either horizontally and drooping (*a*), or in the stellate manner (*b*).

4617. *Renovating old mulberry-trees.* *Miller*, *Forsyth*, and *Knight*, agree that this may be done with trees of almost any age, by removing part of the branches; or by completely heading down, and renewing the soil by fresh mould enriched by dung.

4618. *Taking the crop.* "The most forward berries attain maturity about the end of August; and there is a succession of ripening fruit on the same tree for about a month or six weeks; the ripening berries gradually change from a reddish to a black color, and should be gathered accordingly for immediate use; this delicate fruit will not keep good off the tree above a day or two." *Coke* and *Knight* have had mulberries from wall and espalier trees in gathering from July to the end of October. (*Hort. Trans.* vol. iii. 394.)

4619. *Forcing the mulberry.* *Knight* observes, that "the mulberry is a much finer fruit when ripened under glass, in the north of Herefordshire, than in the open air; and in the still colder parts of England it is probably the only means by which it can be ripened at all. The culture of this fruit, by me, under glass, has been confined to plants growing in pots; but I am not acquainted with any species of fruit-tree which, under such circumstances, produces more abundantly, or which requires less care. Its blossoms set equally well in different degrees of heat, and the same continued temperature which will ripen the earlier varieties of the grape in the end of July, will afford perfectly ripe mulberries early in June; and a tree of the latter species, when fully loaded with fruit, presents at least as agreeable an object to the eye as many plants which are cultivated as ornaments only. It is not subject, under common care, to any disease or injury, except the attacks of the red spider; and as the foliage and growing fruit of the mulberry-tree are not at all injured by being wetted every evening with clear water, the red spider can never prove a very formidable enemy." (*Hort. Trans.* ii.)

SUBJECT. 2. *Barberry.* — *Berberis vulgaris*, L. (*Eng. Bot.* 49.) *Hexan. Dig.* L. and *Berberidea*, J. *Epine Vinette*, Fr.; *Berberitzen*, Ger.; and *Berberio*, Ital.

4620. *The barberry* is a branchy prickly shrub, rising to the height of eight or ten feet, with ash-colored bark, yellow inside. The flowers appear in pendulous racemes towards the ends of the branches; the corolla, yellow; the berries at first green, but of a fine red when ripe. The flowers appear in May with a cowslip odor; and the fruit, which is of an acid flavor, ripens in September. It is a native of the eastern countries, and also of most parts of Europe, and is found in woods, coppices, and hedges in England, especially in a chalky soil. It is generally supposed that the *Puccinia*, a fungus which closes up the epidermis of the leaves of corn crops, and appears on their surface like rust, is generated by the *Æcidium berberides*, an insect which inhabits the barberry. (*Sir J. Banks on Blight, &c.*)

4621. *Use.* The fruit is used for preserving, candying, and pickling, as well as for garnishing dishes; the plant is also an ornamental shrub, both when in flower and in fruit.

4622. *Varieties.* Those most esteemed for their fruit are the following, viz.

Red barberry without stones; which has an agreeable flavor when full ripe. It is only found without stones when the plant has attained considerable age, and is on a poor soil.

White barberry. (*Poit. et Turp. Fr. t. 51.*)

Black sweet; which is the tenderest of them, and should be planted in a warm situation.

Common red with stones. (*Duham. 1. p. 152. et tab.*) This is planted more for ornament than use, on account of its beautiful red berries.

Purple-fruited. (*Poit. et Turp. Fr. t. 59.*)

4623. *Propagation.* "All the varieties are propagated commonly by suckers, also by cuttings and layers of the young branches, and occasionally by grafting; the common red sort is also raised by seed; each of which methods of propagation may be performed in the spring; that by suckers and layers may be effected also in autumn."

4624. *Soil and final planting.* The barberry prefers a light dry soil. One or two plants may be planted in a complete orchard, and trained as standards; but where the shrubbery is the site, it may be allowed to grow as a bush or shrub. "According to the nature of the ground, plant either at any time from autumn to spring, or only in the spring; the plants may be already furnished with a head pretty well advanced, if thought proper; allow them square distances of from fifteen to thirty feet."

4625. *Mode of bearing and pruning.* "The barberry produces its fruit at the sides of the branches in small loose bunches: it bears both on young and old wood, chiefly toward the extremities. The branches should not be shortened, except the design be to force out new wood; permit the head to extend freely; and give only occasional pruning, to keep it in a pretty round form, open in the middle; cutting out weak, luxuriant, crossing, superfluous, and decayed branches; reduce also long ramblers, and trim up low stragglers, also lateral shoots on the stem, and eradicate all root-suckers."

4626. *Taking the crop.* "As a proportion of the berries ripen in the course of September, they will afford occasional gatherings for present use; and as they will be wholly ripe in October, all that are wanted for domestic supply should be then pulled; always pick them in bunches." (*Abercrombie.*)

SUBJECT. 3. *Elder.* — *Sambucus nigra*, L. (*Eng. Bot.* 476.) *Pent. Trig. L.* and *Caprifoliaceæ*, J. *Sureau*, Fr.; *Hollunderbaum*, Ger.; and *Sambuco*, Ital.

4627. *The common elder* is a bushy tree of twelve or sixteen feet in height, much branched, and covered with a smooth grey bark, becoming rough on old stems. The leaves are unequally pinnate. The flowers appear in terminating cymes, and are succeeded by globular blackish-purple berries, mawkishly sweet. It flowers in May, and the berries ripen in July. The whole plant has a narcotic smell, and it is not prudent, we are told, to sleep under its shade. It is a native of Britain, and many other parts of Europe, and of Africa, Japan, &c. It is common in damp woods and hedges, and is sometimes introduced in cottage gardens and plantations for the fruit, and in forest plantations, exposed to the sea air, as a nurse plant.

4628. *Use.* The fruit is in demand in many places, but especially in London and the principal English towns, for making elder wine of the expressed juice; a powerful, warming, and enlivening article for the cottager. The tree, professor Martyn observes, is a whole magazine of physic to rustic practitioners, nor is it quite neglected by more regular ones. An excellent healing ointment is made of the green inner bark, which is also purgative in moderate, and diuretic in small doses. A decoction of the flowers promotes expectoration and perspiration, and they give a peculiar flavor to vinegar. The flowers are reported to be fatal to turkeys, and the berries to poultry in general. No quadruped will eat the leaves of this tree; notwithstanding it has its own *phalæna* and *aphis*. The wood is used by the turner and mathematical instrument maker; and is made into skewers for butchers, tops, angling rods, and needles for weaving nets.

4629. *Varieties.* Miller mentions several, but those cultivated for their fruit are chiefly the white and black. The scarlet and green berried may also be used like the black, and are very ornamental trees in the shrubbery.

4630. *Site and soil.* "As the tree will grow any where, either in open or shady situations, it may be planted in any out-ground or waste spot, in single standards or in rows, to assist in forming boundary fences. Trees planted in the hedge order, if suffered to grow up untrimmed, will produce abundance of berries for use."

4631. *Propagation and rearing.* "The elder is raised by cuttings of the young shoots in the spring, and by seed in the autumn. Select for cuttings some strong young shoots of last summer, cut into lengths of one foot, and thence to three feet or more: these may be planted either where it is intended the plants should remain, or in a nursery for a year's growth. Insert them from six to fifteen inches into the ground, according to their length; they will soon strike root; and will shoot strongly at top the same year. Train those designed for standards with a single stem from three to five feet high; and those for hedges, with branches out from the bottom. To raise this tree from seed: sow in autumn, October, or November, or later in mild weather, or soon in the spring, either for a hedge, in drills, where the plants are to remain; or in a bed or border for planting out when of one or two years' growth."

4632. *Final planting.* "Standards may be planted from ten to twenty feet apart. They should be allowed to shoot out above to form a branchy head, nearly in their natural order: in which they will soon become plentiful bearers. For hedge-planting, insert cuttings or year-old plants into the sides or tops of banks or ditches, or other suitable boundary lines, a foot asunder. Permit them to branch out from the bottom; and where they are designed for full fruiting, merely cut in the sides a little regular below, leaving them to run up above in branchy growth, for producing large crops of berries."

4633. *Taking the crop.* "The berries ripen in perfection for the purpose of making wine, about the middle and end of September, and in October, and should then be gathered in bunches." (*Abercrombie.*)

SUBJECT. 4. *Gooseberry.* — *Ribes Grossularia*, and *R. Uva-crispa*, L. (*Eng. Bot.* 1292. 2057.) *Pent. Monog. L.* and *Cacti*, J. *Groseille à maquereau*, Fr.; *Stachelbeerstrauch*, Ger.; and *Uva-spino*, Ital.

4634. *The gooseberry* in Piedmont, where it is found wild, and the berries eatable, but astringent and neglected, is called *griselle*. Some derive our name gooseberry from gorseberry, or the resemblance of the bush to gorse; others, as Professor Martyn, from its being used as a sauce with young or green geese. Gerrard says, it is called feaberry (feverberry) in Cheshire, and it has the same name in Lancashire and Yorkshire. In

Norfolk this term is abbreviated to feabes, or, as they pronounce it, thapes. Carberry is another British name for this fruit. The gooseberry-bush is a low, branching, prickly shrub, with trilobate sub-pubescent leaves, one-flowered nodding peduncles, and pendulous berries, hairy or smooth. It is a native of several parts of Europe, and abounds in the Vallais in copsewoods, where it produces a small, green, hairy, high-flavored fruit. In England it is naturalised in various places on old walls, ruins, and in the woods and hedges about Darlington. It is cultivated in greater perfection in Lancashire than in any other part of Britain; and next to Lancashire, the climate and treatment of the Lothians seem to suit this fruit. In Spain and Italy the fruit is scarcely known. In France it is neglected and little esteemed. In some parts of Germany and Holland the moderate temperature and humidity of climate seems to suit the fruit; but in no country is its size and beauty to be compared with that produced in Lancashire, or from the Lancashire varieties cultivated with care in the more temperate and humid districts of Britain. Neill observes, that when foreigners witness our Lancashire gooseberries, they are ready to consider them as forming quite a different kind of fruit. Happily this wholesome and useful fruit is to be found in almost every cottage garden in Britain; and it ought to be considered a part of every gardener's duty to encourage the introduction of its most useful varieties in these humble enclosures. In Lancashire, and some parts of the adjoining counties, almost every cottager who has a garden, cultivates the gooseberry, with a view to prizes given at what are called gooseberry-prize meetings; of these there is annually published an account, with the names and weight of the successful sorts, in what is called the *Manchester Gooseberry-Book*. The prizes vary from 10s. to £5 or £10. The second, third, to the sixth and tenth degrees of merit, receiving often proportionate prizes. There are meetings held in spring to "make up," as the term is, the sorts, the persons, and the conditions of exhibition; and in August to weigh and taste the fruit, and determine the prizes. In the gooseberry-book for 1819 is an account of 136 meetings; the largest berry produced was the *top-sawyer* seedling, a red fruit, weighing 26 dwts. 17 grs. Forty-six red, thirty-three yellow, forty-seven green, and forty-one white sorts were exhibited, and fourteen new-named seedlings, which had been distinguished at former meetings, stated as "going out," or about to be sold to propagators.

4635. Use. The fruit was formerly in little esteem; but it has received so much improvement, that it is now considered very valuable for tarts, pies, sauces, and creams, before being ripe, and when at maturity it forms a rich dessert fruit for three months; and is preserved in sugar for the same purpose, and in water for the kitchen. Unripe gooseberries can be preserved in bottles of water against winter; the bottles are filled with berries close corked and well sealed; they are then placed in a cool cellar till wanted. By plunging the bottles, after being corked, into boiling water for a few minutes, (heating them gradually to prevent cracking,) the berries are said to keep better. (Neill.)

4636. Varieties. The gooseberry is mentioned by Turner in 1573. Parkinson enumerates eight varieties: the small, great, and long common, three red, one blue, and one green. Ray mentions only the pearl-gooseberry; but Rea has the blue, several sorts of yellow, the white Holland, and the green. Miller only says, there are several varieties obtained from seed, most of them named from the persons who raised them; but as there are frequently new ones obtained, it is needless to enumerate them. The present lists of London nurserymen contain from 80 to 100 names; but those of some of the Lancashire growers above 300. Forsyth, in 1800, mentions ten sorts as common; and adds a list of forty-three new sorts grown in Manchester. The following may be considered established varieties, and such as merit cultivation:—

Red.		Yellow.	
Old ironmonger	Nutmeg	Great amber	Golden knap
Early black	Captain	Globe amber	Royal sovereign
Damson, or dark red	Wilmot's early red.	Great mogul	Tawny.
Large rough red	Green.	Hairy globe	White.
Red walnut	Green Gascoigne	Golden drop	Large crystal
Warrington	Green walnut	Honeycomb	White-veined
Smooth red	White Smith	Sulphur	Royal George
Hairy red	Green globe	Conqueror	White Dutch
Red champagne	Green gage.	Yellow champagne	White walnut.

4637. Selection of sorts. "It must be admitted," Neill observes, "that although the large gooseberries make a fine appearance on the table, they are often deficient in flavor when compared with some of smaller size. Many of them have very thick strong skins, and are not eatable unless thoroughly ripened. Some of the large sort, however, are of very good quality, such as the red champagne and the green walnut. Among these also Wilmot's early red deserves further notice. It was raised by Wilmot, at Isleworth, in 1804, and has been cultivated by him very extensively on account of its valuable properties; being early ripe, of excellent flavor, and extremely productive. It usually ripens from the middle to the end of June. For culinary use in the month of May it is larger and better than most others, the skin not being tough, but the whole berry melting to a fine consistence." Forsyth very judiciously recommends cultivating the early and late sorts, in order to prolong the season of this fruit. In Lancashire, the Warrington or Manchester red, which is an improved variety of the old ironmonger, is esteemed the best dessert fruit; and the shoots growing upright, the shrub occupies less horizontal space than most varieties. The walnut red they consider the best sort for preserving. The best mode to obtain a complete collection is to send to a Lancashire nurseryman, stating whether the object desired be an assortment of large showy sorts, a numerous variety, or a selection of the most useful sorts; but, all the sorts worth having as dessert or kitchen fruit, are in the London and Edinburgh nurseries.

4638. Propagation. The gooseberry may be propagated by all the modes applicable to trees or shrubs; even by pieces of the roots; but the mode by cuttings is usually adopted for continuing varieties, and that by seeds for procuring them.

4639. *By seeds.* As far as we know, the scientific mode of impregnating one variety with another has not been applied to this fruit. In general, the seed of some choice variety thoroughly ripe is taken and sown in autumn or early in spring, in beds or pots of rich light mellow earth: when the plants are a year old they are planted out in nursery rows, to be cultivated and trained there a year or two; in general they will bear the third year.

4640. *By cuttings.* Miller says, the best season for planting gooseberry-cuttings is in autumn, just before their leaves begin to fall. The cuttings should be taken from bearing shoots, rather than those *gourmands* which issue from the main stem. Cut them to such a length as the strength and ripeness of the wood will bear, and cut off all the buds excepting three, or at most four at top, and train the plants with a single stem of nine inches, or a foot high, from the top of which the branches should radiate upwards at an angle of 40°, or better if 45°. Haynes advises taking off cuttings in July, when the fruit is on the tree, in order to make sure of the sorts. He says, by immediate planting, watering, and shading, as good plants are produced as from ripe wood-cuttings. (*Tr. on the Gooseberry, &c.* p. 92.)

4641. *Soil and site.* Any good garden-soil, on a dry bottom and well manured, will suit the gooseberry. That which is soft and moist produces the largest fruit. The situation should not be under the drip of trees over-much shaded or confined, otherwise the fruit will be small, ill flavored, and the plants apt to mildew. Forsyth says, gooseberries should be dunged every year, or at least have a good coat of dung once in two years. Haynes recommends a mixture of peat and loam well manured, and a shaded situation. The last he proposes to effect by planting among his compartments of gooseberries, rows of Jerusalem artichokes in the direction of east and west.

4642. *Final planting.* "The season for planting gooseberries is any time during open weather from October till March. When trees are procured from the public nurseries choose such as are of some advanced size, about three years' growth, with pretty full heads, for immediate plentiful bearers. Let the general supply be in standard bushes, and planted principally in the kitchen-garden, in single rows, along the boundary edges of the main compartments, or outward borders, from six to eight feet apart; or some may be planted in cross rows, to subdivide extensive compartments. When the object is to raise large quantities of fruit, plantations are made in continued parallel rows, eight or ten feet asunder, by six feet in the row. It would be eligible to plant a few choice sorts against south and other sunny walls or paling, for earlier and larger fruit; and on north walls, to ripen late in succession." (*Abercrombie.*)

4643. *Forsyth says,* "The market-gardeners about London plant them in rows, from eight to ten feet apart from row to row, and six feet from plant to plant in the rows. In small gardens I would recommend planting them in a compartment by themselves, at the distance of six feet between the rows, and four feet from plant to plant; or you may plant them round the edges of the compartments, about three feet from the path; you will then have the ground clear for cropping, and a man, by setting one foot on the border, can gather the gooseberries without injuring the crop."

4644. *Neill says,* "In some places gooseberry-trees, on the sides of the borders, are trained to a single tall stem, which is tied to a stake: this, though six or eight feet high, occasions scarcely any shade on the border, and it does not occupy much room, nor exclude air; while, at the same time, the stem becomes close hung with berries, and makes a pleasant appearance in that state." (*Ed. Enc. art. Hort.* § 161.)

4645. *Maier observes (Hort. Trans. ii. 146),* that as "the crop of ripe fruit is often injured, by having the largest and earliest berries prematurely gathered, whilst green, for tarts, a sufficient number of trees of such varieties as are the earliest, should be planted in a separate compartment of the garden, and devoted exclusively to the use of the kitchen, for tarts and sauce."

4646. *Mode of bearing.* "The gooseberry produces its fruit not only on the shoots of last summer, and on shoots two or three years old, but also on spurs or snags arising from the elder branches along the sides; but the former afford the largest fruit. The shoots retained for bearers should therefore be left at full length, or nearly so." (*Aber.*)

4647. *Pruning.* "The bushes will require a regulating pruning twice in the year."

4648. *Summer pruning.* "Where any bushes are crowded with cross and water shoots, of the same year, shading the fruit from the sun, and preventing the access of air, thin the heart of the plant and other tufted parts moderately, pinching off or cutting out close what spray is removed; but do not touch the summer shoots in general." Maier says, "it will greatly contribute to the perfection of the fruit, if the very small berries are taken away with a pair of scissors about the middle or end of May; and these small berries will be found quite as good for sauce or gooseberry-cream as the larger."

4649. *Winter pruning.* "You may proceed to the winter pruning any time from November until the end of February, or until the buds are so swelled that farther delay would endanger their being rubbed off in the operation. Cut out the cross shoots and water-shoots of the preceding summer, and the superfluous among crowded branches. Prune long ramblers and low stragglers to some well placed lateral or eye; or if an under-straggler spring very low, cut it away. Of last year's shoots retain a sufficiency of the best well placed laterals and terminals, in vacant parts, to form successional bearers, and to supply the places of unfruitful and decayed old wood, which, as you proceed, should be removed. Mostly retain a leading shoot at the end of a principal branch, leaving it either naturally terminal, or where the branch would thus be too extended, pruning to some competent lateral within bounds. The superfluous young laterals on the good main branches, instead of being taken off clean, may be cut into little stubs of one or two eyes; which will send out fruit-buds and spurs. Of the supply reserved for new bearers, a small number will probably require shortening, where too extended, or curved inconveniently; leave these from eight to twelve inches in length, according to strength and situation; those of moderate extent and regular growth will require very little shortening, and many none at all. Observe, too close cutting, or general shortening, occasions a great superfluity of wood in summer: for the multiplied laterals thus forced from the eyes of the shortened branches increase to a thicket, so as to retard the growth and prevent the full ripening of the fruit: on which account it is an important part of pruning to keep the middle of the head open and clear, and to let the occasional shortening of the shoots be sparing and moderate. Between the bearing branches keep a regulated distance of at least six inches at the extremities, which will render them fertile bearers of good fruit. Some persons, not pruning the gooseberry-tree on right principles, are apt to leave the shoots excessively close and tufted, while they shorten the whole promiscuously; others sometimes clip them with garden-shears to close round heads; in consequence of being pruned in these methods, the bushes shoot crowdedly, full of young wood in summer, from which the fruit is always very small, and does not ripen freely with full flavor."

4650. *Forsyth says,* "Many of the Lancashire sorts are apt to grow horizontally, and the branches frequently trail on the ground, which renders them liable to be broken by high winds, especially when they are loaded with fruit. In that case I would recommend two or three hoops to be put round them, to which the branches may be tied, to support them, and prevent their being broken by the wind."

4651. *Jeeves* has tried training gooseberries on an arched trellis, in the manner of a *berceau*, or arbor-walk. For this purpose, he plants in rows, five feet and a half apart, and the plants three feet distance in the row. He chooses the strongest-growing kinds, and trains four branches, at nine inches' distance

from each plant, till they meet at top. The advantages of this plan are, beauty of appearance, fruit not splashed by rain, easily gathered, and the ground more readily cultivated. (*Hort. Trans.* vol. iv. p. 194.)

4652. *Taking the crop.* "From gooseberries being useful for different purposes, both in a green and in a mature state, and from the compass of time afforded by early and late sorts, they are in season and great request four or five months in summer, from April till September. The early sorts, on south walls, come in for gathering in small green berries, for tarts, &c. in April or early in May, and attain maturity in June. From common standard bushes an abundant supply is yielded in May and June of gooseberries in a green state; and in proportion as part is reserved to ripen, a succession, in full size and maturity, is obtained in June, July, and August. Some late kinds, either planted in shady situations, or shielded with mats from the sun in their ripening state, continue good on the tree till September."

4653. *Prolonging of the crop.* In addition to planting late sorts in shady situations, the bushes, whether standards or trained, may be matted over when the fruit is ripe, and in this way some of the reds, as the Warrington, and the thick-skinned yellow sorts, as the Mogul, will keep on the trees till Christmas.

4654. *Suckling.* By preparing a very rich soil, and by watering, and the use of liquid manure, shading, and thinning, the large fruit of the prize cultivator is produced. Not content with watering at root and over the top, the Lancashire connoisseur, when he is growing for exhibition, places a small saucer of water immediately under each gooseberry, only three or four of which he leaves on a tree. This is technically called *suckling*. He also pinches off a great part of the young wood, so as to throw all the strength he can into the fruit.

4655. *Accelerating maturity.* Hunt tried ringing on half a gooseberry-bush, which half produced ripe fruit a week sooner than the other, and twice the usual size. (*Hort. Trans.* iv. 565.)

4656. *Insects, diseases, &c.* The caterpillars of saw-flies (*Tenthredinidæ*, Leach) (fig. 495.), of butterflies (*Papillæ*, L.), and of moths (*Phalænæ*, L.) are well known and serious enemies to gooseberries. The larvæ of the *Tenthredinidæ* have from sixteen to twenty-eight feet; a round head; and when touched, they roll themselves together. They feed on the leaves of the gooseberry, apple, and most fruit-trees, as well as roses, and other shrubs and plants. When full-grown, they make sometimes in the earth, and sometimes between the leaves of the plant on which they feed, a network case, which, when complete, is strong and gummy, and in that change to a pupa incompleta, which for the most part remains during the winter in the earth. The perfect fly emerges early in the ensuing spring; its serrated sting is used by the female in the manner of a saw, to make incisions in the twigs or stems of plants, where it deposits its eggs. The Caledonian Horticultural Society having "requested information respecting the best method of preventing or destroying the caterpillar on gooseberries," received various communications on the subject, and the following are extracts from such as they deemed fit for publication:—

4657. *Gibbs* describes the large black, the green, and the white caterpillars, with his methods of destroying them. During the winter months, the large black kind may be observed lying in clusters on the under parts, and in the crevices of the bushes; and even at this season (Feb.) I find them in that state. In the course of eight or ten days, however, if the weather be favorable, they will creep up in the day-time, feed on the buds, and return to their nest during the night. Whenever leaves appear upon the bushes they feed upon them till they arrive at maturity, which is generally in the month of June; after which they creep down upon the under sides of the branches, where they lodge till the crust or shell is formed over them. In July they become moths, and lay their eggs on the under sides of the leaves, and of the bark. The produce of these eggs, coming into life during the month of September, feed on the leaves so long as they are green, and afterwards gather together in clusters on the under side of the branches, and in crevices of the bark, where they remain all the winter, as already said. Winter is the most proper time for attacking this sort with success, as their destruction is most effectually accomplished by the simple operation of pouring a quantity of boiling hot water upon them from a watering pan, while no injury is thereby done to the bushes.

4658. The green sort are at present (Feb.) in the shelly state, lying about an inch under ground. In April they come out small flies, and immediately lay their eggs on the veins and under sides of the leaves. These eggs produce young caterpillars in May, which feed on the leaves till June or July, when they cast a blackish kind of skin, and afterwards crawl down from the bushes into the earth, where a crust or shell grows over them, and in that state they continue till the following April. The only method which I have hitherto found effectual in destroying these is, 1st, to dig the ground around the bushes very deep during the winter season, by which means the greater part of them are destroyed, or buried too deep ever to penetrate to the surface: 2dly, in April, when the flies make their appearance, to pick off all the leaves on which any eggs are observable; this is a tedious operation, but may be done by children. If any of the enemy should escape both these operations, they will be discernible as soon as they come to life, by their eating holes through the leaves, and may then easily be destroyed, without the least injury to the bushes or fruit.

4659. The white kind, otherwise called *borers*, are not so numerous as the other kinds, though very destructive; they bore the berry, and cause it to drop off; they preserve themselves during the winter season, in the chrysalis state, about an inch under ground, and become flies nearly at the same time with the last mentioned kind; they lay their eggs on the blossoms, and these eggs produce young caterpillars in May, which feed on the berries till they are full-grown, and then creep down into the earth, where they remain for the winter in the shelly state. (*Caled. Mem.* vol. i.)

4660. *Macmurray*, in autumn, pours a little cow-urine around the stem of each bush, as much as suffices merely to moisten the ground. The bushes which were treated in this manner remained free of caterpillars for two years; while those that were neglected, or intentionally passed over, in the same compartment, were totally destroyed by the depredations of the insects. A layer of sea-weed laid on in autumn, and dug in in spring, had the same effect for one year. (*Caled. Mem.* vol. i. 95.)

4661. *R. Elliot* says, "Take six pounds of black-currant leaves, and as many of elder-leaves, and boil them in twelve gallons of soft water; then take fourteen pounds of hot lime, and put it in twelve gallons of water; mix them all together; then wash the infested bushes with the hand-engine; after that is done, take a little hot lime and lay at the root of each bush or tree that has been washed, which completes the operation. By these means you will completely destroy the caterpillars, without hurting the foliage of the bush or tree in the least. A dull day is to be preferred to any other for washing. When the foliage is all off the bushes and trees, wash them over with the hand-engine, to clean them of decayed leaves; for this purpose, any sort of water will do; then stir up the surface of the earth all round the roots of the bushes and trees, and lay a little hot lime about them to destroy the eggs. This I have never found to fail of success since my first trial, six years ago. The above-mentioned proportion of leaves, lime, and water,

will serve for two acres of ground or more, covered with trees and bushes in the ordinary manner, and will cost very little money indeed. The same proportion is to be observed in making a wash for the rest of the trees or bushes."

4662. *Macbray* procured some tobacco and soft or black soap, and boiled a quarter of a pound of tobacco with one pound of soft soap in about eighteen Scots pints of water, and kept stirring the liquid while boiling with a whisk, in order to dissolve the soap; this liquor, when milkwarm, or so cool as not to hurt the foliage, he applied to the bushes with a hand-squirt in the evening, and in the morning found all the ground under the bushes covered over with dead caterpillars. This practice he continued for six years, always when he saw any symptoms of the approach of caterpillars.

4663. *Tweedie*, in the course of any of the winter months, pares all the earth from under the bushes to the depth of about three inches, into a flat ridge betwixt the rows; and on the first dry day following, either treads, beats, or rolls these ridges, and trenches the whole down one and a half or two spades deep, observing to tread the foul earth into the bottom of the trench.

4664. *Forsyth's method* is as follows: "Take some sifted quick-lime and lay it under the bushes; but do not at first let any of it touch the branches or leaves; then shake each bush suddenly and smartly, and the caterpillars will fall into the lime; if the bush be not shaken suddenly, the caterpillars, on being a little disturbed, will take so firm a hold as not easily to be shaken off. After this is done, sift some of the lime over the bushes; this will drive down those which may have lodged on the branches. The caterpillars ought to be swept up next day, and the bushes well washed with clear lime-water mixed with urine; this will destroy any caterpillars that may still remain, and also the aphides, if there are any on the bushes."

4665. *Sweet* first syringes the plants, and then powders them with quick-lime by hand, so that every leaf both above and below is covered with it. This he found destroyed not only gooseberry caterpillars, but the black fly on the peach-tree. (*Hort. Trans.* v. 76.)

4666. *Harrison* considers, that in the winter season, "the eggs of the insects are deposited in crevices and joints of the tree, also in the ground." In the pruning season, he burns the prunings, and washes the trees with a mixture of quick-lime and water, and then casts in powdered lime among the branches; or, instead of this, he washes the trees with twelve gallons of water, half a pound of tobacco, and six ounces of black pepper boiled together for half an hour, and used when cold. In the following spring, "just before the trees come into bloom," he sprinkles them with lime-water, and throws on them powdered lime, spreading some at the roots of the tree. Soon after the berries are set, he smokes the trees with straw fires. When summer flies visit the trees, he picks off the leaves on which their eggs are deposited. "This," he says, "is readily done, and very effectual." If they increase very rapidly, he uses lime-water as in spring. (*Tr. on Fr. Tr.* 348.)

4667. *Our opinion* is, that no reliance is to be placed in powdered hot lime alone, for destroying either the insects or their eggs. Hot water, applied in Gibbs's manner; lime-water, or water and powder of lime, in the manner of Elliot and Sweet; and digging down, as performed by Tweedie, may be of real service; but the only effectual plan seems to be that of previously hand-picking; which, however tedious it may seem, will often be found a more economical mode than any of the above. Hand-picking, with the spring-generated kinds, should commence as soon as the eggs are observed on the under sides of the leaves, of a white color, and not thicker than hairs; the whole leaf may be picked off, or the eggs brushed or sponged off: with the winter kinds it ought to commence as soon as they leave their nidus in the soil or bark and appear on the leaves.

4668. *Preventive treatment.* Sprinkling gooseberry and currant bushes with tar-water, prevents the fly or moth from settling on the plant to lay its eggs; this must be done early in the spring, for if done after the fruit is set, it will taste of tar. (*J. Busch*, in *Hort. Trans.* iv. 568.)

4669. *Forcing.* The gooseberry may be forced in pots or boxes placed in pits, or in the peach-house or vinery. Hay plants in pots in November, removes to the peach-house in January, and has ripe fruit in the end of April, which he sends to table growing on the plants. (*Hort. Trans.* iv. 415.)

SUBJECT. 5. *Black Currant.* — *Ribes Nigrum*, L. (*Eng. Bot.* 1291.) *Pentand.*
Monog. L. and Cacti, J. *Groseille à fruit noir*, or *Poirvri*, Fr.

4670. *The black currant* is an humble shrub, with smooth shoots, strong-smelling trilobate leaves and hairy racemes, with a solitary one-flowered peduncle at the base of the raceme. The flowers appear in April, of a greenish-white, and the fruit ripens in June and July, and changes from a green to a black color. It is a native of most parts of Europe, especially the more northern parts. It abounds in the woods in the north of Russia; and in the subalpine regions of Siberia, where the branches and berries are very large and sapid. In Britain, it is found in wet hedges, on the banks of rivers, in alder swamps, and sometimes in woods.

4671. *Use.* The fruit, which has a peculiar flavor, and disliked by some, is seldom brought to the dessert; but it is eaten in puddings and tarts, and made into jellies, and wines. The Russians put the berries into brandy, and the Irish into whiskey, in the same way as the English put cherries; the Russians also ferment the juice with honey, and so form a strong and palatable wine. Many cottagers, who cannot afford to mix green tea with common bohea, substitute one or two dried leaves of black currant, the flavor produced by which few are so acute as to distinguish from that of a mixture of green and black tea. There are no varieties of the black currant.

4672. *Propagation.* By cuttings. See *Gooseberry*.

4673. *Soil and site.* A moist soft soil and shady situation, such as is afforded by borders of north exposure is preferable. Miller says, "The fruit is always best when the plants are placed in an open situation, and light loamy soil."

4674. *Final planting.* As only a few plants are in general required for private gardens, these may be placed at the distances recommended for gooseberries, in the margin of a shady border, or against a wall of a north exposure. Neill says, it produces most fruit as a standard, but the largest berries when trained to a wall.

4675. *Mode of bearing.* The black currant bears chiefly on the shoots of the preceding year, and also from snags or spurs, which, however, are less abundant, and of smaller size in the black currant than in the gooseberry or red currant.

4676. *Pruning.* Attend to the general directions giving for pruning gooseberries, observing to depend less on spurs than on the preceding year's wood, cutting out the old as it becomes naked and barren, to make room for the new.

4677. *Insects and diseases.* The black currant is seldom attacked by insects; though, like the elder-tree, it has its own variegated caterpillars, which sometimes reduce it to a state of complete nudity. (4657.)

4678. *Gathering the fruit.* See *Red Currant*.

4679. *Forcing.* The black currant may be forced in pots like the gooseberry. In Russia this is often done for the sake of the fragrance of the leaves.

SUBJECT. 6. *Red Currant*. — *Ribes Rubrum*, L. (Eng. Bot. 1289) *Pentandria Monogynia*, L. and *Cacti*, J. *Groseille à grappes d'outre mer*, Fr.; *Johannisbeere*, Ger.; and *Uvetta*, Ital.

4680. *The red currant* is a low shrub, with smooth branches, doubly serrate, pubescent leaves, yellowish-green flowers on pendulous racemes, which appear in May, and the fruit ripens in June and July. The berries of this shrub, in its wild state, are red; cultivation has produced white and pale-red berried varieties. It is a native of the northern parts of Europe, and found in hedges and woods in England. Professor Martyn observes, that "the currant does not seem to have been known to the ancient Greeks and Romans, as the southern nations of Europe have not even an appropriate name to it at this day. The old French name *groseilles d'outre mer*; and the Dutch, *beskins overzee*, proclaim their having been strangers imported. Our English name of currant is evidently from the similitude of the fruit, to that of the *uva corinthiaca*, the small grape of Zante, or the common grocers' corinths, or currants. The red currant has been long cultivated in Britain, and very much improved in the size of the bunch and berry.

4631. *Use*. The fruit is acceptable at the dessert, being of an agreeable acid taste. It is much used for jellies, jams, and wines. Forsyth says, it is the most useful of all the small fruit, either for the table and kitchen, or for preserving, making wine, &c.; and continues longer in succession than any other. According to Withering, the juice forms an agreeable acid to punch; and Professor Martyn says it was a common beverage in Paris in 1763. Its medicinal qualities are similar to those of other subacid fruits, allaying thirst, lessening an increased secretion of the bile, and correcting a putrid and scorbutic state of the fluids.

4682. *Varieties*. These are —

Common red or wild currant	Champagne large red	Large new white Dutch	Large pale-red Dutch
Large red	Champagne pale red	(Hook P. L. t. 56.)	Gooseberry-leaved.
Long clustered red	White Dutch	White crystal	

4633. *Propagation and nursery culture*. The same as in the gooseberry. With a view to obtaining improved varieties from seed, that indefatigable horticulturalist, Knight, procured cuttings, in the year 1810, of the finest varieties of the red and the white currant, which he planted in pots of very rich mould and placed under a south wall, to which the trees were subsequently trained. At the end of three years, within which period the pots had been as often changed, the trees were first suffered to produce blossoms. These were, with the exception of a very small number, removed from the white currant trees, as soon as their buds unfolded; and those which remained were deprived of their stamens, whilst immature, and subsequently fertilised by the pollen of the red variety. The seeds thus obtained were sowed in pots, as soon as the fruit had become perfectly mature, and were subjected, early in the following spring, to the artificial heat of a forcing-house; by which means, and by proper subsequent attention, the plants grew more than a foot in height in the first season. At two years old, in the year 1816, several of the plants, and, in 1817, the greater part of them, produced fruit of great variety of character, and merits; but out of about two hundred varieties, only three red and two white appeared to possess greater merits than their parents. (*Hort. Trans.* iii. 88.)

4634. *Soil and site*. All the sorts are very hardy, will grow freely, and bear plentifully almost any where, alike in open and shady situations, by which the fruit may be obtained early, in June and July, and prolonged for several months in succession till October. As to soil, the currant generally does well in any common garden-ground, well tilled and recruited; it bears the greater crop in a strong loam, or improved clay, somewhat moist; the earlier in a sandy light mould, which is not poor. Previous to planting, the ground should be dug two feet deep.

4635. *Final planting*. "The season for planting on a dry soil is any time in open weather, from the fall of the leaf till February or March. Plants expected to bear the following summer are best moved in October, unless the ground be wet in winter. Allot a competent supply of standard bushes, to be planted chiefly in the kitchen-garden, in a single row round the main compartments, or in the outward borders, or some in cross rows, to divide extensive compartments. Plant them from five to ten feet distant in the row. To raise large supplies, full plantations are formed in parallel rows, with intervals between the rows of eight or ten feet, and between the trees in each row of six feet. Where convenient, have also some choice sorts trained against walls or palings, of different aspects, to obtain early and late fruit in perfection: some against a south exposure, for early production; others on east, west, and north walls, for intermediate succession and late fruit. Plant them at six, eight, or ten feet distance; letting them occasionally fill up the vacant spaces between other wall-trees. The branches should be allowed to advance from near the bottom, and be trained in a nearly horizontal direction from three to six inches asunder. Before nailing them, cut out superabundant and irregular growths, retaining a competency of regular shoots for orderly training, among which, if any are of very considerable length, prune them to moderate extent. Some may likewise be trained as espaliers, in a detached row, in the borders or divisions of the compartments. The trees so trained may either be left to grow without support, or be tied occasionally to stakes, and the branches thus will not overspread the ground. Being kept moderately thin and regular, they will bear fine large fruit, and make an agreeable appearance."

4686. *Mode of bearing*. Currant-trees, in general, bear the fruit both on the young wood of one, two, and three years' growth; and on the older branches, from small spurs, and snags along the sides, which continue several years fruitful, but the fruit produced on the last year's shoot is always finest, especially when the old mother bearers have borne more than four years.

4637. *Pruning*. The chief part of the future culture is seasonable pruning. After the plants are furnished with full heads, they produce many superfluous and disorderly shoots every summer, crowding the general bearers, so as to require retrenchment and regulation, both in the young growths of the year and older wood. The season for the capital pruning is winter; but a preparatory part is performed in summer, to thin the superfluous shoots of the year where too crowded, excluding the sun and air from the fruit. First, as to standards: —

4638. *Summer pruning*. "In May or June cut out close the most irregular shoots rising in the centre of the tree, with all the cross and water-shoots, to admit more freely the essential influence of the air

and sun, and promote the growth of the fruit and improve its flavor. Also twist off all root-suckers as they appear.

4689. *Winter pruning.* "This extends both to the old and young wood; the time for it is when the plant is at rest. Of the shoots of the preceding summer, cut out the cross-placed and the otherwise irregular, with those which are not wanted for vacancies; but superfluous good lateral shoots are to be cut down to short stubs or artificial spurs, about half an inch long, so as to leave an eye or two, in order that they may send out fruit-shoots and spurs. With regard to the old bearers, take away those which are naked, or getting unfruitful, or of which the fruit is declining in size; reduce any of excessive length, pruning in to some well placed lateral young shoot, to preserve the head within some regular compass: cut out also any decayed or cankerous parts; retain a competency of the finest best-placed new shoots above and below vacant parts, to come in for successional bearers, or to supply the places of defective old wood; and preserve a leading shoot to the principal branches, where within orderly limits: shortening such terminal shoots as are of greatest length, to ten, twelve, or fifteen inches, according to their strength and situation on the branches; and leaving those of small extent mostly entire. Take care of the small natural fruit-spurs, and occasionally select short lateral roots of one, two, or three inches, for bearing fruit; or similar small shoots may be cut to short snags of an inch or two long, also for fruiting. Thin out spurs on the old branches where very thick. As the old fruit-branches decline bearing or decay, cut them away, taking care to provide young ones in succession; and thus keep the trees always furnished with full-bearing branches, and advancing young bearers, in a regular open expansion, six, eight, or ten inches asunder at the extremities; circumscribing the general head within the height of three or four feet, or five at most."

4690. *Macdonald*, at Dalkeith House, Neill observes, "raises currants of the finest quality. A good deal depends on the way in which he manages the bushes, especially during the ripening of the fruit. He prunes the bushes at the usual season of mid-winter, shortening the last year's shoots down to an inch or an inch and a half. Next summer the plants show plenty of fruit, and at the same time throw out strong shoots. As soon as the berries begin to color, he cuts off the summer shoots to within five or six inches before the fruit. This is commonly done with the garden-shears, with which a man may go over half an acre of bushes in a day. Sun and air thus get free access, and more of the vigor of the plant is directed to the fruit: the berries are found not only to be of higher flavor, but larger than usual." It appears (*Caled. Hort. Mem.* ii.) that Macdonald had used the knife for his summer pruning till within two years. We confess we regret to hear of the introduction of the shears into the kitchen-garden, and especially into that of so opulent a proprietor, who ought to set an example of order, progress, and perfection, and not of reviving random work, for the sake of economy. It would certainly be better to employ women and children.

4691. *To wall-trees, espaliers, and fan-standards* without support, the same course of summer and winter pruning is applicable, with the obvious variations required by their figure. In training wall-trees, two branches are led in a horizontal direction along the bottom of the wall or trellis, perhaps half a foot from the surface of the earth, and the growth from these of all upright shoots, which will admit of being arranged at the distance of five or six inches from each other, is encouraged. Fan-standards are sometimes trained in a manner nearly similar (*fig. 496.*), and sometimes with the branches radiating from the crown of the stem.

4692. *Insects, &c.* The red currant is occasionally attacked by the caterpillar (*Phalæna grossularia*), and very frequently by the *Aphis ribes*, which changes the color of the leaves to red, pits and puckers them, and causes the fruit to be shrivelled and flavorless. These are to be destroyed by watering with lime-water, and water alone.

4693. *Forsyth* says, "As currants are very liable to be devoured by earwigs, which take shelter under their leaves and branches, bundles of bean-stalks should be hung up some time before the bushes are covered with mats or nets. If proper attention be not paid to this, the fruit will generally suffer very much from these insects. After the bushes are covered, take the mats off once in three or four days, and kill the earwigs that have got into the bean-stalk, which it will be necessary still to keep hung up. As there is a sweetness in the inside of bean-stalks which attracts the earwigs, they very readily take shelter in them from rain."

4694. *Taking the crop and preserving.* "The ripening fruit comes in for small gathering in June, advances to maturity in July, and continues in perfection till the end of August: or if trees in a full exposure are timely defended from birds and the full sun with garden-mats, or protected with nets where they grow about north walls, the fruit may be continued good till September or October." Gather in a dry state, as in rainy weather they lose their flavor. (*Abercrombie.*)

4695. *Forcing.* To obtain early currants by forcing, let some good bearing trees, in pots, be placed, as early as January or February, in any common forcing department: they will produce ripe fruit in April and May.

SUBJECT. 7. *Raspberry.* — *Rubus Idæus*, L. (*Eng. Bot.* 2442.) *Icos. Polyg.* L. and *Rosaceæ*, J. *Framboisier*, Fr.; *Himbeerstrauch*, Ger.; and *Rovo ideo*, Ital.

4696. *The raspberry* plant has stems which are suffruticose, upright, rise about two feet high, and are biennial in duration; but the root is perennial. The leaves are quinate-pinnate, the flowers come in panicles from the extremity of the present year's shoots; they are white, appear in May and June, and the fruit, which in the wild plant is red, ripens about a fortnight afterwards. It is a native of Britain, and not uncommon in woods in low moist situations.

4697. *Use.* The fruit is grateful to most palates, as nature presents it, but sugar improves the flavor; accordingly, it is much esteemed when made into sweetmeats, and for jams, tarts, and sauces. It is fragrant, subacid, and cooling; allays heat and thirst, and promotes the natural excretions in common with other summer fruits. It is much used in distilling, to make the cordial spirituous liquor, to which it gives name. Raspberry-syrup is next to the strawberry in dissolving the tartar of the teeth; and as, like that fruit, it does not undergo the acetous fermentation in the stomach, it is recommended to gouty and rheumatic patients.

4698. *The varieties are —*

Early small white	Most large red Antwerp	Twice bearing white	Woodward's raspberry.
Large white	Large yellow Antwerp	Twice-bearing red	(<i>Hook. P. L. &</i>
Large red	Cane or smooth-stalked	Smooth cane, twice-bearing	

4699. *Estimate of sorts.* "With respect to the varieties of fruit: the first in the above list is a small fruit, but esteemed for its early bearing. The second and third, the common large white and red sorts, are cultivated in fuller crops, as plentiful bearers of larger berries. The two Antwerp sorts are still superior in yielding fine large fruit, and deserve a wall or espalier. The cane-raspberry is a good sort for the main crop. The twice-bearers are esteemed for their singular property of producing two crops of fruit the same year, of which the first commonly ripens in July, and the second in September or October; and in fine dry seasons the plants will afford some production from the second crop till November."

4700. *Propagation.* "The varieties can be perpetuated by young sucker-shoots rising plenteously from the root in spring and summer: when these have completed one season's growth, they are proper to detach with roots for planting, either in the autumn of the same year or the next spring, in February or March, but not later than the middle of April. These new plants will bear some fruit the first year, and furnish a succession of strong bottom shoots for full bearing the second season. New varieties are easily raised from seed; and they come into bearing the second year."

4701. *Soil and site.* "All the varieties will succeed in any common mould trenched about two feet deep, and sufficiently manured; but the soil in which the raspberry-bush most prospers and bears the finest fruit, is a light rich loam. Allot the main crop a free exposure to the sun, that the berries may ripen in perfection. Be careful to favor the twice-bearers with a dry soil, and a sheltered sunny situation, to give the second crop every aid in coming to maturity. When raspberries are cultivated on a large scale, it is best to keep them in plantations by themselves. Set these in rows, from four to six feet asunder, as the bushes are of the smaller or larger kinds, by three or four feet in each row. Scattered bushes may either occupy a single row lengthwise along the back part of a border, or stand in detached stools, at ten or fifteen feet distance. Select sorts are frequently trained against walls, stakes, or espaliers, from the most sunny to the most shady aspect, for early and late fruit of improved growth and flavor." Neill says, "the raspberry-bush grows freely in any good garden-soil; but it is the better for being slightly moist. Although the place be enclosed by trees, and even slightly shaded, the plant succeeds. In an enclosed and well sheltered compartment, with rather a damp soil, containing a proportion of peat-moss, we have seen very great crops of large and well flavored berries produced; for example, at Melville House, the seat of the Earl of Leven, in Fifeshire." Haynes also recommends well manured bog-earth, and a situation naturally or artificially shaded.

4702. *New plantation.* "Raspberry-bushes are in their prime about the third and fourth year; and if well managed, continue in perfection five or six years; after which, they are apt to decline in growth, and the fruit to become small, so that a successive plantation should be provided in time. Select new plants from vigorous stools in full perfection as to bearing."

4703. *Summer culture.* "Keep them clear from weeds during the summer by hoeing between the rows; at the same time, loosen the earth about the plants. Under this management the plants, if tolerably strong, will both yield a moderate crop the first summer, and supply young stems for bearing in greater plenty and perfection the following season; and so, from year to year, the summer culture should be repeated. As the plants get established, let all straggling suckers between the rows, or from the extreme roots of single stools, be cleared out by hoeing, or twisted off, to admit the air and sun freely to the fruit."

4704. *Pruning and winter dressing.* "It is requisite every winter or spring to cut out the dead stems, and to thin and regulate the successional young shoots. This annual pruning may be performed any time, during open weather, from November till the beginning of April. When kitchen-garden crops are cultivated between the rows, it is most convenient to do this as soon as the old bearers begin to decay. As to pruning indiscriminately in the open weather of winter, it sometimes happens that severe frosts immediately follow, and partially kill the plants; therefore it is safer to shorten the tender young stems early in spring; but let it not be deferred till the buds are making new shoots, as that would weaken the root. Cut out all the old dead stems clean to the bottom; and having selected from the strongest young shoots on each main stool, three, four, or five, to be preserved for a succession of bearers, cut away the superabundant close to the ground. Let each of the shoots retained be pruned at top, below the weak bending part; cutting them in the smaller plants, to about three or four feet in length, and in the large sorts, to the length of five or six feet. If any of the stems diverge irregularly, or straggle much asunder, they may be tied together at top, and thus the strong ones will support each other; or the taller varieties may have the support of stakes. Prune plants against a wall or trellis as above; and train the shoots to rise a little diagonally. After pruning, having cleared away the cuttings, dig the ground between and about the plants. To turn in a little rich compost every year will conduce to plentiful and fine returns; lay it at the extremities of the roots, and deeper as the plantation gets older. Eradicate all straggling suckers."

4705. *To obtain fruit of a very large size.* The fruit of the raspberry may be obtained of a very large size, other circumstances being of the most favorable kind, by destroying all the suckers; but in this way, the plant being destroyed, a double plantation is wanted, one to grow only suckers, and the other fruit. In this way Kecht, at Berlin, produces plants ten and twelve feet high, with fruit larger than any we have seen in this country (*Versuch den Weinbau, &c.* p. 46.)

4706. *Taking the crop.* "The fruit of the different varieties comes in from the end of June or July till October or later. As it ripens, it should be timely gathered for immediate use; because, when fully ripe, it will not keep above two or three days before it moulds, or becomes maggoty, and unfit to be used." (*Abercrombie.*)

4707. *Raspberries may be forced* equally well with gooseberries and currants, and like them either planted in pots or in the soil or floor of the house. In M. Hope's garden at Haarlem, the raspberry is planted outside along the north and south sides of a pit; the shoots of the preceding year are introduced under the glass and trained to a trellis, and forced while the suckers are left to grow upright in the open air.

SUBJECT. 8. *Cranberry.* — *Vaccinium*, L.; *Oxycoccus*, P. S. Octan. Monog. L. and *Ericae*, J. *Airelle*, Fr. and *Heidelbeere*, Ger.

4708. *The American cranberry* (*Oxycoccus macrocarpus*, P. S.) (*Hort. Kew.* ii. t. 7.) is a native of North America, and by the ingenuity of Sir Joseph Banks, it may be said to be now added to our cultivated fruits. The plant was known to Miller, who, of the cranberry tribe, in general, observes, "they can only be cultivated for curiosity in gardens, for they will not thrive much, nor produce fruit out of their native swamps and bogs." A very interesting account of the mode adopted by the illustrious horticulturist above mentioned is given by himself in the *Hort. Trans.* i. 71. and of the produce, which was large and uniform. In one year, viz. 1813, from three hundred and twenty-six square feet, or a bed about eighteen feet square, three and a half Winchester bushels of

berries were produced, which, at five bottles to the gallon, gives one hundred and forty bottles, each sufficient for one cranberry-pie, from two and a half square feet.

4709. *Culture in moist soil.* "Wherever there is a pond," Neill observes, "the margin may, at a trifling expense, be fitted for the culture of this plant, and it will continue productive for many years. All that is necessary is to drive in a few stakes, two or three feet within the margin of the pond, and to place some old boards within these, so as to prevent the soil of the cranberry-bed from falling into the water; then to lay a parcel of small stones or rubbish in the bottom, and over it peat or bog-earth, to the depth of about three inches above, and seven inches below the usual surface of the water. In such a situation the plants grow readily; and if a few be put in, they entirely cover the bed in the course of a year or two, by means of their long runners, which take root at different points. From a very small space a very large quantity of cranberries may be gathered; and they prove a remarkably regular crop, scarcely affected by the state of the weather, and not subject to the attacks of insects." The cranberry will also succeed when planted as an edging to any pond, provided some bog-earth be placed for its roots to run in; or if a bed of bog-earth be sunk in any shady situation, so as its surface may be a few inches below the general level, for the sake of retaining water, the plant will thrive well, and being regularly watered in the driest weather, produce abundant crops.

4710. *Culture on dry beds.* "The American cranberry," Salisbury observes (*Hort. Trans.* ii. 96.), "may be cultivated very successfully in situations not positively wet, if only planted in bog-earth, which retains moisture longer than any other soil; for a few plants, even in pots, which had stood some time neglected under a hedge, so that their branches were matted together, produced a plentiful crop." Hallet found the cranberry, and also the bilberry succeed perfectly in a dry bed of peat-earth, so that it may now be cultivated in any garden where that soil can be procured. (*Hort. Trans.* iv. 483.) Milne also found vigorous shoots and abundant crops produced on dry beds of peat-earth, even in the warm summer of 1822. He finds the American cranberry easier cultivated than the common; but some prefer the flavor of the latter. (*Hort. Trans.* v. 279.)

4711. *The common cranberry (Oxycoccus palustris, P. S.) (Eng. Bot. 319.)* may be subjected to the same treatment. "Great quantities of this berry are gathered in upland marshes and turf-bogs, both in England and Scotland. The berries are made into tarts, and have much the same flavor as the Russian imported cranberries, or those procured by cultivation." (Neill.) Twenty or thirty pounds worth are sold each market-day for five or six weeks together in the town of Langtown, on the borders of Cumberland. (*Light-foot.*)

SUBJECT. 9. *Strawberry.* — *Fragaria, L. Icos. Polyg. L. and Rosaceæ, J. Fraisier, Fr.; Erdbeerpflanze, Ger.; and Pianta di fragola, Ital.*

4712. *The strawberry* is a small creeping plant, with a perennial root, and, in general, ternate leaves. There are numerous sorts by some botanists distinguished as species, by others considered as only varieties. Knight (*Hort. Trans.* vol. iii. 207.) considers the *grandiflora* or pine, the *Chiloensis* or Chili, and the *Virginiana* or common scarlet, (the first supposed to be a native of Surinam, the second of Chili, and the third of Virginia,) to be varieties only of one species; as all may be made to breed together indiscriminately. The fruit has received its name from the ancient practice of laying straw between the rows, which keeps the ground moist and the fruit clean. They are natives of temperate or cold climates, as of Europe and America. The fruit, though termed a berry, is, in correct botanical language, a fleshy receptacle, studded with seeds.

4713. *Use.* The fruit is fragrant (whence *fragaria*), delicious, and universally esteemed. It consists almost entirely of matter soluble in the stomach, and neither there nor when laid in heaps and left to rot, does it undergo the acetous fermentation. Hence it is very nourishing, and may be safely eaten by gouty and rheumatic persons. "In addition to its grateful flavor, the subacid juice has a cooling quality, particularly acceptable in summer. Eaten either alone, or with sugar and cream, there are few constitutions with which strawberries, even when taken in large quantities, are found to disagree. Further, they have properties which render them, in most conditions of the animal frame, positively salutary; and physicians concur in placing them in their small catalogue of pleasant remedies. They dissolve the tartareous incrustations of the teeth. They promote perspiration. Persons afflicted with the gout have found relief from using them very largely; so have patients in cases of the stone; and Hoffman states, that he has known consumptive people cured by them. The bark of the root is astringent." (*Abercrombie.*)

4714. *The species and varieties are —*

The wood-strawberry (*F. vesca*) (*Eng. Bot. 1524*); with oval serrated leaves; the fruit round and small, red, white, and green. A native of Britain.

The scarlet (*F. virginiana*) (*Duh. arb. 1. t. 5*); with leaves like the preceding; the fruit roundish and scarlet-colored. A native of Virginia. Varieties. Early scarlet, Wilmot's late, common late, Wilmot's cockscomb scarlet. (*Hort. Trans.* v. 262.)

The roseberry (*F. virg. var.*) (*Hort. Trans.* ii. pl. 27.); an Aberdeen seedling, introduced in 1810. The plants have few roundish leaves; larger fruit than the scarlet, and are very prolific. Continues bearing till August.

The Downton (*F. virg. var.*) (*Hort. Trans.* ii. pl. 15.) The fruit is large, irregular, and cockscomb-like; leaves large; plant hardy and prolific.

The Carolina (*F. carolinensis*); red, from North America. Bostock.

The musky or hautboy (*F. elatior*) (*Eng. Bot. 2177*); with oval rough javelin-edged leaves; the fruit large, of a pale red color. A native of Britain.

The Chili (*F. Chiloensis*) (*Duh. arb. 1. t. 5*); with large, oval, thick, hairy leaves and large flowers; the fruit large and very firm. A native of South America. Keen's imperial, or new Chili (*F. Chil. var.*) (*Hort. Trans.* ii. pl. 7.); a large

showy fruit. Keen's seedling. (*Hort. Trans.* v. pl. 12.)

The pine (*F. grandiflora*) (*Miller, icon. 2. t. 288*); the leaves small and delicate; there are two sorts, the red and the white, or greenish-tinted, of this most rich-flavored fruit. South America. Mathven castle. Princess Charlotte.

The alpine or prolific (*F. collina*); which commonly lasts from June till November, and in a mild season, till near Christmas; two sorts of the fruit, the red and the white. Alps of Europe.

The one-leaved (*F. monophylla*) (*Bot. Mag. 63*); the pulp of the fruit pink-colored. South America.

4715. *Modes of propagation.* "The plants multiply spontaneously every summer, as well by suckers from the parent stem as by the numerous runners; all of which, rooting and forming a plant at every joint, require only removal to a bed where there is room for them to flourish. Each of these separately

planted, bears a fine fruit the following season, and will bear in full perfection the second summer. A plantation of the alpine yields fruit the same year that it is made. The woods and the alpine come regularly from seed, and bring a finer fruit than from offsets. The other species are uniformly propagated by offsets, except the intention be to try for new varieties." Knight, in making experiments, with a view of ascertaining whether most of the sorts would not breed together indiscriminately, raised above four hundred varieties, "some very bad, but the greater part tolerably good, and a few very excellent." The fruit of above a dozen sorts was sent to the Horticultural Society in August, 1818, and found of various degrees of excellence. The seeds, if sown immediately after being gathered, will produce plants which will come into bearing the following year.

4716. *Soil and site.* Neill says, "Strawberries are generally placed in a compartment of the garden by themselves, and it should be one which is freely exposed to sun and air. They are sometimes, however, planted in single rows, as edgings to borders, and in this way they often produce great crops. In either case care must be taken to replant them every fourth or fifth year at the farthest. The alpine and wood species may be placed in situations rather cool and shady; perhaps as an edging in the shrubbery. In such places they produce their fruit perfectly well, and late in the season, which is desirable."

4717. *General culture.* The following original and excellent instructions for cultivating the strawberry, are given by Keen, of Isleworth; a most successful grower of this fruit. He says, "I will commence with a general detail of my practice: this may be considered as applicable to all the varieties of the strawberry; and afterwards, in noticing each kind that I cultivate, I will specify such peculiarities of treatment as are exclusively applicable to each."

4718. *In preparing the soil for strawberries,* "if it be new, and, as is frequently the case, very stiff, it should be trenched; but if the bottom spit of soil, as sometimes happens, be of an inferior quality, I then recommended only a simple digging, placing dung at the bottom, underneath the mould so dug; on the contrary, should the land have been kept in a high state of cultivation, or be good to the full depth, it will be advisable for the bottom spit to be brought up to the top, placing the dung between the two spits. The best way to obtain new plants is, by planting out runners in a nursery, for the express purpose, in the previous season: for it is a very bad plan to supply a new plantation from old plants. With respect to the time of planting, I have always found the month of March better than any other. Sometimes, when my crops have failed, I have had runners planted in the autumn, for the following year, but these have always disappointed my expectations. I plant them in beds, containing three or four rows, and the plants, in each row, at a certain distance from each other, leaving an alley between each bed, the distance of the rows and of the plants in the rows, as well as the width of the alleys, depending on the kind of strawberry planted. The width of the alleys, as it will afterwards be stated, may appear considerable; but, I am satisfied, that allowing this space for the workmen to stand on, when they water the plants, or gather the fruit, is beneficial, because I have observed in other persons' grounds, where less space is allotted for this purpose, that great damage is done to the plants and fruit by the trampling of the people."

4719. *General culture.* "After the beds are planted, I always keep them as clear of weeds as possible, and on no account allow any crop to be planted between the rows. Upon the growing of the runners, I have them cut when necessary: this is usually three times in each season. In the autumn, I always have the rows dug between; for I find it refreshes the plants materially; and I recommend to those persons to whom it may be convenient, to scatter in the spring, very lightly, some loose straw or long dung, between the rows. It serves to keep the ground moist, enriches the strawberry, and forms a clean bed for the trusses of fruit to lie upon; and thus, by a little extra trouble and cost, a more abundant crop may be obtained. A short time before the fruit ripens, I always cut off the runners, to strengthen the root; and after the fruit is gathered, I have what fresh runners have been made taken off with a reaping-hook, together with the outside leaves around the main plant, after which I rake the beds, then hoe them, and rake them again. In the autumn, unless the plants appear very strong, I have some dung dug in between the rows, but if they are very luxuriant the dung is not required; for in some rich soils it would cause the plants to turn nearly all to leaf. I also have to remark, that the dung used for manure should not be too far spent; fresh dung from the stable-door is preferable to spit-dung, which many persons are so fond of. The duration of the bed must be determined by the produce of the plants, which varies much according to the different sorts; it also varies with the same sort in different soils, so that the precise time of the renewal of the beds must be regulated by the observation of the gardener, in each particular case."

4720. *Sorts grown by Keen.* The pine Keen grows in a light loam, "though no other kind of strawberry will bear a strong loam better than this. It is likewise to be noticed, that this is of all others the most difficult strawberry from which to procure a good crop. Particular care must be taken that they are planted in open ground: for in small gardens they grow very strong, but seldom bear fruit, in consequence of being so much shaded by standard trees; and I have observed the shade of the walnut-tree to be much more injurious to these than to others: for under it they seldom bear at all, but run entirely to leaf. In planting the beds of pines, I keep the rows two feet apart, and put the plants eighteen inches from each other in the row, leaving alleys of three feet wide between each bed: these large distances I find necessary, for the trusses of fruit in my garden-ground are frequently a foot long. The duration of this strawberry, with me, is three years: the first year it bears the best, the second year the crop is very good, and the third year it is less."

4721. *The imperial strawberry,* "which was raised by myself from seed, may be treated in a similar way, with respect to planting, distance, &c. as the pine; but I have to remark, that it requires rather a lighter and richer soil, and is not so liable to run to leaf, when planted under trees."

4722. *The scarlet strawberry* must be treated also like the pine. "With respect to distance for planting the beds of scarlets, I put each row twenty-one inches apart, and each plant eighteen inches distant in the row, and make the alleys two feet six inches wide. The duration of this strawberry, with me, seldom exceeds three years."

4723. *The haultboy* "I have always found to thrive best in a light soil: and it must be well supplied with dung, for excess of manure does not drive it into leaf like the pine-strawberry. In planting the beds, each row must be two feet apart, and from plant to plant, in the rows, must be eighteen inches, leaving the alleys between the beds three feet wide. There are many different sorts of haultboys: one has the male and female organs in the same blossom, and bears very freely; but that which I most approve, is the one which contains the male organs in one blossom, and the female in another: this bears fruit of the finest color, and of far superior flavor. In selecting these plants, care must be taken that there are not too many of the male plants among them; for as these bear no fruit, they are apt to make more runners than the females. I consider one male to ten females the proper proportion for an abundant crop. I

learned the necessity of mixing the male plants with the others, by experience, in 1809; I had, before that period, selected female plants only for my beds, and was entirely disappointed in my hopes of a crop. In that year, suspecting my error, I obtained some male blossoms, which I placed in a bottle on the bed of female hautboys. In a few days, I perceived the fruit near the bottle to swell; on this observation, I procured more male blossoms, and in like manner placed them in bottles, in different parts of the beds, removing the bottles to fresh places every morning, and by this means obtained a moderate crop where I had gathered no fruit the preceding year. The duration of the hautboy, with me, seldom exceeds three years."

4724. *The wood-strawberry* is best raised from seed, "which I obtain from fruit just gathered, sowing it immediately in a bed of rich earth. When the plants are of a proper size, I transplant them into other beds, where I let them continue till the March following. They are then planted in rather a moist soil, in beds, as the others, each row being two feet apart, and the plants in each row eighteen inches distant, the alley between each bed being three feet wide: in this way I produce abundant crops of very fine fruit. I have propagated this strawberry from runners, but never with such good success as from seeds, particularly if the runners were taken from old roots. The duration of this strawberry, with me, seldom exceeds two years."

4725. *The alpine strawberry* must always be raised from seed, which should be sown in a bed of rich earth, in the spring. "When the plants are of a proper size, which will be in July or August, I plant them in rows at the back of hedges or walls, in a rich, or in a very moist soil: the rows should be two feet apart, and the distance, from plant to plant, in the rows, twelve inches. My alpine, this year, thus managed, are bearing most abundantly, so much so, that in gathering them there is not room for the women to set their feet, without destroying many. The alpine differs from all other strawberries in quickness of bearing; for no other sort, sown in the spring of the year, will produce fruit, under two years, whereas this yields a crop at the end of one year. Its duration, with me, seldom exceeds two years, and frequently it lasts only one year." (*Hort. Trans.* ii.) Williams considers that the fruit of plants raised from seed, comes in very well as a late autumn crop, but is certainly inferior in flavor to that produced from transplanted runners. (*Hort. Trans.* i. 247.)

4726. *The Rev. T. Garnier*, a successful cultivator of strawberries, never suffers any of the varieties to remain in the ground more than one year. "Early in August, or as soon as the gatherings are over, I destroy all my beds, and proceed immediately to trench, form, and manure them in the manner before directed, to receive the plants for the crop of the ensuing year, taking care to select for that purpose the strongest and best-rooted runners from the old rejected plants. If at this season the weather should be particularly hot, and the surface of the ground much parched, I defer the operation of preparing my beds and planting them till the ground is moistened by rain. Such is the simple mode of treatment which I have adopted for three successive years, and I have invariably obtained upon the same spot, a great produce of beautiful fruit, superior to that of every other garden in the neighborhood. Depth of soil I have found absolutely necessary for the growth and production of fine strawberries, and when this is not to be obtained, it is useless, in my opinion, to plant many of the best varieties. It is not generally known, but I have ascertained the fact, that most strawberries generate roots, and strike them into the ground, nearly two feet deep in the course of one season. The pine and roseberry succeed better than any other in stiff and shallow soils, but they should always be planted in an open situation, and not, as is too commonly the practice, in shady and neglected parts of the garden" (*Hort. Trans.* iv. 480.)

4727. *Young* justly blames gardeners for cutting over the leaves of strawberries after they have borne a crop, thereby preventing proper buds being formed for next year, and also depriving the roots of the plants of their natural protection from the frost. He is also adverse to the practice of digging between the rows in winter, which, he says, cuts off the fibrous roots, and prevents the plants from setting out in spring with that vigor which they otherwise would do. Instead of supplying manure in this way, he recommends the appropriation of liquid manure; or what is better, never letting a crop remain above three years on the same piece of ground. (*Calcd. Hort. Soc. Mem.* iii. 291.)

4728. *Brick-beds for strawberries.* These were observed in a small garden near Chatham, and are thus described: "The beds (*fig.* 497. *a*) were upon flat ground, each about three feet wide, and between them were trenches about nine inches wide, and four-inch walls of brick on each side of the trenches (*b*), to keep up the earth on the sides of the beds. These trenches were about the depth of two or three courses of bricks laid flat, without mortar, and were intended for the purpose of holding water, which was supplied from a pump whenever the ground was dry, while the plants were in fruit. By this

method, a much greater crop of fruit was obtained, and the plants continued bearing much longer than in beds where there were no trenches for water. In Devonshire, strawberry-beds are constructed against the side of a hill or bank, by building up beds in steps, with rough granite at the front, to keep up the earth, each step being about two feet high and three feet wide. These steps were filled with good loam, and the surface of each was covered with rough pieces of granite bedded into the loam, leaving openings between the stones, just sufficient to put in the plants. The surface being covered with granite, kept the ground longer in a moist state, and the fruit always clean. "I should expect," observes the writer, "that chippings of stone, such as may be had from the masons in London, might answer the same purpose. I have found a great advantage in keeping the fruit clean, by laying a row of common bricks on each side of the rows of strawberry-plants; I tried plain tiles, but found bricks answer better, as the tiles are apt to be broken in gathering the fruit, and will not do to use a second time." (*Atkinson, in Hort. Trans.* v. 191.)

4729. *Taking the crop.* The fruit ripens from June to August and September; but the main crop is usually over in July. Gather when the weather is dry, and the same day that the fruit is to be sent to table, otherwise it will soon lose its flavor. Pinch off the calyx and a quarter of an inch of the peduncle, along with the berry.

4730. To have a regular succession of strawberries throughout the autumnal months. This is commonly done by means of the wood and alpine species, and their varieties. Garnier thinks it may be accomplished by late planting; for example, of Wilmot's late scarlet, or the common scarlet about May. He has planted runners of the roseberry on the 1st of July, and gathered fruit on the 7th of September. (*Hort. Trans.* iv. 482.) Williams cultivates the alpine for this purpose. "Early in the month of May, when they are in flower, he cuts away all the blossoms, preserving the leaves uninjured; this is again repeated at the end of the month. Towards the middle or end of June more blossoms appear, and the plants afford flowers and fruit, all the latter part of the summer, and till cut off by the autumnal frosts. If the first blossoms were not removed, the principal crop of alpine would be ripe at the time the larger strawberries are in season, and consequently of little worth; but by this mode of culture, they come into bearing in the latter part of the summer, just at the time the other kinds are over." (*Hort. Trans.* v. 247.)

4731. For forcing the strawberry, see Chap. VII. Sect. VIII.

SECT. IV. Nuts.

4732. Among nuts the most useful in this country is the walnut, both for the dessert and pickling; the filbert is also a very useful fruit; chestnuts are wholesome and nutritive, and form, in Spain and Italy, an important article of human food.

SUBJECT. 1. *Walnut*. — *Juglans regia*, L. (*Lam. ill.* 781.) *Monac. Polyan.* L. and *Terebinthaceæ*, J. Noyer, Fr.; *Walnussbaum*, Ger.; and *Noci*, Ital.

4733. The walnut is a large and lofty tree, with spreading boughs, and pinnate leaves, having a very strong aromatic odor. The male flowers come in subterminating aments; the females scattered two or three together in close sessile buds on the young wood near the extremities of the branches. The fruit is an ovate, coriaceous, smooth drupe, enclosing an irregularly grooved nut, which contains a four-lobed oily eatable kernel, with an irregular knobbed surface, and covered with a yellow skin. The flowers are produced in the end of April and beginning of May, and the fruit ripens in September and October. It is a native of Persia and the south side of Caucasus; but it is supposed to have been introduced here from France, and called *gaul-nut*, before 1562.

4734. *Use*. The kernel, when ripe, is in esteem at the dessert; and the fruit whole, in a green state, before the stone hardens, is much used for pickling. An oil which supplies the place of that of almonds, is expressed from the kernel in France. In Spain they strew the gratings of old and hard nuts, first peeled, into their tarts and other meats. The leaves strewed on the ground and left there annoy worms; or macerated in warm water, afford a liquor which, from its bitterness, may effect their death. The unripe fruit is used in medicine for the same purpose. Pliny says, "the more walnuts one eats, with the more ease will he drive worms out of his stomach." The timber is used in this country for gun-stocks, being lighter in proportion to its strength and elasticity than any other. It is almost exclusively used in cabinet-work in most parts of the continent. The young timber is held to make the finest-colored work, but the old to be finer variegated for ornament.

4735. *Varieties*. Those commonly cultivated for their fruits are —

The round early oval
Double large French
Tender-shelled, and thick-shelled

Highflyer of Thetford, the best variety known.
(*H. Trans.* iv. 517.)

4736. *Propagation*. It has generally been propagated from the nut; and this mode is recommended by Miller and Forsyth; probably from their not having known that the tree may be continued by inoculation as practised successfully by Knight. Inarching this tree was long ago recommended by Boucher, who says, "he found the fruit in this way produced in one third of the time necessary for plants raised from the nut."

4737. *Knight*, "having planted, in the spring of 1799, some walnut-trees of two years old in garden-pots, raised them up to the bearing branches of an old walnut-tree, and grafted them, by approach, with parts of the bearing branches of the old tree. An union took place during the summer, and in the autumn the grafts were detached from the parent stock. The plants thus obtained were planted in a nursery, and, without any peculiar care or management, produced both male and female blossoms in the third succeeding spring, and have since afforded blossoms every season." (*Hort. Trans.* i. 61.) After numerous trials, he also succeeded in propagating the walnut-tree from budding. "The buds of trees," he observes, "of almost every species, succeed with most certainty when inserted in the shoots of the same year's growth; but the walnut-tree appears to afford an exception; possibly, in some measure, because its buds contain within themselves, in the spring, all the leaves which the tree bears in the following summer: whence its annual shoots wholly cease to elongate soon after its buds unfold; all its buds of each season are also, consequently, very nearly of the same age: and long before any have acquired the proper degree of maturity for being removed, the annual branches have ceased to grow longer, or to produce new foliage. To obviate the disadvantages arising from the preceding circumstances, I adopted means of retarding the period of the vegetation of the stocks, comparatively with that of the bearing tree; and by these means I became partially successful. There are at the base of the annual shoots of the walnut and other trees, where those join the year-old wood, many minute buds, which are almost concealed in the bark, and which rarely or never vegetate, but in the event of the destruction of the large prominent buds which occupy the middle and opposite end of the annual wood. By inserting in each stock one of these minute buds, and one of the large and prominent kind, I had the pleasure to find that the minute buds took freely, whilst the large all failed without a single exception. This experiment was repeated in the summer of 1815, upon two yearling stocks which grew in pots, and had been placed, during the spring and early part of the summer, in a shady situation under a north wall; whence they were removed late in July to a forcing-house, and instantly budded. These being suffered to remain in the house during the following summer, produced from the small buds, shoots nearly three feet long, terminating in large and perfect female blossoms, which necessarily proved abortive, as no male blossoms were procurable at the early period in which the female blossoms appeared: but the early formation of such blossoms sufficiently proves that the habits of a bearing branch of the walnut-tree may be transferred to a young tree by budding, as well as by grafting by approach. The most eligible situation for the insertion of buds of this species of tree (and probably of others of similar habits) is near the summit of the wood of the preceding year, and of course, very near the base of the annual shoot; and if buds of

the small kind above mentioned be skilfully inserted in such parts of branches of rapid growth, they will be found to succeed with nearly as much certainty as those of other fruit-trees, provided such buds be in a more mature state than those of the stocks into which they are inserted."

4738. *Carlisle* (*Hort. Trans.* ii.) mentions the case of a walnut-tree raised from the nut in the usual way, on a light soil, on a sandy sub-soil, and in a warm sheltered situation, which produced fruit in six years; but the usual period is eighteen or twenty.

4739. *Abercrombie* says, the walnut-tree is propagated, in general, by sowing well ripened nuts of the finest varieties: but as seedlings are apt to vary, new plants are occasionally raised by layers and inarching, to continue particular sorts permanent. The nuts may be sown in autumn or spring, in drills, nine to twelve inches apart, and two or three inches deep; place the nuts two inches asunder, and having earthed them in, smooth the surface. They will come up in the spring. When of one year's growth, set out the plants in nursery rows, a foot asunder by six inches in the rows, to remain two years, then to be transplanted (doubling the distance) into other nursery lines. Train each with a single stem of six or seven feet high: then to be permitted to branch out above, and form a spreading head. Layers may be made, in autumn or spring, of young shoots produced near the ground from proper stools formed for that purpose: they will be rooted in one season, to plant off in nursery rows for training as above. Inarching may be performed in February or March upon seedling walnut-stocks, advanced in proper stems.

4740. *Soil and site.* The walnut-tree will succeed in any common fertile soil, a light or a clayey loam, so as the sub-soil be dry, and the site a little sheltered; but it thrives best where there is a good depth of loam mixed with sand or gravel rather than clay. As this tree is long before it bears fruit, there is a particular inducement for procuring plants from the nursery, either inarched, budded, or in as advanced a stage as it will be safe to remove them at. This may be when they are from eight to twelve years old, according as they may have been prepared by repeated transplantations. Walnut-trees may be planted in orchards or small paddocks, in a row towards the boundaries; or in parallel double rows in a quincunx order, in extensive grounds, but detached from fruit-trees of more contracted growth. The line of walnut-trees, when fully grown, will serve as a screen to the fruit-trees occupying the interior ground. The plants should stand at twenty-five and the trees to fifty feet distance.

4741. *Mode of bearing.* On the extremities of the preceding year's shoots.

4742. *Pruning.* Walnut-trees, when finally planted, may be permitted to branch out in their natural order, with the exception of a little occasional pruning, to regulate any casual disorderly growth, to reduce over-extending branches, and to prune up the low stragglers.

4743. *Ringing to induce bearing,* is practised by the Baron de Tschoudi, near Metz, in Lorraine. A zone of bark two inches broad is taken out, and the part plastered over with cow-dung and loam; the consequence is that the trees prove more prolific, and the fruit ripens sooner.

4744. *Taking the crop.* Walnuts should be taken for pickling while the internal parts remain tender and fleshy, which may be ascertained by probing them with a pin or needle. The nuts are ripe in September and October, and should then be gathered so as not to injure the tree, and housed in the proper manner for winter use.

SUBJECT. 2. *Chestnut.* — *Fagus Castanea*, L.; *Castanea Vesca*, W. (*Eng. Bot.* 886.)
Monac. Poly. L. and *Amentaceæ*, J. *Châtaigne*, Fr.; *Castanienbaum*, Ger.; and *Castagno*, Ital.

4745. *The chestnut* is a large tree, spreading its branches finely on every side where it has room, but, planted closely, will shoot up straight to a great height. The leaves are lanceolate, serrated, and very large. The aments, or catkins, of male flowers are pendulous at the ends of the branches; very long, resembling those of the walnut. They have a strong spermiatic smell; the flowers are collected in remote little balls, and are sessile. The proportion of male flowers to the females is prodigious. The calyx of the female flowers becomes an echinate capsule or four valves, of a silky smoothness in the inside, and containing two or three nuts or one only. It flowers in May, and ripens its fruit in October. It is supposed to have been originally brought from Sardinia to Italy by Tib. Cæsar. It is so common as to be considered a native in France and Italy; and some consider it as naturalised in England, though it is not likely to propagate itself in this country. Some of the oldest trees in the world are of this species; as that mentioned by Brydone on Etna, and the great tree at Tortworth in Gloucestershire.

4746. *Use.* The fruit is a desirable nut for autumn and winter, and is eaten roasted, with salt, and sometimes raw. Abroad, it is not only boiled and roasted, but puddings, cakes, and bread are made of it. "Chestnuts stewed with cream," according to Phillips (*Pomarium Brit.* 95.), "make a much admired dish, and many families prefer them to all other stuffings for turkeys." He says, "I have had them stewed and brought to table with salt fish, when they have been much admired." The timber was formerly in very general use in house-carpentry, though some, with every appearance of reason, consider what is generally called old chestnut as old oak.

4747. *Varieties.* There are none of any note. Some varieties ripen their fruit a few days earlier than others, but none of these have been fixed on and perpetuated by the nurserymen so as to be rendered available by purchasers.

4748. *Propagation.* Miller and most gardeners recommend propagation from nuts; but, for fruit, the Devonshire practice of grafting is decidedly preferable. Sir Joseph Banks says, "the nurserymen there deal in grafted chestnut-trees;" and we may add, that they are now to be had in the London nurseries. (*Hort. Trans.* i. 62.) Knight says, "The Spanish chestnut succeeds readily when grafted in almost any of the usual ways, and when the grafts are taken from bearing branches, the young trees afford blossoms in the succeeding year; and I am much inclined to think, from experiments I have made on this tree, that by selecting those varieties which ripen their fruit early in the autumn, and by propagating with grafts or buds from young and vigorous trees of that kind, which have just attained the age necessary to enable them to bear fruit, it might be cultivated with much advantage in this country, both for its fruit and timber." (*Hort. Trans.* i. 62.)

4749. *Soil and site.* The tree prefers a sandy loam with a dry bottom; but will grow in any soil on a dry sub-soil. Distribute the plants towards the northern boundary of orchards; and in larger groups, over any vacant tracts in extensive pleasure-grounds or parks, and to form spacious avenues, or a row along any out-boundary. A great number should not be placed close to a residence, as the smell of the flowers is offensive. Plant them at not less than thirty feet, and thence to fifty feet distance.

4750. *Subsequent culture.* "Permit the trees to branch out freely above, mostly in their natural order, to advance in large regular heads. Give occasional pruning only to very irregular and cross branches, and low stragglers. After they have attained some tolerably branchy growth, they will come into bearing in moderate plenty; and when they have expanded into large full heads, they may be expected to yield considerable quantities of nuts."

4751. *Taking the crop.* "The nuts ripen from the end of September to the end of October. When the outer capsule containing the nuts begins to divide, and the nuts appear of a brown color, and some fall promiscuously from the tree, their full maturity is indicated. They may be gathered by hand, or beat down by long poles. Selecting the finest and best-ripened, clear them from the husks; let them be well dried, and deposited in the fruitery, upon shelves, &c.; and some packed in layers of very dry fine sand for longer keeping." (*Abercrombie.*)

SUBJECT. 3. *Filbert.* — *Corylus Avellana*, L. (*Eng. Bot.* 723.) *Monœc. Poly.* L. and *Amentaceæ* J. *Noisette*, Fr.; *Nussbaum*, Ger.; and *Avellano*, Ital.

4752. *The common hazel-nut*, or the filbert in its wild state, is a large-sized shrub, with an ash-colored bark, and alternate roundish cordate leaves. The male catkins appear on the preceding year's shoots in autumn, and wait for the expansion of the female gems in the spring. It is a native of Britain, very common in most woods, and extensively cultivated about Maidstone, in Kent.

4753. *Use.* As a table nut it is in universal esteem; and the wood and twigs of the wild plants are used for sticking peas, forming pegs, number-sticks, staking green-house plants and raspberries, and many other similar purposes in gardening.

4754. *Varieties.* These are—

The common hazel nut
The red-kernelled (*Lang P. t.* liv. 2.)
The white-kernelled filbert (*Lang. P. t.* liv. 1.)

The red-kernelled filbert
The great cobnut (*Hort. P. L.* t. xlix.)
The large long nut
The Barcelona, or Spanish

The Constantinople, or dwarf Byzantine
The cossford (*Hort. Trans.* ii. 405.)
The frizzled, or Norfolk variety. (*Hort. Trans.* v. 263.)

4755. *Estimate of sorts.* The common wood-nut, the least desirable for horticultural plantations, may be admitted for variety. The filbert merits culture in a large proportion, and its returns are very profitable for sale. The red-filbert is accounted to have a finer flavor than the white. The cob-nut is large, with a thick shell, but the kernel is considerable in size, and sweet. The Barcelona, a good large nut, with a thin shell, is well known, great quantities being imported as well as grown here. The long native nut seldom kernels well. The cossford is very sweet, kernels well, and the tree is a great bearer.

4756. *Soil and site.* Abercrombie says, "A cool, dry, poorish soil is to be chosen for filbert and nut trees in general; for example, a sandy loam, mixed with minute shatter stones or grit, and with a low proportion of vegetable or animal remains; for the plants fruit best when but moderately strong. About Maidstone, according to the Rev. W. Williamson, they prefer a hazel loam of some depth, on a dry sub-soil, which they dress every year, as the filbert requires a considerable quantity of manure. They are generally planted in the orchard, or in the slips which surround the kitchen-garden."

4757. *Propagation.* "All the sorts can be propagated by grafting, by layers, by suckers, and by sowing the nuts. The most advisable methods, because they are certain to keep the respective variety permanent, are, either by grafting them in February or March upon seedling or sucker stocks of the filbert or hazel; or by layers of the young wood in the spring. Sow the nuts in October or November, or in the spring, in a bed of light earth, covering them about two inches. The greater part will germinate in spring, and when the plants are one or two years old plant them out in nursery lines in autumn or spring. Train a principal supply in standards, half-standards, and dwarf standards, each with a single clean stem, from six feet high down to twelve inches." (*Abercrombie.*) About Maidstone, according to Williamson, they are almost universally propagated by suckers.

4758. *Mode of bearing.* All the species bear principally upon the sides and ends of the upper young branches; and from small shoots, which proceed from the bases of side branches cut off the preceding year.

4759. *Final planting.* "The season for planting all the sorts is autumn or spring, or any interval in mild weather from October till the beginning of March. Allot detached standards, not less than ten, and thence to twenty feet distance, to have room to branch out in full heads. In the filbert-grounds about Maidstone it is usual to plant hops, standard apples, and cherries among the filberts. When the filberts come into a bearing state the hops are destroyed, and the fruit trees only suffered to remain. The ground is then planted with gooseberries, currants, &c. and herbaceous vegetables." (*Hort. Trans.* iv. 152.)

4760. *Pruning.* "In the filbert-orchards, about Maidstone in Kent, it is a prevailing practice to train the trees with short stems, like a gooseberry-bush, but with the heads in the shape of a punch-bowl, and exceeding thin of wood, and to prune them with exact attention to the mode of bearing. The filbert is there propagated by suckers, and Williamson advises to plant them where they are to remain; to suffer them to grow without restraint for three or four years; and then to cut them down within a few inches of the ground. They will push five or six strong shoots which, the second year after cutting down, are to be shortened one third. Then place a small hoop within the branches, and fasten the shoots to it at equal distances. In the third year, a shoot will spring from each bud; these must be suffered to grow till the following autumn or spring of the fourth year, when they are to be cut off nearly close to the original stem, and the leading shoot of the last year shortened two thirds. In the fifth year, several small shoots will arise from the bases of the side branches, which were cut off the preceding year; from these the fruit is to be expected, and the future object of the pruner must be directed to produce an annual supply of these by cutting out all that have borne fruit. The leading shoot is every year to be shortened two thirds or more, and the whole height of the branches must not be suffered to exceed six feet. Every shoot that is left to produce fruit should also be tipped, which prevents the tree from being exhausted in making wood at the end of the branch. Observe, in pruning early in spring, to have a due supply of male blossoms and to eradicate all suckers." Such is the Maidstone practice, which "has been long celebrated;" by which 30 cwt. of nuts per acre have been grown on particular grounds, in particular years; but 20 cwt. is considered a large crop, and rather more than half that quantity the usual one, with a total failure three years out of five, so that the average produce is not more than 5 cwt. per acre. Williamson thinks the failure, happening so often, may be owing to the excessive productiveness of the successful years owing to the mode of pruning, by which "the whole nourishment of the tree is expended in the production of fruit." He recommends leaving the trees rather more in a state of nature, and, from experiments in his own garden, thinks a regular crop in succession will thereby be obtained. (*Hort. Trans.* iv. 154.)

4761. *Insects.* The leaves are little troubled with vermin of any sort; but the eggs of the weevil (*Curculio nucum*) (fig. 498. a) and *C. pyri* (b) are deposited in the germen, and nourished on the kernel, which they effectually destroy. The only way of lessening this evil is by taking care to de-

stroy all the nuts so infested, in order that the larvæ may never attain to the fly state.

4762. *The Rev. G. Swayne* having had a plantation of filberts, which for the 20 years of their existence had produced very little fruit, began to suspect a want of male blossoms. He therefore selected a number of catkins from the common hazel, and suspended them over the scarlet blossom of his filberts; and the result was, that the first year he had more fruit than he had during the 20 preceding years. To prove that it was owing to the farina of the male blossoms, he tried some with and some without this assistance, and found the fruit produced as the male blossoms applied. He taught this mode to a neighboring farmer's wife who had a row of barren trees, and she was "much delighted" with the plan; put it in execution the next day, and the same season sent her instructor 6 lbs. of very fine filberts from four old stunted trees that had not borne one for many years. (*Hort. Trans.* v. 316.)

4763. *Taking the crop.* "The maturity of the fruit is indicated by the cup turning brown, and by the nuts, which have also become brown, readily quitting the husk. House a quantity for keeping; gather them in bunches as they grow. If a portion, after being properly dried, be laid in boxes, and covered with dry sand to exclude the air, it will tend to preserve the kernels from shrinking; and they will thus keep well for a month or two." Braddick's mode of keeping nuts two years by closing them up airtight in emptied butter-firkins has been already mentioned. (2308.)

SECT. V. Native, or neglected Fruits, deserving Cultivation.

4764. Though some of our native fruits recommend themselves by their already known utility, as the cranberry; yet others, as the sorb, haw, &c. are only mentioned with a view of directing scientific horticulturists of leisure and means, to try what can be done in improving them. We shall enumerate them in the order of stone-fruits and berries.

4765. *The sloe* is the *Prunus spinosa*, L. (*Eng. Bot.* 842.) *Icos. Monog.* L. and *Rosaceæ*, J. Ripe, it makes an excellent preserve; unripe, the inspissated juice forms the German *acacia*, and affords an almost indelible ink used to mark linens. It is used in home-made wines, to communicate the color and roughness of red port; and the leaves are employed to adulterate the teas of China. Knight and others consider the sloe as the parent of the bullace (*P. insititia*), and all the varieties of the common plum (*P. domestica*). As a shrubby plant the sloe is most ornamental, blossoming before all others of the prunus tribe.

4766. *The bird-cherry* is the *Prunus padus*. (*Eng. Bot.* 1383.) The fruit is nauseous to most palates; but infused in gin or whiskey it greatly improves these spirits, and is only surpassed by an infusion of peach-leaves. A few trees therefore are desirable, especially in Scotland and Ireland.

4767. *The mountain-ash* is the *Sorbus Aucuparia*, L. *Pyrus Aucuparia*, E. B. (*Eng. Bot.* 337.) *Icos. Di-Pent.* L. and *Rosaceæ*, J. The berries are eaten in some parts of Scotland and Wales, and afford an agreeable fermented liquor, and, by distillation, a strong spirit. Grafted on the service-tree, as is frequently done in France, the fruit is said to become larger and more abundant. (*Neill, in Hort. Tour.* 364.)

4768. *The wild service* (*Pyrus torminalis*, W.) (*Eng. Bot.* 298.) (fig. 499.), *the bastard service* (*P. pinatifida*, E. B.) (*Eng. Bot.* 2331.) (fig. 500.), and *the whitebeam-tree* (*P. Aria*) (*Eng. Bot.* 1858.), afford agreeable mealy berries, with much less acid than those of the mountain-ash. These trees are most ornamental in shrubberies or on lawns; and the two last are not undeserving a place in orchards.

4769. *The tree-currant* (*Ribes spicatum*, L. (*Eng. Bot.* 1290.) *Pentand. Monog.* L. and *Cacti*, J.) affords a fruit somewhat smaller and more acid than the common red currant; but by crossing and cultivation might, no doubt, be greatly improved; and from its comparatively tree-like habits, might be a more convenient fruit-shrub in respect to crops below or around it.

4770. *The common bramble*, *Rubus fruticosus*, L. (*Eng. Bot.* 715.) *Icos. Polyg.* L. and *Rosaceæ*, J. The fruit is powerfully acid and astringent, forms agreeable pies and tarts, medicinal gargles, and may also be used raw. There are two single varieties, the white-fruited and smooth, and one with double blossoms.

4771. *The cloud-berry*, *Rubus Chamæmorus*, L. (*Eng. Bot.* 716.) (figs. 20. and 501.) "In Scotland," Neill observes, "the fruit is also called roebuck-berries or knot-berries, and they are perhaps the most grateful and useful kind of fruit gathered by the Scots Highlanders. On the sides and near the bases of the mountains it may be collected for several months in succession. It is not cultivated without difficulty, and it seldom yields its fruit in a garden." By raising from seed, and again from the seeds of plants so raised, and so on for six or eight generations, perhaps at the same time crossing the flowers with those of the bramble or raspberry, in all probability this plant might become a valuable accession to the kitchen-garden. Its berries are ripe in September. (See a curious paper in *Caled. Hort. Mem.* i. 383.) In Lapland and Sweden the fruit is much prized, and used for a great variety of purposes. Dr. Clarke, as we have seen (249.) found it medicinal. (*Scandinavia*, chap. xv.)

4772. *The dwarf crimson bramble* (*Rubus arcticus*) (Eng. Bot. 1585.) (fig. 502.) produces an excellent berry, found only on the highest and wildest mountains of Scotland. By successional sowing of the seeds on different levels, doubtless it might be brought down, step by step, to live and produce fruit on plains, and in appropriate parts of gardens.

4773. *The dewberry* (*Rubus cæsius*) (Eng. Bot. 826.) (fig. 503.), *the stone-bramble* (*Rubus saxatilis*) (Eng. Bot. 2233.) (fig. 504. a), and *the upright bramble* (*Rubus suberectus*) (Eng. Bot. 2572.) (fig. 504. b), afford agreeable acid and aromatic fruits, which come in late in the season, and merit attempts with a view to accommodating them to habits of cultivation. The same remarks will apply to a plant common in the woods of Russia and Poland, and which Dr. Clarke has figured, and named *Cripsia*; but which appears to be a species of *Rubus*, and probably a variety of *R. suberectus*.

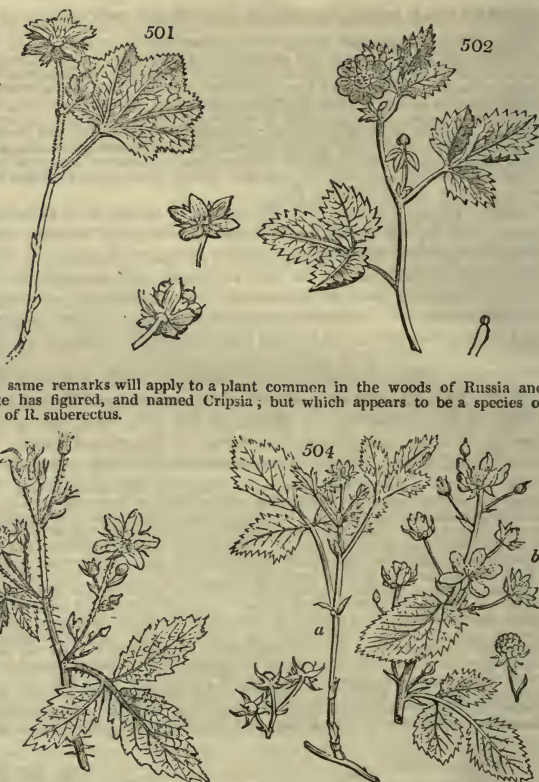

4774. *The snowberry* is the *Gaultheria serpyllifolia*, P. S.; *Vaccinium hispidum*, L.; and *Chioberis* of Salisbury. (Mich. Am. i. t. 23.) Decan. Monog. L. and *Ericaceæ*, J.

"At Shaw-hill, near Halifax, it produced fruit abundantly, planted under a north wall, shaded behind by high trees, in a border of sandy peat; and it succeeded pretty well in nearly a similar situation at Chapel Allerton, during the eighteen years of my residence at that place, often ripening its berries; but they being little esteemed, I only preserved a patch of it as a rare plant. The flavor of the fruit, however, is exceedingly agreeable to some persons, being strongly perfumed, like *eau de noyau*, or bitter almonds, and mixed with a pleasant acid. I now regret that I never tried the berries baked with sugar in a tart: if gathered before they are too soft, they may, no doubt, be preserved in bottles, like cranberries, and possibly prove a valuable addition to our winter fruits of that sort." (Salisbury, in Hort. Trans. vol. ii.)

4775. *The purple or common bilberry, blackberry, or whortleberry*, (*Vaccinium Myrtillus*, L.) (Eng. Bot. 456.) is another bog-plant common in Britain and the north of Europe. The berries are gathered in autumn for making tarts; in Devonshire they are eaten with clotted cream; in Poland they are ripe in July, and, being mixed with wood-strawberries, and eaten with new milk, are considered a great delicacy. In the Highlands of Scotland they are eaten with milk, and made into jellies. They may be successfully cultivated in a shady border of bog-earth.

4776. *The red bilberry, or crowberry*, *Vaccinium Vitis Idææ*, L. (Eng. Bot. 598.) The fruit is acid and somewhat bitter, but makes a very good rob or jelly, which in Sweden is eaten with all kinds of roast meat, and forms a sauce for venison, which is thought superior to currant jelly. In Wales we have experienced it to be an excellent addition to roast mutton. It may be cultivated in a moist shady border of bog-earth, like the common bilberry.

4777. *The broad-leaved whortleberry* (*Vaccinium amænum*, L.) (Bot. Rep. 138.) is cultivated at Enghien, in the Duc d'Arenberg's garden, and the fruit used in the same way as the cranberry. (Neill, in Hort. Tour, 322.)

CHAP. X.

Horticultural Catalogue. — Exotic Fruits.

4778. Among exotic fruits we comprehend such fruits as require the aid of artificial heat to bring them to perfection, and among these we have included the vine and the fig; for though these fruits ripen in the open air in very favorable situations and warm seasons, yet it is allowed on all hands, that in by far the greater number of situations and seasons, grapes and figs, grown in the open air, do not attain any thing like their proper size and flavor. Exotic fruits may be arranged as follows: —

4779. Those in general cultivation; as the pine, vine, fig, melon, and cucumber.

4780. Those *well known*, but neglected, as such ; as the orange, pomegranate, olive, Indian fig, torch-thistle, and strawberry-pear.

4781. Those *little known*, some of which seem to merit cultivation ; as the akee-tree, alligator-pear, anchovy-pear, durion, guava, granadilla, jamrosade, malay apple, leeches, loquat, mango, mangosteen, pishamin, and various others.

4782. *The varieties* of some of these species, as the vine, fig, and melon are very great ; in making a selection we would recommended the plan submitted as to the selection of hardy fruits. (4367.)

SECT. 1. *Exotic Fruits in general Cultivation.*

4783. *The exotic fruits in general cultivation* include the three first fruits in the world ; the pine pre-eminent for its flavor ; the vine, for its generous and enlivening juice ; and the melon, approaching in flavor to the pine. All circumstances considered, it is doubtful if the durion, mangosteen, and other Indian fruits, equal these ; certainly no fruit hitherto discovered in any region surpasses the pine-apple.

SUBJECT. 1. *Pine-apple.* — *Bromelia Ananas*, L. (*Bot. Mag.* 1554.) *Hexan. Monog.* L. and *Bromeliaceæ*, J. *Ananas*, Fr., Ger., and Ital.

4784. *The pine-apple* is described in Miller's *Dictionary* (art. *Bromelia*), as herbaceous ; but it is by others considered as a shrub. Its common name of *pine-apple* is supposed to be derived from the resemblance of the fruit in shape to the cone of some species of pine-tree. In richness of flavor this fruit stands unrivalled ; and, as Neill observes, "it is one of the greatest triumphs of the gardener's art, to be able to boast that it can be produced in Britain in as high perfection as in a tropical climate." The leaves of the pine-plant are long, narrow, channelled, and in general furnished with spines or prickles on the edges. The flowers are in a loose spike, on a scape, which is leafy at top ; "as the spike ripens, it takes the form of a fleshy scaly strobile, vulgarly called the fruit, and composed of many coadunate berries, which have scarcely any cells or seeds." Professor Martyn doubts whether there may not be some of the fruits with male flowers only, and others with hermaphrodite flowers ; "because those fruits which have seeds are remarkably different from the others when cut through the cells, in which the seeds are lodged ; for in these they lie near to the centre of the fruit, whereas in those which have abortive cells, they are chiefly close to the rind." South America is generally considered the native place of the pine, though it is indigenous in uncultivated places in Africa, in great abundance. Linnæus ascribes it to New Spain and Surinam ; and Acosta says, that it was first sent from the province of Santa Croce, in Brasil, into the West, and afterwards into the East Indies. Professor Martyn thinks it may be common to the tropical parts of the three continents. The pine-plant has been long cultivated in Jamaica and other West India islands with great success, and was introduced to the gardens of Europe by Le Cour, of Leyden, about the middle of the seventeenth century. This gentleman, Miller informs us, received his first plants from America, and "after a great many trials with little or no success, did at length hit upon a proper degree of heat and management, so as to produce fruit equally good (though not so large) as that which is produced in the West Indies." From Le Cour "our gardens in England were first supplied with this king of fruits ;" and it is "commonly said that Sir Matthew Decker, of Richmond, was its earliest cultivator ;" but, as a botanical plant, it was introduced so far back as 1690, by Bentick. (*Hort. Kew.*) Miller informs us, that at first the plants were kept in dry stoves, during winter, placed on scaffolds, after the manner in which orange-trees are placed in a green-house ; and that in summer, they were removed to hot-beds of tanners' bark, under frames. They soon, however, began to erect "low stoves," called succession-houses, and bark-pits under deep frames, for the suckers and crowns. Bradley informs us, that by the year 1730, pine-stoves of the different kinds were established in all the principal English gardens ; and Justice, in his *British Gardener's Directory*, published in 1744, states, that pine-apple stoves had also been erected in Scotland, and he gives the plan of one erected by him in his own garden at Crichton, near Edinburgh, in the year 1732, in which the pine was fruited for the first time in Scotland. He recommends such as intend cultivating this fruit, to get their plants and furnaces (the latter cast in one piece) of Scott, of Turnham Green, London, and their thermometers from Coles, in Fleet-street.

4785. *Use.* It is the first of dessert-fruits ; and is also preserved in sugar, and made into marmalades and other confectionaries. In preparing to eat this fruit, first twist out the crown and then cut the fruit into horizontal slices : these being served, the rind and scales of the pips are pared off by the guest with a knife and fork. (*Speechly.*)

4786. *Varieties.* There are many varieties of this fruit, independently of some distinct species, as the *B. Penguin* and *B. Karatas* ; the fruit of these species being sometimes eaten in the West Indies. If the seeds of the ananas were sown frequently in their native country, Professor Martyn considers that varieties might be rendered as nu-

merous as those of the apple and pear. Miller, in sowing the seeds, found a variety of sorts produced from the same fruit; and Speechnly mentions, that he raised in 1768 above seventy plants, from seeds sent to the Duke of Portland from the West Indies, most of which varied in some distinctive circumstance, either in their leaves or fruit. Many of these fruits turned out of inferior quality, probably from the seeds having been gathered indiscriminately. Seeds are not usually produced in this country; when they occur it is generally in those pines which blossom in August, and ripen their fruit in December. (*Buck, in Hort. Trans. iv. 535.*) The most esteemed varieties in present cultivation are —

The old queen. Fruit oval-shaped, and of a gold color. Esteemed the hardest kind, and fruited in fifteen or eighteen months. The fruit grows to a large size, often weighing from three to four pounds. It is much more certain of showing fruit at a proper age and season than most of the other sorts, and has a just preference in most hot-houses.

Ripley's new queen. A subvariety of the old queen, with a large elegant fruit; fruited also in an equally short period.

Welbeck seedling; fruit small, generally broader at the head than at the base; of a pale yellow, or sulphur color, with very flat pips; flesh white and tender, rich in flavor, with less acidity than is found in most other pines. (*Hort. Trans. iv. 213.*)

Pyramidal, or brown sugar loaf. Cone-shaped, and dark-colored till it ripens; the leaves brownish, and flesh yellow.

Prickly striped sugar-loaf. Cone-shaped, the fruit of a golden color, the leaves striped with black or purple lines.

Smooth striped sugar-loaf; similar to the above, but the leaves not prickly.

Havannah. Tankard-shaped; dark-colored till it ripens.

Montserrat. The leaves of a dark-brown, inclining to purple in the inside; fruit middle-sized and tun-shaped, and the pips or protuberances of the fruit being larger and flatter than in the other kinds.

King pine, or shining green. The leaves of a grass-green, the pulp hard and rather stringy, but of good flavor when ripe.

Green, or St. Vincent's pine. A rare variety; when ripe the fruit is of an olive hue, middle-sized, and pyramidal.

Black Antigua. The fruit is shaped like the frustum of a pyramid; leaves of a brownish tinge, and drooping at the extremities, with strong prickles, thinly scattered. The pips of the fruit are large, often an inch over; and it attains a large size, weighing from three to four pounds. It is of a dark color till it ripens; very juicy, and high flavored.

Black Jamaica. The fruit is large, and the plants similar in character and habits to the above.

Providence pine, or new providence. There are two varieties, the white and green; the fruit is larger than that of any of the kinds cultivated in this country; the form inclining to pyramidal; the color at first brownish-grey, but when mature of a pale-yellow.

The flesh yellow and melting, abounding with quick lively juice. Speechnly produced in the gardens at Welbeck, in 1794, a fruit that weighed five pounds and a quarter, or eighty-four ounces, and from a plant that was not a large one. Griffin had, in 1803, two plants placed under his care, which fruited in July 1804, the fruit of one plant weighing seven pounds two ounces, and the other nine pounds three ounces, avoirdupois.

This sort, and the two preceding, require generally three years, and sometimes four or five to produce their fruit. What is called the old providence, is a small fruit from one of the Bermuda islands of that name.

Blood red; fruit equal in bulk at both ends. Pips of moderate size, color brick red; flesh white and opaque; leaves of a changeable hue; the flavor of the fruit being inferior to that of most others, this is to be considered merely as a curious variety. (*Hort. Trans. iv. 214.*)

Silver-striped queen. Leaves beautifully striped with white, yellow, and red; but the plant, though elegant, is a reluctant fruiter.

Variegated-leaved pines. Besides the striped-leaved queen, there are several sorts with beautifully varied leaves and fruits, and some with red or brown leaves; but in general they are tardy in fruiting, and more to be considered as ornamental than as useful varieties.

New sorts. Pine plants are frequently imported from the West Indian islands, and in this case generally bear their names. In general, however, these plants are far inferior, both as to kinds and condition, to those grown, and to be procured from nurserymen in this country. They are generally infested with the bug, and very uncertain in their time of fruiting, as well as to their flavor. If these were to be enumerated, the list of pines known in this country would amount to upwards of forty sorts. Specimens of above thirty sorts are grown in the gardens of Gunter, at Earl's-court. The globe pine-apple, a subvariety of the queen, was sent to Russia, above thirty years ago, by Lordige, and is now reimported under the name of the Russian globe. (*Hort. Trans. v. 265.*)

4787. The insects which more especially infest the pine are, the brown turtle bug (*Coccus hesperidum*, L.) (fig. 505. a to e). The female has at first the appearance of a flat scale (a); afterwards, when depositing its eggs, it becomes fixed and turgid (b); these eggs (c) are hatched under the mother, who soon afterwards dies; the young insects, seen under a magnifier, appear like turtles in miniature (d). Only the males (e), which are few in proportion to the females, have wings; these devour nothing, and having performed the office of impregnation, die.

4788. The white scaly bug (*C. hesp.* var.) (f to l) bears a considerable resemblance to the above; but the scale (f) is somewhat smaller: the color is white, and the males or flies (l) not so large as those of the brown.

4789. The white mealy crimson-tinged bug (*C. hesp.* var.) (n and m) differs from the former in being larger and crimson-colored. Speechnly considers it as viviparous. This and the former species are much the most pernicious. The various modes of destroying them, and also the other insects which attack the pine, have been already detailed.

SUBJECT. 2. Grape-Vine. — *Vitis Vinifera*, L. (*Jac. Ic. i. t. 50.*) *Pentan.* Monog. L. and *Vites*, J. *Vigne*, Fr.; *Weintrauben*, Ger.; and *Vigna*, Ital.

4790. The grape-vine is a trailing, deciduous, hardy shrub, with a twisted irregular stem, and long flexible branches, decumbent, like those of the bramble, or supporting themselves when near other trees, by means of tendrils, like the pea. The leaves are large, lobed, entire, or serrated and downy, or smooth; green in summer, but when mature, those of varieties, in which the predominating color is red, constantly change to, or are tinged with some shade of that color; and those of white, green, or yellow grapes, as constantly change to a yellow, and are never in the least tinged either with purple, red, or scarlet. The breadth of the leaves varies from five to seven or ten inches, and the length of the foot-stalks from four to eight inches. The flowers are produced on the shoots of the same year, which shoots generally proceed from those of the year preceding:

they are in the form of a raceme, of a greenish-white color, and fragrant odor, appearing in the open air in this country in June ; and the fruit, which is of the berry kind, attains such maturity as the season and situation admit, by the middle or end of September. The berry or grape is generally globular, but often ovate, oval, oblong, or finger-shaped ; the colors green, white, red, yellow, amber, and black, or a variegation of two or more of these colors. The skin is smooth, the pulp and juice of a dulcet, poignant, elevated, generous flavor. Every berry ought to enclose five small heart or pear shaped stones ; though, as some generally fail, they have seldom more than three, and some varieties, as they attain a certain age, as the ascalon or sultana raisin, none. The weight of a berry depends not only on its size but on the thickness of its skin, and texture of the flesh, the lightest being the thin-skinned and juicy sorts, as the sweetwater or muscadine ; and what are considered large berries of these varieties, will weigh from five to seven pennyweights, and measure from one to two thirds of an inch in girth. A good-sized bunch of the same sorts may weigh from two to six pounds ; but bunches have been grown of the Syrian grape, in Syria, weighing forty pounds, and in England weighing from ten to nineteen pounds. A single vine in a large pot, or grown as a dwarf standard in the manner practised in the vineyards in the north of France, ordinarily produces from three to nine bunches ; but by superior management in gardens in England, the number of bunches is prodigiously increased, and one plant, that of the red Hamburgh sort, in the vinery of the royal gardens at Hampton Court, has produced 2200 bunches, averaging one pound each, or in all nearly a ton. That at Valentine's, in Essex, has produced 2000 bunches of nearly the same average weight.

4791. *The age to which the vine will attain* in warm climates is so great as not to be known. It is supposed to equal or even to surpass that of the oak. Pliny speaks of a vine which had existed six hundred years ; and Bosc says, there are vines in Burgundy upwards of four hundred years of age. In Italy there are vineyards which have been in a flourishing state for upwards of three centuries ; and Miller tells us, that a vineyard a hundred years old is reckoned young. The extent of the branches of the vine, in certain situations and circumstances, is commensurate with its produce and age. In the hedges of Italy and woods of America, they are found overtopping the highest elm and poplar trees ; and in England, one plant trained against a row of houses in Northallerton (lately dead), covered a space, in 1585, of one hundred and thirty-seven square yards ; it was then above one hundred years old. That at Hampton Court, nearly of the same age, occupies above one hundred and sixteen square yards ; and that at Valentine's, in Essex, above one hundred and forty-seven square yards. The size to which the trunk or stem sometimes attains in foreign countries, is so great as to have afforded planks fifteen inches broad, furniture, and statues ; and even in this country, the Northallerton vine above mentioned, in 1785, measured four feet in circumference near the ground ; and one branch of the Hampton Court vine measures one hundred and fourteen feet in length. Vine timber is of great durability. It may be remarked, that vines regularly pruned and dressed, can rarely attain similar magnitudes, nor is it desirable that they should.

4792. *The native country of the vine*, like most of our acclimated fruits, is generally considered to be Persia ; and Dr. Sickler (*Geschichte der Obst. Cult.* vol. i.) has given a learned and curious account of its migration to Egypt, Greece, and Sicily. From Sicily it is supposed to have found its way to Italy, Spain, and France ; and in the latter country it is believed to have been cultivated in the time of the Antonines, in the second century. It has been found wild in America, and is now considered as a native, or naturalised in the temperate climates of both hemispheres. In the old world, its culture forms a branch of rural economy from the 21st to the 51st degree of north latitude, or from Schiraz in Persia to Coblenz on the Rhine. Some vineyards are to be found even near Dresden and in Moravia ; and by means of garden-culture, it is made to produce fruit for the table still farther north ; being grown to a considerable degree of perfection in the hot-houses of St. Petersburg and Stockholm.

4793. *The introduction of the vine to Britain* is supposed by some to have taken place under the first Roman governors, though, from Tacitus, it appears to have been wanting in Agricola's time. There is evidence, however, to prove that vineyards were planted here in the year 280, A. D. (see 312.) ; and Bede, writing in 731, says, there were vineyards growing in several places. Harte observes, that the religious fraternities of the dark ages spread out from Italy in all directions, carrying with them the knowledge of agriculture and gardening ; there is little doubt, Professor Martyn remarks, that orchards and vineyards were common appendages to abbeys and monasteries from their first establishment, at least in the southern parts of the island, to the time of the reformation. From this period they have disappeared, in part, perhaps, from the culture of the vine being little understood by those to whom the lands of religious houses were sold or granted ; and in part, because a better article would be introduced from our French provinces in the time of the Henries, and continued to be imported when we lost these.

4794. *Vineyards* have also been planted in modern times, and wine produced, nearly, if not entirely equal, to that of France. In the *Museum Rusticum*, it is stated, that at Arundel Castle in Sussex, the Duke of Norfolk had a vineyard, of which there were in his Grace's cellar, in 1763, above sixty pipes of excellent Burgundy. Bradley informs us, that Warner, a gentleman of Rotherhithe, made good wine from his own vineyards. Switzer mentions several instances, and among others, that of Rocque, of Walham Green, who made wine for thirty years from a vineyard he had planted in a *common field-garden*. Hanbury and Hales confirm these accounts, and cite others; and Barry, in his *History of Wines*, gives an account of a very productive vineyard, formed by the Hon. Charles Hamilton, at Painshill, in Miller's time, which succeeded for many years, and produced excellent champagne. It is not yet twenty years since this vineyard was neglected or destroyed. There can be no hesitation, therefore, in agreeing with these authors, and with Miller, Martyn, and Speechly, that vineyards would succeed in various parts of England, and produce wine equal to much of that imported from France. But, in a national point of view, we may conclude with equal safety, that the culture of the vine, as a branch of rural economy, would not be a profitable concern here, on the broad general principle, that it cannot be long worth while to grow any thing at home which we can get cheaper from abroad. The high duties on imported wines may seem to bear against this opinion; but this is merely a temporary cause; for, in the progress of international commerce, governments gradually discover the advantage of leaving trade comparatively free; and in proportion as this becomes the case, each country will feel its advantage in pursuing those branches of industry in which nature or habit has rendered it pre-eminent. It may, however, afford much rational satisfaction for individuals, in favorable situations, to form vineyards, and drink their own wine.

4795. *Grapes for the table* appear to have been in demand as early as the beginning of the 16th century; for Tusser includes "grapes white and red," in his list of fruits, published about the year 1560; but as far as appears from horticultural literature, the vine had only been grown as dwarf standards, or trained against walls or buildings, till the beginning of the 18th century. Stoves for preserving curious exotics had been introduced soon after the middle of the 17th century; but we find no mention of the application of artificial heat to the vine, till 1718, when Lawrence informs us, in his *Fruit-Gardener*, published that year, "that the Duke of Rutland, at Belvoir Castle, has done so much justice to the vine as to have fires constantly burning behind his slope walls, from Lady-day to Michaelmas; whereby he is rewarded by the largest grapes, and even the best Frontignacs, in July." These sloped walls, we are informed, were afterwards covered with glass. Switzer (*Pract. Fruit. G.* 2 edit. 1763.) appears to be the first author who gives a regular plan of a vinery, with directions for forcing the grape. He advises making fires as early as the middle of December, so as to make the vines push by the middle of January. Since his time, the art of forcing has made such rapid progress that no kitchen-garden worth notice is now without a vinery: the fruit is produced in some vineries during every month of the year; and in the London markets is to be had in the highest degree of perfection from March to January. Vines are at the same time still grown on walls unaided by fire-heat, and in favorable seasons, the more hardy early sorts attain a tolerable degree of maturity. In the nursery-gardens of Joseph Kirke at Brompton, a wall upwards of two hundred and twenty yards long, and ten feet high, is covered with plants of the white muscadine, which have produced regular crops for many years. On the border to this wall are standard vines of the same sort, trained to stakes about four feet high, which also bear in proportion, though the fruit does not ripen quite so early, nor attain an equal degree of flavor with that on the wall. In propitious seasons these grapes attain a tolerable degree of flavor; but even then they are of little value, compared to those grown in vineries and hot-houses.

4796. *Use.* The uses of the grape in Britain are well known; in the dessert it ranks next the pine, and is by some preferred to it. The berries, when green or not likely to ripen, may be used in tarts or pies; and the leaves form an elegant garnish to other table-fruits. Wine is sometimes made in England, by expressing and fermenting the juice, either alone or with that of other fruits; and it has even been made from decoctions of the leaves of some sorts. In warmer climates, the grape is not only used in the dessert, but eaten with bread, either newly gathered or dried as raisins; and in these countries, from the fermented juice, a wine or liquor is made superior to all others for stimulating the stomach, and exhilarating the spirits of man. Some of the most important consequences in the mythological history of man, are referred to its last-mentioned qualities. (See the *Histories of Lot, Noah, and Bacchus*.) The medical products of the vine are verjuice, formerly used as the juice of lemons: tartar, a gentle cathartic: vinegar, used as a condiment; for extracting the virtues of other medicines; and for counteracting the effects of vegetable poisons. Even wine itself is given as a medicine, in typhus fevers; in nervous disorders; in putrid sore throats; and even in the plague. "In almost all cases of languor, and great prostration of strength," Martyn observes,

"wine is a more grateful and efficacious cordial than can be furnished from the whole class of aromatics."

4797. *Varieties.* These are exceedingly numerous; partly from the antiquity of the vine, it having, as Professor Martyn remarks, been cultivated from the time of Noah; partly from the influence of soils and climates in changing the qualities of grapes, there being hardly two vineyards in France or Italy where the sorts, though originally the same, remain long precisely alike; but chiefly, as far as respects this country at least, from the facility with which new sorts are procured from seed. Tusser, in 1560, mentions only "white and red" grapes. Parkinson, who was more of a horticulturist, gives, in 1627, a list of twenty-three sorts, including the white muscadine, "very great, sweet, and firm; some of the bunches have weighed six pounds, and some of the berries half an ounce." Ray, in 1688, enumerates twelve sorts as then most in request. Rea, in 1702, gives most of those in Ray's list, and adds five more sorts, recommending the red, white, and the d'Arbois, or royal muscadine, the Frontignacs, and the blood-red, as the fittest sorts for England. The best vines, he says, were then on the walls of the physic-garden at Oxford.

4798. *Switzer*, in 1717, says, "It is to Lord Capel and Sir William Temple that we are owing that collection of good grapes now so plenty in England; the latter" he says, "brought over the Chasselas, parsley, and Frontignac; and also the Amboyna, Burgundy, black muscat, and grizzly Frontignac; all highly approved, and distributed amongst the nurserymen, as well as the nobility and gentry. The best grapes," he tells us, "were grown at Twickenham, Isleworth, and Richmond." Speechly, from 1760 to 1790, excelled in the culture of the vine at Welbeck.

4799. *The most valuable modern additions to the varieties of grapes in this country have been procured by sowing the seeds of sorts ripened in this country. That excellent grape, the red Hamburg, was raised from seed, about a century ago, by Warner, of Rotherhithe, already mentioned. Miller in the same way produced the variety of the black cluster, which bears his name. Speechly produced various new sorts, which have now a place in the catalogues of nurserymen. Williams of Pittmaston, Braddick of Thames Ditton, and, above all, the President of the Horticultural Society, have raised several excellent varieties of the sweetwater, Chasselas, and Hamburg grapes. The great attention paid to natural history by such as go abroad, has also contributed to the number of grapes. New sorts have been sent from Spain, Italy, and the East Indies, and many from France; so that the lists of some British nurserymen exceed two hundred and fifty names. In France, during the consulship, in 1801, the celebrated chemist, Chaptal, when minister of the interior, ordered a specimen of every known variety of the grape to be collected from the different departments where the vine is grown, and planted in the nursery of the Luxembourg garden, with a view to ascertain their respective merits. Though this assortment was never completed, the number collected amounted to upwards of three hundred distinct varieties.*

4800. *A classification of the numerous varieties of the vine has not yet been made, either in France or England. Bosc, the inspector of government-nurseries in France, was employed to compare and class those collected at the Luxembourg; but in 1809 he had only succeeded in describing and figuring fifty distinct sorts. The groundwork of his classification was, the color, form, and size of the fruit; the surface, margin, texture, color, and position of the leaves; and the redness, greenness, or variegation of the foot-stalks. From these eleven characteristics combined, he forms 156 classes, in which, he says, may be placed all the possible varieties of grapes. Bosc, aware of the great variety of considerations of another order, which augment the number of characteristics, such as grapes which are in other respects alike, yet differ in their time of ripening, in the time they will hang without alteration on the plant, in the quantity produced on a plant, quality of the pulp, &c. acknowledges, that, after four years' labor, he could offer no useful result. In the catalogue of the Luxembourg collection, published by Hervey in 1802, the arrangement is, 1. vines with black oval fruits, 37 sorts; 2. black round fruits, 98 sorts; 3. white oval fruits, 44 sorts; 4. white round fruits, 73 sorts; 5. grey or violet oval fruits, 5 sorts; and 6. grey or violet round fruits, 10 sorts; in all, 267 sorts. The most elaborate descriptions of the varieties of the vine which have yet appeared are contained in a Spanish work, *Ensayo sobre las variedades de la vid comun, que vegetan en Andalucia*, &c. by D. Simon Roxas Clemente, librarian to the botanic garden at Madrid. This author founds his varieties on the character of the stem, shoots, leaves, flowers, bunches, and berries. He describes 120 varieties, comprising them in two sections, *downy and smooth-leaved*. Each section is arranged in tribes or clusters of subvarieties, bearing one common name, and distinguished by a common character in some of the parts of the fundamental characteristics above named, and into isolated varieties, which he describes singly. He enumerates thirty-six authors who have written on the vine, since Columella, by whose names he has distinguished many of his tribes; the others by their local appellations. The table of grape-vines here given is, we acknowledge, very imperfect, but it contains all the information which we have been able to embody from the best authors, and especially from Speechly and Forsyth. More than triple the names it contains might have been inserted; but, without being accompanied by any descriptive particulars, they could be of no real use.*

4801. *Estimate of sorts.* As it is generally a puzzling consideration for inexperienced persons to make a selection from the ample semi-descriptive catalogues of authors and long lists of names kept by nurserymen, we shall here submit a few selections suitable to common cases.

Vines to plant against a common garden-wall of south exposure, or against the walls of a house. The July black, white muscadine, white and black sweetwater, small and large black and white cluster, black espérone, &c.

To plant a vine for early forcing.

Take the preceding sorts.

To plant a vine for a full crop of good grapes of various flavors. Take a

white and red, or black muscadine, a white and red muscat, a white and a red Frontignac, a black or red muscadine, a white raisin-grape, a white and red Hamburg, a Sitwell's and red sweetwater, a white and red Nice.

There are here 26 grapes of 14 distinct flavors; an equal number of both colors; large showy bunches and berries, as those of the Nice; and small high-flavored ones, as those of the Frontignacs; the whole placed in the order

in which they will ripen. The foliage in autumn will be alternately tinged with red and yellow; and, supposing the muscadines to be placed next the end at which the flue enters, they will ripen nearly a month earlier than any of the others: the Muscats, Frontignacs, and Muscadels being hot-house grapes, will have a sufficient heat to ripen them; and the three last sorts, being somewhat more tardy, will come in succession.

To plant a vine for a late crop. Take the black Damascus, black Frontignac, black Hamburg, red Syracuse, black and white raisin, black and white St. Peter's, black prince, &c.

To plant a hot-house in which pines are grown: one plant under each rafter. Take the white and red muscat, black muscadine, red or black Hamburg, red Syracuse, red and white raisin, black

Damascus: and for early sorts, Sitwell's sweetwater, royal muscadine, white Frontignac.

To plant vines to run up the rafters of green-houses, or plant-stoves. Choose such sorts as have small leaves and short foot-stalks.

Hardy small-leaved sorts for the rafters of a green-house. White and black sweetwater, black cluster, black muscadine, parsley-leaved muscadine, black morillon.

Small-leaved sorts, requiring more heat, and fit for the rafters of a plant-stove. Black Morocco, blue Frontignac, blue toky, claret, white Teneriffe, white morillon, &c.

Small-fruited sorts for planting in pots or boxes. Black and white Corinth, black and white cluster, red and grizzly Frontignac, white and red Burgundy, &c.

Abbreviations. — *h.* hot-house; *v.* vinery; *w.* common wall.

GRAPES WITH ROUND BLACK BERRIES.

No.	Name.	Synonyms.	How, when, and where origi- nated, procured, or abounding.	Where figured.	Where de- scribed.	Size of bunches.	Size of the berry.	Flavor and consistence.	Time of ripening, a wall.	Ber- r. of leaf.	Local.	Character of the tree, and general reputation of the fruit.
1.	July											
2.	Black Muscadine	Morillon noir Hâfiz.	An old variety from France	Lang. P. t. 47. f. 3.	Forst. 11.	Small	Small	Sugary	Sept.	6in.	<i>v. w.</i>	Estimated for being early ripe
3.	Black Damascus	Black Frankendale	An old approved variety common on dwelling-houses about London	Lang. F. t. 36.	For. 4.	Medium	Medium	Rich and juicy	Sept.	9	<i>h. v.</i>	Good bearer. Leaves in autumn fine scarlet and yellow
4.	Black Lisbon		A new sort from Portugal, about 1780	-	For. 11.	Resembles those of the black Hamb.	Large	Rich and well flavored	Late	11	<i>h.</i>	An excellent late grape
5.	Black Frontignac	Muscatoir de Frontig.		Lang. P. t. 38.	For. 15.	Large and mealy	Large	Rich and vinous	Oct.	12	<i>h. v.</i>	A much-estimated grape
6.	Black sweet water	Le Cœur, raisin d'Afric.		Lang. P. t. 51.	For. 20.	Small	Small	Sweet; apt to crack	Sept.	8	<i>v. w.</i>	Not in repute, as berries crack
7.	Black Morocco			Lang. P. t. 41.	For. 33.			Extremed. Berries tawny colored		9½	<i>h.</i>	Berries black; juice claret-red;
8.	Claret	Clairette. Rose	Wine from white berries may be colored with its leaves	Lang. P. 47.	For. 42.	Small	Small	Juice of a blood color, and harsh-tasted		6	<i>h. v.</i>	leaves veined in autumn
9.	Black prince			Hook. P. 45.	For. 53.	Large	Large		Oct.	-	<i>h. v. w.</i>	Deserves a place in hot-house and vinery; ripens well on open wall
10.	Turner's hardy	Black Esper, Hardy blue	Some very prolific specimens in the royal garden at Windsor	Hort. Tr. iii. 93.						-	-	Very prolific, hardy. Alton com- mended it one of the best
11.	Black Corinth	Zante. B. Ascalon, cur- rant	From Ascalon in Palestine	Lang. P. 46.	For. 49.	Small	Small	Sweet		-	<i>w.</i>	Grown in the south of France, which produces dark Corinth, or currants of shops
GRAPES WITH LONG BLACK BERRIES.												
12.	Black Muscadine		An old variety from France	-	For. 9.	Large	Large	Pleasant juice	Late	11	<i>h.</i>	A showy good grape
13.	Black Hamburg		An old variety	-	For. 21.	Large	Large	Pleasant and vinous	Nov.	7	<i>h. v.</i>	A black grape, and one of the best grapes we have
14.	Purple Hamburg		Resembles the above, excepting as to color	-	-	Large	Large	Pleasant and vinous	Nov.	10½	<i>h. v.</i>	A good bearer, very dark fruit
15.	Small black cluster	Black Burgundy	An old var. orig. from Burgundy	Lang. P. t. 41.	For. 24.	Small & close berr.	Small	Pleasant	Sept.	5	<i>v. w.</i>	Hoary leaves, a good wall-fruit
16.	Miller's Burgundy	Miller's cluster.	The	-	-	Medium	Medium	Pleasant	Oct.	-	<i>h.</i>	A hardy grape; used for wine at Fainsbill vineyard, 1750.
17.	Large black cluster		about the year 1740, from S. to S. W. of Portugal.	Lang. P. t. 42.	For. 30.	Medium	Medium	Rough and harsh		6	<i>v.</i>	
18.	Black raisin	Augibert noir	Originated from Languedoc	-	For. 32.	Large	Large	Juicy	Late	10	<i>h.</i>	An approved late grape
19.	Black St. Peter's			-	For. 47.					7	<i>h.</i>	A curious finger-shaped fruit
20.	Black Cornichon	Cornichon noir. Dedos de Damas. Pitotella		-	-					-	-	
GRAPES WITH ROUND WHITE BERRIES.												
21.	Royal Muscadine	D'Arbores. Chasselas blanc. Amber Muscat.	Said to have been introduced by Sir William Temple, in 1660	-	For. 2.	Large	Medium	Rich, vinous	Sept.	12½	<i>h. v.</i>	One of the best hardy white grapes, and excellent bearer
22.	Malmsey Muscadine	Malvoisie musquée, clo- tat. Parsley-leaved. Vi- tis laciniosa. Lin.	An old variety from France	-	For. 3.	Large	Medium	Rich and musky	End of Sept.	12	<i>w. v.</i>	A beautiful leaf and fine fruit
23.	Common white Muscad.	Amber. M. Chasselas blanc	Introd. by Sir W. Temple, in 1660	Lang. P. t. 35.	For. 5.	Medium	Medium	Sugary	Sept.	11	<i>w.</i>	Best grape we have for a common wall, a great bearer
24.	White Frontignac	Muscatoir blanc		Lang. P. t. 57.	For. 17.	Large		Exquisite		11	<i>h. v. w.</i>	Much-estimated hot-house and vinery grape

A DESCRIPTIVE CATALOGUE OF GRAPE-VINES — continued.

GRAPES WITH ROUND WHITE BERRIES — continued.

No.	Name.	Synonyma.	How, taken, and where originated, procured, or abounding.	Where figured.	Where described.	Size of the bunch.	Size of the berry.	Flavor and consistence.	Time of ripening, a week.	Local.	Character of the tree, and general reputation of the fruit.
25.	White sweet water	Pareyl druyl.	A favorite Dutch grape	Lang. P. t. 50.	For. 19.	Medium	Large	Sugary	Sept.	h. v. n.	Excellent grape; blossoms do not set so well as most others
26.	White Corinth	White Ascalon.	From Ascalon in Palestine	Duh. 14. t. 7.	For. 30.	-	Small	Fine juicy flesh; agreeable flavor	4	-	Often grows without stones
27.	Pitaston, new white cluster	White Ascalon.	Raised by Williams of Pitaston, from seeds of the black cluster	Hort. Tr. ill. t. 8.	Hort. Tr. ill. t. 219.	Close crowded bunch	Medium	-	-	-	Very hardy tree, a great bearer
28.	Pitaston, mignon wh. cl.	White Ascalon.	Raised from seed by a blacksmith at Edinburgh, about 1812	Hort. Trans.	-	Medium close	Small	Juicy and sweet	Sept.	h.	Very hardy tree, a great bearer
29.	Scotch, white cluster	White Ascalon.	Originated from seed by W. Williams of Pitaston, in 1816	-	-	Small	Small	Sugary	Sept.	n.	Hardy grape, remarkable for the beauty of its leaves in autumn
30.	Scarlet-leaved, black cluster	White Ascalon.	-	-	-	-	-	-	-	-	-
GRAPES WITH LONG WHITE BERRIES.											
31.	White Muscat of Alexandria	Alexand. Frontignac	-	Duh. 12. 10.	For. 6.	Large	Large	Rich, musky, and vinous	Late	h.	One of the richest, and particularly adapted for the hot-house
32.	White Muscat of Lunel	White Muscat of Lunel	-	-	For. 8.	Medium	Large	Rich and vinous	Late	h. v.	Good bearer, highly-esteemed
33.	White Muscat of Portugal	White Muscat of Portugal	-	-	For. 23.	-	Large	Juicy	12	h. v.	A pretty good bearer
34.	White Morillon	White Morillon	-	-	For. 27.	-	Large	Tolerable flavor	11	h. v.	Leaves downy on the under side
35.	Golden Galicien	Golden Galicien	-	-	For. 34.	-	Large	Thick-skinned and firm flesh	10½	h.	-
36.	White Ascalon	White Ascalon	-	Lang. P. t. 43.	For. 36.	Very large	Very large	Thick skin and hard flesh	11	h.	-
37.	White Syrian	White Syrian	-	-	For. 38.	-	-	Sweet juice	17½	h.	Great bearer, the largest of all, both as to berries and bunches
38.	White Cornichon	Cornich. blanc, Dolget de Donzelle, Zeta de Voca	-	Duh. 12. 6.	For. 50.	-	-	Rich saccharine flavor	9½	h.	A good bearer, but not otherwise remarkable
39.	Verdelho	Verdelho	-	Hort. Tr. i. 106. tab.	Hort. Tr. i. 238.	Small	Small	-	-	n.	Hardy fruit, fit for a com. wall; the stones eaten with the fr. deleter.
40.	Amlens	Amlens	-	Hort. Tr. ii. 11. tab.	-	-	-	-	-	-	The grape from which Madeira wine is made
								-	-	-	A very hardy grape, and ripens at Amlens, in July
GRAPES WITH RED, ROSE-COLORED, BLUE, GREYISH, OR STRIPED BERRIES.											
41.	Red Muscat of Alexandria.	Muscat rouge	Resembles the white Muscat, excepting as to color	For. 7.	For. 10.	Large and long	Large	Rich, musky, and vinous	Late	h.	A rich hot-house grape, like the white Muscat of Alexandria
42.	Red Muscadal	Muscatoir rouge de Frontig.	-	For. 10.	For. 10.	Very large	Large	Pleasant juice	Late	h.	A showy good fruit
43.	Red Frontignac	Muscatoir rouge de Frontig.	-	For. 16.	For. 16.	Medium	Large	Highly vinous	10	v.	A greatly-esteemed grape
44.	Grizzly Frontignac	Muscat gris	-	For. 18.	For. 18.	Small	Small	Excellent	Late	h. v.	An excellent keeping fruit
45.	Red Hamburgh	Warner's, or Hampton-court vine; Gibraltar	Originated by Warner of Rotherhithe, about 1730	For. 22.	For. 22.	Large	Thin-skinned, large	Rich and vinous	Nov.	h. v.	Reckoned the best of Hamburgh
46.	Giles's Seedling Hamb.	Clozet rouge.	A new variety of Warner's H.	For. 164.	For. 164.	-	-	-	7½	v.	Elegant leaves as to form and col.
47.	Red parsley-leav. Muscadale	Striped Aleppo; purple-colored grape	-	For. 31.	For. 31.	Medium	Medium	Juicy flesh, very fine flavor	-	h. v.	A curious grape; the berries frequently striped black and white
48.	Aleppo	Striped Aleppo; purple-colored grape	-	For. 32.	For. 32.	Very large, oval	Very large, oval	Coarse	Late	h.	Coarse fruit as to flavor, but very
49.	Red Syracuse	Malvoisic	-	For. 37.	For. 37.	Small	Small	Rich	5	h. t.	Berries powdered with blue bloom
50.	Blue Tokay	Lombardy; Flame-col.	-	For. 40.	For. 40.	-	-	Very fine flavor	10	h. v.	A very good grape
51.	Red Smyrna	Tokay, Rhenish	-	Lang. P. t. 39.	For. 41.	Small	Small	Sweet	6	v. n.	Berries of a brick-color
52.	Brick grape	Red Muscadine, coral	-	-	For. 51.	Small and round	Small and round	Highly musked, vinous, and rich	Late	h. v.	A good grape
53.	Red Chasselas	Orig. from the Aleppo	Originated by Miller about 1738	Hort. Tr. i. 258.	For. 52.	Large	Very large	-	Late	h. v.	Forsyth has seen the berries as large as gooseberries
54.	New Muscat of Jerusalem.	Striped Muscadine	-	-	-	-	-	-	-	-	Variegated berries and leaves
55.	Variegated Chasselas	Striped Muscadine	A French ornamental grape	-	-	-	-	-	-	-	Variegated in leaves and fruit; more ornamental than useful
56.	Chasselas Panaché	Striped Muscadine	-	-	-	-	-	-	-	-	-

4803. *Propagation.* The vine is propagated from seed, layers, cuttings, grafting, and inoculation. By seed, for the sake of obtaining new varieties; by layers, to get strong showy plants the first year; by cuttings, for economy in management, and to get plants with tops proportioned to their roots; and by grafting and inoculation, for various useful and curious purposes.

4804. *By seed.* The first thing is to select the seeds. If the object be to propagate an esteemed variety from which cuttings cannot be obtained, or to procure a subvariety of any esteemed sort, then select the largest and best-ripened berries from the largest and best-formed bunches, out of which to take the seeds. But if the object be to procure an entirely new variety, then the first preparatory steps must be taken when the vines are in flower, either by bringing two or more sorts so near together as that the pollen of the anthers may effect a promiscuous impregnation, as was practised by Speechly; or by cutting out, with small scissors, the stamens from the flowers to be impregnated, before their anthers had burst, and introducing the pollen of the variety with which it is to be crossed or impregnated, by dusting the stigma with the ripe anthers, as was practised by Knight. This is the most certain and effectual method; the most certain, because if the blossom destined to bear seeds be fecundated or set, it must evidently have been set through the influence of the stranger pollen; and the most effectual, because the stranger pollen operating alone must have more influence on the progeny than when operating in conjunction with that of the blossom to be crossed.

4805. *As some guide for the selection of sorts to breed from,* (to borrow the phraseology of a sister art,) we may state, that the legitimate object which ought to be had in view, should not merely be to obtain a new variety, but one, either superior in the size, both of the bunch and berry, superior in flavor and delicacy of skin and flesh, superior in point of hardness and bearing, or in earliness or lateness. In connection with each of these particulars, the form of the bunch, and the length of the foot-stalk of the fruit, and even the size of the leaves and the length of their foot-stalks, are also objects deserving attention; close-growing grapes, which always have short foot-stalks, being subject to many misfortunes. "All the sorts of Frontignac grapes," Speechly observes, "are proper to add an excellency of flavor to other kinds: but there is a superior richness in the black, blue, and red Frontignacs; and they do not partake so much of the strong muscat flavor as the white and grizzly do. But it must be considered, that the blue Frontignac grows close upon the bunch, and therefore is only proper to be coupled with the loose-growing kinds, that have long foot-stalks. The white muscat of Alexandria produces large loose-growing bunches, and the berries being very large and well flavored, it must be a proper kind to be coupled with many sorts. There is a peculiar delicacy in the flesh of the white sweetwater; it is also a remarkably thin-skinned grape, with large berries; consequently, it is a proper kind to couple with various sorts that are small and less delicate. Were the red Frontignac and white sweetwater wedded together, their union would probably produce a very valuable sort, as there would be a good chance of its being both large and delicate, and well flavored. The Syrian vine is only admired for producing most astonishingly large bunches, and, therefore, I would not advise the joining this coarse sort to any other except the following, as, in all likelihood, the offspring would only produce bunches much less ponderous. But the white muscat of Alexandria, having larger berries and longer foot-stalks, there would be a probability of producing a kind between this and the Syrian grape, that would exceed the original parents both in size and flavor." The following kinds also admit of a junction with great propriety, viz. "the black Damascus and grizzly Frontignac; the flame-colored Tokay and red Frontignac; the white muscat of Alexandria and white sweetwater; the black Frontignac and white muscadine; the St. Peter's grape and white muscat of Alexandria." Other examples might be cited, but these Speechly considers as "sufficient to stimulate persons of taste and curiosity to pursue an amusement that one may venture to pronounce will contribute both to their advantage and pleasure." He augurs, "that the best sort of grapes hitherto known will at some future day be esteemed only as secondary kinds." (*Treatise on the Vine*, p. 44.) Neill observes, that, as several persons are now engaged in the raising of seedling vines, in all probability some excellent and hardy kinds will soon be produced; so that another generation may once more see vineyards common in this country. (*Ed. En. art. Hort.*) Grapes, for seed, should be permitted to remain on the plant till the fruit is perfectly mature, and the seeds of a very dark brown color. They should be separated from the pulp, and preserved till February or the beginning of March. They should then be sown in pots filled with light fresh-mould, and plunged in a moderately warm hot-bed; they will come up in four or six weeks, and when the plants are about six inches high, they should be transplanted singly, into forty-eighths, and afterwards into pots of larger size. Water gently, as circumstances require, allow abundance of light and air, and carefully avoid injuring any of the leaves. Cut down the plants every autumn to two good buds, and suffer only one of these to extend itself in the following spring. Shift into larger pots as occasion requires, till they have produced fruit. This, under good management, will take place in the fourth or fifth year, when the approved sorts should be selected and the rest destroyed, or used as stocks on which to graft or inarch good sorts.

4806. *Forsyth*, and some other authors, advise planting seedling vines the second year of their growth, against a wall in the open air, and there letting them remain till they produce fruit. Where there is abundance of walling to spare, and no great haste requisite for proving the fruit, this is a very good mode, as the fruit in such a case is certain of growing larger, and therefore affording a better opportunity of judging of its merits, as to size of bunch and berry. Keeping the plants in large pots, on the other hand, though the bunches and berries may not grow quite so large, yet as both the wood and fruit may be ripened under glass, is a more eligible mode; the plants will produce fruit sooner, and that fruit will be of better flavor.

4807. *Speechly* says, "it would not be prudent to furnish a wall, or any part of a hot-house, with seedling vines in their untried state, or before they have produced fruit; for although the prospect of obtaining good kinds from seed saved in a hot-house, be more promising and certain than that of getting them from seed of grapes in vine countries, (because there, when the vines flower, the very air is impregnated with the farina of the grapes of the vineyard, which are, generally, of sorts of harsh, austere qualities, esteemed only for making wine, and not at all fit for eating); yet many of the new kinds from seed will prove to be worse sorts than the originals from which the seed was saved. A specimen, therefore, of the fruit should be obtained from each plant, be tried and tasted before it is permitted to be planted against the walls in a vinery or hot-house, or in any permanent situation. The fruit of seedlings is not even always such as to render it advisable to introduce the plants in a vineyard; for though it may not have the sweetness, flavor, bulk, or precocity desired in an eating grape, it may be of that insipid large-berried kind, which is fit only for making the most inferior wines. In most vine countries, a small black berry with an austere taste, and aromatic flavor, and a close bunch like that of our black cluster, is preferred to all others." (*Treat. on the Vine*, 8vo. edit. p. 60.) It may be observed, that though vine-plants raised from the seeds of black or red grapes will generally produce red or black berries, yet they will occasionally produce white ones; and the produce of white berries will sometimes, in like manner, be berries of other colors. Thus plants, from stones of the peach, will sometimes produce nectarines; and though a nectarine-stone will, in general, produce a tree of the same kind, as Collinson experienced (*Smith's Correspond. of Linn.* 71.), yet it will sometimes also, as the French gardeners declare, produce trees bearing peaches.

4808. *By layers.* The advantages of layers are generally stated to be that of procuring large showy plants that come immediately into bearing, and we have given (2957.)

a successful instance of this practice from layers made in a vinery; but when taken from stools in the open air, it happens almost always that the roots of the layer are not ripened; the consequence of which is, that their extremities rot off, and the following year the plants make hardly any shoots. Layering without, or but with a trifling incision, as is too frequently done in the hurry of nursery business, greatly contributes to this effect, by obliging the shoot to derive all its nourishment from the parent plant or stool, to which, in autumn, the descending sap is returned. Whereas, when a deep incision is made, or a ring of bark taken off in Williams's manner (2168.), less sap ascends, the shoot is not so long, it ripens sooner, and the descending sap reposes in, and ripens the roots. It is not easy to conceive in what way plants so raised can be inferior to those raised from cuttings of one or of several eyes; though it appears to be the general opinion that they are not so long-lived as plants raised from one eye. "Vine-plants raised by layers," Speechly observes, "are much inferior to plants raised by cuttings, both in point of future vigor and durability." Hitt wonders how any one can prefer cuttings to layers, since the former are always one year beyond the latter.

4809. *By cuttings.* The advantages of propagating by cuttings are economy in labor, economy in the wood or shoots to be propagated from, and tops or shoots proportioned to the roots. There are three kinds of cuttings used in propagating vines:—

4810. *Long cuttings.* The first are from a foot to eighteen inches long, consisting of new or young wood, with a joint or two of that of the preceding year. This is the sort recommended by Miller; adopted in forming vineyards on the continent; and formerly also in this country in planting walls or vineries. They are inserted so as to leave only two eyes above ground; the earth is firmly pressed round the lower part, to which the old wood is attached; they are mulched, and water is supplied regularly in dry weather. Cuttings of this sort, so treated, strike freely, as Speechly observes, either with or without bottom heat. We have seen them in some French nurseries producing luxuriant shoots and branches of grapes the first year. Justice says he prefers stocking a vinery from such cuttings to using rooted plants.

4811. *Short cuttings.* The second mode is that of forming the cuttings with only one eye on young or one-year-old wood, and a few inches of that of the preceding year attached. "Each cutting should have two inches of the old wood, with one eye of the new. The bottom part should be cut perfectly smooth; plant in pots, one cutting in each pot, which, as to size, should be a forty-eight. When the plants begin to get strong, and the pots full of roots, it will be necessary to shift them from the forty-eights to the thirty-twos." (*Speechly.*)

4812. *Single eyes.* By the third mode, the cuttings have only a single eye on young or one-year-old wood. This mode was first adopted by the Rev. M. Mitchell, and by him communicated to Speechly, about the year 1770. The following is Speechly's reasoning in its favor: "It is allowed," he says, "that cuttings are generally preferable to layers, and that plants of any sort raised from small cuttings, commonly make the best plants. The new plant is injured in proportion as it partakes too abundantly of its original or mother plant. Hence, the less the bulk of the matter that forms the new plant the better; for plants raised from seed have the smallest beginning of any, and are preferable both to layers and cuttings." (*Tr. on Vine*, 52.) Perhaps, the chief advantage of propagating by eyes in preference to short or long cuttings or layers, is, that the sets are more manageable, and can be more readily potted and placed in pits or frames to receive bottom heat; on which, applied early in spring and continued through summer, accompanied by proper shiftings and waterings, much more than on the form of the cuttings, depend abundance of roots and fitness for bearing the second year. We have seen single eyes raised in pineries, produce strong shoots from ten to twenty feet the first year, and others, in cold frames or pits, with only a little bottom heat to start the plants in spring, produce weak shoots, not longer than two or three feet. Ripe wood is to be chosen for propagating by eyes; and though some are of opinion that cuttings taken from the lower part of the vine are preferable to those that grow higher and at a distance from the root, yet Speechly says, he never could find any difference, provided the wood was equally well ripened. Forward shoots, from vines forced early, he considers as the most eligible; and these will generally be found at the most distant parts from the root, as vines generally break first at the extremities of the shoots; and at these extremities will be found both the strongest, earliest, and best-ripened wood, and largest and most abundant bunches of fruit. Very strong shoots abound too much with pith to make good cuttings, the requisites to which are as follow: "1. The eye or bud should be large, prominent, and bold. 2. The shoots should be moderately strong, round, and short-jointed. 3. The texture of the wood should be close, solid, and compact; and the best criterion of its maturity is, its solidity, and having very little pith." (*Tr. on Vine*, 57.) "Choose fit shoots at the pruning season, and preserve them till wanted in spring, by cutting them into moderate lengths, and placing their lower ends in earth, which must be moistened, if it get very dry. Cut the upper part of the shoot sloping, with a sharp knife, about a quarter of an inch above the eye; and, at about three inches below the eye, cut off the wood horizontally, or right across, and smooth the section." In some of the London nurseries, Speechly's mode of forming vine-cuttings is reversed, and the wood is cut off horizontally close below the eye, and at three inches above it: others cut at equal distances from the eye, and bury the whole cutting in the soil, with the eye uppermost, which appears superior even to Speechly's mode, where no bottom heat is given, as affording a greater supply of nourishment to the young shoot. Plant in pots, and apply bottom heat as in propagating by short cuttings.

4813. *By grafting.* The advantages of this mode of propagation may not at first sight appear, but they are, Speechly observes, "many and important." First, when a wall, or vinery, is planted with inferior kinds of vines, the usual method of stubbing them up and supplying their places with better sorts, is attended with much expense and loss of time: as several years must elapse before the wall can be completely finished with new vines; but, by grafting, the nature of the vines may be changed without expense or loss of time; for I constantly have good grapes from the same year's graft; and in a hot-house the grafts, if permitted, will frequently shoot thirty or forty feet the first summer. Secondly, in small vineries, or vine-frames, where it would be inconvenient to have any considerable variety of sorts from roots, they may be procured by grafting different kinds upon one and the same plant. A Syrian vine now (1759) growing in the hot-house at Welbeck, produces sixteen different sorts of grapes. But the most important advantage, Speechly considers to be, "the improving the various kinds

of grapes, and particularly the small kinds, which generally make weak wood. By grafting the weak and delicate growing vines, as the blue Frontignac, upon robust and vigorous stocks, as the Syrian, it will produce well-sized handsome bunches, almost as large as those of the Hamburgh." The Syrian vine, raised from seed, is greatly preferable to all others for stocks. If the seed degenerate to a kind of wildness, so much the greater will be the vigor of the plants, and the higher the flavor of the sorts grafted on them. At the pruning season select cuttings for grafts from the best bearing branches, in general preferring the bottom part of last year's shoot; preserve them, by inserting them three parts of their length in pots, till wanted. The season for grafting in stoves is the beginning of January; in the open air, the middle of March. On small stocks not more than one inch in diameter, cleft-grafting will be found the most proper; but, upon larger stocks, whip-grafting is to be preferred. As vine-grafts do not take so freely as those of most other fruits, the operation must be performed with the greatest care. But the most eligible mode of grafting vines is that by approach, in which case either the stock or scion must be growing in a pot. Strong plants, two years potted, are to be preferred for the open air; but, for a vinery or hot-house, plants from the nursery may be potted, or shifted, if already in pots, and inarched the same season. In whip or cleft grafting, the clay may be taken off when the scion has made shoots five or six inches long; but here both clay and bandage should remain two or three months after the graft has formed a union, lest the grafted part spring from the stock.

4814. *Knight* finds grafting most successful when the lower part of the scion consists of two-year-old wood, and when the graft is well covered with clay kept moist, or if the branch be on a horizontal trellis with a pot or saucer placed under the graft, and the point of junction kept well covered with earth occasionally watered. (*Hort. Trans.* iv. 105.)

4815. *Braddick* has made several experiments on grafting vines: he found the scion generally sodden by the bleeding of the stalk; but, at last, he contrived by a very close bandage round the graft to force the sap of the stock up through the vessels of the scion, when the latter grew. From these, and various other experiments, he says, "I feel confident in stating, that healthy vines may be successfully grafted with young wood of the preceding year's growth, from the time that the shoots of the stocks which the grafts are to be put upon, have made four or five eyes, until midsummer, with every prospect of the graft's growing, and without the least danger of the stocks suffering by bleeding. They may likewise be grafted with shoots of the same summer's growth, worked into the rind of the young wood, from the time that the young bunches of grapes become visible on the stocks till July, out of doors; or till a month later, under glass. The operation must not be performed later than the periods here specified, because time is necessary for the young shoots of the graft to become hard and ripen before winter." (*Hort. Trans.* v. 204.)

4816. *Culture.* For the culture of the vine in the forcing department, see Chap. VII. Sect. II. What follows concerns chiefly the management of vines in the open air.

4817. *Soil.* The vine will thrive in any soil that has a dry bottom; in such as are rich and deep, it will grow luxuriantly and produce abundance of large fruit; in shallow, dry, chalky, gravelly, or schistuous soils, it will produce less fruit, but of better flavor. The greater part of the vineyards of France, *Bosc* observes (*Cours complet d'Agriculture*, &c. art. *Vigne*), are on a soil *argil-calcareous*: sometimes primitive, as those near Dijon; and sometimes secondary, as those at Bourdeaux. Argillaceous gravel is the next in frequency, as near Nismes and Montpellier, and that which produces the *Vins des Graves* of Bourdeaux. Both good and bad wines are produced from the *débris* of granites; among the former are the *côtes roties* and hermitage on the Rhone. The excellent wines of Anjou are made from vines growing among schistuous rocks. Wines which are made from vines planted in chalky soils, are weak, colorless, and do not keep well, as those of Champagne. Wines grown on the ashes discharged from volcanoes are excellent, as those of Vesuvius and Etna. Soils surcharged with oxide of iron, red or yellow, are not less proper for making good wine. Retentive clays are the worst soils for the vine; the flowers are in great part abortive; the fruit, if it sets, does not ripen; the shoots not ripening well are more easily affected by frosts; and the wine, if any can be made, is weak and flavorless. Such a soil, even when in a warm climate, is particularly obnoxious to the vine, as *Bosc* observed in the botanic garden established at Charleston, in South Carolina, by Michaux. There vines brought from France produced for six months in the year, buds, leaves, and shoots; flowers, the greater part of which proved abortive, and green and ripe berries. This circumstance, he considers, will prevent the successful culture of the vine in that part of America.

4818. *Switzer* observes, that the soil for the vine should be light, having a bottom of chalk or gravel under a surface of about two feet deep and free from springs; it cannot be too hot nor too dry, provided it be not in its own nature so very barren that nothing will grow upon it. If given to brambles, it is a certain sign of fitness, as no plant whatever is so co-natural to the vine as this shrub. In chalky-bottomed lands, and in gravel, which is not springy or spewy, grapes are the largest and sweetest of any; and where these are most abundant, we dare challenge even Paris itself to excel us. (*Pr. Fruit Gard.* 149.)

4819. *Hilt*, having observed a vine at Belvoir Castle growing out of the stony foundation of a wall, without any other roots than what were fixed therein, producing better fruit, and earlier ripe, than any other in the open ground in these gardens, advises the mixture of lime-rubbish, brick-bats, &c. for a foot deep in the bottom of wall-borders destined for the vine. (*Tr. on Fr. Tr.* 12.)

4820. *Lawrence* says, "he cannot easily be brought to think that any soil or situation can be too dry for the roots of the vine, after having seen at Barnwall, near Oundle, a flourishing vine grow from between the joints of an old castle-wall, near twenty feet high from the ground, and which produced admirable crops of grapes when well managed." (*Fruit Gard.*)

4821. *Speechey* says, "the soil in which I have known the vine to prosper in the most superlative degree without artificial aid, was a kind of rich sandy loam, intermixed with beds of materials like jointed slate or stone, so very soft in its nature as almost to be capable of being crumbled between the fingers." Strong and deep lands most suitable for tillage are the least so for vines, and hence the introduction of vineyards would have no bad effect respecting agriculture." (*Tr. on the Vine*, 29.)

4822. *Manures.* Dung, *Speechey* observes, should not be permitted to approach the roots of vines till it be perfectly reduced to a kind of black mould. Soot, wood-ashes, pigeons' and hens' dung, he considers too hot for the root of the vine; pond-mud and moor-earth too cold. Stableyard-dung is too spirituous, hot, and fiery, when introduced before its heat is thoroughly abated. Some sorts of lime are bad; but others might be advantageous, if introduced into vine-compost. "Vines are greatly injured in their roots by the common practice of laying lime-rubbish for the bottom floor in the preparation of the ground. Blood, the offal of animals or shambles' manure, horn-shavings, old rags, hair, shavings of leather, bone-dust, dung of deer and sheep, and human ordure," are admissible when duly meliorated by time, a win-

ter's frost, and repeatedly turning over. The dust and dirt of roads, Speechly greatly esteems as a manure for vines; its fertile nature he attributes, "in part, to the dung, urine, and other rich materials of which it is composed; and in part to a kind of magnetic power impressed upon it by friction, and its perpetual pulverisation." (*Tr. on the Vine*, p. 37.) Cow-dung is generally preferred for the vine in France; but the vine-growers take every sort they can get: the more careful, however, form composts of earths, leaves, weeds, cleanings of ditches, rivers, and ponds, which they turn over a year at least before using. In some places, littersy dung is buried in trenches between the rows; but in general, the dung, of whatever kind, is spread on the surface, and regularly dug in. Green crops are sown and dug in in some places. (*Cours. Complet*, &c. art. *Vigne*.) Forsyth considers the best manure for vines to be a mixture of vegetable mould, rotten spit-dung, and fresh loam; these ingredients should be thrown into a heap, and frequently turned a year or two before it is used. The vine is allowed by all gardeners to be a gross feeder; the fertility of both the Hampton Court and Valentine's vines are attributed to their roots having found their way, the former into a large common sewer, and the latter into a pond of stagnated muddy water. (*Hort. Trans.* iii. 337.) Some vines in the hot-houses at Earl's Court produced abundance of blossoms the second year from the eye, and the young wood of the same vines the third year is now (June 1. 1820.) throwing out laterals with large bunches of flowers; so that these vines the third year are producing two crops, one of which is now ripe and the other in blossom. The cause of this extraordinary fertility appears to be the soil of the border, which is composed of equal parts of garden-earth and blood mixed together, and repeatedly turned over one year before using.

4823. *Vine-walls.* A south wall is always to be preferred for vines; though, in some years, the hardier sorts may attain a tolerable degree of perfection on a wall considerably inclined to the east or west. Vines, Speechly observes, do well on low walls six feet high; and it has been found that the plants grow stronger, and afford larger grapes when they do not exceed four or five feet in height; they enjoy in this way both the reflected heat of the wall and of the earth. Flued walls have been tried for vines in some parts of the north of England; but Speechly, and English gardeners in general, do not approve of the practice. In Scotland, though flued walls are more common and better understood, yet vines are seldom planted in the open air. For standards or plantations in the way of vineyards, Switzer recommends, "that side or declivity of a hill lying to the south or south-east, which, if favored with other hills, somewhat higher, clothed with wood on the north, north-east, and north-west, will break the severity of those perishing quarters." Speechly concurs in this opinion, adding, that the hills in the counties bordering on the English channel, have in general declivities tending to the south, and are, therefore, highly favorable for vineyards. Steeps of poor gravelly and rocky soils, in warm situations, would produce more under vines than under any other crop.

4824. *Sorts for the open air.* Some of these have been already enumerated. (4801.) And an addition may be made from the hardy sorts described in the table.

4825. *Planting.* Where a wall is to be entirely covered with vines, three plants of a sort may be planted at the distance of three, or if a large-leaved kind, of four feet from each other; the two outer plants to be considered as temporary, to fill the wall and produce a supply of fruit; and the centre plant to be considered as permanently to fill the space occupied by the other two. The temporary plants will, therefore, be trained chiefly on the upper part of the wall, and the permanent ones below; and in four or five years the latter will be in a state to cover the wall, when the former may be rooted out. When vines are only planted in the intervals between other fruit-trees, or on piers, to be trained within a narrow upright space, then one plant to each is sufficient. Some however, as Forsyth, place two against a pier, one on each side; but this is more to obtain a variety of sorts than to fill the space.

4826. *In pruning and training in the open air*, any of the modes described as applicable to forced vines (2965.) may be adopted. As they break more regularly in the open air than when forced, the spur-method (*fig.* 455.) and the fruit-tree method (*fig.* 456.) seem to deserve the preference.

4827. *Williams*, of Pitmaston, (*Hort. Trans.* iii. 250.) describes a mode of training so as to fill up the vacancies of other fruit-trees, which seems well deserving attention. "A vine," he says, "might be trained horizontally under the coping of a wall to a great distance, and by inverting the bearing shoots, the spaces between the other fruit-trees and the top of the wall could readily be filled up, and if different vines were inarched to the horizontal branch, the south wall of a large garden might be furnished with a variety of sorts from the stem and root of a single plant, the roots of which would not encumber the border in which the other fruit-trees were growing. I have an experiment of this kind now in progress in my garden. With a few years past, I have gradually trained bearing branches of a small black cluster-grape to the distance of nearly fifty feet from the root, and I find the bunches every year grow larger, and ripen earlier as the shoots continue to advance. According to Knight's theory of the circulation of the sap, the ascending sap must necessarily become enriched by the nutritious particles it meets with in its progress through the vessels of the albumen; the wood at the top of tall trees, therefore, becomes short-jointed and full of blossom-buds, and the fruit there situated attains its greatest perfection. Hence we find pine and fir trees loaded with the finest cones on the top boughs, the largest acorns grow on the terminal branches of the oak, and the finest mast on the high boughs of the beech and chestnut; so likewise apples, pears, cherries, &c. are always best flavored from the top of the tree. But I suppose there are certain limits beyond which the sap would be so loaded with nutriment that it could not freely circulate."

4828. *Training the shoots of vines along the ground* like those of melons and cucumbers has been proposed by Vispre (*Dissert. on the Growth of Wine in Eng. Bath, 1786.*), and was practised by him on a small scale at Chelsea, where "the grapes were considerably larger than those of the same kind growing on a south wall, and well ripened." Bacon had before suggested this mode, from a report that "in some places these vines are suffered to grow like herbs, spreading upon the ground, and the grapes of these vines are very large, &c." It appears from Vispre, that the Rev. M. Le Brocq had taken out a patent for training fruit-trees in this manner. Speechly says, "Fruit-trees of various sorts have been so trained at Welbeck for fourteen years;" and we have seen the practice adopted in the Earl of Selkirk's garden at St. Mary's Isle in Kircudbrightshire, above fifteen years ago.

4829. *Growing the vine on espaliers.* This may be done, following the same directions in all respects as for walls; but it is evident that, under such treatment, the fruit will not come to the same degree of maturity as when enjoying the shelter and reflection of a compact screen. Where wine is made from green grapes, as is now frequently done, the practice may be preferable to growing the vine as dwarf standards.

4830. *Growing the vine as standards.* This practice may be adopted either in the borders of gardens, or in extensive plantations as vineyards, and the plants may be trained either like red currants or raspberries. In the former case no stakes are used; but about a foot from the ground, three or more shoots,

eighteen inches or two feet in length, diverge from the stem, and supply young wood annually for bearing. The summer pruning consists in removing shoots which have no fruit, or are not wanting for the succeeding season; in topping fruit-bearing shoots, and also those for the succeeding years, when inconveniently long and straggling. For as by this mode the shoots destined to bear are all cut into three or four eyes at the winter season, no inconvenience arises from their throwing out laterals near the extremities, which stopping will generally cause them to do. This mode is adopted in vineyards on dry rocky situations where they do not run much to wood. In training standard vines, as raspberries, the single stem at bottom is not allowed to exceed six or eight inches in height, and from this two or three shoots are trained or tied to a single stake of three or four feet in length. These shoots bear each two or three bunches within a foot or eighteen inches of the ground, and they are annually succeeded by others which spring from their base; that is, from the crown or top of the dwarf main stem. This is the mode practised in the north of France and in Germany; in the south of France and in Italy, the base or main stem is often higher, and furnished with side shoots, in order to afford a greater supply of bearing wood, which is tied to one or more poles of greater height. The summer pruning in this case is nearly the same as in the last. In the winter pruning, the wood that has borne is cut out, and the new wood shortened in cold situations to three or four eyes, and in warmer places to six or eight eyes.

4831. *Formation of vineyards.* A vineyard is a collection of standard vines, planted in rows of a greater or less width, according to the height and mode of training proposed to be adopted; and according as the soil may be rich and deep, or poor and thin, or its surface flat or inclined. A square yard of surface to each plant, when they are kept low, may be considered as a desirable medium.

4832. *Where plantations of vines are made on the sides of very steep hills,* it is sometimes customary to form the surface into terraces or horizontal beds rising one above another. The width of these beds or terraces depends on the regular or irregular declivity of the hill. When the declivity is regular and the hill steep, each terrace is narrow and supported by a wall, against which the vines are planted and trained as on low garden-walls or espaliers; but, in general, the irregularity of the declivity and surfaces of hills, causes a very great inequality in the breadth and height of the terraces, and in these cases the vines are planted as standards, according to the room afforded by the platforms of the terraces. The walls which support these platforms in vine-countries, are generally too rude to admit of training against them, and therefore one of the standard modes above described is almost always adopted.

4833. *Sorts of grapes proper for a vineyard.* On the continent the vines reckoned best for making wine are by no means the most agreeable to eat; and there is always a clear distinction made between fruits to eat, and fruits for the press, by the nurserymen, who, in general, have only plants of the former sort for sale. The names of vineyard-grapes vary in every district; so that were it desirous to procure sorts from France or Germany, only a general order could be given. In this country, however, it would probably, in the event of planting a vineyard, be found preferable to select from the sorts already acclimated, and rendered hardy by many years' culture and propagating from seed, such as the clusters, sweetwaters, esperione, &c. The sorts planted in the vineyard at Painshill, were the Burgundy, or large black cluster, and the miller-grape, or small black cluster. The vineyard-grapes in France, Germany, and Italy, and we are informed, in Spain, Portugal, and every other wine-country, may be considered as varieties or subvarieties of the black cluster; and the vines which are grown to produce sweet wines, as the Constantia and Malmsey Madeira, variations of the chasselas or muscadine.

4834. *Making of wine from grapes.* The making of wine is a part of domestic economy that can hardly be considered as included under gardening. We shall, therefore, merely suggest, that where grapes are to be pressed in any quantity, the management of the liquor should not, if possible, be left to mere empiric practitioners. Some knowledge of the general principles of fermentation will help to guard against accidents, and direct in doubtful cases. The assistance, therefore, of a person possessing some knowledge of chemistry, or one who has been concerned in the manufacture of British wines, will be found desirable on such occasions. An excellent paper "On the Processes of Wine-making," will be found in the second volume of the *Memoirs of the Caledonian Horticultural Society*, by Dr. Macculloch, of Woolwich. Mat. thews (in the *Hort. Trans.* ii.), has given a receipt for making a very tolerable sort of red wine from the leaves of the claret grape; these leaves, it is suggested, might be employed to give color to wine produced from certain sorts of white grapes, green gooseberries, or other fruits producing a colorless fermented liquor.

4835. *Insects which infest the vine.* The red spider, of which there are many sorts, attacks the leaves in spring, or early in summer; increases prodigiously in dry weather, and soon damages and destroys the foliage. Speechly says, red spiders "generally reside and breed on the under side of the leaves, and the infested leaves are very distinguishable as soon as they are attacked by them, for the insect wounds the fine capillary vessels with its proboscis, and this causes the upper surface of the leaf to appear full of very small dots, or spots of a light color. When the acari are very numerous, they work a fine web over the whole under side of the leaf, as also round the edges thereof; and it is curious enough to observe, that they commonly carry this web in a straight line, from one angular point of the leaf to another, on which boundary line, in a warm day, they pass and re-pass in very great numbers. Watering is the only effectual means of destroying this insect." (*Tr. on the Vine*, 162.) The thrips (*Thrips*, L. Latr. and Leach.) is more injurious to vines in the forcing department than to those in the open air. However, if young shoots chance to receive any injury from late spring frosts, the tender part of the leaf will immediately curl up, and change to a dark-brown color; and in this state, the thrips generally attacks them with great greediness, especially the white sweetwater and white muscadine kinds. The green fly sometimes attacks vines; but seldom so as materially to injure them. Smoking destroys

both insects There are two or three kinds of cocci, or turtle insect, that sometimes infest the vine, (*Coccus hesperidum* and *adonidum*,) but they rarely do much injury in the open air.

4836. *The blue fly* (*Musca vomitoria*, Latr.) attacks the fruit when nearly ripe, before the wasp or birds begin to devour it. Forsyth says, "As soon as it makes its appearance, you must provide betimes plenty of bottles, a little more than half filled with some sweet liquor, to entice them to enter and be drowned. Hang the bottles on the nails, at proper distances, all over the vines, and also place some of them at the bottom of the wall."

4837. *The wasp* (*Vespa vulgaris*), and in some places the hornet (*V. Crabro*, fig. 506.), attacks the fruit like the blue fly, and is to be destroyed in a similar manner; or by tying up the bunches in gauze bags.

4838. *Birds of various species*, but chiefly the smaller kinds which may abound in the neighborhood, also attack grapes. A few of them may be shot and hung up as scares; or bagging may be adopted; or where there is a full regular crop over the wall, trellis, or standards, the trees may be protected by netting or bunting. The latter will protect them also from the fly and wasp.

SUBJECT. 3. Fig.—*Ficus Carica*, L. (Trew. Ehret. t. 73, 4.) *Polygam. Diœc.* L. and *Urticeæ*, J. *Figuier*, Fr.; *Feigenbaum*, Ger.; and *Figo* or *Fico*, Ital.

4839 *The fig-tree* is a low tree, a native of Asia and Barbary; naturalised in Italy and the south of France, and enduring the open air in the mildest parts of Britain. The fig-tree in France and Italy grows as large as our apple-trees, but in this country seldom exceeds two yards in height; the trunk is about the thickness of the human arm; the wood, porous and spongy; the bark, ash-colored; the branches smooth with oblong white dots; the leaves annual in Europe, but perennial within the tropics, cordate, ovate, three or five lobed, thick, and the size of the hand. The fruit is a berry, turbinate and hollow within; produced chiefly on the upper part of the shoots of the former year, in the axils of the leaves on small round peduncles. The flower is produced within the fruit; what is considered as the fruit being a common calyx or receptacle: the male flowers are few, and inserted near the opening in the extremity of the receptacle, or fruit; the female flowers are very numerous, and fill the rest of the hollow space within. The greater part prove abortive, both with and without the process of caprification. The fig forms an important article of culture in the isles and borders of the Mediterranean sea, and especially in Greece, Italy, and Spain. It is also much cultivated for drying in the south of France; and for the table, at Argenteuil, near Paris. The earliest notice we have of its culture in England is by Turner in 1562. The first trees were brought over from Italy by Cardinal Pole, in 1525, during the reign of Henry the Eighth, and yet exist in the gardens of the archbishop at Lambeth. They are of the white Marseilles kind, and still bear delicious fruit. They cover a space of fifty feet in height, and forty in breadth; the circumference of the trunk of two of the trees is twenty-eight, and of another twenty-one inches. In the severe winter of 1813–14, these trees were greatly injured, and in consequence their principal stems were cut over near to the ground; but they are fast recovering. At Oxford, in the garden of the Regius Professor of Hebrew, is a fig-tree, which was brought from Aleppo, and planted by Dr. Pocock, in 1643. It is in a thriving condition, and bears a black fig. Gerrard says, "the fig requires a hot-wall;" and Parkinson, that they are planted in great square tubs, to be removed into the sun in the summer time, and into the house in winter. The culture of the fig was little known here till the time of Miller, who introduced above a dozen new sorts from Italy. He observes, that the generality of Englishmen are not lovers of this fruit, and that, therefore, few trouble themselves with the culture of it. Since Miller's time, the fig has been introduced to the forcing department, and there cultivated to a much higher degree of perfection than before on open walls; and though it be still true, that a taste for the fig in its green or fresh state is less prevalent in England than elsewhere, yet, by those who have been some time abroad, it is generally much esteemed.

4840. *Monck* "believes the fig-tree to be of all the fruit-trees which we cultivate in our gardens, the least understood; but, to those who may have acquired a knowledge of its habits, the most tractable. No tree is propagated more easily. I sent from London in April last to Kelsay in Northumberland, two cuttings of figs. They were so small as to travel by the post in a common letter-cover. I have gathered this autumn from one of them three ripe figs, and two from the other. The fig-tree may be checked in its useless habit of luxuriant growth by ringing, so as to become fruitful at a very small size. It may be forced by heat and liquid manure, with copious irrigation, so as to support an abundant crop of fruit, and bring them to perfection, to a greater extent than any other tree. Spare branches of a large fig-tree growing out of doors may be ringed, and surrounded by a small pot of earth, into which they will speedily strike root, so as to bear being separated in autumn from the tree; and they may be used to furnish any glass houses with trees to bear fruit through the next summer. I believe, too, that the fig-tree may be easily propagated by inoculation, if that should be desired." (*Hort. Trans.* v. 173.)

4841. *Use.* It is cultivated here entirely for the dessert; but in fig-countries it is eaten green or dried, fried or stewed, and in various ways, with or without bread or meat, as food. Abroad the fig is introduced during dinner, as well as at the dessert.

In common with the melon, it is presented after soup; and the person who cuts a fig, holds it by the small end, takes a thin circular slice off the large end, and then peels down the thick skin of the fruit in flakes, making a single *bonne bouche* of the soft interior part. All the species of the genus *Ficus* have more or less the quality of interenerating animal fibre, like the pawpaw-tree (*Carica papaw*); the *F. elastica* in the greatest degree, and next, the common fig. The milky sap may be used as rennet, and for destroying warts. Philips says, "a gentleman who lately made the experiment, assured me that a haunch of venison, which had lately been killed, was hung up in a fig-tree when the leaves were on, at about ten o'clock in the evening, and was removed before sunrise in the morning, when it was found in a perfect state for cooking, and he adds, that in a few hours more, it would have been in a state of putrefaction." (*Pom. Brit.* 169.) Burying in the soil for ten or twelve hours is a well known and effectual resource for interenerating recently killed fowls, or tough butcher-meat.

4842. *Varieties.* These, in fig-countries, are almost as numerous as those of the grape; new sorts being readily procured from seed, and continued by cuttings, layers, or grafting. Bosc says, that even in France new sorts are continually produced, and as quickly falling into neglect. The varieties most esteemed in England are the following: those marked thus (*) will ripen as standards under favorable circumstances.

*Brown chestnut-colored Ischia (Island of Ischia). This is one of the largest that we have: it is of a brown or chestnut color on the outside, and purple within; the grains are large, and the pulp sweet and high-flavored. It ripens in August; and if planted against a hot-wall, two crops may be obtained annually.

*Black Genoa fig. This is a long fruit of a dark purple color, the inside being of a bright red, and the flesh very high-flavored. It ripens in the latter end of August.

*Small white early fig. (*Langley Pom.* 52.) The skin of this fruit is of a pale yellow when ripe; the flesh is white and sweet. It is ripe about the latter end of August or beginning of September.

*Large white Genoa fig. (*Poit. et Turp. Fr.* t. 4.) This is a large fruit, the skin is thin and yellow when ripe, and red within. It is a good fruit, and is ripe about the latter end of August. This and the preceding bear two crops annually.

Black Ischia fig. This is a middle-sized fruit; the skin is almost black when

ripe, and the inside of a deep red. The flesh is high-flavored, and the trees good bearers.

Brown and black small Italian figs. These are cultivated in pots; the fruit is small, round, and very delicious. Forsyth gathered from one plant in a twenty-four pot, two dozen of figs at one gathering.

Malta fig. This is a small brown fig; the skin of a pale brown, the inside of the same color; the flesh is sweet and high-flavored. It is ripe in August and September.

Murrey; brown Naples fig. This is a pretty large fruit, of a light brown color, and the inside nearly of the same color; the flesh is well-flavored; and it ripens about the middle of September.

Green Ischia fig. This is an oblong fruit with a green skin; but being thin, is stained through of a brownish cast by the pulp when full ripe. The inside is purple, and the flesh high-flavored. It is ripe about the middle of September.

Madonna, Brunswick, or Hanover fig. This is a large pyramidal fruit; the

skin brown; the flesh a lighter brown, coarse, and has but little flavor. It ripens about the middle of September.

Common blue or purple fig. (*Duham.* n. 2. tab. 2. f. 1.) This is a large oblong fruit, ripens in August, and is a good bearer.

Long brown Naples fig. The skin of this fruit is of a dark brown when ripe; the flesh inclining to red. It has large grains and a good flavor, and ripens about the beginning of October.

Small brown Ischia fig. This is a small pyramidal fruit; the skin of a light brown; the flesh of a purple cast, and of a high flavor. It ripens in October.

Yellow Ischia fig. This is a large fruit; the skin yellow; and the flesh purple and well flavored. It ripens in October.

Gentile fig. This is of a middle size; roundish fruit; the skin yellow; and the flesh inclining to the same color. It has large grains, and a good flavor. ripens very late; and the trees are but indifferent bearers.

4843. According to Forsyth, the figs proper for a small garden are the

Large white Genoa | Early white | Murrey fig | Small brown Ischia | Black Ischia.

4844. Sawyer recommends for a regular succession of figs from August to October, inclusive, the

Brown Ischia, Large white Genoa,
Green Ischia, Brown Naples, White

Marseilles, Black Province, Yellow
Ischia, and Gentile; which ripen in

the order in which they are here placed, from the middle of August to the end of October.

4845. *Propagation.* Figs may be propagated from seed, cuttings, layers, suckers, roots, and by ingrafting; the most generally approved method is by layers or cuttings, which come into bearing the second, and even the first year.

4846. *By seed.* Here the same process as that directed for raising seedling vines is to be followed, with this difference, that the young plants should not be cut down on account of their mode of bearing. They will produce fruit in the sixth or seventh year. The process of crossing to obtain new varieties can here be performed only in the general way, of placing two or more sorts together; or of introducing with a small hair pencil the pollen from the father variety, to take effect in conjunction with that of the male blossoms in the plant destined to bear seed. Possibly, however, some curious horticulturist may find a mode of cutting out the male blossoms without destroying the females; in which case the pollen from the father variety may be introduced to take effect alone. Lee, of Hammersmith, has raised several new sorts from seed.

4847. *By cuttings.* These are formed of young wood from eight inches to twelve inches in length, with an inch or two of old wood attached. They should be taken from the most fruitful, well ripened, short-jointed boughs in autumn, and either preserved from the frost till spring, or planted in pots or in a bed of earth from six to nine inches deep, without cutting off their tops. The soil should be a loam inclining to sand, and in a warm situation; it should be covered with old bark, leaves, or ashes, to keep out the frost in spring, and the drought in summer. If the cuttings have been planted in autumn, then their tops will require the additional protection of hawl or litter during winter. Give water and keep clear of weeds during summer, and by the following autumn, the plants will be fit to be transplanted into nursery rows; where they must be again mulched at root, and protected at top. They require no pruning farther than what may be required to rear them with a single stem, and keep their heads of a regular shape; the second or third year they may be removed to where they are finally to remain. Cuttings of roots readily make plants, but the process is too slow for general use, and the plants so produced are not likely to come so soon into bearing as by the layers or cuttings.

4848. *By layers.* This is the quickest mode of getting bearing trees, as shoots of two or three years' growth, if laid down, will make abundant roots the first summer, and admit of being taken off and placed where they are finally to remain in the autumn. Miller says, "young shoots or suckers produced from old stools should never be taken, as they are too soft and spongy, liable to be affected by frost, and not likely to prove good bearers."

4849. *By suckers.* This is an easy, but a bad method, for a common reason, that all trees raised from suckers are subject to send out great quantities of suckers again from their roots, which branches are never compact and fruitful, because too luxurious to be ripened in our climate. Miller says, "this vicious habit, contracted while the trees are young, may be afterwards corrected."

4850. *By grafting.* This mode can only be advantageously adopted in cases similar to those recommended for grafting the vine. (4813.) The process by any of the modes readily succeeds, and we have seen in Italy above a dozen sorts of figs on one tree.

4851. *Culture.* For the culture of the fig in the *Forcing Department*, see Chap. VII. Sect. V. In the open air, the plants are grown as standards, espaliers, and against walls; but, as already observed, the fruit produced in any of these situations is of very inferior flavor to that grown under glass. A crop of figs, Miller observes, is generally more uncertain than that of any other fruit: and Neill says, Britain is certainly not the country for figs. From the attention now paid to this fruit, however, by some eminent horticulturists, we may hope for improvement, and, at any rate, for a more general taste for the fruit.

4852. *Soil.* The fig-tree thrives in all soils not wet at bottom; but they produce a greater quantity of fruit upon a strong loamy soil than on dry sandy ground, a dry soil being apt to make them cast their fruit. Miller says, "I have always observed those fig-trees to bear the greatest quantity of well flavored fruit which were growing upon chalky land, where there has been a foot or more of a gentle loamy soil on the top. They also love a free open air; for although they will shoot and thrive very well in close places, yet they seldom produce any fruit in such situations." Smith (*Caled. Hort. Mem.* vol. ii.), after trying several soils, found the fig-tree thrive best in a rich friable loam, free from latent water at bottom.

4853. *Growing the fig as standards.* In fig-countries, this tree is always grown as a standard; and here dwarf standards, planted in very warm situations, will, in very favorable seasons, afford tolerable crops of fruit. Some of the best in England are at Arundel Castle; and there is a fig-orchard of 100 trees at Tarring, and another of 14 at Tompting, near Worthing. (*Hort. Trans.* vol. iv. 505.) Those at Arundel are planted six or eight feet apart, and from a single stem allowed to continue branching into regular conical heads; pruning chiefly irregular and redundant growths, and cutting out decayed or injured wood. Miller says, standard fig-trees, when protected during winter, generally bear better than those against walls; which, however, may be considered as in great part owing to the mode of training and pruning figs in the latter situation not having then been generally understood. At Argenteuil, where the fig is cultivated in immense quantities for the supply of the table, the plants are grown as dwarf standards; and the chief part of their culture, Bose observes, consists in keeping their branches short, low, and spreading, to enjoy both the heat of the sun and reflection of the earth. The ground is manured occasionally, and stirred at least once a-year; and for protection from the frost during the winter, the circumferential low branches are buried six inches in the soil, and the central ones enveloped in litter.

4854. *On espaliers.* Where figs will succeed as standards, they will also thrive against espalier-rails; in which situation they admit of being more readily covered or protected during winter. The plants may be placed at ten or twelve feet distance, and trained in the fan or horizontal manner.

4855. *On walls.* This is unquestionably the best mode for our climate, as it admits of more readily protecting the plants during winter, and is more likely to bring the fruit to maturity in the summer or autumn. The distances at which the plants are placed will depend on the height of the wall. In general, a low wall is to be preferred, both because the fig is naturally adapted for being kept low, and because, when low, it admits more readily of protection. The plants may be placed from fifteen to twenty feet apart, with temporary trees of the fig, peach, or any other fruit between.

4856. *Mode of bearing.* "The fig-tree," the Hon. W. Wickham observes, "is distinguished from most, if not from all, other trees, by this extraordinary property, that it bears, and, in warmer climates, brings to maturity, in every year, two successive and distinct crops of fruit, each crop being produced on a distinct set of shoots. The shoots, formed by the first or spring sap, put forth figs at every eye, as soon as the sap begins to flow again in July and August. These figs (which form the *second crop* of the year,) ripen, in their native climate, during the course of the autumn; but rarely, if ever, come to perfection in England, where, though they cover the branches in great abundance, at the end of that season, they perish, and fall off, with the first severe frosts of winter. The shoots, formed by the second flow of sap, commonly called midsummer shoots, put forth figs in like manner at every eye, but not until the first flow of sap in the following spring. These last mentioned figs, which form the first crop of each year, ripen, in warmer climates, during the months of June and July, but not in this country before September or October. In warmer climates, indeed, very little attention is given to this first crop, because the midsummer shoots, on which it is borne, are commonly in the proportion only of one to six or eight in length, when compared with the shoots of the spring, which produce the second crop; and the crop itself is always small, in the same proportion. But in England, it is the reverse. As no care or skill of the gardener can ever ensure a second crop of ripe figs in the open air."

4857. *Pruning and training.* Most gardeners, Miller observes, imagine that fig-trees should never have much pruning; or, at least, that they should always be suffered to grow very rude from the wall to some distance. A *pruned fig-tree never bears*, is a common saying, nor, according to Wickham, can its truth be denied, when applied to the most common method of pruning these trees, *i. e.* by cutting away or shortening the last year's shoots, instead of cutting away old wood, and training those shoots to the wall in its place.

4858. Wickham recommends a system of pruning which may increase the proportion which the midsummer shoots (the only ones, as stated above, which produce fruit that ripens in this country,) bear to the spring shoots, both in number and length. For this purpose, he breaks off the spring shoots as they nearly attain their full growth, and just as the spring sap in each begins to abate something of its full vigor. He breaks them at moderate distances (six to fifteen inches, according to the strength of each shoot), from the place whence they severally spring, taking care that enough of the shoot be left to admit of its being bent back, and nailed close to the wall at the ensuing winter pruning, and that one eye, at least, be left uninjured by the fracture, and always preserving a quantity unbroken, sufficient to keep up a future supply of branches and wood. The shoot may be either broken short off, or left suspended by a few ragged filaments, which may afterwards be separated with a knife, when the spring sap has ceased to flow. The former mode is less unsightly, and will therefore be generally preferred by the gardener; but the latter has been found more successful in practice. It is of consequence, however, to the full success of this system, that the shoots should be broken and not cut. If left to their natural growth, or shortened by a sharp smooth cut with a knife (instead of a fracture), they would produce, at their extremities, only one single midsummer shoot, being a simple prolongation of the wood, formed in the spring; but when the shoot is broken at the time, and in the manner above described, it generally happens that, on the second flow of sap in July, two or three more shoots (forming a kind of stag's horn) are pushed from the fractured part instead of one; and it is hardly necessary to add, that each of these, according to its length, will produce several figs in the ensuing spring, (making the first crop of that fruit,) all of them capable of being ripened by our ordinary summer and autumn heats. A sufficient supply of midsummer shoots being thus procured during the summer, room must be made for them at the succeeding winter pruning, by cutting away so much of the old wood as will admit of their being all trained in, at full length, and nailed close to the wall, which should always be done before the first severe frosts. Keeping this object in view, the knife cannot well be used too freely in cutting away the old wood, nor is there any reason to fear that its free use will either injure the future crops, or deprive the tree of its regular supply of branches. The midsummer shoots being trained in, each of them will produce, in the following

year, one spring shoot, at least, at its extremity, whilst another will rise from each eye of the remnants of the old spring shoots that had been preserved in the manner above described, when these shoots were broken, in the preceding month of June. From this fresh supply, by pursuing the system here explained, either wood or fruit, or both, may be obtained for the succeeding year, at the discretion of the gardener. Where he wishes for wood, he must suffer these new shoots to grow to their full length : where fruit, and not wood, is desired, he must break them in the month of June, in the manner and with the precautions that have been minutely explained. (*Hort. Trans.* vol. iii. 74. et seq.)

4859. *Knight* disapproves highly of training the branches of fig-trees perpendicularly, as encouraging too much the prolongation of the shoots ; he approves of *Wickham's* mode in warm situations, but in high cold situations, he radiates his branches from the top, and parts near it, of a single stem. He says, "Let the stems, if there be, as usual, many within a narrow space, be gradually reduced to one only ; and from the top, and parts near it, of this, let lateral branches be trained horizontally and pendently, in close contact with the wall. Under such treatment, all troublesome luxuriance of growth will soon disappear ; the pendent shoots will not annually extend more than a few inches, and few or no more leaves will be produced than those which the buds contain before they unfold. The young wood consequently ceases to elongate very early in the season, and thence acquires perfect maturity ; and by being trained close to the wall, is placed secure, or nearly so, from injury by the severest frost. The quantity of mature and productive young wood thus necessarily become very great, relatively to the size of the tree : and the fruit being in contact with the wall, and not shaded by excess of foliage, acquires an early and perfect maturity." (*Hort. Trans.* vol. iii. 307.)

4860. *The Rev. G. Swayne*, from the various papers on the culture of the fig-tree, published in the *Horticultural Transactions*, but particularly from that of *Wickham*, infers, "that the principal defect requiring a remedy is a deficiency of fruitfulness, or bloom, in the early spring, on the whole of the last year's shoots, excepting on the few joints at their extremities," and he describes a remedy which he has for a long time been in the habit of using, and which he "considers as a specific." It is simply to rub off, as soon as they can be discovered by the naked eye, all the figs which are produced after midsummer on the same year's shoots. The object is not only to prevent those figs which would never ripen without artificial heat to exhaust the tree, but to give it sufficient time to employ the strength which would have been employed in nourishing these "sterilising incumbrances," in the seasonable preparation of new embryo figs for the following year. "If this operation," he says, "be performed in due time, it will not fail to prepare on one, and often on both sides, of almost every fig so displaced, such embryos. For this purpose, the trees should be examined once a-week, from the beginning of August, at which time the figs of this second crop usually begin to show themselves, and this examination must be repeated as long as any of these make their appearance." Most gardeners, he says, omit removing these late figs at all, or delay the practice till October or November, when no benefit is derived from it. He trains the trees horizontally, and does not prune them till late in the spring, when he can plainly distinguish between a leaf and a fruit-bud, as well as appreciate the whole of the mischief occasioned by the frosts of the preceding winter. (*Hort. Trans.* vol. iv. 430.) The above practice, in connection with the mode of training recommended by *Knight*, would, we think, effect an important improvement in the culture of this fruit. *Wickham's* mode appears to excite too much the powers of the tree ; and the common mode of fan-training from three or four root-stems, which are in fact so many suckers, is only calculated to produce wood and leaves. Training the fig-tree on walls, as a rider, and in the stellate manner (*fig. 386. c.*), and pinching off all the embryo fruit after midsummer, would probably effect every thing that can be desired in the culture of this tree on the open wall in this country.

4861. *Protecting during winter.* This is found necessary in many parts of France, and every where in Britain. *Miller* recommends tying together the branches of standards, and applying pease-haulm, straw, or any other light covering ; rolls of reeds to be placed on each side of espaliers, removing these coverings in mild weather, to prevent the figs from coming out too early. *Forsyth* covers fig-trees against walls with "laurel, yew, fir, or spruce boughs," and then "tucks in short grass or moss among the branches." *Smith* covers with spruce fir branches, from three to six feet long, fastening them to the wall by the middle rib of the branches, at two different places. "To prevent any friction by the wind, the branches should be made to fit each other, that the covering may be of a regular thickness over every part of the trees. As the covering is generally put on the trees in the month of December, the branches remain green all the winter ; and in the month of March, when the days get long, the leaves begin to drop from the branches, and continue falling through April ; and by the beginning of May, when the covering is entirely removed, only the ribs of the branches are found remaining. Thus, the progress of the season reduces the coverings in a gradual manner, so as not to expose the trees to any sudden check, which might otherwise be the case, if they were all at once laid open to the weather."

4862. *Sawyer*, in November, detaches the branches of his fig-trees from the walls, picks off all the autumnal fruit that are larger than a filbert, or not of a dark shining green : he then ties the branches of the tree together in bundles forming a sort of cones, filling the interstices with dry hay, and wrapping mats round the whole. After this he lowers the cones to the right and left, and makes them fast to the wall with rope-yarn. In this state they remain till March, when the whole is undone, and the branches replaced and covered first with treble, then double, and lastly single netting, which last is removed in May.

4863. *Mean* (*Hort. Trans.* vol. ii.) adopted the French mode of burying the branches in the soil, in 1789, and has practised it with success ever since.

4864. *Wickham* observes (*Hort. Trans.* iii. 80.), in respect to covering fig-trees, that "much must be left to the care and skill of the gardener, whose precautions must be determined, as well as varied, by the situation, aspect, and local shelter belonging to each particular tree, and by the varying temperature of each particular winter ; but he may, however, be laid down as a general rule, that the covering, where used, should be as thin and light as a due consideration of all the above circumstances will admit, and that it should generally be removed in the day-time, and always on the return of moderate weather."

4865. *Ripening the fruit.* *Williams* suggests that the practice of taking off a circular ring of bark from the lower part of the branches of the fig, in the manner he has so successfully practised on the vine, might accelerate the maturity of the fruit. *Monck* tried ringing, and found that it may be practised on the fig-tree with "as much safety, and more effect upon the age of its fruit than on the pear-tree." (*Hort. Trans.* v. 172.) A very general French practice is to prick the fruit with a straw or quill dipped in olive-oil. In Italy, a wound with a knife is sometimes made on the broad end of the fig, or a very small part of the skin of the fruit removed for the same purpose. Brandy is also sometimes applied, either by a puncture on the side of the fruit with a bodkin dipped in the spirit, or by dropping a small quantity in the eye of the fruit. "Plums and pears," *Tournefort* observes (*Travels*, letter viii.), "pricked by insects, ripen the faster for it, and the flesh round such puncture is better tasted than the rest. It is not to be dis-

puted but that considerable change happens to the contexture of fruits so pricked, just the same as to parts of animals pierced with any sharp instrument." Monck split a fig from the eye to the stalk, and found it ripen six weeks before others that were untouched. (*Hort. Trans.* v. 172.)

4866. *The process of caprification of figs* is performed in the Levant to hasten the maturity of the autumnal crop, and consists in placing on the fig-trees what are called *figues-fleurs*, or spring figs, in which a certain insect of the gnat species (*Culex*, L.) has deposited its eggs. From these eggs, in the spring figs, proceed a multitude of gnats, which, in their turn, deposit their eggs in the autumn figs, or rather in their flowers, effecting in their passage the fecundation of these flowers, and, by consequence, hastening the maturity of the fruit. The most enlightened French naturalists are of opinion that this is a very unnecessary part of the culture of the fig. Olivier, member of the Institute, and author of a *Journey through the Ottoman Empire*, considers it as "a tribute which man pays to ignorance and prejudice." "In many countries of the Levant," he says, "it is not performed, nor is it done in France, Italy, or Spain; and it is now neglected in some of the isles of the Archipelago, where was it practised formerly." Bosc says, "the larva of the *Cynips*, in eating the interior of the figs, can be no otherwise useful than the larva of the *Pyrale pommonelle*, Hubner, (*Phalena*, Linn.) or apple-worm, can be in hastening the maturity of the apple: and who would take it upon him to advise rendering apples worm-eaten in order to enjoy the advantage of eating them a fortnight sooner?" This observation, it may be observed, rather confirms the idea that caprification hastens maturity, which, from what we have seen in the neighborhood of Rome and Naples, we believe to be the case. Though we think with Olivier, that it is by no means absolutely necessary to fecundation; and even if it were, that fecundation is not essentially requisite to the swelling and ripening of the fig.

4867. Monck has made some curious experiments and observations on this subject, from which he is led to conjecture, 1. That fig-trees never bear figs which contain both kinds of florets in an efficient state; 2. That figs in which the anther-bearing florets only are perfect, never come to be eatable fruit; 3. That you may pronounce, from the external shape of a fig, which kind of floret prevails — the stigma-bearing in the pear-shaped (fig. 507. a), the anther-bearing in the squat figs (b); 4. That fig-trees, which put forth crops of figs, and cast them, most probably do so from defect of setting. (*Hort. Trans.* v. 168, 169.)

4868. *Insects and diseases.* The fig is subject to few of either of these in this country. In forcing-houses it is liable, in common with other plants, to the attacks of the red spider, coccus, and aphides, and occasionally also on garden-walls. The remedies are obvious. In France they are attacked by a species of coccus, vulgarly called the fig-louse, which proves very injurious, and is only to be destroyed by rubbing them off with a coarse cloth.

SUBJECT. 4. *Melon.* — *Cucumis Melo*, L. *Monacica Monadelphia*, L. and *Cucurbitaceæ*, J. *Melon*, Fr.; *Melone*, Ger.; and *Mellone*, Ital.

4869. *The melon* is a tender annual, producing one of the richest fruits brought to the dessert, and cultivated in England since 1570; but the precise time of its introduction, and the native country of the plant, are both unknown. It was originally brought here from Jamaica, and was, till within the last fifty years, called the musk-melon. The fruit, to be grown to perfection, requires the aid of artificial heat, and glass, throughout every stage of its culture. Its minimum temperature may be estimated at 65°, in which it will germinate and grow; but it requires a heat of from 75° to 80° to ripen its fruit, which, in ordinary cases, it does in four months from the time of sowing the seed.

4870. *Varieties.* There are numerous varieties, many of which, especially those raised from seeds brought from Italy and Spain, are not worth cultivating. The best sorts are included under the name of cantaleupes, an appellation bestowed on them from a seat of the Pope near Rome, where this variety is supposed to have been originally produced. The general character of the *cantaleupes* is a roundish form, rough, warty, or netted outer coat; neither very large in fruit or leaves. The *Romanas*, the Italian sort, next in esteem, are generally oval-shaped, regularly netted; the fruit and leaves middle-sized, and the plants great bearers. Many varieties of both these sorts, however, that were formerly in esteem, are now lost, degenerated, or supplanted by others of Spanish or Persian origin. The following are among the best both of the old and new varieties: —

The early golden cantaleupe. It is deep-furrowed, middle-sized, longish, golden colored; flesh not very high-colored nor high-flavored. The plant grows freely, shows early, sets its fruit well; and is a very great bearer.

The orange cantaleupe. Smaller than the above, round, and pale-yellow. The flesh, when just fit for cutting, is orange; but when ripier, it is more red. As it swells and ripens, it becomes partly netted. In respect to flavor, it is excelled by none of the melon kind; being juicy, sugary, and rich. The plant is a free grower, an early setter, and a great bearer.

The netted cantaleupe. This is equally juicy and high-flavored as the last-mentioned; a good deal larger, round, solid, and very ponderous; having a very small vacuum for the seeds; and it may be eaten nearer to the rind than

most other kinds. The plant sets freely and is a good bearer.

The silver cantaleupe. Round, of a middle size, shallow furrowed; and when full-grown, before it begins to color, is all over mixed silver and green. A very good bearer.

The black rock cantaleupe. This is a very large-growing melon; round, black, or very dark green when full grown, but yellow when ripe. It is juicy, but not so high-flavored as any of the above cantaleupes, except the first-named; nor is the plant so good a bearer. Four or five fruit in a light is a medium crop.

The carbuncled rock cantaleupe. Two varieties, a large and a small; both very similar to the black rocks, as to color and flavor; but flat or cheese-shaped, and covered with large protuberances or carbuncles. The small-

kind bears pretty freely, and the large sort less so.

Lee's rock cantaleupe. Rather long than round, and more green than black. The flesh and flavor much the same as those of the last-mentioned variety.

The Italian green-fleshed cantaleupe. Small, nearly globose; usually about four inches and a half in diameter; coat pale greenish-white, moderately thin; flesh opaque, soft, and melting; in flavor both rich and sweet. (*Hort. Trans.* iv. 319.)

The smooth scarlet-fleshed cantaleupe. Roundish, inclining to oval; outside greenish-yellow, with fine white vermicular reticulations; flesh nearly an inch and a half in thickness, of a uniform bright scarlet from the edge of the coat to the centre, and tolerably firm; it is particularly high flavored (*Hort. Trans.* iv. 320.)

The montagu cantaloupe, is a variety produced from the two last-named sorts; intermediate in size between them; greenish-white without; the flesh an inch and a half in thickness, not very high colored, but soft and juicy, completely melting in the mouth, and with a very sweet and delicate flavor. (*Hort. Trans.* iv. 120.)

The green-fleshed Ionian cantaloupe. Lemon-colored and lemon-shaped; large, thin-skinned, no great bearer, and does not readily mature seeds, but of excellent flavor. (*Caled. Mem.* iv. 210.)

The green-fleshed Egyptian melon. Middle-sized, round, netted; in habits and flavor resembling the last-named variety. (*Caled. Mem.* iv. 210.)

Lee's romana. Middle sized, longish; shallow-furrowed, solid, and ponderous. Rind hard, partly netted, and pale-yellow; flesh a full yellow, pretty high-flavored, but not very juicy. Plant a good bearer.

The large netted romana. The largest of the romanas, regularly netted all over, shallow-furrowed, oval, solid, and very ponderous, often attains to nine or ten pounds in weight. Rind hard, pale-yellow when fit to cut; the flesh a full yellow but not very juicy;

very high-flavored, if eaten sharp-ripe. The plant is a better bearer than any other large sort.

Fair's romana. Small, oval, smooth, solid and ponderous; the rind hard, greenish-yellow when fit to cut; and the flesh a pale yellow, not very juicy; well-flavored and agreeable; may be pared very near to the rind. The plant is a very great bearer.

The polignac. A rich-flavored middle-sized oval fruit, in frequent cultivation. The small Portugal, or dormer, noted as a good bearer, and a very early variety.

The black Portugal, or Galloway. A sub-variety of the former.

The salonica. Nearly spherical, and without any depressions on its surface; color that of gold, pulp, pure white; improves in flavor and richness till it becomes quite soft; consistence of its pulp is nearly that of a water-melon, and it is very sweet. A full-grown specimen of the fruit generally weighs about 7lb. (*Knight, in Hort. Trans.* ii.) The damped melon. A variety from Persia; nearly cylindrical and netted; color varying from pale and yellowish-green to dark-olive; flesh bright and

deep green near the skin; pale towards the centre, quite melting, and of excellent flavor; hung up by the stalk, or in nets in a dark room, it keeps until the winter months. (*Old-acre, in Hort. Trans.* iv. 212.)

The sweet melon of Ispahan. Fruit ovate, varies in length from eight to twelve inches; nearly quite smooth, of a deep sulphur-color; skin very thin, flesh white, extending about half way to the centre; crisp, sugary, and rich in taste. (*Hort. Trans.* iii. p. 117.)

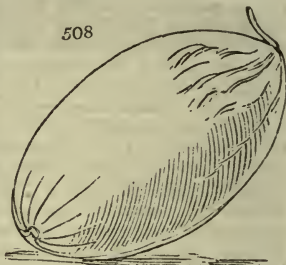

The Levant melon. Oval, slightly lobed, green-fleshed, milky, sweet and high-flavored. (*Hort. Trans.* iv. 514.)

The winter melon. (*fig. 508.*) Cultivated in various countries bordering on the Mediterranean sea, and particularly in the orange gardens at Hieres, in Toulon, whence its fruit is sent to Paris. Skin thin, flesh white, firm, saccharine, and juicy; not rich, but pleasant. The shape oval; size, about a foot long, and eight inches broad; color a dark green. This fruit is regularly imported, and may be had in the fruit-shops from September to January. (*Hort. Trans.* iii. p. 116.)

The water-melon. *Cucurbita*. (See 4209.)

4871. *Choice of seed.* In the cultivation of the melon, Knight observes, it is a matter of much importance to procure proper seed. Some gardeners are so scrupulous on this point that they will not sow the seeds unless they have seen and tasted the fruit from which they were taken. It is proper at least not to trust to seeds which have not been collected by judicious persons. Some make it a rule to preserve always the seeds of those individual specimens which are first ripe, and even to take them from the ripest side of the fruit. A criterion of the goodness and probable fertility is generally sought by throwing them into a vessel containing water; such as sink are considered as good and likely to prove fertile, those that float, as effete. It is remarked of seeds brought from the continent, that they must have more bottom heat, and the young plants less water, than are necessary for seeds ripened in this country, or young plants sprung from these.

508

4872. For the entire course of culture of the melon, see Chap. VII. Sect. VII.

SUBSECT. 5. *Cucumber.* — *Cucumis sativus*, L. *Monac.* *Monadelph.* L. and *Cucurbitaceæ*, J. *Concombre*, Fr.; *Gurke*, Ger.; and *Citriuolo*, Ital.

4873. *The cucumber* is a tender annual, a native of the East Indies, and introduced in 1573. It is a trailing and climbing plant, with large roundish rough leaves, furnished with tendrils, and if sown in the open air in May, produces flowers from July to August. The cucumber is of nearly as great antiquity as the vine, for Moses, the earliest Jewish author, mentions it as abounding in Egypt, when the children of Israel were there, above three thousand years ago. (*Numbers*, chap. ii.) In England it is cultivated generally and extensively, in forcing-frames and in the open air, and especially near large cities and towns. "Not only gentlemen," as M^r Phail observes, "but almost every tradesman who has a garden and dung, have their cucumber-frame." In Hertfordshire, whole fields are annually seen covered with cucumbers without the aid of dung or glass, and the produce of which is sent to the metropolis for pickling. In March, cucumbers fetch in the London market a guinea a dozen; in August and September one penny a dozen. The village of Sandy, in Bedfordshire, has been known to furnish 10,000 bushels of pickling cucumbers in one week.

4874. *Use.* The green fruit is used as a salad; it is also salted when half-grown; and preserved in vinegar when young and small. In Germany and Poland, barrels of half and also full grown cucumbers, are preserved from one year to the other, by immersion in deep wells, where the uniform temperature and exclusion of air seem to be the preserving agents.

4875. *Varieties.* The principal of these are —

The early long prickly; from five to seven inches long, of a green color, with few prickles. The plant is a good bearer; and upon the whole, this is accounted the best cucumber for the general summer crop, the pulp being very crisp and pleasant.

Longest green prickly; from seven to ten inches in length; it has dark-green skin, closely set with small prickles. This is a hardy sort, but does not come early.

Early short prickly; not more than four inches long; the skin green, rather smooth, but with a few small black prickles. This is one of the hardest and earliest sorts, and is often preferred for the first crop. Dutch, or white short prickly, though not much cultivated, is recommended by some, as preferable even to the early long prickly; it has fewer seeds; is evidently different in taste from most

other cucumbers, but of agreeable flavor.

Cluster cucumber; a very early sort, the flowers appear in clusters of three or four together; the fruit is seldom more than five inches long; it is at first of a fine green color, but becomes yellowish as it ripens. The stems of this variety are much inclined to climb by means of their tendrils upon sticks; the leaves are small, and the plant altogether occupies but little room.

Smooth green Roman; an early sort; the fruit becomes large and long, and is quite smooth; the plants grow very strong, and require a good deal of room.

White Turkey; the stalks and leaves are larger than in the other varieties; the fruit also is very long, sometimes from ten to fifteen or even twenty inches; it is quite straight, and has a smooth skin destitute of prickles; it is produced sparingly, and late in the season.

Long green Turkey; sometimes sown for the late crop. Late cucumbers, however, are much less cultivated than the early varieties; most gardeners being of opinion, that those kinds which are best for the early crops are also best for the late.

Napal; fruit very large, usually weighs upwards of twelve pounds weight, measures in girth twenty-four inches,

and in length seventeen inches; flavor pleasant and esteemed for stewing. Sent to the Horticultural Society from Calcutta by Dr. Wallick. (*Hort. Trans.* iv. 136.)

Fianagan's. Near two feet long and of superior crispness and flavor. (*Hort. Trans.* iv. 560.)

Fluted cucumber. A Chinese variety. (*Hort. Trans.* v. 56.)

4876. *Culture.* The culture of the cucumber, as a table esculent, is chiefly carried on by artificial heat or protection, and is therefore treated of under the *Forcing Department*, Chap. VII. Sect. VII. For pickling, it is chiefly cultivated in the open ground, by what is termed drilling, and which forms the only branch of the culture of this vegetable reserved for this article. To have a crop in the natural ground, the seed is sown in warm compartments of rich earth, towards the end of May, or beginning of June, when the weather is settled, warm, and dry. The plants should mostly remain where sown, to produce late fruit, towards the end of July, or more generally in August and September, small for picklers, and in larger growth for ordinary consumption. Sow a portion in a warm border, and the main crop in an open compartment. Dig the ground neatly even. Trace lines with intervals of five or six feet; and in the lines mark stations three and a half feet distant; then, with a trowel at each of these spots, form shallow circular saucer-form cavities in the surface, ten or twelve inches wide, and about an inch deep in the middle. Sow in the middle of each cavity eight or ten seeds, half an inch deep. When the plants are come up, and begin to put forth the first rough leaves in the centre, thin them to three or four of the strongest in each hole. Earth these up a little, between and close round the stems, pressing them a little asunder; and give them some water, to settle the earth below and above. In their advancing growth, train out the leading runners. Supply them with requisite waterings, in dry weather, two or three times a week, or sometimes every day in very dry hot weather, in July, August, or September. At this season, water early in a morning, or late in the afternoon, towards evening.

4877. *Gathering.* "The crop comes in sometimes towards the end of July, but more generally not before August in full production; continuing till about the middle or end of September, when the plants decline. Be careful to gather the fruit in a prime state, both for pickling and other purposes. They must be quite young for pickling, not exceeding two or three inches in length." (*Abercrombie.*)

SECT. II. *Exotic Fruits, well known, but neglected as such.*

4878. Among *neglected exotic fruits* we include the orange tribe, one of the most beautiful, and also, a very useful class of fruits. The culture of oranges and lemons for the table is not at present common in England; but, in our opinion, it might be pursued with much enjoyment to the amateur, since, independently of the gratification of seeing fruit of one's own growth at the dessert, no object of the fruit-tree kind can be more splendid than a large healthy orange-tree covered with fruit. The pomegranate seems also to merit culture, both for its singular beauty while on the tree, and the addition it would make to the dessert.

SUBJECT. 1. *Orange Tribe.* — *Citrus*, L. *Polyadel.* *Polyan.* L. and *Aurantia*, J.

4879. Of the *genus citrus* there are five species or leading sorts, of which the fruit are used; all natives of Asia, viz. the common orange, the lemon, the citron, the lime, and the shaddock. The common character of the plants bearing these fruits is that of low evergreen trees, with ovate or oval-lanceolate, entire or serrated, leaves. On the ungrafted trees are often axillary spines. The flowers appear in peduncles, axillary or terminating, and one or many flowered. The fruits are large berries, round or oblong, and generally of a yellow color. The species seem best distinguished by the petiole, which, in the orange and shaddock, is winged; in the citron, lemon, and lime, naked. The form of the fruit, although not quite constant, may also serve for a distinction. In the orange and shaddock, it is spherical, or rather an oblate spheroid, with a red or orange-colored rind; in the lime, spherical, with a pale rind; in the lemon, oblong, rough, with a nipple-like protuberance at the end; in the citron, oblong, with a very thick rind. The flowers of the citron and lemon have ten stamens, and those of the orange more. Professor Martyn observes, that it is very difficult to determine what is a variety, and what is a species in this genus. The trees in the eastern countries, where they are natives, vary in the size and shape of the fruit and leaves; and many of those considered varieties in Europe, preserve their differences in their native woods. He has no doubt that any one who would pursue this subject in the native countries of these fruits, would detect varieties connecting all those generally considered as species. This opinion appears highly probable when we examine the catalogues of the continental writers on this fruit; who, in general, finding it difficult to make botanical distinctions, are obliged to rest satisfied with popular descriptions. In *Nouveau Cours*, &c. art. *Oranger*, those cultivated in France, and in Dr. Sickler's work, and that of Galesio, those of Italy, are so described.

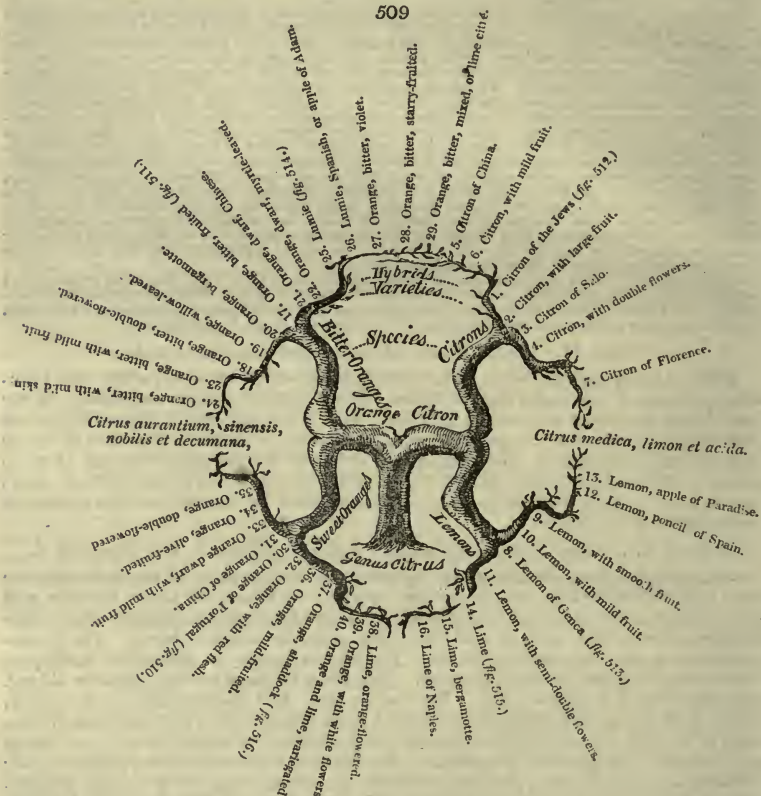

4880. Dr. Sickler, who spent several years in Italy, and paid great attention to the kinds and culture of the orange, published in 1815, *Der Vollkommen Orangerie-Gartner* (*The Complete Orange-Gardener*), in which he describes above seventy sorts of *citrus*, including all the species above mentioned. He arranges the whole in two classes, and these classes into divisions and subdivisions, without regard to their botanic distinctions or species, thus: —

	Cedrates or Citrons	4 sorts.
Lemons...	Round-shaped lemons	6 ditto.
	Pear-shaped ditto	11 ditto.
	Cylindrical ditto	4 ditto.
	Gourd-shaped ditto	12 ditto.
	Wax lemons	5 ditto.
	Cedrate lemons or cidronates	6 ditto.
Limes or Lemies	Limes or Lemies	5 ditto.
	Apple limes	3 ditto.
	Limes	4 ditto.
Oranges...	Bitter oranges	6 ditto.
	Sour oranges	6 ditto.
	Sweet oranges	12 ditto.

The names and some descriptive traits of these seventy-four sorts of citrus will be found in *A Short Delineation of Dr. Sickler's Treatise*, by Dr. Noehden, in the *Hort. Trans.* vol. iii. App.

4881. *Gallesio* (*Traité du Genus Citrus*, &c. Savonna, 1818.) has given a synoptic tree (fig. 509.), in which he has introduced ramifications which display an arrangement of the forty principal sorts cultivated in Italy.

509

4882. The most splendid work on oranges which has yet appeared is the *Histoire Naturelle des Orangers*, by Risso, of Nice, and Poiteau, of Versailles. (Paris, fol. 1818.) Here 169 sorts are described, and 105 of them figured, and their French and Italian culture given at great length. They are arranged as sweet oranges, of which they describe 43 sorts; bitter and sour oranges, 32 sorts; bergamots, 5 sorts; limes, 8 sorts; shaddocks, 6 sorts; lumes, 12 sorts; lemons, 46 sorts; citrons, 17 sorts.

4883. All the species of citrus endure the open air at Nice, Genoa, and Naples; but at Florence and Milan, and often at Rome, they require protection during the winter, and are generally placed in conservatories and sheds. The largest conservatory in Italy is that of Prince Antonio Borghese, at Rome, which contains seventy select sorts of *agrumi*. The largest trees are at Sorrento, Teracina, Gaeta, and Naples; but the most regular and garden-like culture of the orange, is in the orange-orchards at Nervi, Monaco, and other places in the neighborhood of Genoa. At Nervi are also the orange-nurseries which may be said to supply all Europe with trees; they are, in general, wretchedly cultivated, and the stocks inoculated in the most unscientific manner; but the fine climate, strong clayey soil, and abundant manurings, supply in a great degree the nicer practices of gardening. There the names of varieties vary as much as those of gooseberries do in England; but from upwards of one hundred names, not above forty distinct sorts can be procured. Good plants of the Maltese and other varieties of orange may be procured from Malta; and some sorts also from Lisbon. From the nurseries

at Paris about thirty sorts may be obtained, much smaller plants than those from the other places named, but more scientifically grafted or inoculated. At Vallet's nursery at Rouen, is a collection of very large plants of the common kinds. The catalogues of London nurserymen enumerate above thirty varieties of orange, twelve of lemon, and several varieties of the other species; the plants are generally inoculated, and small, and are more calculated for pots than for planting in the soil for producing fruit. As being most useful for the British horticulturist, we shall place under each species the names of the varieties which may be procured in England.

4884. *The common orange* is the *Citrus Aurantium*, L.; the orange of the French; pomegranze of the Germans; and arancio of the Italians. (fig. 510.) It is a middle-sized evergreen tree, with a greenish-brown bark; and in its wild state, with prickly branches. The fruit is nearly round, from two to three inches in diameter, and of a gold color. It is a native of India and China, but now cultivated in most countries of Europe; in the open air in Italy and Spain; and in conservatories or green-houses in Britain and the north of Europe. The orange is supposed to have been introduced into Italy in the fourteenth century, above a thousand years after the citron. In England, the tree has been cultivated since 1629. Parkinson, writing at that time, says, "it hath abiden with some extraordinary looking and tending, when neither citron nor lemon trees could be preserved any length of time."

4885. *The orange-trees of Beddington, in Surrey*, introduced from Italy by a knight of the noble family of the Carews (*Gibson's edit. of Camb. Brit.*), were the first that were brought into England; they were planted in the open ground, placed under a moveable cover during the winter months, and they had been growing there before 1595. It has been said, that these trees were raised by Sir Francis Carew, from seeds brought to England by Sir Walter Raleigh: but as such trees would not have readily borne fruit, Professor Martyn thinks it much more likely that they were plants brought from Italy. Bradley says, they always bore fruit in great plenty and perfection; that they grew on the outside of a wall, not nailed against it, but at full liberty to spread; they were fourteen feet high, the girth of the stem twenty-nine inches, and the spreading of the branches one way nine feet, and twelve feet another. These trees, Evelyn informs us, were neglected in his time during the minority of their owner, and finally entirely killed by the great frost in 1739-40.

4886. *During the latter end of the seventeenth and beginning of the eighteenth centuries*, the orange-tree was a very fashionable article of growth in conservatories, when there were but few exotics of other sorts kept there. The plants were procured from Genoa, with stems generally from four to six feet in height; they were planted in large boxes, and were set out during summer to decorate the walks near the house in the manner still practised at Versailles and the Tuilleries. About the middle of the eighteenth century, when a taste for botany and forcing exotic fruits became general, that for superb orange-trees began to decline; many of these large trees have decayed through neglect; and those which are now to be found in the greater number of green-houses, are generally dwarf plants bearing few fruit, and those of small size. In some places, however, are still to be found large and flourishing trees. Those at Smorgony in Glamorganshire, are the largest in Britain; they are planted in the floor of an immense conservatory, and bear abundantly. It is said that the plants were procured from a wreck on the coast in that quarter, in the time of Henry VII.

4887. *At Nuneham, near Oxford*, are some very fine trees, planted under a moveable case, sheltered by a north wall. In summer, the case is removed, and the ground turfed over, so that the whole resembles a native orange-grove. At Wormleybury, Hertfordshire, and Shipley Hall, in Derbyshire, are very fine large orange and lemon trees grown in borders and in boxes. (*Hort. Trans.* vol. ii. 295. and iv. 306.)

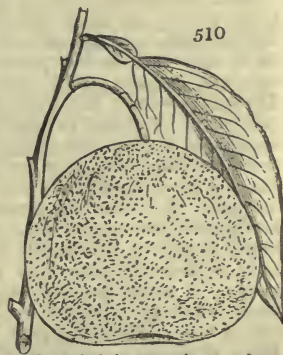

4888. *At the Wilderness, Kent*, (Marquis Camden's,) are three trees in boxes, not surpassed by any trees so grown in Europe. C. Bingham, at Isleworth, possesses a very fine collection; and various others might be enumerated.

4889. *At Woodhall, near Hamilton*, trees of all the species of citrus are trained against the back wall of forcing-houses, in the manner of peaches, and produce large crops of fruit.

4890. *In the south of Devonshire*, and particularly at Saltcombe, one of the warmest spots in England, may be seen, in a few gardens, orange-trees that have withstood the winter in the open air upwards of a hundred years. The fruit is as large and fine as any from Portugal. Trees raised from seed, and inoculated on the spot, are found to bear the cold better than trees imported.

4891. *Use.* As a dessert-fruit, the orange is well known. The varieties imported, which are most esteemed for this purpose, are the China, Portugal, and Maltese. It is also used in confectionary, both ripe, and when green and not larger than a pea: it forms various liquors and conserves, either alone or with sugars, wines, or spirits; and either the pulp or skin, or both, are used for these purposes. In cooking, it is used to aromatise a number of dishes. The juice of the Seville orange is used in medicine, in febrile and inflammatory disorders; and that of the other sorts possesses the same qualities in a lesser degree. The acid of oranges, Dr. Cullen says, unites with the bile, takes off its bitterness, and may prove useful in obviating disorders arising from its redundancy and acidity. In perfumery, the orange is used to form various perfumes and pomades: and the flower distilled, produces orange-water, used in cooking, medicine, and as a perfume.

4892. *Varieties.* These are very numerous in the eastern countries, and even in Italy and France. About forty sorts are cultivated in the neighborhood of Paris, and about thirty in the London nurseries, of which we shall give a list. The two principal varieties are the sweet or China orange, the orange douce of the French, and porto-gallo or poma de sino of the Italians; and the bitter or Seville, the bigarade of the French, and arancio volgare of the Italians. The Maltese orange, distinguished by its red pulp, is also a noted and much-esteemed sort. The box-leaved, willow-leaved, and some others, are cultivated more as curious varieties than for their fruit.

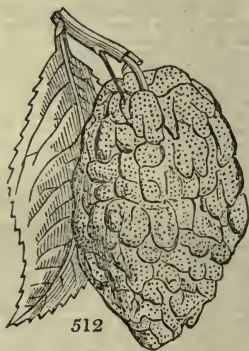

Common orange
Bloody-fruite
Broad-leaved
Bergamot large
Bergamot small
Cluster-fruited
Curled-leaved
Double-flowered
Fine-leaved
Laurel-leaved
Lisbon
Maltese
Bloody Maltese

Monstrous
Myrtle-leaved large
Myrtle small
Narrow-leaved
Oval-fruited
Pale-leaved
Seville or bitter orange,
(fig. 511.) chiefly used for
making marmalade
Spike-flowered
Striped common
Striped curled-leaved
Striped gold

Striped silver
Striped tricolor
Striped willow-leaved
Sweet-skinned
Sweet China
Tanjierino
Thick-leaved
Weeping
Willow-leaved
Clove, or mandarin, (*C. No-
bilitis*, H. K.) (*Bot. Rep.* 608.
and 211.), distinguished from
the common orange by its

curious form, and by the
pulp adhering so loosely to
the rind as to be separable
from it by the slightest effort,
and leaving in many places
a considerable opening be-
tween them. It is the most
delicate of the orange tribe,
whence its name by the Chi-
nese of mandarin, or noble
orange. — Probably only a va-
riety, though named as a spe-
cies.

4893. *The Citron* is the *C. Medica*, L. (*Gär. fru.* 2. t. 121. f. 2.); the *citron* of the French; the *citronier* of the Germans; and *cedrate* of the Italians. (fig. 512.) In its wild state the tree grows to the height of about eight feet, erect and prickly, with long reclining branches. The leaves are ovate, oblong, alternate, subserrate, smooth, pale green. The fruit or berry is half a foot in length, ovate, with a protuberance at the tip. There are two rinds, the outer thin, with innumerable miliary glands, full of a most fragrant oil; the inner thick, white, and fungous. The citron was introduced into Europe from Media, under the name of *malus medica*, and was first cultivated in Italy by Palladius in the second century. The date of its introduction into England is not exactly known; it would probably be coeval with that of the lemon, which was cultivated in the botanic garden at Oxford in 1648. The fairest fruit, Miller states, was in the Duke of Argyle's garden at Whitton, where the trees were trained against a south wall, through which there were flues for warming the air in winter, and glass covers put over them, when the weather began to be cold. Thus the fruit was as large and as perfectly ripe, as it is in Italy or Spain. In Italy citrons and lemons are generally trained on walls or espaliers, because, being considerably more tender than the orange, they require, at least in the north of Italy, some protection in winter; the fruit does not ripen regularly at one time, like that of the orange, but comes successionally to maturity almost every month in the year.

4894. *Use.* The fruit is seldom brought to the dessert in a raw state, but it forms excellent preserves and sweetmeats, to furnish the table when other fruits are scarce. The juice, with sugar and water, forms lemonade, a most refreshing, salubrious, and universally esteemed beverage. Its use in punch and negus is well known. It is much used in medicine, and also in perfumery and dyeing.

4895. *Varieties.* Dr. Sickler enumerates only about a dozen citrons and citronates as grown in Italy. The French nurseries have nearly twenty names in their lists. In England the six following are cultivated for sale: —

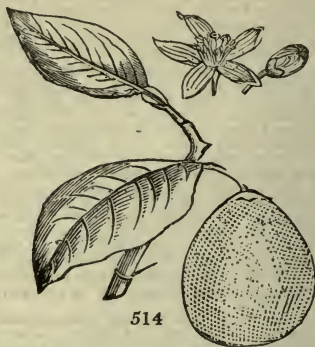

The common citron
The flat-fruited

The rough-fruited
The forbidden-fruited

The grape-fruited Barbadoes
(*Hort. Trans.* vol. iii. p. 358.)

The round-fruited
The thick-leaved.

4896. *The lemon* is the *C. Medica*, var. *Limon*, W. (*Blackw.* 362); the *limon* of the French; *limonier* of the Germans; and *limone* of the Italians. (fig. 513.) The distinction between the lemon and citron is very trifling. The fruit is less knobbed at the extremities, is rather longer, and more irregular, and the skin is thinner than in the citron; the wood is more knotty, and the bark rougher. Cultivated in the Oxford garden in 1648.

4897. *The uses* of the lemon are the same as those of the citron.

4898. *Varieties.* Dr. Sickler enumerates twenty-eight as grown in Italy. The French, according to Ville Hervé, have eleven sorts; in the London nurseries are cultivated the twelve following: —

Common
Broad-leaved
Chinese
Imperial

Pear-shaped, or Lime (fig. 514.)
Rough-fruited
Smooth-leaved
Striped gold

Striped silver
Striped three-colored
Upright
Warted fruited.

515

4899. *The lime* is the *Citrus Acida*, Rox. (*Brown's Jam*. 308.) by some esteemed a variety of the *C. Medica*; the *lime* of the French, Italians, and Germans. (fig. 515.) The sour lemon, or lime, grows to the height of about eight feet, with a crooked trunk, and many diffused branches, with prickles. The leaves are ovate, lanceolate, almost quite entire. Berry an inch and a half in diameter, almost globular, with a protuberance at the top; the surface regular, shining, greenish-yellow, with a very odorous rind, enclosing a very acid juice. It is a native of Asia, but has long been common in the West Indies, where it is grown both for its fruit and for fences.

5900. *The uses* of the lime are the same as those of the lemon, to which, in the West Indies, it is preferred; the juice being reckoned more wholesome, and the acid more agreeable to the palate.

5901. *Varieties*. By the catalogue in *Nouveau Cours*, &c. the French have two sorts of lime; and according to Dr. Sickler, the Italians have four varieties. The following five kinds are grown in the London nurseries:—

The common lime	The broad-leaved	The Chinese spreading.
The weeping	The West India	

5902. *The shaddock* is the *C. decumana*, W. (*Rump. am.* 2. t. 24. f. 2.); the *orange pampelmousse* of the French; and the *arancio massimo* of the Italians. (fig. 516.) The tree is above the middle size, with spreading prickly branches. The leaves are ovate, subacute, seldom obtuse; the petioles are cordate, winged; the wings as broad as the leaves. The berry spheroidal, frequently retuse at each end, of an even surface, and greenish-yellow color; pulp, red or white; juice, sweet or acid; rind, white, thick, fungous, and bitter. Thunberg says, the fruit in Japan grows to the size of a child's head, and Dr. Sickler states its weight as fourteen pounds, and its diameter as from seven to eight inches. It is a native of China and Japan, and was brought to the West Indies by Captain Shaddock, from whom it has derived its name. From the West Indies it was sent to England, and cultivated by Miller in 1739.

5903. *Use*. The shaddock is certainly the least useful of the species enumerated, and is cultivated chiefly for show. It has the handsomest leaf of the whole tribe, and the fruit is larger than the orange. Where several sorts of oranges are presented at the dessert, it makes a striking addition to the variety. The juice is of a subacid sweetness, and excellent for quenching thirst; and the fruit, from the thickness of its skin, will keep longer in sea voyages than any of the other species of citrus.

5904. *Varieties*. The Italians, according to Dr. Sickler, have one; and the French, according to the *Nouveau Cours*, &c. four sorts. The following four are grown in the English nurseries:—

The common shaddock	The rough-fruited	The largest-fruited	The West India.
---------------------	-------------------	---------------------	-----------------

5905. *Propagation of the citrus tribe*. All the sorts may be propagated by seeds, cuttings, layers, and grafting, or inoculation.

5906. *By seed*. The object of raising plants from seed is either to obtain new varieties or stocks for grafting. To attempt raising new varieties in Britain will in general be found a tedious process, as the trees do not even in Italy show fruit for six or eight years or more; and there is now in the botanic garden at Toulon, a large handsome tree, of twenty-five years' growth, which had not in 1819 blossomed. However, if new varieties are attempted, select the largest and best-formed ripe fruit of the kind to be raised, extract the seeds, dry them, and sow and nurse as hereafter directed for raising stocks. Where trees are to be raised for stocks to bud oranges, Miller advises to procure citron-seeds, as stocks from these are preferable to any other for quickness of growth; and also that they will take buds of either orange, lemon, or citron. Next to these are the Seville orange seeds; and the best of either sort are to be had from rotten fruits. Prepare in spring a good hot-bed of dung or tan, and when it is in moderate temper sow the seeds in pots of light earth; plunge them, give water frequently, and raise the glasses in the heat of the day. In three weeks the seeds will come up, and in a month's time be fit to transplant into single pots. Then renew the bed, and fill pots of five inches in diameter half full of good fresh earth, mixed with very rotten cow-dung: shake out the seedlings, and plant one in each pot, filling it up with the same earth, and replunge as before. Give a good watering at the roots, and repeat this often, as the orange tribe in a hot-bed require a good supply of water. Shade in the day-time, when the sun is powerful, and give air so as not to draw the plants. By this method, with due care, the plants will be two feet high by July, when they must be hardened by degrees, by raising the glasses very high, and afterwards, in fine days, taking them entirely off, shading the plants from the sun with mats or other screens. Towards the end of September, house them in a dry part of the green-house, near the glass, where they will not be liable to damp off. During winter refresh them with water, and in April now and then wash their stems and leaves, to clear them from any filth they may have contracted. Place them again in a moderate hot-bed, and harden them by the beginning of June, that they may be in a right order to bud in August.

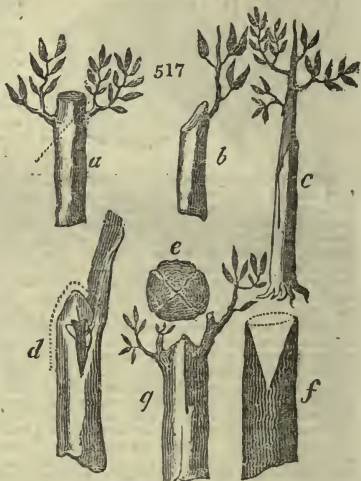

5907. *Budding*. Make choice of cuttings from trees, that are healthy and fruitful, observing that the shoots are round; the buds of these being much better and easier to part from the wood than of such shoots as are flat or angular. After performing the operation, remove the plants into the green-house, or under glass frames, to defend them from wet, turning the buds from the sun; but let them have as much free air as possible, and refresh them often with water. In a month it will be observable which has taken, then untie them, and let them remain in the green-house all the winter. In spring cut off the stocks about three inches above the buds, and place them in a moderate hot-bed, giving air and water, and shading as before. By the end of July they will have made shoots of two feet or more; then harden them before the cold sets in, that they may the better stand the winter. In the first winter after their shooting, you must keep them very warm, for by forcing them in the bark-bed they will be somewhat tenderer; but it is very necessary to raise them to their height in one season, that their stems may be straight, for in trees which are two or more years growing to their heading height, the stems are always crooked. In the succeeding years their management will be the same as for full-grown trees.

5908. *The Italian process of raising and budding*. In the orange-nurseries at Nervi,

516

the seeds of the citron or orange, as it may happen, are sown in beds in the open ground in February or March, and in September planted out in compartments, in rows generally about eighteen inches wide, and the plants six or eight inches in the row. They are placed thus close to draw them up with clean straight stems. There they remain generally four years, and in April or May of the fifth year they are taken up, their roots cut within four or six inches of the tap-root, which is also shortened to six or eight inches, according to the size of the tree. The stem, if it has any side shoots, is pruned clean, and sawn off horizontally, at such a height as that the section is from half an inch to an inch in diameter. (fig. 517. *a*) The general heights are one foot, which forms the lowest-growing plants; eighteen inches for trees to be sold in Italy; from two to four feet for trees to be sent abroad; and five or six feet for extraordinary orders. These last are not so common; as the stocks require six or eight years' growth, and some care to attain that height with clean stems, and a diameter of three quarters of an inch. The plants thus pruned are budded, sometimes when out of ground, and sometimes after planting. One bud is inserted on each side of the stock (*a*), within an inch of the section. In a month buds and roots begin to push, and in December or January following these plants are in fit state for taking up for exportation. After being taken up, the roots, now well furnished with fibres, are enveloped in a ball of stiff clay; this is covered with moss carefully tied on, and in this way they are laid in boxes, or in casks; and sent not only to most parts of Europe, but to North and South America. The chief defect in this system is the naked horizontal section at the top of the stem (*a*), which, not being smoothed with the knife and covered with clay or any other protection, to cause the bark to grow over it, indurates and cracks with the drought; retains moisture and decays, so that in almost all trees that have been budded in this way, a dead stump or a rotten hole, may be observed during the whole period of their existence. This evil is often lessened by covering with a cap of lead or a patch of wax; but it might readily be obviated by peeling off a piece of bark from one side of the part of the stock to be sawn off (*d*), letting it remain attached to the lower part or stem; and after removing the head, bringing it down close over the section, inserting its end under the bark in the opposite side, somewhat in the manner of saddle-grafting; or the manner employed by surgeons in amputating a limb (*e*) might be adopted. A similar object might probably be effected by removing a wedge-shaped section from the top of the stock (*f*), and then compressing its sides, so as to present a wedge-shaped termination covered with bark (*g*). But the gardeners at Nervi are too indolent and obstinate to hear of any thing new, and will persist in their present plan till the credit of Genoa for orange-trees is gone, or till some strong necessity urges them to improvement.

5909. *The Maltese*, aware of the defects in Italian trees, make a sloping section (*b*), paring it clean, and budding on one side only; the consequence of which is, that the section becomes covered with bark, and, which it never does in the Italian method, as sound and healthy as any part of the stem. The French graft and inoculate in a very neat manner (*c*), and indeed their orange-trees, though small, are much handsomer than the Italian ones.

5910. *By grafting*. This mode is occasionally resorted to in Italy, and is that most generally adopted in the nurseries at Paris. The stocks, when of two years' growth, and not much thicker than the scion, are cut over within six inches of the ground, and then grafted in the whip manner. The trees continue small, but have clean stems of from one to three feet, and generally make handsome plants, prolific in flowers and fruit, of a small size. Grafting, both by the whip manner and by approach, is frequently practised in England, in nearly the same circumstances of age, size, and effect, as practised in France. A variety of the whip-manner is described by Cushing, in which the top of the stock is left on, but the scion is cut off as in grafting. "Form the scion as for the common whip-graft, and then, without taking off the head of the stock, cut from the clearest part of its stem an equal splice as smoothly as possible; do not tongue the scion, but tie it on neatly and firmly with matting and clay, in the manner of a graft: plunge them in a hot-bed, and cover with a cap-glass till the scion begins to grow, and then cut away the top of the stock, and remove the matting by degrees." (*Exotic Gard.* 103.)

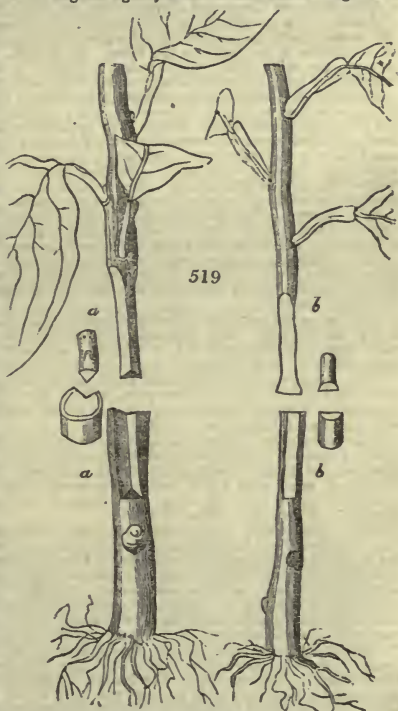

5911. *Whip-grafting* in the common way has lately been successfully performed, even with fruit or flowers on the scion, by Nairn, who gives the following account of the process: "Let the operator select as many orange or lemon stocks as he wishes to work, and place them on a moderate hot-bed for a fortnight, by which time the sap will have risen sufficiently to move the bark; the stocks must then be cut off, about two inches above the surface of the pot, and an incision made with a sharp knife, similar to what is done for budding, separating the bark from the wood on each side. Let the scion be cut thin, in a sloping direction, and thrust between the bark and wood, and then bound tight with woollen yarn; but very great care must be taken, in binding, to prevent the bark from slipping round the stock, which, without attention, it is very apt to do. After it is properly and neatly bound, put a little loam or clay

close round the stock, to the surface of the pot, then, with a glass of a proper form (fig. 518.), to prevent the damp from dripping on the scion, cover the whole, and press it firmly into the mould, to prevent the air or steam from getting to the plant; the glass must not be taken off, unless you find any of the leaves damping, and then only till this is remedied, when it must be immediately returned. The stocks must next be placed on a brisk hot-bed of dung, and in about six weeks, the glasses may be taken off, and the clay and binding removed; but it will be necessary to bind on a little damp moss, in lieu of the clay, and to keep the glasses on in the heat of the day, taking them off at night; when, in about three weeks or a month, they will be fit to be put into the green-house, where they will be found to be one of the greatest ornaments it can receive. I should recommend the *mandarin orange* for the first trial, as the fruit is more firmly fixed than that of any of the other sorts. I have, by the above method, had seven oranges on a plant, in a pot, commonly called a small sixty, which I conceive to be both curious and handsome." (*Hort. Trans.* iii.)

5912. *Henderson's mode of grafting* is well adapted for proving successful. "Take two-year-old wood, cut into lengths of about seven inches. If the stock is much thicker than the graft (fig. 519. a), cut a piece out of the stock of a triangular figure, about an inch and two eighths in

length, regulating the depth according to the thickness of the graft, and keeping it square at the bottom. Displace two leaves at the bottom of the graft, for the convenience of getting it put on, cut the graft right across under one eye, where a leaf has been taken off: dress the graft to fit the receptacle made in the stock, observing to keep the lower end of the graft equal in thickness as above; always let three or four leaves remain untouched on the graft. After the graft is fitted in the stock, tie it up with bass matting, and put clay around it. If the grafts and stocks are nearly of the same thickness (b), cut the stock, at right angles, nearly half through. Cut off the piece, keeping it equal at top and bottom: cut the lower end of the graft right across under an eye (a), and with a knife prepare the graft to fit the stock. When the grafted plants are tied up and clayed, set them at the back of the vinery or peach-house, observing to keep them away from the flues, as fire-heat is hurtful to them at first: cover them with hand-glasses, or, if a frame can be spared, it is still better. Shade them every day, but take the mats off at night; continue the shading till they begin to grow, when they may be exposed to the light. If any stock happens to be so tall and thick that it cannot be placed under a hand-glass or frame, put two or three grafts on it, set in any convenient place in the house, and shade it with mats; it will succeed perfectly in this way, the grafts lose none of the old leaves; and, in five or six months, they will make three or four young shoots six or eight inches long; these, with the leaves that were on the grafts when put on, form a well-clothed little plant."

5913. *By cuttings*. This method, though little practised on the continent, where the object is large trees and fine fruit, is frequently adopted by the British gardener, whose object is generally small handsome plants. Two methods are adopted; the first is to take young succulent wood as soon as it has done growing, and the lower end has become somewhat mature. These cuttings, prepared properly (5914.), are inserted with a small dibber in pots of light sandy loam, with two or three inches of gravel or broken pots at bottom. They are then covered close with a crystal bell, and plunged in a gentle heat, and shaded. The glasses are taken off only to wipe them when damp, and to remove any decaying leaves. In two months such cuttings either strike or rot off. The second method is in spring to take the shoots of last year; to prepare and plant them as above; but after covering them with glasses to plunge them in a cold-frame, where they remain in a state of apparent inaction for three or four months, when they either form a callous excrescence at the lower end of the cutting and push at top, or die off. After preserving them in a low temperature through the winter, they are placed the succeeding spring in a gentle hot bed, where they will push freely, and make tolerable plants. The success of either mode may be facilitated by taking care to place the cuttings so as their ends may touch the bottom of the pot, or the potherd or gravel with which that is covered. The advantages of so placing cuttings is generally known to gardeners, and has been noticed by Hawkins in the *Hort. Trans.* vol. ii. p. 12.

5914. *Henderson* considers cuttings as the quickest mode of getting plants, and has practised it for thirty-seven years past on the orange tribe, and his directions are as follow: "Take the strongest young shoots, and also a quantity of the two-year-old shoots; these may be cut into lengths from nine inches to eighteen inches. Take the leaves off the lower part of each cutting to the extent of about five inches, allowing the leaves above that to remain untouched: then cut right across, under an eye; and make a small incision in an angular direction on the bottom of the cutting. When the cuttings are thus prepared, take a pot, and fill it with sand; size the cuttings, so that the short ones may be all together, and those that are taller in a different pot. Then, with a small dibble, plant them about five inches deep in the sand, and give them a good watering overhead, to settle the sand about them. Let them stand a day or two in a shady place, and if a frame be ready with bottom heat, plunge the pots to the brim. Shade them well with a double mat, which may remain till they have struck root; when rooted, take the sand and cuttings out of the pot, and plant them into single pots, in the proper compost (see 5922.) Plunge the pots with the young plants again into a frame, and shade them for four or five weeks, or till they are taken with the pots; when they may be gradually exposed to the light. From various experiments, I found that pieces of two-year-old wood struck quite well; and in place, therefore, of putting in cuttings six or eight inches long, I have taken off cuttings from ten inches to two feet long, and struck them

with equal success. Although I at first began to put in cuttings only in the month of August, I now put them in at any time of the year, except when the plants are making young wood. By giving them a gentle bottom heat, and covering them with a hand-glass, they will generally strike roots in seven weeks or two months. The citron is most easily struck, and is the freest grower. I therefore frequently strike pieces eighteen inches long; and as soon as they are put into single pots, and taken with the pots, they are grafted with other sorts, which grow freely. I am not particular as to the time either of striking cuttings or of grafting." (*Caled. Hort. Mem.* iii. 308.)

5915. *By layers.* This mode is occasionally practised both on the continent and in England. At Monza, near Milan, there is a very fine collection of lemon-trees in boxes, trained as espaliers, which were so raised. The trees are five feet high, and each box has a portion of trellis attached to it of that height, and ten or twelve feet long, which is wholly covered with branches. Where laying is adopted, the plants may either be laid down on their sides, and laid as stools, or pots may be raised and supported under the branches to be propagated from. These branches, or their shoots of one or two years' growth, may then be cut or ringed, and bent into the pot, or down through the hole in the bottom, and treated in the usual manner, taking care to supply water with the greatest regularity. Shoots layered in March will be fit to separate from the stools as mother plants in the September following. In general, it may be observed, that the citron tribe, like other fruit-bearing plants raised from cuttings or layers, though they may prove very prolific trees, yet seldom grow with that vigor, and produce such large fruit, as those propagated by budding or grafting on seedling stocks.

5916. *Soil.* At Genoa and Florence they are grown in a strong yellow clay, which is richly manured; and this soil is considered by the first Italian gardeners, as best suited to their natures. At Rome and Milan the natural soil is lighter; but a strong soil is adopted generally for all the *agrumi*, and particularly in the garden of his Holiness the Pope. At Naples, where the trees are always planted in the open ground, the soil is lighter and of volcanic origin. A strong soil, in imitation of that of Nervi, is recommended and adopted by the Dutch. (See *Van Osten. Nied. Hesperides*, &c.)

5917. *The French gardeners*, according to Bosc (in *N. Cours d'Ag.* in loco.), in preparing a compost for the orange-tree, endeavor to compensate for quantity by quality; because the pots or boxes in which the plants are placed ought always to be as small as possible, relatively to the size of the tree. The following is the composition recommended: To a fresh loam which contains a third of clay, a third of sand, and a third of vegetable matter, and which has lain a long time in a heap, add an equal bulk of half-rotten cow-dung. The following year turn it over twice. The succeeding year mix it with nearly one half its bulk of decomposed horse-dung. Turn it over twice or three times, and the winter before using, add a twelfth part of sheep-dung, a twentieth of pigeon-dung, and a twentieth of dried ordure.

5918. *Miller* says, the best compost for orange-trees is two thirds of fresh earth from a good pasture, and one third part of neat's dung. These should be mixed together at least twelve months before using, turning it over every month to mix it well and to rot the sward. Pass it through a rough screen before using.

5919. *M'Phail and Abercrombie* recommend "three eighth parts of cow-dung, which has been kept three or four years; a fourth part of vegetable mould from tree-leaves; one sixth part of fine rich loam; and one twelfth part of road-grit; to this may be added one eighth part of sheep-dung." (*G. Rem.* 242. *Pr. Gard.* 574.)

5920. *Mean* has tried the following mixture (*Hort. Trans.* ii. 295.), and with which he has "every reason to be satisfied. Well-prepared rotten leaves, two to three years old, one half; rotten cow-dung, two, three, and four years old, one fourth; mellow loam, one fourth; with a small quantity of sand or road-grit added to the compost, which ought not to be sifted too fine."

5921. *Ayres*, who grows excellent table fruit of the citrus, at Shipley, uses ten parts of strong turf-loam, seven of pigeon-dung, seven of garbage from the dog-kennel or butcher's yard, seven of sheep-dung, seven of good rotten horse-dung, and ten of old vegetable mould, mixed and prepared a twelvemonth before using. (*Hort. Trans.* iv. 310.)

5922. *Henderson*, of Wood Hall, a most successful cultivator of the genus citrus, gives the following directions as to soil: "Take one part of light-brown mould from a piece of ground that has not been cropped nor manured for many years; one part of peat-earth, such as is used for growing heaths; two parts of river-sand, or pit-sand if it be free from mineral substances; and one part of rotted hot-bed dung; with one part of rotted leaves of trees. Mix them all well together, so as to form a compost-soil of uniform quality." (*Caled. Hort. Mem.* iii. 302.)

5923. *Temperature.* The standard temperature for the citrus tribe is 48°; but in the growing season they require at least ten degrees of additional heat to force them to produce luxuriant shoots. The air of the house in which the plants are kept, whether in boxes or in the ground, should never be allowed to fall under 40°, for though the orange, like the pine-apple, will endure a severe degree of cold for a few hours without injury, yet, as *Mean* has observed, the leaves once injured the trees will require three years to recover their appearance. *Ayres* never suffers his orangery to be heated above 50° by fire-heat, until the end of February; when the trees show blossom, it is increased to 55°, but never allowed to exceed 60° by sun-heat, the excess of which he checks by the admission of air till the early part of June, when he "begins to force the trees, by keeping the heat in the house up as near as possible to 75°. For I do not consider (he adds) that either citrons, oranges, lemons, or limes, can be grown fine and good with less heat." (*Hort. Trans.* iv. 811.) The orange, *Humboldt* observes (*De Distrib. Plant.* 158.), which requires an average temperature of 64 degrees, will bear a very great degree of cold if continued only for a short time. This is proved by an observation of *Dr. Sickler*, who says, "It is remarkable how much cold and snow the common lemons and oranges will bear at Rome, provided they are planted in a sheltered situation, not much exposed to the sun. Thus I saw in the two winters of 1805 and 1806, under my windows, on Monte Pincio, three standard orange-trees in the open ground, heavily covered with snow for more than a week. The green leaves, but still more the golden fruits, nearly ripe, looked singular but beautiful amidst the snow; neither fruits nor trees had suffered, being in a sheltered place, while many branches and leaves of other trees of this kind, which were exposed to the sun, turned black and died, rendering the whole tree sickly." (*Volk. Oran. Gart.* 9.) It appears that the snow had been thawed from off these trees gradually, and more by the temperature of the atmosphere than by the direct rays of the sun, or a current of heated air. This resulted from their sheltered and partially shaded situation; and, as *Dr. Noehden* has remarked (*Hort. Trans.* iii. 43.), it proves the truth of the observation of *Knight*, that it is more the sudden transition from cold to heat, and the contrary, than the degree of either, which destroys vegetables. Whenever orange-trees or any tender exotics have been touched during night by frost, they should either be immediately shaded by mats from the next day's sun, or thawed by water at not more than 32 or 33 degrees of temperature. In the northern regions the same treatment is successfully applied to animals. (See *Hort. Trans.* iii. 42. and 144.)

5924. *Water.* Orange-trees, like other evergreens which delight in a strong soil, are not naturally fond of water; but in this country those in boxes are often much injured for a want of a due supply of this material; for the earth becoming indurated, the water wets only the surface, and runs over and escapes by the sides of the pot or box; so that while the mass of earth below is dry, the surface has a sane moist appearance. *Mean* says, "When I think from the appearance of a plant, that the water does not freely enter by the middle or sides of the box, a sharp iron rod, about three feet long, is made use of to penetrate to the bottom of the earth, and to form a channel for the water, too little or too much of which is equally injurious to orange-trees." *Knight* (*Hort. Trans.* ii. 229.) watered an orange-tree with very strong liquid manure, and found it grow with equal comparative vigor to the vine and mulberry. *Ayres*, after the fruit is set, waters with water, in which, at the rate of three barrows of fresh cow-dung, without litter, two barrows of fresh sheep's droppings, and two pecks of quick lime have been added to every hoghead; when

used, the water is about the consistence of cream. (*Hort. Trans.* v. 310.) The French water once after shifting with a very strong lessive; they also mulch with recent cow and horse droppings, renewing these once a-month or oftener during summer, that there may be always abundance of soluble matter for the water to convey to their roots. (*Nouveau Cours, &c.* art. *Orange.*) M^r Phail mentions a case in which very large orange-trees in the border of a conservatory looked sickly; when, on digging deep into the borders to examine the cause, he found the earth quite dry, and by afterwards continuing to water them regularly he recovered them. (*G. Rem.* 242.)

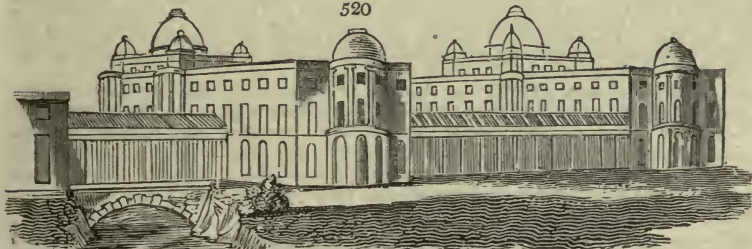

5925. *Air.* During the winter season, Miller observes, orange-trees require a large share of air when the weather is favorable; for nothing is more injurious to these trees than stifling them. The prevention of damp, Mean observes, is as essential to the perfection of the plants as the exclusion of cold. Where these trees are kept in old-fashioned opaque-roofed green-houses, these cautions as to air and damp deserve particular attention. Ayres says, the more air orange-trees have during the blossoming season, the more certain will they be of setting the fruit.

5926. *Light.* Many gardeners are of opinion that the orange tribe do not require so much light as other exotics, which may have arisen from the gloomy conservatories in which they used to be formerly kept during winter; for certainly to look at the orange-houses at Versailles and Kew, one would not conclude light to be a very essential requisite. But though these trees, like other evergreens, when in a state of inaction, will live with less light than evergreens or deciduous plants in a growing state, they always suffer for the want of it, which is indicated by the paleness of the leaves in spring, and by their falling off when set out in the open air and fully exposed to the influence of day. Whoever intends to grow the orange in any degree of perfection, should adopt houses, if not with glass on all sides, at least with glass fronts and roofs. When the plants are placed in the naked ground as standards, glass on all sides is highly desirable; for otherwise their leaves and shoots will all be turned to the south, and the north side of each tree will in a short time become naked and unsightly.

5927. *Manner of growing the trees.* All the species may either be grown as dwarfs in moderate-sized pots or boxes; as standards with stems from two to six feet high in large boxes; as standards planted in the naked ground; and either as dwarfs or standards planted and trained against a wall or trellis under glass. The two first modes are more adapted for ornament than producing crops of large fruit; for all the art of the gardener will never make plants grow as vigorously in boxes as in the free ground. Standards planted in the free ground or floor of the conservatory, combine both elegance and utility; as in a house properly constructed, they will make handsome heads, and produce abundant crops of fruit. The last mode, or that of planting against walls or trellises, is much the most certain way of having large crops. Every part of the plant above ground can thus be brought near the glass and equally exposed to the sun's influence and that of the air and heat; they can be more readily pruned, and correctly trained, watered, and washed; and they occupy less room in proportion to the produce. The trees at Wood Hall, in West Lothian, some of those at Shipley, and at some places in Devonshire, are trained in this way. In a very few favorable situations in the South of England, as at Gerston and Woodville, in Devonshire, they are trained against walls in the open garden.

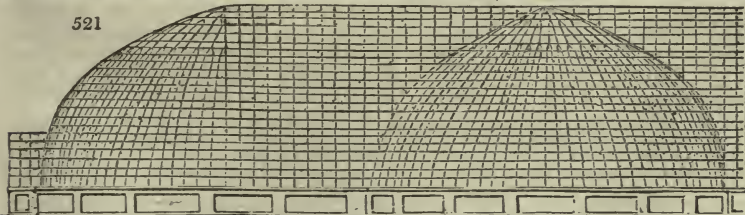

5928. *Plans for orange-houses.* These must naturally depend on the mode of growing. For plants in moderate-sized pots and boxes, a common green-house is the obvious habitation; for, being plants of ornament, they require merely the treatment of that department. The conservatories in Italy have generally opaque roofs, but some of the more enlightened nobles of Lombardy have lately erected splendid constructions with glass roofs, in which they combine the culture of the citron tribe with other, large-growing exotics. (*fig.* 520.)

520

5929. For trees in large boxes, a proportionably large and lofty house is requisite; it may be opaque on the north side with a glass roof, front, and ends, of any convenient or desired length, width, and height. For one of moderate size, the height at the back wall may be fifteen feet, at front ten feet, and the width of the house fifteen feet. The floor may be either perfectly level, and the boxes placed on it, the largest behind, so as their tops may form a slope to the front glass, as in the conservatory of Prince Borghese,

521

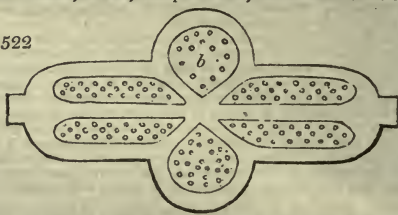

at Rome; or if the trees are young, a stage may be erected for a few years, in order to raise the plants to the light: but if the trees are of a considerable size, the best way is to have square pits in the floor at regular distances, somewhat larger than each box, and in these to sink the boxes, covering them with

mould, sand, or moss nearly to the level of the pavement, so that each tree so placed and dressed, will appear as if planted in a small compartment of earth. Such is the plan of the large conservatory in the royal gardens at Monza. The walk, unless where a stage is adopted, should be in the front of the house, with corresponding doors in each end; but where the trees are young, and placed on a stage like green-house plants, the walk should be in front, as in no other situation could the eye of the spectator meet the foliage of the plants. Where the walk is in the middle, and a double row of trees on each side as at Monza, the effect in winter is truly magnificent and gratifying.

5930. *Where the trees are to be planted as standards in the borders or floor of the house, it is essentially requisite to the health and beauty of the plants that the building be glazed on all sides.* (fig. 521.) Showers might be supplied in Loddiges's manner; heat by steam or flues (fig. 522. a) and in winter, the beds (b) might be covered with turf, strewed with daisies, violets, and primroses; these would come early

522

into flower, and if the turf were kept very short about the roots of the flowering plants, and the trees in excellent condition, only those who have seen the first-rate, regularly planted, standard orange-groves of Nervi could form an idea of the effect, which, by contrast with the external winter, would be felt as luxurious and as anticipating real spring.

5931. *Where orange-trees are to be trained against the back wall or a trellis, under the glass, the forms adopted for common peach-houses or vineries are perfectly suitable; but as by training close under the glass, as is done with vines, much of the beauty of the foliage would be lost, training on a trellis a few feet distant, with a path between it and the glass, is preferable.*

5932. *Plans for tubs, pots, and boxes.* Unglazed pots of earthenware are preferable to glazed stone ware or China pots; the form need not be different from that in common use, and the size must depend on that of the plants. At Florence, where the largest and best garden-pots in Europe are made, the rim and part of the outside of pots destined for oranges and ornamental plants, are often decorated with festoons of flowers or fruit, and lions' heads, or other ornaments; which some potters near London have begun to imitate.

5933. *Tubs may be of any size, and in these and in boxes, trees thrive better than in pots.* One advantage of tubs is, that by unhooping them, the staves are instantly removed, and the roots examined and dressed, and by having a cooper at hand they are immediately replaced; thus saving much of the trouble necessarily incurred in shifting plants in pots or boxes.

5934. *Boxes.* All boxes which are larger than the largest-sized pots, should be contrived to take to pieces, in order to examine the roots, or to shift into larger boxes. Square boxes held together by an iron hoop, and taking to pieces on the principle of tubs, are most convenient for trees which do not require more than five or ten cubic feet of earth; and such as are used at the Tuilleries and by Mean (figs. 177 to 179.) answer very well for plants requiring from ten to sixty cubic feet. Those of Mean contain sixty-four cubic feet of compost.

5935. *Proportioning the size of boxes to that of the plants.* The general opinion of gardeners is in favor of small pots or boxes; and where the object is dwarf plants, or merely to preserve the trees without much increasing their size or regarding their fruit, they are the most proper. But where the object is luxuriance of growth and fruit, it does appear to us that the pots or boxes cannot be too large; unless, as Van Osten observes, it is meant to be asserted that plants grow larger in pots than in the free ground. It is, however, expedient to plant at first in small boxes, and remove into larger ones by degrees. The largest boxes in use in Holland and France are four feet square, which serve for trees with stems from six to eight feet high, with globular heads of six feet in diameter, and above a century old. Henderson has "always found that the citrus tribe, and plants in general, grow best in pots or boxes, regarded as rather small in proportion to the size of the plants." (Caled. Mem. iii. 303.)

5936. *Choice of sorts.* Where the object is more ornament than fruit for the dessert, a selection may be made from the varieties of each species at pleasure; where the object is fruit for the dessert, the following sorts are to be preferred: the common, bloody-fruited, Bergamot, Maltese, sweet China, Seville, and Mandarin oranges; the common lemon, citron, and lime, and one or two plants of the shaddock. These include all the essential varieties of the orange tribe as far as respects fruit; variations in the leaves and mode of growth.

5937. *Choice of plants.* For moderate-sized trees to be treated like green-house plants, such as are raised in this country or in the Parisian nurseries are preferable; but where the object is large handsome trees in boxes, standards in the free soil, or trained trees, then plants from Genoa or Malta are decidedly preferable; indeed, no plants fitting for the purpose of standards could be elsewhere procured. Miller is of this opinion, observing, that "by much the quicker way of furnishing a green-house with large trees, is to make choice of such as are brought over every year in chests from Italy; for those which are raised from seeds in England will not grow so large in their stems under eighteen or twenty years, as those are when brought over; and although their heads are small when we receive them, yet in three years, with good management, they will obtain large heads, and produce fruit." When the plants are purchased in London, at the Italian warehouses, without names, the greater number will be found to be of the shaddock and citron kinds; as the Italian gardeners find these sorts make stronger shoots and more showy plants, and therefore send a less number of the less luxuriant but more useful varieties. But the best way is to send an order, through a British merchant who has a correspondent at Genoa, for named sorts, ordering so many of each class, either from the table of Dr. Sickler (1880.) or the synopsis of Gallesio. (fig. 4881.)

5938. *Management in pots and boxes.* The management of dwarf English or French plants in moderate-sized pots or boxes, for the green-house stage, consists in common green-house treatment. Being potted in the proper soil, the roots are to be annually examined before the growing season in spring, and when matted or diseased, trimmed off and repotted, or shifted into larger pots at discretion. Henderson says, "The general management of the orange-trees from the middle of March till the 1st of October, may be discussed in a few words. I give the trees a good watering all over the leaves once a-week with the engine, excepting when they are in flower. Till the end of May this watering is given about 11 o'clock in the forenoon. After the end of May, I give them a good dashing over the leaves twice a-week with the engine, and now I do it in the evening. In very hot weather I repeat the engine-watering thrice a-week.

I never set the orange-trees out of doors during summer; for, from thirty-eight years' experience, I find it is much against them, in the climate of Scotland. In hot weather I keep them in the back of the vinery, under the shade of the vines, or behind the stage of the green-house. Orange-trees delight to be in the shade in sunny weather; they here grow freely, and keep a fine dark-green color. From the frequent waterings over the leaves in summer, the pots require less water, but they must be carefully attended to, and when the plants are making their young shoots, the pots or tubs require a good supply of water. From October to March, I give them a gentle sprinkling over the leaves once in two or three weeks, but only in fresh weather, taking the opportunity of a mild day, when there is a little sun, and always in the forenoon." (*Caled. Hort. Mem.* iii. 303.)

5939. *For the management for Italian plants, destined to grow large trees and produce crops of fruit in boxes or tubs, the treatment requires to be more particularly detailed.*

5940. *The following are Miller's directions:—* Having furnished yourself with a parcel of trees, prepare a moderate hot-bed of tanner's bark, in length and breadth according to the number of trees to be forced, then put your trees into a tub of water upright, about half way of the stems, leaving the head and upper part of the stem out of water, the better to draw and imbibe the moisture. In this situation they may remain two or three days, according to their plumpness when you received them; then take them out and clean their roots from all filth, cutting off all broken or bruised roots, and all the small fibres which are quite dried by being so long out of the earth, and scrub the stems with a hard hair brush, cleaning them afterwards with a cloth; then cut off the branches about six inches from the stem, and having prepared a quantity of good fresh earth, mixed with very rotten neat's dung, plant your trees therein, observing never to put them into large pots; for if they are but big enough to contain their roots it is sufficient at first planting. Wrap the stems round with hay-bands from bottom to top to prevent the sun from drying their bark: plunge the pots in the bark-bed, watering well to settle earth to their roots, frequently repeating the same all over their heads and stems, being very careful not to over-water them before they have made good roots, and shade from the sun in the middle of the day. If they have grown kindly they will have made strong shoots by the beginning of June; at which time stop them to obtain lateral branches to furnish their heads; harden them to admit their removal into the open ground in July; house them about the end of September; and, during winter, water frequently but moderately, guarding against frost. In the following spring clean the stems and leaves of the plants, top-dress the earth, and mulch, with rotten cow-dung, round the edges of the pots, taking care that none touch the stems. Remove to a sheltered situation in the open air by the end of May. As the trees advance, stop strong irregular-growing shoots in the summer season, to force out lateral branches, to fill the head, and render it regular and free from weak trifling branches. The trees will require to be shifted and new-potted, every other year, in April. In performing the operation, having drawn the trees out of the pots, cut off all the roots round the outside of the ball of earth, and take away all mouldy roots; then with a sharp iron instrument, get as much of the old earth from between the roots as possible; then set the root of the tree into a large tub of water, for about a quarter of an hour, to soak the under part of the ball of earth, then clean the stems. Repot the trees, and water, letting them remain in the house till they have taken root.

5941. *The operation of shifting, when the plants become very large, is much facilitated by adopting boxes which admit of being taken to pieces, as already described; the balls of earth can thus be slid from one box to the other instead of being lifted out of the box. Where the boxes do not separate, the tree and ball must be lifted out by fixing one end of a rope to the stem of the tree, and passing the other over a pulley suspended from a triangle. This mode is recommended by Van Osten, while some French authors recommend a carriage-lever and rope. The tree and ball of earth are thus, by either mode, suspended in the air, the latter is examined, the roots pruned, &c.; and this done, the same or a larger box is placed directly below the ball, with a proper quantity of compost at the bottom, and into this the tree is lowered, and the sides filled with earth, &c. The worst thing attending this mode is the liability of injuring the bark of the stem by the noose of the suspending rope.*

5942. *Henderson shifts oranges only once in two years, and frequently after a longer interval. "I never shift any plant till the pot is very full of roots. In shifting the oranges, I always take as much of the exhausted mould away as I can; and, on account of the light and free nature of the compost used, it comes easily from among the roots. The best season for this operation is about the beginning of March. Having turned the plants out of the pots or tubs, pick as much of the old exhausted mould from the ball as you can, without injuring the roots. They should be shifted into the pots or tubs only one size larger, and some of the plants will perhaps do better if replaced into the same pots again. Let the pots be all clean washed and dried before any plants be again put into them. Put a piece of crockery or broken pot over the hole in the bottom of the pit, with the convex side down; then cover the bottom, above the piece laid over the hole, three quarters of an inch thick, with char made from pit-coal, broken small, about the size of peas. This both forms a drain, and prevents the entrance of worms. On the top of the charred cinders place a layer of dried moss (*hypnum*), which prevents the compost mould from getting down amongst the char, and lets the water pass off freely from the roots of the plants. The bottoms of the pots being prepared in this way, put in a little of the compost; then introduce the roots of the plant into the pot, and fill it up with the compost, observing to keep a little of the mould betwixt the side of the pot and the roots. The plants may be set partly into the peach-house or the vinery, and some into the green-house, which will give a longer succession of their flowers. The orange-trees that are placed in the vinery or peach-house, if there be any fire-heat used at the time, must be watered as soon as put in; but those put into the green-house where there is little heat, may stand a day without getting any. After that space they may get a moderate watering; and this may be repeated once a-week till the weather become warm, when they will require it oftener. Those placed in the vinery or peach-house will require watering very frequently, according to the degree of heat kept in the house." (*Caled. Hort. Mem.* iii. 304.)*

5943. *Renovating old trees in pots or boxes.* Where orange-trees have been ill managed, and their heads become ragged and decayed, Miller directs to restore them by cutting off the greatest part of their heads by March; drawing them out of the pots or tubs, and shaking off the earth from their roots; then cutting away all small fibres and mouldy roots; and next soaking and cleaning their roots, stems, and branches, planting them in good earth, plunging them in a hot-bed, and treating them as directed for trees received from abroad.

5944. *Management of the citron tribe as standards.* Prepare foreign plants as directed above, and instead of planting in pots, plant in the border or floor. This must have been laid dry by proper drains, and if on a wet sub-soil, floored, to prevent the roots from penetrating into it. On this, lay the sort of earth, or compost, most approved of, to the thickness of three or four feet; care having been taken in constructing the house, that all the walls (excepting the north wall, if the house be opaque on that side); flues, paths, &c. be supported on pillars or piers, so as the compost may extend under them, and ten or twelve feet without the house, according to circumstances. Plant the trees either in squares, or better in quincunx, allowing six or eight feet between the trees, which will give thirty-six or sixty-four square feet to each plant. This distance will suffice for several years, and afterwards every other tree can be taken out. After planting,

which should be finished in April, water at the root, and morning and evening sprinkle a little over the tops to assist in causing them to break freely. Apply fires, and keep the house close night and day, with a moist heat of from 55° to 60° till the plants have made shoots of three or four inches; then begin to give a little air, gradually increasing it, but still keeping up the heat till the growth of the shoots is completed, when the sashes should be taken off to harden and color the shoots and leaves. It will be necessary to attend to the above directions annually, for three or four years, in the growing season, in order to procure as much wood in a short time as possible. Keeping the heads open and regular, with the common routine culture, is all that is necessary at other seasons.

5945. *On walls and espaliers.* Prepare the plants and the border as before, and plant about ten or twelve feet distance, allowing a larger space for the citron, lemon, and shaddock, than for the common orange, as the former grow faster and more luxuriantly. In the growing season, observe the directions already given, continuing them annually. The fan manner of training is that generally adopted.

5946. *Pruning.* The French pay great attention to this part of the culture of the orange tribe; and, indeed, display greater art in pruning every sort of tree, than the British. They have their winter *taille*, and their *ébourgeonnement*, or summer pruning, of the orange-tree, as of the peach and vine. Those at Versailles and the Tuilleries are looked over every year, and receive a very elaborate pruning every sixth or eighth year. The object of this pruning is to keep the head proportioned to the capacity of the box containing the roots. The heads of these trees, notwithstanding the annual prunings, become too large and show indications of suffering for want of nourishment every sixth or eighth year. The shoots are then shortened to within an inch or two of the old wood, and the tree, thus almost completely deprived of leaves, does not produce blossoms during the two next years: it pushes, however, vigorous shoots, which are trained to form a bushy well furnished head of the same shape and size as before. Such has been the practice of the late M. Pethon, who was head gardener at Versailles for forty years. The form of the heads of the trees at Versailles is that of a cylinder, spreading out at top, of which the height is greater than the breadth; those in other places are ovate, globular, or mushroom-shaped, and some are even square and triangular. (See *Van. Osten. c. xi.*) The blossoms of the orange-trees in the royal gardens of France, and in most gardens of Holland and the Netherlands are carefully picked off as they appear; as well to prevent the tree from being exhausted by bearing fruit, as for the use of the flowers in perfumery. Those of the Tuilleries, Neill informs us (*Hort. Tour.*), are farmed at the rate of 200*l.* a-year; and those of Versailles are let annually, in lots, and produce 125*l.* a-year, or upwards. In Holland the flowers are commonly the perquisite of the gardener. Thus the beauty of the continental orange-trees is far inferior to those of Italy or Britain, which are covered with fine large fruit.

5947. *The pruning which orange-trees receive in England*, does not differ, in general, from that given to any green-house tree or shrub; and the consequence is, handsome bushes or trees, with the blossoms and fruit on the surface of the foliage. But when the orange-tree is cultivated for fruit, whether as standards or against walls, the branches ought to be kept thin, like those of other fruit-trees, so as to admit the sun, air, and water, freely to every part, and thus have the blossoms and fruit regularly distributed from the centre to the extremities. This is readily effected where the trees are flat-trained, which, where fruit is the object, is a great argument in favor of that mode of culture.

5948. *In pruning, with a view to fruit*, it must be considered, that the most useful blossoms of most sorts of citrus are produced in the form of terminating peduncles, on the wood of the current year; and hence, the grand object of the pruner ought to be to encourage the production of young wood in every part of the tree; by cutting out naked wood, and shortening vigorous shoots where wood is wanting. A powerful co-operating measure is the exposition of all the parts of the tree to the light and air, which, as already observed, is only to be done in standards, by keeping the trees open, or by flat training. There are also blossoms produced by various sorts of citrus, in tufts, directly from the axillæ of the leaves of the wood of the preceding year: these expand earlier than the others, but generally drop off in plants kept under cover. Ayres cuts away the old and least-promising branches, in February, to make room for younger and more productive wood, and shortens very strong branches to keep the trees in proper shape. After the fruit is set, it ought to be thinned, seldom leaving more than one on a peduncle. In France they thin the flowers, which, by that means, they are enabled to use for distillation. The thinned fruit is used in confectionary. Mean observes, "In regard to the necessity of thinning the fruit, lest the trees should exhaust themselves, it appears to me to depend on the state of the trees: if they are flourishing, I never observed that it was at all required, either here or at Bromley Hill, where the orange-trees belonging to the Right Honorable Charles Long are very fine, and loaded with peculiarly large fruit." Ayres thins when the fruit are about the size of green-gage plums, and never leaves two fruit together. Will standard trees, pruned with a view to fruit, be equally beautiful with the compact geometrical-headed trees of Paris, and the old conservatories of this country? Those who prefer a full-bottomed periwig to a natural disposition of the hair will not think so. The two beauties, or effects, are of different kinds; the latter has utility to recommend it; the former, associations of the pomp and formal grandeur of past times. Quintiney, and other French authors, direct the wounds or sections made in pruning orange-trees, to be covered with a composition to exclude the air; which deserves to be attended to, as the growth of the bark is otherwise very slow over wounds in these trees.

5949. *Manure.* About Genoa, the best cultivated orange-groves are manured annually. In France and this country, the best practitioners stir the surface and apply a top-dressing of rich compost when the trees begin to grow, generally in April or May. Ayres top-dresses in June.

5950. *Gathering the fruit.* In the Italian gardens, and those at Hieres in France, where the fruit of the orange is raised for sale, it is gathered every year, generally in May. If not then gathered, it will hang on the tree for one or two years longer; but when the young fruit is green and swelling, the old ripe becomes somewhat shrivelled, and if then gathered is found almost void of juice. But as the new fruit begins to arrive at maturity, the juice begins to return to the old fruit; so that both old and new crops are in perfection together the following May. In this way, at Genoa, the orange is sometimes allowed to remain on the tree three years, and being then gathered, has a peculiar subacid sweetness and flavor, and is sold at a very high price to connoisseurs at Milan, Turin, and other places. The lemon differs from the orange in that it ripens irregularly, and drops off when ripe. It is therefore gathered at almost every season. The orange-tree, kept in conservatories, generally requires fifteen months to ripen its fruit, and hence, both green and ripe fruit are together on the tree. Some authors assert, that the leaves remain on the same period with the fruit; but Quintiney says, "on a vigorous plant they will remain three or four years." In Britain they often remain three years on moderately strong plants without fruit. In gathering for the table in this country, the fruit should not be pulled with the hand, but carefully cut off with a few leaves attached, and, thus garnished, sent to the dessert. By allowing them to hang two years, the trees will at all times have green and yellow fruit, which, in connexion with their shining green leaves and fragrant blossoms, forms, early in spring, in such a house as we have hinted at (5929. and fig. 521.), one of the most splendid of horticultural scenes.

5951. *Insects and diseases.* The chief insects injurious to the citrus tribe, are the coccus and red spider; both to be removed or destroyed by water applied with the engine, brush, or sponge. Mean, early in March, when he top-dresses his plants, applies a copious washing with the engine; then shuts up the house close for three or four hours, which produces a strong heat, as high as 70°, which effects the destruction of the red spider; while the stems and leaves are wiped with a wet sponge to remove other insects and dirt. (*Hort. Trans.* ii. 296.) Henderson destroys the aphid by fumigation; the red spider by sprinkling and dashing with water; the coccus, by laying on the leaves with a brush some black soap dissolved in water, or by watering and dusting the leaves with sulphur; and the only remaining insect which infests the orange, the thrips, he destroys with water. (*Caled. Hort. Mem.* 315.)

SUBJECT. 2. *Pomegranate*. — *Punica Granatum*, L. (*Bot. Mag.* 634.) *Icos. Monog.* L. and *Myrtaceæ*, J. *Grenadier*, Fr.; *Granatenbaum*, Ger.; and *Melagrano*, Ital.

5952. *The pomegranate* is a low deciduous tree, rising fifteen or twenty feet high, thickly clothed with twiggy branches, some of which are armed with sharp thorns. The leaves are long and narrow, of a light shining green with red veins. The flowers are produced at the ends of the branches, in the shoots of the same year, single or three or four together; frequently one of the largest terminates the branch, and immediately under that are two or three smaller buds, which continue a succession of flowers for some months, generally from June to September. The calyx is very thick and fleshy, and of a fine red color; the petals are scarlet. The fruit is a berry covered with a hard coriaceous rind, and beautifully crowned with the tube of the calyx, which is sharply toothed, and remains even after the fruit is ripe, contributing greatly to its singular and beautiful appearance. The fruit ripens in October, and, in a green-house, will hang on the trees till the spring or summer following. It is a native of most parts of the south of Europe and of China. In Languedoc, and some parts of Italy, it is used as a hedge plant. It was cultivated in England in 1596, by Gerrard; but though it grows very well in the open air, it seldom ripens its fruit so as to render them worth any thing. It used formerly to be kept in boxes, and housed like the orange-tree, which is still the practice near Paris and in the Netherlands. Some of the orange and pomegranate trees in the orangery at Versailles, Risso informs us, are believed to be between two and three hundred years old.

5953. *Use*. The fruit having an acid pulp is very refreshing, and is eaten like the orange; its singular and beautiful appearance contributes to the variety of the dessert. It is used medicinally in fevers and inflammatory disorders; being powerfully acid and astringent.

5954. *Varieties*. The Paris nurseries propagate the following sorts: those marked thus (*) may be had in the London nurseries.

The wild, or very acid-fruited
The subacid-fruited, or cultivated *
The sweet-fruited
Large-flowered single red and white

The semi-double, and double red and white *
The yellow-flowered *
The variegated-flowered

The prolific; in which a shoot proceeds from the middle of the flower.

5955. *Propagation*. The single-flowering sorts may be raised from seed, and all the varieties by cuttings, suckers, or layers, or by inoculation or grafting on the wild sort. The last is considered much the best mode where fruit is the object; and the next best is by layers, but the common mode is by suckers, which these plants send up abundantly. Inoculated plants, both of the single and double sorts, may be procured from Genoa; and this is the most desirable plan where the plant is to be cultivated for its fruit.

5956. *Culture*. The directions given for raising and cultivating the orange-tree may be considered as equally applicable to the pomegranate, which, with the olive, was formerly the common companion of these trees in conservatories. Miller has observed, "that both the single and double pomegranate are hardy enough to resist our most severe winters in the open air; and that if planted against walls, the former will often produce fruit, which ripen tolerably well in warm seasons, but ripening late, are seldom well tasted." Where it is to be grown for fruit, therefore, either the standard or flat trained mode, under glass, as recommended for oranges, should be adopted. A few trees may be introduced along with those of the citrus tribe.

Soil. Miller recommends a strong rich soil, in which he says, "they flower much better, and produce more fruit than if planted on dry poor ground." In regard both to soil and mode of growth, the pomegranate bears a close resemblance to the hawthorn.

5957. *Pruning and training*. As already mentioned, the flowers of this tree always proceed from the extremity of the branches produced the same year, hence all weak branches of the former year should be cut out, and the stronger shortened, in order to obtain new shoots in every part of the tree. When the trees are trained against a wall, the shoots having small leaves, may be laid in four or five inches asunder. The season for the winter pruning, Miller says, is about Michaelmas; for if left till spring before they are pruned, they seldom put out their shoots so early. In summer they require no other dressing than pinching off fore-right and over vigorous shoots, as it is the middling only which are fruitful. In a warm situation Miller obtained a great quantity of fruit from trained trees; which, though not very well flavored, were of full magnitude, and made a very handsome appearance on the trees. The double and other varieties, cultivated for the sake of their flowers, should be pruned, whether in boxes or against walls, on the same principle.

SUBJECT. 3. *Olive*. — *Olea Europæa*, L. (*Fl. Græc.* i. t. 3.) *Diand. Monog.* L. and *Oleinæ*, B. P. *Olive*, Fr.; *Oehlbaum*, Ger.; and *Uliua*, Ital.

5958. *The olive* is a low branching evergreen tree, rising from twenty to thirty feet, with stiff, narrow, bluish-green leaves. The flowers are produced in small axillary bunches from wood of the former year, and appear in June, July, and August. The fruit is a berried drupe of an oblong spheroidal form, hardish thick flesh, of a yellowish-green color, but turning black when ripe. The tree is supposed to be originally from Greece; but it is now naturalised in the south of France, Italy, and Spain, where it has been extensively cultivated for an unknown length of time, for the oil expressed from its fruit. The tree attains an incredible age. Near Terni, in the vale of the cascade of Marmora, is a plantation above two miles in extent, of very old trees, and supposed to be the same plants mentioned by Pliny, as growing there in the first century. It appears to have been cultivated in the botanic garden of Oxford, in 1648, and is generally treated as a green-house plant. With protection from severe frost, Miller says, "it may be main-

tained against a wall in the latitude of London." In Devonshire, some trees have stood the open air for many years; but the fruit does not arrive at maturity. Some trees planted against a warm wall at Camden House, near Kensington, succeeded so as in 1719 to produce fruit fit for pickling.

5959. *Use.* At the dessert, and frequently, also, during dinner, unripe olives appear as a pickle; which, though to those who taste it for the first time, it appears somewhat harsh, yet it soon becomes extremely grateful; and is said to promote digestion and create an appetite. Pickled olives are prepared by steeping in an alkaline lessive, to extract a part of their bitter; they are next washed in pure water, and afterwards preserved in salt and water, to which an aromatic, as fennel, &c. is sometimes added. The ripe olive, pressed and washed with hot water, furnishes, when skimmed, the well known condiment and corrective, salad-oil, employed both in food and medicine. It may be considered as the butter of Italy and Spain.

5960. *Varieties.* In the olive-countries these are nearly as numerous as the sorts of the grape and fig. The French (*N. Cours*, &c. in loco) describe between thirty and forty sorts. The following are grown in English nurseries:—

The common | Large-leaved | Broad-leaved | Iron-colored | Twisted-leaved | Box-leaved.

5961. *Propagation.* By seeds, cuttings, layers, suckers, and inoculation. The last mode is adopted where the culture of the olive is conducted with care; but the *olivettes*, or olive-plantations, are generally furnished from suckers, which arise abundantly from the roots of old trees. In England, as a green-house plant, it is raised from cuttings; but where it is intended to grow a few trees in the forcing-department, for the sake of their fruit, we would recommend procuring strong plants from Genoa; these will produce fruit in three or four years, but the others not for an unknown length of time.

5962. *Culture.* Some plants used formerly to be received by the Italian merchants along with their imports of orange-trees, and were planted, like them, in pots or boxes; but in order to grow the tree for fruit, the modes to be adopted are either planting as standards in the area, or training on a wall, as recommended for the orange and pomegranate. If a house is not devoted to this fruit, one might be appropriated for it and the pomegranate; giving each their respective soils, and recollecting that the olive will not bear a very high degree of heat.

5963. *Soil.* The olive will grow luxuriantly in a strong clayey richly manured soil, but will not prove nearly so prolific as in a dry, calcareous, schistous, sandy, or rocky situation; which ought to be imitated in some degree in the composition prepared for the area or border of the olive-house.

5964. *Temperature.* That suitable for the orange will, agree with the olive; but it cannot bear so high a degree of heat as that plant, never being found in Africa south of Atlas, nor in the East or West Indies. It is also easily affected by cold, but not more so than the orange.

5965. *Pruning.* The object here is to have a regular distribution of wood of the former year, from the axils of the leaves of which, the flowers spring out. When shoots of three or more years are shortened for this purpose, they do not produce blossoms; but wood of the preceding or current year may be shortened, and the shoots proceeding from them will produce blossoms in due course. Ringing, to induce fruitfulness, was practised on the olive so early as the seventeenth century. (*Bosc*, in *N. Cours*, &c. art. *Olivier*.)

SUBJECT. 4. *Indian Fig, or Prickly Pear.*—*Cactus opuntia*, L. (*Knor. Thes.* 1. t. *F. a.*)
Icos. Monog. L. and *Cacti*, J. *Raquette*, Fr.

5966. The genus *cactus* consists of succulent plants, permanent in duration, singular and various in structure, generally without leaves, and having the stem or branches jointed, and for the most part armed with spines and bristles. The joints or branches of the *C. opuntia* are ovate, compressed, and have very small cadaverous leaves coming out in knots on their surface, and accompanied by four short bristly spines. The branches spread near to, or trail on the ground. The flowers come out on the upper edges of the branches in June and July. The fruit is in the form of a fig or pear, with clusters of small spines on the skin, which encloses a fleshy pulp of a red or purple color, and agreeable subacid flavor. It is a native of Virginia and Barbary, but is now naturalised in the south of Italy, being found on the rocks at Terracina and Gaeta. It was cultivated in England by Gerrard, in 1596, in the open air, but without bearing fruit. It was cultivated in the stove by Justice at Crichton near Edinburgh, in 1750, and ripened its fruit. Miller says, "it will live abroad in England in a warm situation and dry soil; but in severe winters will be destroyed if not protected from frost."

5967. *Use.* The fruit is sent to the dessert in the West Indies; and might add to the variety of exotic fruits in this country. Braddick observes (*Hort. Trans.* ii. 239.), that in countries where the fruit abounds, it is considered very wholesome, and though the taste of it is not agreeable to all persons till after they have eaten of it several times, yet they soon become very fond of it.

5968. *Sorts.* There are several species of that division of the genus *cactus*, called prickly pears or figs, which produce edible fruit in their native countries, as the great Indian fig, or upright prickly pear, (*C. tuna*) (*Plant. grass* 138.); oblong Indian fig (*C. ficus Indica*) (*Reich*, vol. ii. 470.); Barbadoes gooseberry (*C. pereskia*) (*Dill. elt. t.* 227. f. 294.); the *C. opuntia* is deemed the most hardy, and by consequence the easiest to fruit in Britain; but there can be no doubt that the other sorts might also be brought to mature their fruit with very little expense or trouble. They are at present kept in dry-stoves for the sake of variety.

5969. *Propagation and culture.* All the above sorts may be propagated from seed or cuttings; the latter mode is most common. Cut off the branches at the joints, in July, or after the plants have done flowering, and let them dry for a fortnight, that the wounded part may be healed over; then plant in small pots, and plunge in the bark-bed, or in a moderate hot-bed, watering sparingly, giving air to avoid damps, and shading from the midday sun.

5970. *Soil.* Miller recommends the following: one third of light fresh earth from a pasture; a third

part of sea-sand; and the other part, one half rotten tan, and half lime rubbish. These are to be mixed and laid in a heap, three or four months before using, turning it over once a month; then pass it through a rough screen, but do not sift it fine; reserving some of the small stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off. The Barbadoes gooseberry requires less lime-rubbish and more of vegetable earth.

5971. *Temperature.* All the sorts, excepting the prickly pear, require the temperature of a dry-stove in winter, and an increased degree of heat, say 80° or 90° in summer, when it is intended they should produce fruit. They may either be planted in large boxes, filled with the soil above described, with a portion of vegetable mould added; or in borders, to be trained on a wall or trellis near the light. In either case, by supplying them liberally in summer, whilst in a growing state, with heat at bottom and top, air, light, and some moisture, they will thrive abundantly, and produce fruit certainly not of exquisite flavor, but agreeable and singular, and worthy of being added to the British dessert.

5972. *Culture of the prickly pear in the open air.* Braddick having eaten, with pleasure, of this fruit in Virginia, was desirous of cultivating it here. He recollected that the plant in its wild state delighted in a dry soil, amongst rocks, near the skirts of the sunny sides of the forests; and having heard that it would stand the open air in this country, he planted it in the compost described below, placed in a sheltered situation open to the sun. "The first plant that I turned out has lived in the open ground of this country for six or seven years, during which period it has endured one exceeding hard winter, and several trying springs; and in all, except the two first years, it has never failed to ripen its fruit and seeds, so that it may be now considered decidedly acclimated. The compost used by me for growing the *Cactus opuntia* is the following: one half is carbonate of lime, for which lime-rubbish from old buildings will answer; the remaining half consists of equal portions of London clay and peat-earth, having the acid neutralised by barilla: these are intimately blended and sifted. One square yard of this compost I conceive to be sufficient for one plant, which must be placed in the middle of a small artificial hillock, raised eighteen inches above the surface of the ground, which ground should be rendered perfectly dry, if not naturally so, by under-draining. Neither the leaves, flowers, nor fruit should ever be suffered to touch the ground, but they should, as constantly as they are produced, be kept from the earth by placing stones, pebbles, flints, or bricks under them, in imitation of artificial rock-work." (*Hort. Trans.* 238.)

5973. *The torch-thistle, or upright cereus*, of which there are four species which bear edible fruit, and the *strawberry-pear* (*C. triangularis*), the *poire de chardon* of the French, may also be cultivated as fruit-bearing stove plants, in the same way as recommended for the Indian fig.

SECT. III. Exotic Fruits little known, some of which merit Cultivation for their Excellence or Rarity.

5974. *The introduction and cultivation of new exotic fruits* may be considered as a very rational and entertaining object, for such as have the means, the time, and a taste for gardening. It seems to deserve the particular attention of retired persons of solitary habits, aged or inactive, by presenting an end to be attained; it may serve as a gentle stimulus to such as, from indolence or bilious complaints, are apt to sink into a state of torpid unenjoyed existence. A few of the plants, which we shall here enumerate, have been cultivated so as to produce fruit in this country, as the granadilla, lee-chee, loquat, banana, &c.; most of the others have hitherto served only to increase the variety of our stove or green-house plants.

5975. *The akee-tree* is the *Blighia Sapida*, H. K. (*Ann. Bot.* 2. t. 16, 17.) *Oct. Monog. L.* and *Sapindi, J.* (fig. 523.) It is a tree rising from twenty to twenty-five feet in height, with numerous branches, and alternate pinnate leaves, like those of the common ash. The flowers are small, white, on axillary racemes. The fruit is a pome, reddish or yellow; about the size of a goose's egg, with a pulp of a grateful subacid flavor; and in the West Indies esteemed very wholesome and nourishing. It is a native of Guinea, and was introduced in Jamaica in 1778, and from thence brought to this country in 1793.

5976. *Propagation and culture.* It may be propagated from seeds, cuttings, or layers; but as the former mode would prolong the period of culture for fruit, and the two latter produce but weak plants, the better plan would be to order a few trees to be inoculated in Jamaica, and then sent over in tubs; these might be treated as directed for orange-trees (5939), and then planted in a border of rich earth, submitted to a Jamaica climate, and flat-trained near the glass. By such treatment, there can be no doubt the akee-tree would in a few years produce fruit as readily as the orange.

5977. *The alligator, or avocado pear*, is the *Laurus Persea*, L. (*Pluk. Alm.* t. 267. f. 1.) *Ennean. Monog. L.* and *Laurinae*, B. P. It is a stove tree which, in the West Indies, grows to the height of thirty feet or upwards, with a trunk as large as that of our common apple-tree. The leaves are like those of laurel, of a deep-green. The flowers are produced towards the extremities of the branches. The fruit is the size of one of our biggest pears, and is held in great esteem in the West Indies; the pulp is of a pretty firm consistence, and has a delicate rich flavor; it gains upon the palate of most persons, and becomes soon agreeable even to those who cannot like it at first; but it is so rich and mild, that most people make use of some spice or pungent substance, to give it a poignancy; and for this purpose some make use of wine, some of lime-juice, but most of pepper and salt. Miller, from whom the above account is extracted, cultivated it in 1739.

5978. *Propagation and culture.* Miller gives directions for raising the tree from seeds, which, he says, may be brought over in dry sand from the countries where it is cultivated. There is nothing uncommon in the process of raising, which is conducted in a hot-bed or pit; and when the plants have made their summer shoots, they are removed to the stove during winter. But where it is intended to cultivate this tree for its fruit, a better way would be to send to the Botanic Garden of St. Vincent's, and request

524

5981. *The durion* is the *Durio Zibethina*, L. (*Rumph. Amb.* p. 99) *Polyadelph. Polyan.* L. and *Capparidæ*, J. (*fig. 525*). This is a lofty East Indian tree, with leaves resembling those of the cherry, and large bunches of flowers coming out below the leaves, of a pale-yellow color. The fruit is the size of a man's head, roundish or oblong; resembling in some degree a rolled-up hedgehog, with a hard bark or rind; the fleshy part of the fruit is of a creamy substance, and of a delicate taste; but of an unpleasant heavy smell, somewhat resembling that of rotten onions; and the smell of the breath of those who eat it is infected also in a high degree; but when once a person has accustomed himself to eat this fruit, he generally considers it the most excellent of all. Rumphius says, it is by much the most excellent fruit of India. The tree has not yet been introduced; but if a few fruit or plants were sent for from the Calcutta garden, and submitted to the general plan of culture for trees difficult to fruit, there can be no doubt of success.

5982. *The white guava* is the *Psidium pyriferum*, L. (*Rumph. Amb.* l. t. 47.) *Icos. Monog.* L. and *Myrtacæ*, J. (*fig. 526*.) It is a West Indian tree, growing to the height of seven, eight, or twelve feet, with numerous branches and blunt, entire, smooth leaves, two or three inches long; the flowers are in solitary peduncles and sweet-smelling; fruit bigger than a hen's egg, roundish or oblong, smooth, yellow; the rind thin, brittle, and yellow; pulp firm, full of bony seeds, flesh-colored, sweet, aromatic, and pleasant. It is eaten with avidity both by West

526

Indians and Europeans, raw in the dessert, and preserved with sugar. It has been grown here as a stove plant since 1656; it is propagated by seeds from ripe fruits brought over; and to be fruited should be treated as directed for other similar fruit-trees already mentioned.

5983. *The red guava* (*P. pomiferum*) has a beautiful fruit, crowned like a pomegranate; but is not so agreeable to eat as the other.

5984. *Cattley's Guava*, *P. Cattleanum*. A new species introduced from China by Messrs. Barr and Brooks, nurserymen, and fruited by W. Cattley, F. H. S., in 1820. The plant resembles the other species in general habit and appearance; but the fruit is larger, nearly spherical, of a fine deep claret color, growing in the axilla of the leaves; the skin has much the consistence of that of a ripe fig, but is thinner; the interior is a soft fleshy pulp, purplish-red next the skin, but becoming paler towards the middle, and at the centre it is quite white; it is juicy, and in consistence is much like a strawberry, to which it bears some resemblance in flavor. (*Hort. Trans.* iv. pl. xi. 317.)

5985. *The jamrosade, or rose-apple*, is the *Eugenia Jambos*, L. (*Bot. Mag.* 1696.) *Icos. Monog.* L. and *Myrtacæ*, J. (*fig. 527*.) It is a branchy tree, rising from twenty to thirty feet high, with long narrow leaves not unlike those of the peach. The flowers come out in terminal bunches in July, are of a greenish-yellow color, and succeeded by fruit about the size of a hen's egg, white, red, or rose-scented, with

the flavor of a ripe apricot, and ripening from September to December. There are several varieties of this tree differing in the size and color of the fruit. That with white fruit has been cultivated by Professor Thouin in the National Garden at Paris. This horticulturist endeavored to harden the tree by exposing it annually to the open air during the two hottest months of the year; but, after persisting in this mode of cultivation for several years, and finding the leaves and part of the shoots die off annually, in consequence of the cold while exposed, he at last had recourse to a hot and moist atmosphere, and was successful. (*Hort. Trans.* i. App.) Cattley has a plant which regularly yields him abundance of fruit. (*Hort. Trans.* v. 112.)

5986. *The Malay apple* is another species of *Eugenia* (*E. Malaccensis*). (*Bot. Rep.* 458.) The tree resembles the former, but has broader leaves. The fruit is ovate, an inch and a half in diameter, fleshy, very sweet-smelling, like the rose, agreeable to the taste, smell, and sight, and esteemed wholesome. It is common in most of the islands in the South Sea, and was cultivated by Miller in 1768.

5987. *The bastard guava* (*E. Pseudo-Psidium*) and the *Cayenne cherry* (*E. cotinifolia*) produce

a few stocks to be inoculated from bearing trees. These being properly cased and packed, would arrive as safe as orange-trees usually do; might be treated like them when unpacked; and planted in a border of strong rich soil, to be trained on a trellis or wall near the glass. After the plants were established, horizontal training and ringing, accompanied by a Jamaica temperature, would soon produce fruit.

5979. *The anchovy-pear* is the *Grias cauliflora*, L. (*Sloan. Hist.* 2. t. 217. f. 1. 2.) *Polyan. Monog.* L. and *Guttiferæ*, J. (*fig. 524*.) It is a stove tree, frequently growing to the height of fifty feet in the West Indies, where it is a native. The leaves are oblong, and two or three feet long. The flowers numerous on short peduncles, large and whitish. The drupe is ovate, and crowned with a calyx like the pomegranate, about the size and shape of an alligator's egg: it is pickled, and eaten like the East Indian mango, which it greatly resembles in taste. It grows generally in low moist bottoms, or shallow waters, and has a most elegant appearance. Introduced here from Jamaica in 1768.

5980. *Propagation and culture.* It is very readily propagated from the stones, and the plants must be kept in a moist heat. To grow it for fruit, plant in a border, and train horizontally near the light, as directed for the avocado-pear. (5978.)

525

edible fruits, held in considerable esteem in the West Indies, and with the Malay apple appear to deserve culture in this country. (See *Miller's Dict.*)

5988. The custard-apple (*Anona reticulata*), alligator-apple (*A. palustris*), sweetsop (*A. squamosa*), and soursop (*A. muricata*), are esteemed West Indian fruits; and the Chermoyer (*A. tripetala*), the *Cherimolia* of some botanists, is the fruit most prized by the natives of Brazil and Peru. All these plants are already in our stoves, and might easily be cultivated as fruit-trees.

5989. The mammee-tree (*Mammea americana*, L.) *Polyan. Monog. L. and Guttifera*, J. is a tall handsome tree, with oval, shining, leathery leaves, and one-flowered peduncles, producing sweet white flowers an inch and a half in diameter, succeeded by roundish fruit, about the size of an egg, and in pulp and taste not unlike the apricot. It is eaten raw alone, or cut in slices with wine and sugar, or preserved in sugar. It is a native of the Caribbee Islands, and was cultivated in 1739 by Miller.

5990. *Propagation and culture.* It may be raised from the stones or seeds, and treated like other stove fruit-trees. It has been cultivated by Knight, who found it rather impatient of a very high temperature. (*Hort. Trans.* iii. 464.)

5991. The lee-chee and long-yen. The lee-chee is the *Dimocarpus Litchi*, W. (*Lam. ill. t. 306.*) *Octan. Monog. L. and Sapindaceae*, J. It is a stove tree, with compound leaves, not unlike those of the common ash-tree; a native of China, and introduced in 1786. The fruit is a berry of a red color when ripe, except in one variety, which remains green: it is much esteemed by Europeans.

5992. The long-yen is the *D. Longan*, H. K. (*Buch. Ic. t. 99.*) The tree resembles the former, but the fruit is not so large, and is of a light-brown color. "In both species the pulp of the fruit is surrounded with a tough, thin, leathery coat; it is a colorless, semi-transparent substance; in the centre of which is a dark-brown seed of different sizes in the different varieties. The flavor of the pulp is slightly sweet, sub-acid, and particularly pleasant to the taste in a warm climate. The fruit of the lee-chee, dried either in the sun or by fire-heat, is frequently brought to England from China. In this state the pulp is shrivelled and reduced within the coat, or shell, to half its usual size, and has a rich and sweet taste, if it has been well preserved. The fruit of the long-yen has been ripened by John Knight, Esq. of Lee Castle, in a lofty stove, erected for the purpose of growing tropical fruits; and a bunch was presented by him to the Hort. Society, in September, 1816, supposed to be the only one ever produced in Europe, and which persons well acquainted with the long-yen in its native places of growth, pronounced quite as good as those grown within or near the tropics." (*Hort. Trans.* ii. 408.)

5993. *Propagation and culture.* Both species may be raised from seeds or layers, and the plants may be afterwards placed in a bed or area of rich soil, and trained or spread out near the glass. The temperature should never be under that of the pine-apple.

5994. The lo-quai is the *Mespilus Japonica*, L. (*Vent. Malm. 19. and Hort. Trans.* iii. tab. 11.); *Eriobotrya japonica*, Lam. *Icos. Di-Pent. L. and Rosaceae*, J. (*fig. 523.*) In a wild state it is a lofty tree with thick knobbed branches, and tomentose spray or branchlets; the leaves are narrow, a span long, bright-green and cinereous tomentose below. The flowers come in spikes at the end of the shoots in October and November. The fruit is a five-celled pome, about the size of a gooseberry, and in taste approaching to that of the apple. It ripens in May and June. It is a native of Japan, and was introduced in 1787 to Kew-gardens, where, as well as in some other places, it has produced fruit.

5995. *Propagation and culture.* It may be raised from seeds, or continued by cuttings or layers; but the best method, when it is intended to produce fruit, is to graft it on any other species of *mespilus*. It is considered as a frame or half-hardy tree; but, to ripen its fruit with flavor, should have the temperature of the stove, in which, planted in a border of rich soil, it will add to the variety of the dessert. Sir Joseph Banks (*Hort. Trans.* i.) considers the fruit as equally good with that of the mango. Lord Bagot, who has fruited the plant in a very superior manner for several years at Blithfield, gives the following outline of his practice: "The plan I have usually followed has been to give it a

winter (out of doors) during the months of July, August, and September, and about the middle of October to replace it in a very warm situation in the tan. This summer, however, I was obliged to alter my mode; for, just at the moment when I was going to put it out for its winter, it became covered with at least twenty bunches of the finest flowers possible; I was therefore obliged to let it remain where it was. The present year's treatment, therefore, is an exception to the former practice; under that, it usually breaks into flower about the end of December, and the fruit becomes ripe in March or April. The last time my plant was in fruit, Sir William Coke, who had resided many years in Ceylon, where he is at present, was with me at Blithfield; he told me that he was in the constant habit of eating very large quantities of the fruit daily in that island, but that he had never tasted any so good, and with so much flavor, as those produced in my garden."

5996. The mango-tree (*Mangifera indica*, L. (*Bot. Rep. 425.*) *Pent. Monog. L. and Terebintaceae*, J.) (*fig. 529.*) is a large spreading tree, like the walnut, with lanceolate shining green leaves, seven or eight inches long, having a sweet resinous smell; the flowers are white, growing in bunches at the extremity of the branches. The fruit a drupe, large, kidney-shaped, covered with a smooth, softish, resinous pale-green, yellow, or half-red skin, and containing an ovate, woody, fibrous, compressed nut or stone,

within which is an ovate kernel, soft and pulpy, like a damascene plum. "When ripe, it is replete with a fine agreeable juice; it eats like an apple, but is more juicy, and some are as big as a man's fist. It is esteemed a very wholesome fruit, and, excepting very fine pine-apples, is preferable to any fruit in India: gentlemen there eat little or other fruit in the hot months. In Europe we have only the unripe fruit brought over in pickle." (*Martyn, in Miller's Dict.*) It is a native of the East Indies, and was introduced in 1690; but has not yet been cultivated for its fruit. According to Governor Raffles, forty varieties of mango are known in Java.

5997. *Propagation and culture.* It may be increased by cuttings like the gardenia, which it somewhat resembles in habit, or from nuts; but as the vegetative quality of these does not seem to admit of long preservation, they must be enveloped in wax, or otherwise managed (2312.), to preserve it. Miller says, the tree will not thrive in the tan-pit; and he recommends the dry stove, a temperate heat, and light kitchen-garden earth. This tree seems particularly deserving culture for its fruit, both on account of its quality, and the plants not requiring so much heat as most of the other untried Indian fruits. Knight raised some mango-plants from seeds in October, 1818, which in the following March, shot very vigorously in a temperature of 60°; he is "much inclined to believe that the mango might be raised in great abundance, and considerable perfection, in the stove, in this country; for it is a fruit which acquires maturity within a short period. It blossoms in Bengal in January, and ripens in the end of May." (*Hort. Trans.* vol. iii. 463.)

5998. *The mangostan, or mangustin.* — *Garcinia Mangostana*, L. (*Lam. Ill. t. 405.*) *Dodec. Monog. L. and Guttiferae*, J. (fig. 530.) It is a tree rising near twenty feet high, with a taper stem, sending out many branches, not unlike a fir-tree; with oval leaves, seven or eight inches long. The flower is like that of a single rose; the fruit round, the size of a middling orange; the shell is like that of the pomegranate, the inside of a rose-color, divided by thin partitions as in oranges, in which the seeds are lodged, surrounded by a soft juicy pulp, of a delicious flavor, partaking of the strawberry and the grape, and is esteemed one of the richest fruits in the world. It is a native of the Molucca islands, whence it has been transplanted to Java and Malacca. The head of the tree is in the form of a parabola, so fine and regular, and the leaves so beautiful, that it is looked upon in Batavia as the tree most proper for adorning a garden, and affording an agreeable shade. It was introduced to England in 1789. According to Dr. Garcin (*Phil. Trans.*), "it is esteemed the most delicious of the East Indian fruits, and a great deal of it may be eaten without any inconvenience; it is the only fruit which sick people are allowed to eat without scruple. It is given with safety in almost every disorder; and we are told that Dr. Solander in the last stage of a putrid fever in Batavia, found himself insensibly recovering by sucking this delicious and refreshing fruit. The pulp has a most happy mixture of the tart and sweet, and is no less salutary than pleasant."

5999. *Propagation and culture.* It may be raised from seeds or cuttings; and in procuring the seeds from the East Indies, the same precautions must be taken as suggested for those of the mango. (5997.) Miller says, "the surest way to obtain the plants, is to sow the seeds in tubs of earth in their native country, and when the plants have obtained strength, they may be brought to Europe; but there should be great care taken to screen them from salt water in their passage, as also not to give them too much water when in a cool or temperate climate. When the plants arrive in Europe, they should be carefully transplanted each into a pot filled with light kitchen-garden earth, and plunged in the tan-bed, and shaded from the sun till they have taken new root. Then treat them as suggested for fruiting other stove plants."

6000. *The pishamin, or European date-plum, (Diospyros Lotus, L. (Mill. Lc. t. 116.) Polyg. Diac. L. and Ebenaceae, B. P.)* is a small tree, rising six feet high, with spreading branches, and large shining lanceolate leaves. The flowers are small, of a reddish-white; the fruit is a berry half an inch in diameter, yellow when ripe, sweet, and somewhat astringent: it is used like the medlar, in a state of incipient decay. It is a native of Italy and some parts of France; was introduced to this country in Gerrard's time, and will grow in the open air, but not ripen its fruit freely.

6001. *Propagation and culture.* It may be raised from seeds sown in a hot-bed, and afterwards hardened, or from layers; but when it is intended to fruit the plant, it may be procured from Genoa of a good size; and, planted in a temperate forcing-house, it will not fail to mature its fruit.

6002. *The granadilla, or little pomegranate.* This name is applied to the edible fruit of five species of the *Passiflora* genus; *Monadel. Pentan. L. and Passiflorae, J.* The common character of which is that of climbing herbaceous plants, woody at bottom, generally with lobed leaves, and all natives of warm climates.

6003. *The granadilla, or granadilla-vine of the French, is the P. quadrangularis, L. (Bot. Reg. 14.)* The leaves are oval and subcordate, five or six inches long and entire; the stem luxuriant and four-cornered. The flowers are odoriferous, red within and white on the outside, and appear in August and September, both fruit and flowers growing at the same time. The fruit, Sabine describes (*Hort. Trans.* iii. 100.) as very large, of an oblong shape, about six inches in diameter, from the stalk to the eye, and fifteen inches in circumference. It is externally of a greenish-yellow when ripe, soft and leathery to the touch, and quite smooth; the rind is very thick, and contains a succulent pulp of a purple color (which is the edible part), mixed with the seeds, in a sort of sack, from which it is readily separated. Wine and sugar are commonly added to it, when used. The flavor is sweet, and slightly acid, and it is very grateful to the taste, and cooling in a hot climate. It is a native of Jamaica, and other West India islands, where it grows in the woods, and was cultivated by Miller in 1768, as a stove plant. It has since been successfully cultivated for its fruit in a few places, as at Lord Harewood's (*Hort. Trans.* iv. 60.), Farnley Hall, &c.

6004. *The apple-fruited granadilla, or sweet calabash, is the P. maliformis, L. (Bot. Reg. 95.)* It has a thick triangular stem, with leaves oblong, cordate, six inches long, and four broad, in the middle of a lively green. The flowers are sweet-scented, large, of a pale red and blue: "the fruit round, smooth, about two inches in diameter, of a dingy yellow color when ripe; the coat is hard and stringy, nearly a quarter of an inch in thickness, full of a very agreeable gelatinous pale yellow pulp, in which many oblong black seeds are lodged," (*Hort. Trans.* iii. 101.) and is eaten like that of the former species. It is a native of the West India islands, and was introduced here, and cultivated by Miller in 1751. It has borne fruit in the stove of the Bishop of Durham in Oxfordshire, and at Vere's, Kensington Gore.

6005. *The laurel-leaved granadilla, or water-lemon, the Pomme de Liane of the French, is the P. laurifolia, L. (Bot. Reg. 13.)* It has a suffrutescent stem, with divaricating filiform branches, oval smooth leaves, and very long tendrils. Flowers red and violet, sweet scented; the fruit about the size of a hen's egg, but rather more elongated, and tapering equally at both ends; when ripe, it is yellow and dotted over with white spots; it contains a whitish watery pulp, which, in the West Indies, is usually sucked through a small hole made in the rind; the rind is tough, soft, and thin; the juice has a peculiar

530

aromatic flavor, is delicately acid, and allays thirst agreeably. It is a native of Martinique and Surinam, and was introduced here in 1690. It is grown in the stove, but has not yet been cultivated for its fruit.

6006. *The purple-fruited granadilla* (Hort. Trans. vol. iii. pl. iii.) (fig. 531.) is by some botanists considered as a variety of *P. incarnata*, but by Sabine, who thus describes it (Hort. Trans. iii. 99.), as a distinct species. "The stem is thick and woody, the leaves three-lobed, and of considerable size; the flowers proceeding from the axilla of the leaves, fragrant, and of a white color, tinged with purple. The fruit when unripe, is green, but as it ripens changes to a dark livid purple, and much resembles the fruit of the purple egg-plant. The shape is elliptic, an inch and a half in diameter, and two inches from the stalk to the top; the pulp is orange-colored, and the seeds numerous; the taste acid, and the flavor somewhat like that of the orange. It is a native of the Brazils, was introduced from Portugal by Boehm, in 1810, and has produced fruit abundantly in the stoves at Walton-on-Thames, at the royal gardens at Windsor, and other places. Such is the rapid growth of this species, that a single plant will in one season extend in a line over upwards of forty feet of glass, on which space it will produce from 400 to 500 fruit."

6007. *The flesh-colored granadilla, or May apple*, is the *P. incarnata*, L. (Abb. in Geor. t. 12.) The root is perennial, sending up annually a number of herbaceous shoots, with three-lobed leaves, and sweet-scented flowers, variegated with purple, and appears from July to September. The fruit when ripe is about the size of an apple, orange-colored, with a sweetish yellow pulp. It is a native of Virginia, was cultivated in the open air by Parkinson in 1629, and afterwards by Miller in the stove, with whom it bore fruit.

6008. *Propagation and culture.* All the sorts may be propagated from seed, layers, and even cuttings; but layers come soonest into bearing. Having procured plants with good roots, plant such as are intended to fruit in a border in the stove, and train them to a trellis near the glass; they will in general produce fruit the second year. The seedlings of the purple-fruited sort will produce fruit the first year. All the species will fruit even in large pots; but Sabine says, the "best method is, to plant them in an angle of the bark-bed, which has been parted off, either by boards or nine-inch brick-work, as low as the pit goes. At the bottom of the cavity, formed by this division, should be laid some brick-rubbish, over which may be thrown a little dead tan, and the whole be then filled with equal parts of very old tan, and a compost of leaf-mould and rotten dung. Herein the roots will strike freely, and will even spread through the partition into the pit, growing into the fresh tan. Such roots may be trimmed and reduced whenever the tan is changed; but should the plant have been some time in its station, it will be as well to leave part of the old tan in the bottom of the pit, in which the protruded roots may remain undisturbed. They do not require the full heat of the pine-stove, for they flourish best in a temperature of from 65 to 70 degrees; but they do not bring their fruit to perfection if kept in a common green-house or conservatory, though they will grow and flower in it. The shoots as they advance must be trained near to, and under the inclined glass of the stove: the first flowers will appear in May, and the blooming will continue until September, the fruit setting the whole time; but if it does not set well, it will be advisable to impregnate the stigmas, by applying the pollen with a feather. As they grow, the very strong shoots should be cut out from their origin, for these do not bear fruit so abundantly as those which are less vigorous; but the fruiting branches must not be shortened on any account. The temperature must be kept up equally, during the time of flowering and fruiting; the crop will begin to come in in August, and will continue until January; but the earlier produce is the best. When the crop is all off, which will be early in January, the heat must be reduced to about 50°, so as to check or stop the growth; this being effected, the shoots must be well cut in. As little old wood as possible, besides the main stem, which rises from the pit to the glass, and a few pieces (about two or three feet of each) of the old branches should be retained: for all that is to be trained under the glass to bear in each year, ought to be the growth of the same season. It is found that the shoots break better, and in greater quantity, from the older wood than from that of two years' standing. In this dormant and reduced state it is to be kept during January and February, after which the necessary heat may be applied to cause it to resume its functions for the ensuing season."

6009. *The cocoa-nut-tree* is the *Cocos nucifera*, L. (Roxb. Cor. I. t. 73.) Monoc. Hexan. L. and Palmae, B. P. (fig. 532.) It is an East Indian palm; but cultivated in most places within the tropics. The trees grow to a great height, with leaves thirteen or fourteen feet long; the flowers come out round the top of the trunk of the tree in large clusters, enclosed in a spathe or sheath; and the nuts succeed them commonly ten or twelve together. Their form and use is familiar.

6010. *Propagation and culture.* The nuts are to be planted where they are designed to remain, as the tree will not bear transplanting unless when very young. In a moist heat they will push in six weeks or two months. To cultivate for fruit, plant in the centre of the area of a house, twenty-five feet wide, and either lofty, or with a moveable roof, which will admit of being raised as the tree advances in height. In this way, with a strong heat, there can be no doubt this tree would produce fruit in England; but even if it did not, or did not for a great many years, the magnificence of its appearance, under such a mode of treatment, would compensate a curious horticulturist for the labor and expense. Though the cocoa-nuts to be obtained in the shops are supposed to be gathered before being ripe, yet they have been found to grow with no other care than planting in a large pot or box of rich earth, and plunging in a bark-bed. It may be observed here, that this is almost the only palm that could be cultivated in this country for perfecting its fruit; for the others being dioecious plants, unless a great number were grown together, there would be no legitimate means of impregnating the female blossoms.

6011. *The plantain-tree* (*Musa paradisiaca*, L. Hex. Monog. L. and Musaceæ, P. S.) rises with a soft, herbaceous, conical stalk, fifteen or twenty feet high, with leaves issuing from the top, often more than six feet long, and near two feet broad; the spike of male and female flowers appear from the centre of the leaves, and is succeeded by pudding-shaped fruits, eight or nine inches long, above an inch in diameter, pale-yellow when ripe, of a soft, sweet, luscious flavor; the spikes often so large as to weigh upwards of forty pounds. It is a native of the East Indies, and other parts of Asia, and probably of Africa,

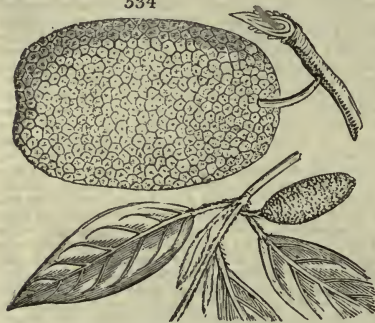

and was cultivated at Hampton Court in 1690. Gerrard says, the pulp eats something like that of a muskmelon; he calls the plant Adam's apple-tree, from a notion that it was the forbidden fruit of Eden; others suppose it to have been the grape brought out of the promised land to Moses. Dampier says, it is the king of all fruit, not excepting the cocoa itself. There are numerous varieties.

6012. *The banana-tree* (*M. sapientum*, L.) (fig. 533.) differs from the plantain in having its stalks marked with dark-purple stripes and spots, and the fruit is shorter and rounder. Some botanists, however, consider them as only one species. The fruit is mellow than the other, is eaten raw or roasted, in fritters, preserves, marmalades, and the fermented juice affords an excellent wine. It has been fruited for upwards of seven years, at Wynnstay, the seat of Sir W. W. Wynne, in Denbighshire. Specimens were sent to the Horticultural Society in August 1819, which were between four and five inches long, and possessed an agreeable, luscious, and acid flavor, and the produce from a single plant is "so abundant, as to entitle the banana to be considered as a useful fruit for the table."

6013. *Propagation and culture.* Suckers rise from the root, which should be planted in light rich earth, in pots, and afterwards, if the plant is cultivated for its fruit, planted in a bed or pit of earth, kept rather moist. The plant at Wynnstay was planted in the pit of a stove about 1811. "It was then about six feet high, with a single stem. In each succeeding year it has produced a bunch of fruit; but in the present year (1819) two bunches; the first was ripe in May, the other in August, having about four dozen fruit on each bunch. The plant is now sixteen feet high, and measures three feet round at the bottom." (*Hort. Trans.* iv 138.)

534

6014. *The bread-fruit.* — *Artocarpus incisa*, L. (*Rumph. Amb.* 3. t. 33.) *Monac. Monan.* L. and *Urticæ*, J. Rima or Fruit-à-pain, Fr. and *Brodbaum*, Ger. It is a stove tree, growing in the South Sea Islands to the height of a moderate-sized oak, with alternately leaves, deeply gashed, glaucous, and two feet long. Aments on the outmost branches, violet-colored, peduncled, male and female on the same twig. The whole tree and the fruit, before it is ripe, abounds in a very tenacious milky juice. The fruit is about the size and shape of a child's head, and the surface is reticulated, not much unlike a truffle; it is covered with a thin skin, and has a core about as big as the handle of a small knife; the eatable part lies between the skin and the core; it is as white as snow, and somewhat of the consistence of new bread. It must be roasted before it is eaten, being first divided into three or four parts; its taste is insipid, with a slight sweetness, somewhat resembling that of the crumb of wheaten bread mixed with Jerusalem artichoke. Five plants were brought to England, the remain-

der of the stock brought from Otaheite by the unfortunate Captain Bligh in 1793. In Professor Martyn's edition of *Miller's Dictionary* will be found a variety of interesting details relative to this tree, and another species, the *A. integrifolia*, or *Jacca-tree*, which also well merits culture for its fruit.

6015. *Propagation and culture.* This tree will grow either from seeds, layers, or suckers; the latter the plants send up abundantly in their native climates. They succeed best in a rich soil; and to induce them to produce fruit, should be treated as already advised for other stove fruits not easily fruited. As the bread-fruit-tree has been introduced in the West India Islands, the shortest way would be to procure good sized plants from Jamaica or St. Vincent's though they may be occasionally obtained from the London nurserymen.

6016. *The true lotus* (*Ziziphus lotus*, W.), the *jujube-tree* (*Z. Jujuba*, W.), and the *kaki* (*Diospyros Kaki*, W.), are branching shrubs or small trees of the easiest culture in Italy, Barbary, and China, and abundant bearers. They might readily be cultivated in this country, and as the jujube grows in hedge-rows about Genoa and Nice, it is probable it would bear fruit abundantly in a green-house. The jujube is served up in Italy as a dry sweetmeat. The fruit of the kaki are orange or apple shaped.

6017. *Other exotic fruits.* The following have been enumerated by Lindley (*Hort. Trans.* v. 88.), as meriting introduction, or where already introduced, to be cultivated as dessert-fruits.

6018. Of *African* fruits we might have from Sierra Leone, the cream-fruit, country cherries, country plums and figs; from Congo, the conte, mabocche, gangi, safu, and anona senegalensis; from Loango, the cazou as large as a melon; from Madagascar, the voanato, voutaca, voaucrome, azonaluala, and alamotou.

6019. From the *West Indies*, the sappodilla-plum (*Achras Sapota*), country cherries which are various species of Malpighia, the callimato-tree (*Chrysobalanus Icaeo*), the star-apple (*Chrysophyllum Cainito*), the country plums (*Spondias*) various species, the sea-side grape (*Coccoloba uvifera*), the garlic-pear (*Cratæva Tapia*), and various species of cactus. Most of these fruits are cultivated both in the West India Islands and on the American continent, and plants of all of them may be had from the London nurseries.

6020. From *South America* numerous fruits may be introduced: from Guiana, the tapaculo (*Carica microcarpa* ?), the pinaoi (*Anona punctata*), the pinaïoua (*A. longifolia*), the marmalade-box of Stedman (*Surinam*, vol. ii. p. 330.); from Brazil, Peru, &c. the achocon (*Leonia glycyarpa*), the queule or keule (*Gomortega nitida*), and others of less note.

6021. From *Asia* the first fruits in the world have been obtained, and others are yet to introduce. From the Indian Archipelago, the lanshe (*Lansium domesticum*), a fruit considered as next to the mangosteen and durian, the rose-water jambu (*Eugenia aquea*), and other species; the blimbing (*Averrhoa Carambola*), the cheremi (*A. acida*), the rambutan (*Nephelium lappaceum*), the tomi-tomi (*Flacourtia inermis*), the Xanthochymus dulcis, Sandoricum indicum, and some others. From the continent of India, the maredoo, or elephant-apple (*Egle Marmelos*), the yellanga (*Feronia elephantum*), the latti am (*Wilughbeia edulis*), the iwara mamady (*Xanthochymus pictorius*), the caraunda (*Carissa Carandas*), the launzan (*Buchanania latifolia*), and others. From China and Japan many new sorts of pears and peaches, it is supposed, may be obtained, and probably also apples and other European fruits; the Pomaceæ and Prunaceæ occupying the place in higher latitudes which the Myrtaceæ, Guttiferæ and Terebintaceæ do in countries nearer the equator. From the Society Islands, the Otaheite apple (*Spondias cytherea*), &c. Though we think it probable that few or none of these, grown in this country, would be

found to equal our best peaches, pears and plums, or even gooseberries and strawberries; yet we cannot but wish to see this or the contrary proved by the wealthy and curious horticulturist.

SECT. IV. *Erotic Esculents, not hitherto cultivated as such.*

6022. *Of erotic esculents, some, as the yam and sweet potatoe, are worthy of being experimented on with a view to their naturalisation as articles of food; and even as furnishing a variety of esculent root, they deserve to be grown and sent to table, where there is a complete or extensive garden establishment.*

6023. *The West Indian yam* (the *inhame* of the Portuguese, and *igname* of the French,) is the name applied to several species, with their numerous varieties of the genus *Dioscorea*, L. *Dioc. Hexan. L.* and *Dioscorea*, J. They are climbing, perennial, herbaceous plants, with tuberous roots, and axillary flowers in spikes or racemes. The name yam is more particularly applied to the *D. sativa*. (*Rheed. Mal. 8. t. 51.*) (*fig. 535.*) This plant has tender stalks, climbing to the height of eighteen or twenty feet, and furnished with smooth-nerved roundish leaves. From the base of the leaves arise spikes of small flowers of no beauty. The root is flat, brownish, a foot broad, and nearly palmated like those of some of the orchideæ. It is a native of, and cultivated extensively in, Africa and the East and West Indies, and was introduced here from the latter country in 1733. The roots are mealy, easy of digestion, palatable, and not inferior to any roots now in use, either for delicacy of flavor or nutriment. They are eaten instead of bread, either roasted on the cinders or boiled; the flower is also made into bread and puddings.

6024. *The D. alata*, (*Rheed. Mal. 7. t. 38.*) or *winged yam*, is in equal, if not more universal cultivation than the former species. Its roots are frequently three feet long, and weigh thirty pounds. Of both these species there are numerous varieties, differing in the size and form of their roots.

6025. *Propagation and culture.* They may be propagated like the common potatoe, and cultivated in nearly the same manner as the forced potatoes. Browne (*Hist. of Jam.*) affirms, "that the roots must be cut so as to leave a little of the skin to each piece, for by that alone they germinate; the roots having no apparent buds or eyes, but casting out their weakly stems from every part of the surface alike. They are planted commonly in August, and are ripe in November or December following."

6026. *The Spanish, or sweet potatoe*, is the *Convolvulus Batatas*, L. (*Rheed. Mal. 7. t. 50.*) *Pent. Monog. L.* and *Convolvulaceæ*, B. P. (*fig. 536.*) It is a herbaceous perennial, with a round stem, hispid, prostrate, creeping, of a whitish-green, putting out scattered, oblong, acuminate tubers, purple or pale on the outsides. The leaves are angular, on long petioles; the flowers purple, on upright peduncles. It is a native of both the Indies, and was introduced here, and cultivated by Gerrard in 1597. He calls the roots *potatus*, *potades*, or *potatoes*, and says, that they are by some named *skirrels* of Peru. They flourished in his garden till winter, when they perished and rotted. *Batatas* were then sold at the exchange in London, and are still annually imported

into England from Spain and Portugal. They were, as already observed (3647), the common potatoes of our old English writers; the *Solanum tuberosum* being then little known. The tubers of the *batatas* are sweet, sapid, and nourishing. They are very commonly cultivated in all the tropical climates, where they eat not only the roots but the young leaves and tender shoots boiled. There are several varieties, if not distinct species, differing in the size, figure, and taste of the roots.

6027. *Propagation and culture.* In warm climates this plant is cultivated in the same manner as our potatoe, but requires much more room, for the trailing stalks extend four or five feet every way, sending out large tubers, forty or fifty to a plant. In the national garden at Paris, the plants are raised in a hot-bed, and about the middle of May, transplanted in the open ground, where they are earthed up, and otherwise treated like the potatoe. In warm seasons they produce a tolerable crop, and we have been informed by Professor Thouin, that he hopes, after several years, at least so far to acclimate the plant as to fit it for field-culture in the south of France. Lelieur, who grows it in the same manner, also strongly recommends its culture. Both consider it as much lighter food than the common potatoe, and equally nourishing. In England, Miller observes, the roots must be planted on a hot-bed in the spring, and if the plants are kept covered in bad weather with glasses, they will produce flowers and many small tubers from the joints; but if they are exposed to the open air, they seldom make much progress. This, however, ought not to discourage the curious or patriotic horticulturist, either in his attempts to raise the roots for the table, or to acclimate the plant.

6028. *The caper* (*Capparis spinosa*, L. *Polyan. Monog. L.* and *Capparidææ*, J.) (*fig. 537.*) is a trailing shrub, a native of the south of Italy and Sicily, where it abounds on rocks, ruins, and old walls: it has been long cultivated in France, and was introduced in this country in 1596, as a stove plant; but there is reason to believe it may be naturalised. It is cultivated, Neill observes, in the neighborhood of Paris, with no other protection than that of being trained against a low wall, and the shoots in winter laid down and covered with litter or fern, like those of the fig.

In the garden at Camden House, Kensington, a caper-tree stood alive in the open air for near a century: it had a south-east aspect, and was well sheltered from the north; it had no covering, and was generally much injured by the frost; but the roots of this plant being particularly strong and vivacious, it made strong shoots, and produced flower-buds every year. It is probable, therefore, that a plantation, so situated, if covered every autumn with litter, mats, or ferns, would succeed. Such a plantation, not trained on walls, but planted in an open compartment, would, like those near Toulon, in France, have the general appearance of a plantation of brambles, and might be yearly covered with very little trouble. Neill suggests, that a hardy variety might possibly be obtained by repeatedly raising from seed, at first in Guernsey or Jersey, and the plant thus gradually inured to this country. The part used is the flower-bud, which forms a well known pickle, and an article of considerable commerce from Sicily, and other islands in the Mediterranean.

6029. *Propagation and culture.* It may either be raised from seed, cuttings, or pieces of the root. The authors of the *Cours complet d'Agriculture* prefer the mode by cuttings, and direct them to be cut a foot long, and planted in autumn. The autumn following, they will be fit to remove to a general plantation. They describe two modes of culture; one, that of planting in walls, where no farther care is wanting, but that of gathering the buds; and the other, that of planting in quincunx in open compartments, like other fruit-shrubs; the latter mode is greatly to be preferred.

6030. *The salsilla, or edible alstræmeria.* — *Alstræmeria Salsilla*, B. M. (*Bot. Mag.* 1613.); and *S. edulis*. (*Hort. Trans.* vol. ii.) *Her. Monog. L.* and *Asphodeleæ*, B. P. This is a herbaceous plant of great beauty, a native of Peru, and introduced in 1806. It is cultivated in the West Indies, where its roots are eaten like the potatoe. It was flowered here in 1811, in the Comte de Vande's garden at Bayswater. It requires the temperature of the stove, and may be cultivated in a hot-bed like the early potatoe.

6031. *The bread-root.* — *Psoralea esculenta*, Ph. (*Pursh. Amer. t.* 22.) *Diadelph. Decan. L.* and *Leguminosæ*, J. It is a perennial herbaceous plant, a native of Missouri, and introduced here in 1811. It will grow in the open air, but requires the protection of a frame to produce abundant crops of roots, which are used like those of the potatoe in the countries where it is a native.

6032. *The pi-tsi, or water-chestnut of the Chinese.* — *Scirpus tuberosus*, Rox. (*Rox. iii.* 26.) *Triand. Monog. L.* and *Cyperaceæ*, B. P. (*fig.* 538.) It is a stoloniferous rush, without leaves, excepting a slender short sheath or two at the base of each culm. On the stolones grow tubers which are in high estimation among all ranks of the Chinese, not only as a pot-root, but as a medicine. It is eaten either boiled or raw.

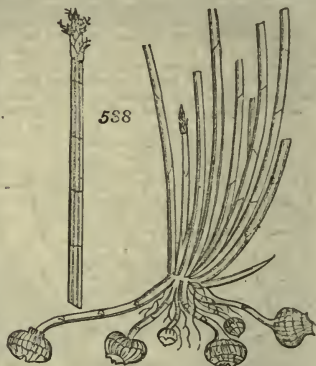

6033. *Cultivation.* "The maa-tai, pu-tsai, or pi-tsi, of Abbé Grosier, grows in tanks; these are matured for its reception about the end of March. Thus a tank being drained of its water, small pits are dug in its bottom; these are filled with human manure, and exposed to the sun for a fortnight; their contents are next intimately blended with the slimy bottom of the tank, and the slips or roots of the plant deposited therein; the water is now returned to the tank, and the new crop of tubers comes to perfection by the first of September." (*Rox. Corom.*)

6034. *The earth-almond, or rush-nut, (Cyperus esculentus, L. Triand. Monog. L. and Cyperaceæ, J. Souchei comestible, Fr. and Zizole di Terra, Ital.)* is a fibrous-rooted grass, with small round tubers hanging from the fibres, about the size of peas, which taste like chestnuts or almonds. It is a native of Italy and Montpelier, and is cultivated in some parts of the south of Europe and Germany for food. The tubers are planted in spring, and taken up in October, and preserved for winter use in the manner of potatoes. It might probably be cultivated in this country in dry warm situations, or in a frame. (*Bon Jardinier.*)

6035. *The eatable hibiscus.* — *Hibiscus esculentus, L. Monadelph. Polyan. L. and Malvaceæ, J. Gombaud or Gombo, Fr.* This is a stove annual, a native of the West Indies, and introduced in 1692. A soft herbaceous stalk rises from three to five feet high, with crenate leaves, and axillary, pale sulphur-colored flowers, succeeded by capsules. These, in the West Indies and the south of France, are put green into soups, or eaten with butter. In the south of France it is cultivated in the open air for this purpose; and at Paris it is treated as we do the capsicum and love-apple. A similar treatment would, no doubt, succeed in this country.

6036. *The arracacha, of the order of Umbelliferae, J.,* is a South American plant, said to resemble the *Apium* in habit; *Conium Arracacha, Hook.*, and probably the *Conium moschatum* of Humb. The main roots divide into four or five others, which grow to the size of cows' horns. These are used in the manner of potatoes by the inhabitants of Santa Fé and the Caracas. They are light, starchy, and easy of digestion. The plant is said to thrive best in the elevated regions of mountains, where the medium heat does not exceed 58° or 60°. (*Annals of Bot. i.* 400.) This plant, through the exertions of the Horticultural Society, has recently been introduced to England, and will soon be subjected to examination and improvement.

6037. *Other exotic esculents.* To the above we might add, the *Dahlia*, recommended to be grown for its tubers by Thiébaud-de-Berneaud. The *Dolichos Soja*, a stove annual, the seeds of which form, or ought to form, the chief ingredient in the fish-sauce of that name. The earth-nut of South America (*Arachis hypogæa*), a stove annual, raised in a few places near Paris, on hot-beds, and then transplanted in the open air. The *Convolvulus reptans*, a shrubby stove plant, grown in China, in trenches filled with water, and used as a spinaceous or oleraceous plant. The *Basella nigra*, and other species, stove biennials, used for the same purpose: the European and Chinese water-caltraps (*Trapa natans* and *bicornis*), both greenhouse annuals, but fruited by Lambert in the stove. (*Hort. Trans. iv.* 563.) The *T. natans* is grown in the ponds in Holland, according to Professor Martyn, and the nuts are used there as chestnuts both by men and hogs; and Neill informs us that the canal at Versailles is covered with the plant, and that the fruit is sometimes served up at table. These, and a variety of others, the curious cultivator will find noticed in botanical works and books of travels, and will enjoy greater satisfaction in discovering them himself than in finding them here ready named for his experimental enquiries.

CHAP. XI.

Horticultural Productions which may be expected from a first-rate Kitchen-garden managed in the best Style.

6038. *The sources of edible enjoyment afforded by a first-rate kitchen-garden are numerous and varied ; and consequently a proprietor, who spares no expense on this department, ought to be informed of what he has a right to expect, subject, however, to the drawbacks of bad situations, uncertain seasons, and unforeseen accidents. Many gardeners object to tables of this kind, as leading to unreasonable expectations, disappointments, and quarrels, and as, in short, enlightening too much their employers. On this we shall only observe, that the more a proprietor requires, the more he must conform to the conditions on which alone these products are to be expected. As to the subject of enlightening masters, much might be said in its favor, and nothing founded in right reason against it. It is only by a knowledge of gardening that a master can distinguish a bad gardener from a good one ; and only from this appreciation that a good gardener can be properly valued and rewarded. Community of knowledge must be better than no community at all. A man who employs a gardener as he does a tailor, merely to supply his wants, may look on him as a very convenient machine, and useful to have about his premises ; but where a knowledge and taste for gardening exists in the employer, one point of union is formed between him and his servant, which must be productive of a certain degree of humanity, if not of mutual respect and consideration. It is only bad gardeners, therefore, that have to fear the dissemination of knowledge among their masters. In a work of this nature, however, in which the object is more to give the opinion of others than our own, we subjoin what M^r Phail observes on the subject, which may be reckoned the opinion of most men of his order. "The book called *Every Man his own Gardener*," he says, "gives a list of what fruits, &c. gentlemen may expect from their gardens in every month of the year ; such a list not only of fruits, but of flowers and esculent vegetables, which nature, assisted by artificial means, is incompetent to produce in every month of the year in any country, in any degree of latitude under the sun ; hence, from lists of this kind being given in books said to be written by practical gardeners, ariseth strife between masters and mistresses and their servant-gardeners."*

(*Gard. Rem.* Pref. xxviii.)

SECT. I. *January.—The Productions arranged in the Order in which they have been treated in the preceding Chapters.*

6039. *Culinary vegetables from the open garden or garden-stores.* Strassburgh cabbage, savoy, borecoles, Brussels sprouts. Kidneybeans for haricots, and Prussian and other peas. Potatoes, Jerusalem artichokes, turnip, carrot, parsnep, red beet, skirret, scorzonera, and salsify, from the root-stores and seed-room. Spinage in mild seasons ; also sorrel and white beet. Onions, leeks, garlic, shallot, and romacole. Sea-kale from the covered beds. Lettuce, endive, celery, American and winter cress. Parsley, if protected, horse-radish, and dried fennel, dill, chervil, &c. Thyme, sage, rosemary, lavender, from the open garden, and dried marjoram, savory, mint, basil, &c. from the herb-room. Rhubarb-stalks from covered roots ; anise, coriander and caraway-seeds, chamomile, elecampane, blessed thistle, &c. dried. Red cabbage and samphire. Wild rocket, wild spinage, sauce-alone, and sorrel, if a mild winter. Mushrooms from covered ridges. Sea-belt, or sweet fucus, dried.

6040. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, quinces, medlars, services from the fruit-room. Some plums and morello cherries, carefully preserved on the trees. Some thick-skinned gooseberries, currants, and grapes, preserved on the trees. Some dried fruits of the same sorts on branches hung up in the fruit-room. Almonds, walnuts, chestnuts, filberts from the fruit-room. Sloes from the bushes, wild services, hips, haws, and sometimes a few cloud-berry.

6041. *Culinary vegetables and fruits from the forcing department.* Kidneybeans. Potatoes. Sea-kale. Small salads. Parsley. Fennel. Rhubarb. Mushrooms. Fines, winter melons, grapes, strawberries, cucumbers occasionally. Oranges, olives, and pomegranates. Malay apple, loquats, and lee-chees. Yams and Spanish potatoes.

SECT. II. *February.*

6042. *Culinary vegetables from the open garden or garden-stores.* Scotch or Strassburgh cabbage, savoy, borecoles, Brussels sprouts, and, if a mild winter, cabbage-coleworts, broccolis. Haricots, beans, and soup-peas from the seed-room. Potatoes, Jerusalem artichokes, turnip, carrot, parsnep, red-beet, skirret, scorzonera, and salsify. Spinage, if a mild winter. Onions, leeks, garlic, shallot, and romacole. Sea-kale from covered beds. Lettuce, endive, celery. American and winter cress. Parsley, if protected, horse-radish, and dried fennel, dill, chervil, &c. Thyme, sage, rosemary, and lavender, from the open garden ; dried marjoram, basil, &c. from the herb-room. Rhubarb-stalks from covered roots ; anise, coriander and caraway-seeds, from the seed-room ; chamomile, &c. from the herb-room. Red cabbage, samphire. Nettle and thistle tops ; towards the end, sorrel-leaves, and if a mild winter, sauce-

alone. Mushrooms from covered ridges. Sea-belt preserved, and occasionally badderlocks.

6043. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, quinces, medlars, services from the fruit-room. Some plums from branches hung up in the fruit-room. Dried grapes and currants from branches hung up in the fruit-room. Almonds, walnuts, chestnuts, filberts from the fruit-room. Sloes from dried branches hung up in the fruit-room.

6044. *Culinary productions and fruits from the forcing department.* Kidneybeans. Potatoes. Sea-kale, asparagus. Small salads. Parsley, mint, chervil. Rhubarb. Mushrooms. A pine occasionally ; grapes, cucumbers, strawberries. Oranges, lemons, olives, pomegranates. Pishamin-nuts, lee-chees. Yams and Spanish potatoes.

SECT. III. *March.*

6045. *Culinary vegetables from the open garden, or garden-stores.* Brussels sprouts, borecoles of sorts, especially the early greens, and Breda kale, broccolis. Haricot-beans and soup-peas from the seed-room. Potatoes, Jerusalem artichokes, turnip, carrot, red-beet, parsnip, skirret, scorzonera, and salsify. Spinage occasionally, if mild. Onions from the root-room ; Welsh onions, ciboules from the garden ; garlic, shallot, romacole from the root-room ; Sea-kale from covered beds. Lettuce, endive, celery, American and winter cress ; also water-cress, barnet and others. Parsley, horse-radish, and dried fennel, dill, chervil, &c. Thyme, sage, rosemary from the open garden ; and dried marjoram, basil, mint, savory, &c. from the herb-room. Rhubarb-stalks from covered roots ; anise, coriander, caraway, and other seeds, chamomile, blessed thistle, and other dried herbs. Samphire. Nettle-top, dandelion-

leaves, bladder-campion-tops, water-cresses, brook-lime, sauce-alone. Mushrooms from covered ridges. Common and red dulse, sea-belt, and pepper-dulse.

6046. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, quinces, medlars, services from the fruit-room. Some dried grapes. Almonds, walnuts, chestnuts, filberts from the fruit-room.

6047. *Culinary productions and fruits from the forcing department.* Kidneybeans. Potatoes. Radishes. Sea-kale, asparagus. Small salads, onions. Parsley, mint, chervil, sweet marjoram. Rhubarb. Mushrooms. A pine occasionally ; grapes, cucumbers, strawberries. Oranges, shaddock, lemons, olives, preserved pomegranates. Loquats, pishamin-nuts, lee-chees, &c. Yams and Spanish potatoes.

SECT. IV. April.

6048. *Culinary vegetables from the open garden, or garden-stores.* Brussels sprouts, borecoles, broccolis, coleworts. Haricot-beans, and soup-peas from the seed-room. Potatoes, Jerusalem artichoke, yellow turnip, carrot, red beet, parsnep, skirret, scorzonera, and salsify. Spinage, orache, wild spinage, sorrel, fat hen, herb-patience. Bulbed and young onions, ciboules, and Welsh onions; garlic, shallots, rocambole, &c. from the stores. Sea-kale and asparagus at the end of the month; hop-tops, campion-tops, and thistle-tops throughout the month. Lettuce, endive, celery, American and winter cress; burnet, water-cress, and other salads. Parsley, purslane, tarragon from the garden; horse-radish and dried herbs, from the herb-room. Thyme, sage, mint, rosemary, lavender, tansy, from the open garden. The others of this class from the herb-room. Rhubarb-stalks from covered plants; angelica, elecampane, and thistle-stalks from the garden. The seeds and dried herbs of this class from the stores.

Samphire and buds of marsh-marigold. Nettle, campion, thistle, bryony, burdock, ox-tongue, sauce-alone, and other tops; chickweed, wild rocket, sea-belt, and other leaves. Mushrooms from covered ridges. Dulse, tangle, and other fuel, in a fresh state; sea-belt preserved; and floating fucus pickled.

6049. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, services, from the fruit-cellar. Some dried grapes from the fruit-room. Almonds, walnuts, chestnuts, filberts, from the fruit-room or cellar.

6050. *Culinary productions and fruits from the forcing department.* Kidneybeans, peas. Potatoes, carrots, radishes. Sea-kale, asparagus. Small salads, lettuce, onions. Parsley, purslane, mint, &c. Rhubarb. Mushrooms. A pine occasionally; grapes, cherries, peaches, cucumbers, melons, strawberries. Oranges, lemons, limes, pomegranates. Loquats, pishaminuts and dried lee-chees, and long-yens. Yams and Spanish potatoes.

SECT. V. May.

6051. *Culinary vegetables from the open garden, or garden-stores.* Early cabbages, cauliflowers, broccolis, and coleworts. Haricot beans, and soup-peas from the seed-room, and sometimes, though rarely, young peas, towards the end of the month, from a warm border. Potatoes and Jerusalem artichokes from pits, or cold cellars; turnip, carrot, and red beet from cellars or the open ground, if not destroyed by the frost; young radishes. Spinage, orache, wild spinage, sorrel, and herb-patience in perfection. Housed onions, and winter leeks; young onions, ciboules, and chives, garlic and shallot from cold rooms. Asparagus and sea-kale in perfection. Lettuce, endive, celery, succory, young radishes, and all the salads in perfection; winter radish, lamb-lettuce. Parsley, purslane, horse-radish, tarragon, and all this class, either fresh or from the herb-room. Thyme, sage, mint, tansy, costmary, &c. from the open garden; the others from the herb-room. Rhubarb-stalks, blanched, or otherwise, from the earthed-up or uncovered plants, angelica-stalks, anise, and other seeds, and the dried herbs, as before,

from the herb-room. Samphire, and buds of mar h-marigold. Charlick, fat hen, chickweed, sea-orache, sea-belt, &c. as greens; ladies'-smock and orpine, as salads; speedwell and vernal grass, as tea-plants. Morels from their native habitats; garden-mushrooms from covered ridges in the open garden. Dulse, tangle, and the other sorts of fuel, in a fresh state, and floating fucus for pickling.

6052. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, from the fruit-cellar. Dried grapes from the fruit-room. Almonds, walnuts, chestnuts, filberts, from the fruit-cellar.

6053. *Culinary productions and fruits from the forcing department.* Kidneybeans, peas, beans. Potatoes, carrots, radishes. Sea-kale, asparagus. Small salads. Chervil, purslane, &c. Mushrooms. A pine occasionally; grapes, peaches, melons, cucumbers, cherries, figs, apples, pears, gooseberries, and strawberries. Lemons, shaddockes, oranges, pomegranates. Yams.

SECT. VI. June.

6054. *Culinary vegetables from the open garden, or garden-stores.* Cabbages and cauliflowers in perfection. Kidneybeans, peas, and common beans. New potatoes, turnips, carrots, radishes. Spinage, orache, and sorrel, in perfection. Young onions and chives; rocambole and garlic from the root-room. Asparagus and sea-kale in perfection till the middle of the month. Small salads, lettuce, lamb-lettuce, radishes. Parsley, purslane, tarragon, horse-radish, fennel, dill, marygold, &c. Thyme, sage, mint, savory, basil, &c. from the garden, and the others from the herb-room. Rhubarb-stalks, angelica. Samphire, three sorts. Charlick, chickweed, fat hen, orache, and willow-herb, as pot-herbs; orpine, ladies'-smock, &c. as salads; sweet cicely as a garnish;

sea-bindweed as a pickle, and butterwort as rennet; ficaria-roots as saloop. Morels from their native habitats; and the garden-mushroom from covered ridges. Dulse, tangle, and the other sorts of edible fuel.

6055. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, from the fruit-cellar. Some cherries towards the middle of the month. Gooseberries, currants, strawberries, and raspberries, towards the end of the month. Almonds, walnuts, chestnuts, filberts from the fruit-cellar. Some snowberries and tree-currants.

6056. *Culinary vegetables and fruits from the forcing department.* Mushrooms. Pines, grapes, peaches, nectarines, figs, cherries, &c. melons, cucumbers. Shaddockes, oranges, lemons.

SECT. VII. July.

6057. *Culinary productions from the open garden, or garden-stores.* Cabbages and cauliflowers in perfection. Peas, beans, sugar-pea, and kidneybeans. New potatoes, turnips, carrots, radishes. Spinage, orache, sorrel, and white beet. Onions bulbed and ciboules, for salading. Artichokes, alisanders, rampion. Small salads, lettuce, radishes. Parsley, purslane, Indian cress, marigold, borage, fennel, &c. Thyme, sage, mint, balm; and all the others from the open garden, and also from the herb-room. Angelica-stalks, gourds; the aromatic seeds from the seed-room, and the herbs either from the herb-room, or open garden. Caper, Indian cress, radish-pods, kidneybeans, and pickling cucumbers. The pot-herbs and salads as in June, the seeds of some sorts of vetches, as legumes; the

cow-parnsep for its different uses, and butterwort; the roots of ficaria. Morels from their native habitats; garden-mushrooms from covered ridges. Dulse, tangle, &c. as in June.

6058. *Hardy fruits from the open garden, orchard, or fruit-room.* Juneating, margaret, and codlin apples; James and other pears from the trees. Some peaches, nectarines, and apricots; also cherries. Gooseberries, currants, strawberries, raspberries. Almonds, walnuts, chestnuts, filberts, from the fruit-cellar. Bird-cherries, tree-currants.

6059. *Culinary productions and fruits from the forcing department.* Mushrooms, pines, grapes, peaches, nectarines, figs, cherries, apples, melons, cucumbers, &c. Lemons.

SECT. VIII. August.

6060. *Culinary vegetables from the open garden, or garden-stores.* Cabbages, cauliflowers, broccolis. Peas, beans, sugar-pea, kidneybean. Potatoes, turnips, carrots, radishes, Jerusalem artichoke, red beet. Spinage, white beet-chard, orache, sorrel. Onions, bulb or small, shallots, garlic, and rocambole, from the garden. Artichoke, cardoon, rampion. Small salads; lettuce, endive, radishes, &c. Parsley, purslane, Indian cress, marigold, borage, fennel, &c. Thyme, sage, mint, balm, and all the others, green or dried. New seeds of caraway, anise, &c.; new hyssop, chamomile, and other herbs; gourds. Love-apple, egg-plant, capsicum, Indian cress, radish-tops, kidneybean, and pickling cucumbers. Most of the pot-herbs and salads of June; the roots of arrow-head, silver-weed, ficaria, and earth-nut roots; heath-tops and cow-parnsep. Mush-

rooms and champignons from pastures, and the open garden; truffle from commons. All the sorts of fuel in their greatest perfection for the table or pickling.

6061. *Hardy fruits from the open garden, orchard, and fruit-room.* Apples, pears. Peaches, nectarines, apricots, plums, cherries. Gooseberries, currants, strawberries, raspberries. Nuts, if desired, from the fruit-cellar; almonds, and some walnuts and filberts from the trees towards the end of the month. Tree-currants, roan-berries.

6062. *Culinary productions and fruits from the forcing department.* Mushrooms. Pines, grapes, peaches, figs, melons, cucumbers. Indian figs, straw-berry-pears. Alligator, granadillas, guavas, pears. New yams and Spanish potatoes.

SECT. IX.

September,

6063. *Culinary vegetables from the open garden, or garden-stores.* Cauliflowers, cabbages, broccolis. Peas, beans, and kidneybeans. Potatoes, turnips, carrots, parsneps, skirret, and all the roots. Spinage, beet-chard, orache, and sorrel. Onions, shallots, garlic, rocambole, and leeks. Artichokes, cardoons, rampions. Small salads, endive, lettuce, celery, tarragon. Parsley, horse-radish, Indian cress, marigold, fennel, chervils, &c. Thyme, sage, mint, and all the class, dried or green. Gourds and pumpkins; the aromatic seeds from the seed-room; and the herbs from the garden or herb-room. Love-apple, capsicum, egg-plant, samphire, red cabbage, kidneybean, &c. pickling cucumbers. Sea-peas and various legumes of the vetch kind, dropwort, Solomon's seal, saloop; and other roots; heath-tops and cow-parneps. Mushrooms and cham-

pignons from their native habitats, or from the open garden. Dulse, and all the sorts of edible fuel, in perfection.

6064. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, quinces, medlars. Peaches, nectarines, apricots, plums, cherries. Grapes, gooseberries, currants, strawberries, raspberries. Almonds, walnuts, filberts. Wild services, cloudberrys, bilberries, cranberries, brambles, hips, haws, &c.

6065. *Culinary productions and fruits from the forcing department.* Mushrooms. Pines, grapes, melons, cucumbers, figs. Pomegranates, Indian figs, torch-thistles, and strawberry-pears. Akees, alligator, and anchovy pears, guavas, and granadillas, some mangoes. Yams and Spanish potatoes.

SECT. X. October.

6066. *Culinary vegetables from the open garden, or garden-stores.* Cabbages, cauliflowers, broccolis. Peas and kidneybeans, if the weather is dry. Potatoes, turnips, carrots, radishes, Jerusalem artichokes, red beet, skirret, salsify, scorzonera. Spinage, beet-

chard, sorrel. Onions, leeks, garlic, shallots, and rocambole. Artichokes, cardoons, rampion, celery. Small salads, endive, succory, lettuce, winter-cress, burnet. Parsley, horse-radish, Indian cress, marigold, fennel. Thyme, sage, mint, and all of

this class green or dried. Gourds and pumpkins, aromatic seeds, and dried herbs, as in September. Love-apple, capsicum, egg-plant, red cabbage, kidneybean. Meadow-sweet, and the other edible roots, and heath for brewing. All the sorts of edible fuci.

6067. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, quinces, medlars, services. Some peaches, nectarines, apricots, plums, and protected or covered morello cherries. Grapes and strawberries, raspberries, and protected or

covered gooseberries and currants. Almonds from the fruit-room; and walnuts, chestnuts, and filberts from the trees. Wild services, cloudberry, bramble-berries, and cranberries.

6068. *Culinary productions and fruits from the forcing department.* Mushrooms. Pines, grapes, melons, cucumbers, figs. Pomegranates, olives, Indian figs; torch-thistles and strawberry-pears. Akees, alligator, and anchovy pears; guavas, granadillas, durions, mangoes, and mangosteen. Yams and Spanish potatoes.

SECT. XI.

November.

6069. *Culinary vegetables from the open garden, or garden-stores.* Cabbages, cauliflowers, protected by frames; broccolis, Brussels sprouts, savoy, borecoles. Dried kidneybeans and peas, from the seed-room. Potatoes, turnips, carrots, winter radish, Jerusalem artichoke, red beet, skirret, salsify, scorzonera. Spinage beet-chard, sorrel. Onions, leeks, garlic, shallot, romacole. Cardoons, rampions, celery. Endive, lettuce, winter cress, burnet. Parsley, horse-radish, fennel, and dried chervil, &c. Thyme, sage, and rosemary, the others chiefly from the herb-room. Caraway, anise, and other aromatic seeds from the seed-room; the family herbs from the herb-room. Red cabbage. The edible roots, as in October. Sea-belt, badderlocks, and other species of fuci.

6070. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, quinces, medlars. Some plums, and protected cherries from the trees. Grapes from the trees, and protected gooseberries, currants. Almonds from the fruit-room, and walnuts, chestnuts, filberts. Wild services, cloudberry, bilberries, cranberries, hips, and haws.

6071. *Culinary productions and fruits from the forcing department.* Mushrooms. Pines, grapes, melons, cucumbers, figs. Oranges, lemons, pomegranates, olives. Akees, guavas, granadillas, bananas, durions, mangoes, and mangosteens. Yams, &c.

SECT. XII.

December.

6072. *Culinary vegetables from the open garden, or garden-stores.* Strassburgh cabbages, cauliflowers, where preserved or protected, broccolis, savoy, Brussels sprouts, borecole. Dried kidneybeans for haricots; and soup-peas from the seed-room. Potatoes, turnips, carrots, winter radish, Jerusalem artichokes, red beet, skirret, salsify, and scorzonera, from the open garden or root-room. Beet-chard, where protected. Onions, leeks, garlic, shallots, and romacole. Cardoons, celery. Endive, lettuce, winter and American cress. Parsley, horse-radish, dried herbs. Thyme, sage, rosemary, lavender, &c. green, the other dried. The anise and other aromatic seeds from the seed-room; and the herbs of this class from the herb-room. Red cabbage. Edible roots from the stores or pits. Preserved sea-belt, and when the weather admits of gathering, other edible fuci; the floating fucus in pickle.

6073. *Hardy fruits from the open garden, orchard, or fruit-room.* Apples, pears, quinces, medlars, services. Some protected plums and cherries from branches hung in the fruit-room. Grapes from the trees, or from branches hung in the fruit-room. Almonds, walnuts, chestnuts, filberts, from the fruit-room. Sloes, from the bushes, wild services, hips, haws, cranberries, and cloudberry.

6074. *Culinary productions and fruits from the forcing department.* Kidneybeans. Potatoes. Sea-kale. Small salads. Chervil, fennel, &c. Rhubarb. Mushrooms. Pines, grapes, melons, &c. winter melons, cucumbers, figs. Oranges, lemons, pomegranates, olives. Akees, guavas, durions, mangoes, mangosteens, rose-apples, pishamins, lee-chees, &c. Yams and sweet potatoes.

BOOK II.

FLORICULTURE.

6075. *Floriculture* we consider as comprehending whatever relates to the culture and arrangement of vegetables, grown chiefly on account of their flowers, or as objects of taste or curiosity. The culture of flowers was long carried on with that of culinary vegetables, in the borders of the kitchen-garden, or in parterres or groups of beds, which commonly connected the culinary compartments with the house. In places of moderate extent, this mixed style is still continued; but in residences which aim at any degree of distinction, the space within the walled garden is confined to the production of objects of domestic utility, while the culture of plants of ornament is displayed in the flower-garden and the shrubbery. These, under the general term of pleasure-ground, encircle the house in small seats, and on a larger scale embrace it in one or more sides; the remaining part being under the character of park-scenery. Many of the most interesting plants belonging to this branch of culture are natives of warm climates, and require the protection of glass and artificial heat. On a limited scale, such plants are grown in the culinary-forcing-houses, or in green-houses, or botanic stoves, connected with the others in the kitchen-garden. In complete residences, however, the culture of exotics forms a distinct department of ornamental horticulture, and the hot-houses requisite for this purpose are placed in the flower-garden, or variously arranged within the precincts of the pleasure-ground. In both departments, separation is attended with the usual advantages resulting from a division of skill, labor, and effect. Floriculture is obviously of limited interest and utility, compared to horticulture; much less has accordingly been written on it, and our view of modern practice will, therefore, be proportionately brief. The order adopted, is the formation, planting, and general culture of the flower-garden; the formation, planting, and general culture of the shrubbery; the design and general culture of the floricultural hot-houses; the catalogue of plants and trees used in ornamental horticulture; and, lastly, the monthly table of floricultural productions.

CHAP. I.

Of the Formation of the Flower-garden.

6076. *The situation of the flower-garden, as of every department of floriculture, should be near the house, for ready access at all times, and especially during winter and spring,*

when the beauties of this scene are felt with peculiar force. "The flower-garden," Neill observes, "should form an ornamental appendage to the mansion, and be easily accessible in all kinds of weather. There is no objection to its being seen from the windows of the house : on the contrary, this is sometimes considered as desirable." Nicó., as we have seen (2382.), approves of having the various gardens of a place combined, and placing them at no great distance from the house ; and Repton strongly recommends this practice.

6077. *Abercrombie* says, "While the kitchen-garden is concealed by buildings or plantations, the flower-garden and pleasure-ground should stand conspicuously attached to the family residence. When the horticultural establishment includes a conservatory, it is proper to have it in sight, and connected with the ornamented grounds ; because the style of such a building, the plants within, and the scene without, under a tasteful arrangement, harmonise in character and effect. The botanic-garden, the range of stoves, and all the departments, a visit to which renders a walk about the grounds pleasing and interesting, should be at hand."

6078. *The author of the Florist's Manual* confines her observations to the "construction of that humble flower-garden," which she calls "the common or mingled flower-garden." "This," she says, "should be situated so as to form an ornamental appendage to the house, and where the plan of ground will admit, placed before windows exposed to a southern or south-east aspect ; and although to this position there may appear the objection of the flowers turning their petals to the sun, and consequently from the windows, this predilection in the tribe of Flora for the rays of that bright luminary, will produce the same effect in whatever place our flowers may be situated, when in the vicinity of a building, as they invariably expose the front of their corols to the lights from which both the petals of flowers, and the leaves of plants are believed to derive material essential to their existence." She adds, "when apart from the house, the mingled flower-garden may be introduced with great advantage, if situated so as to form a portion of the pleasure-ground : in this case it should not be distinct from the house, but so contrived as to terminate one of the walks of the home shrubberies." (*Flor. Man.* p. 10. 15.)

6079. To place the flower-garden south-east or south-west of the house, and between it and the kitchen-garden, is in general a desirable circumstance. In a design for a villa farm (*fig. 539.*), supposing the entrance-front of the house (*a*), to face the north-west, then the farm-offices (*b*), horse-pond (*c*), &c. may be placed to the north-east ; the kitchen-yard (*d*) and livery-stable-yard (*e*) to the south-west ; against these may be placed the exotic hot-houses, looking to the flower-garden (*f*), and beyond this the American garden (*g*), and lastly, the kitchen-garden (*h*), and walk through the farm (*i*). If concealed approaches to the farm and stable-offices (*c*, *n*), and from the kitchen-garden to the kitchen (*h*, *e*, *d*), be contrived, such an arrangement will be found to combine both elegance and economy, and to admit of bringing the wire fence (*m*), which separates the mown from the fed lawn, near the house, without being unsightly : a desirable object in farm villas, as it saves mowing, and increases pasturage.

6080. In exposure and aspect, the flower-garden should be laid out as much as possible on the same principles as the kitchen-garden (2390.), not only on account of the advantages to be derived from the full influence of the sun during winter on the hot-house department, but also for the better enjoyment of the open air scenes, in weather favorable for walking out of doors. It should not be naturally low in surface, nor of a wet retentive soil, nor rendered damp and gloomy by surrounding high trees, or lofty walls or buildings. If it happen that a house be nearly surrounded by a flower-garden, the variety of aspect thence afforded will be favorable to the continuance of the bloom of our flowers, far beyond what can be obtained if confined to a southern exposure. South, south-east, and east, are the aspects most advantageous to the growth of flowers ; and, possessing these varieties of exposure, the bloom of a garden may be protracted some weeks beyond the time it could be preserved under a single aspect.

6081. The extent of the flower-garden depends jointly on the general scale of the residence, and the particular taste of the owner. If any proportion may be mentioned, perhaps, a fifth part of the contents of the kitchen-garden will come near the general average ; but there is no impropriety in having a large flower-garden to a small kitchen-garden or mansion, where the taste of the owner leads to such a deviation from common rules. As moderation, however, is generally found best in the end, we concur with the author of the *Florist's Manual*, when she states, that "the compass of ground appropriated to flowers must vary according to the size of the place of which that ground forms a part, and should in no case be of great extent. If the form of ground, where

a parterre is to be situated, is sloping, the size should be larger than when a flat surface, and the borders of various shapes, and on a bolder scale, and intermingled with grass; but such a flower-garden partakes more of the nature of pleasure-ground than of the common parterre, and will admit of a judicious introduction of flowering shrubs." "To cover twenty acres with mere flowering plants," Abercrombie observes, "producing nothing esculent in the root, leaves, or fruit, would be puerile and ridiculous, as it would exceed the moderation with which nature scatters her ornaments." (*Pract. Gard.* 338.)

6082. *Shelter* is equally requisite for the flower as for the kitchen garden, and, where naturally wanting, is to be produced by the same means, viz. planting. The plantation on the side next the garden, should begin with the lowest shrubs, and rise in gradation to the trees, which, unless on the north, or very exposed points, should not be of the tallest kinds. A few elegant shrubs, and one or two trees may be scattered through the scene, either in the dug compartments or in the turf-glades, for the purposes of shelter and shade as well as ornament; but in general, much of either of the two former qualities are highly injurious both to the culture of flowers, and the thick closeness of turf; besides rendering the garden unfit to be resorted to in the winter and spring seasons. Sometimes an evergreen-hedge will produce all the shelter requisite, as in small gardens composed of earth and gravel only (*fig.* 541.); but where the scene is large (*fig.* 540.), and composed of dug compartments (*a*), placed on lawn (*b*) the whole may be surrounded by an irregular border (*c*) of flowers, shrubbery, and trees.

540

6083. *Soil.* Most of the hardy herbaceous flowers, and the deciduous and evergreen ornamental shrubs, will succeed in a soil of common good qualities, moderately light and mellow. Negatively, the ground should not be excessively strong and clayey; and mere gravel is very intractable. (*Abercrombie.*)

6084. *Nicol* observes, that flowers in general "will thrive very well in common garden-earth of a middling texture, if broke fine, to the depth of a foot. Some, no doubt, do better in light than in heavy soils; and the contrary: and others do best in rich humid earth. Bulbous flowers, in general, do best in light sandy earth; though some require a stronger and a richer soil. In general, the soil for these should be formed at least eighteen inches deep, and should be made very fine by the spade, or be put through a coarse screen." In parterres where the finer flowers are cultivated, a variety of soils will be required according to the nature of the plants, as rich sandy loam for bulbs, loamy earth for the primula tribe, bog-earth for American plants; and hence it follows, that, provided the sub-soil be dry, the nature of the surface-stratum is of the less consequence.

6085. *Surface.* Where the extent is small, and the plants grown to be chiefly florists' flowers, or other select kinds, in beds separated by gravelled paths, a level or gentle and uniform slope will be found most suitable; but where the limits are more extensive, and turf and shrubs are introduced, a wavy surface, either naturally or rendered so by art, will have much the best effect. "In recluse scenes immediately under the eye, art may create a sort of miniature of beautiful ground. Man is but a puny object compared to those of inanimate nature. He may overlook a distant hill, separated by low ground; but a mound of less than three yards in height, placed near the eye, confines the view, and all other objects being shut out, acquires, if apparently a work of nature, a degree of importance in his imagination: winding walks, four feet below the original surface, will supply earth for accompanying them by wavy hills or swells eight feet high. If these hills and swells are formed and contrived so as to produce a varied and natural-like whole, with every change of position, a very suitable basis will be raised for a picturesque shrubbery or flower-garden. It was to this sort of art that Pope's garden, at Twickenham, was indebted for so great a variety of beauties in a small space; and the flower-garden at Lord Harcourt's, at Nuneham, was laid out under the eye of Mason the poet, on the same principle." (*Ed. Ency. art. Landscape Gardening.*)

6086. *Water.* This material, in some form or other, is as essential to the flower as to the kitchen garden. Besides the use of the element in common culture, a pond or basin affords an opportunity of growing some of the more showy aquatics, while jets, dropping-fountains, and other forms of displaying water, serve to decorate and give interest to the scene. Besides choice aquatics, the ponds or basins of flower-gardens may be stocked with the gold-fish (*Cyprinus auratus*), and will serve as a hybernaculum for that elegant and interesting animal the tree-frog (*Rana arborea*), so amusing in the gardens of the south of Germany.

6087. *The form of a small garden (fig. 541.)* will be found most pleasing when some regular figure is adopted, as a circle, oval, octagon, crescent, &c. : but where the extent is so great as not readily to be caught by a single glance of the eye, an irregular shape is generally more convenient, and it may be thrown into agreeable figures, or component scenes, by the introduction of shrubs so as to subdivide the space. "Either a square or an oblong ground-plan," Abercrombie observes, "is eligible; and although the shape must be often adapted to local circumstances, yet, when a garden is so circumscribed that the eye at once embraces the whole, it is desirable that it should be of some regular figure."

6088. *Nicol* says, "a variety of forms may be indulged in, without incurring censure; provided the figures be graceful, and not in any one place too complicated. An oval is a figure that generally pleases, on account of the continuity of its outlines; next, if extensive, a circle. Next, perhaps, a segment in form of a half-moon, or the larger segment of an oval. But hearts, diamonds, triangles, or squares, if small, seldom please. A simple parallelogram, divided into beds running lengthwise, or the larger segment of an oval, with beds running parallel to its outer margin, will always please." Neill concurs in this opinion.

6089. *The author of Hints on the Formation of Gardens, &c.* says, "a symmetrical form is best adapted to such parterres as are small and may be comprehended in one view; and an irregular shape to such as are of a considerable size, and contain trees, shrubs, statues, vases, seats, and buildings."

6090. *Boundary fence, or screen.* Parterres on a small scale may be enclosed by an evergreen hedge of holly, box, laurel, privet, juniper, laurustinus, or Irish whin (*Ulex europæus*, var. *a*); but irregular figures, especially if of some extent, can only be surrounded by a shrubbery, such as we have already hinted at (6082.) as forming a proper shelter for flower-gardens.

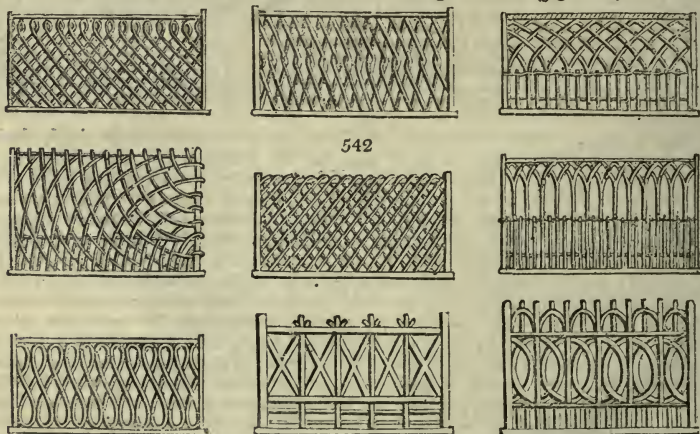

6091. *Abercrombie* says, "for the enclosure, a wall or close paling is, on two accounts, to be preferred on the north side; both to serve as a screen, and to afford a warm internal face for training rare trees. When one of those is not adopted, recourse may be had to a fence of white thorn and holly," &c. (*Pract. Gard.* 339.)

6092. *Rustic fences* formed of shoots of the oak, hazel, or larch, may often be introduced with good effect both as interior and surrounding barriers. (fig. 542.)

541

542

6093. *Laying out the area.* This is the most difficult part of the business, and is not to be excelled in without a considerable degree of taste and experience. In laying out

the area of the kitchen-garden, its destination being utility, affords in all cases a safe and fixed guide ; but the flower-garden is a matter of fancy and taste, and where these are wavering and unsettled, the work will be found to go on at random. As flower-gardens are objects of pleasure, that principle which must serve as a guide in laying them out, must be taste. Now, in flower-gardens, as in other objects, there are different kinds of tastes ; these embodied are called styles or characters ; and the great art of the designer is, having fixed on a style, to follow it out unmixed with other styles, or with any deviation which would interfere with the kind of taste or impression which that style is calculated to produce. Style, therefore, is the leading principle in laying out flower-gardens, as utility is in laying out the culinary-garden. As subjects of fancy and taste, the styles of flower-gardens are various. The modern style is a collection of irregular groups and masses, placed about the house as a medium, uniting it with the open lawn. The ancient geometric style, in place of irregular groups, employed symmetrical forms ; in France, adding statues and fountains ; in Holland, cut trees and grassy slopes ; and in Italy, stone walls, walled terraces, and flights of steps. In some situations, these characteristics of parterres may with propriety be added to, or used instead of the modern sort, especially in flat situations, such as are enclosed by high walls in towns, or where the principal building or object is in a style of architecture which will not render these appendages incongruous. There are other characters of gardens, such as Chinese, which are not widely different from the modern ; the Indian, which consists chiefly of walks under shade, in squares of grass, &c. ; the Turkish, which abounds in shady retreats, boudoirs of roses and aromatic herbs ; and the Spanish, which is distinguished by trellis-work and fountains : but these gardens are not generally adapted to this climate, though from contemplating and selecting what is beautiful or suitable in each, a style of decoration for the immediate vicinity of mansions might be composed, greatly preferable to any thing now in use.

6094. *Abercrombie, Nicol, and most practical gardeners*, seem not to understand the subject of style, and their rules amount to little more than that of subdividing the area by paths in different directions. The former author says, " If a piece of ground be set apart for the cultivation of flowers, in what style should it be laid out ? This may vary with the quantity of surface, and the object of the cultivator. In the first place, carry a border round the garden, nowhere narrower than three or four feet, unless it may be proper to contract its breadth under the windows of the house ; or unless there be a green hedge, on any side, rooted in the level of the garden, which might be expected either to draw the earth, or to encroach on the small plants, in which case flowering shrubs in little slips of mould would do better than dwarf-stemmed flowers. In contact with the surrounding border, may be either a grass-plot or a gravel-walk. The latter is most convenient for approach at all seasons. If the ground be at all dilated, handsome walks, crossing or leading to the centre, will be also requisite : let the principal walks be five or six feet in breadth. The interior of the garden is usually laid out in oblong beds, three or four feet wide, with intervening alleys, two feet wide, or from that down to twelve inches, when it is intended to abstract as little space as possible from the cultivation of the flowers ; or, the same end may be obtained by circular or oval beds, with smaller compartments between, of such a form as will leave the alleys of one regular width." (*Pract. Gard.* 340.)

6095. According to *Nicol*, the laying out of flower-gardens is a "matter very much of fancy. Too many gravelled alleys offend the eye, especially if they be much twisted, or run across ; as it comprehends the whole at once. Their breadths should be proportioned to that of the beds ; nor should they be much

544

sunk; seldom more than an inch; otherwise they have a bad effect, and look rather like furrows than alleys. They may be edged with box, with daisies, with violets, gentianella, or thrift, according to fancy. But the edging, whatever it be, should be kept low, thin, and neat. It should seldom be allowed to rise two inches high, or spread two inches wide. A linear box-edging always pleases, if kept quite close and connected." (*Kal.* 458.)

6096. *The author of the Florist's Manual*, though she confines her directions to one style, has much more correct ideas on the subject than our practical authors. "It is more difficult," she says, "than may at first appear, to plan, even upon a small scale, such a piece of ground, nor, perhaps, would any but an experienced scientific eye be aware of the difficulties to be encountered in the disposal of a few shaped borders interspersed with turf; the nicety consists in arranging the different parts so as to form a connected glow of color, to effect which it will be necessary to place the borders in such a manner that when viewed from the windows of the house, or from the principal entrance into the garden, one border shall not intercept the beauties of another, nor in avoiding that error, produce one still greater, that of vacancies betwixt the borders forming small avenues, by which the whole is separated into broken parts, and the general effect lost. Another point to be attended to, is the just proportion of green turf, which, without nice observation, will be too much or too little for the color with which it is blended; and, lastly, the breadth of the flower-borders should not be greater than what will place the roots within reach of the gardener's arm without the necessity of treading upon the soil, the mark of footsteps being a deformity wherever it appears amongst flowers." (*Flor. Man.* 13.)

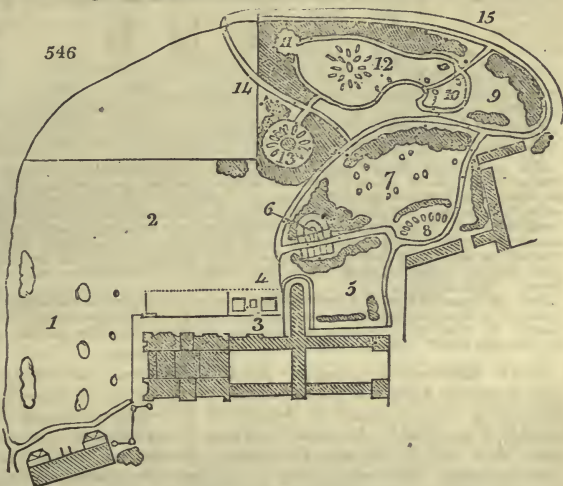

6097. *The materials which form the surface of flower-gardens* (figs. 543, 544.) are gravel (a), turf (b), and dug borders (c), patches (d), or compartments (e), and water (f); but a variety of other objects and materials may be introduced as receptacles for plants, or on the surfaces of walks; as grotesque roots, rocks, 545.

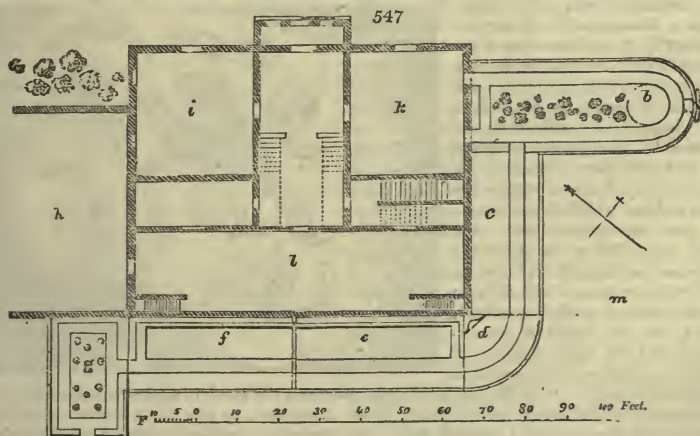

6098. *Rock-works.* The author of the *Florist's Manual* observes, on this subject, that "fragments of stone may be made use of, planted with such roots as flourish among rocks, and to which it might not be difficult to give a natural appearance, so far as by bringing forward to the view the utility of these stones in the culture of the vegetables growing thereon. The present fashion of introducing into flower-gardens this kind of rock-work requires the hand of taste to assimilate it to our flower-borders, the massive fabric of the rock being liable to render the lighter assemblage of the borders diminutive and meagre: on this point, caution only can be given, the execution must be left to the elegant eye of taste, which, thus warned, will quickly perceive such deformity. I must venture to disapprove the extended manner in which this vegetable rock-work is sometimes introduced, not having been able to reconcile my eye, even in gardens planned and cultivated with every advantage which elegant ingenuity can give them, to the unnatural appearance of artificial crags of rock and other stones interspersed with delicate plants, to the culture of which the fertile and sheltered border is evidently necessary, being decided that nothing of the kind should be admitted into the simple parterre that is not manifestly of use to the growth of some of the species therein exhibited. In pleasure-grounds or flower-gardens on an extensive scale, where we meet with fountains and statuary, the greater kinds of vegetable rock-work might probably be well introduced; but to such a magnificent display of art I feel my taste and knowledge wholly incompetent." (*Flor. Man.* 15.) "Where neither expense nor trouble," the same author adds, "oppose their prohibitory barrier, many of the vegetable tribe may be cultivated to greater perfection, if we appropriate different gardens to the growth of different species, as, although it is essential to the completion of our garden to introduce, on account of their scent and beauty, some of the more hardy species of the flowers termed annuals, in that situation room cannot be afforded them sufficient to their production in that full luxuriance which they will exhibit when not crowded and overshadowed by herbaceous vegetables; and hence becomes desirable that which may be called the annual flower-garden, into which no other kind of flower is admitted besides that fugacious order, and under which is contained so great a variety of beauty and elegance, as one well calculated to form a garden, tying in brilliancy with the finest collection of hardy perennials. Also, the plants comprised under the bulbous division of vegetables, although equally essential to the perfection of the mingled flower-garden, lose much of their peculiar beauty when not cultivated by themselves, and will well repay the trouble of an assiduous care to give to each species the soil and aspect best suited to its nature. Two kinds of garden may be formed from the extensive and beautiful variety of bulbous-rooted flowers; the first, wherein they should be planted in distinct compartments, each kind having a border appropriated to itself, thus forming, in the Eastern taste, not only the 'garden of hyacinths,' but a garden of each species of bulb which is capable of being brought to perfection without the fostering shelter of a conservatory. The second bulbous garden might be formed from a collection of the almost infinite variety of this lovely tribe, the intermixture of which might produce the most beautiful effect, and a succession of bloom to continue throughout the early months of summer. A similar extension of pleasure might be derived from a similar division of all kinds of flowers, and here the taste for borders planted with distinct tribes may be properly exercised, and, as most of the kinds of bulbs best suited to this disposition have finished their bloom before the usual time at which annuals disclose their beauties, the annual and the bulbous gardens might be so united, that, at the period when the bloom of the latter has disappeared, the opening buds of the former might supply its place, and continue the gaiety of the borders."

6099. *The green-house or conservatory is generally placed in the flower-garden*, provided these structures are not appended to the house. In laying out the area, a fit situation must be allotted for this department of floriculture, and the principles of guidance laid down in treating of the situation of the culinary hot-houses (2475.) require here also to be applied. Some recommended the distribution of the botanic hot-houses throughout

the flower-garden or pleasure-ground; but we are decidedly of opinion, that much the best effect is produced when they are connected together in one scene. By the other mode they may form objects agreeable enough to look at externally; but to derive the full effect of their internal beauties, it appears to us that they must be examined in succession and without interruption. No arrangement can be better, in our opinion, than to connect the whole of the botanic hot-houses with the mansion as an introductory scene to the flower-garden. This was Repton's favorite mode, of which, among other examples, he has left that of Ashridge Park. (fig. 546.) Here, to the original lawn and pleasure-ground (1), he made an addition in the same style (2), uniting by walks the following interesting scenes. The botanic stoves and paved terrace (3); broad-sanctuary and holy-well (4); pomarium and winter walk (5); the monk's garden (6); arboretum of exotic trees (7); magnolia and American garden (8); embroidered parterre (9); grotto and garden for rock-plants (10); *cabinet de verdure* (11); mount garden (12); rosarium and fountain (13); connecting and interior walks (14); open terrace and exterior walks (15).

6100. In particular situations, as where the prospect and space are both confined, the plant hot-houses may embrace the house or the court-yard on two or more sides. In a case of this kind, which occurred in our practice (fig. 547.), a large conservatory (a) and aquarium (b) were connected with the library (k):

from the conservatory, a green-house (c) led to an aviary (d), and this was connected with a house for standard peach-trees, with vines as climbers (g), by two plant-stoves (e and f). The furnaces were placed in the court-yard (l), and attended from the stable-yard (h), without interfering with the house (i), or the flower-garden (m). The elevation of such a range (fig. 548.) does not pretend to architectural or picturesque beauty; but it is such as is best suited for the culture of plants; and from the peculiarity of the situation it is seen from no point beyond the limits of a very moderate-sized flower-garden.

6101. According to Neill, a green-house, conservatory, and stove should form prominent objects in the different parts of the flower-garden. The author of the *Florist's Manual* recommends a spring-conservatory, annexed to the house, consisting of borders sheltered by glass, and heated only to the degree that will produce a temperature, under which all the flowers that would naturally bloom betwixt the months of February and May might be collected, and thence be enabled to expand their beauties with vigor. (*Flor. Man.* v. 23.)

6102. According to Nicol, "the most proper situation for the green-house and conservatory, in an extensive and well laid out place, is certainly in the shrubbery or flower-garden; and not, as they are very generally to be found, in the kitchen-garden, combined with the forcing-houses. In smaller places, no doubt, they must be situated so as to suit other conveniences; and we often find them connected with the dwelling-house. In this latter way they may be very convenient, especially in the winter season, and may answer for keeping many of the hardy kinds of exotics; but it is seldom they can be so placed and constructed, on account of their connection with the building, as to suit the culture of the finer sorts, and bring them to a flowering state. Such may rather be termed green-rooms, as being connected with the house." (*Kal.* 539.)

6103. Abercrombie says, "A green-house may be made a very ornamental object as a structure; its situation is, therefore, usually in a conspicuous part of the pleasure-ground, contiguous to the family residence. The front of the building should stand directly to the south, and the ends have an open aspect to the east and west." (*Pract. Gard.* 557.)

6104. *Flower-nursery, and pits for forcing flowers.* To every complete flower-garden and shrubbery, a piece of ground should be set apart in a convenient and concealed situation, as a reserve-ground, or nursery of flowering plants and shrubs. The situation should, if practicable, be behind and near to the range of hot-houses, and it may at the same time include the pits for forcing flowers, and the hot-bed department of the flower-garden. Here plants may be originated from seed, cuttings, pipings, and a proper stock kept up, partly in beds and partly in pots, for more easy removal, to supply blanks, and in the more select scenes, to replace such as have done flowering. No flower-garden can be kept in complete order without a nursery of this description; nor could the management of some sorts of florists' flowers, as the auricula, during the latter part of summer and winter, the carnation, &c. be well carried on without it. Here they may be grown, and, when in bloom, exhibited in proper stages in the main garden.

6105. *Walks.* In most styles of parterres these are formed of gravel; but in the modern sort (*fig.* 549.), which consist of turf, varied by wavy dug beds (1 and 2), and surrounded by shrubbery, they

549

are sometimes dispensed with. Such a flower-garden is recommended by the author of the *Florist's Manual*, as suitable for the "midst of pleasure-ground," and the beds "peculiarly adapted to the advantageous exhibition of flowers." The general length of the beds she recommends to be from twenty-three to twenty-five feet, and the width in the broadest part, about four feet; the grass to be five or six feet wide between the beds, that it may be conveniently mown and rolled; all the beds a good deal raised, and a tree (3) placed at the entrance (4) of light and rather pendulous foliage, and pruned to form a high stem. "If the space of grass between the borders appear too great, it may be lessened by baskets of ever-blowing roses, carnations, or any other plants; and these baskets may be formed by circular beds, surrounded by cast-iron, made to resemble the open edges of a basket, and painted of a very dark-green color." (p. 6.)

6106. In extensive and irregular parterres, one gravel-walk, accompanied by broad margins of turf, to serve as walks by such as prefer that material, should be so contrived as to form a tour for the display of the whole garden. There should also be other secondary interesting walks of the same width, of gravel and smaller walks for displaying particular details. The main walk, however, ought to be easily distinguishable from the others by its broad margins of fine turf. In general the gravel is of uniform breadth throughout the whole length of the walk; but in that sort of French parterres which they call parterres of embroidery (*fig.* 550.), the breadth of the gravelled part (a) varies like that of the turf. Such figures, when correctly executed, carefully planted, judiciously intermixed with basket-work, shells, party-colored gravels, &c. and kept in perfect order, are highly ornamental; but very few gardeners enter into the spirit of this department of their art. The French and Dutch have long greatly excelled us in the formation of small gardens, and the display of flowers; and whoever wishes

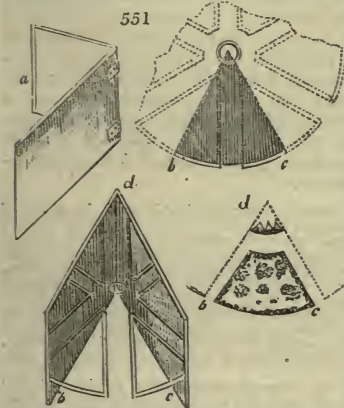

to succeed in this department ought to visit Amsterdam, Antwerp, Brussels, and Paris; and consult the old French works of Mallet, Boyceau, Le Blond, &c. 550

6107. *Edgings.* In parterres where turf is not used as a ground or basis out of which to cut the beds and walks, the gravel of the latter is disparted from the dug ground of the former by edgings or rows of low-growing plants, as in the kitchen-garden. Various plants have been used for this purpose; but, as Neill observes, the best for extensive use is the dwarfish Dutch box, kept low and free from blanks. Abercrombie says, "Thrift is the neatest small evergreen next to box. In other parts, the daisy, pink, London-pride, primrose, violet, and periwinkle, may be employed as edgings. The strawberry, with the runners cut in close during summer, will also have a good effect; the wood-strawberry is suitable under the spreading shade of trees. Lastly, the limits between the gravel-walks and the dug-work may sometimes be marked by running verges of grass kept close and neat. Whatever edgings are employed, they should be formed previous to laying the gravel."

6108. *Basket-edgings.* Small groups near the eye, and whether on grass or gravel, may be very neatly enclosed by a worked fence of basket-willows from six inches to a foot high. These wicker-work frames may be used with or without verdant edgings; they give a finished and enhance the value of what is within, and help to keep off small dogs, children, &c.

Abercrombie scarcely approves of them. He says, "Where round or oval parterres stand on a ground of lawn, it is a prevailing fashion to surround them with what are termed baskets. These are commonly made either of wood or cast-iron; those of the latter material of course are durable; and the others, if painted, and removed under shelter in winter, will last ten or twelve years. Novelty is all attractive; and when men have walked as far as they can in the path of nature for principles of embellishment, for the sake of novelty they will walk back again. A bed of flowers and shrubs within a basket looks very much like a large bouquet. What is artificial, should have some use. Where cattle are to be kept off, a basket is serviceable." (*Pr. Gard.* 454.)

being hinged (a). One part of a circular figure being then drawn on paper (b, c, d), the frames are to be opened the width of the figure (b, c, d), and placed on edge so as to include it, when the form will then be so multiplied by the looking-glass as to complete the circle. The kaleidoscope may also be resorted to, of which this instrument of Bradley's is supposed to be the origin or prototype.

CHAP. II.

Of Planting the Flower-garden.

6110. *The manner of planting the herbaceous plants and shrubs in a flower-garden depends jointly on the style and extent of the scene. With a view to planting, they may be*

divided into three classes, which classes are independently altogether of the style in which they are laid out. The first class is the *general or mingled flower-garden*, in which is displayed a mixture of flowers with or without flowering-shrubs according to its size. The object in this class is to mix the plants, as that every part of the garden may present a gay assemblage of flowers of different colors during the whole season. The second class is the *select flower-garden*, in which the object is limited to the cultivation of particular kinds of plants; as, florists' flowers, American plants, annuals, bulbs, &c. Sometimes two or more classes are included in one garden, as bulbs and annuals; but, in general, the best effect is produced by limiting the object to one class only. The third class is the *changeable flower-garden*, in which all the plants are kept in pots, and reared in a flower-nursery or reserve-ground. As soon as they begin to flower, they are plunged in the borders of the flower-garden, and, whenever they show symptoms of decay, removed, to be replaced by others from the same source. This is obviously the most complete mode of any for a display of flowers, as the beauties of both the *general* and *particular* gardens may be combined without presenting blanks, or losing the fine effect of assemblages of varieties of the same species; as of hyacinth, pink, dahlia, chrysanthemum, &c. The fourth class is the *botanic flower-garden*, in which the plants are arranged with reference to botanical study, or at least not in any way that has for its main object a rich display of blossoms. On each of these gardens, or manners of arranging plants grown for their beauty or curiosity, we shall offer some remarks.

6111. The *mingled flower-garden*, or *border*, is by far the most common; it is what every gardener attempts at in planting his flower-borders, and the aim of the greater number of such as form parterres, or separate scenes for the culture of flowers, seldom goes further. The object here is to display a gay assemblage of colors during the season of flowers, without much regard to variety of form or diversity of character in these flowers, or the plants that produce them. The great art, therefore, in this kind of flower-border, is to employ such plants as produce large heads, or masses of flowers; to plant an equal number of every color, and such a variety in regard to time of flowering as may afford some of every color in flower from February to October. This object does not require a great variety so much as a judicious selection; for, supposing the number four to include all the colors of flowers, and one sort to continue in bloom a month, then for nine months of the year, viz. from February to October inclusive, only thirty-six sorts will be requisite to commence, as it were, the pattern of the border. Much more may be effected by a few sorts than by a great number, for the greater the number of sorts introduced in the pattern above thirty-six, supposing it correct that one sort continues in bloom a month, the greater the blank spaces that must remain between the plants in bloom. A moderate number of select sorts, or of what are called border-flowers, and that number selected equally from the different colors, and the sorts in bloom in the nine months of blooming season, is what demands the exclusive attention of whoever would plant a mingled border, or flower-garden. It has been frequently observed that flower-gardens have been on the decline for the last half century; and the cause of this appears to have been the influx of new plants during that period, by which gardeners have been induced without due consideration to be more solicitous about rarity and variety, than well disposed colors and quantity. The same error, and from the same cause, has prevailed, during the above period, in the planting of shrubberies and tree-plantations.

6112. *Abercrombie, Nicol*, and other practical gardeners, seem to have no distinct ideas on the subject of arranging flowers in flower-gardens; but the authors of *Hints on laying out Gardens*, and of the *Florist's Manual*, have viewed the subject in its proper light. Neill also has some judicious observations on the subject. He says, "the plants are arranged in mingled flower-borders, partly according to their size, and partly according to color. The tallest are planted in the back part, those of middling size occupy the centre, and those of humble growth are placed in front. The beauty of a flower-border, when in bloom, depends very much on the tasteful disposition of the plants in regard to color. By intermingling plants which flower in succession, the beauty of the border may be prolonged for some weeks. In a botanic-garden the same plant cannot with propriety be repeated in the same border; but in the common flower-garden a plant, if deemed ornamental, may be often repeated with the best effect; nothing can be finer, for example, than to see many plants of double scarlet lychnis, double sweet-william, or double purple jacobea." (*Ed. Encyc. art. Hort.*)

6113. The author of *Hints*, &c. remarks "that the beauty of parterres depends more on the materials with which they are planted than on their form; and that the prevailing error consists in crowding them with all sorts of trees and plants at random, or filling them entirely with rare species, which will ever want one principal source of beauty — health." In the *Florist's Manual* it is observed, that "the fashionable novice, who has stored her borders from the catalogue of some celebrated name with variety of rare species; who has procured innumerable rose-trees, chiefly consisting of old and common sorts, brought into notice by new nomenclature; who has set apart a portion of ground for American plants, and duly placed them in bog soil, with their names painted on large-headed pegs, becomes disappointed when, instead of the brilliant glow of her more humble neighbor's parterre, she finds her own distinguished only by paucity of color, and fruitless expenditure. Variety of species, bog borders, and largely lettered pegs, are all good in their way, but they will not produce a *gay* flower-garden; and the simple cause of the general failure in this particular is the prevalent solicitude for rarity and variety, in preference to well blended quantity; as, without the frequent repetition of the same plant, it will be in vain to attempt a brilliant flower-garden, and, as in the judicious mixture of every common color, the art of procuring it consists. Hence, the foundation thus laid, the solicitude of those who wish to complete the superstructure must not be for rare species, but for new color, so that the commonest primula which presents a fresh shade of red, blue, yellow, &c. ought to be esteemed more valuable than the most rare American plant which does not bring a similar advantage. In the formation of that assemblage of

flowers, which may be distinguished by the term of 'The Mingled Flower Garden,' it is essential that the separate parts should, in their appearance, constitute a whole; and this appearance is not incompatible with any form into which the ground may be thrown, if attention be given to the manner of planting. In some gardens this appearance of a whole is entirely destroyed by the injudicious taste of setting apart distinct borders for pinks, hepaticas, primulas, or any other favorite kinds of flowers; also for different species of bulbs, as anemones, ranunculuses, hyacinths, &c.; these distinct borders, although beautiful in themselves, break that whole which should always be presented to the eye by the mingled flower-garden, as single beds, containing one species only, form a blank before that species produces its flowers, and a mass of decaying leaves when the glow of their petals is no more. The reverse of this mode of planting is essential to the perfection of the mingled flower-garden, in each border of which there should be, at least, two of every species; but the precise number must be regulated by the force of color displayed by the plant, and the size and the relative position of the borders. It will be only necessary to observe that, to whatever view the garden presents itself, the eye should not be checked by the failure, in any part of it, of the prevalent colors of the season." (p. 5.)

6114. *Hogg*, who may be considered an unprejudiced observer of the different tastes in disposing of flowers, has the following remarks: "We are apt to ridicule the Dutchman, as well as the imitators of him here at home, who divide their gardens into small beds, or compartments, planting each with separate and distinct flowers: we ridicule the plan, because it exhibits too great a sameness and formality; like unto the nosegay that is composed of one sort of flowers only, however sweet and beautiful they may be, they lose the power to please, because they want variety. It must undoubtedly be acknowledged, that a *parterre*, no matter in what form, whether circular or square, elliptical or oblong, where all the shrubs, plants, and flowers in it, like the flowers of a tastefully arranged bouquet, are variously disposed in neat and regulated order, according to their height and color, is a delightful spectacle, and worthy of general imitation. Yet still in some particular cases I am disposed to copy the Dutchman, and I would have my bed of hyacinths distinct, my tulips distinct, my anemones, my ranunculuses, my pinks, my carnations distinct, and even my beds of hollyhocks, double blue violets, and dwarf-larkspurs distinct, to say nothing of hedge-rows of different sorts of roses. Independent of the less trouble you have in cultivating them when kept separate, you have beauty in masses, and you have likewise their fragrance and perfume so concentrated, that they are not lost in air, but powerfully inhaled when you approach them. Mrs. Siddons, the celebrated tragic actress, is a great admirer of this mode of planting, and fond of contemplating this 'beauty in masses.' She adopted this style of gardening at her late residence on the Harrow-road. Her favorite flower was the *viola amena*, the common purple heart's-ease, and this she set with unsparing profusion all around her garden. Her garden was remarkable in another respect, and might with great propriety be styled a garden of evergreens, which, together with a few deciduous shrubs, were of the most sombre, sable, and gloomy cast, such as box-trees, fir, privet, phillyrea, arbor vitæ, holly, cypress, the red cedar, laurel, Irish ivy, bay-tree, arbutus, spurge-laurel, &c. The only part of the year in which it could be viewed with any degree of satisfaction was the winter, as giving rise to a pleasing association of ideas in beholding these retain their green verdure and clothing, at a time when the rest of the surrounding trees were stript naked and bare." (Tr. on Flowers, 69.)

6115. To give an example of the manner of planting a bed or border in the mingled style, suppose the various colors of flowers to be all included under the four common colors, red, white, blue, and yellow; that for the time of blowing, we allow February and March as one division, March and April as a second, May and June as a third, July as a fourth, August as a fifth, and September and October as the sixth and last. Then suppose the border, or bed admits of four rows in width; the lowest plants to be placed next the walk, or the eye of the spectator, and the tallest at the back in regular gradation. Mark out the border in rows length-ways and across, so as each plant may stand in the angle of a square, whose side is, say eighteen inches. Then begin at the first row (fig. 552. a), and fix on the order in which the plants are to be placed as respects their time of flowering. To distribute the plants in flower at one time as equally as possible over the border, the order of 1, 6, 3, 5, 2, 4, will, it is believed, be found the best. Next, fix as to the order of colors; and here it is of little consequence what order is fixed on, provided that order be maintained throughout the border: say that we adopt the order of red white, blue, and yellow; then the first row to be of the lowest plants will stand thus: 1r. 6w. 3b. 5y. 2r. 4w.: that is, a red flower to come into bloom in February and March; next to it, a white flower to come into bloom in September and October; next, a blue flower to come into bloom in May and June; then a yellow flower to come into bloom in August; then a red flower to come into bloom in April and May; and lastly, a white flower to come into bloom in July. The second, third, and fourth rows, (b, c, d) are to be arranged in the same way, observing, however, not begin with the same month and color for the sake of more effectually mingling the tines of flowering and color of the flowers. Where roses or other shrubs are to be introduced, a plant must be omitted, which, however, should not be allowed to derange the order of the rest.

6116. If a double border, with a walk on each side (fig. 552. a to h) a bed-group, or compartment on a lawn, to be viewed on all sides, is to be planted, then it is only necessary to fix on the number of rows, and to keep the lowest plants in the margin and the tallest in the centre, adhering in the rows, to the order of time, and of colors given above, or to any order that may be fixed on, and inserting shrubs in lieu of plants where it may be deemed advisable.

6117. Flowers in borders should always be planted in rows, or in some regular form, and that this appearance should be assiduously kept up by trimming off all irregular side-shoots and straggling stalks, and reducing the bulk of plants which grow too fast. Every approach to irregularity and a wild, confused, crowded, or natural-like appearance, must be avoided in gardens avowedly artificial.

6118. With four colors, four sizes, and six times of coming into flower, a mingled border may be commenced with ninety-six sorts; and the pattern may be repeated like the border of any work of art *ad infinitum*; but it is also evident, that it may include any number of species, provided these have the desired requisites of height, color, and time of flowering; the second and every successive repetition of the pattern being made up of different, and not before-introduced species, but still of the heights, colors, and times of flowering required for the first example of the pattern. The safest way, however, as we have

already observed, is to adopt but a moderate number of species, and those of the showy sorts that have numerous varieties, and are of hardy vigorous growth. A suitable list for this purpose is given in the floricultural catalogue, under the head of *Border Flowers*, and the reader may increase it at pleasure from the *Prodromus* of Page.

6119. *The select flower-garden* being limited to one kind, or class, of plants, is comparatively simple as far as respects planting. It may be devoted to florists' flowers, as the hyacinth, tulip, pink, auricula, &c.; to select flowers, as the dahlia, pæony, chrysanthemum, &c.; to annuals, hardy, half hardy, and tender; to American or bog-earth shrubs and plants; to any one natural order, as the bulbous-rooted tribe; or to spring, summer, or autumn flowers, &c.

6120. *Florists' flowers* and *select flowers* are planted in beds or compartments of carefully prepared soil, and the arrangement in the beds is generally conducted on the principle of mixing the colors and shades of color as much as possible. As the plants being of the same species generally grow of the same height, and come into flower at the same time, no particular attention is requisite in these respects. (See *Hyacinth* and *Auricula*, in the catalogue.)

6121. *A parterre of annuals*, as the different sorts generally come into flower about the same time, may either be arranged according to their colors and heights jointly; or, as there are numerous varieties of some sorts, as of larkspur, chrysanthemum, lupin, &c., each species with its varieties may be sown in groups or beds, by itself; and the general principle by which to determine the sorts which are to join each other, may either be color and height, or natural character. If the latter, then the table exhibiting the genera, arranged according to the Jussieuan classification (589.), will be found a convenient guide.

6122. *An American garden* combines shrubs and even low trees. These may be arranged in the mixed method, according to color, height, and time of flowering, the trees and shrubs alone, and the plants alone, or both combined: but the most suitable way is to follow the natural orders, attending, at the same time, to keep the higher sorts farthest from the walk or side from which the group or border is to be chiefly viewed. This arrangement has an excellent effect in an American shrubbery, where the low species of heaths and other bog under-shrubs which are introduced, supply the place of herbaceous plants.

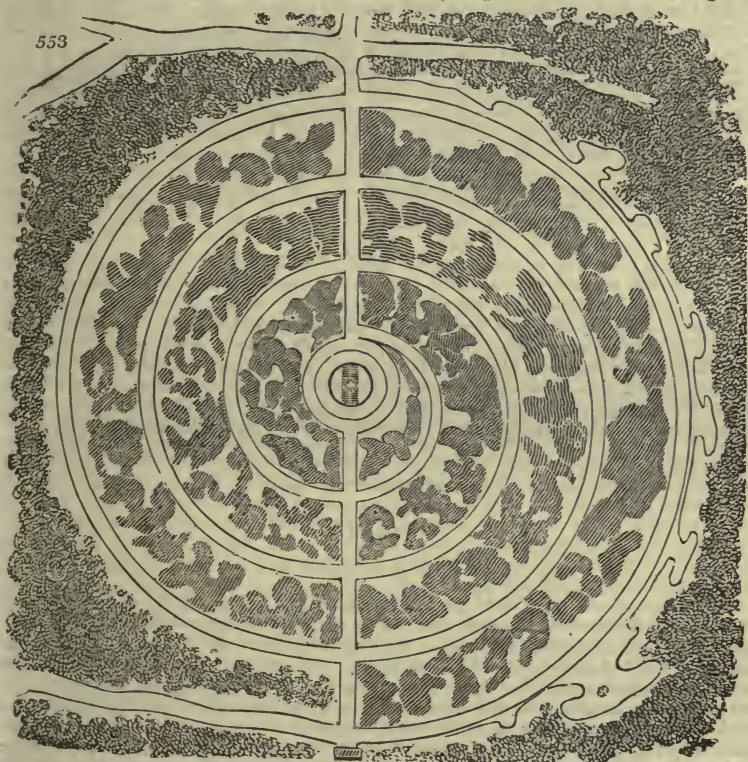

6123. *A garden exclusively devoted to bulbous-rooted flowers*, admits of being very perfectly arranged after the natural method. No orders run into other so naturally as, and none present a more harmonious assemblage both of foliage and flowers than, the Phanerogamæ. (589.) The planting of such a garden would require very little nicety beyond introducing the proper genera and species in succession, taking care to keep the taller bulbs, as liliun, fritillaria, &c. in the interior of the groups or beds.

6124. *Gardens of spring, summer, or autumn flowers* may be planted on any of the principles that have been mentioned.

6125. *The changeable flower-garden*. The essential principle of this garden consists in the power of changing its productions at pleasure, so that whenever any plant, or group of plants, begin to decay, they can be removed and their places supplied by others coming into bloom. To admit of this a large reserve-nursery is requisite, in which the plants must be kept in pots, and removed and plunged in the borders as wanted. The Chinese, Sir W. Chambers informs us (*Dissert. on Orient. Gard.* 96.), excel in this mode of gardening; and we have been informed by a traveller who has resided some time at Canton, that he has known a mandarin (or noble) have the whole furniture and style of his parterre changed in a single night, so as next morning to present not only a different description of flowers, shrubs, and dwarf trees, but a different arrangement of the beds and compartments. Something of the same kind is practised in the gardens of the Tuilleries in Paris; in some of the Imperial gardens at Petersburg, and in the vice-royal gardens at Monza. Gardens of this description admit of a very perfect arrangement of the flowers, whether in the mingled manner, in select groups, or according to the natural method. It is only with such resources that a flower-gardener can "paint his way," as Sir W. Chambers says the Chinese artists do, "not scattering their flowers indiscriminately about their borders, but disposing of them with great circumspection along the skirts of the plantations, or other places where flowers are to be introduced. They reject all that are of a straggling growth, of harsh colors, and poor foliage, choosing only such as are of some duration, grow either large or in clusters, are of beautiful forms, well leaved, and of tints that harmonise with the greens that surround them. They avoid all sudden transitions, both with regard to dimension and color, rising gradually from the smallest flowers to the hollyhocks, pæonies, sun-flowers, carnation-poppies, and others of the boldest growth; and varying their tints, by easy gradations, from white, straw-color, purple, and incarnate, to the deepest blues, and most brilliant crimsons and scarlets. They frequently blend several roots together, whose leaves and flowers unite, and compose one rich harmonious mass; such as the white and purple candytuft, larkspurs, and mallows of various colors, double poppies, lupins, primroses, pinks, and carnations; with many more of which the forms and colors accord with each other; and the same method they use with flowering shrubs, blending white, red, and variegated roses together, purple and white lilacs, yellow and white jessamine, altheas of various sorts, and as many others as they can with any propriety unite. By these mixtures they increase considerably the variety and beauty of their compositions. In their large plantations the flowers generally grow in the natural ground; but in flower-gardens, and all other parts that are highly kept, they are in pots, buried in the ground, which, as fast as the bloom goes off, are removed, and others are brought to supply their places; so that there is a constant succession for almost every month in the year; and the flowers are never seen but in the height of their beauty." (*Dis. on Orient. Gard.* 96.)

6126. *The botanic flower-garden* being intended to display something of the extent and variety* of the vegetable kingdom, as well as its resemblances and differences, should obviously be arranged according to some system or method of study. In modern times, the choice is almost limited to the artificial system of Linnæus, and the natural method of Jussieu, though Adanson has given above fifty-six different methods by which plants may be arranged. (*Fam. des Plants*.) The latter has much the best effect in a garden, and corresponds better with culture. The former, though most convenient for the young student, yet by bringing plants together that have few or no obvious relations, it destroys that harmony which is so gratifying in viewing natural families. Whatever method is adopted, the plants may either be placed in regular rows, or each order may be grouped apart, and surrounded by turf or gravel. For a private botanic garden, the mode of grouping on turf is much the most elegant, and it has this advantage, that as the species belonging to the group are increased, it can be enlarged by appropriating a part of the turf, and any group containing few species may be filled up with repetitions for effect. The groups may be of the most irregular outlines, and those which are to contain trees may be raised or lowered in surface, according as the species may be natives of hills or

valleys, and the trees and plants so dispersed as that the former shall not conceal the latter, nor present a compact lumpish appearance at the edges, or in the outline against the sky. Rock-work may be introduced in groups where there are many alpine to be grown; and bogs, ponds, and springs imitated in others destined for aquatics, &c. as far as consistent with botanical purposes. A gravel-walk may be so contrived as to form a tour of all the groups (*fig. 553.*), displaying them on both sides; in the centre, or in any fitting part of the scene, the botanic hot-houses may be placed; and the whole might be

surrounded with a sloping phalanx of evergreen plants, shrubs, and trees. The plants in such a garden should generally be neatly, but inconspicuously named, or, at all events, numbered; but naming is greatly to be preferred, as saving trouble to the spectator, and more inviting to the novice desirous of knowledge. It is hardly necessary to observe that the above modes, or others that we have mentioned, of planting a flower-garden, are alike applicable to every form or style of laying out the garden or parterre, and that they do not interfere with any mode of enclosing or surrounding it, or of edging the walks.

6127. *Decorations.* It is usual to employ different objects of art as decorations to flower-gardens, and the practice is founded in reason, since the works of nature and of art lend force to each other by their contrast. We have, in a former part (1805. to 1846.), enumerated the principal garden-decorations. Those more especially applicable to the flower-garden are the fountain in various forms; the open and covered, or rustic seat (*fig. 555.*); the statue (*fig. 554.*) in all its varieties of therm, bust, single figure and group, and in the various materials of stone, metal, or verdure; the arbor, and a variety of others. Even the apiary and aviary, or, at least, here and there a beehive, or a cage suspended

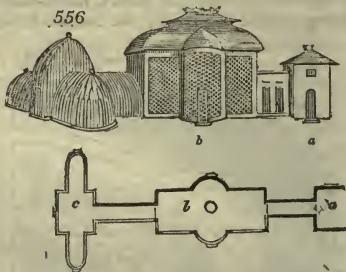

from a tree, will form very appropriate ornaments. Sometimes inoffensive birds, as the sea-gull, may be introduced to run at large; gold-fish are very appropriate in the aquarium; and an animal which affords great amusement by its cry and song in the flower-gardens of the south of Germany, the tree-frog (*Rana arborea*), would be an acquisition in this country. In some families there is a taste for minerals or antiquities; and here, besides larger specimens distributed in the garden, a building (fig. 556.) may be introduced, combining a mineral cabinet (a), an aviary (b), and the botanic hot-houses (c).

6128. Where the old French style (figs. 545. 550.) is imitated, a profusion of marble and vegetable sculptures, verdant arcades, colonnades, arbors, &c. are in character; but in the more simple and modern forms (figs. 540. 541. 543.) a few stools, sofa-chairs, a pavilion-seat (fig. 338.), a sun-dial, fountain, some urns, and a few good statues, will, in most cases, be sufficient. In the distribution of even these few decorations much judgment is requisite to avoid exciting ridicule by falling into the rapid, the flippant, or some other species of deformity. (See *Schimmelpeninck on Beauty*, &c.)

6129. Time of planting herbaceous plants.

This is, in general, autumn and spring; but any perennial plant may be safely removed after it has done flowering or produced seed. With respect to biennials and annuals, they may be planted at almost any season before they have begun to throw up flower-stems. Biennials, however, are generally sown early in autumn in the flower-garden nursery, and transplanted either late in the same season or early in the following spring, to where they are to flower. Annuals are commonly sown in spring, where they are finally to remain. The culture of herbaceous flowers of the more valued sorts is exceedingly varied, and will be found under each species or class in the *Flower-garden Catalogue*. For the preparation of the soil and the manner of performing the operation, see these articles in (Chap. IV.) *Planting the Shrubbery*.

CHAP. III.

Of Forming the Shrubbery.

6130. By a shrubbery, or shrub-garden, we understand a scene for the display of shrubs valued for their beauty or fragrance, combining such trees as are considered chiefly ornamental, and some herbaceous flowers. The form or plan of the modern shrubbery is generally a winding border, or strip of irregular width, accompanied by a walk, near to which it commences with the herbaceous plants and lowest shrubs, and as it falls back, the shrubs rise in gradation and terminate in the ornamental trees, also similarly graduated. Sometimes a border of shrubbery accompanies the walk on both sides; at other times only on one side, while the other side is, in some cases, a border for culinary vegetables surrounding the kitchen-garden, but most generally it is an accompanying breadth of turf, varied by occasional groups of trees and plants, or decorations, and with the border, forms what is called pleasure-ground.

6131. The sort of shrubbery formed under the geometric style of gardening (fig. 557.) was more compact; it was called a *bosque*, thicket or wood, and contained various compartments of turf or gravel branching from the walks, and very generally a labyrinth. The species of shrubs in those times being very limited, the object was more walks for recreation, shelter, shade, and verdure, than a display of flowering shrubs. What was wanting in natural beauty and variety, however, was made up by the art of the gardener in cutting such trees and shrubs as he had, into curious shapes. Shrubberies are often made for the sake of obtaining an agreeable walk to some particular place or scene, as the kitchen-garden, farm, wood, &c.; and sometimes in order to lead the spectator to different points, where views or distant prospects may be obtained. The most desirable shrubbery is one where both these objects are combined; and the least so, where the walk leads to no particular object, is shut up on both sides, and has no beauties to depend on but those of the shrubs. Hence Sir W. Chambers complains of walks *en cul de sac*, and Knight of "the shrubbery's insipid scenes," &c. (*Tr. on Country Res.* i. 352.) The shrubbery, however, judiciously laid out and planted, will always be a scene of considerable beauty and use about a country-seat. It is one of the principal resources for a home-walk for exercise; and as Repton has observed, a tolerable walk, even round one's own field, is more interesting than a better one where we have no interest. "We are greatly indebted to shrubs," Nicol observes, "for much of the pleasure and delight we enjoy in our gardens. Though they produce no eatable fruits, nor afford us any sort of nourishment, yet they are particularly conducive to our comfort. In winter, they shelter us in our walks; in summer, they shade us from the sun. They afford a great variety of flowers, a varied foliage, and are standard ornaments that give us no great trouble. They are particularly useful in the character of screens, whether against the weather, or to hide disagreeable objects, in which case they may be planted nearer to the house than forest-trees. When planted in masses at a distance, they become agreeable objects, and often improve the scenery of a place. The shrubbery is often a matter of utility as well as of ornament, in which case it gives the highest satisfaction. When formed for the purposes of shutting out the offices or the kitchen-garden from the view of the house; for sheltering the latter or the garden, or for connecting the house with the garden and the orchard, the shrubbery becomes useful and interesting."

6132. In respect to situation, it is essential that the shrubbery should commence either

immediately at the house, or be joined to it by the flower-garden ; a secondary requisite is, that however far, or in whatever direction it be continued, the walk be so contrived as to prevent the necessity of going to and returning from the principal points to which it leads over the same ground : but as this is a matter which must be arranged in the general disposition or laying out of the residence, it need not be here entered on.

6133. *The extent of the modern shrubbery must depend more on the extent of that place of which it is a part than on any other principle, and it is, or ought to be, so blended with the flower-garden lawn, as scarcely to admit of its quantity being estimated apart. Where the proportion of pleasure-ground, which may be judiciously apportioned to a residence, depends so much on the ground's surface, and on the character or style of the whole seat, nothing definite can be laid down in the way of rules. The walks in the pleasure-ground should generally exceed a mile or two for the sake of recreation ; but what proportion of these should be in open lawn, and what in flower-garden, or along the margin of a shrubbery, is too vague a question to receive any useful answer. Local circumstances and the character to be created must determine every thing. It may be mentioned as a characteristic distinction between the ancient and modern shrubbery, that the former was of limited extent, compact form, situated near the house, and that the length of walk was made up by repetition of parallel and cross walks. The whole of these had little distant prospect, and were generally more sheltered and shaded than is suitable for our climate ; whereas, in the modern shrubbery, the length is made up by stretching out the walk to a distance ; and air and ventilation, as well as views and prospects, are obtained by its being planted chiefly on one side. Such shelter and shade as is deemed requisite for the walk is obtained by the introduction of scattered trees along its open margin.*

6134. *Soil.* "Shrubs, in general," Nicol observes, "thrive very well in ordinary garden-land, and better in light than in heavy soils. Most shrubs, likewise, do well in ground a foot in depth ; but it is always advisable to trench to the full depth of the soil, previous to planting, if that were even two feet. Manure is seldom bestowed on shrubs, and if the soil be not far below mediocrity, it is seldom necessary, provided the ground be otherwise well prepared, and be meliorated by trenching or digging. In the case of planting screens, where it is desirable to have them effectual as soon as possible, or in planting favorite shrubs in particular situations, every justice should be done to the soil in preparing and enriching it, either with manure or by the addition of fresh earth. Those who are curious in collections of certain shrubs, prepare or choose certain soils for them. Evergreens, for the most part, thrive well in loam of a middling texture ; but some kinds do better in mossy humid earth, as the azalea and rhododendron. Deciduous shrubs, in general, thrive well in light loams or sandy soils ; but certain kinds flower better in rich mellow earth, as the moss-rose and the robinia."

6135. *Walks.* "The conducting of walks," Nicol says, "through the shrubbery, is a matter both of conveniency and of taste : of conveniency, when the shrubbery is merely a passage from one place to another, or a narrow screen to the garden. In the former case, the walk should be simple and direct : in the latter case it may be circuitous ; and if there be any variety in the ground, it ought to lead to particular points of view. The walks, however, should seldom cross one another ; they should rather take off at oblique angles ; nor should one run parallel to another within view. It is proper to show off the shrubs, but too many walks perplex. Their breadths may be various. If short, they should be narrow ; if long, and if a considerable reach be caught at once, they should be broad. A medium may be taken at five feet, the extremes being three and eight. They may be of turf or of gravel ; but the latter is always most wholesome, and most agreeable in winter." In the ancient style, where the shrubbery, or umbrageous scene (*fig. 557. a*), often enclosed the flower-garden (*b*), both being situated in front of the house (*c*), the walks (*d*) were laid out in arbitrary geometrical shapes, crowded and numerous, to afford sufficient space for recreation, and varied by niches (*e*), boudoirs (*f*), salons (*g*), and other open parts to give variety.

6136. *Fence.* Local circumstances must, in almost every case, determine the sort of exterior or boundary-fence most proper for the shrubbery or pleasure-ground ; the interior, or that on the open side, should, in almost every case, be one of the inconspicuous kind ; either light iron-railings, moveable hurdles of wood or iron, or the sunk-fence. Where the shrubbery is not a boundary plantation, a light fence may include it on both sides ; but so much depends on locality and other arrangements, that the subject cannot be profitably discussed separately from that of laying out the entire residence. Under the geometric style, the business of fencing the shrubbery or woody scene, was very simple, the whole being generally surrounded by a high wall. "Fences of all kinds," Abercrombie observes, "are rather necessary and useful as instruments of shelter and security than to be chosen as materials of ornament. Whether the view terminates on the fence, or is directed beyond it, the effect on the scene, at best, is negative : thus, a fence is sometimes made higher than its proper use requires, merely to shut out something more unsightly ; and, in judiciously employing that capital invention, the sunk-fence or

ha-ha, the advantage, though great, is purely negative; some prospect worth retaining at considerable cost is not obstructed."

6137. *Reserve-ground for the shrubbery.* A plot of ground should be set apart for the propagation and culture of the more tender shrubs, to supply deaths or accidents in the front of the shrub-border. This reserve-nursery will be most conveniently situated when joined to that of the flower-garden; but it may also be taken from the interior of any wide part of the plantation where it will not be seen. Here roses, mezerions, American shrubs, honeysuckles, and a variety of the more ornamental and tender sorts should always be in readiness, partly in pots and partly in nursery lines, to remove to the principal scene, either to add to its usual beauty, or to compensate for accidental defects. To the same ground may be added a space for accumulating leaves, spray, and other refuse of the shrubbery, to ferment and produce manure for the nursery in the same way as is done in the compost-grounds of the kitchen and flower garden.

CHAP. IV.

Of Planting the Shrubbery.

6138. *On planting the shrubbery* the same general remarks, submitted as introductory to *planting the flower-garden*, are applicable; and shrubs may be arranged in as many different manners as flowers. Trees, however, are permanent and conspicuous objects, and consequently produce an effect during winter, when the greater number of herbaceous plants are scarcely visible. This is more especially the case with that class called evergreens, which, according as they are employed or omitted, produce the greatest difference in the winter aspect of the shrubbery. We shall here describe four leading modes for the arrangement of the shrubbery, distinguishing them by the names of the mingled or common, the select or grouped manner, and the systematic or methodical style of planting. Before proceeding farther it is requisite to observe, that the proportion of evergreen trees to deciduous trees in cultivation in this country, is as 1 to 12; of evergreen shrubs to deciduous shrubs, exclusive of climbers and creepers but including roses, as 4 to 8; that the time of the flowering of trees and shrubs is from March to August inclusive, and that the colors of the flowers are the same as in herbaceous plants. These data will serve as guides for the selection of species and varieties for the different modes of arrangement, but more especially for the mingled manner.

6139. *To dispose shrubs and trees in the mingled manner*, proceed as under. The width of the space to be covered with trees, shrubs, and flowers being given, first mark it out in rows lengthways. The first

row may be two feet from the margin of the turf or the edge of the walk; the second, three feet from the first; the third, four feet from the second; and so on to the back of the plantation. Suppose the width to admit of ten rows (*fig. 558. a to k*), then the six rows next the walk will occupy a space of twenty-seven feet, which may be devoted to shrubs, and the remaining three rows will occupy a space of thirty-seven feet, and may be planted with trees. Then beginning with the first row, which is destined for the lowest class of shrubs, arrange them according to the times of their flowering, which will, as in arranging herbaceous plants, be most conveniently done at six times; viz. 1, March; 2, April, &c. to 6, August; and they will stand as in the flower-border in the order of 1, 6, 3, 5, 2, 4, and with the colors in the same manner (*a*). The second row (*b*) is to be arranged in the same manner; and as trees, though nearly of the same size when planted, yet attain finally very different degrees of bulk, provision must be made for the plants in each row to expand year after year, till they attain their full growth. This we propose to do by planting two plants of a sort in the second row (*b*), three in the third, and so on (as indicated in the figure), till in the last or tenth row (*k*), there will be ten plants of a sort in a line together. It is to be observed, that a deciduous and an evergreen sort (marked *d, e*, in the figure) are to be planted alternately, in order to ensure an equal mixture in respect to verdure; and that the colors (denoted by *r, w, b, y*, in the figure) are mixed as in the mingled border, to ensure a general display of mixed blossoms. The second or third year such of the plants are to be thinned out as crowd the others, reserving, however, as final plants, one of each sort, (say *E* for the evergreens, and *D* for the deciduous sorts), so placed in respect to the plants in the other rows, as that the whole, when finally thinned out, may stand in quincunx. The largest trees will then occupy about 100 square feet each; and each of the shrubs in the front row about a square yard: there will be the same number of deciduous plants as evergreens; some shrubs of all the four colors in blow throughout the whole season, and a verdant aspect in summer as well as winter.

n. *1*

6140. *The distance between the rows of trees* (ten feet) may in some cases be an objection, for a year or two at first; but this, we consider, will be more than counterbalanced by the opportunity afforded of cultivating the ground between them, and by the air and light admitted to their side shoots, which will the sooner fit them for producing blossoms. All formality of appearance will soon be done away by the irregular growth of the plants, and by the thinnings which must take place in, at the latest, three years after planting. If any, however, object to the appearance of rows, they may be obliterated, by introducing some plants in the intervals of the same sort as those in the lines adjoining; but in doing this, care must be taken never to lose sight of the shrub or tree which is finally to remain, as it is of importance to this plan, (which is not natural or picturesque planting), that the regular disposition of the whole be preserved, as well with a view to the gradation of height as to the mixture of color in the flower, and of permanent and deciduous foliage. The herbaceous plants only remain to be added. These are to be inserted one row in front of the first row of shrubs (*o*), and three or more rows (*p, q, r, s*) in the intervening spaces between the next rows. The plants are to form a quincunx with the shrubs; and the same arrangement as to height, color, and time of flowering, adopted as in the mingled border. Such a shrubbery may be commenced with (2×6) twelve sorts of evergreen, and the same number of deciduous trees; with (6×6) thirty-six sorts of shrubs, half the number deciduous, and half evergreen; and with (5×6) thirty sorts of herbaceous plants. It may then be continued either by repeating the pattern with the same sorts, or by other sorts; or principally by the same sorts, with some others occasionally. If a show of flowers is valued, the sorts employed must be comparatively few, as the flowers of the greater number of trees and shrubs are of dull colors, or little conspicuous. The evergreen trees, in a popular sense, can hardly be said to have any flower; but still a number of them must be introduced in the back rows, to blend with horse-chestnuts, limes, acacias, wild cherries, wild pears, &c. &c.

6141. *The select or grouped manner of planting a shrubbery* (fig. 559.) is analogous to the select manner of planting a flower-garden. Here one genus, species, or even variety, is planted by itself in considerable numbers, so as to produce a powerful effect. Thus the pine tribe, as trees; may be alone planted in one part of the shrubbery, and the holly, in its numerous varieties, as shrubs. After an extent of several yards, or hundreds of yards, have been occupied with these two genera, a third and fourth, say the evergreen fir tribe and the yew, may succeed, being gradually blended with them, and so on. A similar grouping is observed in the herbaceous plants inserted in the front of the plantation; and the arrangement of the whole as to height, is the same as in the mingled shrubbery.

559

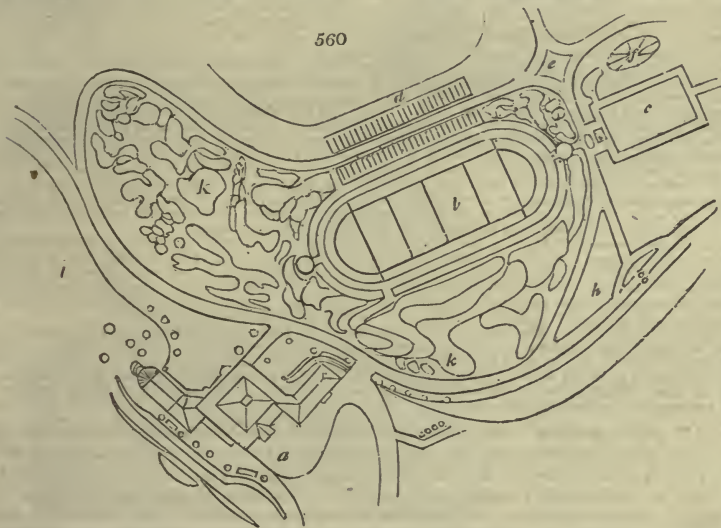

6142. *The chief difficulty* in this manner of planting is so to select the sorts that are to succeed each other, so to blend one group or kind with those adjoining, and at the same time maintaining the requisite gradation from the front to the back of the plantation, as to preserve to the spectator in walking along, the appearance of a *whole*. When this is successfully accomplished, and on a large scale, no kind of shrubbery can be more beautiful in summer; but in winter it will present parts wholly without evergreens, and it will only be rich in flowers in some parts; as for example, where the roses, spireæ, mespileæ, &c. are introduced. By proper contrivance, however, the evergreens, the showy flowering deciduous kinds, and the less showy deciduous sorts may form three divisions, and the two former can be kept nearest the mansion. The best guides as to the sorts proper to adjoin each other, are the general form and mode of growth; and next, the color and foliage. In these particulars the transition should always be gradual. Thus, among the trees, the pines, cedars, firs, and yew, form a regular gradation, and the shrubs which may be placed near them are the arbor vitæ, juniper, whin, &c. To place groups of weeping-willow or elm adjoining the pines, and to select roses and lilacs as shrubs, would produce a harsh and incongruous effect. There is obviously much less natural affinity between herbaceous plants and shrubs than between shrubs and trees; but the groups of the herbaceous plants must harmonise among themselves on the same general principles as the trees; thus pink-looking plants (*caryophyllææ*), should not be succeeded by coarse broad-leaved sorts (*boraginææ*), but rather by more delicate kinds, as grasses or primulæ, &c. There may sometimes also be a certain species of relation between the herbaceous plants and shrubs; thus the bulbous-rooted kinds, and small early flowers, as violets, primulæ, will be more fitly planted among evergreens and early-flowering deciduous shrubs than among late deciduous kinds.

6143. *Various other modes of select-planting shrubberies* may be adopted; such as collecting together all such shrubs, trees, and flowers as flower at the same time, or have the same color of flower, or foliage, or the same odors, or the same general shape, or the same natural habitation, as of marshes, mountains, &c., or the same country, as America, Switzerland, Sweden, &c. But the intelligent gardener who has attended to what has been already advanced, can hardly require farther instructions to form such plantations. We would suggest, as worth trial, where there was ample space, the mode of arranging by odors; the ancients are said to have paid particular attention to this in mixing their trees. (*Falconer*, &c. and see 37.) Every one must have experienced a difference in this respect between walking in a pine-forest, a plantation of balsam-poplars, a birch-copse, and beside sweet-briar and juniper hedges. An arrangement of this kind, depending on the smell of the buds and leaves, rather than of the flower, would have its effect the greater part of the year, especially after showers.

6144. *Systematic or methodical planting in shrubberies* consists, as in flower-planting, in adopting the Linnæan or Jussieuean arrangement as a foundation, and combining at the same time a due attention to gradation of heights. This mode, executed on a grand scale, would unquestionably be the most interesting of all, even to general observers; but on a small scale it could not be so universally pleasing as the mingled manner, or the mode by select grouping. The uninstructed mind might be surprised and puzzled by such an assemblage; but not perceiving the relations which constitute its excellence, they would be less pleased than by a profusion of ordinary beauties; by a great show of gay flowers and foliage. Dr. Darwin is said to have blended picturesque beauty with scientific arrangement in a dingle at Litchfield, where he disposed of a large collection of trees and plants in the Linnæan manner. The same thing may be attempted on any description of surface, and with any form of ground-plan, provided turf be introduced, and care be taken to elongate the groups containing trees in such a way as to preserve a sufficient degree of woodiness throughout, both for shelter, shade, and picturesque effect. In this way we have arranged a spot (*fig. 560.*) of little more than an acre and a half,

560

so as to ordinary observers, to be nothing more than a house surrounded by pleasure-ground, but to the botanist and painter, to be a scientific and picturesque scene. This spot combines a villa and offices (*a*), a kitchen-garden (*b*), reserve-garden and melon-ground (*c*), botanic ground for herbaceous plants (*d*), rock-work (*e*), rosarium (*f*), aquarium (*g*), American ground (*h*); besides a variety of other subordinate scenes, a scattered orchard (*i*), and the shrubbery (*k*), arranged in irregular, elongated groups on lawn, in the manner mentioned. But much the most interesting mode of arrangement would be that of Jussieu, by which a small villa of two or three acres might be raised, as far as gardening is concerned, to the *ne plus ultra* of interest and beauty. To aid in the formation of such scenes the tables (588, 589.) exhibiting the genera contained in each Linnæan or Jussieuean order, and also the number of species distributed according to their places in the garden, will be found of the greatest use.

6145. *Chinese arrangement.* It is only since the great influx of trees and shrubs from America, during the latter half of the last century, that the idea of arranging shrubs found a place in the writings on gardening. Sir W. Chambers seems to have been the first who suggested it in his account (whether correct or not, is of little consequence to our present purpose), of the practice of the Chinese gardeners. The Chinese, he says,

in their plantations, do not, as is the practice of some European gardeners, plant indiscriminately every thing that comes in their way; nor do they ignorantly imagine, that the whole perfection of plantations consists in the variety of the trees and shrubs of which they are composed: on the contrary, their practice is guided by many rules founded on reason and long observation, from which they seldom or never deviate. Many trees, shrubs, and flowers, they say, thrive best in low moist situations; many on hills and mountains: some require a rich soil; but others will grow on clay, in sand, or even upon rocks; and in the water: to some a sunny exposition is necessary; but for others, the shade is preferable. There are plants which thrive best in exposed situations; but, in general, shelter is requisite. The skilful gardener, to whom study and experience have taught these qualities, carefully attends to them in his operations; knowing that thereon depend the health and growth of his plants; and, consequently, the beauty of his plantations.

6146. *The perfection of trees for ornamental gardening* consists in their size, in the beauty and variety of their forms, the color and smoothness of their bark, the quantity, shape, and rich verdure of their foliage, with its early appearance in the spring, and long duration in the autumn; likewise in the quickness of their growth, and their hardiness to endure the extremities of heat, cold, drought, or moisture; in their making no litter, during the spring or summer, by the fall of the blossom; and in the strength of their branches, to resist, unhurt, the violence of tempests.

6147. *The perfection of shrubs* consists not only in most of the above-mentioned particulars, but also in the beauty, durability, or long succession of their blossom; and in their fair appearance before the bloom, and after it is gone. We are sensible, say they, that no plant is possessed of all good qualities; but choose such as have the fewest faults; and avoid all the exotics that vegetate with difficulty in our climate; for though they may be rare, they cannot be beautiful, being always in a sickly state.

6148. *The excessive variety* of which some European gardeners are so fond in their plantations, the Chinese artists blame; observing, that a great diversity of colors, foliage, and direction of branches, must create confusion, and destroy all the masses upon which effect and grandeur depend: they observe too, that it is unnatural; for, as in nature most plants sow their own seeds, whole forests are generally composed of the same sort of trees. They admit, however, of a moderate variety; but are by no means promiscuous in the choice of their plants; attending, with great care, to the color, form, and foliage of each; and only mixing together such as harmonise and assemble agreeably. They observe, that some trees are only proper for thickets; others, only fit to be employed singly; and others, equally adapted to both these situations. The mountain cedar, the spruce and silver firs and all others whose branches have a horizontal direction, they hold improper for thickets: because they indent into each other; and likewise cut disagreeably upon the plants which back them. They never mix these horizontal-branched trees with the cypress, the oriental arbor vitæ, the bamboo, or other upright ones; nor with the larch, the weeping willow, the birch, the laburnum, or any of a pendent nature; observing, that the intersection of their branches forms a very unpicturesque kind of network: neither do they employ together the catalpa and the acacia, the yew and the willow, the plane and the sumach, nor any of such heterogeneous sorts; but, on the contrary, they assemble in their large woods, the oak, the elm, the beech, the tupelo, the sycamore, maple, and plane, the chestnut, the walnut, the arbutus, the lime, and all those whose luxuriant foliage hides the direction of their branches; and growing in globular masses, assemble well together; forming, by the harmonious combination of their tints, one grand group of rich verdure.

6149. *In their smaller plantations*, they employ trees of a smaller growth, but of the same concordant sorts; bordering them with Persian lilacs, guelder-roses, syringas, coronillas of various sorts, flowering raspberries, yellow jessamine, hypericum, the spiræa frutex, altheas, roses, and other flowering shrubs peculiar to China: and wherever the ground is bare, they cover it with white, blue, purple, and variegated periwinkle, the convolvulus minor, dwarf stocks, violets, primroses, and different kinds of creeping flowers; and with strawberries, tutsan, and ivy which climbs up and covers the stems of the trees.

6150. *In their shrubberies* they follow, as much as possible, the same rules; observing farther, to plant in some of them all such shrubs as flourish at one time; and in some, such as succeed each other: of which different methods the first is much the most brilliant; but its duration is short; and the appearance of the shrubbery is generally shabby, as soon as the bloom is off: they therefore seldom use it, but for scenes that are to be enjoyed at certain periods; preferring the last, on other occasions, as being of long duration, and less displeasing after the flowers are gone. (*Dissert. on Orient. Gard.*)

6151. *British practice.* Soon after Sir William Chambers's work appeared that of Wheatley, which contains some excellent remarks on the subject (*Obs. on Gard.* sect. xii. xiii. xiv.), and subsequently Uvedale Price's excellent *Essays on the Picturesque*, vol. i. In 1804 we endeavored to enforce the principle, not only in planting trees, but in arranging herbaceous plants, and the plants in botanic hot-houses. (*Obs. on Planting and Landscape Gard.* 8vo.) All these efforts were at first treated as visionary by Marshal, Nicol, and other planters and gardeners. But Nicol, in the last editions of his works, allows there may be some merit in grouping; and Sang, his editor, highly approves of following nature in the arrangement of trees. (*Planter's Kalend.*)

6152. Nicol says, "the proper disposition of shrubs, where many are to be planted, is a matter of considerable importance to the future welfare of the whole, and that whether they be mixed, or be grouped; that is to say, whether deciduous or evergreen shrubs be indiscriminately mixed, as is often done, or the evergreens be planted distinctly by themselves. The arrangement of shrubs is a matter, no doubt, very much of fancy. In some parts they may be mixed; in others grouped; but, in general, there ought to be plenty of evergreens planted, in order that the whole may be the more cheerful in winter. Generally speaking, however, the method of mixing all kinds of shrubs indiscriminately, prevails too much in modern shrubberies. Much more character and distinctness may be given, by judiciously grouping them, than by following the common methods of planting."

6153. *Abercrombie*, or rather his posthumous editor, seems undecided in his observations on this subject. In one place he says, "in the distribution of plants over grounds dedicated to elegance, there are two rival systems, each of which has its practical followers and theoretical vindicators. One proposes the indiscriminate mixture of many different species; the other deliberately groups those only which have some marks of affinity. It is still a question, which order of planting is countenanced by the practice of nature in self-sown vegetables; and which will confer on a garden the stronger claims to character and beauty?" He elsewhere observes, that "the different natures of herbaceous flowers, shrubs, and trees stand in the way of every attempt to govern their distribution or assemblage by a common principle." In planting trees, however, he subjoins, "the principle of unity may be consulted, without losing sight of the advantage of variety," &c. (*Pr. Gard.* 477.)

6154. *Fruit-trees in shrubberies.* "In shrubberies of considerable extent, fruit-trees may be interspersed at fifteen or twenty yards' distance, by which means a good deal of fruit may be obtained, and very much beauty added to the shrubbery. In spring the blossoms of apples, cherries, and pears are beautiful; in autumn their fruits and the foliage of cherries in particular, give a lustre and variety that highly brightens the appearance of other plants, especially of evergreens." (*Villa Gard. Direct.* 16.) This mode, Sir W. Chambers tells us, is practised, by the Chinese *when the patron is poor*; that is, their shrubbery is composed of fruit-trees, and shrubs, and forms a sort of ornamental orchard. This we consider an advisable mode for an economical farm-residence; but the general introduction of fruit-trees, in even mingled shrubberies, unless of the species in their wild state, as crabs, wildings of pears, cherries, quinces, raspberries, &c. we consider as likely to destroy the character of the scene. It must be recollected too, that grafted trees, especially the apple and cherry, seldom grow so freely and produce such vigorous and natural-like heads as plants raised from seed; they are, therefore, soon overtopped by the others, or where they are placed among trees that do not grow higher than themselves, they seldom fail of producing deformed stunted heads.

6155. *Forsyth, Abercrombie, and others,* recommend their introduction, as it appears to us, without due regard to any other object than the fruit they will produce, and the fugacious beauty of their blossoms; but their unaccommodating form, and their influence as to character in ornamental plantations, we consider as sufficient arguments against the practice in general cases.

6156. *Decorations in shrubberies.* Those of the shrubbery should in general be of a more useful and imposing character than such as are adopted in the flower-garden. The green-house and aviary are sometimes introduced, but not, as we think, with propriety, owing to the unsuit-

561

562

ableness of the scene for the requisite culture and attention. Open and covered seats are necessary, or, at least, useful decorations, and may occur here and there in the course of the walk, in various styles of decoration, from the rough bench to the rustic hut (*fig. 561.*) and Grecian temple. (*fig. 562.*) Great care, however, must be taken not to crowd these nor any other species of decorations. Buildings being more conspicuous than either statues, urns, or in-

scriptions, require to be introduced more sparingly, and with greater caution. In garden or ornamented scenery they should seldom obtrude themselves by their magnitude or glaring color; and rarely be erected but for some obvious purpose of utility.

6157. *Covered seats and shelters* are introduced of many forms, and under a great variety of names, such as root-houses, heath-houses, moss-houses, huts, shelters, (*fig. 563.*) bowers, caverns, caves, grottoes, temples, mosques, &c. besides plain covered seats either of wood or stone. The imitation of temples or mosques, as they must be on a small scale, is generally quite ridiculous. The propriety of introducing the others depends entirely upon the character of the scene. Light bowers formed of lattice-work, and covered with climbers, are in general most suitable to parterres; plain covered seats suit the general walks of the shrubbery. Most of the others may be introduced in romantic, singular, wild, or melancholy places.

563

6158. *Statues, whether of classical or geographical interest (figs. 564. and 565.), urns, inscriptions, busts, monuments, &c. are materials which should be introduced with caution.*

564

None of the others require so much taste and judgment to manage them with propriety. The introduction of statues, except among works of the most artificial kind, such as fine architecture, is seldom or never allowable; for when they obtrude themselves among natural beauties, they always disturb the train of ideas which ought to be excited in the mind, and generally counteract the character of the scenery. In the same way, busts, urns, monuments, &c. in flower-gardens, are most generally misplaced. The obvious intention of these appendages is to recall to mind the virtues, qualities, or actions of those for whom they were erected: now this requires time, seclusion, and

565

undisturbed attention, which must either render all the flowers and other decorations of the ornamental garden of no effect; or, if they have effect, it can only be to interrupt the train of ideas excited by the other. As the garden, and the productions of nature, are what are intended to interest the spectator, it is plain that the others should not be introduced. This reasoning, while on the one hand it shows the absurdity of such a practice, on the other, directs that urns, monuments, &c. should only be placed in solitary unfrequented places, where the mind is naturally led to contemplate, and where the remembrance of the virtues of great men, or the worth of relations now no more, afford proper subjects for contemplation. But even in places apparently solitary, or secluded, these have been introduced in so affected or improper a manner, as to furnish reason for the greatest caution in future. (*Tr. on Country Res.*)

6159. *A cottage, when the walk of a shrubbery is of great extent, may sometimes be advantageously introduced in a distant part of it, with an occupant, for the purpose of keeping one apartment in order as a place of repose. Such a cottage (fig. 566.) may be designed in any style, according to the taste of the owner, and may serve a variety of useful purposes. In the gardens laid out under the direction of the Queen of Geo. III. at Frogmore, and in the walks of what are called the slopes at Windsor, are some good examples of rustic seats, and ornamented shrubbery cottages.*

566

6160. *On the subject of planting both flower-gardens and shrubberies we may remark, with the author of the Florist's Manual, that it is considered in much too unimportant a light, both by gardeners and their employers. The business is almost every where performed at random, instead of being conducted with a specific object in view. To remedy this evil, gardeners should first make a correct plan of the border, parterre, or plot, of whatever kind it may be, that is to be planted; and then having determined the mode of arrangement most proper, and selected the names of plants to effect it, from the proper catalogues, the situation of every plant and its name should be determined on the plan. This done, all these points should be correctly transferred to the ground, and a pin or stake inserted at each, numbered in correspondence with a list of the sorts. The plants being procured, should then be distributed and planted according to these stakes and numbers; and the stakes should be allowed to remain for a year or two, to make certain as to the sort to be replaced there, in the case of death or accident. If ever this branch of gardening should attain a high degree of perfection in Britain, it will probably be deemed as necessary to call in a professor to direct the arrangement of flowers and shrubs in parterres and shrubberies, as it is now to require his aid in arranging the ground-plan.*

CHAP. V.

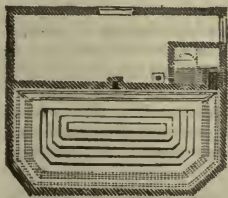

Of the Hot-houses used in Ornamental Horticulture.

6161. *The hot-houses of floriculture* are the frame, glass case, green-house, orangery, conservatory, dry-stove, the bark or moist stove, in the flower-garden, or pleasure-ground; and the pit and hot-bed in the reserve-garden. In the construction of all of these the great object is, or ought to be, the admission of light and the power of applying artificial heat with the least labor and expense. In culinary forcing-houses, it is requisite to attend to the angle of the glass roof, so as to obtain most of the sun's influence at the time the fruit within is to be ripened; but in the hot-houses of the flower-garden or pleasure-ground, the construction ought to be such as to admit as much light as possible in winter; for then in the stoves a heat is kept up by art, which is not to be found in any natural climate connected with so little light as is then afforded in our latitude. Hence, as a general principle it may be affirmed, that the roofs of all plant or botanic hot-houses should be steep rather than flat, and, perhaps, the angle of 45° may be fixed on as the fittest average. It was adopted by Miller, both in culinary and ornamental hot-houses, and is fitter for general purposes than any other.

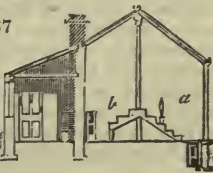

6162. *The frame* used in ornamental horticulture is generally of the same form as those of the kitchen-garden. For alpine plants this form succeeds perfectly, but for frame-shrubs, the ends and front should be deeper than usual, and glazed half their depth, to admit the sun to the surface of the adjoining pots. Frames for the taller bulbous-rooted flowers, should either be glazed in front and at both ends, or if opaque in those parts, should be placed on a steep surface for the same general object. Frames of every description should have a gutter or spout in front, to carry off the rain-water which falls on the sashes.

6163. *The glass case* may be variously constructed from detached sashes; it is used to protect standard trees or shrubs, and sometimes to place against walls or espaliers. (see fig. 326.)

6164. *The green-house* may be designed in any form, and placed in almost any situation as far as respects aspect. Even a house looking due north, if glazed on three sides of the roof, will preserve plants in a healthy vigorous state. A detached green-house, even in the old style, may be rendered an agreeable object in a pleasure-ground, of which, as an example, we may refer to one (fig. 567.) erected by Todd, for

567

E. Liebenrood, Esq. near Reading; but the curvilinear principle applied to this class of structures, admits of every combination of form, and without militating against the admission of light and air. Though we are decidedly of opinion, however, that as iron roofs on the curvilinear principle become known, the clumsy shed-like wooden or mixed roofs now in use will be erected only in nursery and market-gardens; yet we are not to be understood as exclusively recommending our own plans, and we, therefore, describe that of Todd, whose book contains a number of examples, erected in different parts of the country, and in the best manner of the old style. "This house (fig. 567,) has a span roof, and the centre lights, which are balanced by weights, made in imitation of acorns, suspended from the ridge of the roof, are made to slide, to admit air from the roof. The front and ends are formed with folding case-ments, hung so as to be taken away at pleasure; and between each is a pilaster of treillage-work. A cast-iron column at each extremity of the upper part of the roof, is placed for the purpose of keeping it from spreading, as such roofs generally do, unless held together by a transverse tie, which has a less pleasant appearance than a column. A

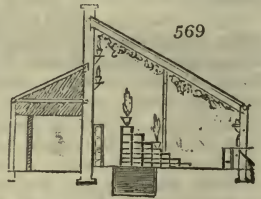

568

single fire heats this house; the flue goes under the floor round the front and ends, rises and continues above the floor along the back wall, and terminates in a chimney in the centre. Over the stock-hole is placed a cistern, which is supplied from the roof, and occasionally from a pump adjoining, with water, which is conveyed into the green-house by a lead pipe." (*Plans for Green-houses, &c.* p. 11.)

6165. *The most suitable description of green-house or conservatory for the flower-garden* is that with span roof (fig. 568.), because such a house has no visible "hinder parts," back sheds, stock-holes, or other points of ugliness, with which it is difficult to avoid associating all the shed, or lean-to forms of glazed buildings with back walls. Several elegant houses of this description have been erected by Messrs. Bailey. An example occurs in the Regent's Park, at the villa of W. H. Cooper, Esq.; another at Walthamstowe, in the grounds of P. Kendal, Esq.; and several more are mentioned in the table already given (1587.), or are in course of erection.

6166. *In the interior of the green-house* the principal object demanding attention is the stage, or platform for the plants. In a double-roofed house, surrounded by a path, the stage generally consists of shelves, rising from the path to the middle of the house (fig. 567. *a* and *b*); but in a house with a single roof (fig. 569.) it generally rises from the front path to the back, and in both cases the slope of the stage is generally the same or somewhat less than the slope of the roof. In the green-houses destined for very large or tall-growing plants, as camellias, and many of the New Holland plants, no stage is requisite; and in such as are destined for small plants, as heaths and geraniums, the first step of the stage, when there is a path between it and the front glass, should be raised at least two feet and a half high, and it may then be continued parallel to the roof. The object of this arrangement is to bring the plants near the glass, so as they may obtain the benefit of the light in a state as little decomposed as possible. Flues in green-houses are frequently carried above ground, which is inelegant and too much in the style of the common forcing-house. They may in almost every case be conducted under the paths or stage, and by keeping them detached so as air may circulate round them, as much heat will be given out as by the common mode. In general one fire will be sufficient to warm from 4000 to 5000 cubic feet of air, of the temperature requisite for green-house plants. (see 1662.) In some cases trellis-rods are placed at regular distances under the roofs of green-houses, for the purpose of training vines; but this practice is incompatible with a high degree of culture and beauty in the green-house plants, on account of the light it excludes; besides, it interferes with character. If any creepers or climbers are to be trained under the roofs, they should be of the ornamental kind; but it is generally best to train them to upright rods at the back part of the house, or rods forming intersecting arches over the back paths, or against the back wall; for by either of these modes they exclude less light, better display their foliage and flowers, and less recal the idea of the forcing-house.

6167. *Abercrombie and Nicol* give descriptions of green-houses, such as they approve; the former is rather indefinite in his remarks; but the latter has given the best instructions that have yet appeared, as far as respects the old forms and mode of treating and ventilating.

6168. *According to Abercrombie*, "The green-house may be made a very ornamental object as a structure. The front of the building should stand directly to the south, and the ends have an open aspect to the east and west. The extent of the green-house may vary, according to the largeness of the collection to be cultivated: when most contracted it should considerably exceed the breadth and height, in order to have handsome proportions. As to the breadth, were it more than twenty feet, those plants most remote from the windows would be troublesome to manage, as they must stand on very high stages to be reached by the sun; between twelve and twenty feet will be found the most commodious latitude. The front, including a low parapet wall and a row of windows, or upright glasses, may be eight or ten feet high, measured from the interior floor. It will be proper to lay the floor at least twelve inches above the level of the ground, and in damp situations two feet. The back is the only part at which an entire wall should be carried up to the roof; the precise height of this wall depends upon that of the glass front and the breadth of the house; the proportions of these three must be so accommodated as to give the proper slope to the roof." (*Pract. Gard.*)

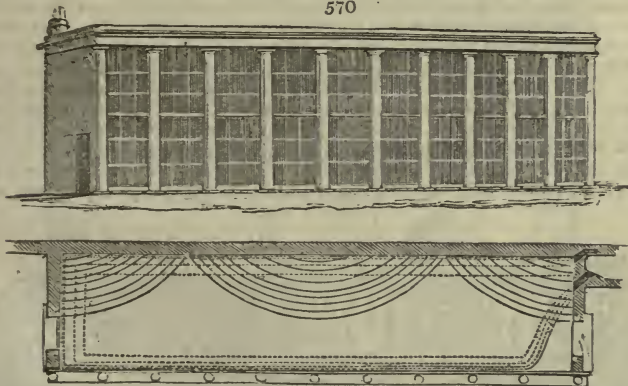

6169. *According to Nicol*, "In the construction of green-houses, fancy may be indulged, and a greater scope may be allowed to taste, than in the construction of forcing-houses. These are generally confined to one object, the production of certain fruits in perfection; which renders the observance of forms and dimensions in their construction more necessary than in that of the green-house, where a variety of plants of different habits are to be cultivated. Nevertheless, in order that these plants may generally thrive, there are certain rules to be observed, and errors to be guarded against, which I shall briefly point out. Green-houses with upright fronts, and with perpendicular lights only, whether the columns that separate them be of wood or of masonry, are the most objectionable; as the plants in such are always drawn up weak, and are distorted by continually stretching towards the light. Neither do they enjoy the genial effects of the sun, except in the winter months, when his rays, though feeble, strike horizontally on the windows, and for a few hours in the middle of the day perhaps, shine on the low plants, and those placed most forward. If such houses be very wide, they are the most objectionable on that account; as, in that case, the plants placed near to the back of the stage are never visited by the rays of the sun, and enjoy but little light to what they may require. But such green-houses may be, and indeed have been, much improved, by taking off their leaden or slated roofs, and by substituting roofs consisting of wooden framing and glass, for the admission of sunshine and perpendicular light. But still they are so far defective, as that, by their great height, the plants are much more drawn than they ought to be, or would be, in a

lower and better-constructed house. Houses that are open on the front only, although they have sloping lights on the roof, are next to be objected to; as the plants in such are necessarily more drawn and distorted than if the ends were also glazed. If such be not placed among other buildings, so as that they cannot be altered, they might be very much improved by pulling down the close ends, and by substituting glazed lights; which, if they be of a moderate height, would render them next best to such houses as are described below."

6170. *A complete green-house, being quite detached from other buildings, should be glazed on all sides.* "It may be a circular, oval, hexagonal, octagonal; or with two straight sides, and circular ends, which I think the best form of any; the next best, an octagon, whose sides are not equal, but with two opposite longer sides, and six shorter sides; three and three opposite, forming, as one might say, an angular oval; the ends being angular, instead of round. In either of these last-mentioned forms, the stages and plants may, at least in my mind, be more tastefully arranged, than in any other. Granting either of these cases, the house should be about thirty-six or forty feet long, eighteen or twenty feet wide, and ten, or at most twelve feet high, above a given level line for its floor. The parapet all round to be a foot or fifteen inches high, and the upright glasses placed on it, four, or four and a half feet at most. For it is of importance, for the sake of the finer kinds of plants, and in order to have all kinds grow bushy, and flower while young and small (in which state they are certainly most attractive and pleasing), to keep the roof-glasses as low as possible; just allowing sufficient head-room to the tallest person when walking in the alleys. The furnace and stock-hole may be placed at either end, or at either side, as may be most convenient; and they should be sunk under ground, and be concealed. The flue to be constructed, to run parallel to, and be separated from the parapet by a three-inch cavity; its surface being level with the top of the parapet, and being crib-trellised for heaths, Botany Bay, and other rare plants. A walk thirty or thirty-six inches broad, to be conducted all round next the flue; within which to be placed the stages for the more common, and the taller plants; being raised in the middle, and falling to either side and end; corresponding with the glasses, though of course not so steep. A row of columns should be placed in the centre, in order to support the ridge of the roof; to which climbing plants might be trained in various forms, and might be hung in festoons from column to column at top, or otherwise, as may be dictated by fancy. The front of the stage all round should be raised about eighteen or twenty inches above the walk, in order to raise the whole of the plants placed on it sufficiently near to the glass; thus forming the walk into a deep alley; the person walking in it having a narrow border of the finer and smaller plants on the one hand, and a bank of the more common and larger kinds on the other; than which, when the plants are healthy and thriving, few scenes can be more pleasing. The aspect of such a house should be towards the south; that is to say, it should stretch from east to west, or as nearly so as circumstances will permit. It may have an entrance on the south side, or one at either end, as shall be most convenient and suitable to its connection with the walks of the shrubbery or parterre in which it is placed. If a green-house must necessarily be attached to a wall or other building, it might be constructed very much as above; with this difference, having one of the ends, as it were, cut off; in which case, it should be placed with its circular end south, or towards that point, and the sides pointing east and west. This I should consider as the second best-constructed green-house, and in which, excepting in the above-described house, the plants would enjoy the fullest share of sun and light. In either of these houses, and in plant hot-houses of every description, a sufficient number of the upright and sloping sashes should be made moveable, for the admission and regular circulation of air in the better seasons of the year; and ventilators should be placed at regular distances all round, for the purpose of airing and ventilating them in the winter months, or at times when it may not be safe to open the lights. Such a house as either of these, would form a very complete receptacle for a handsome and pretty extensive collection." (*Kal. and Villa Gard. Direct.*)

6171. *The orangery* is the green-house of the last century, the object of which was to preserve large plants of exotic evergreens during winter, such as the orange tribe, myrtles, sweet bays, pomegranates, and a few others. Geraniums, heaths, fuchsias, and other delicate plants requiring much light, were then unknown. The orangery was generally placed near to or adjoining the house, and its elevation corresponded in architectural design with that of the mansion. From this last circumstance has arisen a prejudice highly unfavorable to the culture of ornamental exotics, namely, that every plant-habitation attached to a mansion should be an architectural object, and consist of windows between stone piers or columns, with a regular cornice and entablature. By this mode of design, these buildings are rendered so gloomy as never to present a vigorous vegetation, and vivid glowing colors within; and as they are thus unfit for the purpose for which they are intended, it does not appear to us, as we have already

570

observed at length (1590.), that they can possibly be in good taste. Perhaps the only way of reconciling the adoption of such apartments with good sense, is to consider them

as lounges or promenade scenes for recreation in unfavorable weather, or for use during fêtes, in either of which cases they may be decorated with a few scattered tubs of orange-trees, camellias, or other evergreen coriaceous-leaved plants from a proper greenhouse, and which will not be much injured by a temporary residence in such places, which, as Nicol has observed, "often look more like tombs or places of worship, than compartments for the reception of plants; and, we may add, that the more modern sort look like a combination of shop-fronts, of which that at Claremont is a notable example." Sometimes structures of this sort are erected to conceal some local deformity, of which, as an instance, we may refer to that (*fig. 570.*) erected by Todd, for J. Elliot, Esq., at Pimlico. "This building was constructed for the purpose of preventing the prospect of some offices from the dwelling-house. The architectural ornaments, and the roof, not being of glass, are points in the construction not generally to be recommended; but, as it was built for the purpose above mentioned, the objections were overruled. There are three circular stages to this house, which are made to take out at pleasure. The ceiling forms part of a circle, and the floor is paved with Yorkshire stone. It is fifty feet long, and thirteen feet six inches wide, and heated by one fire, the flue from which makes the circuit of the house under the floor." (*Plans of Green-Houses &c. p. 10.*)

6172. Of the orangery considered as a house for growing the orange tribe, as a dessert-fruit, we have already treated. (5930.)

6173. A recent and very considerable improvement in the construction of green-houses and orangeries consists in forming the shelves and stages of thin plates of stone, instead of boards; and very frequently the flag-stones are hollowed out, so as to leave a raised margin of half an inch or more, for the purpose of retaining moisture, preventing dripping, and raising, when the air of the house is warm, a general steam or dew. This may be considered, on the whole, as a real improvement, a proof of which is the readiness with which it has been adopted by nurserymen and practical gardeners. A substitute consists in raising marginal slips of boards to wooden shelves, and covering the board with a thin layer of gravel or scoria.

6174. The conservatory is a term generally applied by gardeners to plant-houses, in which the plants are grown in a bed or border without the use of pots. They are sometimes placed in the pleasure-ground along with the other hot-houses; but more frequently attached to the mansion. The principles of their construction is in all respects the same as for the green-house, with the single difference of a pit or bed of earth being substituted for the stage, and a narrow border instead of surrounding flues. The power of admitting abundance of air, both by the sides and roof, is highly requisite both for the green-house and conservatory; but for the latter, it is desirable, in almost every case, that the roof, and even the glazed sides, should be removable in summer. When the construction of the conservatory does not admit of this, the plants in a few years become etiolated, and naked below, and are no longer objects of beauty; but when the whole superstructure, excepting the north side, is removed during summer, the influence of the rains, winds, dews, and the direct rays of the sun, produce a bushiness of form, closeness of foliage, and a vividness of color, not attainable by any other means. We are decidedly of opinion, therefore, that a conservatory of any of the common forms, unless it were one devoted entirely to palms, ferns, scitamineæ, or other similarly growing plants, should always be so constructed as to admit of taking off the sashes of the roof and the front; and if it were a detached structure in the flower-garden, we should prefer a plan that would admit of the removal of every thing excepting the flues and the plants. There is an old conservatory of this sort in the flower-garden at Nuneham Courtenay, planted with orange-trees; and when the roof is removed, the flues, border, and bed are covered with turf, so that the trees appear as if planted in the open garden. The trees have stood there for upwards of half a century, are vigorous, and bear annually abundance of fruit. On the other hand, there are two conservatories at Knowle, with roofs fixed, or partially opening, which have not been erected more than four years, and in which the plants are already etiolated, and the lower branches dying off. When a conservatory is glazed on all sides, it should, if possible, be placed south and north, in order that the plants on both sides of the pit should equally benefit from the sun; when placed against a wall, the glazed side may front any quarter except the north. But as the removal and replacing of the roof of such immense conservatories as are sometimes attached to man-

sions (*fig. 571.*), is attended with considerable expense, risk of breakage, and what is of still more consequence, risk to the plants, if they happen to be uncovered too soon in spring, or left too long uncovered in autumn, we would recommend the polyprosopic roof (1610. and *fig. 261.*) as by far the most perfect description of a hot-house roof that has yet been devised. With such a roof, the plants within may, at any time, in a few minutes, be as completely exposed to air, rain, dew, and sun, if these exist without, as if the roof were removed; and again, in a few minutes, they may be completely shut up. The improver who shall erect an extensive conservatory of this kind (*fig. 571. a*), and apply to it the regulating apparatus of Kewley (*fig. 217.*), will find himself in possession of the most unique and complete plant-structure in the world.

6175. *The conservatory in comparatively humble and economical residences* (*fig. 572.*), may consist of a number of rectangular sashes, connected and supported by means of light iron rafters. In the beginning of summer, the sashes may be removed and applied

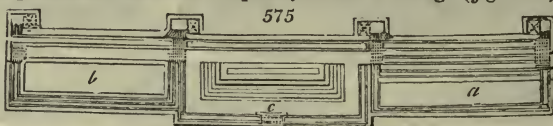

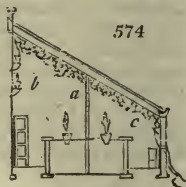

to the ripening of peaches, vines, or figs against walls, or laid over excavations in the form of pits, containing melons, cucumbers, &c. The light iron frame-work may either be removed, or remain, and be disguised by annual creepers, or by vines of the narrow-leaved sorts. Sometimes a cistern is placed in the conservatory for growing aquatics, and containing a few gold-fish; but as there are very few exotic aquatics which will thrive in the temperature of the green-house, this is seldom requisite, unless as a decoration, and for the use of the water in culture, and the appearance of the fishes. The temperature of conservatories being the same as of green-houses, the same proportion may exist between the flues and volume of air to be heated.

6176. *The dry-stove* is chiefly devoted to the culture of succulents. In design it need not differ from the green-house, unless, perhaps, in the stage (*fig. 573. a*) being

placed somewhat nearer to the roof. The name and character of this structure is derived from the higher degree of heat generally kept in it, and from the air being less moist than in the bark-stove, where more water is used, and consequently more vapor generated. The volume of air to be heated by one fire in the dry-stove, should not exceed two thirds of that to be heated in a green-house or conservatory, similarly constructed and situated.

6177. *The bark or moist stove* differs from the last only in having a pit (fig. 573. *b*) for bark or other fermenting matter instead of a stage. This pit may be from two and a half to four feet deep, according as bark or leaves are to be used, the latter material requiring the greatest depth. It is commonly surrounded by a thin brick wall, but, in elegant structures, planks of stone, or plates of slate or cast-iron, are to be preferred, as a higher finish, and occupying less space. The roof, when necessary, may be supported from the iron columns from the middle of the pit. (fig. 574. *a*) Shelves may be placed against the back wall (*b*), and occasionally a narrow-leaved creeper run up the roof (*c*). Such is the common interior arrangement of a botanic stove, as may be exemplified in that designed by Aiton, and erected by Todd, in the royal garden at Frogmore. (fig. 573.) We may add, that houses of this description are generally placed east and west against walls, on account of the shelter thereby obtained during winter, when a high degree of heat is kept up within, while the cold is excessive without. There are exceptions, however, in the plant-stoves of the more recent public botanic gardens, especially those of Dublin and Liverpool, which are placed with their ends to the south, and in the immense palm-house erected by Messrs. Loddiges, which stands east and west, and is glazed on all sides. In private flower-gardens the hot-houses frequently consist of a range (fig. 575.) containing

a green-house (*a*) at one end, a dry-stove (*b*) at the other, and a stove (*c*) in the centre. By this disposition the stove is easier kept up to the required temperature, though it loses the full influence of the light at the ends. In general, a stove requires double the number of fires required to a green-house of the same size.

6178. *There is a peculiarity in the construction of plant-stoves* which deserves particularly to be noticed; namely, that fewer openings for the admission of air are requisite than in any other hot-house, excepting the pine-stove. One reason of this is, that the degree of heat which must at all times be kept up in the enclosed atmosphere, is so much greater than that of the open air, that the difference in the specific gravity of the two fluids, when permitted to mingle by opening two or three sashes, produces a more active circulation, and sooner approaches to an equilibrium of temperature: another is, that however numerous the openings in the hot-house roof may be, they could seldom be made use of without reducing the house to too low a temperature; and a third and last is, that the plants being mostly kept in pots, and many of them, as the palms, being of slow growth, they are not so apt to etiolate as those of the green-house and conservatory. Hence it is, that the roof of a botanic stove may generally be erected at less cost than that of a green-house or conservatory; but particularly where iron is employed, and the curvilinear principle adopted.

6179. *Houses of magnificent forms, and almost as light within as in the open day*, might thus be constructed for the growth of palms, scitamineæ, bamboos, and other tropical trees to be planted in the ground, as in the conservatory. These might also be detached in the flower-garden (as figs. 10. and 20. in *Sketches for Curvilinear Hot-houses*), or they might form an appropriate appendage to a palace in the oriental style. (fig. 576.) Indeed,

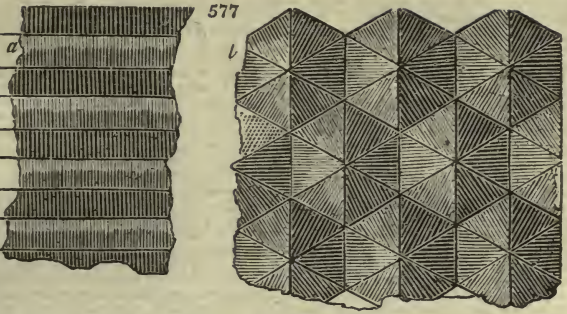

there is hardly any limit to the extent to which this sort of light roof might be carried; several acres, even a whole country residence, where the extent was moderate, might be covered in this way, by the use of hollow cast-iron columns as props, which might serve also as conduits for the water which fell on the roof. Internal showers might be produced in Loddiges' manner; or the roof might be of the polyprosopic kind, and opened at pleasure to admit the natural rain. Any required temperature might be kept up by the use of concealed tubes of steam, and regulated by the apparatus of Kewley. Ventilation also would be effected by the same machine. The plan of such a roof might either be flat ridges running north and south (fig. 577. *a*), or octagonal or hexagonal cones (*b*), with

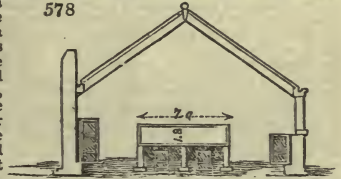

a supporting column at each angle, raised to the height of a hundred or a hundred and fifty feet from the ground, to admit of the tallest oriental trees, and the undisturbed flight of appropriate birds among their branches. A variety of oriental birds, and monkeys, and other animals, might be introduced; and in ponds, a

stream made to run by machinery, and also in salt lakes, fishes, polypi, corals, and other productions of fresh or sea water might be cultivated or kept. The great majority of readers will no doubt consider these ideas as sufficiently extravagant; but there is no limit to human improvement, and few things afford a greater proof of it than the comforts and luxuries man receives from the use of glass — a material, as Cuvier observes (*Magazin Encyclopédique*, 1816), manufactured from seemingly the most useless *débris* of our globe, and an insignificant plant (*salicornia*) found on sea-shores. In northern countries civilised man could not exist without glass: and if coal is not discovered in these countries, say in Russia, it may at some future period become a question whether, instead of separate fires and stoves, double windows, &c. the most economical mode of procuring a proper temperature will not be by at once to cover whole towns with immense teguments of glass, and heating by steam or otherwise, the enclosed air common to all the inhabitants; or where glass was considered too expensive, whole villages might be covered with a roof of boards, and lighted night and day in the winter season by gas previously obtained from the fuel used to produce the steam: or the gas might be employed for heating, either by the generation of steam, or passing the air heated by the flame through metallic tubes.

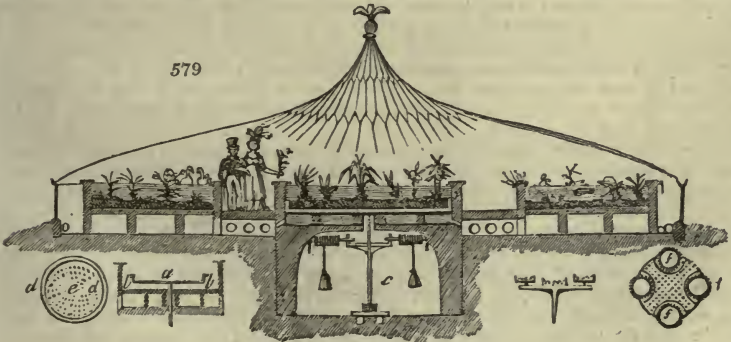

6180. *The aquarium.* The greater number of exotic aquatics being stove plants, a cistern of water for their culture is commonly placed in the bark-stove, generally at one end of the pit, and so as to be as near the light as possible. The Duke of Marlborough, however, and some others, have erected houses on purpose for this beautiful class of plants, substituting a large cistern for the bark-pit. The aquarium, at White Knights, (*fig. 578.*) built by Todd, "is constructed with a span roof of glass; the sides and ends are also of glass, as low down as the top of the flue. A cistern occupies the interior of the house, having a walk round it; it is lined with lead, and filled with a mixture of mud and water, proper for the reception and growth of such plants as require aqueous nourishment. A flue goes round, directly under the bottom of the cistern, for the purpose of keeping the water of a certain temperature. Another flue goes round the house above ground, and terminates in a chimney at the north-west corner. The bottom of the cistern, to receive the lead, is formed with slates, supported by transverse bars of cast-iron; a bottom of wood would have been more convenient for laying the lead upon, but as the flues are so near the bottom of the cistern, danger of fire was apprehended. The cistern is supplied with water by means of a pump placed at a convenient distance for that purpose." (*Plans for Green-Houses, &c.* p. 17.) This aquarium suits very well for such aquatics as grow to some height above the water; but for those whose leaves float on its surface, as is the case with the most numerous and beautiful genus of this class (*Nymphaea*), it is too far from the light. A more perfect plan would be, to have the cistern close under the front glass, and to have that glass rather flat, say at an angle of 15° ; or two cisterns might be formed, one in the back part of the

578

579

house for tall plants, and the other in front for floating foliage, with a broad path between. But the most elegant plan would be, to have a circular house, glass on all sides (*fig. 579.*), to have a cistern in the centre for river-plants, and a surrounding cistern for those which grow in stagnant water. To imitate the effect of the motion of water in the central cistern, the mould or pots in which the plants grow might be placed on a bottom (*a*), apart from that of the cistern (*b*), and this bottom being on the end of an upright shaft, might, by the aid of proper machinery in a vault below (*c*), be kept in perpetual circular motion. Those plants, which grow naturally in rapid streams, might be planted or placed on the circumference of the bottom (*d*), and those requiring less agitation towards its centre (*e*). If reversed motion was required to imitate tides (where marine aquatics were cultivated), nothing could be easier than by the sort of wheel used in the patent mangle to produce it to any extent; or by another still more simple plan known to every engineer, it might be changed seldom, say only once or twice in twenty-four hours. If a rapid and tortuous motion was required, then let the bottom on which the plants are placed, be furnished with small circular wheels (*f*) placed on its margin, working on pivots, and furnished on their edges with teeth like a spur wheel. Then let there be a corresponding row of teeth fixed to the inside of the wall or side of the cistern, into which they are to work like a wheel and pinion. By this means, pots of plants set on the small wheels, will have a compound motion, one round the centre of the small wheels, and another round that of the large bottom, something of the nature of planetary motion, but more like that of the waltz dance. It is almost needless to add, that exotic aquatic fowls and fishes might be kept in such an aquarium, and either of the sea or fresh-water rivers, according as salt water or fresh was used. It may be thought by some that the machinery would be intricate and troublesome; but the power requisite is so very small, that it might easily be obtained by machinery on the principle of the wind-up jack, such as was used by Deacon in his ventilating Eolians. (*Rem. on Hot-h.* 68.) This kind of mechanism very seldom goes out of order, or requires repairs, and would require no other attention than being wound up twice in twenty-four hours, and oiled occasionally. The same vault that contained it might serve for the furnace or boiler for heating the house.

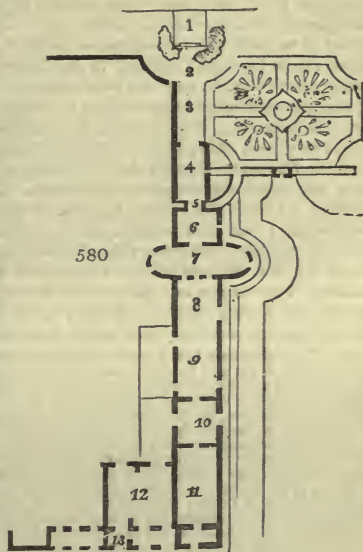

6181. *Wind.* If instead of water in a circular cistern with its bottom so constructed, we suppose air, then the same arrangement would serve for producing artificial wind to plants, the beneficial effects of which in producing bushiness and strength of stem are well known. The motion thus given would probably be extremely useful for young plants in close damp weather in winter, by preventing some sorts from getting mouldy and damping off, and by moderating the growth, and preventing the etiolation of others. For this purpose the machine might be considered as a kind of hospital, and the plants being in pots, might be set on either the large or small wheels, and kept there in motion for a longer or shorter period, according to circumstances.

6182. *The substitution of fire-heat for that produced by the fermentation of vegetable substances*, is a recent innovation in the construction of plant-stoves. This has been done by heating the air of a vault or chamber below the pit, with smoke or steam, either by circulating these fluids in flues or tubes in the chamber, or by simply filling the vault with them. In some cases, also, flues or steam-pipes have been conducted through the tan with a view to prolong its heat. The mode by heating an air-chamber below the pit was carried into execution by us so long ago as 1804, at Glenfuir (*Tr. on Hot-h.* p. 249.); and more recently upon a larger scale, for the purpose of growing pines, at Underley Park. (*Tr. on Coun. Res.* p. 295. pl. 11. fig. 3.) A plan very similar to the last has been adopted by Kent (*Hort. Trans.* ii. 389. and iii. 287.), who at first plunged the pots in a bed of sawdust over the vault, thinking thereby to avoid the worms and insects that generate in decaying tan. He found, however, that when the sawdust became rotten, worms generated in it as freely as in any thing else, and has therefore given up the practice of plunging altogether, setting the pots on a thin layer of coarse sand placed over the pavement, which forms the roof of the hot air chamber. Thus situated, the plants are not apt to run through the bottoms, and over the tops of the pots, as is the case when they are plunged, which always occasions a serious check to the plants, whenever they are removed or required to be shifted. After above a year's trial, he says, "I think I can with certainty pronounce that plunging is not only unnecessary, but really worse than useless to plants, except where they have been injured and require to be drawn." A very obvious extension of this principle was the disuse of bottom heat altogether, and the substitution of a platform of brick or pavement, or merely a bed of scoria or gravel for the bark-pit. This has been done extensively by Messrs. Loddiges, Kent, the Comte de Vande, and various others, with perfect success as far as respects large plants; but most stove-plants require to be originated and brought forward till they are one or two feet high in bottom heat. By keeping up a considerable atmospheric temperature, and by frequent waterings over the leaves, that sort of moist heat is produced which seems most congenial to vegetation, and it may, we think, be assumed as experimentally proved, that where such heat is produced in plant-stoves the bark-pit is unnecessary for all general purposes. "If we reflect for a moment," says Kent, "that in tropical countries, the stem, branches, and leaves receive a greater degree of heat from the atmosphere than the roots can possibly do; it appears extraordinary that a system of management so directly opposite to nature should have ever been adopted, or that it should have been so long practised. If a quantity of earth was to be raised from the root of any tropical shrub, growing in its native situation, there is no doubt its heat would be below the temperature of the air, therefore the roots of the plants in a stove ought not at any rate, to receive more warmth than their other parts." (*Hort. Trans.* iii. 288.)

6183. *A propagation-house* is a requisite appendage wherever a general collection of exotic plants is maintained; and the proper situation for it is in the reserve-garden. Such a house, like the houses used by nurserymen, does not require to be so light as fruiting or flowering houses; it may be little more than a large pit with the roof very flat (say from 12° to 15°), in order that all the plants may be near the glass; it should contain a bark-pit, raised to within eighteen inches of the glass in front, and $2\frac{1}{2}$ feet behind, a broad stone shelf in front, and two or more shelves in the back of the house, close under the roof, that is, over the path and flue. All shelves in hot-houses, it may be observed, whether of stone or timber, ought to have narrow ledgments along their edges, not less than an inch deep, by which the water which escapes through the bottoms of the pots is not only prevented from dropping, but retained to generate a salutary coolness and moisture. The fire-place should be formed at one end of the front (say the south-east corner), and the flue conducted along the front from about nine inches or a foot from the parapet, and so along the opposite end and back wall, till it terminates at the extremity of the latter, or the north-east corner. The door may be formed in the back part of the end in which the furnace is placed, and the path which surrounds the pit, should be made sufficiently low to admit of head-room. This plan may in some cases be doubled; that is, a similar arrangement of flues, &c. may be erected alongside the other, that is, the north side, with a moveable boarded partition between them. The house fronting the north may be used for striking cuttings, or raising seedlings, and that fronting the south, for

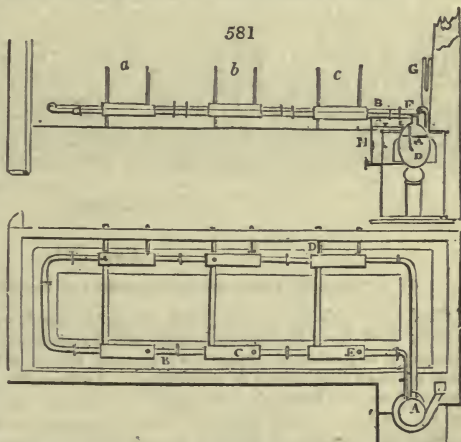

nursing the plants so raised, till they are fit for removal to the principal green-houses and stoves. The partition is made to remove, in order to admit or exclude the sun's rays to the back-house in spring or autumn at pleasure.

6184. We have already stated that we consider *steam the best vehicle for heating hot-houses* of every kind, especially where there are several connected together. Thus where all the hot-houses of a residence are connected with the mansion, both the latter and the former, with drying rooms, hot water or vapor-baths, steaming apparatus for horse-food, poultry-houses (under particular circumstances), and various other appendages might be heated as well as the hot-houses. The spare steam might be employed as the first power to machinery, to raise water, to drive a mangle, &c. and a gas apparatus might be added, to admit of lighting up the whole. Repton has given a plan well adapted for this purpose. (*fig. 580.*) At one end of this design an aviary (1) is surrounded by a conservatory (2), and joined to a glass passage for flowers (3), which leads successively through an orangery (4), lobby (5), music-room (6), library (7), print and picture-room (8), breakfast-room (9), anti-room (10), dining-room (11), hall (12), and peach and green-house (13). The whole length of this range is three hundred feet. Even single stoves or green-houses may be

more agreeably heated in this way than by smoke-flues, which are very generally attended by a bad smell, and vapors of carbonic acid and hydrogen. A very neat example of this kind (*fig. 581.*) is given by Hayward. (*Hort. Trans. iv. 434.*) "It is

erected in a small conservatory, the boiler (A) contains about thirty gallons, and the pipes (B, B) are three inches in diameter, and so laid as to have thick planks resting on props (a, b, c) placed over them, to form the pathway round the house. Chambers are formed round the pipes, communicating with the external air, by surrounding them with larger pipes (c, c); and by means of small pipes (D, D) as much heated fresh air can be admitted into the house through different apertures (E, E) as can be wished." By laying the pipes with a declination of a few inches from their departure from the boiler till their return to it, the water of condensation is returned through a valve (A D), which is a

very considerable advantage; but this valve is much better placed in a close box outside the boiler, (an improvement made by Messrs. Bailey,) as admitting thereby of examining it with ease when out of repair. The air-cock (F), safety-valve (a), steam-gauge (H), and water-gage in Hayward's boiler, do not differ from the usual construction. The mode here described of admitting heated air, we would observe, must be used with very great caution, for we know experimentally, that no mode is more liable to overheat the atmosphere of the house when the fire or steam is brisk in the beginning of the night, and overcool it when the fire declines towards the morning. We have the same objection to *Walker's Improved Construction of Hot-house Flues*, as described (*Hort. Trans. iv. 237.*), by A. Seton, Esq. Here a cast-iron flue is enclosed in one of masonry, and the vacuity between them communicates with the open air at the stock-hole, and with the air of

the house at certain distances, by means of apertures in the top of the flue. The argument in favor of this arrangement, is that usually given for vacuities around furnaces connected with flues, as adopted by Stewart, Gould, and various others (*Tr. on Hot-houses*, p. 132.), viz. that "the current of external air, by commencing, when cold, at that part of the flue which is hottest, takes up the heat there where it is least wanted, and carries it to those parts at a distance from the furnace where it is most needed; and as the valves are to be chiefly opened in the latter situations, to permit its escape, it diffuses a nearly equal warmth over the whole house." Every thing in this plan evidently depends on the management of these valves; if they are left open during the night, the risk above stated is incurred; if during day, less heat being wanted, little advantage is obtained. In stoves, however, this plan, under judicious management, might be useful; but it must never be forgotten, that air can be rendered much hotter by a fire-flue than by a steam-pipe, and hence the danger to the plants. No one was ever more sanguine as to the advantages to be derived from furnace vacuities and air-flues than ourselves (see *Tr. on Hot-houses*); but after twenty years' experience, we must acknowledge that they are so liable to produce accidents, either by admitting smoke or burning up the plants (as the phrase is), that we now seldom recommend their adoption.

6185. *Various pits and hot-beds* will be required in the reserve-department of the flower-garden, for forcing shrubs and flowers, raising annuals, &c.; the construction of which having nothing peculiar, need not be here detailed. (See 1591. et seq.)

6186. *The idea of cold-houses* seems to have been first suggested by Sir W. Chambers (*Dissert. on Orn. Gard.* p. 90.), and it may be worth while to submit some hints on their construction for such amateurs in this country as may be curious in the cultivation of *musci*, *jungermanniæ*, and other cryptogamous vegetables which grow in the lowest temperatures; and for botanists in warm climates, who may wish to cultivate not only mosses, but the more perfect plants of elevated regions or northern climates; as for example, of the British or Swedish alps in Spain, or in the south of Italy. The simplest form of a *cold-house* may be a vault of rustic masonry open at one end, along the floor of which a rill of water may pass, and from every part of the ceiling water may drop on the floor or bed, and descend to the rill in the centre. This is an obvious imitation of the dripping caves sometimes found in tracts of country abounding with calcareous rocks, of which, as an example, we may cite the dripping rock at Knaresborough, and the dripping cave near Rousseau's walk at Lyons; in which last, on the 19th day of June 1819, we found the thermometer at 48°, whilst in the open air, under the shade of an adjoining mulberry-tree, it stood at 72°. Various mosses and *jungermanniæ* were in luxuriant vegetation in the interior of the cave; and some sorts of ferns near its mouth. Another imitation of such caves might consist of an open grove of elms or oaks, among the lower branches of which lead pipes pierced with small holes, in Loddige's manner (1689), might be fixed horizontally at regular distances, and these being supplied, during the warmer months, with water from a proper reservoir, would furnish a continual shower, which, with the assistance of the small rills furnished by the collected rain thus produced, would lower the temperature of the atmosphere sufficiently for the growth of such mosses and ferns as do not require much light; and the margin of the grove might be devoted to plants of a more perfect kind, requiring a low temperature and moist atmosphere. But a more perfect plan would be to form a house like a large pit, with a double glass roof, fronting the north. Over the outer roof should be a system of pierced pipes to keep it cool by a continual shower during sunset, and at the top of the back wall an arrangement whereby two or more separate and concentric coverings of canvass could be let down to exclude the sun during the day. Instead of flues of masonry, large tubes of lead or cast-iron should surround the house, to be kept cool by a continual stream of water passing through them. The pit might contain a large metallic cistern, filled with ice, to be renewed when thawed, &c. It would be advancing too far into the regions of speculation to particularise other minor details that would be requisite to render such a house complete; let it suffice to say, that such houses might be erected either in Britain or the south of Europe, so as to produce a temperature of 32 degrees throughout the year. This would admit the cultivation, in pots and on pieces of rock, of lichens, mosses, and of all the more perfect plants which grow in the regions of perpetual snow. (See 1696.)

CHAP. VI.

Of the General Culture and Management of the Flower-garden and Shrubbery.

6187. *The cultivation of the flower-garden* is simple compared with that of the kitchen-garden, both from its limited extent and the general sameness of its products; but to manage it to perfection requires a degree of nicety and constant attention beyond any other open-air department of gardening. As the stalks of flowering plants shoot up, they generally require thinning, and props for support; and the blossom, both of plants and shrubs, no sooner expands than it begins to wither, and must be cut off, unless, as in some of the ornamental shrubs, they are left for the sake of the beauty of their fruit. Weeding, watering, stirring the soil, cutting off stems which have done flowering, attending to grass and gravel, must go hand in hand with these operations.

6188. With respect to *the general culture and manuring of the soil*, it should be subjected, as far as practicable, to the same process of trenching to different depths as that of the kitchen-garden. In the shrubbery this cannot be done, but it, and also the earth compartments of the flower-garden, should be turned over a spit in depth, and some vegetable mould, or very rotten cow-dung, added occasionally. Every two or three years the plants in the flower-garden should be taken up and reduced in size, and the beds or borders trenched, say one time at two spits deep, another at three, and so on (see 2549.), adding enriching compost or manure completely rotted, according to circumstances. If, instead of trenching, the old earth were entirely removed, and replaced by good loam from a dry upland parterre, the improvement would be still greater. Most herbaceous plants flower well in such loam, and for the more cultivated sorts, as border pinks, auriculas, &c. that require a rich soil, a portion of enriching matter could be added to each plant as planted, and a corresponding attention paid to such as required peat-earth, sand,

clay, or lime. In the shrubbery, a similar renewal of soil, and attention to the soils required by particular shrub-plants, is also required, at least in front, where the more delicate shrubs naturally rank, and where the herbaceous plants are chiefly arranged.

6189. With respect to the *times of planting, or sowing, and manner of cropping* the flower-garden and shrubbery, the greater part of the surface being covered with shrubs or plants of perennial duration, very little cropping is required, and as a substitute for a rotation, recourse must be had to the renewal of the soil as recommended above. Annuals are sown at various periods from February to June; but for the principal show, generally in March; the half-hardy sorts are raised in hot-beds in the reserve-department, and transplanted when they are to flower in April and May, and later sowings and transplantings are made to procure a protracted display. Biennials and perennials of the fibrous or ramose rooted kinds are transplanted from the reserve-department in September or in March; and such bulbous roots as are annually taken up, are generally replanted in November or February. When bulbs and other florists' flowers are cultivated in beds, a rotation may be adopted as far as respects them: thus the hyacinth, tulip, &c., may be succeeded by annuals, and those by the dianthus tribe, or dahlias, &c.; but in borders and compartments planted in the mingled manner, as well as in shrubberies, a rotation is out of the question. Particular care is requisite to remove weak, ill-conditioned, or ill-flowering plants, and to replace them by others of the same height and color. This may be done at all seasons of the year by the use of the planter; but the better mode is to have always an ample stock in the reserve-garden, of all the colors and heights, both of herbaceous plants and low shrubs, (of all the sorts is unnecessary,) in pots, and whenever, when any plant is in flower, a defect appears, it can be remedied at once by turning the plant out of the pot into its situation in the border. Independently of disease or accident, fine showy species, answering in general color and height, may thus at pleasure be substituted for such as are less showy, or less to the taste of the master.

6190. Ornamental plants, whether shrubby or herbaceous, require to be *pruned, trained, thinned, and dressed*, according to the sort of beauty or effect expected from them. If they are grown chiefly on account of their blossoms, then they must be pruned on the same general principles as fruit-trees; but little more than thinning out weak and crowded shoots will be required where they are grown chiefly on account of the beauty of their foliage; and still less where the tree or bush is planted for the sake of its natural shape. It is customary in some places to apply the hedge-shears to shrubs; but this is a barbarous practice, destructive of all these beauties, which ought to be exploded, unless in cases where, in imitation of the ancient style, trees are to be trained in artificial shapes. Herbaceous plants require little pruning, but nevertheless something in this way may be occasionally required on the same general principles applied to trees. Where very large flowers are wanted, it is obviously advantageous to prevent the plant from expending its vigor in too great a number of them, or in mere shoots and leaves. Top-heavy plants, as some thistles, solidagos, &c. may require to be lightened, and almost all are benefited by thinning out a part of their shoots. In some annuals, thinning is effected both by eradication and pruning, and in the more delicate sorts by pinching off the young shoot, when an inch or two high. Creepers, climbers, and shrubs planted against walls or trellises, either on account of their rarity, delicacy, or to conceal the object against which they are placed, require different degrees of training; those which attach themselves naturally, as the ivy, merely require to be occasionally guided so as to induce a regular distribution of their shoots; the others must be treated like fruit-trees, training thinly, if blossoms are the object; and rather thicker, if a mass of foliage be what is chiefly wanting. Hedges and edgings require to be cut and otherwise kept in order by the obvious means. "Edgings of all sorts," Marshall observes, "should be kept in good order, as having a singularly neat effect in the appearance of a garden. The dead edgings will sometimes, and the live edgings often, want putting to rights; either cutting, clipping, or making up complete. Where there are no edgings, or but weak ones, let the earth bordering on the walks be kept firm, and now and then worked up by line in moist weather, beating it smooth with a spade." (Intro. 57.)

6191. *Grass-plots require to be regularly mown* at least once a-fortnight, and where extraneous plants, of broad-leaved kinds, make their appearance, as plantagos, crowfoots, &c. they must be carefully removed. Worms should be gathered by hand before sunrise, or their casts swept off with the wire besom (1321.), and then the ground watered with lime-water. Rolling and watering must be applied according to circumstances, and nothing neglected to ensure that deep-green color and velvet texture which is, or ought to be, the characteristic of the British lawn, and which is indeed the pride of our island.

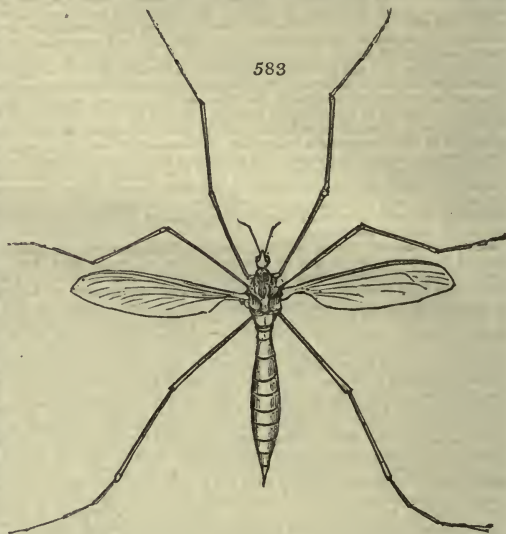

6192. *Various tender sorts of plants and shrubs require protection* by one or other of the different utensils, structures, or contrivances (2206. to 2218.) destined for that purpose. Alpine plants require protection from cold, by covering with snow, or by hand-glasses, or frames during winter; and from heat, by screens to produce shade during summer. The roots of many sorts require to be protected by ashes, rotten tan, or litter, from frost, and the tops of others both shrubs and plants, to be guarded by fronds of fern, fir-branches, mats, or portable glass cases, from rain, hail, and cutting winds. Great care must be taken to protect pots of plants from frost; by always keeping them plunged in earth or some non-conductor; for no state in which a plant can be placed is so obnoxious to the baneful influence of congelation as that of being grown in a pot. Climbing plants require to be supported by poles or rods, as some sorts of honeysuckle, bignonia, aristolochia, &c.; by props, as pyramidal bell-flower, lobelia fulgens, &c. or by branches or spray, as the nasturtium and pea tribe. Much of the beauty of the flower-garden depends on the manner in which these operations are performed. The prevalent error consists in overdoing the thing, in employing too stout and too long rods or props, and too many thick tufty branches, instead of such as are free-grown and open. Watering must be liberally applied to almost every part of the flower-garden during summer, and in the evening; it increases the progress, and enlarges the parts of all vegetables; gives a fresh appearance to the soil as well as the plants, disperses their odors in the surrounding atmosphere, and tends to subdue various kinds of insects.

6193. *Water*, whether as an ornamental feature, or as an aquarium, should be kept clear both of weeds and insects. Of aquatic weeds the most troublesome in small aquariums are the confervæ and byssi, which can only be removed by hand, or by entangling them with a rake or broom. The larvæ of numerous land-insects are deposited in water or in the muddy sides of ponds and ditches, as the elephant-hawk-moth (*Sphinx Elpenor*, L.) (fig. 582.), the dragonfly (*Libellula*, L.), and many others. Of the aquatic kinds are the well known tipulæ, of which some species (*T. oleracea*) (fig. 583.) glide over the water, and are by many considered rather ornamental than otherwise, and others live entirely under it, and feed on the roots of plants. To de-

stroy, or at least greatly to keep under all aquatic insects, an effectual mode is to dry the pond for a day or two; but in the case of an aquarium it cannot be done; fish and frogs, their natural enemies, must therefore be encouraged, in order that they may attack them.

6194. *Insects and vermin.* These must be kept under in every part of the flower-garden and shrubbery, and we perfectly agree with the author of the *Florist's Manual*, that "the simple and laborious mode of picking away the animal, is the only one to which recourse can be had with permanent advantage. To give full efficacy to this method of rescuing plants from caterpillars, snails, &c. our attacks must be made upon them at particular seasons, which can only be done from such a knowledge of their history, as shall enable us to have swarms of them destroyed in the destruction of an individual of the species. Without, however, much research into their natural history we may, from common observation, understand that in the winged insect we may free our plants from an innumerable tribe of those which crawl, and which, in that reptile state, have the capacity of devouring the whole product of a garden. The two periods of change of form in the caterpillar species, seem to afford the most advantageous times to put an end to their existence. Thus, the ephemeral butterfly; if timely attended to, we may destroy the animal before it has acquired the power of disseminating its young progeny; and, in the intermediate and voracious state of caterpillar, every single one which is prevented attaining the winged form, preserves our flowers from a host of enemies. The green caterpillar is the most common foe to our flower-borders and in autumn attacks the branches of mignonette in such numbers as to afford an easy opportunity of their destruction. A more persevering enemy, and more difficult to exterminate from gardens, is the snail (*Helix*) and slug (*Limax*); which, forming their habitations under the soil, attack the roots of the flowers, and frequently destroy them before the gardener can be aware of the mischief, that too often becomes visible only when past reparation. Under a vigilant eye, however, plants will not twice suffer from the enemy not being ostensible; as the symptoms of his vicinity may be marked by flowers perishing as they first emerge from their buds or bulbs, by leaves or petals being pierced in small holes, or having the appearance of being gnawed in growth, or from almost any failure in vigor which cannot be accounted for by external causes. In cold and dry weather the snail rarely appears, but after warm showers it may generally be found; early in the morning, and about the close of evening, are the usual times of their coming abroad, when they may be picked up in large quantities. They will, however, frequently molest a plant for a length of time without being visible, in which case, when there is reason to suspect their hidden attacks, the only method to entrap them is to place a common garden-pot over the infested root, and it will rarely occur that the enemy is not discovered, as snails fasten themselves to the sides or tops of boards, or mats, or cabbage-leaves, so placed, and thence are easily taken. In droughty seasons it will be of use to water the plant before it is covered, as the moisture of the earth will be an additional motive of attraction to draw the animal from his hiding-place. The smaller insects which infest rose-trees, and some herbaceous plants, can only be kept within moderate bounds by sweeping them from the branches, or by cutting off those whereon they are found in most profusion. In carrying off these diminutive enemies, birds are peculiarly serviceable. Insects generally attack those plants which are least vigorous; and the reason of the selection of such leaves as are beginning to decay may be, that in their declining

state they have usually a peculiar sweetness, probably perhaps owing to some saccharine juices which are preparing for the nutriment of the bulb or bud which is forming in their bosoms, for the nascent vegetable derives its sustenance from the recrements of the one from which it takes its birth." (*Flor. Man.* 25. et seq.) The cultivated bee is an insect which the gardener will of course take care not to destroy on account of its use; and it may be a question whether some species of the butterfly, moth, dragon-fly, &c. should be destroyed on account of their beauty. Some species of these genera are highly beautiful, as the four-blotched dragon-fly (*Libellula quadrimaculata*, L.), and the swallow-tailed butterfly (*Papilio Machaon*, L.) (*fig.* 584.), which is reckoned the most superb of the British species. It is very local, but occurs near Bristol, Beverly, and in the New Forest. The larva feed on umbelliferous plants; the caterpillar is green, banded with black, marked by a row of red spots. It changes into the chrysalis state in July; and the perfect insect is found in August. There are two broods, the first appears in May, having been in the pupa state all the winter, and the other in August from the pupa of July. (*Samouelle.*)

6195. *The cutting off flower-stalks, decaying flowers, leaves, &c.* is to be done in most cases immediately after the flowers are faded; but there are exceptions where the leaves on the lower part of flower-stems may be requisite to strengthen the root, and where, as in the case of stipa, some convallarias, eringoes, &c. the parts of the flower are persisting, or the fruit or seed-pods are objects of beauty. The leaves of bulbous-rooted plants, and such others as are not prolific in foliage, should be carefully preserved till they have begun to decay; and, indeed, the base or root-leaves of no plant whatever should be cut off till this is the case, unless for some particular object. Every single flower, as soon as the petals begin to droop, should be pinched off, and especially every flower of the double kind. Every rose, when it begins to droop, should be clipped off near to the foot-stalk of the one which is about to succeed it; and when the last of the corymb has done flowering, then the common foot-stalk should be cut off back to the first strong leaf-bud: nothing is more unsightly in a flower-garden than rose-bushes where this has not been attended to. By employing women or apprentices to go over the whole pleasure-ground every morning during the four summer-months, to attend to this business, it may be completely accomplished at very little expense. These and other points of management, we know, are considered needless niceties by many gardeners: but what is a flower-garden unless it is kept with the utmost nicety? Others will tell you, they have not time for such things; but where there is a real taste for neatness, time will be found. "No gentleman," Sir G. Mackenzie observes (*Caled. Hort. Mem.* iv. 194.), "ought to keep a gardener who does not understand that there is time enough for every thing, provided that time is not wasted, but properly regulated, and nothing too long delayed."

6196. *Gathering flowers.* Gather, if possible, only from the reserve-garden; for if the main borders and compartments are managed as they ought to be, much gathering will disfigure the plants. Always use the knife, and prefer such as are coming into flower, rather than such as are fully expanded. If possible, gather from crowded plants, or parts of plants, so that every gathering may operate at the same time, as a judicious pruning and thinning.

6197. *The French rose-gatherer* presents a refinement in floricultural instruments highly characteristic of its origin. The general form of this little engine is that of a pistol: it has a handle and trigger like it, and a cutter in the manner of the wire pliers, or flower-gatherer (*fig.* 152.), disguised as a barrel. A rod, answering to the ramrod, connects the pincers with the trigger, which last, being pressed, opens the pincers, that is, charges the pistol; the operator then presents the pistol to the rose to be gathered, and so that when the cutter operates, it may separate it at the precise point of the stalk deemed proper: things being thus adjusted, the trigger is drawn, and the deed is done. — Of course this instrument, like a number of other horticultural toys manufactured by the Parisians, is chiefly *pour les dames*.

6198. *Flowers may be preserved, when gathered,* by inserting their ends in water, moist earth, or moss; and may be freshened, when withered, by sprinkling with water, and putting them in a close vessel, as under a bell-glass, hand-glass, flower-pot, or in a botanic box; if this will not do, sprinkle them with warm water, or with spirits of wine, or ether, and if this fails, insert their ends in water heated to 80° or 90°, and cover them with a glass.

6199. *Grafting, budding, laying, &c.* Operations of this sort require to be performed in the flower-garden and shrubbery, for enlarging, renovating, and otherwise improving shrubs and plants, or introducing new sorts; they are also required for the common purposes of propagation.

6200. *Ordering seeds, bulbs, and plants.* This business is much simpler in the flower than in the kitchen garden. For flower-seeds of most sorts, an order is simply given for a *paper* of a sort; mignonette, lupins, sweet peas, and a few others, may be ordered by the ounce; bulbous roots are generally ordered by number, either of mixtures or single sorts; and herbaceous plants, shrubs, &c. by name and number, or by the hundred or dozen in mixture. See the priced catalogue of any nurseryman.

6201. *Neatness* has been already a good deal insisted on in different parts of this work. We repeat, it is the dress and visage of gardening, and if necessary any-where, is more especially so in the flower-garden. A gardener who pretends to manage a flower-garden without the most vigilant attention to this point, at all times, is unworthy the charge. The first thing is to have a quick intelligent eye, so as instantly to perceive what is wanting, and the second is to be possessed of that principle of activity which immediately sets about supplying the want. Many gardeners have certain times for *cleaning up*, &c. and will go fifty times past a weed, stone, dead leaf, or some such article, which disfigures or injures a scene, without removing it, merely because the time for cleaning, &c. has not come. This is most abominably formal conduct, deserving the severest reprobation. A gardener ought to have his eye, his head, his heart, his hand, his knife, and apron, ready for action at all times, places, and seasons, when within the precincts of his charge. Let him drown this incessant care in his own way when he is without his scene of business, or in the hours of rest and refreshment; and let him not undertake it without adequate terms of remuneration. (See 2355. 2373.)

CHAP. VII.

General Culture and Management of the Ornamental or Botanic Hot-houses.

6202. *The general culture of floricultural hot-houses* respects soil, choice of plants, planting in pots or beds, and arranging: after offering some remarks on these heads, we shall submit a few as to what is general in the management of the principal floricultural habitations, as the frame, green-house, and stove.

6203. *Soil for beds or borders.* The first operation of the gardener, after a conservatory or stove is finished, is to fill up the beds and borders with prepared earth. These being narrow, should seldom be less than three feet in depth, the bottom should generally be paved, and sloping to a drain or drains; and in cases of very dry soils, provision may be made for the roots extending themselves beyond the area of the house. In general, however, this is not desirable in stoves, as the roots might be chilled during severe frosts; but provision may be made for their extension under the paths, and every other part of the area of the house. When a variety of plants and trees are to be grown in such pits, no soil can be fixed on that will suit them all; but if the main body be a sandy loam, then, as each particular tree is planted, a few cubic feet of this loam may be removed, and replaced by the soil best suited to the plant. The plant once established, be it what species it may, will not languish in a sandy loam, other circumstances being favorable.

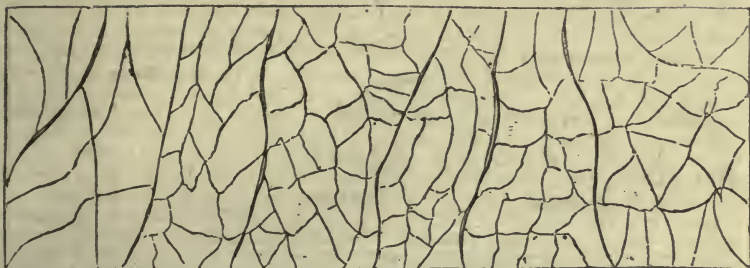

6204. *Choice of species and planting.* The species of stove or green-house plants must depend on the sort of house, and a variety of circumstances which need not be entered into. For common purposes choose the showy-flowering, easily cultivated, and vigorous-growing genera, as geranium, camellia, fuchsia, jasminum, &c.; or evergreens, as the myrti, proteaceæ, &c. choosing (from the tables in Chap. X.) some plants of the principal colors to flower in every month. In planting broad central beds in a house, glass on all sides, the highest-growing kinds will be placed along the middle of the bed; but where there is a wall to the north, the highest kinds will be placed next it. With respect to arrangement, the limited space admits of very little; in general, it will produce the most showy and immediate effect to adopt the common mingled and shrubbery arrangement, which we have recommended (6139.); but as the spectator lingers longer on the pavement of the conservatory or stove, than in the walk of the shrubbery, more prolonged interest will be produced by assembling such plants as belong to one genus, or natural order, by themselves; because this will be to unite what used to be considered the desideratum of taste—*unity and variety*; that is, a general harmony of character in the genus, tribe, or family, and yet, when examined in detail, a distinctive character belonging to each of the individual species which compose it. It is a very common practice to plant climbers in such beds and along narrow borders, close to the upright or front glass, to be trained under the roof. We most decidedly disapprove of this plan, in almost every case, as tending to defeat the whole object in erecting such houses. Very luxuriant climbers are thus produced, but it is at the expense of light, not one ray of which, if possible, should be prevented from falling on the plants in the body of the house. Climbers or creepers are highly ornamental, and may be planted in a variety of situations without injuring the other plants: for example, in the bed, and trained on rods, or up such props as may be necessary to support the roof; or, along the sides of a central walk in a house standing north and south, and trained over the walk on an arcade of rods; or, on a similar arcade over the back path of a single-roofed house, or on the back wall. It is a very common thing to see the cobæa in green-houses, and the fruit-bearing passion-flowers in stoves, darkening the greater part of the roof, and the plants beneath growing or elongating fast enough, but weak and of an unhealthy languid green. It is only under the broad wooden rafters of old-fashioned hot-houses that any sort of creepers may be trained up the roof without materially injuring the plants below; and even in these cases the injury is considerable, unless they are kept within very narrow bounds. But if creepers are injurious in plant hot-houses, the introduction of vines under the rafters is still worse; for, besides darkening the plants below more than the others with their broader leaves, the incongruity of effect produced by the attempt to unite two opposite characters, is exceedingly disagreeable, and only to be tolerated in humble economical residences, where a green-house, perhaps, is the only glass structure.

6205. *Arrangement of plants in pots.* Where the house and the collection are small, or the plants few and large, the same observations will apply which we have advanced on the subject of planting the beds of conservatories or stoves; but when the houses and collections are extensive, then some plan of arrangement ought to be adopted. Here, as in shrubberies and flower-gardens, there are three modes, by *mingling*, by *grouping*, and by *method*. For general effect the first is the best, but for prolonged enjoyment and examination in detail, the two others are greatly preferable. An abstract view of the modes by mingling and grouping might be represented by lines (figs. 585, 586.), in

585

which, by the mingled mode, the colors are as regularly arranged as chequer-work, while, by the grouping mode (fig. 586.), they succeed each other in large irregular masses. By the first mode, there is only one plant of a color by itself; by the second, from half a dozen to three or four dozen, according to the size of the group and the plants.

Thalamiflo. sect. 1. | Thalam. sect. 2. | Thalamiflo. sect. 3. | Calycifloræ. | Corollifloræ. | Monochl. & Phanerog.

6206. By either mode regard must be had to *place the plants in gradation* according to their size, from the front to the back, or from the lowest to the highest part of the stage, as well to give them every possible advantage as to light, as to present the greatest surface to the eye of the spectator. It is not desirable, however, to dress them so regularly, as that the general slope of verdure shall appear as if shorn or mown, for that both deprives the sides of the plants of a considerable portion of light and air, and the eye of variety of form, and light and shade; it will have a much better effect if somewhat irregular, and if here and there a distinguished individual appear above the rest as a standard.

6207. *In arranging by method or botanically*, either the Linnæan or Jussieuan classification may be adopted; the latter is unquestionably preferable, as exhibiting a more perfect relationship; and it may be considered as represented by the same lines as those delineating the mode of grouping by colors. (*fig. 586.*) Where the Linnæan method is adopted, the classes may either be grouped in irregular roundish masses; or, as the tallest trees and lowest herbs are often placed in the same class, it will answer better to dispose each class and its orders in irregular strips (*fig. 587. m. d. t. tet. pentandria, &c.*), from the lowest to the highest part of the stage, by which the dwarf plants of each class may be placed in front, and the taller farthest back.

m. d. t. tet. pentan. hex. h. o. en. d. dod. icos. poly. did. tet. mon. dia. polyad. syn. gr. mo. di. po. crypt.

6208. *The botanic arrangements*, it has been already observed, are only adapted for extensive collections and capacious hot-houses; on a smaller scale the mingled method, or that by grouping, will be most advantageously adopted. In the case of green-houses attached to living-rooms, and where there are reserve-houses to keep up a supply, only such plants as are in bloom should be introduced, and there the method by grouping the colors may be adopted with great effect. But whatever be the size of the house, or even the extent of a bed, or shelf, or any part of them, never let the plants be placed there in the present indiscriminate mode. In this, no regard is paid to any thing but height; or if any farther object is taken into consideration, it is to mix the kinds as much as possible, with a view, as is alleged, to produce variety. But the effect of this mixture, whether on a large or small scale, instead of variety, is sameness or monotony, which lessens interest, and finally produces indifference in the spectator. It is true, there is as great a degree of sameness in the mingled mode; but then it is the sameness of a formal and avowed regularity; whereas, the sameness resulting from the common mode of mixture, is the sameness of affectation,—a sameness resulting from an abortive attempt at something not attained. The one mode may be compared to the geometrical manner of laying out grounds, and the other to the mode by clumps and belts; both are alike artificial, but the former is avowedly so, and therefore has attained its end, while the latter affects to be an imitation of nature, and therefore disappoints. A safe rule for every gardener to adopt, whether in setting pots of plants on a shelf or a stage, however small either may be, and however limited the collection, is to keep each genus together, placing the tallest plants farthest from the eye. Sometimes this will form a thin, straggling group from the front of the shelf or stage to the back (*fig. 588. pelargonium, geranium, and crodium*), and at other times, a sub-orbiculate group in the front (*oxalis*), middle (*olea*), or back parts (*cassia*). This is a very simple rule, easily recollected and applied, and every master and head gardener who approves of it, ought to insist on its being carried into execution in every case, whether in the open air or in hot-houses, where pots of plants are to be set down together; unless, indeed, it should, in the case of diseased plants, interfere with culture. The effect of this mode may be very well estimated by inspecting the hot-houses, or open air collections of pots

in some of the nurseries, and more particularly in Messrs. Loddiges', where this arrangement, both in the extensive green-houses and beds of pots of alpine and other herbaceous plants, is adopted on account of its utility.

6209. The following directions respecting the particular plant-habitations of floriculture, are chiefly taken from Sweet's *Botanical Cultivator* (of 1820), and Cushing's *Exotic Gardener* (of 1814).

6210. *Frame*. Very little management is requisite for this department, as the plants kept in cold-frames are so hardy, that for seven or nine months of the year the sashes do not require to be put on. All that is requisite is to expose the plants to the air the whole of every day during winter when the weather is open, by drawing off the lights; to attend to watering them moderately, during winter in mild weather in the morning after sunrise, and in summer in the evening. Once a-year in spring each plant should be examined, and such changes made in the soil, size of the pot, head of the plant, roots, &c. as the experience of the gardener, the appearance of the plant, or the object desired by cultivating it may dictate. The routine culture of weeding, staking, picking off decayed flowers, leaves, &c. need not be insisted on; and the culture of particular species or even tribes cannot here be entered into. (See the *Catalogue of Frame Plants*, in Chap. VIII.)

6211. *Green-house*. The plants of this department, Sweet observes, only require protection from frost in winter. The more air they have given them when not frosty, the more healthy they will be. On a fine morning, the sooner air is admitted the better; but it is best to shut up pretty early in the afternoon, particularly if likely to be a cold night. No fire is required, except frost is expected in the night, or the house should be damp with continued wet weather; then a little fire is requisite to dry the house, as plants are more liable to be injured by damp than by cold. The plants should be looked over most days to see if any require water, which must only be given when quite dry, in the winter season: from nine to twelve o'clock in the morning is the best time for watering them; for, if watered in the afternoon, they are apt to be chilled at night, which makes their leaves look yellow and unhealthy. When the surface of the mould is green with moss, &c. the top should be taken off, and the surface moved with a flat stick, but not deep enough to disturb the roots; if a little fresh mould is wanting on any of them, it should be added. Always be careful to put the same kind of soil they are already grown in; for a different kind put on injures plants more than some cultivators are aware of.

6212. When the weather begins to get warm in spring, some air should be left all night to harden the plants before they are set out; a little must be left at first, and continue to increase it every night till they have full air, if the weather will allow of it. The time of setting them out in the open air depends entirely on the weather. Sometimes they may be put out with safety by the middle of May, in other seasons not till the latter end; but they had better stay in a little too long than be put out too soon. Calm cloudy weather is the best time for setting them out, when as sheltered a situation as possible should be chosen for them. The best time for shifting them in fresh pots is early in spring: some shift them before they are set out, and let them make fresh roots while in the green-house, which is a very good plan, particularly for young or tender plants. If any plants are too tall, and want cutting back, it should be done early in spring, as soon as they begin to grow; then they have time to recover themselves, and make good bushy plants by autumn.

6213. *Cuttings* require to be put in at various seasons, and in different situations. From Christmas to May may be considered the best time for cuttings in general; but some will require to be put in at various seasons throughout the year, according to the state of the shoots. The best time for watering green-house plants in summer is as late as possible in the afternoon, then they have all the night to refresh them. If watered in the morning of a warm day, they will dry again almost immediately. Plants should not remain out too long in autumn, as they are liable to get too much wet, and the worms get in the pots. The middle of September should be the latest, but give them full air as long as the weather will permit. (*Bot. Cultivator*, 121.)

6214. *Stove*. The management of stove plants, according to the same author, whose experience and success are exceeded by none in the cultivation of exotics, depends a great deal on the kind of house in which they are grown; but there is little difficulty in growing them well, if the house can be kept up to a proper heat, and a sufficient quantity of air can be given when required. Close glazing is to be preferred;

either the lights should be leaded, or the laps stopped with putty, so that a sufficient quantity of air may be always given, and the house kept to a more regular heat. When the laps of the glass are left open, a great deal of air is admitted, which is often injurious, particularly on a cold windy night. The thermometer should never be allowed to be below 60° of Fahrenheit's scale; if it gets above 70° on a fine day, a little air may be given, which should be taken away early, and the house shut up warm; it then requires less fire to keep up the heat through the night. If the house is heated in the common way by flues, and the plants are plunged in tan, care must be taken not to give these too much bottom heat, as it will injure their roots, or too much water in winter, as it is apt to rot them. Particular caution is necessary for watering in winter, not to wet the tan, as it makes the worms very troublesome; they often destroy young plants by throwing the mould out of the pots; but a better way is the one now very generally adopted, viz. to do without plunging in tan. Some hot dung or tan may be still kept in the pit to throw up a little warmth, on which should be put a good thickness of sand or gravel for the pots to stand on, and the plants will thrive much better than when plunged in tan: it is also coming nearer to nature, which should be always studied in the cultivation of plants, both in soil and situation. In tropical countries it is the sun that heats the earth in which the plants grow, not the earth that heats the air; and the heat must be kept up in the stoves accordingly. If the houses are heated by steam, no tan is required. The plants may be set on stages, or any way that is most convenient. Some of them may be planted out in the house, where they will grow in greater perfection, and flower and ripen fruit better than when confined in pots.

6215. *To have plants look well* they should be always kept clean and free from insects: if infested with any species of aphid, the house should be smoked with tobacco, which instantly destroys them. The red spiders are likewise a great pest to cultivators, but are also easily destroyed. One pound of sulphur vivum, mixed up in a pail of quick-lime, and the flues brushed all over with it as a common whitewash, will destroy any quantity of them, and make the house look light and clean. The mealy bug is also troublesome if left to increase on the plants; but as soon as they appear they should be brushed off as well as the scaly insects; for, if left to increase, they will disfigure the plants, and be very difficult to get rid of. In fine weather the plants should be often sprinkled over with water from an engine, and the house shut up warm afterwards, which is a great means of keeping them clean and making them grow luxuriantly. Air should be given in the morning as early as possible, in fine weather, as it sweetens the house, and makes the plants healthy. It should also be taken away early in the afternoon, and the house shut up warm, that they may not be chilled by the night air.

6216. *In potting plants*, care should be taken to drain the pots well with broken potsherds or rough bits of turf; for nothing injures them more than letting them get sodden with too much wet. The best time to shift them in fresh pots is the spring, but some will require to be shifted again in autumn, to have them thrive well. The free-growing kinds cannot be well overpotted if there be plenty of room for them in the houses: they will thrive and flower better for being in large pots. Others that are more tender should be kept in as small pots as possible, that they may not get sodden, and lose their roots. (*Bot. Cultivator*, 1.)

6217. *The reserve hot-houses of the ornamental garden* may be divided into those for forcing hardy flowering plants and shrubs, and those for propagating exotics by seeds, cuttings, or otherwise.

6218. *Herbaceous plants and flowering shrubs* are generally forced in pits or low houses; and as soon as the flower-buds begin to expand, removed to the green-house or drawing-room, there to prolong the flowering season. The shrubs should be previously established in the pots, by being planted and plunged in the open reserve-garden a year beforehand: the autumn before forcing they should be thrown early into a state of rest, by covering them with canvass frames to exclude rain and sun, but so as to admit cold and air. This operation should be commenced in July; and the first course of pots may be removed to the pit in November or earlier. Herbaceous plants of most sorts, especially of the fibrous-rooted kinds, may be taken up with balls, and planted in pots early in the autumn preceding the winter in which they are to be forced. Fusiform-rooted sorts earlier, as they do not rise so easily with balls; and the bulbous sorts, the bulbs being out of ground, may be planted in the end of autumn, plunged in the open ground, and covered with rotten tan or ashes, and taken up as wanted. It is of some consequence to remark, that the flowers should be pinched off both the shrubs and herbaceous plants, the summer preceding the forcing season, in order to communicate additional strength, and aid in throwing them more early into a state of rest. The bottom heat may either be from tan or dung, or a vault heated by flues or steam; but the former we consider as most to be depended on. The temperature of the air of the house may at first setting in the plants be kept at 50° or 55° ; and in a fortnight, raised 10 degrees higher. After that, it may be kept up to 65° or higher, admitting air during sunshine. The temperature of the pit should be kept as high as that of the air. Successional supplies should be kept for the first fortnight in a cooler house, or in the coolest part of the pit; or the temperature, on their admission, may be somewhat lowered. The other points of routine culture need not be entered into.

6219. *The propagation-house* requires to be kept at a much more moderate temperature both as to the atmosphere and the bottom heat than the forcing-pit or the principal stove. It need seldom exceed 60° in winter, and 65° in summer. Abundance of air must be given at certain seasons when damp and mouldiness begin to appear; and shading and watering, so as to produce a moist atmosphere, must be attended to in the summer season.

CHAP. VIII.

Floricultural Catalogue. — Herbaceous Plants.

6220. *A floricultural catalogue*, as copious as that which we have given of culinary plants and fruits, would greatly exceed our limits. Plants grown for ornament are so numerous, that we cannot particularise separately the culture of each individual species; but, with the exception of some of the more choice sorts, as the florists' flowers, &c., must collect them in groups, and detail a mode of culture applicable to the whole group. We shall first commence with herbaceous flowers, and these we shall arrange as florists', or select flowers, border-flowers, and herbaceous plants for particular purposes.

SECT. I. *Florists', or Select Flowers.*

6221. *Florists' flowers* are so called as being "flowers" by way of eminence, and because the principal sorts of them for a long time almost exclusively engaged the attention of the flower-gardener. The Dutch, in this, as in most other departments of gardening, were the first to bring it into notice, and more particularly by the great excellence to which they attained in the culture of florists' bulbs. In the culture of that tribe, they still excel; but the fibrous-rooted flowers, as the carnation, auricula, &c.; and the tuberous-rooted kinds, as the dahlia, pæony, &c. are brought to a higher degree of perfection in Britain than any where else. Ornamental flowers, like culinary vegetables which have been long and highly cultivated, acquire a magnitude, succulence, and conformation of parts which render them widely different from what they are in their natural state. This takes place both in double flowers, that is, when the petals of the corolla are increased in number, or by the transformation of other parts of the flower into petals; and also in single flowers, or those in which the petals do not exceed the common number. A flower so changed by cultivation, can no more be compared to the blossom of the same species in its wild state, than a headed cabbage or a broccoli can be compared to the wild cabbage of our sea-shores. Hence have been formed, by the common consent of florists, what are called canons of criticism, by which to estimate the properties of new varieties of established sorts of florists' flowers. To the hyacinth, tulip, auricula, and a few other sorts, particular canons are adapted; but the merits of a number of other select flowers, double and single, are only to be judged of by general rules, such as fulness of floral leaves, roundness of outline, brilliancy and distinctness of color, &c. Under each species we shall give the established criterion, or canon, as far as generally agreed on. We shall take the plants of this section in the order of bulbous, tuberous, ramose, and fibrous rooted flowers.

SUBJECT. 1. *Hyacinth. — Hyacinthus Orientalis*, L. (*Bot. Mag.* 937.) *Hexandria Monogynia*, L. and *Asphodeleæ*, B. P. *Jacinte*, Fr.; *Hyacinthe*, Ger.; and *Giacinto*, Ital. (*fig.* 589.)

6222. The bulb of the *hyacinth* is tunicated, the leaves broad and green, from the centre of which arises a scape, with a spike of flowers, pointing in all directions, and by which it is known, at first sight, from *Hyacinthus nonscriptus*, L. (*Scilla nonscripta*, W.), in which the scape is drooping, and the flowers all turned to one side. It is a native of the Levant, and abundant about Aleppo and Bagdat, where it flowers in February; here it flowers in March and April. It was cultivated by Gerrard in 1596; but had, doubtless, long before been improved by the Dutch, who have added greatly to the strength and beauty of the plant, and produced almost innumerable varieties.

6223. *Varieties.* Gerrard mentions the single and double blue, the purple, and the white. Parkinson, in 1629, enumerates eight sorts. Miller says, the Haerlem gardeners distinguish near 2000 sorts, and generally publish catalogues of them from year to year. At present, the taste for this flower being considerably abated, the Dutch and English catalogues contain only a few hundred sorts. Mason's catalogue for 1820, contains three hundred sorts with names. These names are quite arbitrary, being given by the grower after himself or some public character; and therefore they are here omitted. They are arranged as double blues, whites, reds, and yellows, and single sorts of the same colors; the blues and reds are the most numerous; the yellow, those of which there is least variety. Only single hyacinths were at first cultivated; but about the beginning of the last century attention was paid to double flowers by Peter Voerhelm, whose first double flower was named *Mary*, and is now lost; but his third flower, the *King of Great Britain*, which is now looked upon as the oldest double hyacinth, was greatly preferred to all the flowers known, and the price of it was then above 1000 florins, or 100*l.* sterling. Up to the middle of last

century, the greatest attention was paid at Haarlem to raising new sorts of double flowers; and as much as 200*l.* has been known to be given for a root: but, since that period, the taste for this and other bulbous flowers has considerably declined, and at present there are few sorts for which more than 10*l.* are asked; the general price being from one to ten shillings a bulb for the varied sorts, and what are called the common mixtures are sold at from 2*l.* to 3*l.* a hundred. A variety degenerates, under bad treatment, in two or three years; but in Holland some have been preserved nearly a century.

6224. *Criterion of a fine double hyacinth.* (fig. 589. a) "The stem should be strong, tall, and erect, supporting numerous large bells, each suspended by a short and strong peduncle, or foot-stalk, in a horizontal position, so that the whole may have a compact, pyramidal form, with the crown, or uppermost flower, perfectly erect. The flowers should be large, and perfectly double, i. e. well filled with broad bold petals, appearing to the eye rather convex than flat or hollow; they should occupy about one half the length of the stem. The colors should be clear and bright, whether plain, red, white, or blue, or variously intermixed and diversified in the eye; the latter, it must be confessed, gives additional lustre and elegance to this beautiful flower. Strong bright colors are, in general, preferred to such as are pale."

6225. *Propagation.* By seed for new varieties; and by offset-bulbs for continuing approved sorts.

6226. *By seed.* "The seed should be saved from such sorts as have strong and straight stems, and a regular well formed pyramid of bells, not perfectly single, but rather semi-double. It should not be gathered till it has become perfectly black and ripe, at which time the pericarpium will appear yellow on the outside, and will begin to open. The stem, with which the seed is connected, is then to be cut off, and placed in a dry, airy, cool situation, where it may remain undisturbed till the time of sowing, which is the latter end of October, or beginning of March: it should then be sown about half an inch below the surface of the soil, in a deep box, filled with good sound garden-mould, mixed with sand, or the hyacinth compost, which should be afterwards placed in a warm situation during winter. It will never require to be watered, or have any other attention paid to it than to keep it free from weeds and frost, till it has remained in this state two years; it must then, on the approach of winter, have an additional stratum of the compost placed upon it, about half an inch thick; and at the third year, in the month of July, the roots may be taken up, dried, and treated in the same manner as large bulbs or offsets: some of the roots will flower the fourth year, one half of them will at the fifth, but by the sixth year, every healthy root will exhibit its bloom, and then the hopes and expectations of the cultivator will be realised or disappointed. He may think himself fortunate, if one half of the plants that first appeared, are in existence at this period; and if he can at last find one flower in five hundred deserving a name or place in a curious collection, he may rest perfectly content, and be assured that he has fared as well as could reasonably be expected, and better than many who have bestowed equal attention on the subject." (Maddock.)

6227. *By offsets.* These may be planted in the beginning of October, or soon after they have been separated from the parent bulbs. Plant them in an open part of the garden, in rows about two inches deep, upon a bed raised six or eight inches above the common level, consisting of a sandy soil, pulverised, eighteen inches deep; the surface of the bed should be made rather convex or rounding, so as to throw off heavy rains; no further attention is necessary, except to stir the surface of the bed occasionally, keep it free from weeds, and preserve it from very severe frost. The proper time to take them up is the same as for large roots. Offsets, if preserved in health, will bloom weakly the second year; but by the third tolerably strong, and may afterwards be placed on the best bed.

6228. *Choice of full-grown roots.* "Such roots as have attained the age of four or five years, bloom stronger in this country than any other; they afterwards gradually decline, either by dividing into offsets, or diminishing in size and strength: but in Holland, owing to the peculiar circumstances of the soil, climate, situation, &c. the same bulb has been known to produce blossoms twelve or thirteen times, nor is it ever known to die merely with age."

6229. *Soil and site.* "The bed on which they are to be planted should be situated in rather a dry and airy part of the garden; a southern aspect is to be preferred, sheltered on the north and east. When the situation is determined on, the dimensions of the bed should be marked out, and the soil entirely taken away to the depth of at least two feet; the earth in the bottom must then be dug up and pulverised, one spit or nine inches deeper, and the space above filled up with a compost consisting of one third coarse sea or river sand; one third fresh sound earth; one fourth rotten cow-dung, at least two years old; and earth of decayed leaves for the remainder. These ingredients are to be well mixed and incorporated, and about a fortnight previous to planting, the bed should be filled up with the compost to about four inches above the level of the path on the south or front side, and ten inches on the north side, so as to form a regular slope or inclination towards the sun."

6230. *In the Dutch Florist* of Nicholas Van Kampen and sons, florists at Haarlem (Haarlem 1760, and Newcastle-upon-Tyne, 1763), sandy earth is said to form the basis of the culture of the hyacinth. It ought to be of a bluish-grey or blackish-red color, not sharp, but rather handling smooth, a little greasy, and taking a pearl color when dry; the water passing through it being sweet and of a delicate taste. The best method of enriching sandy earth, according to their experience, "is to make use of cow-dung, rotted leaves of trees, and tanners' bark; but the bark ought not to be taken fresh out of the pits, but laid up for two years at least, that it may be well rotted and consumed to one half:—Our method, then, of making compost for hyacinths is as follows: Two sixth parts of grey sand; two sixths of well rotted cow-dung; one sixth of tanners' bark, quite rotted and reduced to earth; one sixth of tree-leaves, also well rotted. All these materials must be thrown into a heap, not more than three feet thick, so that the rays of the sun may have power to penetrate through it, and warm it to the bottom; for which purpose the heap must be laid in a high and open place exposed to the south. Once a month it ought to be carefully turned, and the bottom thrown to the top, that all parts of it may partake of the benign influence of the sun and elements: this is essential; and this turning must be continued for twelve months, taking care not to sift the compost, because, in that case, it is apt to run into lumps, which would be of dangerous consequence." (Quot. by Neill, in *Hort. Tour*, 536.)

6231. *In St. Simon's work*, entitled *Des Jacintes* (Amst. 1768, 4to.), in which the Dutch mode of cultivating the hyacinth is fully detailed, the compost used at Haarlem is said to be rotten cow-dung, rotten leaves, and fine sand. The leaves of elm, lime, and birch are preferred to those of oak, chestnut, walnut, beech, plane, &c. which do not rot so quickly. The cow-dung is collected in winter from cattle, stall-fed upon dry food, without any mixture of straw or other litter. The leaves, when decayed and fit for use, are thus mixed with the other materials: "First, they place a layer of sand, then one of dung, and then one of rotten leaves, each being eight or ten inches thick. These layers are repeated till the heap is six or seven feet high, a layer of dung being uppermost, sprinkled over with a little sand to prevent the too powerful action of the sun upon it. After the heap has lain thus for six months or more, it is mixed, and thrown up afresh, in which state it remains some weeks to settle before it is carried into the flower-beds. This compost retains its qualities about six or seven years; but the Dutch avoid setting hyacinths in it two years successively; in the alternate years they plant tulips, jonquils, narcissuses, crocuses, irises, &c. in the same beds; nor do they venture to set hyacinths in the compost the first season, when the fresh manure might be injurious to them." (Herbert, in *Hort. Trans.* vol. iv. 165.)

6232. *Planting.* This should take place "from the middle of October to the middle of November; if it is done earlier the plants will appear above ground in the middle of winter; or if it is deferred later, the roots will be weakened by their natural tendency to vegetate. On planting the roots, the surface of the bed should be covered with a little fresh sandy earth, about one inch thick, raked perfectly smooth

590

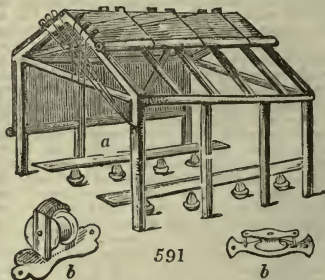

and even, and have the exact situation for every bulb marked upon it (*fig. 590.*), regularly mingling the colors of red, blue, and white; the yellows being classed with the latter. The width of the surface of the bed may be four feet, and six rows may be placed across it at eight inches asunder, the two outside rows being each four inches from the sides of the bed; consequently the space between the centre of each bulb will be about nine inches and a quarter. On planting hyacinths, a little clean sand should be placed underneath, and likewise upon the roots, to prevent the earth adhering too closely to them; the whole are then to be covered with sound fresh sandy earth, from three to four inches deep, according to the size of the bulb; when this is completed, the bed will be about eight inches above the level of the walk on the south or front side, and about fourteen inches on the north; it will look neater and have a better effect, if it is supported on each side with a strong frame of thick boards or brick-work.

6233. *The Dutch Florist* directs, "After a place has been pitched on for planting the flowers, the natural earth must be dug out to the depth of three feet, and the bottom covered with a stratum of cow-dung half a foot thick; which must be beaten and trod down till it be very firm and compact like a hard crust, so as to prevent any communication with the sub-soil. Then the hole is to be filled up with compost, six inches above the level of the garden. The compost should be laid into the designed bed about a month before the roots are planted; for if it be put in later, the earth might settle while the roots are in it, which would lay them too deep. The proper season for putting in the bulbs is October and November. They ought to be set at the depth of four or five inches; but early flowering varieties may be one inch deeper, which will bring them to flower at the same time with the others." (*Quot. by Neill, in Hort. Tour, 537.*)

6234. *Culture.* "In order to preserve it from very heavy rains or severe frosts, it should be hooped over, and mats or canvass should be placed at hand ready to cover the bed on such emergencies; but it will not be necessary to defend it from moderate rains or slight frosts: for too frequent and long covering will deprive the roots of the due action and influence of the air, which ought to be avoided as much as possible: it were even better to run the hazard of incurring a slight injury by the omission of covering on some occasions, than overdo it to the certain detriment of the plants. If frost is permitted to penetrate so far into the soil as to reach the bulbs, especially about the time that the plants begin to appear above ground, it will produce a singular effect, by causing some of them to shoot forth or discharge their stems and blossoms; but if the roots become entirely frozen through, they are in danger of being destroyed. The earlier sorts will begin to open and show color about the beginning of April; it will be proper to screen such from the too powerful effects of the sun, which, if not prevented, would bleach and tarnish their colors, particularly the reds and deep blues; but if they are properly defended from it, their colors will be preserved, and they will, in some measure, be kept back, so as to be in full bloom with the later sorts, especially if the roots of the early sorts have been planted about an inch deeper than the rest: it is a very desirable object to have a uniform bloom. It will be necessary to support the stems as they advance in height; for this purpose, small sticks or wires, painted green, should be forced into the ground, immediately behind the bulbs, either in an erect position or leaning a little backwards, to which the stems are to be rather loosely tied with small pieces of green worsted, as soon as they begin to bend, or are in danger of breaking with the weight of the corolla or bells: this operation must be repeated as they advance in height, for it is impossible to do it at one time so as to answer the purpose. When the greater part of the bed appears in color, a covering, or awning, should be erected over it and the path in front: the awning should consist of a strong frame of wood, ten feet high in the centre, and seven feet at the sides, covered with Irish or Scotch sheetings, or Russia duck, which will effectually keep out rain, and admit a great degree of light; it should come down close to the bed on the north side, in order to preserve it from cold winds, which are prejudicial to the bloom. The covering (*fig. 591.*) should be so constructed, by means of lines (*a*) and pulleys (*b*), as to be easily and expeditiously rolled up, or let down, as occasion requires, to afford the plants the full benefit of light and air, at all favorable opportunities, that is to say, when the air is mild, and light clouds intervene, so as to blunt the sun's ray. This sometimes, and, indeed, often happens to be the case from seven to nine o'clock in the morning, and from four to six in the evening, at which time the sun has also less power than in the middle of the day. A bed of hyacinths never requires to be watered at any period; the rains that happen after planting are generally more than sufficient both for the roots and the bloom; and after the bloom is over they are rather prejudicial than otherwise, except when very moderate. Although covering in the manner described presents and exhibits the bloom to the greatest advantage, yet it evidently has a tendency to weaken and injure the bulbs, and ought not, therefore, to be continued more than two or three weeks at most; but as soon as the general bloom declines, the beds should be immediately exposed to the open air, and the mats and hoops should be replaced, as before, to keep off heavy rains."

6235. *Taking up the bulbs.* "It is the practice in Holland, to take up the bulbs about three weeks or a month after bloom, in the following manner: As soon as the plants begin to put on a yellowish decayed appearance, they take up the roots and cut off the stem and foliage close to, or within half an inch of, the bulb, but leave the fibres, &c. attached to it; they then place the bulbs again on the same bed sideways, with their points towards the north, and cover them about half an inch deep, with dry earth or sand, in the form of a ridge, or little cone, over each: in this state they remain about three weeks longer, and dry or ripen gradually; during which, as much air is admitted as possible, but the bed is preserved from heavy rains, and too hot a sun; at the expiration of this period the bulbs are taken up, and their fibres, which are become nearly dry, gently rubbed off; they are then placed in a dry room for a few days, and are afterwards cleaned from any soil that adheres to them, their loose skins taken off, with such offsets as may be easily separated. When this dressing is finished, the bulbs are wrapped up in separate pieces of paper, or buried in dry sand, where they remain till the return of the season for planting. Another, and less troublesome, mode of treatment after bloom, though perhaps more hazardous, is to keep the bed airy, and rather dry, till the stems and foliage appear nearly dried up or consumed; this will seldom happen to be the case in less than two months; the bulbs are then to be taken up, cleaned from the fibres, soil, &c. and preserved in sand or papers as before directed."

R	B	W	R	B	W	R	B	W	R
W	R	B	W	R	B	W	R	B	

6236. *Van Kampen and son* say, "We take up the roots as soon as the leaves begin to wither, that is, when their plants begin to turn yellow. We then break off the stems an inch above the bulbs, which we afterwards cover with earth, in which they are to lie till the gross moisture be dried up by the warmth of the sun. We make a little heap of earth, and place the roots in it, bottom downwards as they grew; and the heap is covered with an inch or two of soil. When the bulbs have lain in this heap for three weeks, they are to be taken out in fair weather, and laid on a board in the sun for an hour, after which, they are to be cleared of the earth and offsets about them, taking great care not to give the least bruise or wound." (Quot. by *Neill, in Hort. Tour*, 558.)

6237. *Herbert* says, "The bulbs should be placed in an airy store-room, and not suffered to touch each other; a moveable stage of open lattice-work, furnished with drawers, may be used, and the utmost attention should be paid to ventilation." A French florist, *Baudry*, is said (*Caled. Hort. Mem.* iv. 76.) to have lost annually a number of his hyacinth-bulbs through dampness until he adopted the expedient of placing them in the store-room with the base of the bulb upwards. Drawers of lattice-work would effect the same object.

6238. *Diseases.* "Hyacinths are subject to various diseases, arising from different causes; that distemper commonly known by the appellation of the ring-sickness, is of all others the most dangerous and most difficult to cure; in short, the only effectual remedy is to cut out the diseased part, till no brownness, yellowness, or other symptom of distemper remains. The sound part will survive the operation, if it consist of no more than the outside tunic of the bulb, without any heart; but it will, in such case, only be able to produce offsets, and will never recover itself so as to flower again: as soon as the operation is performed, the wounded part should be exposed to the sun, till it becomes dry, to prevent mouldiness, and it will be best to replant it in some dry situation soon after." "The Dutch," *Herbert* observes, "are much troubled with this disease; the cause of which appears to be a fungus, the spawn of which is nurtured in the caw-dung. The only remedy is the removal of the distempered bulb, and the compost that was in contact with it."

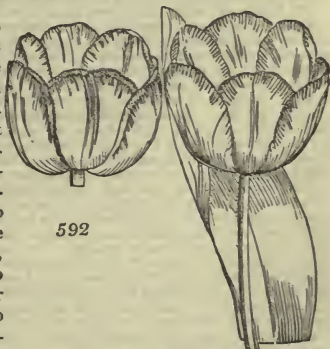

6239. *Duration of bulbs.* "The hyacinth delights in a sandy soil and saline atmosphere; of consequence it succeeds best on the sea-coast, or in situations very near to the sea. In more inland parts, it will generally be found necessary to procure an annual reinforcement of fresh imported bulbs, in order to make good or supply the deficiencies arising from the loss, or impaired health and strength of many of those that have bloomed on the best bed the preceding spring. Those who are well acquainted with the hyacinth, always allow about one bulb in twelve to fail, notwithstanding no visible blemish or decay is discernible at the time of planting; such generally have a *corps de réserve*, in narrow deep pots, which, at the commencement of bloom, they plunge or sink into the bed, wherever a vacancy, or weak sickly plant makes its appearance; by which means the uniformity and regularity of the bed is preserved, without any visible defect or alteration." *Herbert* says, "My own experience enables me to say, that the nurseryman in the neighborhood of London may produce hyacinth-bulbs equal, if not superior, to those imported from Holland; though, perhaps, with greater loss from disease, owing to his not being able to procure the dung of cattle fed upon hard food, and free from straw." (*Hort. Trans.* vol. iv. p. 168.)

6240. *Forcing the hyacinth.* Plant the roots in narrow deep pots, filled with sandy loam, in October; plunge them in and cover them with old bark-leaves or sand; they will soon throw down roots, and a part may then, say in November, be plunged in bottom heat, which will come into bloom by Christmas, and successional supplies can be taken from the store planted in October, and a bloom thus kept up till they flower in the open air. The best sorts to force are the single blues and reds.

6241. *Blowing hyacinths in water-glasses.* Blue or dark-colored glasses are more favorable to the progress of the roots than light ones, light being injurious to all roots. The bulbs to be blown in the glasses should be planted in October, in earth in which they push their fibres more regularly, and taken up as wanted, washed from the earth, and placed in the blowing-glass: the glasses may be kept in a warm room or in a stove. The water should be soft, and the glass so full that it may rise a fourth of an inch on the bulb. As often as it becomes fetid, it should be renewed.

SUBJECT. 2. *Tulip.* — *Tulipa Gesneriana*, L. (*Bot. Mag.* 1135.) *Her. Monog.* L. and *Liliæ*, J. *Tulipe*, Fr. and Ger. and *Tulipano*, Ital. (fig. 592.)

6242. The bulb of the tulip is solid, and sends up an upright stem from twelve to eighteen inches high, with glaucous leaves, and a large erect flower, the petals in its wild state having a black base. It is a native of the Levant. It is common in Syria, and is supposed by some to be the "lily of the field," referred to in Christ's address from the mount; though Sir J. E. Smith thinks the *amaryllis lutea* is there meant. In Persia, where the tulip is abundant, it is considered as the emblem of perfect lovers. "When a young man," says *Chardin*, "presents one to his mistress, he gives her to understand, by the general color of the flower, that his body is on fire with her beauty, and by the black base of it, that his heart is burned to a coal." According to *Gesner*, the tulip was brought to Europe in 1559. It was cultivated in England by *James Garnet*, in 1577, having been introduced, according to *Hakluyt*, from Vienna. Towards the middle of the 17th century, the tulip became the object of considerable trade in the Netherlands; it rose to its greatest height in 1634, and the three following years. According to *Beckmann* (*History of Inventions*, art. *Tulip*), for one root of a variety called the *Viceroy*, articles to the value of 2500 florins were agreed to be delivered. The *Semper Augustus* has been sold for 2000 florins; one person agreed to give 4600 florins (about 460*l.*), with a new carriage, two horses, and complete harness; and another agreed to give twelve acres of land for a single root. The trade was generally followed for a time, and having no foundation in real utility, like the Mississippi and South Sea schemes, it was a mere gambling business, and rightly named *Tulipomania*. *John Barclay*, the celebrated author of the romance of *Argenis*, is said to have had this mania to such an excess, that he placed two mastiffs as

592

sentinels in his garden. This was between 1600 and 1621, when he lived at Rome, in an ill aired and unwholesome habitation; in which, however, he chose rather to continue than abandon his favorite flowers. (*Chalmers's Biog. Dict.*) The taste for tulips in England was at its greatest height about the end of the 17th and beginning of the 18th century; about the year 1730 or 40, it had declined and given way to the taste for botany, and new plants from America and other foreign countries. The tulip, however, is still much cultivated both in Holland and England, near large towns, though in the latter country there are now very few good collections in the private gardens of the higher classes. Like the auricula and some other flowers, it is more the flower of the tradesman and operative manufacturer than of the botanist or man of fortune.

6243. *Varieties.* Parkinson, in 1629, enumerates 140 sorts: but "to tell of all the kinds," he says, "which are the pride of delight, they are so many, and as I may say almost infinite, doth both pass my ability, and, as I believe, the skill of any other." In Parkinson's time, tulips were divided into *præcoces*, or early blowers, and *serotinae*, or late blowers, with an intermediate division of *dubie mediæ*, doubtful or middle blowers, which, for the most part, however, belonged to the *serotine*. The early blowers have short stems, and the *Duc Van Tholl* is almost the only variety in repute among modern florists. The great variety in the catalogues is produced from the late blowers, which have tall stems and much richer colors; of these the catalogue of Maddock in 1792 contained the names of 665 sorts. In Mason's catalogue for 1820, are six sorts of early tulips; four of perroquets, or middle blowers; 22 double sorts, and upwards of 600 single late sorts. The Dutch florists class their late-blowing tulips as under: a variety will last an unknown number of years.

Prime baguets (*baguette*, Fr. a rod or wand); very tall; fine cups with white bottoms, well broken with fine brown, and all from the same breeder.

Baguets Rigaut's (supposed from Rigaud, some eminent florist's name, or *vougeande*, red-faced); not quite so tall, but with strong stems, and very large

well formed cups, with white bottoms, well broken with fine brown, and all from the same breeder.

Incomparable Verports; very perfect cups, cherry and rose, and white bottoms, well broken with shining brown. Byblomens, or next flowers, the *flamands*

of the French florists, with bottoms white, or nearly so, from different breeders, and broken with variety of colors.

Bizarres (*bizarre*, Fr. odd, irregular); ground yellow, from different breeders, and broken with variety of colors.

6244. *The names of the different varieties*, classed under these heads, being perfectly arbitrary, and constantly changing, their insertion here could be of no use. (See the *Annual Catalogues of Bulbous Roots*, published by the nurserymen and florists.) What are called *breeders* are procured from seed, and consist of one plain color on a white or yellow bottom. These being cultivated on a dry and rather poor soil become broken or variegated, and produce new varieties. The time that elapses before they break varies from one to twenty years or more, and sometimes this change never takes place, so that whoever thinks of raising new varieties of tulips from seed must be possessed of an ample fund of patience and perseverance. The early dwarf tulip, known among florists as the Van Tholl, is a distinct species, *T. suaveolens*. Formerly there were several varieties of early dwarf kinds.

6245. *Criterion of a fine variegated late tulip.* "The stem should be strong, elastic, and erect, and about thirty inches above the surface of the bed. The flower should be large, and composed of six petals: these should proceed a little horizontally at first, and then turn upwards, forming almost a perfect cup, with a round bottom, rather widest at the top. The three exterior petals should be rather larger than the three inferior ones, and broader at their base: all the petals should have perfectly entire edges, free from notch or serrature; the top of each should be broad and well rounded; the ground-color of the flower, at the bottom of the cup, should be clear white or yellow, and the various rich-colored stripes, which are the principal ornament of a fine tulip should be regular, bold, and distinct, on the margin, and terminate in fine broken points, elegantly feathered or pencilled. The centre of each leaf, or petal, should contain one or more bold blotches, or stripes, intermixed with small portions of the original or breeder color, abruptly broken into many irregular obtuse points. Some florists are of the opinion that the central stripes, or blotches, do not contribute to the beauty and elegance of the tulip, unless confined to a narrow stripe, exactly down the centre, and that they should be perfectly free from any remains of the original or breeder color: it is certain that such appear very beautiful and delicate, especially when they have a regular narrow feathering at the edge; but the greatest connoisseurs in this flower unanimously agree, that it denotes superior merit, when the tulip abounds with rich coloring, distributed in a distinct and regular manner throughout the flower, except in the bottom of the cup, which, it cannot be disputed, should be a clear, bright white or yellow, free from stain or tinge, in order to constitute a perfect flower."

6246. *Propagation.* By seed for new varieties, and by offsets for continuing approved sorts.

6247. *By seed.* Select such breeders as have tall strong stems, with large well formed cups, clear in the bottom, and save seed from these in preference to the finest of the variegated or broken sorts, as the seed of such sorts produces nothing but poor weak breeders of no value. "It should remain growing on the stem till the pericarpium becomes of a brownish color, and begins to open; it is then sufficiently ripe, and should be cut off, with six or eight inches of the stem, and treated afterwards, in all respects, agreeable to the directions given for the management of hyacinth-seed. Some of the seedlings will bloom by the fourth or fifth, and most, if not all, by the seventh year."

6248. *By offsets.* These should be planted soon after they are separated from the parent bulb, in beds of fresh sandy loam, with a little rotten cow-dung placed from seven to twelve inches below the surface, in a dry airy situation, from two to four inches deep, according to the size of the roots. The beds should be raised six or eight inches above the alleys, formed rather convex on the surface, and may be provided with hoops and mats, to be used to guard them, as occasion may require, from heavy rains and severe frosts.

6249. *Choice of full-grown bulbs.* Select such as have not lost the brown skin, are not mouldy or soft at the root end, and are full, solid, and rather pointed at the other. Just before planting, strip off the brown skin so as to leave the root perfectly bare and white, performing the operation with great care, to avoid bruising or wounding the root, especially at the lower end, where the fibres are formed, which is, at the season of planting, extremely tender.

6250. *Soil and situation.* "The situation for the best bed should be in an open airy part of the garden; when that is fixed upon, the ground should be marked out, agreeable to its intended dimensions, and the soil taken out twenty inches deep; the bottom is then to be filled up with sound fresh earth, ten inches thick, upon which is to be placed a stratum of two-year-old rotten cow-dung, and earth of the above description, about one half of each, well mixed together, twelve inches thick; and again, upon this is to be placed another stratum of the same kind of earth as that of the bottom; this is only to be two inches thick at the sides, and three inches at the middle, which will give it a small degree of convexity; this is to be performed about the 20th of October, *i. e.* a week or two before planting, to give the bed time to settle; at the expiration of two weeks, the earth will have subsided, so as to be about two inches higher than the circumjacent paths; but if heavy rains intervene between this preparation of the bed, and the time of planting, it will be proper to keep them off, in order to preserve the temperature of the earth, as it would be rendered too compact and adhesive, by a redundancy of moisture for the fibres to pass freely through it, which ought to be avoided." Hogg recommends a fresh, rich, loamy soil, of rather a sandy nature, which should be dug twelve months at least before it is used, and a small portion of well rooted dung must be added. He says, an intelligent old tulip-grower assured him, that the best compost he had ever hit on "was three fourths rich yellow loam; one fourth leaf-mould; one sixth two-year-old horse-dung; and

one eighth sea-sand, well incorporated, and laid in a bed, or stratum, for the plants, two feet deep." (Tr. on the Carnation, Auricula, Tulip, &c. 142.)

6251. *Planting.* The most proper time is from the end of October to the tenth of November. On the day made choice of for planting, rake the surface of the bed smooth and even, still preserving its convexity, and mark the exact situation for every root upon it. The proper distance between each root is seven inches from centre to centre; and if the rows are seven inches asunder, the roots will form squares of similar diameter on all parts of the bed. A bed consisting of seven rows makes the noblest appearance, when it is of sufficient length, with a path round it about two and a half or three feet wide; but where the number of roots is small five rows may suffice, and the path, in that case, may either extend quite round the bed, or only on one side, at pleasure. If, therefore, the bed consists of seven rows, it should consequently be fifty inches wide, which will allow a space of four inches between the outside rows and the sides of the bed; but if the bed contains only five rows, it will only require to be three feet wide, to give the roots similar distances. Having sprinkled a little clean sand where the roots are to be set, place them with great exactness and add some very sandy earth, so as to completely envelope each root in a little cone of it; then cover the whole very carefully with strong, sound, fresh loam, about four inches thick at the middle of the bed, gradually decreasing as it approaches the sides, where it should be about three inches thick; thus will the convexity of the surface be increased in a proper degree, and the roots will be covered with soil, to a depth proportionate to their size and strength; the largest and strongest having been placed in the centre rows, and the smaller and weaker on those of the outside. No tulip-root, whatever may be its size or strength, should be planted more than four inches deep from the upper side of the root; nor should any blooming root be planted less than two and a half or three inches deep, however small it may be. The soil made use of for covering the bulbs should be frequently turned over, and thoroughly exposed to the sun and air, some time before it is made use of, that it may be rendered perfectly sweet and free from the acrid quality that most soils are subject to, when taken considerably below the surface. But if the bed is only to contain five rows, with a path in the front, and none behind, then it will be proper to plant the smallest and lowest growing roots in the front, next the path, and so gradually to increase in the size of the roots to the fifth or last row, which should contain the strongest and largest of all; when the roots are properly covered with soil, as before directed, the surface of the bed will slope one way, forming an inclined plane: it will be necessary to support its highest side at least with boards or brick-work, otherwise the earth would be liable to crumble down and leave the roots bare or too shallow.

6252. *Future culture and management.* "When the operation of planting is concluded, the bed may be hooped over, and taken care of, in the manner directed for hyacinths, *i. e.* so as to preserve it from very heavy rains, and severe frosts; but either one or the other, in moderation, will be of more service than injury to it. By the end of February every plant in health will be visible above ground; some tall early sorts will be two or three inches high, others one inch, and the latter sorts just making their appearance; indeed, a very few remarkably late sorts may be a week longer before they appear, but not more: if, on examination, any distemper or canker is discernible on the foliage, about this time, either above or an inch or two below the surface of the soil, it should be carefully cut out with a sharp knife, and the wounded part left exposed to the sun and air, which will presently heal it: a fine dry day should be made choice of for this operation. If the surface of the bed appears to be of too close and solid a contexture, it should be carefully stirred up, about two inches deep, which will admit the air more freely, and prove, in all respects, very beneficial. By the end of April, some of the plants will probably be grown so tall as to require the hoops to be raised a little, to secure the blossom from injury: attention to this part must not be omitted, for the blossom is very tender and likely to be bruised and disfigured, by a very slight blow, or rub against the hoops. As soon as any of the earlier sorts begin to show color, they should be shaded from the sun, for, when its heat is considerable, it will cause the colors to run and intermix, in such a manner as to destroy the elegance and beauty of the flower; some sorts are more particularly liable to this effect than others, and will be spoiled in five minutes. When the greater part of the blossoms have begun to open, a frame, or awning, should be erected over the bed and paths, nearly similar to that for hyacinths (*fig. 591*): that is to say, so as to keep out rain, and admit as much light as possible; this must be thrown off, or rolled up, at every favorable opportunity, as directed for hyacinths, except that it should be done rather earlier in the morning, and later in the evening; because the sun has acquired a greater degree of power at this season of the year than earlier. If these frequent exposures to the light and air be omitted, the colors of the flowers will be faint and weak, and the grandeur of effect will be lost, or considerably lessened. The cloth covering should come down on each side, within about three feet of the ground, to allow a free circulation of air, except in windy weather; from the effects of which, the flowers must be most carefully preserved, by a continuation of the covering quite down to the ground, on the windy side; a line of mats sewed together, and their upper edge nailed to the frame on that side, may answer the purpose, if the cloth is not of sufficient length. Tulips never require to be artificially watered, in the hottest and driest seasons, at any period from planting to taking up the roots; nevertheless, moderate rains may always be admitted before, and if very small quantity after the bloom is over; but early in the spring, they are absolutely necessary, in order to procure a strong bloom. When the awning is erected, the hoops should be carefully taken away, the sides and ends of the bed should be neatly boarded up, and the paths lowered two or three inches, to bring the flowers nearer to the eye: a slight frame, about two feet high, should surround the bed, to prevent the garments of spectators from rubbing against, or breaking off the flowers; lines of small twine, painted green, and corresponding with the rows of flowers, should pass from one head of the bed to the other, fastened to the end pieces of the frame, and stretched tight; to these the stems of the flowers are to be loosely tied with short pieces of green worsted, which will preserve a pleasing regularity of appearance, without stiffness and formality. Tulips will bear to be covered a longer time in bloom than most other flowers, without sustaining any considerable injury: it may be continued three weeks with great safety. If any roots should perish, or fail to produce bloom, the deficiency may be made good by transplanting, with the tube transplanter (*fig. 93*), from a reserve-bed, or the lower end of the stems of flowers, taken from the reserve-beds, may be immersed in phials, filled with water, and sunk into the bed, so as not to appear above ground: these will continue in bloom

several days, without requiring to be changed, and will make a tolerable appearance. About a week or ten days after full bloom, when the petals of many begin to drop off, the awning should be taken down, together with the frame, boards, &c. that surround the bed; and the mats and hoops may be replaced as before, to throw off excess of rain, as the case may require: and as the leaves or petals of any fall, the seed-vessel of such should be immediately broken off close to the stem; for if suffered to remain on the plant, it will procrastinate the period of its maturity, and weaken the root considerably. The bed may remain in this state about a fortnight longer, by which time the grass, or foliage, will become of a yellowish-brown, and two or three inches of the top of the stem will wither, dry up, and become purplish: this denotes the critical period to take up the roots, because if done earlier, they will be weak and spongy, and if deferred later, their juices will become gross; this will be manifest at the succeeding bloom, by too great a redundancy of colorific matter in the petals, and the flowers being what is generally termed foul."

6253. *Taking up the roots.* Dig them up carefully, and place them under cover, in a dry, airy, shaded situation. Here they may remain untouched till August or September following. "Then it is proper to take off their loose skins, fibres, and such offsets as are easily separated; observing not to leave the roots too bare, because the action of the air upon such would have a tendency to weaken and injure them, by drying up part of their juices; the last brown skin, which is so intimately connected with the root, should remain on it till the time of planting."

6254. *Diseases.* The tulip is hardier, and less liable to disease and injury from weather, than most sorts of flowers; it is sometimes attacked by grubs and wire-worms at the root early in spring, and then the best mode is to remove the plant and a portion of the soil, replacing the former from the reserve or offset-buds.

6255. *Forcing the tulip in pots or water-glasses.* The early dwarf sorts are well adapted for this purpose, especially the *Duc Van Thol*. They may be treated as in forcing the hyacinth.

SUBJECT. 3. *Ranunculus.* — *Ranunculus Asiaticus*, L. (Mill. Ic. 2. t. 216.) *Poly. Polyg. L.* and *Ranunculaceæ*, J. *Renoncule*, Fr.; *Ranunkel*, Ger.; and *Ranuncolo*, Ital. (fig. 593.)

6256. *The ranunculus* from a fasciculus of small tubers sends up several bipartite leaves, and an erect branched stem with a terminating flower variously colored. It is a native of the Levant, and was cultivated by Gerrard in 1596. Though rather a tender plant, innumerable and highly beautiful double-flowered varieties have been raised from seed, chiefly by the English florists, from the middle to the latter end of last century.

6257. *Varieties.* Only double ranunculuses are held in esteem: of these, Parkinson, in 1629, enumerates eight; and Ray, in 1665, twenty sorts. Justice, in 1764, divides ranunculuses into Turkey and Persian; of the former he enumerates eighteen sorts, and of the latter a hundred. What he calls the Turkey ranunculus is only a variety or subspecies with a very dark flower, which Miller also considered as a species, and named it *R. sanguineus*. Maddock, in 1792, had upwards of eight hundred sorts. Mason's catalogue for 1820 contains about four hundred names. "There are more varieties of ranunculuses," Maddock observes, "than of any other flower;" but as their names are arbitrary, it would be of little use to enumerate them here. A variety will last from twenty to twenty-five years.

6258. *Criterion of a fine double ranunculus.* (fig. 593. a) "The stem should be strong, straight, and from eight to twelve inches high, supporting a large well formed blossom, or corolla, at least two inches in diameter, consisting of numerous petals, the largest at the outside, and gradually diminishing in size as they approach the centre of the flower, which should be well filled up with them. The blossom should be of a hemispherical form; its component petals should be imbricated in such a manner as neither to be too close and compact, nor too widely separated; but have rather more of a perpendicular than horizontal direction, to display their colors with better effect. The petals should be broad, and have perfectly entire well rounded edges: their colors should be dark, clear, rich, or brilliant, either consisting of one color throughout, or be otherwise variously diversified, on an ash, white, sulphur, or fire colored ground, or regularly striped, spotted, or mottled in an elegant manner."

6259. *Propagation.* By seed, for new varieties, and by offset-tubers, or dividing the tubers for continuing approved sorts.

6260. *By seed.* The seed of the ranunculus, Maddock observes, in no instance ever produces two flowers alike, or the same as the original. It should be saved from such semi-double flowers as have tall strong stems, a considerable number of large well formed petals, and rich good colors, chiefly preferring the darker, but not to the exclusion of the lighter colored, when their properties answer the foregoing description. "The seed should remain on the plant till it has lost its verdure, and becomes brown and dry; it may then be cut off, and spread abroad upon paper in the seed-room, exposed to the sun, that every degree of humidity may be exhaled from it; in which state it should be put into a bag, and preserved in a warm dry place"

6261. *January is the proper time to sow the seed*; and in order to prepare it, it must be separated from the stalks to which it is connected, in the following manner, viz. in the first place, it should be taken out of the bag, and spread thin upon a sheet of paper or tea-tray, &c. and placed before a moderate fire, till it is just warm, and no more; the seed will then easily scrape off, by means of a penknife; but great care must be taken to avoid scraping it off in lumps, or suffering any pieces of the stalk, dried petals of

the flower, or other extraneous matter to be mixed with it, which would create a mouldiness when sown, of very destructive consequence: when the seed is scraped in a proper manner, it will have much of the appearance of clean coarse bran, with a little brown or purple speck in the centre of each cuticle, which is the kernel. When the seed is thus prepared, it should be sown in a shallow frame, provided with sashes; the soil should have been previously taken out, three feet deep, and spread thin upon the ground, till it has been perfectly frozen throughout, in order to destroy any vermin it may have contained, more particularly the common earthworms. When the pit is filled up again with the frozen lumps of earth, it should remain till the whole mass has thawed, and subsided to its pristine bulk, or nearly so; its surface should then be made perfectly smooth and even, and the seed sown upon it with the utmost regularity, in such quantity as nearly to cover it; the glasses should be placed over it immediately, and the frame kept closely covered with them, for two or three days, till the seed begins to swell and soften; a little light earth should then be sifted upon it, through a fine sieve, but not sufficient to cover it; this should be repeated once or twice a-week, till the greater part of the seed disappears: it is proper to remark in this place, that such seeds as happen to be covered deeper than the thickness of a half-crown piece, will never vegetate, and must of course, inevitably perish.

6262. It is necessary to keep the seed moderately moist, by gentle waterings with soft water, that has been exposed to the sun till it is a little warmed; the rose of the watering-pot should be hemispherical, and perforated with a great number of very small holes, that will discharge fine streams of water, in a very distinct and regular manner. About the time that the plants begin to make their appearance, it is proper to stir the surface of the earth with a pin, or silver bodkin, just sufficiently to admit air, and give liberty to the young plants to pass easily through; this operation should be very carefully performed, to prevent breaking off the fibres, or raising and leaving any of the plants out of the earth, because one hour's sun upon such would inevitably destroy them. When the sun shines very hot, it is necessary to admit some fresh air under the glasses, and shade the frame with mats; but it should be close shut up with the glasses when the air is cold, and always at night.

6263. After the plants are all up, and their two interior leaves appear, more air must be given, by having burdles or lattice-work substituted for the glasses; waterings must be regularly continued, in the manner before described, when the long continuance of dry weather renders it necessary: but fine warm showers of rain are always preferable, when they happen in due time. This kind of management is to be continued till the roots are matured, and fit to take up, which is known by the foliage becoming perfectly brown, dry, and nearly consumed.

6264. The speediest and safest method of taking up these small roots is to pare off the earth, three inches deep, with a trowel or shovel, having previously carefully picked off the dried leaves, and any other extraneous matter that may be found upon it. The earth and roots, thus collected, are to be thrown into a fine brass-wire sieve, that will not permit the smallest roots to pass through it; the sieve is then to be worked in a large vessel or tub, nearly filled with water; the earthy part will, in consequence, be dissolved and washed away, and the roots will remain in the sieve, where, by a little management, they may be easily separated from the stones, &c. which are mixed with them. The upper rim of the sieve must, at all times, be held above the surface of the water, otherwise some of the smallest roots will be lost, as they are frequently found floating on the surface, till they have imbibed a sufficient quantity of water to make them sink. The roots are to be dried and preserved, and are to be planted at the latter end of October, or beginning of November; the greater part, or such as have two or more claws, will blow strong the following summer. The Rev. W. Williamson sows half his seed in autumn, and the other half in January, in the open air. He prefers the autumnal sowing, if the winter proves mild.

6265. By offsets. Unlike the offsets of the hyacinth and tulip, those of the ranunculus generally attain perfection in the season of their formation on the parent plant, and are therefore fit to be planted as full-grown tubers the same season in which they are removed. Smaller ones, which are unfit to bloom the following year, may be planted in a bed prepared as to be directed for the full-sized roots.

6266. By dividing the tubers. "In minutely examining the crown of a ranunculus-root, several small protuberances will be found; from each of which a shoot will arise, and the root may therefore be divided by a sharp knife into as many parts as there are protuberances; and thus the danger of losing any rare variety is much diminished. These sections will not bloom till the second year." (*Hort. Trans.* iv. 380.)

6267. Choice of full-grown roots. Select such as are sound and full in every part, and have plump and prominent buds.

6268. Soil and situation. According to Maddock, a fresh, strong, rich, loamy soil is preferable to all others. Hogg recommends fresh loam, with a considerable portion of rotten horse or cow dung. The Rev. W. Williamson (*Hort. Trans.* iv. 375.) uses a stiff clayey loam with a fourth part of rotten dung. The situation should be open, but not exposed to violent winds or currents of air. "The bed should be dug from eighteen inches to two feet deep, and not raised more than four inches above the level of the walks, to preserve the moisture more effectually: at about five inches below the surface should be placed a stratum of two-year-old rotten cow-dung, mixed with earth, six or eight inches thick; but the earth above this stratum, where the roots are to be planted, should be perfectly free from dung, which would prove injurious, rather than of benefit, if too near them. The fibres will draw sufficient nourishment from it at the depth above mentioned; but if the dung was placed deeper, it would not receive so much advantage from the action of the air, which is an object of consequence."

6269. Planting. "This may be done either before or after winter: if the soil and situation is remarkably cold and wet, it will be better to defer planting till the middle or end of January or beginning of February, as the weather may favor; but, in other situations, the latter end of October or beginning of November is to be preferred, as the roots will have more time to vegetate and form themselves, and will in consequence bloom rather stronger, though only a few days earlier than those later planted. A bed, consisting of the variety called the scarlet-turbaned ranunculus, will produce a most brilliant effect; if planted at the same time as the tulip-bed, they will bloom together; they are harder than any other ranunculuses, but may, in other respects, be treated in the same manner. The surface of the bed should be raked perfectly even and flat, and the roots planted in rows, at the distance of about five inches from each other. It is better to plant in shallow trenches, made nearly two inches deep, than to make holes for the reception of the roots: there should be a little clean coarse sand sprinkled into the trench, and the roots should be placed with their claws downwards, from three to four inches asunder, according to their size: when the trench has received its roots, it should be carefully filled up level with the same earth that was taken out, so as to cover the root exactly one inch and a half deep, which is the only true depth to procure a good bloom: it is pointed out by nature in a singular manner; for when these roots have been planted too shallow or too deep, in either case, a second root is formed at the proper depth, by which the plant is weakened to such a degree that it seldom survives a repetition of it. Williamson plants in spring, but never after the tenth of February; and he frequently plants the roots in the same place for several years successively." (*Hort. Trans.* iv. 376.)

6270. Future culture and management. Ranunculus-roots will remain several days in the ground after planting, before they begin to vegetate; during this period, they become very much swelled, by imbibing the moisture of the soil, and are, in this state, extremely susceptible of injury from frost, much more so than when vegetation has actually taken place. As soon as the bed is planted, a sufficient quantity of barley or oat straw should be placed near it, ready for a covering: in case of frost, it may perhaps be

necessary, during a very severe winter, to cover the bed in this manner ten or fifteen inches thick; but the straw should be taken off at all favorable times: for the effects of covering too much or too long are as destructive as the reverse, especially before the roots have begun to vegetate, because they are then more liable to become mouldy than at any other period, than which nothing can be more prejudicial. Early in the spring, when the plants make their appearance above ground, so as to render the rows easily discernible, the surface of the earth between each row should be trodden or beaten, so as to make it firm and compact; and if the soil is compressed with the fingers, quite close to the plants, it will keep out cold drying winds, and prove beneficial. It is advisable to make choice of a fine dry day, soon after rain, whilst the ground is still moist, to perform the above operation: when it is finished, a little long straw should be placed between each row, to preserve the surface of the soil cool and moist, till the foliage of the plants is sufficiently grown and expanded, to afford it shade without further assistance.

6271. *Water.* April showers, and frequent rains in May, are essentially necessary to the growth and vigor of the plants: if these fail, soft water must be administered in sufficient quantity between the rows, by means of a common watering-pot, with a long tube or spout, held low, so as not to wash the earth into holes; for it is better to avoid watering the plants themselves, as it may chill them too much, and stagnate their juices. The consequences of omitting to water when necessary are these, viz. the plants will make little progress; the blossom-buds of the strongest will be small, and the weaker plants will not bloom at all; the grass, or foliage, will put on a sickly yellowish appearance, from which it will never recover during the season; and, lastly, the roots will, when taken up, be small and lean. But such kind of waterings, however necessary, are by no means so salutary to these, or any other flowers, as fine, warm, natural showers; they can neither be so equally dispensed, nor are the plants naturally disposed to receive them when the atmosphere is dry, because their pores and fibres are contracted, and they are, as it were, in the expectation of dry weather. Since it is evident that artificial waterings are, in all respects, so much inferior to natural, it is better therefore to wait a day or two, in hopes of a change of weather, than to be too hasty in watering, although the plants may appear to suffer for the moment, by the omission; for if such a change should fortunately take place, they will receive infinitely more benefit from it than when both themselves and the soil are already saturated, or replenished, with moisture.

6272. *Shading.* The weather in May is sometimes very clear and hot; the plants ought to be shaded at such times by means of lofty hoops and mats, or some better contrivance, that will admit light and air freely; a frame and covering, similar to that for hyacinths, would answer best, if expense and trouble were not to be considered: it will, however, be absolutely necessary to shade them, in some manner, during the period of bloom, otherwise they will continue but a very short time, especially the dark rich-colored sorts; for, in proportion as their colors approach to black, is the injury they will receive from the rays of the sun, if permitted to shine upon them in full force; some of the very darkest cannot stand it one hour without being entirely spoiled. The light-colored sorts will bear the sun's rays much better, reflecting them in proportion as they approach to white; green is the only color that reflects and absorbs the rays of light in equal proportion, and is more predominant in the vegetable kingdom than any other. After the bloom is over, watering is no longer necessary, but shading, in the middle of hot days, is still very beneficial to the plants: it tends to prolong their vegetation, and the size and substance of the roots are thereby increased.

6273. *Taking up the roots.* By the end of June, or soon after, the greater part of the plants will appear brown and dry: vegetation has then ceased, and it is the exact time to take up the roots, because if they are suffered to remain in the ground till rainy weather ensues, they will begin to shoot afresh, and thereby sustain considerable injury. When the roots are taken up, their stems, &c. should be cut off close, and they should be placed in a shady airy room, or situation, to dry gradually; but before this is perfectly accomplished, it will be proper to clean and separate them, because, when quite dried, they become very hard and brittle, and there is great danger of breaking off their claws: some may be separated into many complete roots, although they are so closely connected, as, on a superficial observation, to have the appearance of only one large root. Nothing more remains to be done, till the return of the planting season, except to stow the sorts separately in bags or boxes, for the sake of convenience, in a dry room, in which state it is possible to keep them out of ground for two or three years without perishing, although it evidently tends to weaken and injure them: there have been instances known of the ranunculus-roots surviving till the fifth or sixth year; they were, however, rendered extremely weak, nor could any but very strong roots retain their vegetative powers for so long a period. Williamson takes up the roots immediately after the color of the foliage begins to change.

6274. *Forcing.* The ranunculus may be forced, but loses much of its strength of stem and brilliancy of color.

SUBSECT. 4. *Anemone.*—*Anemone*, L. *Polyand.* *Polygyn.* L. and *Ranunculacææ*, J. *Anémone*, Fr.; *Windblume*, Ger.; and *Anemone*, Ital.

6275. There are two species of *anemone* cultivated as florists' flowers, under the common name of *anemone*: the *A. coronaria*, L., or poppy-anemone (*Bot. Mag.* 841.) (fig. 594. a), a native of the Levant, and introduced in 1596; and the *A. hortensis*, the star or broad-leaved *anemone* (b), a native of Italy, and introduced from Holland in 1597. The *anemone* has been cultivated from as early a period as the tulip, and many fine double varieties produced both by the Dutch and British. The single and semi-double flowers are nearly in as high estimation as the double ones.

6276. *Varieties.* These are numerous, but few of them are named. Parkinson, in 1629, enumerates thirty sorts of single narrow leaved *anemones*, and nearly as many double and single of the broad-leaved sort. Mason's catalogue for 1820 contains seventy-five sorts. A variety will last for twelve or fifteen years.

6277. *Criterion of a fine double anemone.* (fig. 595.) "The stem should be strong, elastic, and erect, not less than nine inches high. The blossom, or corolla, should be at least two inches and a half in diameter, consisting of an exterior row of large substantial well rounded petals, or guard-leaves, at first horizontally extended, and then turning a little upwards, so as to form a broad shallow cup, the interior part of which should contain a great number of long small petals, imbricating each other, and rather reverting from the centre of the blossom; there are a great number of small slender stamens, intermixed with these petals, but they are short, and not easily discernible. The color should be clear and distinct when diversified in the same flower, or brilliant and striking if it consists only of one color, as blue, crimson, or scarlet, &c., in which case the bottom of the broad exterior petals is generally white; but the beauty and contrast is considerably increased when both the exterior and interior petals are regularly marked with alternate blue and white, or pink and white, &c. stripes, which in the broad petals should not extend quite to the margin."

6278. *Propagation.* By seed for new varieties, and by dividing the root for continuing approved sorts.

6279. *By seed.* Select "single or semi-double flowers, that have strong, tall, and erect stems, large well formed cups, and petals of very brilliant colors. The seed must be gathered from time to time as it opens; for, being very downy and light, it will otherwise be blown away by the first breeze of wind, or fall down and be lost: it may be sown at the same time, and be treated in all respects like that of ranunculuses; the seedlings will, like those, blow strong the second year. It will be found very difficult to sow anemone-seed in a regular manner: it is united with, and enveloped in a downy substance, that upon being put together in quantity, adheres in such a manner as to render it necessary to make use of some sand or earth to separate it on sowing; nor will this be effected sufficiently without considerable labor in rubbing it for a long time amongst the earth, as it ought not to adhere together in lumps, which would not allow the young plants space enough to form their roots. There will be found but few double flowers amongst the seedlings, nor can it hardly ever be expected there should, if the seed be entirely saved from single ones; of course, the greater number of broad petals the flower of the seed-bearer possesses, so much greater is the probability of procuring large double flowers from the seed of it."

6280. *By dividing the root.* When the division is properly made, every piece will blow the first year, and is therefore to be treated in the same way as such as are full-grown.

6281. *Choice of full-grown roots.* Select fresh plump roots of moderate size; large overgrown roots, which are hollow in the centre and often decayed, are to be avoided, as they never blow strong.

6282. *Soil and situation, and preparation of the bed.* The same as for the ranunculus.

6283. *Planting and future culture.* The distance between the roots may be the same as for the ranunculus. Attend to place that side of the roots next the soil in which the decayed rudiments of small thread-like fibres will be observed, and cover about two inches deep. "Anemones are harder than ranunculuses, and, consequently, may be always planted in the autumn with safety; the most advisable time is about the middle of October, by which means they will blow a week or two earlier than the tulips: if they are planted ten days or a fortnight after the tulips, they will all bloom together; but a few days earlier or later in the planting will scarcely be perceptible at the time of flowering: it is, however, proper to observe, that such roots as are planted in October, will blow stronger, and, when taken up, will be found of a larger size than those that are planted towards the end of November, especially if the winter proves mild; but if the winter sets in early, and proves severe, late-planted roots will not have time to vegetate before frosty weather takes place; in which case there will be great danger of their perishing, unless they are covered with straw, just sufficiently to keep frost from the roots, as they are then in a state of inactivity, but replete with moisture, which renders them more susceptible of injury from frost, and, at the same time, in much greater danger of mouldiness than after vegetation has commenced. The covering must therefore be taken off and put on, as often, and in such proportion, as the exigency or circumstance of the case requires." Water and protect from high winds and heavy rains, as directed for ranunculuses.

6284. *Taking up the roots.* "Anemones continue longer after bloom in a state of vegetation than ranunculuses, probably because of their greater degree of succulency; and even at the proper time to take them up, it will sometimes happen, that part of their foliage will not be entirely divested of greenness and moisture; this will often be the case when frequent showers of rain intervene, and are admitted between the times of blowing and the maturity of the roots: when it thus happens, much skill is required to ascertain the critical period to take up the roots; for if they are suffered to remain in the damp or wet ground a few days too long, they will shoot afresh, and be thereby materially weakened and injured; it is, indeed, better to take them up rather too early, than suffer them to re-vegetate in this manner; but the roots will not be so firm and solid as if done at the exact time. The safest and most effectual method to preserve them from these disagreeable consequences, is to keep off all rains after the bloom is quite over, by means of mats or hoops; the roots will then regularly and gradually mature, and the foliage will, in like manner, become brown and dry, which will point out the true time to take up the roots; and this will usually happen to be about a month after full bloom. The whole subsequent treatment of the roots, till the time of planting, is the same as for ranunculuses, with only the following caution, viz. that as the roots are exceedingly brittle, it is necessary to handle them very gently upon dressing or cleaning away their fibres, and the soil that adheres to them; however, should only small pieces break off, such should not be thrown away, as each will, in the course of a few years, become a blooming root, if it has an eye, without which it is of no value; but that seldom happens to be the case." (Maddock.) Anemones may be forced like the ranunculus; but, as it generally destroys the roots, the finest sorts should not be devoted to this purpose.

SUBJECT. 5. *Crocus*. — *Crocus*, L. *Trian.* Monog. L. and *Irideæ*, B. P. *Safran*, Fr.; *Safran*, Ger.; and *Zaffarano*, Ital.

6285. The bulb of the *crocus* is round, solid, and compressed, with a netted skin, from the centre of which arise four or five grass-like leaves, and one or two flowers. Out of the centre of the tube of the flower arises a slender style, crowned by a broad flat stigma of a gold color. After the flower is past, the germ, which hitherto was seated on the bulb at the base of the tube, pushes out of the ground, and ripens its seeds; a singular economy in nature, and which occurs only in the colchicum, and a few other plants. All the known species of this genus may be considered as florists' flowers. Many botanists, indeed, reckon only two species, the *C. vernus*, or spring-blowing *crocus*; and the *C. sativus*, the saffron, or autumn *crocus*.

From the *Crocus vernus* (Eng. Bot. 343. and our fig. 596.), they consider that the *C. versicolor* (fig. 597.), the *C. biflorus* (fig. 598. a), the *C. asiatica* (b), the *C. alpinus* (c), and the *C. masiacus* (d and e), with their numerous subvarieties, have been produced by culture or locality.

From the *Crocus sativus*, or saffron-crocus (Eng. Bot. 343. and our fig. 599. a), they think it likely that the *C. serotinus* (fig. 599. b) and the *C. nudiflorus* (fig. 599. c) have been also originated by cultivation or accident.

6286. All the sorts of *crocus* have been, time out of mind, and still are, great ornaments to the garden; the spring sorts coming into flower in February and March, and the autumn sorts in September and October. The color of the spring *crocus* in its wild state, in Switzerland, is white with a purple base; it is considered as naturalised in England, but, when found wild, is almost always of a yellow color. The autumn *crocus*, or saffron, is also found wild in some places, and considered as naturalised; but it appears to be an African plant, which its Arabic name, *sahafaran*, seems to justify, and introduced originally in Edward the Third's time. Its color is generally purple or blue, as is that of most of the autumn varieties in cultivation at present.

6287. *Varieties*. None of these are double. Of the spring *crocus*, Parkinson has enumerated twenty-seven varieties; the fundamental colors of which are blue, purple, yellow, and white. Miller recites twelve as leading sorts. Mason's catalogue for 1820 mentions "twenty named sorts," besides the light, dark, and striped purple, cloth of gold, the Scotch *crocus* beautifully striped, the white, the large and small yellow, and several striped sorts. The Dutch are continually producing new varieties, as are some florists in this country, of which Haworth (*Hort. Trans.* i. 122.) may be cited as an instance. Of the autumn *crocus*, Parkinson has enumerated four, and Ray six varieties. Miller has only four: the sweet-smelling, of a deep blue; the mountain, of a paler blue; the many-flowering, bluish; and the small-flowering. Most of these varieties are now lost.

6288. *Criterion of a good crocus*. Clear or brilliant colors, and each color distinctly marked and finely pencilled in the striped and variegated sorts.

6289. *Propagation*. By seed, for new varieties; and by offset-bulbs, for common

purposes. The latter generally flower the first spring after planting, and are treated in all respects as full-grown roots.

6290. *By seed.* The following directions are by Haworth. "The seeds of crocuses are best sown, immediately after being gathered, in light dry earth, in large pots, or pans, or small shallow boxes, with a sufficiency of holes and potsherds at the bottom, for the purpose of draining off with certainty all superfluous moisture thinly; for almost every seed will vegetate, and cover not more than half an inch with the mould. The most eligible aspect, or situation, for the seminal boxes, until the autumnal rains set in, is a moderately shady yet unsheltered one: permitting them to receive all the influence of the weather, except such heavy showers as would wash bare the seeds. As soon, however, as the autumnal rains commence, remove the boxes to a warm aspect; and protect them from all excessive rains, frosts, and snows, by the occasional shelter of a garden-frame: allowing them, nevertheless, the benefit of the full air at other times, but more especially after the seminal leaf (for they have but one, being monocotyledonous plants), eager to commence the career of life, urges its fine setaceous point above the surface of the earth. This occurs sometimes about the end of the year; but oftener in earliest spring. After this it is quite essential that they should have complete exposure to the air, even in frosty weather; screening them, however, occasionally, like early radishes, with loose straw, from other injurious effects of frost; so as to prevent their being raised out of their infantile beds by its baneful effects. In this manner may the young crocuses be treated until the sun acquires sufficient power to dry the earth in their boxes, so as to require daily waterings. It will be then found advantageous to remove them to a cooler, but not sheltered situation, and here they may remain until their leaves die down; giving them, as just hinted, at all times, and in every situation, while their leaves are growing, such discretionary rose-waterings, when the sun is not shining, as they may reasonably appear to require: but never until the earth they grow in becomes dry: not any whatever, after their leaves begin to look yellow. After this period, it is necessary to defend them from all humidity, except dews and gentle rains, until the end of August, or beginning of September."

6291. *From weeds, worms, slugs, and snails,* "it is almost needless to observe, they should constantly be kept as clear as possible. And if the surface of the earth in their boxes is occasionally stirred with the point of a knife, or fine piece of stick, it will never fail to be attended with beneficial effects, and invigorate the bulbs: operating no doubt, as a sort of hoeing, and, like that important practice, (as the writer of this paper conceives,) proving salubrious to vegetables of every denomination, not only by lightening the soil, but by admitting new access of atmospheric air towards their roots; and thereby facilitating, and stimulating their absorbent inspiration of its oxygen: without a due supply of which all vegetables, as well as animals, eventually become feeble and sick. If, notwithstanding the precaution of thinly sowing the seeds, the plants in any of your seminal boxes should have grown so thickly together as to have incommoded each other, it will be desirable to have such taken up, and replanted immediately further asunder in fresh earth, and about three quarters of an inch deep. But if they are not too crowded, they will require no shifting this their first autumn; but merely about a quarter of an inch of fresh mould sifted over them, previously stirring and cleaning the surface of the old from moss and weeds; and observing not to bury the young bulbs not yet so large as lentils, deeper than three quarters of an inch, or an inch at the most. The second season requires exactly the same management as the first. But as soon as their second year's foliage has passed away, the roots should all be taken up, and replanted again the same or following day, into fresh earth, of the same kind as before, about an inch deep, and as much apart, and treated as above. Nor does the third season demand any alteration in their management; sifting over them in autumn half an inch of fresh earth. The spring following, if they have been duly attended to, most of them will show flowers (a few, perhaps, having done so the season before) in the midst of their fourth crop of leaves; fully rewarding with the cheering colors of their new faces all the preceding assiduity and care." (*Hort. Trans.* i. 125.)

6292. *Choice of bulbs.* Observe that the base is not mouldy, nor the bud or summit of the bulb decayed.

6293. *Soil, situation, and culture.* They will grow in any common soil, but prefer a loamy sand. October is the best season for planting; the more select varieties are grown in beds like the hyacinth, and the colors mingled in the same manner; the distance from bulb to bulb about three inches. The more ordinary sorts are grown as border-flowers, and form an important part of the early flowers of the front row. (*fig. 552. a*) They are very hardy, and require no care till the leaves begin to fade, when they should be taken up, and kept in a state of rest for two or three months. Some do not take them up oftener than once in three years, which answers very well for the border sorts. Even these, however, should not be left longer, because, as the young bulbs are formed on the tops of the others, they come nearer to the surface every year, till at last, if neglected, they are thrown out and lost.

SUBJECT. 6. *Narcissus.* — *Narcissus*, L. *Her. Monog.* L. and *Amaryllideæ*, B. P. *Narcisse*, Fr. and Ger.; and *Narcisso*, Ital.

6294. *The bulb of the narcissus* is pear-shaped and tunicated, the leaves succulent and linear, and the flower-stems, which are from six to eighteen inches in height, bear either solitary or fasciculated flowers; the color of the flower is either white or yellow, and generally odoriferous. Most of the species are natives of the south of Europe, but one, the *N. Pseudo-Narcissus*, is a native of England, and common in woods in clayey soils. They come into flower in February, March, and April.

6295. *Species and varieties.* The popular division of this genus is into daffodils, white narcissus, jonquils, and polyanthus narcissus.

The daffodils are *N. Pseudo-Narcissus* (*Eng. Bot.* 17.), of which the varieties are the common double, the double with white petals and a yellow cup, the single with yellow petals and a golden cup, three or four concentric cups, iridescent's daffodil, and above a dozen other nameless varieties; the peerless, or two-flowered daffodil (*N. biflorus*) (*Eng. Bot.* 276.), and a variety (*N. b. a. tenior*) with one flower only on the scape; the two-colored daffodil (*N. bicolor*) (*Bot. Mag.* 1187.), a native of Spain, and a variety of the great yellow Spanish, the largest flower of the genus; the least daffodil (*N.*

minor) (*Bot. Mag.* 6.); the rush-leaved (*N. triandrus*) (*Bot. Mag.* 48.); and some other species and varieties. The white narcissi are the poets' narcissus (*N. poeticus*); the early-flowered (*N. p. a. unguiculatus*); and the late-flowered (*N. p. b. majalis*); the musk-narcissus (*N. moschatus*) (*Eng. Bot.* 1300.); the eastern narcissus (*N. orientalis*) (*Bot. Mag.* 948.); and the yellowish and large-flowered varieties; the hoop-petticoat narcissus (*N. bulbocodium*) (*Bot. Mag.* 88.); and the paper narcissus (*N. papyraceus*), with other varieties

The jonquils are the common (*N. jonquilla*) (*Bot. Mag.* 15.), so named from its rush or jonc-like leaves; the double-flowered jonquil; the sweet-scented jonquil (*N. odoratus*) (*Bot. Mag.* 934.); the great jonquil (*N. calathinus*) (*Bot. Mag.* 78.); and some minor varieties. The polyanthus narcissi are the common (*N. tazetta*) (*Bot. Mag.* 925.); the sulphur-colored, single and double; the white and yellow, single and double; and above a hundred other sorts, with arbitrary names given by the Dutch, who have highly improved this division of the genus. Some of these sorts are considered species by botanists.

6296. *Criterion of a good narcissus.* Strong erect stems; regularity of form and disposition in the petals and nectars; distinctness and clearness of color; and in the many-flowered sorts, the peduncles all of the same length, and coming into flower at once.

6297. *Propagation.* By seed for new varieties, but generally by offsets, which, as they

seldom flower the first year after separation, should not be planted with the full-grown roots, but in a bed of light loamy soil by themselves in the reserve-garden. They should not be planted later than the beginning of September.

6298. *By seed.* Miller directs to sow in flat pans, filled with fresh, light, sandy earth, about the beginning of August, soon after the seed is ripe; to place the pans where they will receive only the morning sun till October. Then expose them to the full sun, and protect them from heavy rains and frosts till April, when they will have come up, and must be removed to their first situation. In June, the leaves will have decayed, when some fresh earth is to be shifted over the surface of the pans. Treat them in other respects during the second winter as during the first. The end of the second summer after sowing, the roots are to be taken up and planted at about three inches' distance every way, in beds raised and rounded to throw off the water. These beds are to be protected in winter by old tan-ashes or haultm. After remaining two years in this situation, they are to be taken up and planted in others, dug deep, and with a little rotten cow-dung buried in the bottom of the fibres to strike into. Here the roots are to be planted at six inches' distance, having earth sifted over them when the leaves decay, and tan or ashes in winter. The second season of their growth in this bed, that is, the fifth from sowing, most of the bulbs will come into flower. Such as are esteemed good flowers may be taken up and treated as full-grown bulbs; but those which have not flowered, or of which the flowers are of doubtful excellence, may remain another year. Miller says, none should be rejected till they have flowered two or three times: as it often happens, that their first blowing is not near so beautiful as their second and third.

6299. *Choice of full-grown bulbs.* Select such as are rounded towards the base rather than compressed, with full sound tops, and bottoms free from mouldiness or decayed fibres.

6300. *Soil, situation, and planting.* As eastern aspect is to be preferred; and, according to Miller, the best soil is fresh, light, hazel loam, mixed with a little very rotten cow-dung. The bed in which they are to be planted must be excavated three feet deep, and filled with this compost, and then the roots planted on it about eight inches' distance every way, and covered from six to eight inches, in the manner directed for tulips. The best time for planting is August, or the beginning of September.

6301. *Culture.* Stirring the soil, weeding, and watering are all that is in general required: but such as wish to produce a very perfect show of flowers, shelter with an awning in the manner recommended for hyacinths. In winter, the beds require the protection of tan or litter, which should be put on in October or November, and removed, and the soil stirred in February or March. Where the narcissi are cultivated for commercial purposes, the strength of the bulb is greatly increased by cutting off the flower-stem when the flowers begin to expand. The flower is still valuable, being expanded till in a marketable state by inserting the stalk in water. "Some years ago I gained admittance into the grounds of Daniel Carter, at Fulham, who has long cultivated large quantities of polyanthus narcissuses for sale, and was surprised to find all the crop nearly gathered, though very early in the season. His son, however, explained the mystery, by taking me into a large barn, which was filled with the gathered flowers, blowing in pans of water; and he told me that by doing this, the bulbs continued to produce as abundant crops every year, as new ones imported from Holland. The practice was suggested to him by remarking, that in a bed left for seed one year, very few roots sent up a complete bunch of flowers the following season, and many roots none at all. He therefore now cuts off the stalk close to the ground, as soon as two or three of the flowers are expanded, but is very careful not to injure the leaves." (*Hort. Trans.* i. 352.)

6302. *Taking up the bulbs.* The bulbs should not be taken up oftener than every third year, if they are expected to flower strong and make a great increase. If they remain longer than three years, the offsets will become so numerous as to weaken the bulbs, which will at first flower weakly, and in time cease almost entirely to show flowers. The Dutch take up these roots every year, because their object is to furnish a round plump root, and the way to accomplish this is to take off the offsets annually, to prevent their pressing against and flattening the parent bulb. The bulbs being dried in the shade, may be laid in an airy situation in the seed-loft till wanted for planting.

6303. *Forcing.* These bulbs force well, and either in deep pots of sandy loam, or in water-glasses; their previous treatment is the same as we have prescribed for the hyacinth; and they are highly odoriferous and ornamental in apartments.

SUBJECT. 7. *Iris*. — *Iris*, L. *Trian.* Monog. L. and *Iridææ*, B. P. *L'Iris*, Fr.; *Schwerlilie*, Ger.; and *Iride*, Ital. (figs. 600, 601.)

6304. There are several species of *iris* which are considered florists' flowers.

The Persian *iris* (*I. Persica*) (*Bot. Mag.*, and our fig. 601 a); a very low bulbous rooted plant, with delicate blue and violet-colored flowers, greatly esteemed for their beauty and sweet smell, which is so powerful that one plant will scent a whole room. It is a native of Persia, and was cultivated by Parkinson in 1629. The bulbs are ge-

nerally imported from Holland, and blow in water-glasses, or pots of sand with very little earth intermixed, in February and March.

The snake's-head *iris* (*I. tuberosa*) (*Bot. Mag.* 531. and fig. 601 b) has long narrow four-cornered leaves, and a dark purple flower, which appears in April. It is a native of the Levant, and was

cultivated in 1597. The tubers are generally imported from Holland.

The Chalcedonian *iris* (*I. sasianna*) (*Bot. Mag.* 91. and fig. 600 c) has finely striated leaves, a scape a span high, and the largest and most magnificent corolla of all the species. Its petals are of a delicate texture, almost as broad as a hand, purple or black,

striped with white. It flowers in the beginning of June; is a native of the Levant, and was cultivated by Gerrard in 1596.

The bulbous-rooted, or Spanish iris (*I. siphium*) (*Bot. Mag.* 686, and *fig.* 601. a) has channelled leaves, convoluted during their whole length, and awl-shaped at the tip; the flowers of the

wild plant are blue, with emarginate petals, and appear in June; but cultivation has produced a great number of varieties with yellow, white, violet, and variegated flowers. It is a native of the south of Europe, and was cultivated by Gerrard in 1596.

The great bulbous-rooted iris, the English iris of the Dutch, (*I. siphionides*) (*Bot.*

Mag. 602. and *fig.* 601. b), is much larger than the other in all its parts, the flower-stalk is near twice the height, and the flowers are more than double the size. It is equally prolific in varieties as *I. siphium*, of which it is by some botanists considered only a variety. The tubers of both sorts are annually imported from Holland.

6305. Culture of the first three species. These seldom ripen their seeds in this country, nor are they often propagated here from offsets, annual supplies of bulbs being obtained from Holland, and generally forced like the hyacinth. Justice says (*Brit. Gard. Direct.* 222.) the Dutch florists told him, that they never could obtain any varieties from sowing the seeds of the Persian iris; nor could this author himself, who cultivated the plant, and raised seedlings at Crichton, near Edinburgh, with great care and considerable success. The three sorts are best cultivated under the protection of a frame, where their flowers will be less liable to injury than in the open air, and where their leaves will be stronger and more able to nourish the bulbs and offsets. The Chalcædonian iris, Curtis observes, thrives best in a loamy soil and sunny exposure, with a pure air, but guarded from moisture, and from frosts during winter. The Persian iris thrives best in a light sandy loam and eastern exposure, sheltered from rains and frosts, like the other. The snake's-head iris is the hardiest of the three, requires the same soil and exposure as the Persian, but less care during winter. None of these sorts need be taken up oftener than once in three years, when the leaves decay; they should be replanted in a month or six weeks afterwards, at six inches' distance every way, and covered from two to four inches according to the size of the bulbous tuber. If the soil in which the bulbous and tuberous sorts of iris is planted be loose and deep, and the plants not taken up every three, or at most four years, they will run down and be lost.

6306. Culture of the bulbous irises. Miller and Justice recommend a light sandy loam, not rich, and an eastern exposure. The plants are multiplied abundantly by offsets, and as they also produce seeds freely, many new varieties are obtained in that manner. Justice says, he raised a great number with very little trouble (*Brit. Gard. Direct.* 430.); and Masters says, "I know of no flower that better repays the time and attention of the horticulturist." The following are this author's directions for its propagation by seed. "In August the seeds become ripe, and are plentifully produced on all seedling plants, although, like many other plants, but sparingly, and very frequently not at all, on such as have been long increased by offsets, or parting the roots; they may be sown in slight drills, about six inches asunder, as soon as ripe; and in the March following, they will make an appearance very similar to rows of young onions. With no other care than frequent weeding, they may remain in the seed-bed for three years, for they are much more hardy than most kinds of seedling bulbs, and, therefore, will not even require protection from the frosts. In August or September of the third year, it will be necessary to transplant them into beds, at one foot's distance, row from row, and the bulbs six inches apart; and in two years from their removal, most of the strongest will show blossom, and nearly all in the year following, or the sixth from the seed. If, during the time the roots are at rest, the top surface of the earth is carefully removed, and fresh light loam is substituted, a year will be saved, for this treatment will greatly promote the growth of the bulbs, and with these, as well as many other seedling plants, it is not a stated time that must pass before they blossom, but only such a portion as will allow the bulb to attain a size sufficient to contain vigor to produce and perfect a flower-stem, the rudiment of which is formed in the preceding summer. When they blossom, a selection can be made, and the varieties perpetuated by the increase of their offsets. The most proper time for removing the bulbs is in August and September, those kept out of ground until Christmas rarely blossom in the succeeding summer." (*Hort. Trans.* iv. 413.)

6307. Flowering bulbs. Every third year, in August, is the most proper time for taking them up; and they should, if possible, be replanted in September following. Masters says, those kept out of ground till Christmas rarely blossom in the succeeding summer. They may be planted either in beds, at eight inches or a foot distant every way, or in mingled borders, care being taken in either case to prevent the roots running down by removal every third year, or by a substratum of tiles or compact rubbish within eighteen inches of the surface. These species are very hardy, and flowering so late as June, require no protection either in summer or winter. They are seldom or never forced.

SUBJECT. 8. Fritillary. — *Fritillaria*, L. *Hexan. Monog.* L. and *Lilia*, J. (*fig.* 602.)

6308. Of the fritillary there are three species which are considered as florists' flowers; of these species there are numerous varieties.

The crown-imperial (*F. imperialis*) (*Bot. Mag.* 194.) (*La Couronne Imperiale*, Fr.; *Kaiserkrone*, Ger.; and *La Corona Imperiale*, Ital.) (*fig.* 602. a) has a scaly bulb, from which arise strong stems, from two to four feet in height, furnished with numerous broad shining green leaves, and crowned with a whorl of showy pendulous flowers, yellow, red, or striped in various ways, which appear in March and April. It is one of the earliest ornaments of the flower-garden, producing a fine appearance in the middle of large borders, at a season when such flowers are most wanted. The "singular nectary," Professor Martyn observes, "cannot but engage the attention of the curious observer; it is a white glandular cavity, as the base of each petal, and has a drop

of limpid nectareous juice standing in it, when the flower is in vigor. Another of the wonders of nature may be observed in the peduncles which bend down while the plant is in flower, but become upright as the seed ripens." There are above a dozen varieties in cultivation, distinguished by the different shades of yellow, white, and red in the flower, and by being striped double or semi-double.

The Persian fritillary (*F. persica*) (*Bot. Mag.* 1557, and *fig.* 602. b) has a large round root, the size of an orange; the stem is three feet high, and the flowers in a loose spike at the top, forming a pyramid. They are of a dark purple color, and appear in May, but seldom produce seeds in England. It is a native of Persia, and

was cultivated here in 1596. There is a smaller variety, with a shorter stem, and smaller leaves and flowers.

The common fritillary, or chequered lily, (*F. meleagris*) (*Eng. Bot.* 602.) (*La Fritillaire Melagre*, Fr.; *Kiebitzey*, Ger.; and *Giglio variegato*, Ital.) (*fig.* 602. c), has a solid tuber, about the size of a nut, a stem from twelve to eighteen inches high, with linear leaves, and one or more pendulous flowers on the top of the stem. It is a native of Britain, and flowers in April and May, or in March in mild seasons. There are nearly twenty varieties, with red, white, purple, black, striped, and double flowers, besides an umbellate fritillary, a mule between this species and the crown-imperial.

6309. *Propagation.* The common method is by offsets; but they may be raised from seed, which ripens readily, and is to be treated in all respects like that of the tulip, the seedlings of the crown-imperial flowering in the fifth or sixth year, and those of the two other species in the third or fourth year.

6310. *Culture of flowering bulbs.* They delight in a light soil, not too wet nor very full of dung. It should be dug deep, and the bulbs may be planted six inches deep, and from eighteen inches to two feet distant every way; but they have the best effect in a mingled flower-border. They need not be taken up above once in three years, when the stems are withered in May or June, and they should not be kept longer out of the ground than two months.

SUBJECT. 9. *Lily.* — *Lilium*, L. *Hexand. Monogyn.* L. and *Lilia*, J. *Lis*, Fr.; *Lilie*, Ger.; and *Giglio*, Ital.

6311. Of the lily there are sixteen species introduced in Britain, and the whole of them may be reckoned very choice flowers. We shall notice particularly, only those species, of which numerous varieties have been produced. These are: —

The white lily (*L. Candidum*) (*Bot. Mag.* 278.) has a large scaly bulb, a leafy stem, from three to four feet in height, terminating in large pure white flowers on peduncles. It is a native of the Levant, and was in most gardens in Gerard's time. Of this species there are above eight varieties.

The orange lily (*L. bulbiferum*) (*Bot. Mag.* 36.) has a scaly bulb, a leafy stem, two feet and a half high, terminating in orange-colored flowers. Sometimes

the stem produces small green bulbs in the axille of the leaves. Of this species, there are eight or ten varieties and subvarieties.

The martagon, or Turk's cap, (*L. Martagon*) (*Bot. Mag.* 893.), has a large scaly bulb, a stalk furnished with narrow leaves, near three feet high and terminating peduncles of fine carmine flowers in July. Of this species there are half a dozen varieties, besides the

scarlet martagon (*L. Chalcedonicum*), of which there are also different sorts. Besides the above species and their varieties, there are the *L. Canadense*, *superbum*, or Turk's cap; the *Pomponium*, and *Tigridium*, or tiger lily; the *Japonicum*, or Japan lily, with stems of 5 feet, and the flowers 7 inches broad, pure white with a streak of blue; all equally meriting cultivation as select flowers.

6312. *Propagation.* This is almost always by offset-bulbs; but new varieties may be raised from seed, which ripens in most sorts in August: being treated as directed for raising new varieties of the narcissus, the young bulbs will flower the fourth and fifth years.

6313. *Culture of flowering bulbs.* The more common sorts, species, and varieties, will thrive in any soil and situation, even under the shade of trees. The Canadian, Pomponian, and Philadelphian martagons are somewhat tender, and require the protection of ashes or rotten bark in winter. They are generally planted in borders, and need not be taken up oftener than every three or four years in September, and replanted six inches deep in the October following. None of the species can be safely transplanted, after they have pushed leaves, without weakening them so as to prevent their flowering for several years. This remark, indeed, will apply to most bulbous-rooted plants. Griffin, of South Lambeth, whose superior skill in the cultivation of bulbous plants is well known (*Hort. Trans.* iv. 544.), has been in the practice of keeping the *lilium japonicum* in pots, protected by a green-house or garden-frame; but he thinks they thrive best in the former. He places the bulb in twenty-four-sized pots, not lower than an inch from the surface of the mould, which is composed of about two thirds peat and one third loam, the bottom of the pot being covered to the depth of two inches, with broken pieces of tile and the rough siftings of peat. The plants are kept entirely from frost, and are watered very little when in a dormant state, for they are then very impatient of wet in excess. The pots kept in the green-house are placed at a distance from the flue to prevent the mould drying quickly. (*Hort. Trans.* iv. 554.) Brooks grows in a brick-pit, which he can cover with mats or glasses at pleasure; but he says, it "appears to be sufficiently hardy to endure our winters, as I have had a bed of them two years in the open ground without protection." (*Hort. Trans.* iv. 552.)

SUBJECT. 10. *Amaryllideæ.* — *Amaryllis*, L. *Her. Monog.* L. and *Amaryllideæ*, B. P. *Lis-narcisse*, Fr.; *Narcissenlilie*, Ger.; and *Giglio Narcisso*, Ital.

6314. The *amaryllideæ* is a splendid family, lately subdivided into those of *Nerine*, *Coburgia*, and *Brunsvigia* (see *Bot. Mag.*), of which almost every species may be considered a select flower. The *A. amabilis*, *Josephina*, and *Vittata*, are reckoned the most splendid bulbous-rooted plants; and the *A. formosissima*, or *Jacoba lily*; *Sarniensis*, or *Guernsey lily*; *Belladonna*, &c. are less magnificent, but of very great beauty. Most of the species are green-house or stove plants, and natives of the Cape of Good Hope, China, or South America. Various hybrids of this family have been produced by Herbert, Sweet, Gowen, and others. (*Hort. Trans.* iv. 488. &c.)

6315. *Propagation and culture.* New sorts, as in similar cases, are procured by seed; but the most usual mode, as few of these plants have ripened their seeds in this country, is by offsets from the flowering bulbs, removed yearly, or every time the bulbs are taken out of the ground. The great art in cultivating these, and all other bulbs, is to procure vigorous leaves, as on these depend the quantity of nutritive matter prepared and deposited in the bulb, and consequently its ability to flower the following season. The circumstance of several of these plants, as the *Guernsey lily*, flowering in the autumn, and producing their leaves afterwards under the disadvantages of a winter's sun, is the reason why they have been hitherto cultivated with so little success in this country, and why we are obliged to import the bulbs annually from other countries. The observations of Knight on this subject are particularly valuable; they more immediately refer to the *Guernsey lily*, but they are equally applicable to all exotic bulbs. "Bulbous roots increase in size, and proceed in acquiring powers to produce blossoms, only during the periods in which they have leaves, and in which such leaves are exposed to light; and these organs always operate most efficiently when they are young, and have just attained their full growth. The bulb of the *Guernsey lily*, as it is usually cultivated in this country, rarely produces leaves till September, or the beginning of October, at which period, the quantity of light afforded by our climate is probably quite insufficient for a plant, which is said to be a native of the warm and bright climate of Japan; and before the return of spring, its leaves are necessarily grown old, and nearly out of office, even when they have been safely protected from frost through the winter. It is, therefore, not extraordinary, that a bulb of this species, which has once expended itself in affording flowers, should but very slowly recover the power of blossoming again. Considering, therefore, the deficiency of light and heat, owing to the late period of its vegetation, as the chief cause why this plant so often fails to produce flowers, I inferred that nothing more would be required to make it blossom, as freely, at least, as it does in *Guernsey*, than such a slight degree of artificial heat, applied early in the summer, as would prove sufficient to make the bulbs vegetate a few weeks earlier than usual in the autumn. Early in the summer of 1816, a bulb, which had blossomed in the preceding autumn, was subjected to such a degree of artificial heat, as occasioned it to vegetate six weeks, or more, earlier than it would otherwise have done. It did not, of course, produce any flowers; but in the following season it blossomed early and strongly, and

afforded two offsets. These were put, in the spring of 1818, into pots, containing about one eighth of a square foot of light and rich mould, and were fed with manured water, and their period of vegetation was again accelerated by artificial heat. Their leaves, consequently, grew yellow from maturity, early in the present spring, when the pots were placed in rather a shady situation, and near a north wall, to afford me an opportunity of observing to what extent, in such a situation, the early production of the leaves in the preceding seasons had changed the habit of the plant. I entertained no doubt but that both the bulbs would afford blossoms, but I was much gratified by the appearance of the blossoms in the first week in July. From the success of the preceding experiment, I conclude that if the offsets, and probably the bulbs of this plant which have produced flowers, be placed in a moderate hot-bed, in the end of May, to occasion the early production of their leaves, blossoms would be constantly afforded in the following season; but it will be expedient to habituate the leaves, thus produced, gradually to the open air, as soon as they are nearly fully grown, and to protect them from frost till the approach of spring."

6316. *The Rev. W. Williamson* has adopted the same rationale as Knight; and, with the aid of a glass frame, without artificial heat, brought bulbs which had flowered into a state to flower again after two winters. Had he applied artificial heat, he thinks one winter might probably have been sufficient. (*Hort. Trans.* iii. 450.)

6317. *The Hon. and Rev. W. Herbert* has found a similar treatment attended with corresponding success. He says, "the only attention which the Guernsey lily requires here (Spofforth, Yorkshire), is to give it sufficient air while the leaves are growing, that they may be strong and dark-colored; to protect the leaves from frost, keeping the pots near the light, if under glass; to give a moderate and regular supply of water, and to leave the bulbs nearly dry, from the time the leaves decay, that is, about midsummer, at latest, to the end of August, when the flower-buds should appear. If the bulbs are not left dry early in the summer, the autumnal shoot will be delayed till the season becomes too cold for the proper growth of the flowers or leaves, and the natural course and vigor of the plant will be interrupted, after which it will require at least a year to repair the injury it will have received. Whenever the sprouting of the bulb is tardy, it should be assisted by placing it, for a short time, in a warmer situation. If the stigma does not expand so as to become, after a few days, trifid, it is a sign that the temperature is rather too low to suit the plant, and the leaves will probably not push freely without more heat. I have obtained seed from the Guernsey lily by procuring the blossom early in an airy situation." *The soil* Herbert recommends is a good yellow loam, without any manure; but he thinks "they will thrive in any wholesome compost, which does not canker their bulbs. They should be planted partly above ground, for the wet earth round their necks will prevent their flowering or thriving, and will even sometimes destroy them." (*Hort. Trans.* iv. 177.) The same treatment, with very few exceptions, he adds, suits the whole of the bulbs included under amaryllis, as well as a number of other allied genera, as *hæmanthus*, *pancratium*, *agapanthus*, &c. Some species of these genera, as *Amaryllis longifolia*, W. and *Crinum Asiaticum*, Rox., are natives of dry ditches that communicate at certain seasons with the water of the rivers in Bengal, where they root deeply in the mud. These species, and some others, Herbert found to succeed perfectly when plunged during summer in a pond. "Most of the crinums," he says, "are swamp plants, or grow in river-mud, and should be cultivated in our stoves, with a pan of water under them, the bulbs being raised above the earth, and stripped of all dead integuments. *Agapanthus umbellatus* flowers best when so treated; the *Amaryllis longifolia* (which, he says, should be named *Crinum capense*) will," he has no doubt, "flower as a hardy aquatic, if planted in any pond or river of two feet water, not liable to freeze at the bottom." (*Hort. Trans.* iii. 188.)

6318. *Some account of the culture of the Guernsey lily in the Island of Guernsey* is given by Dr. Macculloch (*Caled. Mem.* ii. 62): there they grow it in the open air, and protect it with sand during winter.

SUBJECT. 11. *Ixiæ* and *Gladioli*, W. *Trian. Monog. L.* and *Irideæ*, B. P.

6319. *The ixiæ and gladioli* include a number of recently formed genera (see *Bot. Mag.* and *Bot. Reg.*) of Cape bulbs, which may be flowered in the open air, under frames without bottom heat, or on shelves near the glass in green-houses. The Hon. W. Herbert, who has paid great attention to the culture of bulbs, is "persuaded that the African gladioli will become great favorites with florists, when their beauty in the open border, the facility of their culture, and the endless variety which may be produced from seed by blending the several species, are fully known, nor will they be found to yield in beauty to the tulip and ranunculus." (*Hort. Trans.* iv. 154.)

6320. *Propagation and culture.* They may either be propagated by seed or offset-bulbs; by the former mode, Herbert has produced numerous beautiful varieties. The proper soil for these and similar bulbs is peat with sand: and in a bed of this compost the seeds should be sown in spring, and well watered before and after they come up. "At the beginning of October, or as soon as the leaves wither, the young bulbs should be taken up and dried; they may be replanted again at any time, placing them about eight inches under ground, to prevent the frost reaching them. Next year they will generally flower." The best way of treating gladioli which are to be flowered in pots is, whenever the bulbs are potted, to plunge the pots about eight inches under ground in a bed of peat, and raise them nearer the surface in spring, as soon as the very severe frosts are over; or not to plunge them so deep, and protect them with moss, leaves, rotten tan, &c.

6321. *Various other bulbous irideæ*, and also *oxalis*, *lachenalia*, *cyclamen*, &c. may be successfully treated in a similar manner. (Herbert, in *Hort. Trans.*; Maddock, in *Flor. Dir.*)

SUBJECT. 12. *Tuberose*. — *Polianthes Tuberosa*, L. (*Bot. Reg.* 63.) *Her. Monog. L.* and *Hemerocallideæ*, B. P. *Tuberose*, Fr. and Ger; and *Tuberoso*, Ital.

6322. *The tuberose* is a bulbous-rooted plant, with linear leaves of a whitish green, and stems four or five feet high, terminating in a sparse spike of white flowers, of very powerful fragrance. It is a native of India, whence it was first brought to Europe about 1524, and to England in 1629. It is generally cultivated in frames or the green-house, but in warm situations will flower in the open air. The tubers of this plant are annually imported from the warm provinces of North America and Italy, but, like those of the Guernsey lily, might, by proper treatment, as Salisbury has proved, be produced in this country equally fit for flowering. There is a double variety, which is in most esteem, but both are equally fragrant.

6323. *General treatment.* The bulbs are planted in pots of sandy loam in March or April, and brought forward in a hot-bed or hot-house till the flower-buds begin to ap-

pear. The plants are then removed to the green-house or the open air, or to halls or churches, as in Italy, where the cooler temperature procures a prolonged bloom.

6324. *Culture to produce flowering roots.* The following is the process followed by Salisbury, by which he produced, for many years, in the open air at Chapel Allerton, flowering bulbs equal to those imported. The situation he preferred was a dry warm border; in this he made an excavation two or three feet deep, and of any convenient length and width; about the middle of April, he filled this pit with fresh stable-dung, and covered it with light sandy earth; then, on the bed so formed, the small lateral roots, or those from foreign bulbs, or from those which had flowered in this country the preceding year, and been preserved through the winter in sand, were planted at five inches' distance every way, the upper part of the tuber being just covered with earth. The bed was protected from nightly frosts and heavy rains, little or no water was given, but when the leaves were an inch long, a little fresh compost was added to the surface. In June and July, when the leaves were in full vigor, it was watered copiously after warm days; but in autumn and the beginning of winter, it was carefully protected from heavy rains. In the beginning of December, the decayed leaves being removed, the bed was thatched over a foot thick with dry straw, sloping it well to throw off the wet; or covered with a frame and litter. In February the roots were taken up, preserving their fibres, and packed in dry sand in a cellar where the cold could not penetrate, till April, when their fibres being shortened in proportion to their decay, and all the offsets excepting one or two on each bulb being removed, they were replanted as before. A few strong roots flowered in this second year. In the succeeding winter the bed was thatched as before, and in February the roots were taken up for forcing, or any of the purposes for which tubercose-roots are grown. By this process bulbs were produced equal, if not superior, to those imported; and therefore the author thinks their culture might become an object to the commercial gardener, especially in the southern counties near the sea, and in the vicinity of London. The great object, he says, is to obtain "a sufficient degree of heat in summer to bring their leaves out to their full magnitude, that of the roots following of course. The theory," he adds, "which I would recommend any intelligent gardener to adopt in its general management is, to keep the roots growing as vigorously as possible from May to October, but in a state of complete rest and drought for the remainder of the year." (*Hort. Trans.* i. 53.)

SUBJECT. 13. *Pæony.* — *Pæonia*, L. *Polyand.* *Digynia*, L. and *Ranunculaceæ*, J. *Pivoine*, Fr.; *Pionie*, Ger.; and *Peonia*, Ital.

6325. Most of the species of *pæony* introduced in this country may be considered as select flowers; but that which has been longest cultivated is the *P. officinalis* (*Bot. Mag.* 1784.) The roots are composed of roundish tubers, the stalks of the leaves rise between two and three feet high, and terminate in large red or purple flowers, which appear in May. The leaves are composed of many unequal lobes, variously cut into many segments. It is a native of Switzerland, Dauphine, and other parts of Europe, and also of China and Japan; and was cultivated here in 1562. The roots were formerly much used in medicine.

6326. *Varieties.* Originally the common *pæony* was said to be of two sorts, male and female, the flowers of the former being smaller and lighter colored than those of the latter. These distinctions, which had no sexual allusion in this case, the *pæony* being hermaphrodite, are now laid aside, and the varieties of *P. officinalis* have been reduced by Sabine (*Hort. Trans.* ii. 273.) to the following:—

The double red; the most common, and formerly highly prized; being, when introduced at Antwerp, near 250 years ago, sold for twelve crowns.

The double flesh-colored
The double white
The double fringed
The double white Chinese

The double sweet-scented Chinese (*Hort. Trans.* vol. ii. pl. 18.)
Whitley's double white Chinese.

6327. *Propagation and culture.* By seed from the single and semi-double sorts for new species, and by dividing the roots for ordinary purposes. Miller directs to sow the seeds which ripen in September, immediately afterwards in light fresh earth, covering them half an inch. They will come up the following spring, and may remain in the seed-bed two years before they are transplanted, sifting a little rich earth over them when the leaves decay at the end of the growing season. Having made two years' growth in the seed-bed, they are to be transplanted in September into other well prepared beds of light fresh earth, and placed six inches asunder every way, and three inches deep. Here they are to remain till they flower, which is generally the fourth or fifth summer after sowing.

6328. *Full-grown roots* are readily propagated by parting, taking care to preserve a bud on the crown of each offset. The plants are very hardy; they will grow in almost any soil and situation, and even under the shade of trees, where, Miller says, they continue longest in beauty. They are chiefly planted in flower-borders, and form a splendid ornament both to the parterre and shrubbery.

SUBJECT. 14. *Dahlia.* — *Dahlia superflua* and *D. frustranea*, H. K. (*Cav. Ic.* i. t. 80. and 266.) *Polyg. Super.* L. and *Corymbifera*. J.

6329. The roots of the *dahlia* are tuberous and fasciculated; the stems rise from five to eight feet, covered with large compound leaves, resembling those of the common dwarf elder, and with side branches bearing numerous flowers of a great variety of colors, which appear in August, and continue till destroyed by frost. The plant grows wild in Mexico, in sandy meadows, and was sent to Madrid in 1789, and thence to England in the same year; but the plants being lost, seeds were reintroduced by Lady Holland in 1804, and from these and some plants imported from France during the peace of 1814, the present extensive stock of dahlias has originated. Till this last period they were much more cultivated in France and Germany than in England, and more especially by the Count Lelieur, at Paris, and Otto, at Berlin. At present the dahlia is the most fashionable flower in this country, and the extent of its culture in some of the nurseries, especially that of Lee, is truly astonishing. Nor is this to be wondered at, as Sabine observes, for, independently of the great beauty and diversity of the

flowers, they are in perfection at a season when, till they came into notice, our gardens had but little ornament. The roots are edible, but not agreeable.

6330. *The varieties are exceedingly numerous.*

The leading varieties of the fertile-rayed species, *D. arifolia*, are the purple, rose, pale, white, sulphur, yellow, tawny, copper, brick-red, dark-red, pomegranate-colored, dark-purple, very dark, and lilac flowered single, semi-double,

and double, with innumerable sub-varieties.

Of the barren-rayed species, *D. frutescens*, there are the scarlet, bright-scarlet, orange, saffron, and yellow flowered, single, semi-double, and double, with

several subvarieties, though this species has not sported nearly so much as the other.

At the Hammersmith nursery, above 200 sorts may be procured.

6331. *Criterion of a good dahlia.* The plant short, stiff, and bushy, prolific in flowers having short peduncles; the flower well expanded and standing boldly to the view, and the colors clear and distinct.

6332. *Propagation.* By dividing the roots, and by cuttings for ordinary purposes; and by seed for new varieties and also for increasing the stock of this plant, as the seedlings flower the first year. In dividing the root care must be had to preserve a bud to each section, otherwise, though the tubers will throw out roots, they will not produce leaves.

6333. *By cuttings.* Take these from the root-shoots in spring, or the tops of the young shoots, as early in summer as may be; cut the lower end smoothly off in the middle of a joint, and leave the leaves on the top, excepting such as would be buried in planting the cutting. Plant in sandy earth on heat, and cover with a hand-glass, and they will strike and produce both flowers and tubers before the autumn.

6334. *By grafting.* This mode of propagating herbaceous vegetables has been known for some time on the continent, and practised, as we have seen (2022), to a considerable extent by the Baron Tschoudi. In this country it seems to have been first adopted by Blake, in 1820, as a more speedy mode of propagating double-flowering plants than striking them by cuttings. The following are the details of his practice: "The cutting intended for the graft should be strong, and short-jointed, having on it two or more joints or buds; it must be also procured as soon in the season as possible; when obtained, select a good tuber of a single sort, taking especial care that it has no eyes; with a sharp knife (for a dull edge would mangle the fleshy root, make it jagged, and so prevent a complete adhesion), cut off a slice from the upper part of the root, making at the bottom of the part so cut, a ledge whereon to rest the graft; this is recommended because you cannot tongue the graft as you do a wood-shoot; and the ledge is useful in keeping the cutting fixed in its place while you tie it; next cut the scion sloping, to fit, and cut it so that a joint may be at the bottom of it, to rest on the aforesaid ledge; a union may be effected without the ledge, provided the graft can be well fixed to the tuber, but the work will not then be so neat. It is of advantage, though not absolutely necessary, that a joint should be at the end of the scion, for the scion will occasionally put forth new roots from that lower joint; the stem is formed from the upper joint. I therefore procure the cuttings with the two lower joints as near together as possible. After the graft has been tied, a piece of fine clay, such as is used for common grafting, must be placed round it: then pot the root in fine mould, in a pot of such a size as will bury the graft half way in the mould; place the pot on a little heat in the front of a cucumber or melon frame, if you chance to have one in work at the time; I prefer the front for the greater convenience of shading and watering which are required. A striking glass may be put over the graft, or not, as you please. In about three weeks the root should be shifted into a larger pot, if it be too soon to plant it in the border, which will probably be the case; for supposing the work was begun in March, the plant cannot go out till the end of May, so that the shifting will be very essential to promote its growth till the proper season of planting out shall arrive." (*Hort. Trans.* vol. iv. 476.)

6335. *By seed.* The following directions are extracted from an excellent paper on this subject (*Hort. Trans.* vol. 238.) by Sabine. Collect the seeds in September from the dwarf plants, where no preference exists on other accounts, and from semi-double flowers when double varieties are chiefly desired. Perhaps seeds obtained from those particular florets of the disc which have altered their form, may have a greater tendency than others to produce plants with double flowers. Sow in March, or earlier, on a heat of 55° or 65°; the young plants to be pricked out, if necessary, in pots, and kept in a moderate temperature, say 50° or 55°, till the end of April. Now plant out where they are to remain, covering each plant at night with an empty pot for some weeks, to avoid injury from spring frosts. If in a compartment by themselves, plant in rows three feet wide, and at two feet distance in the row: if in the flower-border, plant in the back rows. In either case they require to be staked. Seedlings thus treated will blow in July, and continue in perfection till the autumn; but the first frost takes the same effect on the dahlia as it does on the potatoe and kidneybean. A blow may be prolonged by planting in large pots and removing early in autumn to the green-house.

6336. *Soil and situation.* Dahlias thrive best in rich loam, and a clear open space, neither sheltered by trees or walls. Like the potatoe, they exhaust the soil considerably, and do not thrive well when repeatedly planted on the same spot.

6337. *Planting full-grown roots.* These may either be planted on the spot where they are to flower, early in April, and protected by covering with litter or by empty pots, as in transplanting seedlings; or, when an early blow is wanted, they may be planted in large pots and forwarded in frames or pits, or in any spare house, with a temperature equal to that of the green-house, till the middle of May, when they may be planted where they are finally to remain, and will flower in June. Sabine says, "Dahlias look best in a large mass, unmixed with other plants; in this plan of growing them, some nicety is required in the due distribution of the sorts, so as to have a proper and good mixture of colors; and particular care is necessary to keep the tallest plants either in the centre or at the back of the clump, according as it is destined to be viewed, from one side only, or all sides, and to place the whole so that there shall be no unevenness in the general shape of the entire mass, arising from the irregular arrangement of the individual plants, according to their respective heights. The roots should be planted about three feet from each other every way; this distance will keep each sufficiently distinct, and yet so united that the whole clump will have the appearance of an unbroken wood or forest of dahlias. They look very handsome if planted in the manner of an avenue, in a straight line, on each side of a walk."

6338. *General culture.* No particular care is requisite after the plants are neatly tied to stakes, till they have been attacked by the frost, they should then be cut down and the roots covered with as much haulm, old tan, or leaves, as would be necessary to keep the frost from the tubers of a potatoe-plant left in the soil. If this is done, they will blow well and early next season. But the most general way, especially with the valuable sorts, is to dig up the roots with a portion of the stem attached, and plant or bed them in pots or boxes among sand or dry mould, and keep them under the stage of a green-house, or in some dry airy place, free from the access of frost, till the spring. On a large scale, they may be pitted like potatoes, or packed in ridges with sand in cellars, and covered with straw; the object being to keep them sufficiently moist and plump to maintain the living principle, and yet not to rot them, or have them destroyed by frost.

SUBJECT. 15. *Auricula*. — *Primula Auricula*, L. (*Jac. Aus.* 5. t. 415.) *Pent. Monog.* L. and *Primulaceæ*, B. P. *Oreille d'ours*, Fr.; *Aurikel*, Ger.; and *Orecchio d'orso*, Ital. (*fig.* 603.)

6339. *The auricula* is a flower of great beauty: it is a small fibrous-rooted plant, with fleshy succulent leaves, generally mealy on the edges; a native of the mountains of Switzerland, Austria, Syria, and the Caucasus, &c. We have gathered it in abundance near the post-house on the Simplon road. It was cultivated by Gerrard in 1597, under the name of bear's ears, or mountain cowslips. To show what cultivation may perform on this plant, Professor Martyn relates, from Morant's *Colchester* (1768, p. 92.), that Henry Stow, a gardener, near that place, a famous grower of auriculas, had some plants with no less than 133 blossoms on one stem. About a hundred years ago the passion for this flower in England was much greater than at present; and, as Justice remarks, we supplied the Dutch, who afterwards, till the late war, used to re-supply us with the progeny of our own flowers. Justice was the most enthusiastic cultivator of the auricula, and indeed of all florists' flowers of his time. After him the Lancashire growers are the next to be distinguished, and more especially Maddock, the well known author of the *Florist's Directory*, originally from Warrington. Emmerton is, at this time, one of the most enthusiastic admirers of this flower; and the best collections are to be found among the commercial gardeners near London, and the operative manufacturers and artisans near Manchester, Paisley, and other large towns. It is like the tulip, pink, &c., a poor man's flower, and a fine blow is rarely to be seen in the gardens of the nobility and gentry.

6340. *The varieties* are endless.

The colors of the flower in its wild state are yellow, purple, and variegated. Gerrard figures the yellow, purple, red, scarlet, bluish-colored, and bright-red, most of which grew in the London gardens in his time. Parkinson, in 1629, enumerates twenty varieties,

and says many more were to be found. Rea, in 1702, has an increased number, classed as purples, reds, yellows, and whites. In 1792, the catalogue of J. Maddock contained nearly 500 named varieties, divided into *ligioles*, selfs, or plain one-colored

sorts, double flowers, and painted or variegated sorts. The latter only are held in esteem, and few collections contain more than two or three selfs of the fundamental colors, and as many double flowers. Double varieties are not in esteem.

6341. *Criterion of a fine variegated auricula.* (*fig.* 603. *a, b, c, d, e*) “The stem should be strong, erect, and elastic, and of a proper height,

that the bunch or truss may be above the foliage of the plant. The peduncles, or foot-stalks, of the flowers should also be strong and elastic, and of a proportional length to the size and quantity of the pips, which should not be less than seven in number, that the bunch may be rather round, close, and compact. The component parts of the pip are the tube (with its stamens and anthers); the eye; and the exterior circle containing the ground-color, with its edge or margin: these three should be all well proportioned, which will be the case if the diameter of the tube be one part, the eye three, and the whole pip six, or nearly so. All the admirers of this flower agree that the pips ought to be round; but this seldom happens; and we must be content if they are so nearly round as not to be what is termed starry. The anthers, or summits of the stamens, ought to be large, bold, and fill the tube well, and the tube should terminate rather above the eye; the eye should be very white, smooth, and round, without any cracks, and distinct from the ground or self-color. The ground-color should be bold and rich, and equal on every side of the eye, whether it be in one uniform circle, or in bright patches; it should be distinct at the eye, and only broken at the outward part into the edging; a fine black, purple, or bright coffee-color, contrast best with the eye; a rich blue or bright pink is pleasing, but a glowing scarlet or deep crimson would be most desirable, if well edged with a bright green; but this must seldom be expected. The green edge, or margin, is the principal cause of the variegated appearance in this flower; and it should be in proportion to the ground-color, *i. e.* about one half of each. The darker grounds are generally covered with a white powder, which seems necessary, as well as the white eye, to guard the flowers from the scorching heat of the sun's rays, which would soon destroy them if they were exposed to it.”

6342. *Propagation.* By rooted slips, or dividing the root for continuing approved sorts, and by seed for obtaining new varieties. The best time for taking off slips, or dividing the root, is after the plant has done flowering and ripening its seed, if this last

is permitted. The operation is therefore generally performed in July and the beginning of August. Emmerton says, the Lancashire growers will not take off, or sell a slip before the 5th of August, on which day they begin to execute orders for young plants.

6343. *By seed.* Maddock says, "the surest and best method to obtain fine auriculas from seed is to provide young, healthy, and strong plants, of capital high-colored sorts, possessing first-rate properties; these, on the approach of bloom, should be detached from the rest to a remote part of the garden, and there exposed to the sun, air, and rain, when the last is in moderation; but if in excess, they should be preserved from it by mats on hoops, or small hand-glasses may be placed over them. In dry weather, they must be regularly watered, as often as they appear to require it; for much depends on a due attention to this particular point." Emmerton is a warm advocate for raising the auricula from seeds, and says, any one who will follow his directions may be certain of raising very fine sorts. He selects the flowers he intends to breed from, according to the properties he desires in the offspring. Thus, he advises to procure the following sorts, sufficiently well known to the London and Manchester florists, and to plant them in pots; six plants of two sorts in each pot, viz.

For breeding light-green or grey-edged seedlings. A pot with 2 of Barlow's king and 4 of Grimes's privateer; one with 2 of Barlow's king, and 4 of Butterworth's Lord Hood; one with 2 of Barlow's king and 4 of Kenyon's ringleader.

For breeding fine grass-green or clean green-edged seedlings. Pots with six plants in each, viz. 3 of Barlow's king, 3 of Pollet's Highland boy; 3

of Barlow's king, 3 of Buckley's jolly tar; 3 of Barlow's king, 3 of Warris's Prince Blucher; 3 of Barlow's king, 3 of Stretch's Emperor Alexander.

For breeding fine choice-tinted violet ground-colored seedlings with green edges. Pots with six plants in each, viz. 3 of Bearless's superb, 3 of Foden's victory; 3 of Bearless's superb, 3 of Warris's Prince Blucher; 3 of

Bearless's superb, 3 of Chiloot's king.

For breeding fine white-edged seedlings. Pots with six plants in each, viz. 3 of Schooley's Mrs. Clarke, 3 of Taylor's incomparable; 3 of Schooley's Mrs. Clarke, 3 of Crompton's Admiral Gardner; 3 of Schooley's Mrs. Clarke, 3 of Popplewell's conqueror; 3 of Schooley's Mrs. Clarke, 3 of Wild's black and clear.

6344. *Each of these pots is to be set apart,* and at a distance from all other auriculas, before the flowers have expanded, to prevent accidental impregnation, and to be kept so detached till auriculas in general are out of flower. They may then be placed on a platform of scoria or tiles, there to remain till they have ripened their seeds.

6345. *A simple mode is to impregnate the stigmas of one sort with the anthers of another, in Knight's manner; or even without castrating the female parent.* Nicol tried this last mode with the greatest success both in the primula and dianthus genus. (*Caled. Hort. Soc. Mem.* iii. 276.)

6346. *The seed will commonly ripen in June and July,* and is to be gathered in single capsules as it ripens, and kept in them till the sowing season, which is January or February, according to Maddock; and from the middle of February to the 10th or 12th of March, according to Emmerton. Maddock sows in boxes, covers as lightly as possible, and sets the boxes in a hot-bed; preserving a moderate and equal degree of warmth both day and night, admitting fresh air occasionally. The advantage of this mode is, that it forces every live grain into vegetation in about three weeks, if the warmth of the bed be properly kept up; whereas, by the more usual mode of exposure to the open air, the greater part does not vegetate till the second year; and the weaker seeds, which are probably the most valuable, seldom vegetate at all.

6347. *The earth and seed must always be kept moderately moist,* but never very wet; the best method of watering it is by means of a hard clothes-brush, dipped into soft water, which has had its chill taken off by standing in the sun, the hair side being quickly turned upwards, and the hand rubbed briskly over it, will cause the water to fly off in an opposite direction, in particles almost as fine as dew; a sufficient watering may, in this manner, be given in a few minutes. If the surface of the earth in the box is inclining to become mossy or mouldy, it must be stirred all over very carefully with a pin, about as deep as the thickness of a shilling. At the expiration of three, four, or at most, five weeks, the young plants will all make their appearance; it then becomes necessary to give them very gradually more air, in order to harden and render them fit for an entire exposure to it, which they will be able to bear in a fortnight or three weeks afterwards; at which time the box should be taken out of the frame, and placed in rather a warm situation, though not too much exposed to the sun, till towards the end of April, when it may be again removed to a cooler aspect, where it can only receive the sun till nine o'clock in the morning; and in May, if the weather is hot, it should be placed in the most cool and airy part of the garden, not neglecting, at any time, to keep the earth moderately moist; but at the same time preserving it from violent rains whenever they occur. As soon as any of the plants appear with six leaves, such should be taken out from the rest, and transplanted into other boxes, filled with the compost, about an inch and a half or two inches asunder; and when they are again grown, so as nearly to touch each other, they may be a second time transplanted into larger boxes, or round small pots, at the distance of three or four inches, where they should remain till they blow, which will generally happen the following spring, perhaps before they have acquired any considerable size; and then such as appear to be possessed of merit should be marked, and the inferior ones destroyed. As soon as the bloom is over, such as have been marked should be taken up, and planted separately in small pots, and be taken the same care of as other auriculas, till they blow again; at which time their respective merits and properties may be ascertained with more accuracy. Such weakly plants as are not able to blow the first or second year, ought nevertheless to be carefully preserved; for amongst these it often happens that the most valuable flowers are found. A great proportion of the seedlings, although the seed was saved from the best flowers, will be plain-colored, or self, which, unless possessed of excellent properties in other respects, or being singularly beautiful in their colors, are of no value, but as common border-flowers.

6348. *Emmerton sows in small pots,* about six inches over the top, and six deep, filled half full with coal-ashes or cinders, for the sake of drainage. He covers as thinly as possible with the auricula-compost, then puts on a bell-glass, and places the pots in a situation quite excluded from the sun, except in the morning. The bell-glass, he says, will cause the seed to vegetate much sooner, and by pouring the water over the top of it, the earth in which the seeds are will receive sufficient moisture, so that there will be no occasion to remove it. "If convenient," he says, "I would recommend the front of a green-house, or a cool-frame, for the seed-pots to be placed in, but by no means a hot-bed; or if not that accommodation, a hand-glass, having tiles or slates placed underneath, to keep the worms out of the pots; great care being taken to keep the earth in a regular moist state. In about four or five weeks, perhaps three weeks, if in a green-house, the seeds will break ground; and when the leaf begins to appear, you must take care by degrees to admit air." After this, his treatment of the young plants till they flower is essentially the same as that recommended above by Maddock. All *pin-eyed* flowers, or such as show only the stigmas and not the anthers, he throws away as of no value, either as border-flowers or select sorts.

6349. *Hogg says, auricula-seed may be sown either in pots, or in the open air,* about the 1st of March, and covered with a hand-glass. When the plants will bear transplanting, he removes them into pots of the smallest size, one in a pot.

6350. *Soil.* The different composts used by florists in growing this flower are almost as numerous, Hogg observes, as the florists themselves. "Persons often take extraordinary pains, and incur unnecessary expense, to injure, if not destroy, their flowers. Weak minds are soon misled by quackery and novelty, having no sound judgment of their

own; and quackery, even in the growing of flowers, has as many followers as in any other line." (*Treatise*, &c. p. 103.)

6351. *Maddock* recommends "one half rotten cow-dung, two years old. The cow-dung produced near London is more crude and gross than that of the country, occasioned by the difference of food on which the animal subsists; it of course requires longer preparation and exposure to the atmosphere that the latter, but two years and a half will be found sufficient for it in its grossest and most crude state. One sixth fresh sound earth, of an open texture. One eighth earth of rotten leaves. One twelfth coarse sea or river sand. One twenty-fourth soft decayed willow wood. One twenty-fourth peaty or moory earth. One twenty-fourth ashes of burnt vegetables." This compost is to be thoroughly incorporated and exposed to the air in an open situation for a year before it is made use of.

6352. *Emmerton* says, "Good compost is the food, the very life of the auricula;" it must be very rich and properly tempered and sweetened by the sun, frost, and air. His materials are goose or pigeon dung, night-soil, sugar-bakers' scum, yellow loam, or loam from such land as will grow good crops of wheat, and sea-sand. He does not use salts of any kind, which are, no doubt, supplied by the sugar-bakers' scum, that substance being chiefly blood, lime-water, and oily matter. He gives various proportions, all of which he found successful; in some, night-soil and sand are wanting, thus: three barrowfuls of goose-dung, steeped in blood from butchers; three barrowfuls of sugar-bakers' scum; two barrowfuls of fine yellow loam: or, two barrowfuls of goose-dung, steeped in blood; two barrowfuls of scum; two barrowfuls of night-soil; and two barrowfuls of fine yellow loam. These composts require two years' preparation; in the first, they are mixed up in a hole in the earth; and in the next, turned over every month in an open exposed situation, so as every part may be thoroughly frozen in winter, and beaten by the sun and penetrated by the air in summer. Those composts, he says, he used with very great success, though they contained no sand. He next introduces that material thus: four barrowfuls of loam, steeped in night-soil and urine; two barrowfuls of goose-dung, mixed with blood; two barrowfuls of sugar-bakers' scum; and two pecks of sea-sand: or, two barrowfuls of night-soil; one barrowful of cow-dung; one barrowful of fine yellow loam; and one peck of sea-sand: or, two barrowfuls of night-soil; two barrowfuls of goose-dung; two barrowfuls of cow-dung; two barrowfuls of fine yellow loam; and two pecks of sea-sand. Great stress is laid on the blood, which, "when rotted down with other manure, does wonders beyond all idea;" but unless the above composts are "stirred and turned over frequently, it will poison and rather kill and destroy your plants, than nourish them. Rendered sweet and wholesome, it will be the means of throwing brilliant colors into the pips or petals, and of giving life and vigor to the plants, as much as fine old port or rich Madeira wine does to the human constitution." (*Cult. of the Auricula*, &c. p. 77.)

6353. The late *P. Kenny*, Hogg observes, "gardener by profession, was, perhaps, one of the most successful and eminent growers of auriculas in his day, and who won as many prizes as most men, during the course of ten or twelve years that he lived at Totteridge, in Middlesex. He certainly had all the benefit of air, situation, and soil, which, coupled with his fondness for the flower, and his skilful treatment of it, (to say nothing of his being almost constantly in the garden,) gave him a decided superiority over many of his competitors, and ensured, as it were, his chance of success. He always kept by him a quantity of sound staple loam, of rather a sandy nature; this he sweetened, by frequent turning. His next principal ingredient was sheep-dung and hay-litter, obtained from the sheds used to rear early lambs, well rotted, by being turned, mixed, and fermented in the same manner as the gardener does horse-dung and straw-litter. His proportions were one third loam; two thirds sheep-dung and hay-litter; one tenth coarse sand. These formed his compost for growing them in; but he had another of a richer quality, if I may so term it, with which he used to top-dress his plants, and this he would do sometimes twice in the year. When they killed any sheep, he always reserved the blood, and mixed it with the dung of poultry. These two ingredients he added to his loam and sheep-dung, and these constituted his compost for surface-dressing." (*Treatise*, &c. 104.) This compost was employed and much approved of in the Hammersmith nursery.

6354. *The Lancashire growers*, Hogg informs us, "use horse-dung and cow-dung indiscriminately, sometimes mixed, sometimes apart; the dung of poultry most frequently; and old decayed willow wood, when they can get it; with the mould cast up by moles; taking care that the same be properly mixed, sweetened, and pulverised. In winter, they throw it up in narrow ridges, and when the top of it is frozen, they take it off, and so continue to do, till the whole of it has been frozen."

6355. *Justice* gives the culture of the auricula in a "hitherto-unattempted manner, and which, although repugnant to the rules given by our cultivators of auriculas, I shall here insert, as the only true method to procure a fine blow of auriculas, such as I had this last spring, 1762; which, to the sight of numbers of spectators, exceeded all the blows of any auriculas ever seen in Scotland, in England, or in Europe; which was composed of the most capital flowers in England and Holland, and some very fine new seedlings of my own raising." The soil he recommends is, one half free fresh loam, from under an old pasture; one half composed of the following parts, viz. three parts three-year-old cow-dung, and one part sea or river sand: no horse-dung to be used, and the ingredients not to be mixed together till a few days before being made use of: "for otherwise, when they are mixed for some time, they breed vermin and worms." He adds, "if you use fullers' earth to them, it must be done in the proportion only of an eighth part, and at no time but in the spring dressing; for if used in autumn, it is prejudicial; and even when it is used in spring, it must be well dissolved in warm water before being used, and then use no sand." (*Brit. Gard. Direct. art. Auricula*.)

6356. *Curtis*, in a note to the last edition of *Maddock's* work, says, "We have seen the strongest auriculas produced from the following ingredients: two thirds of the rotten dung from old hot-beds reduced to fine mould; one third containing equal parts of coarse sand and peat or bog earth, such as is used in the culture of heaths, mixed well together by sifting or screening, and suffered to be well aired by frequent turnings during the frosts of winter." (*Florist's Direct.* 161.)

6357. *Henderson*, of Delvine, uses two parts of very rotten dung from old hot-beds, one part of vegetable mould, one quarter of river sand, mixing the whole, and exposing it for a winter. (*Calcd. Hort. Soc. Mem.* ii. 230.)

6358. *The compost in most general use* among auricula-growers is of fresh loamy soil and perfectly decomposed cow-dung, equal parts of each, adding one tenth of the mixture of sea or river sand. Some use leaf-mould instead of cow-dung. The whole incorporated and prepared for one summer and one winter in the usual manner.

6359. *Manner of growing.* The common sorts are grown in beds or in mingled borders; but all the fine flowers in pots. *Maddock* recommends pots of six inches and a half interior diameter at top, seven inches deep, and the interior bottom diameter four inches, for full-grown flowering plants; and smaller sizes for seedlings and newly separated offsets. *Emmerton* uses pots for large blooming plants, eight inches high, five inches and a half diameter at the top, and four inches and a half at the bottom outside measure.

6360. *Time of potting and transplanting full-grown plants.* The most advisable time to pot auriculas, according to *Maddocks*, is immediately, or soon after bloom, and

this should be repeated annually (notwithstanding the opinion of some who say the plants bloom better the second year after potting) for this obvious reason, that it preserves the health and constitution of the plants, by affording them a fresh supply of nutriment; and at the same time the cultivator has an opportunity of curtailing their fibres, if grown very long, or of cutting off the lower part of the main root, if too long, or the end of it, if decayed; thereby forcing the plants, as it were, into a state of action, and causing a continued circulation of their juices, during the summer, in the formation of new fibres for their necessary sustenance and support: whereas, if this operation of potting is not performed till the second year, the soil must have lost a considerable part of its nutritious quality, which will produce a proportionate decline in the strength of the plants: and if it be deferred till the autumn, there will not be time for a sufficient reproduction of the fibres before winter sets in, the effects of which will be a faint-colored and weak bloom the ensuing spring. The only objection of any importance, against spring potting, is that some sorts will in consequence be more inclined to blow in the following autumn, and thereby deprive the plant of its capacity to bloom well the ensuing spring; this, however, occurs but in few instances.

6361. *In potting or transplanting auriculas*, the plants should be carefully turned out of the former pot, and the earth shaken from its fibres, which should be curtailed if found too long and numerous, together with the lower end of the main root, and the fibres attached to that part, if it appears too long, or somewhat decayed; the plant is to be at the same time carefully examined, and wherever any unsoundness appears, it must be entirely eradicated by means of a sharp penknife, let the extent of it be ever so great, till no appearance of decay remains; particularly in that part of the main root where it enters the surface of the earth, or, as the sailors phrase it, betwixt wind and water, which, being alternately wet and dry, is more subject to decay than any other part, and for the same reason is the most difficult to heal: the wounded part should be immediately exposed to the sun, and when the surface of the wound is perfectly dry, a cement should be applied, consisting of bees' wax and pitch, about one half of each, warmed and softened in the sun, or by a fire, to make it adhere more firmly on application: this will become close and hard when cold, it will resist moisture, and is the best application yet discovered, to prevent further progress of the decay. Whenever the lower leaves of the plant, next the surface of the earth, become yellow, or dried up, it is proper to strip them off, in a direction downwards. On replanting, a pot suitable to the size of the plant is to be selected; it is to have a hollow oyster-shell placed with its convex side upwards, over the hole at the bottom, and then to be about three parts filled with compost, higher in the middle than at the sides: the plant is next to be placed thereon, with its fibres regularly distributed all round, so as nearly or quite to reach the sides of the pot, which is afterwards to be filled up with the compost, adding a little clean coarse sand close round the stem of the plant, on the surface: the bottom of the pot should then be gently struck two or three times against the table, which is supposed to be made use of for the sake of convenience in the operation, in order to render the soil more firm and compact; this will cause it to sink or subside about half an inch below the top of the pot, which will prevent the loss of water when it is administered.

6362. *The true depth to plant an auricula* is within about half an inch of the bottom of its lowest or outside leaves; as the new and most valuable fibres proceed from that part, so they should immediately meet with earth to strike into, or otherwise they will perish: it will likewise encourage the offsets, if there be any, to strike root sooner than they would do if not in contact with the soil. (*Florist's Direct.* 129.)

6363. *On the foregoing directions*, by Maddock, his editor, Curtis, has the following note: "Notwithstanding the author has so particularly recommended the annual fresh potting of auriculas, we must beg leave to differ in opinion from him, as far as relates to those plants which are intended to bloom strong the following spring, the mode of potting advised being to shake the whole of the earth from amongst the fibres of the plant, in order to examine the lower end of the main root, this severe operation being performed in the spring, when the plants ought to be making their most luxuriant growth, will have evil consequences. The case is simply this: the plant being firmly established, nature intends its greatest growth in the spring; during this rapid growth, the operation gives an unnatural shock to vegetation; the consequence is, the plant must remain dormant until fresh fibres are formed sufficient to draw nourishment for supporting the growth necessary to form a strong-blooming plant. Having given our opinion against it, we substitute the following recommendation: select those plants intended for strong blooms the following spring from the younger ones, turn them out with their balls of earth entire, and if the fibres are healthy, return the balls into a set of pots one size larger than they were in before, adding new compost to fill up; we have no objection to remove as much earth as can be done without disturbing the mass of fibre; in this state treat them as usual, and when those which have bloomed strong on this plan are out of bloom, put them on the plan recommended by the author. We beg leave also to notice, that it sometimes happens that the oyster-shell placed at the bottom of the pot by fitting too close confines the water in it, which is inevitable destruction to the plant; we should advise particular care to be taken for the effectual drainage of a superabundance of wet, by putting two or three pieces of broken pot over the surface of the bottom."

6364. *Enmerton* disapproves both of spring and autumn transplanting, and says, "the best time for the operation is soon after they are out of bloom; say about the 22d or 23d of May;" but he adds, —

6365. *From the 29th of May to the 12th of June*, I have transplanted my flowers with great success, even also as late as the 13th of July. On no account remove a general collection a week later, at least, those you intend to bloom very strong: by this means they will have three or four months to get well rooted before winter, which they ought to have; and if you transplant them early in the spring, it will be so near their time of blowing, that the check they will receive by transplanting will prevent their blooming strong. Strong-blowing roots should not be removed more than once in two years; to do it oftener would be to run a risk of not having any fine flowers to exhibit on your stage; because these plants never thrive rightly, till the roots have reached the sides of the pots, and it seldom or never happens that they get sufficiently well established in a full-sized auricula-pot, in one year. By no means remove your large-blooming auricula-plants in dry hot weather, as by shaking the mould clean out of the plant the roots will not freely draw fresh fibres, except the weather is inclined to be showery, and what is termed a cool moist air. I am satisfied dry hot weather is an improper time, except they are fine young maiden plants, in small pots, which should be slipped out of the pot with the whole ball of earth, and then immediately planted in a full-sized blooming-pot for the ensuing season; in this last case I used to pay no attention whatever to the dry weather. If your large-blooming plants have not been removed for two or three years, their

small roots will have filled the pots, and probably their large, or what is called by some the carrot root, may be grown so long as to require shortening; in this case the plant must be taken out of the pot, and the earth entirely shaken from it; you will see what is necessary to be done; shorten the carrot-root, if necessary, for if you suffer it to remain too long, it will either get rotten at the end, and always keep the plant weak, or will be too long for an ordinary pot; besides, it would want shifting every year, and never produce fine strong flowers. Reduce their small roots to about ten or a dozen, leaving those that are nearest the leaves; they will be sufficient again to support and vegetate your plant. If you perceive any canker or rottenness in the root, cut it boldly to the quick, till it appear fresh and lively, and no spots or symptoms of decay remain; put on the wounds a little mastich, bees' wax, turpentine, and white rosin, in equal parts, to heal and dry them; leaving as many fibres to it as possible. If a large-blooming plant, or any other one you remove, has been in the pot but one year since it was last transplanted, you may slip it out of the pot with all its earth about it, and although its fibres may have reached the outside, they will not be so large and numerous, or so matted together, as the older plants that have remained in one pot two clear years. You need not therefore shake the earth from it, but with a sharp knife cut the fibres and earth away till you reduce it to the size of a cricket-ball, or rather larger, as much depends on the size and age of your plant. (*Treatise*, 132.)

6366. Hogg recommends the first week in August, because "if you put your plants at this early period of the summer into pots, in which they are to remain till they flower again next spring, the space of nearly twelve months, the strength of the compost must be greatly reduced before that time, particularly as they require so much water during the hot months of June and July; this must tend, beyond all doubt, to exhaust the nutriment contained in so small a body of earth, as is in the pots; by which means they will be less able to throw out strong fibres, or to produce you strong blooms in the spring. Early potting is attended with another evil consequence; for, the plants being removed into fresh and more vegetative earth, accompanied with daily waterings, forces them prematurely into a state of active vegetation, and causes them to flower late in the autumn, a circumstance which the florist always views with regret, as it in a great measure destroys his hopes of a fine bloom at their natural and expected season, towards the latter end of April: this last argument of itself appears to me quite conclusive in favor of late potting. The slips or offsets will also have acquired more strength and better roots, by being suffered to adhere to the parent plant till the beginning of August, and will occasion you less trouble in protecting and shading them. From the beginning of August to the beginning of November is a period quite long enough for the plants to strike fresh fibres, and to get well established in the pots, before winter; and, with the return of spring, you may expect a vigorous growth of the plant in all its parts. The customary mode is, to shake the mould completely from the roots every second year; but, in doing this, you must be guided by the state and condition of your plants. The late Kenny let his remain very frequently until the third year, reducing the ball of earth only, trimming the fibres, and examining the carrot or main root. Transplanting should be done in a cloudy sky and a moist atmosphere."

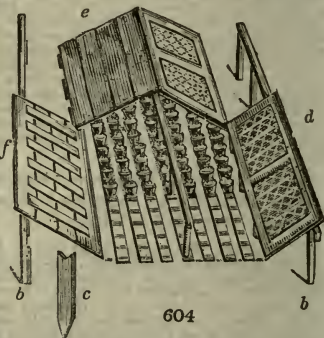

6367. *Justice* pots suckers, and transplants old plants, in August. Henderson, of Delvine, says, "the shifting season is always, with me, about the third week of May, when the plants have done flowering. At that season, I shake the mould from the old plants, and cut the end of the stump up to the fresh young roots, if it has grown too long. (I am now speaking of those plants which have been in the largest-sized pots for two years.) After dressing the wounds with gum-mastich, to prevent gangrene, the plants are repotted in the second size of pots. Next May they are shifted, with the ball entire, into the largest size, or flowering-pots; so that from the first potting of the young plants in small pots, to a complete shifting, four years elapse; the plants having been one year in small pots, one in the second size, and two in the largest, or third size. A little river-sand is put round the stems at all the shiftings; and if any wounds are made by taking off the suckers, they are dressed with mastich. At all times the stems are cleared of sprouts above ground as they appear, but suckers from under are allowed to grow, in order to form young plants." (*Caled. Hort. Soc.* iii. 230.)

6368. *Removal and potting of offsets.* When offsets have formed one or more fibres, an inch or two in length, Maddock directs to remove them by means of a piece of hard wood, or by the use of the fingers, to be separated from the old plant with safety, and replanted round the sides of a small pot, filled with the same compost, till they become sufficiently grown to occupy pots separately: if a small hand-glass be placed over each pot containing these newly-planted offsets, it will cause their fibres to grow more rapidly; but it should not be long continued, as it would have a tendency to draw and weaken the plant. (*Florist's Direc.* 130.)

6369. *Ennerton* says, "You may separate offsets from the mother plant any time between February and August, according as they are in size, or are wanted for increase, and plant them immediately against the side of pots four or five inches in diameter. If a strong and superior bloom of flowers is desired, no offsets must be allowed to grow on the old plant, and especially none on the stem without fibres. Rub them all off when they are about the size of hemp-seed." (*Treatise on the Auricula*, &c. 126.)

6370. *General culture.* Maddock keeps his auriculars during one part of the year in what he calls a summer repository (fig. 604.), and the other in a winter repository.

6371. *Summer repository.* "The following is recommended as a proper plan for the summer repository, viz. in the first place, there should be a bed of coal-ashes formed in the place where it is intended to be erected, about five or six inches thick; or a platform of plain square tiles, closely fitted to each other, on the surface of the ground, to preserve the pots from the common earth-worm, which, by gaining admittance into them, would perforate, and alter the consistence of the soil, in such a manner as to prove very injurious; upon this foundation, rows of bricks (fig. 604.) are to be placed in straight lines, about two or three inches asunder, which will allow a free circulation of air under and between the pots when placed upon them, an object of great importance, especially in warm weather, when the air is most inclined to stagnate, and become impregnated with noxious effluvia. The plants, by the above plan, will be raised from nine to twelve inches above the level of the ashes or platform. There should be two rows of substantial stakes, three feet long, and five inches by three wide, one row of which should be placed on each side, at about three or four inches' distance from the two outside rows of pots (b): these stakes (c) should be driven twenty inches into the ground, with their narrow sides towards the pots, and have notches cut in their tops, to receive the edges of the shutters they are intended to support. By way of illustration, suppose the whole length of the platform to be twelve yards, and the width three feet, it will contain seven rows, and each row about seventy pots; a sufficient number to constitute a moderate collection for a private gentleman. Three shutters (f), made with feather-edged inch-deal boards, each four yards long, and two feet six inches wide, will reach the whole length on one side: three of the notched stakes will be sufficient to support one of these shutters; of course, fifteen stakes at proper distances will completely answer the purposes on one side: the notches are to be cut in the form of a V, two inches deep and three inches wide at the

top, which will give room for the shutters to move backwards and forwards without difficulty or danger of slipping out. Both sides are thus to be provided with stakes and shutters, the upper edge of the latter should meet over the centre of the platform (e), when the plants require to be covered with them, in the form of the ridge or roof of a house, well fitted and sloping equally on both sides, so as to throw off rain, without even admitting it to drip through upon the plants in any part. It is necessary that a rail, or row of stakes, of a proper height and strength, should proceed from the ground between the two middle rows of pots, to support the shutters when closed or closing, especially as it is usually more convenient to begin to cover or uncover on one side first, and finish on the other; without a support of this kind, in such case, the shutters must fall down upon the plants: a similar exterior rail, or row of stakes, is necessary on each side, to support the shutters when open, with the same degree of slope, in a contrary direction than when closed; by which means the plants will have a free communication with the air, whether covered or open; nor are they entirely deprived of light, when the shutters are closed, because the lower edge of the shutters is as high or higher than the top of the plants at all times. The peculiar advantage arising from this plan is, that when the plants require to be shut up from excess of rain, they have at the same time the advantage of a continual supply and free circulation of fresh air, which passes amongst their leaves in all directions; whereas those who are obliged to shut up their plants in a close frame, to exclude excess of rain from them, oftentimes shut them up in a wet state, as soon as it is judged they have had a sufficiency: this is a very dangerous, though not unusual practice, and often produces a mildew which is attended with the most destructive consequences. The importance of a properly constructed repository, and suitable treatment of the plants, for the summer season, will sufficiently apologise for any prolixity in the description: it cannot, indeed, be too strongly impressed on the mind of the cultivator of this delicate flower that his success more particularly depends on the health and vigor of his plants towards the end of summer, than at any other period of the year. The plants, after being placed in the summer repository, are to be kept moderately moist; if the rains that happen are not sufficient, they must be occasionally watered with soft water, by a small pot with a round curved spout, taking care not to let any water fall into the heart or amongst the interior leaves of the plant, as it could not speedily dry up in that part, and, of course, would endanger a decay; any water lodging in the heart of the plants in spring, when the blossoms begin to make their appearance, cannot fail to injure them considerably. The plants are to remain in their summer situation till September or October, as the weather may be more or less favorable, or until the heat of the sun has considerably decreased."

6372. *Emmerton* places his pots, after the plants have done flowering, in a shady situation, and full north aspect. He sets them on bricks placed on a bed of ashes, in the same manner as Maddock; but he provides no covering to exclude the rain. (*Treatise on the Auricula*, &c. 143.)

6373. *Hogg* removes his auriculas which have blown in spring from the show-stage to a north-east aspect, to avoid the scorching rays of the summer sun. He then sets them upon thin boards or thin slates, lying on a bed of coal-ashes. (*Treatise*, &c. 115.)

6374. *Justice* sets his plants in a full northern exposure, and without covering, to the 20th of October. Whichever of these plans be adopted, the plants must be kept clear of weeds, the soil gently stirred when it gets hard or mossy, water supplied in dry weather, and the leaves, as they become yellow, drawn off close to the stem.

6375. *Winter repository.* In the end of September or beginning of October, Maddock removes his auriculas to the winter repository, "which is to be constructed in a manner exactly similar to that for the summer season, with only one exception, viz. that the south side of it should consist of frames of glass (fig. 604. d), instead of the wooden shutters: these are to act in the same manner, but will admit of light when the plants are of necessity shut up from adverse weather, which so frequently occurs during winter; the admission of light at such times is indispensably necessary to the wellbeing of the plants, especially when the long continuance of rain, or severe frost, renders it requisite to keep them covered, sometimes perhaps for a day or two, with little or no intermission. In the first favorable weather that occurs in February, it is necessary to divest the plants of their decayed exterior leaves; and by the middle of that month, the operation of earthing up, as it is termed, should commence; that is to say, the superficial earth of the pots should be carefully taken away, about an inch deep, and fresh compost with the addition of a little loam, to give it more tenacity, should be substituted in its stead: this will contribute greatly to the strength of the plants, and the vigor of their bloom: at the same time it will afford a favorable opportunity to separate such offsets as shall appear possessed of sufficient fibre, to be taken off at this early season with safety: these offsets, when properly planted in small pots, should be placed in a frame, in some warm sheltered situation, till the roots are established. The auricula is by no means a tender plant, yet it will be proper to cover the repository with mats, in case of severe frost; for although it probably would not destroy the plants, unless it happened in an extreme degree; it would, however, injure them, and perhaps spoil their bloom, particularly early in the spring, when the stem begins to rise; it would certainly, at that period, destroy or render the pips or corollas abortive. If any plant is possessed of more than one or two principal stems, it is advisable to pinch off the pips of the smallest and weakest, in order to render the blossoms of the remaining one larger and more vigorous than they would be if this was omitted to be done in due time. It is a curious fact, that those sorts which are naturally possessed of a fine green on the edge, or margin, of the flower are often known to lose that property, when the stem proceeds from the very heart or centre of the plant; whereas those stems that proceed from the side produce larger pips, possessing their true natural colors in much greater perfection: these last are called the winter stems, because they are usually forwarder, and produce their flowers rather earlier in the season than those which proceed from the centre of the plant. When the pips become turgid, and begin to expand, they must be preserved from rain: nor should they remain any longer in a situation exposed to cold winds; on the contrary, such plants ought to be selected from the rest, and removed to a calm shady corner, where they should have small hand-glasses suspended over them in such a manner as to preserve the bloom from rain, &c. and yet admit a free circulation of air, both to the plant and to the blossom, it being equally necessary for the one as for the other."

6376. *Emmerton*, about the middle of October, makes choice of a full southern aspect, and in general puts his pots of plants into small frames of about three and a half to four feet long, and each light about three feet wide. So soon as they are placed in their winter situation, during the autumn and winter months, even down to the 5th of April, or thereabouts, he exposes them, during the day, to as much air as possible, by leaving the lights entirely off. It is necessary they should be kept very dry, in November and December, as in case of a severe frost the weather has less power on the roots of the plants. During January, and most likely the greater part of February, much depends upon the depth of snow and the intense frost. Some winters are more favorable than others: if the season has now the appearance of open weather, you may treat your plants nearly in the same manner as the two last months; but if you have snow, and the weather is now a severe frost, you must be rather more cautious as to the exposure; a trifling frost is of no serious consequence to these hardy plants, but the mould should not be severely frozen in the pots, as by the end of January the bloom is formed, although very low in the heart of the plant; he therefore covers with mats till the weather becomes mild and open, giving air, however, a few hours in fine days; but no water till natural rains fall. (*Treatise on Auricula*, &c. p. 85.) In February he top-dresses with rich compost, and transplants offsets intended to bloom, from small pots into larger ones. He exposes the plants to all the gentle rains of this month, at the same time carefully defending them from frost and hail-storms, or long continued rains. From the 10th or 12th of March he covers up with "warm clothing," to defend the coming bloom against frosts.

6377. *Hogg* puts his auriculas into frames in October; the frames are placed on a bed of ashes, and are raised on bricks to admit a free current of air under them; but when the frost sets in, about Christmas,

the bricks are removed, and the frames rest on the ground. In all dry and temperate weather the plants are exposed to the air, very little water is given, and the plants are kept free from decayed leaves, and the surface of the pots from mouldiness. From the second week of February, and during March, the plants are allowed the benefit of gentle rains for an hour or two; they are top-dressed, such as require it are shifted, and suckers are taken off where they are large, and while all possible air is given during day, the frames are shut close at night, to prevent the opening blossoms being nipped by the frost.

6378. *The Lancashire growers* have no frames or lights, but make use of weather-boarding, with hinges, fixed against some wall or fence, in a south aspect, to defend them against the rain and snow, resting, when shut close, upon a board nine inches high; but this is never done except in very severe weather: the pots are plunged up to the rim in sawdust or coal-ashes. (Hogg.)

6379. *Justice* places his auriculars in what he calls a bunker or shed, on the 10th of October. This bunker is a stage with boarded ends, front and cover, placed against a wall with a north-eastern exposure. He gives water sparingly, but as much air as possible; by the end of February he top-dresses the plants, and if they are weak he adds the proportion of one eighth of fullers' earth to the compost.

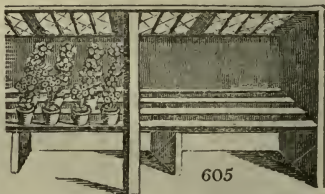

6380. *Blooming-stage.* (fig. 605.) This, according to Maddock, should have a northern aspect, that the sun may not shine on the flowers; it should consist of four rows of shelves, in the form of steps, but must not exceed five; the front, or lowest shelf, should be two feet five inches from the ground, the second about three inches higher than the first, and the rest in the same proportion; these shelves should be about six inches wide, strong, and well supported, otherwise the weight of the pots will cause them to bend or give way. If the stage consists of four rows of shelves, its depth, from front to back, ought to be about two feet eight inches; the north or front elevation of the stage should not be less than seven feet, gradually sloping to about five feet six inches on the south side: the roof should consist of frames of glass. The frames of glass made use of on the south side of the winter repository will answer extremely well for this purpose; but as they will not be wide enough to form the roof completely, without addition, a single row of feather-edged boards may be placed on the lowest part of the slope, and the lower edge of the frames of glass may rest upon them; these boards will answer another good purpose, by preventing the sun, which at this season of the year has obtained a considerable degree of altitude, from shining on the first and second rows of plants, during the middle of the day, when it has most power; although the plants of the back row will, in consequence, have rather less light, yet it is not so materially injurious as the former. The posts supporting the roof of the stage, on the south side, may be so constructed, and placed at such distances from each other, as that the wooden shutters, made use of on the north side of the winter repository, may fit between them, and form a regular shed, as low or lower than the higher shelf: the remaining space to the ground may be left open in mild calm weather, or may be easily closed up, by a line of mats sewed together, when it is otherwise. The east and west ends of the stage should be entirely boarded up from top to bottom, and the front left open, unless in unfavorable weather, and at night; at these times, it may be defended by frames of wood covered with canvass: these should be about six feet wide, suspended from the front edge of the roof by hinges; they will serve both to defend the bloom, when let down, and also by each having two small iron rods, about five feet six inches long, connected with their lowest edges by staples, that will allow them to move in any direction, and support them when up, will defend the path in front from rain, take off the glare of light when the sun shines, and at the same time defend the spectators from its heat. The inside of the back and ends of the stage, and the shelves likewise, should be painted black, or some very dark color, by way of contrast to the white eyes, &c. of the flowers: and if a large looking-glass be placed at each end of the stage, the effect produced will be very pleasing, by apparently lengthening the stage each way as far as the eye can reach.

6381. *As auriculars and hyacinths generally blow exactly at the same time*, the beauty and elegance of the scene is considerably increased by having a stage of the former, and a bed of the latter, under the same awning, with an intermediate path, about six feet wide; in which case, if the cloth covering of the hyacinths is fine enough to admit a sufficiency of light, it may be continued over the auriculara-stage, instead of the glass and boards, and will answer all purposes tolerably well with little trouble: or otherwise, the edge of the cloth covering, for the bed and path, may be nailed to the upper or front edge of the glass frames, over the auriculars, in such manner as effectually to prevent rain dripping through in that quarter. A row of fine polyanthuses, in pots, may likewise be introduced in front of the hyacinths, as they likewise blow at the same time; it will add to the variety, and form altogether a more elegant assemblage or beautiful fragrant flowers than any other season of the year can afford. The tallest blowing auriculars should stand on the last or most distant shelf, and the shortest in front; those stems which are weak and bend should be supported with small wires, fixed in the earth behind them, so as not to be easily discerned. If any of the stems and blossoms of those in the back row incline forward too much towards the light, they may be easily recovered to an erect position, by turning the pots for a few hours in the morning; but the glass roof will render very little of this trouble necessary: the pots must be regularly watered, two or three times every week, during the bloom. No person can depend on a complete stage of auriculars, who is not provided in autumn or early in the spring with twice as many blowing plants as his stage will contain, because some will eventually prove defective, and fail in one respect or other: and a succession of proper plants in bloom will be required to replace such as, being earlier than the rest or of shorter duration, are no longer eligible to remain on the stage, and ought, in consequence, to be taken away, and more suitable ones brought on in their stead.

6382. *When the bloom is declined*, the plants are to be removed into their summer repository, where they will soon recover their former strength and vigor, which, notwithstanding the utmost care and precaution, will have been, in some degree, impaired by standing two or three weeks upon the stage.

6383. *Emmerton* says, "to bloom your auriculars well, too great attention cannot be paid to them for about four or five weeks, viz. to use the language of a florist, to prevent them from being set, when all trouble and danger will be completely over. This strict care commences about the 20th or 22d of March, and ends, as I calculate, by the 25th of April, or thereabouts. Around London, many fine plants of the choicest sorts have always been spoiled by nursing them as they do their geraniums, that is, by keeping their plants under glass so many weeks, night and day. Many florists keep their lights continually over their flowers, day as well as night, from the 1st of January till the 1st of May, and only admit a current of air behind their frames: this is the rock, fatal to bloom, which so many split on. This mode of treatment, I am convinced, is highly improper; it draws up the flower-stem, and renders it weak and spindling, in a state unfit to bear or produce a bold truss. To bloom an auriculara in perfection, it does not require to be continually under glass night and day, longer than twenty-four days, or thereabouts; as a criterion, say from the 4th to the 28th of April: you will find your middle pips expanded, or nearly so, and well adapted to be exhibited on the stage at this time." Previously to this period, however, say from the 10th to the 16th of April, he removes them from the frames (which have a south aspect), and places them under hand-glasses in a full or north-eastern exposure. Here they remain till the 26th or 28th of April, and are then removed to the stage in a full north aspect.

6384. *Hogg* keeps the lights over his auriculars, in April, night and day, to preserve their beauty unimpaired. Air he admits by raising the sashes behind; he covers up close at night, "this being the very crisis of

time that requires your most particular care." He thins out the pips or blossoms, leaving not more than thirteen, nor fewer than seven on a truss or umbel. In thinning, "they should be taken out two or three at a time, and it requires some taste, nicety, and art, to perform this operation well, that the blossoms which are left on may grow in a regular equidistant form, so that any common spectator might suppose that no such thinning of the pips had taken place, but that they had grown exactly in that form, and with that number, from the first." Towards the end of the month the flowers are removed to the stage fronting the east.

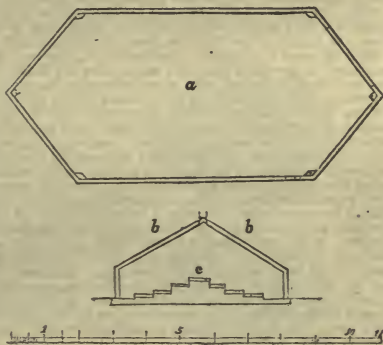

6385. *The Lancashire growers*, "in blooming time, set their large show-plants under hand-glasses, in an east aspect, to receive the morning sun only. The plants are, perhaps, not so early in bloom as those wintered in frames, but when their stems are not drawn, and they are able to support the trusses firmly: the mildew and rot do not take them so readily as when in closer situations."

6386. *Justice* blows his flowers in the bunkers, or sheds, exposed to the full north; he gives them all the air he can, but excludes the sun, shelters them from winds, and waters them well twice a-week. (*Brit. Gard. Direct. art. Auricula.*)

6387. *Henderson, of Delvine*, blows his flowers in a frame (fig. 606.), which he says, "answers all the purposes of frame, hand-glass, and stage, used by the English florists; at least I make it do so. I have only to erect a screen of matting or poles in front, during the flowering season. The plan of it (a) is a long hexagon, which has a span roof (b) and a low stage sloping on all sides. (c) In the elevation are eight ventilators (d), eight hinged sashes (e), and as many iron rods on staples for holding them up (f)." The whole seems a simple, economical, and sufficiently neat structure.

606

SUBJECT. 16. *Primula*, or *Primrose* Family. — *Primula*, L. *Pentand. Monog. L.* and *Primulacæ*, B. P.

6388. *The primrose family*, grown as florists' flowers, consists of the polyanthus, primrose, cowslip, and oxlip.

6389. *The polyanthus* is the *Primula vulgaris*, var. *Polyanthus*, L. *Primula*, French, German, and Italian. In its wild state, the common primrose is too well known to require any description, it produces its flowers on numerous peduncles; but, by cultivation, throws up a scape, bearing an umbel of numerous flowers, brown, purple, red, and yellow. Linnæus asserts, that the peduncles in the common wild primroses spring from a scape, which being so short as to be concealed among the leaves, has not been observed. Curtis, however, found it in a few plants, and also that wild primroses, introduced into Dr. Buxton's garden, at Maize Hill, near Greenwich, produced flowers both with and without a scape, and became, color excepted, perfect polyanthuses. Many botanists consider, that the polyanthus, primrose, cowslip, and oxlip are one species; and the Rev. W. Herbert thinks he has proved it, and the same thing as to *Primula auricula*, *helvetica*, *nivalis*, and *viscosa*. (*Hort. Trans.* iv. 19.) It is sufficient for our purpose to observe, that the polyanthus is a very permanent variety, which does not readily return to the primrose, and that it is in high repute as a select and border flower, appearing in March and April, when there are few others to decorate the flower-garden.

6390. *Varieties*. These are as numerous as the varieties of auricula; and, as in that plant, single flowers are most esteemed.

6391. *Criterion of a fine polyanthus*. "Its properties are, in most respects, similar to those of a fine auricula, viz. the stem, peduncles, or foot-stalks, and formation of the bunch or truss; therefore, a definition of its pips, or petals (fig. 607. a), only remain necessary to be considered in this place. The tube of the corolla above the calyx, should be short, well filled with the anthers or summits of the stamens, and terminate fluted, rather above the eye. The eye should be round, of a bright clear yellow, and distinct from the ground-color; the proportion as in the auricula throughout the flower. The ground-color is most admired when shaded with a light and dark rich crimson, resembling velvet, with one mark or stripe in the centre of each division of the limb, bold and distinct, from the edging down to the eye, where it should terminate in a fine point. The pips should be large, quite flat, and as round as may be, consistent with their peculiar beautiful figure, which is circular, excepting those small indentures between each division of the limb, which divide it into five or six heart-like segments. The edging should resemble a bright gold lace, bold, clear, and distinct, and so nearly of the same color as the eye and stripes are scarcely to be distinguished; in short, the polyanthus should possess a graceful elegance of form, a richness of coloring, and symmetry of parts, not to be found united in any other flower." (*Maddock.*)

6392. *Propagation*. By dividing the root, or by slips, for ordinary purposes: and by seed, for obtaining new varieties.

6393. *By seed.* The plants from which seed is to be saved are to be separated from the stems, and treated in the same manner as seed-bearing auriculas. When ripe, it should be cut off with part of the stem, and so preserved till the sowing season, which, as well as the mode of procedure, are, according to Maddock, the same as for the auricula. Emmerton says, flowers intended for seed should be selected on the same principle as he directs for the auricula; and he recommends Pearson's Alexander and Nicholson's Tantarara as excellent flowers to breed from. Knight's mode of castration may be adopted.

6394. *Justice* says, he "has had great success in raising polyanthus and primroses from seed." He gathered the seed generally about the 25th of June, and sowed it ten days afterwards in boxes, placed in the open air, under a wall or hedge with a north aspect. In July, he directs to "prepare a nursery-bed of the same earth in which they were sown, and plant them carefully out, taking up as much earth about their roots as you can, so as not to disturb their young fibres, planting them twelve inches asunder, and shading them from all sun until they have struck new roots; keep them clear from weeds, and give them gentle waterings, and let this nursery-bed be made in such a situation as to have the morning sun only. Some of them will show their flowers the same autumn, and many of them in the spring following. Select the best, and plant them in a bed by themselves in a shady moist situation. In November, top-dress the plants, which will greatly strengthen them for the succeeding spring. They require to be transplanted every two years." (*Brit. Gard. Direct.* 218.)

6395. *Soil.* Maddock and Emmerton recommend the same compost as for auriculas, but with more loam. Justice used the following: "to one load of well rotted cow-dung, or leaves of trees, take half a load of fine white sand, and two loads of fine hazely loam, taken from a pasture some months before, and which has had the sward rotted amongst the earth: mix all well together before using."

6396. *Hogg* says, "the primrose and polyanthus require a much greater portion of sandy loam than the auricula, a very small quantity of rotten dung, and a little leaf-mould or heath or peat earth, mixed with them: in this they are found to grow extremely well."

6397. *Manner of growing.* Maddock says, they may be grown in the same sized pots as the auricula, and be treated in the same manner; but as they are more impatient of heat and drought, and partial to shade and moisture, they may, with equal propriety, be planted on cool and shady beds or borders. This is the general practice of almost all the growers of this flower.

6398. *General culture.* The polyanthus is very hardy, and seldom perishes in the coldest and wettest seasons; but, during the heats of summer, they are frequently destroyed by snails and slugs, and by a small red spider. "This insect," Maddock observes, "seldom attacks such plants as are in a state of vigor, or when the weather is cold and wet; it generally commences its depredations in the early part of summer, and continues them as the heat and dryness of the weather favor its existence: the juices also of the plants being then more viscous and saccharine, afford it more suitable nourishment than at any other season. Such plants as appear infected should be immediately selected from the rest, taken out of the earth, and soaked for two or three hours in a strong infusion of tobacco-water, and be replanted in a fresh soil or compost, and removed to another situation remote from the former. If the whole bed or border of polyanthus is over-run with this insect, it is best to take up all the plants, serve them in the same manner, and plant them elsewhere. The bed or border from whence the plants have been taken, should be immediately dug up or trenched, and suffered to remain fallow till the following season, or be occupied with some crop not liable to the same calamity." (*Florist's Directory*, 228.)

6399. *The primrose* (*P. vulgaris*, L. (*Eng. Bot.* 4.) *Primevère*, Fr.; *Shafthouse Primule*, Ger.; and *Primavera*, Ital.) (*fig.* 607.) has a perennial root, appearing as if bit off at the end, with a singular smell like that of the anise. It is a native of most parts of Europe, in woods, coppices, and sheltered lanes, particularly in a clayey soil. The flowers of the wild plant are almost always of a brimstone-color, but sometimes of a purple hue; they appear in March and April.

607

6400. *Varieties.* The double varieties produced by culture are in most esteem, of which there are —

The stemless white
Crimson
Hose-in-hose

Purple
Lilac

Scotch
White

Yellow
Brimstone.

6401. *The cowslip* (*P. veris*, L. (*Eng. Bot.* 5.) *Primel*, Fr. and *Schlusselflume*, Ger.) (*fig.* 608.) is distinguished from the primrose, by smelling more strongly of anise, by shorter leaves, and by an umbel with a leafy involucre. It is a native plant, and found in moist pastures, in open situations, flowering in May.

6402. *Varieties.* Both double and single varieties are in esteem; but the plant has not been so much cultivated as the primrose. Gibbs, nurseryman, Brompton, has lately raised a great many very beautiful varieties from seed, differing in color, magnitude of the umbel, and in some being double, and in the hose-in-hose form. "May 19th, 1818, Gibbs sent a large collection of flowers of varieties of the common cowslip, from his garden at Brompton. He had raised them from the seed of plants, originally derived from the wild cowslip, which had sported into varieties, and by frequent reproduction had attained their present excellence. The changes that have taken place are in the magnitude of the trusses, and the size and color of the flowers; the selection appearing to have been from the darker hues, though some paler flowers were in the collection. However great the variation was in the points alluded to, yet none of the specimens appeared to have lost the general character and appearance of cowslip, not running either into the oxlip or the primrose; but some of them had become what florists term hose-in-hose, which appears to be the conversion, more or less, of the calyx, into the appearance of the corolla."

608

6403. *The oxlip* (*P. elatior*, L. (*Eng. Bot.* 518.) *Bavillon*, Fr. and *Gartenprimel*, Ger.) (*fig.* 609) is distinguished from the primrose by its many-flowered scape,

and from the cowslip, by the flat border of the corolla. It is found in woods, thickets, hedges, and sometimes in pastures; but is by no means so common as the primrose and cowslip. It flowers in April and May. Sir J. E. Smith is inclined to think that the oxlip is a hybrid production from a primrose, impregnated by a cowslip; its habit, the contraction towards the middle of the leaf, and the umbellate flower-stalk, indicating the father, whilst in the corolla, its form, color, and scent, it most resembles the mother. (*Eng. Bot.* 513.)

6404. *Varieties.* There are a few; but the plant has not been much cultivated with a view to that object.

6405. *The propagation and culture* of these three species is the same as for the polyanthus:

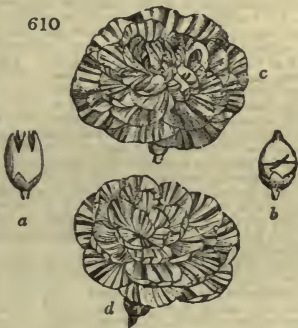

SUBJECT. 17. *Carnation.*—*Dianthus Caryophyllus*, L. (*Bot. Mag.* 39.) *Decand.* *Trigynia*, L. and *Caryophylleæ*, J. *L'oeillet des Fleuristes*, Fr.; *Gartennelke*, Ger.; and *Garofano ortense*, Ital. (*fig.* 610.)

6406. *The carnation* is little known in its wild state, though it has been found in England on rocks and walls. It was unknown to the ancients in its cultivated state; but has been a favorite flower in Europe for an unknown length of time. It is generally supposed to have been introduced from Germany or Italy, in which countries it is more cultivated than in England; Gerrard, in 1597, received it from Poland. "Of all the flowers that adorn the garden," Hogg observes, "whether they charm the eye by their beauty, or regale the sense of smelling by their fragrance, the carnation may be justly said to hold the first rank. The stateliness of its growth, the brilliancy and diversity of its colors, and the sweetness of its perfume, never fail to attract our regard and admiration. The tulip, though styled the queen of the garden, cannot boast of more admirers: they may with propriety be considered the two master-pieces of nature; and, though rival beauties, may be said to share the sovereignty of the garden equally between them. Yet it must be admitted, that the carnation, independent of its fragrance, has this advantage over its rival, that it continues longer in bloom; and that when planted in pots, it can be removed to decorate the green-house, the conservatory, or the drawingroom."

6407. *Varieties.* Parkinson (in 1629) has forty-nine sorts, which he divides into carnations, or "the greatest sorts in leaf and flower," and gillyflowers, or such as are smaller in both respects. One Tugger, in Westminster, was the most remarkable man at that time for the culture of these flowers. Rea (in 1702) has 360 good sorts of carnation; a number scarcely exceeded by the catalogues of modern British florists. The varieties of this flower are now arranged in three classes: flakes, bizarres, and picotées. *Flakes* have two colors only, and their stripes large, going quite through the leaves; *Bizarres* (*Fr.* odd. irreg.) are variegated in irregular spots and stripes, and with not less than three colors: *Picotées* (*Fr.* *piquetée*, pricked or spotted) have a white ground, spotted or pounced with scarlet, red, purple, or other colors. Of each class there are numerous varieties, arranged under the farther subdivisions of scarlet flake, pink flake, purple flake, yellow flake, &c. scarlet bizarre, crimson bizarre, &c. and purple picotée, yellow picotée, &c. Hogg gives a catalogue of nearly 350 sorts, so arranged, named after great personages, all of which were in his possession at the time he published his *Treatise on the Carnation*, in 1820. Only double varieties are in esteem. As an oddity may be mentioned the double dwarf carnation of Liege, with sessile flowers.

6408. *Criterion of a fine double carnation.* (*fig.* 610. c and d) "The stem should be strong, tall, and straight; not less than thirty or more than forty-five inches high; the foot-stalks, supporting the flowers, should be strong, elastic, and of a proportionate length. The flower, or corolla, should be at least three inches in diameter, consisting of a great number of large well formed petals; but neither so many as to give it too full and crowded an appearance, nor so few as to make it appear too thin and empty. The petals should be long, broad, and substantial, particularly those of the lower or outer circle, commonly called the guard-leaves; these should rise perpendicularly, about half an inch above the calyx, and then turn off gracefully, in a horizontal direction, supporting the interior petals, and altogether forming a convex, and nearly hemispherical corolla. The interior petals should rather decrease in size, as they approach the centre of the flower, which should be well filled with them. The petals should be regularly disposed alike on every side, imbricating each other in such a manner as that both their respective and united beauties may captivate the eye at the same instant: they should be nearly flat, however a small degree of concavity, or inflection, at the lamina, or broad end, is allowable; but their edges should be perfectly entire, that is to say, free from notch, fringe, or indenture. The calyx should be at least one inch in length, terminating with broad points, sufficiently strong to hold the narrow bases of the petals, in a close and circular body. Whatever colors the flower may be possessed of, they should be perfectly distinct, and disposed in long regular stripes, broadest at the edge of the lamina, and gradually becoming narrower as they approach the unguis, or base of the petal, there terminating in a fine point. Each petal should have a due proportion of white, i. e. one half, or nearly so, which should be perfectly clear, and free from spots. Bizarres, or such as contain two colors upon a white ground, are esteemed rather preferable to flakes, which have but one, especially when their colors are remarkably rich, and very regularly distributed. Scarlet, purple, and pink, are the three colors most predominant in the carnation; the two first are seldom to be met with in the same flower, but the two last are very frequently. When the scar-

610

let predominates, and is united with a paler color, or, as it sometimes happens, with a very deep purple upon a white ground, it constitutes a scarlet bizarre, of which there are many shades and varieties, some richer and others paler in their colors, as is the case with all the rest. Pink bizarres are so called when the pink abounds; purple bizarres, when the purple abounds; crimson bizarres consist of a deep purple and rich pink. When the pink flake is very high in color, it is distinguished by the appellation of rose flake; but some there are so nearly in the medium betwixt a pink and scarlet, that it can scarcely be defined to which class they belong. In addition to the foregoing varieties, there is a sort held in great esteem by cultivators, called *picotée* (fig. 611. *a*); many of which are very beautiful, and being harder than the other sorts, are in considerable request. The colors are principally yellow, and white spotted; their properties are the same as the other kinds, except that the edges of the petals are serrated or jagged, and the color is disposed in spots, where the others are striped. It is propagated in the same manner as the others."

6409. *Propagation.* By layers and pipings for continuing approved sorts, and by seed for procuring new varieties.

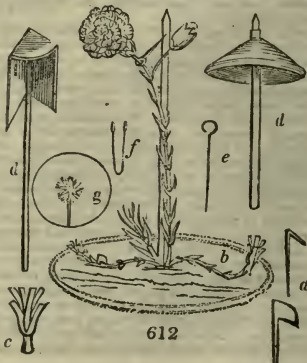

6410. *By layers.* The time for performing this operation is when the plants are in full bloom; some defer it till the flowers are on the decline; but in that case the new plants are not so well rooted as those layered earlier, and consequently less able to stand the winter. Laying, by the wounds it inflicts, considerably impairs the bloom, and generally kills the parent plant. The practical part of the operation has nothing extraordinary in it; a sufficient quantity of pegs (fig. 612. *a*) and of compost being provided, the pot containing the plant to be laid is placed on a table, and the layers prepared by cutting off their lower leaves (*b*); the earth is then stirred, and the pot filled up with "light rich mould, not of too fine a grain." (Maddock.) The incision is made by entering a quarter of an inch below the joint, and passing the knife up through the centre of it; it is then to be pegged down, and buried not more than half an inch deep. "It is advisable," Maddock says, "to peg down the layers in a dry state, being then less brittle, and consequently not so liable to break off as when they are wet and succulent; therefore, as soon as the layers are dressed, the pot should be placed full in the sun for half an hour, in order to render them more flaccid and pliant than they otherwise would be. When the layers are properly rooted, which will be the case with moist sorts in about three weeks or a month after laying, provided due care be taken to keep them regularly moist, and to shade them from the heat of the meridian sun, they are then to be cut off from the old plant, with about half an inch of the stalk which connects them with it, and be immediately planted in small pots, three or four plants in each, placed round the sides. The pots are to be placed under an arch of hoops, where they can be covered with mats, in case of excessive rains, till the severity of the weather renders it necessary to remove them into their winter repository, which is to be constructed in the same manner, and have the same aspect, as that described for auriculars." (Florist's Directory, 196.)

6411. *Hogg* commences laying when the flowers are sufficiently expanded to show which are in color, or true to their kinds, and which not: this he finds to be about the 21st of July, and he continues laying from that time to the 21st of August. The plants receive a good watering the day previous to laying, because they can receive it only for some time after through the fine rose of the watering-pot, on account of preserving the earth on the layed shoots. In performing the operation, he cuts off the nib or extreme end of the tongue, or talus, immediately below the joint, because, "if left on, it is apt to decay," and prevent the protrusion of that granulous matter from which the fibres proceed. Under favorable circumstances they will be fit to take off in seven or eight weeks, and may then be planted two or three in a small pot (No. 48.), three inches in diameter, by four inches deep. The pots are to be set on tiles, slates, or boards, there to remain till the middle or end of October, when they are to be removed to their winter quarters. (Treatise, &c. 56.)

6412. *By pipings.* This mode of propagating the carnation is very precarious. Maddock says, "five thousand plants were piped one season, of which not more than one hundred perished; whereas more than two thousand were lost of the same number the year following, with but very little variation in the management; nevertheless, some sorts succeed much better by piping than laying, and make healthier plants: it requires attention and experience to distinguish such sorts from the rest." Piping, however, is often a necessary resource where the shoots are too short for laying, or where in laying, shoots are broken by accident.

6413. *The first thing is to provide a slight hot-bed,* and cover it four or five inches thick with fine light mould, laid very regular and even. The cuttings intended to be piped are to have two complete joints, that is to say, they are to be cut off horizontally close under the second joint: the extremities or points of the leaves are likewise to be shortened, as for laying, which will leave the whole length of the piping from one inch and a half to two inches, according to its strength (fig. 612. *c*): as soon as thus prepared, it may be thrown into a basin of soft water for a few minutes, to plump it up. The earth on the bed where the pipings are to be placed should be moderately moistened, and rendered rather compact than otherwise, then take a small hand-glass, and with it make an impression neatly on the surface of the soil, in order to know where to stick in the pipings, so as to lose no room, or endanger their being disturbed when the glass is placed over them. The pipings are then to be taken out of the basin singly, and forced into the earth, in their wet state, with a steady hand; but not more than half an inch deep. When a sufficient number for the glass are thus placed regularly, at equal distances from each other, and rather more than an inch within the mark described by the glass, on every side, they are to be very gently watered, in order that the earth may adhere more closely to them, and thereby keep out the air; after this watering, they are to remain open, but not exposed to a hot sun, till their leaves become perfectly dry, after which the glass is to be placed over them carefully, on the same mark that was made by it upon the surface of the soil, before the pipings were placed there. The bottom edges of the glass are to be forced a little into the earth, to prevent the admission of too much air, which so far finishes the operation. What further remains to be done is to attend diligently to their management, with respect to sun and air, &c.

6414. *The soil ought to be kept regularly moist,* till they have formed their fibres; but too much moisture is as prejudicial as too little, and whenever they are watered, the glasses are never to be replaced over them till their leaves

are perfectly dry. The pipings should have a little of the morning sun, but must be shaded from it when the heat becomes considerable; this will be easily effected by placing mats upon a slight frame of hoops or laths erected over the bed about two feet above it.

6415. *The glasses should be occasionally taken off to admit fresh air*; if this material point is neglected, the consequence will be a green mossy appearance on the surface of the earth, and an universal mouldiness amongst the plants, which will destroy them. It requires more skill to know when and how long the pipings should be exposed to the air, while forming root, than for almost any other part of the management; on this single point, in great measure, depends the good or ill success of the whole undertaking. It is almost, or perhaps entirely, impossible to lay down any rules that will not be liable, as circumstances may vary, to mislead the inexperienced in the art of piping; much must depend on the discernment and prudence of the cultivator; there is no great danger to be apprehended from taking off the glasses for a few minutes, or half an hour, when it is cloudy, and the air rather warm and moist; but if no opportunities of this kind occur in due time, it should be done early in the morning: and rather than to omit doing it entirely, it will be better to take the glasses off, if it is only for five minutes, turning them upside down on the path, in order to air them, and replacing them again over the plants; even this will be of great service, though not equal to a more effectual airing at favorable times, which, indeed, becomes more frequently necessary in proportion to the length of time the pipings have been upon the bed; but when once they begin to strike fibre, they will soon spindle up and become extremely weak, if not carefully attended to, viz. agreeably to the following directions: when their fibres are formed, which the additional verdure and growth of the plants will demonstrate, the glasses should be placed over them very lightly, in order that more air may be admitted; and when they become tolerably well rooted, the glasses being no longer necessary, should be entirely taken away: but it seldom happens that all the plants, under the same glass, strike root together; some are generally a few days or a week forwarder than the rest, as will be apparent by their superior growth and verdure: such ought to be carefully taken up and planted in small pots, for winter preservation, or they may be planted round the sides of large carnation-pots, filled with the compost, where they will soon make rapid progress; the remaining plants which are not sufficiently rooted for removal, must be continued under the glasses, as before directed, till they become so.

6416. *Care of pipings as to run or degenerated flowers.* It is necessary to be very careful to mark such pipings as are taken off before it can be ascertained whether the original plant is in true colors, or run (or degenerated); because it very seldom happens that the pipings or layers, taken from a run flower, produce any other than run or plain-colored blossoms; in consequence of which they are not worth the trouble of propagation; the pipings ought therefore to be so marked as that it may be accurately known from what plant or plants they were taken, in order that if any of the originals should prove foul in color, or run, the increase of such may be distinguished from the rest, and destroyed. The layers and pipings of the most beautifully variegated flowers will frequently produce run blossoms; but it is impossible to prevent it, especially amongst the rich high-colored sorts, when they grow in a rich compost.

6417. *Some people pipe their carnations at the third joint*, but it is better to do it at the second; because, in the first instance, the third joint being more hard and woody, the pipings do not strike root so soon, or form afterwards such handsome plants, as when they are piped at the second joint from the extremity of the shoot. (*Flo. Direct.* 202.)

6418. *Hogg* considers, that piping the carnation should commence sooner than laying, before the shoots get hard and woody; he begins about the first of July. Plants raised from pipings, he considers as sounder, and more likely to encounter the rigors of a sharp winter than layers; but still as laying is the surest mode, he only makes pipings of such shoots as appear crowded, or too short or too high up the stalk to be laid easily. He plants them on a bed of dung of blood warmth, in a compost of one third maiden earth, one third leaf-mould, one third rotten horse-dung, and one sixth sand, finely sifted, that "the cuttings, when stuck in, may enter easily and without injury. The piping should be cut with a sharp pen or budding-knife, at the second or third joint, according to the condition of the shoot; but the shorter the better. The cut must take place horizontally, close below the joint, and the sheath, or part that covers the joint, must be carefully removed and peeled off. When the pipings are cut, the surface of the bed made flat and level, and gently watered through a fine rose, they may be stuck in three quarters of an inch deep, in rows not too near together. Then let them be watered again, which will help to fix the earth close round them; the glasses on no account are to be shut down close till they are dry, or they will inevitably fog, rot, and perish. The best glasses for piping are those made of the common window-glass, eight inches square and six inches deep, and the less air they contain the sooner will the cuttings strike root. The striking-glasses in common use, which are blown for the purpose, too often contain such a thick body of glass as to concentrate the sun's rays, and scorch the pipings. They require shading only when the sun is out, and then with a net or old mat, to admit the glimmering of his rays. If the weather continues dry and hot, they will require to be watered occasionally with a fine rose, early in a morning, over the glasses, which, for one fortnight at least, need not be removed if they are doing well. After, you may take them off from time to time as you see occasion, for half an hour or so in a morning, to give fresh air, and dry the glasses; and if any of the pipings appear mildewed or rotten, pull them up. At the end of six weeks they will be sufficiently rooted to be transplanted into small pots or a prepared bed, over which it would be advisable to place a frame and lights for a week or ten days, till they take root again. There they may be allowed to remain till the middle or so of September. In taking them up, if you find any not rooted, but sound, and their ends hard and callous, do not let them remain upon the same spot, but remove them to another bed, with a little temporary heat, and cover them with glasses as before; this will not fail to start them and hasten their fibring." (*Treatise*, &c. 52.)

6419. *By seed.* Carnation-seed is rather difficult to raise or ripen in this country, owing to the moisture and cold of the autumnal months. It is generally procured from Vienna and different towns of Switzerland; and if put in vials and well corked will keep for years. To raise it in this country, Maddock gives the following directions: "Those flowers which have but few petals, or, as it is more commonly expressed, are thin of leaf, generally produce most seed, and therefore are most to be depended on for a supply; but they should be possessed of the best properties in other respects, viz. their petals should be large, broad, substantial, and perfectly entire at the edge, and their colors rich and regularly distributed, and in due proportion, throughout the whole blossom. The plants should be selected from the rest, and their pots should stand upon a stage, defended against earwigs, in an open part of the garden, in which situation they should remain during bloom, and until the seed is perfectly matured; their blossoms should be defended from rain, by having glass, paper, or tin covers (*fig.* 612. *a*), suspended over them, in such a manner as to admit a free circulation of air; the pots should neither be kept very wet nor very dry; nor will it be proper to cut and mutilate the plants, either for their layers or pipings, till the seed becomes ripe, because it would certainly weaken them, and consequently injure, if not destroy, their seed. When the bloom is over, and the petals become withered and dry, they should be carefully drawn out of the pod or calyx, being apt to retain a degree of moisture at their base, endangering a mouldiness and decay in that part which will destroy the seed. There is another mode of treatment adopted successfully in ripening the seed, which is, when the bloom is over, and the petals begin to decay, they are to be extracted as above, taking particular care to leave the two styles, which appear like horns proceeding from the summit of the germin, or future pericarpium: the calyx (*fig.* 610. *a*) is then to be shortened to about one half of its original length, and an aperture made on one side of the remainder, down to the base of the pericarpium, so that no water can possibly lodge there; but in doing this, great care is necessary not to wound or injure the pericarpium, or seed-vessel itself, because it might prove destructive to the seed. After the above is performed, the covers may remain or be taken away at pleasure; but in the latter case it is advisable to loosen the upper part of the stems from the sticks, that the open end of the calyx may incline a little downwards, the more effectually to

preserve it in a dry state; the stems should not be suffered to hang so loose as to be in danger of breaking off with every puff of wind. The seed ripens from the end of August to the beginning of October: the pericarpium becomes brown, dry, and hard, and the seed, when ripe, is of a black or very dark brown color; those who are not sufficiently attentive to the ripening of their seed are apt to gather it too soon, before it is perfectly matured, in consequence of which the greatest part proves small, pale-colored, and unproductive. When gathered it should remain in the pericarpium, in a dry room, till the beginning or middle of May; it is then to be sown in pots filled with the compost, and have a little fine mould sifted upon it, barely sufficient to cover the seed: at this season of the year artificial heat is not required, the pots should therefore be placed in an airy part of the garden, be shaded from the heat of the sun, and kept moderately moist, but never very wet. As soon as the young plants appear with six leaves, and become about three inches high, they should be planted out on a bed of good rich garden-mould, at about ten or twelve inches asunder, and be defended from excess of rain and severe frosts, by mats on hoops, placed over the bed in the usual manner: they will in general blow the following summer. Some persons have advanced an opinion, that the seed of run plants produces as great a proportion of variegated flowers as any other; but the validity of this assertion has not yet been sufficiently demonstrated by experiment." (Maddock.)

6420. Hogg's directions differ in nothing of importance from those of Maddock. He says it often happens, that out of 200 blooming plants you will not be able to get even two pods of perfect seed. More was saved in the dry summer of 1818 than in any seven preceding years. Seedlings require two years to bloom, and the chance of getting a good new flower he reckons as one to 100. If a florist raises six new carnations in his lifetime, he is to be considered fortunate. Seed out of the same pod, he says, is reported to produce flowers of all the different varieties, flakes, bizarres, &c. Emmerton experienced that seed from a scarlet flake will produce a scarlet bizarre, and a rose or pink flake.

6421. Soil. The compost Maddock recommends is as follows: "one half rotten horse-dung, one year old, or that has been used as a hot-bed for cucumbers, melons, &c.; one third fresh sound loamy earth; one sixth coarse sea or river sand. These ingredients are to be mixed together in autumn, laid in a heap about two feet thick, in an open exposure, and turned three or four times during winter; or, otherwise, the dung alone, after being used as a hot-bed, may be thrown together in a heap, in a conical form, in order to rot more perfectly; and, as its surface freezes in winter, it should be pared off, and laid on one side, till the whole mass has been thoroughly frozen throughout; this may be repeated as often as the season permits, and it will be completely fit for use the following spring: the earth and sand may be added to it in March, when wanted to fresh pot the plants for bloom: the whole should then be well mixed and incorporated together, and passed through a coarse screen or sieve, to reduce its parts and take out stones, or any other extraneous substance which it may contain. In country places, where the air is more pure, experience has pointed out the propriety of using less dung and more loam; the proportions of which, for such situations, may be reversed, viz. one half loamy earth and one third dung, with the sand as before specified: the preparation of the compost, in other respects, is to be exactly the same in all situations." (Florist's Direct.)

6422. Hogg takes "three barrows of loam, one and a half ditto of garden-mould, ten ditto of horse-dung, one ditto of coarse sand; let these be mixed and thrown together in a heap or ridge, and turned two or three times in the winter, particularly in frosty weather, that it may be well incorporated. On a dry day towards the end of November, I take a barrow of fresh lime, which, as soon as it is slacked, I strew over it while hot in turning the heap; this accelerates the rotting of the fibrous particles in the loam, lightens the soil, and destroys the grubs, worms, and slugs. Lime is too well known as a manure to say any thing further in its praise here. If there has been much rain during the winter, so that the strength of the compost is reduced, and the salts washed from it, I take about seven pounds of damaged salt and add them to it, either dissolved in water or strewed over with the hand. This, from an experience of three years, I have found to be attended with the most beneficial effect upon the future health and vigor of the plants. During very heavy rains, many florists cover their compost with tarpauling or double mats, to prevent the nutritious particles from being washed out; this is also an excellent precaution. If any objection be started that the quantity of dung is too great in proportion to that of the loam, I answer, that such an objection might be well founded, if the compost were to be used immediately on its being mixed together; but as it has to lie six months before it is used, I am decidedly of opinion, that the quantity is not more than is necessary in order to ensure a luxuriant growth and a generous bloom." For flowers that are apt to sport in color, such as Humphrey's Duke of Clarence, Plummer's Lord Manners, &c. he lowers the compost, and uses "three barrows of sound staple loam, two ditto old rotten cow-dung, one ditto horse-dung, a half ditto sand, a half ditto lime rubbish, or old plaster; to be prepared, and well incorporated, as before." He also uses the same compost for yellow picotees. (Treatise, &c. 45.)

6423. Justice says, "One article with respect to the soil for carnations you must certainly observe; never to use for it the ground wherein hyacinths have been planted; they, from certain experience, being a sure poison to the carnation, and vice versa." (Brit. Gard. 427.)

6424. Manner of growing. The commoner sorts are planted in beds or borders, but the select kinds always in pots.

6425. Pots and potting. Maddock uses pots for flowering plants, "at least twelve inches wide at the top, six inches at the bottom, and ten inches deep in the inside, with a circular aperture in the centre of the bottom, of about an inch in diameter; also three or four smaller holes round the sides of the pot, close to the bottom, to prevent the possibility of water lodging or remaining in that part." Hogg uses pots of twelve or sixteen to the cast, being smaller than those recommended by Maddock.

6426. The operation of potting, according to Maddock, "should commence about the middle of March, if the weather is not extremely unfavorable; but it should not, on any account, be deferred later than the end of that month. The pot is, in the first place, to be half filled with compost, having an oyster-shell, with its hollow side downwards, placed over the hole in the centre of the bottom: this compost is to be higher at the sides than in the centre of the pot, and the plants intended for it, which are supposed to have been wintered in small pots, containing four plants each, are to be carefully turned out of their pots, with all the earth adhering to them, in a ball; and after rubbing off about half an inch of the surface of the old mould, round about the plants, above their fibres, cleaning them and cutting off the decayed points of their leaves, the ball is to be carefully placed in the centre of the pot, and the space between it and the sides filled up with the prepared compost. It is very necessary to be attentive in placing the plants, that they be neither planted deeper nor shallower than they were before; the compost should therefore be high enough to replace the old earth that was rubbed off on potting, exactly to the same height as before, i. e. half an inch higher than the ball of old earth and fibres; and the whole surface of the earth in the pot, when the operation is finished, should be nearly level or flat; but by no means higher at the centre than at the sides, because the plants would thereby be kept too dry; nor should the compost come nearer than within an inch of the top or rim of the pot, after it has been gently shaken, or struck against the ground on finishing, as an inconvenience will attend its being too full, when the operation of laying comes to be performed, which requires some additional mould on the surface, for the layers to strike into." Hogg considers the first week in April as the safest and best time to pot carnations, and he performs the operation in the same manner as Maddock.

6427. General culture. When the plants are potted off for bloom, the pots should be placed in an open airy part of the garden, under an arch of hoops, that in case of cold drying winds, heavy rains, or frosty nights, mats may be thrown over, to preserve them from the effects of such unfavorable weather: in this situation they are to remain, always open to the air, except in the cases above mentioned, and be kept regularly watered with soft water from a fine-rosed watering-pot.

6428. *When their flower-stems are grown eight or ten inches high*, it will be necessary to support them with sticks, forced into the earth in the centre of the pot, to which the stems are to be loosely tied with small pieces of bass mat: these sticks should be as high as the hoops will admit, in order that the pots may remain under them as long as possible; but when the stems are grown too high for this situation, the pots are to be removed to the stage, and remain there till the time of bloom; the small sticks should be replaced with others more suitable for the occasion; these should be about four feet or four feet six inches long, regularly tapering a little from the bottom to the top, and be painted green; they should be substantial and straight, and their lower ends are to be forced into the earth in the centre of the pot, sufficiently deep and firm, not to be shaken loose by the wind. As the stems continue to advance in height, the tying, as above, must be also continued at about every five or six inches: it is proper to look over and examine the plants for this purpose every three or four days, as the stems are rather brittle, and liable to be broken by the wind, if not supported in this manner.

6429. *If any small, green, winged insects appear on the stems or foliage of the plants*, particularly upon or underneath the flower-pods, they must be effectually extirpated or destroyed, either by the means of a small soft brush or feather, by the application of a strong infusion of tobacco-water, or some similar easy and safe expedient: even Scotch snuff dusted upon the infested parts early in the morning, while the plants are wet with the dew of the night, has been sometimes tried in this case with success.

6430. *The calyx of many sorts contains a great number of petals*, which, as they increase in bulk, will distend and burst it, if not timely prevented: this generally happens a few days previous to the proper time for the blossoms opening, and will, if neglected, soon manifest the effects of such neglect, by letting out the petals on one side, and thereby producing a loose irregular appearance, totally destroying that compact, graceful, circular form which a perfect flower ought to possess, and which is one of its greatest ornaments; but this disagreeable effect may be easily avoided, by fastening a small narrow slip of bladder round the middle of the pod, where it is most swelled, and appears to have the greatest inclination to burst. The slip of bladder should be rather longer than is required to go once round, so that one end of it may lay over the other a little, which, by the application of a little gum-water, will adhere firmly together, and answer the purpose completely. Small slips of wet bass mat may be substituted for those of bladder, and being tied with a single knot round the same part of the pod, will answer nearly as well. (fig. 612. b)

6431. *When any of the flowers begin to open and expand*, such should be shaded, both from sun and rain, by means of strong caps or paper covers (fig. 612. d), about twelve inches in diameter, painted white or green, and formed like an umbrella, to throw off rain; each should have a square tin tube on the summit, that will permit the stick, to which the stem is tied, to pass through it as far as is necessary. The tube should be about two inches long, and have a small hole bored through one of its sides, that it may be fixed by a nail to any part of the stick where required. But when the major part are in bloom, a cloth awning should be placed over the whole, and be drawn up or let down by means of lines and pulleys, exactly in the same manner, and on the same occasions, as for the bloom of hyacinths and tulips. The same frame that was used for the hyacinth (fig. 591.) will, without being removed or taken down, answer in every respect for carnations: nor can any other more suitable be contrived or adopted.

6432. *In order that the flowers may appear to the greatest advantage*, it is necessary that the pots should stand upon a stage or platform of boards raised about twelve or fifteen inches above the ground; this stage should be very strongly supported, in order to sustain the immense weight of the pots, without danger of giving way; the supporters of this platform should stand in shallow leaden or earthen vessels, filled with water, to prevent the access of earwigs, which are destructive enemies to the blossoms of carnations: they secrete themselves commonly during night in the calyx (fig. 612. a), and soon commence their depredations, by biting off and devouring the lower ends or claws of the petals, which of course will cause them to drop out, and thereby disfigure the flower.

6433. *The stands, or reservoirs*, should be broad enough to allow an intermediate space of water, three or four inches wide, between their sides and the supporters placed in the centre of each. Earwigs will nevertheless be frequently found amongst the flowers, having been brought upon the stage with the pots, where they remain concealed, or dormant, till the flowers are in bloom; or perhaps they may have gained access by having crept up the external frame, and from thence fallen down upon the pots; or they may possibly have flown upon them, as they are evidently provided with wings, though it does not appear that they often make use of them. At all events, it is necessary frequently to examine the plants, and the sticks which support the stems, as earwigs will be often found concealed there in the daytime, particularly at the part where the stems are tied, which affords them a more secure hiding place. If any of the petals hang loose, or drop out, it is a certain sign that an earwig is, or has been there: in the first case, blowing forcibly with the mouth, into the blossom, two or three times, will cause it to creep out; but if it has quitted the blossom previous to the discovery, it should be carefully sought after and destroyed, or it will continue its depredations the succeeding night; it will, however, most probably be found skulking somewhere about the same pot, but not farther distant than the next, or next but one, unless the search has been deferred too long.

6434. *The flowers should be suspended from the sticks* by small pieces of fine elastic brass wire (fig. 612. e), of unequal lengths, (sold in the pin-shops,) to support them in an easy graceful manner, neither too near together nor remote from each other: one end of the wire should be introduced into the stick by means of a small awl, and there be fixed sufficiently tight to prevent its dropping out by the weight of the blossom; the other end of the wire should be formed into a small ring, about a quarter of an inch in diameter, to enclose the stem below the calyx; this ring should be a little open on one side to admit the stem freely, without bruising it, which would materially injure the bloom.

6435. *Those who are particularly curious in blowing their carnations*, carefully extract such petals as are plain, or run from their true colors: they perform this by means of an instrument adapted to the purpose (fig. 612. f), and with the same arrange the remaining petals, so as to supply the defect; in like manner they dispose the whole with such regularity that the flowers appear to have an equal distribution of beautiful petals, nearly alike on every side, without imbricating each other, so as to hide their respective beauties; and if the blossom consists of too great a number of petals, they extract the smallest, and thereby afford the others more room to expand, which takes off the confused effect always produced by redundancy. The pots must be kept regularly and constantly watered during bloom, in the manner before described, and no favorable opportunity should be neglected to afford them the full advantage of exposure to light and air, by drawing up the cloth covering, in the manner before described; but no rain must be admitted to the blossoms at any period of the bloom. Some place their stage, or platform, on one side, others in the centre; but a double row of pots on each side, with a commodious path in the middle, is preferable. If the pots contain only two plants each, they consequently are not required to be so large as for four or five; but the latter have much the best appearance in bloom, producing a greater number of blossoms: it is not however advisable to permit every pod to blow, especially of such sorts as are naturally possessed of but few petals; because it would render each blossom smaller and thinner than if only one or two were left on each plant: it is, therefore, proper in this case to cut off, or draw out the small lateral pods, close to the main stem, as soon as they can be ascertained, in order that the remainder may have time to reap due benefit by it; but those sorts that have remarkably large short pods, abounding with petals, must be suffered to bloom them all, or the greater part, although, in general, three or four pods are as many as ought to be suffered to blow on one plant. These rules, or remarks, admit of some few exceptions, but the instances seldom occur.

6436. *Carnations are to be treated, during winter, much like auriculas*: with respect to the weather, they are seldom injured by a moderate dry frost, though it is safer to defend them from too much of it; but it is very necessary to caution against covering them up close when the plants are wet, as they are, in

that state, very liable to contract a destructive mildew, if they have not the benefit of a free circulation of air; this mildew makes its first appearance in purple spots on the foliage, which can only be cured or prevented from spreading amongst the adjacent plants, by cutting out the infected part, or removing the pot, as soon as discovered, it being not improbable but that the distemper is, in great measure, owing to a very minute insect, brought into existence by the warmth generated at such times. Plants thus infected have been frequently known to communicate the contagion to others which stand near them, therefore no time should be lost in cutting off the spotted leaves or removing the plants to a distant part of the garden. A repository, constructed in the manner already described, is less liable to the above effects than any close frame or situation can possibly be, because it has the advantage of a free circulation of air at all times, even when shut up, unless indeed when closely covered up with mats, &c. as in cases of severe frost; but at such times no such consequences are to be dreaded.

6437. *The rains of autumn and winter are generally more than sufficient for carnations*, as well as for auriculas, from an excess of which it is proper to defend them: of the two extremes, it is safer to keep them rather too dry than too wet at these seasons, especially during winter; but a moderate degree of moisture is always to be preferred, except when the weather is severely frosty. As too long a deprivation of light is at all times prejudicial to plants, therefore, whenever the winter repository is required to be closely covered up with mats, for several days and nights, with little intermission, no opportunity should be lost during the middle of the day, if the sun shines, to take off the mats in front of the glasses, in order to admit its light and warmth. Whenever the surface of the earth in the pots becomes green with moss, or too compact and adhesive, it will be proper to stir it up carefully, about half an inch deep, and to sprinkle a little coarse dry sand regularly upon it: this will prevent any great degree of tenacity in future, and be of great service; it may be repeated as often as required.

6438. *In spring*, the pots will probably require to be frequently watered, and by the middle of March the operation of potting is to commence, as already described. The blossoms of carnations, particularly the high-colored sorts, are very apt to run from their striped or variegated colors to a plain one; they are then esteemed of little or no value: but when they have only partially run, they may sometimes be recovered to their former state, by being planted in a poor dry soil, that will but just afford sufficient nourishment for their existence. (*Florist's Direct* 166.)

6439. *Hogg* having potted his blooming plants, supports them with green sticks, in the manner of Maddock, and top dresses about the middle of June "with about half an inch of rotten horse-dung passed through a sieve, which he finds materially to assist the plants, and promote the growth of the layers, on which depends the preservation of the collection. Many," he says, "top-dress with some of the hotter manures of night-soil, sugar-baker's scum, &c., but, in my opinion, that is not necessary for carnations, and is attended with danger: for, if they are not reduced to a perfect mould, they will corrode, and burn the plants." He waters freely while the pods are swelling, and during the whole time they continue in blossom. As soon as the side shoots appear, he places "a paper collar round the bottom of the blossom to support it. These collars are made of white card-paper, in the form of a circle of three or four inches in diameter (*fig.* 612. *g*), with a hole in the centre just large enough to admit the calyx or pod, without much compressing, and with a cut extending from the centre to the outside or circumference, like the radius of a circle. On these cards the flower is preserved in shape and form a long time; on these the petals are also finely disposed, and the beauty of the carnation displayed to great advantage." We must confess, we think these collars a great deformity, and much prefer a tie of thread or bass mat, or the slip of bladder recommended by Maddock. When placed on the stage, they should have the benefit of the morning sun till about nine or ten o'clock, according to the intense heat of its rays; the same in the evening, with as much open exposure to the air at all times as you can give them, without injury to the bloom." In winter *Hogg* preserves them in frames, in the same manner as he recommends for auriculas. When he has more plants than he can blow in pots, he plants them in beds of the same compost used for the others, protecting them from severe frosts and heavy rains, and in other respects treating them in the same manner as if in pots. (*Treatise*, &c.)

SUBJECT. 18. *Pink*. — *Dianthus hortensis*, L. *Decan. Trig. L.* and *Caryophyllæ*, J. *L'œillet*, Fr.; *Nelke*, Ger.; and *Garofano*, Ital. (*fig.* 611. *b*)

6440. *The pink* is considered by many to be a subspecies of the *D. caryophyllus*; and by others to have proceeded from *D. deltoides*, a British species, and the pheasant-eye pinks from *D. plumarius*. This flower, Professor Martyn observes, does not seem to have attracted any notice among our ancestors; and it is only within the latter half of the 18th century that pinks were much improved and varied, so as to be greatly valued among florists. It is now much cultivated everywhere, and especially in the manufacturing districts; in the neighborhood of Paisley, it is carried to a high degree of perfection. (See Part IV. Book I. Ch. III. Sec. 3.) The pink is much harder than the carnation, and less liable to the casualties incident to the latter.

6441. *Varieties*. Parkinson, in 1629, mentions six or eight sorts. Rea, in 1704, says, there are many sorts, but of little esteem. *Hogg*, in 1820, gives a list of nearly one hundred names, as containing the best sorts in England; but Davey, who has raised more fine varieties of this flower than any one else, has above double that number; and the Paisley growers reckon above three hundred sorts.

6442. *Criterion of a fine double pink*. "The stem should be strong, elastic, and erect, and not less than twelve inches high. The calyx rather smaller and shorter, but nearly similar in form and proportion to that of a carnation, as well as the formation of the flower, which should not be less than two inches and a half in diameter. The petals should be large, broad, and substantial, and have very fine fringed or serrated edges, free from large, coarse, deep notches or indentures; in short, they approach nearest to perfection when the fringe on the edge is so fine as scarcely to be discernible; but it would be considered a very desirable object to obtain them perfectly rose-leaved, *i. e.* without any fringe at all. The broadest part of the lamina, or broad end of the petals (*fig.* 611. *c*), should be perfectly white and distinct from the eye, unless it be a laced pink, that is, ornamented by a continuation of the color of the eye round it (*fig.* 611. *b*), bold, clean, and distinct, leaving a considerable proportion of white in the centre, perfectly free from any tinge or spot. The eye should consist of a bright or dark rich crimson, or purple, resembling velvet; but the nearer it approaches to black, the more it is esteemed; its proportion should be about equal to that of the white, that it may neither appear too large nor too small." (*Maddock*.)

6443. *Propagation*. Generally by pipings for ordinary purposes, sometimes by layers to preserve rare sorts, and by seed for new varieties.

6444. *By pipings*. The time to commence this operation is immediately previous to or during the bloom, or indeed as soon as ever the new shoots are grown of a sufficient length for that purpose. *Hogg* commences about the twenty-first of June. The operation is the same as in piping carnations; only some do not apply bottom heat. This, however, is the more certain mode, and the pipings are ready to remove sooner, and generally in a fortnight or three weeks.

6445. *By seed*. Proceed as directed for carnations.

6446. *Nicol* has found great advantage from impregnating double and semi-double pinks, with single kinds, both in respect to fecundating more stamens, and producing in consequence more seed; but also in increasing the varieties, or new sorts raised from such seed. (*Caled. Sec. Mem.* iii. 270.)

6447. *Mode of growing.* The common sorts are introduced in borders, and the better varieties in prepared beds. Sometimes rare sorts are planted in pots, but in general they thrive better in the open ground.

6448. *Soil.* Maddock says, "A good fresh loamy soil, dug and comminuted about two feet deep, and manured with a stratum of cow-dung, two years old, mixed with an equal proportion of earth, (this stratum to be about six inches thick, and placed five or six inches below the surface,) is all the preparation or compost that appears necessary for this flower."

6449. *General culture.* As soon as the pipings are struck and will bear removal, they are to be planted on a bed of common garden-mould, where, in a few weeks, it will easily be discernible which are the strongest plants to remove to the blooming-bed. "This bed should be raised three or four inches above the surrounding paths, and its sides may be supported with an edging of boards, to come up even with, or one inch higher than its surface; this last, more for the sake of neatness than any particular utility it will be of to the plants."

6450. *The plants intended for the principal bed for bloom,* should be placed upon it in August, or early in September, as they do not blow quite so well if removed later in the season; they should be planted at about the distance of nine inches from each other, and the bed should be laid rather convex, or rounding, to throw off excess of rain; but will require no other covering than a very slight one in case of severe frost. The bed should be kept free from weeds, and its surface stirred up a little if it inclines to bind, or, in other words, whenever it becomes too firm and adhesive. Larger strong plants will put up numerous flower-stems, but it is proper to thin them out a month or six weeks before bloom; in doing which, the largest and strongest should be left, especially the leading stem, which proceeds from the heart or centre of the plant, together with all its best pods; but no plant, however strong, should be permitted to bloom more than ten or twelve blossoms, nor weakly plants more than four or five. In order to obtain them large and well colored, all the small lateral pods should be cut or pulled off, as they never produce any other than diminutive flowers, and at the same time rob the others of a certain part of their nourishment, which, of course, prevents their attaining the size and beauty they would otherwise arrive at.

6451. *The largest and most bushy plants do not produce the finest flowers;* they naturally put forth numerous small stems, which their roots are not able to support sufficiently to produce large blossoms. Strong healthy plants, not too large, and consisting of a capital leading stem in the centre, with but little surrounding increase, are most proper to select for the best bed; these will seldom put up more than one or two stems, which will, however, be very strong, grow tall, and produce three or four blossoms, as large and fine as the sort is capable of.

6452. *Those pods that appear in danger of bursting* should be tied in the same manner as directed for carnations under similar circumstances. Such sorts of pinks as are most inclined to burst their pods, oftentimes produce larger and finer flowers than others which have smaller pods, because the latter generally consist of too few petals: it is, however, more desirable to have their pods large and long, than too short and round, as it is hardly possible to preserve the latter from bursting, whereby the beautiful circular form which the flower ought to possess is lost. When the calyx is so extremely short that it must inevitably burst, it is better to assist nature by what is called letting down the pod, that is, with a penknife to nick it down at the bottom of each of its indentures, as low as may be deemed necessary, in order to let out petals regularly on every side, and preserve the circular form of the blossoms; for if it is left to nature, the calyx will burst only on one side, and its petals will consequently force their way through that aperture, and produce a loose deformed flower; some kinds are possessed of such weak and short pods, that the calyx (fig. 571. d) will entirely burst from top to bottom on one side, and open so very wide as to suffer almost all the petals to fall out and hang down when they have been in bloom but a short time; such indeed hardly deserve to be classed amongst the best sorts, let their properties, in other respects, be ever so desirable. When the flower-stems are grown sufficiently long, they should be supported with small sticks or wires, as the fancy of the cultivator may direct; but these ought to be disposed of in such a manner as to allow the blossoms to expand and blow perfectly distinct from each other, that the whole may have an easy graceful appearance. Those who can bestow sufficient time and attention to their bloom of pinks, may contribute greatly to the effect, by placing upon the calyx the thin pieces of card, or stiff paper, cut circular (fig. 612. g), already mentioned (6439.); these are to be placed close underneath the guard-leaves, so as to support them horizontally, and will, when they extend just as far as the extreme points of the petals, give the blossom a very circular and pleasing appearance; but they are apt to warp when long exposed to the weather, especially after being wet, and must either be taken off entirely, or exchanged for new ones, as they will no longer answer the intended purpose. Some kinds do not require any assistance of this sort, but the greater part not having their guard-leaves sufficiently strong at the base to support themselves in a horizontal position, are considerably improved by this little contrivance, which, perhaps, by the foregoing description, will not be difficult to comprehend.

6453. *At the time of bloom,* which is towards the end of June, it is proper to defend the bed by a covering or awning, somewhat similar to that used for the bloom of tulips and carnations; they should, in like manner, enjoy the advantage of light and air, and the soil should be kept regularly moist by soft water, administered between the plants, carefully avoiding to wet the blossom. (*Florist's Direct.* 220.)

6454. *Hogg* observes, that "pinks moved and transplanted in the spring never do well, nor show half the beauty which those do that were planted in September; the laced pinks in particular appear almost plain, and without their distinguishing character: they should likewise never be suffered to remain longer than two years without either change of soil or situation."

6455. *Emmerton* says, "your pink-bed should be top-dressed in the spring, if you have a desire to excel in blooms, with some old night-soil, or sugar-baker's scum, finely sifted and sown over it. Your strong-blowing plants should not be allowed to bloom more than eight or ten blossoms, and those that are weaker, of a less size, not more than four." (*Treatise on Auricula*, &c. 191.)

SUBJECT. 19. *Double Rocket.* — *Hesperis matronalis*, L. (*Lam. ill.* t. 564. f. 1.) *Tetrad.* *Siliq.* L. and *Cruciferae*, J. *Julienne*, Fr.; *Nachtviolen*, Ger.; *Esperide*, Ital.

6456. *The double rocket* is a biennial or imperfect perennial; a native of Italy, and cultivated by Gérard in 1597.

6457. *The varieties* are the white and purple, both very double, and forming a spike of about a foot long, of great beauty and fragrance, and considerable duration.

6458. *Propagation and culture.* The plant is extremely difficult to preserve, especially near large towns. It does not thrive either near London or Paris; and both capitals, especially the latter, are supplied with it from provincial growers. It is very much grown in the west of Scotland, and in the Netherlands; and between Calais and Abbeville it may be seen in great perfection in most cottagers' gardens. Van Mons (*Hort. Trans.* ii. 153.) says it prospers best in a clayey soil, but flowers best in one of a lighter texture, like the lobelia cardinalis. The best directions which we have met with for its culture are given by Robertson. (*Caled. Mem.* ii. 245.) He says, "The double rocket is a beautiful plant, rather scarce in this part of the country, owing chiefly, I suppose, to florists not being acquainted with a successful way of increasing it. I had a few plants of rocket under my care, and I did them all justice, as I thought, but all would not do; I lost them all. I tried to part their roots, but being small and weak, the slugs eat them all up in a short time; as slugs are very fond of them, especially of their leaves. I tried to increase them by cuttings in the common way, with as little success. This led me to try another

method, which I would recommend as a never-failing way of propagating this beautiful flower. If a person has but one plant of rocket, and is anxious for its flowers, the first thing is, after the flower is beginning to fade, to eat down the stalks and divide them into ordinary lengths of cuttings; next to cut off the leaves, and smooth the ends; then to make three slits with a knife in the bark or rind, longways, so as to separate or raise the bark for half an inch in length. When the cutting is inserted in the ground, the loose bark naturally curls up; and it is from this bark that the young roots proceed. The partial separation, and the turning up of the bark, seems to promote a tendency to throw out roots. The cuttings may be put into flower-pots, as they may thus be sheltered during winter with more ease; or they may be placed in the natural earth, provided the soil is light and fresh. Covering them with a hand-glass will forward the rooting of the cuttings; or with the aid of a hot-bed they will succeed excellently. I have used this simple way for six years back, and never without success; not one in twenty having failed. This method, it may be remarked, will hold good in cuttings of stock-gilliflowers, and double wallflowers."

SUBJECT. 20. *Cardinal Flower.* — *Lobelia*, L. *Pent. Monog. L.* and *Campanulaceæ*, B. P. *Lobelie*, Fr.; *Kardinalsblume*, Ger.; *Fior Cardinale*, Ital. (figs. 613. and 614.)

6459. There are three species of lobelia which rank high as florists' flowers.

6460. *The common cardinal flower* (*L. cardinalis*) (*Bot. Mag.* 320. and fig. 613.) has roots composed of many white fleshy fibres, oblong leaves, stalks erect, about a foot and a half high, terminated by a spike of flowers, "of an exceedingly beautiful scarlet color," appearing in the end of July and August. It is a native of Virginia; and it is found abundantly by the side of rivers and ditches: introduced in 1629. Justice is in raptures with it, describing it as "a flower of most handsome appearance, which should not be wanting in curious gardens, as it excels all other flowers I ever knew in the richness of its color." There is a dwarf variety, but it is very liable to perish.

6461. *Propagation and culture.* By seeds, offsets, or cuttings; but the former method produces the strongest plants. Sow in pots of rich earth soon after the seed is ripe, and place them under the protection of a frame. The seeds will appear the following spring; and after they have two or three leaves, should be planted in separate small pots, and shifted into larger ones once or twice during the season. Place them in an eastern exposure, and supply them freely with water. Protect, during winter, by a frame; and the following spring, shift them into pots, six or eight inches diameter, in which they will flower. If not much exposed to the sun, they will continue long in beauty. The roots do not last above two or three years; and therefore a succession of young plants, from seed or slips, should be regularly provided. (*Müller.*)

6462. *The fulgent cardinal flower* (*L. fulgens*, W. en.) (*Bot. Rep.* 659. and fig. 614. a) is a native of Mexico, and was introduced into England in 1809: flowers in July and August. Though a native of a warm climate, it has been found to bear the severity of our winters, by being immersed in water, as an aquatic, and with this treatment has flowered well by the sides of ponds and in cisterns.

6463. *Propagation.* By suckers or cuttings, which strike with remarkable facility in any shady situation; and by seed. According to Professor Van Mons, "the seed should be sown, as soon as it is ripe, in earthen pans; the earth should be moistened, and after it has imbibed the water, the seed must be spread over it without being covered. The pans should be sheltered from the frost, and the young plants may be transplanted in April and May. Very few of them remain, more than the second year, without flowering."

6464. *Culture.* This plant has assumed a character of uncommon magnificence under the management of Hedges, which is thus detailed by Sabine: "In October, he takes off the suckers, which are thrown up from the roots of the old plants, and puts them into small pots, one in each pot, and keeps them in a cold-frame till the middle of January: he then removes them into a cucumber-

frame, where the heat is kept up to 65 degrees of Fahrenheit's scale, by linings of hot dung; a pine succession stove of the same temperature will equally suit them. In the middle of February, they are shifted into pots a size larger; and at the end of March, or in the beginning of April, they are again moved into larger pots, and in the middle of May they are a third time shifted; the pots to be used for this last shifting are twelve. As soon as the plants are well rooted, after the last removal, they are carried into a peach-house or green-house, in which they continue till they flower, and are hardy enough to bear the open air. When they are preparing to throw up their flowering stems, and during their growth, it is necessary that they be kept very moist, which is effected by putting pans under the pots, and keeping the pans constantly filled with water. The plants thus managed, begin to flower early in July, and the spikes continue to blow, and are covered with flowers through the autumn. The compost used in the pots is formed of equal parts of brown or yellow loam, and of leaf or bog mould, to which is added sand, equal to one fourth of the previous composition, the whole being well mixed together. The plant of *Lobelia*

fulgens, which was exhibited to the Society on the 19th of last month, by Hedges, had been managed as above directed; but as no notes of its size and height were made at the time, the following dimensions have been taken from another plant in the garden at Kenwood. The base of the stem was near six inches in circumference; the height of the centre spike was five feet and a half; the shoots from the bottom and sides of the main stem were in number seventeen, rising together round the principal stem, to the height of about four feet and a half. Hedges states, that the plants were in the two preceding years, much taller than that now described. Some few plants were observed to be rather shorter, and to have a more bushy appearance: this is produced by stopping the centre stem, after the last shifting, by which the side shoots become more vigorous and fuller of flower, and in this state they form handsome companions to the flowering plants of *campanula pyramidalis*, whose beautiful spikes of blue flowers agreeably contrast with the brilliant scarlet of the lobelia." (*Hort. Trans.* ii. 400.)

6465. *The splendid cardinal flower* (*L. splendens*, W. en.) (*Bot. Reg.* 60. and *fig.* 614. b), a native of Mexico, and introduced in 1814, may be treated like *L. fulgens*; and the *blue cardinal flower* (*L. siphilitica*) (*Jac. Ic.* iii. t. 597.), a native of Virginia, and introduced in 1665, may be treated like *L. cardinalis*.

SUBJECT. 21. *Pyramidal Bellflower*. — *Campanula pyramidalis*, L. (*Park. Parad.* 354.) *Pent. Monog. L.* and *Campanulaceæ*, B. P. *Campanelle Pyramidale*, Fr.; *Pyramidenglocken*, Ger.; and *Campanule*, Ital.

6466. *The pyramidal bellflower*, in its cultivated state, has thick ramose roots, which are milky; oblong leaves; and strong stalks, four feet high, from the sides of which the flowers are produced for more than half their length, forming a sort of pyramid. The most common color is blue, but there is a variety with white flowers. It is a native of Istria and Savoy, and was cultivated by Gerrard in 1596. Formerly it was in demand as an ornament to halls, and for placing before chimneys in summer, being planted in large pots, and trained in the fan manner, so as to cover a large surface. In the shade it continues in flower for two months or more.

6467. *Propagation and culture*. By seed, cuttings from the stem, or by dividing the roots; the last method makes the strongest plants in the shortest time. The season for this operation is after the bloom has faded in September; the sections are to be planted in pots, and protected by a frame during winter. In spring they may be transplanted into large pots, and in the beginning of summer into still larger ones, in which they are to flower the summer following.

6468. *By seeds*. The plants so raised, Miller says, are always stronger, and the stalks rise higher, and produce a greater number of flowers. Good seeds are to be obtained by placing a strong-flowering plant in a warm situation against a wall or under a glass case. They are to be sown in pots of light earth soon after being gathered, protected by a frame during winter, and will come up in spring. When the leaves decay in October, they are to be transplanted to beds of light sandy earth, without any mixture of dung, which is a great enemy to this plant. Here they are to remain two years, being protected in winter by rotten tan; they are then to be removed to their final destination in September or October, and the year following, being the third from sowing, they will flower. The plants, Miller observes, of this species, as of many others which have been long propagated by roots, offsets, or cuttings, do not so readily bear seed as those which have been raised from seed.

6469. *The C. Carpatia, grandiflora*, and several other very showy species, may be similarly treated. |

SUBJECT. 22. *Chrysanthemum*. — *Chrysanthemum sinense*, Sab.; *Anthemis Artemisiæ-folia*, W. *Syng. Polyg. Super. L.* and *Corymbifera*, J. *Chrysantème*, Fr.; *Goldblume*, Ger.; and *Crisantero*, Ital.

6470. *The Chinese chrysanthemum* is a fibrous-rooted half-hardy perennial, with pinnate, gashed, serrated leaves, leafy stems, from three to four feet high, and flowers generally on solitary peduncles. It is a native of China, where it is highly prized and extensively cultivated as an ornamental plant, and was introduced in 1764. Here it contributes greatly to the beauty of the flower-garden in a fine autumn, and of our conservatories in November and December, when scarcely any other plants are in flower.

6471. *Varieties*. The Chinese are supposed from good authority to have fifty varieties or upwards: there are twenty-three sorts described by Sabine, as having flowered in this country, and there are a number more, of recent introduction, which have not yet flowered. Through the exertions of the Horticultural Society, and some nurserymen, and private individuals, it is expected all the Chinese sorts will soon be imported. Sabine describes as having flowered in the garden of the Horticultural Society, and as to be procured in the nurseries, the following:—

The purple
Changeable white
Quilled white
Superb white
Tasselled white
Quilled yellow
Sulphur yellow
Golden yellow
Large lilac
Rose or pink
Buff or orange
Spanish brown

Quilled flamed yellow
Quilled pink-flowered
Early crimson (*fig.* 615. a)
Large quilled orange (b)
Expanded light purple
Quilled light purple
Curled lilac
Superb clustered yellow
Semi-double quilled pink
Semi-double quilled white
Small yellow single.

6472. *Propagation.* By dividing the root, by suckers, and by cuttings: the latter is the best mode, as producing plants less likely to throw up suckers. The cuttings are usually taken from the side branches in August, planted in shallow pots, placed in a warm shaded spot, and covered with a hand-glass. In a month or six weeks, they will have struck, and are then put into pots of the smallest size, and put in a warm situation, where they remain till November; they are then placed under a frame for the winter.

6473. *The soil* used generally for the chrysanthemum, is two thirds of turfy or virgin loam, and one third of leaf-mould or decayed dung.

6474. *Culture in pots* In April, the cuttings of the preceding autumn are shifted into No. 32 pots, and set out into a well sheltered south border, on a bed of scoræ, for the summer. About the beginning of October, when the flower-buds are formed, they are taken into the green-house, on the stage of which they are exposed as much as possible to the air, both night and day, in good weather, but protected by the lights from wind, rain, and frost. The Chinese also propagate the chrysanthemum by cuttings; but they take them off in May, strike them as we do, and then put each plant in a small pot, in which it flowers the succeeding autumn. By this means the plants are much dwarfer than ours usually are, and instead of having great part of their stems naked, or covered with withered leaves, they are clothed with green foliage from the ground to the flower. In order that the blossoms may be strong, they pinch off all the flower-buds, excepting three, or five, or sometimes only one, as soon as they appear, and are liberal in the use of liquid manure; those which remain are as large and fine as are produced by the most bulky plants. (*Wells*, in *Hort. Trans.* vol. iv. 571.) This is by far the most simple, elegant, and economical mode of propagating this beautiful flower; it has been practised several years by the Comte de Vande, at Bayswater, as well as by others in this country, and whenever it is generally known will be as generally adopted. All suckers should be removed, only one or three stems trained erect, and branching regularly on all sides. The side branches and top, or head, should be so arranged and adjusted by a nice application of black threads and wires, attached to the main prop as to render the figure of the entire plant perfectly symmetrical. Three stems may be trained, though one is better than three, because it will grow stronger: but three are better than two, which do not compose a whole; and better than a greater number than three, because unity departed from, there is no limit to irregularity. One and three are unity; because one is complete, and three has a beginning, middle, and end. All possible numbers besides, either fall short of or exceed unity: they are irregularities, and irregularities are redundant and infinite, and therefore unsatisfactory to contemplate.

6475. *Culture in the open border.* Many of the sorts may be planted out in warm borders, or compartments, or against walls, and will flower well in fine autumns; but their roots require protection through the winter, and they should be renewed about every two years; for as they increase much in size by suckers from the roots, the plants, if left for a longer period, become unsightly, and produce small and imperfect flowers. The early flowering varieties, as the purple, changeable white, rose, and buff, seem the hardiest and most suitable for borders. (*Sabine*, in *Hort. Trans.* vol. iv. 323.) To look well in the border the plants should be large, and with many stems; their flowers are consequently more numerous, and produce a greater effect at a distance. The appearances of the flowers on many of the kinds is very different when blossoming in the borders from those which expand under glass, so much so, that they might be easily mistaken by an unexperienced observer for different varieties. (*Hort. Trans.* vol. v. 162.)

SUBJECT. 23. *Hydrangea.* — *Hydrangea hortensis*, L. (*Bot. Mag.* 438.) *Decan. Dig. L.* and *Saxifrageæ*? *J. Hydrangelle*, Fr.; *Kehlknopf*, Ger.; and *Hydrangea*, Ital.

6476. *The hydrangea* is a very low under-shrub, producing broad green leaves, and cymes of monstrous flowers, like the guelder rose in form, and red in color, changing to white and green. Its native place is unknown; but it is commonly cultivated in the gardens of China and Japan, from whence it was introduced to Kew by Sir J. Banks in 1790. It is much valued as a chamber plant, and in consequence, extensively cultivated near London and most large towns of Europe.

6477. *Varieties.* Soon after it was introduced, some plants were found with blue flowers, which some supposed to be produced by salt or saltpetre, and others by oxide of iron. The yellow loam of Hampstead heath and some other places, and some sorts of peat-earth are found to produce this effect; but the cause is not yet ascertained. Dr. Daalen, of Antwerp, finds that turf-ashes, and still more effectually those of the Norway spruce, the wood generally used as fuel by him, applied to the roots of hydrangea, produced the blue color of the petals. (*Hort. Tour*, 122.) According to Busch, of Petersburgh, "the hydrangea will be turned blue by watering the young plant, the summer

before, with alum-water. Our grey-colored earth, under the black moor-earth, has the same effect, being combined with aluminous salt." (*Hort. Trans.* vol. iv. 568.)

6478. *Propagation and culture.* Hedges, who has been "very successful" in treating this plant, gives the following directions. "As a succession of young plants is necessary, I raise some each year by taking, in the beginning or middle of July, young shoots with three or four joints, cutting them off close to the joint which is at the bottom of the shoot; these are planted in rich earth, in a warm border, and covered with a hand-glass; they are shaded during the middle of the day, and sprinkled with water from a fine rose watering-pot, two or three times a-week, in the evening, so as to keep them moist: the glass being kept close over them at all times. They will also grow by layers made in July, in the same way as is usual with carnations. The cuttings or layers will be well rooted by the end of August, at which time, or early in September, they must be put singly into small pots, and placed under a frame, which at first must be shut up close; if they can be assisted by a temperate dung-heat, at this time, it will be better for them. In the frame they must be shaded and watered as before. About the middle or end of October, they are to be taken into the green-house, or other shelter, where they can be protected from wet and frost; during the winter, they must be watered once a week or fortnight, as they may require. In the latter end of May or early in June following, they must be turned out into a bed of rich mould, in the open ground, to remain there till September, when they must be taken up and potted, and kept protected from damp and cold, as in the preceding winter. Instead of turning them out, as stated, in the spring, they may be retained in pots; but they must be shifted twice during the summer. By either method fine strong plants will be formed, fit for forcing or turning out in the succeeding spring. If wanted for the borders, let them be put out when all danger of their sustaining injury by frost is over; they will stand the winter in the borders, and will also bear flowers, though not so well as when protected by a house. Those which are to flower in pots, are taken as soon as their buds begin to swell in the spring; all the old mould being removed from their roots, they are planted in fresh earth, in pots of about eight inches diameter at top, and placed in front of the green-house or peach-house; if the plants are not over large, pots of smaller dimensions should be used; these will come into flower in June. Care must be taken to supply them plentifully with water whilst they are coming into bloom, and it is best to place waterpans under the pots to secure a continual supply of moisture. If it is desired to have plants in flower early in the spring, they must be shifted into their new pots in January, and brought forward with forcing heat. The mould I generally give to my hydrangeas is a compost of loam and bog-earth or leaf-mould, with a little sand, well incorporated together; in this they will produce red flowers; if they are expected to blow blue, they must be planted in the pure yellow loam."

SUBJECT. 24. *Balsam.* — *Impatiens Balsamina*, L. (*Blackw. t.* 583.) *Pent. Monog. L.* and *Geraniæ*, J. *Balsamine*, Fr. and Ger. and *Balsamina*, Ital.

6479. *The balsam* is a tender annual, rising from one to two feet high, with a succulent branchy stem, serrated leaves, and various-colored flowers. It is a native of the East Indies and Japan, where the natives, according to Thunberg, use the juice prepared with alum, for dyeing their nails red. Cultivated by Gerrard in 1596.

6480. *Varieties.* These are infinite, but not so marked or permanent as to have acquired names. The seed from one plant will hardly produce two alike. Double flowers are chiefly held in esteem, and especially those that are striped like flakes and bizarre carnations.

6481. *Propagation and culture.* It can only be raised from seed, which ripens readily from semi-double plants, and should not be less than three or four, or even nine years old, gardeners having experienced that new seed seldom produces double flowers. The best soil is a rich loam, rather lighter than that used for growing melons. At any period between the 1st of March and 1st of May, sow very thin in pots, to be placed in a hot-bed, and as near the glass as possible. When the plants are five inches high, transplant into No. 48. pots, one plant in the centre of each pot. As soon as the roots have filled the pots, move them into pots a size larger, and repeat this operation three or four times, till at last they are in pots of eight inches' diameter or upwards, keeping the plants all the while in a hot-bed or pit, and near the glass. Balsams so treated will rise four feet high, and fifteen feet in circumference, with strong thick stems, furnished with side branches from bottom to top, and these covered with large double flowers. (*Fairweather*, in *Hort. Trans.* iii. 406.)

6482. *The Amaranthus*, *Celosia* or cockscomb, *Gomphrena* or globe-amaranth, *Mesembryanthemum crystallinum* or ice-plant, *Solanum melongena* or egg-plant, and most other tender annuals, will attain to corresponding luxuriance, if similarly treated.

6483. *Knight*, in October, 1820, sent to the Horticultural Society, a cockscomb (*Celosia cristata*), the flower of which measured eighteen inches in width and seven inches in height, from the top of the stalk; it was thick and full, and of a most intense purplish-red. To produce this, the great object was to retard the protrusion of the flower-stalk, that it might become of great strength. The compost employed was of the most nutritive and stimulating kind, "consisting of one part of unfermented horse-dung, fresh from the stable, and without litter, one part of burnt turf, one part of decayed leaves, and two parts of green turf, the latter being in lumps of about an inch in diameter, in order to keep the mass so hollow, that the water might have free liberty to escape, and the air to enter. The seeds were sown in spring rather late, and the plants put first into pots of four inches' diameter, and then transplanted to others a foot in dia-

meter; the object being not to compress the roots, as that has a tendency to accelerate the flowering of all vegetables. The plants were placed within a few inches of the glass, in a heat of from 70° to 100°; they were watered with pigeon-dung water, and due attention paid to remove the side branches when very young, so as to produce one strong head or flower." (*Hort. Trans.* iv. 322.)

SUBJECT. 25. *Mignonette*. — *Reseda odorata*, L. (*Bot. Mag.* 29.) *Dodecan. Dig.* L. and *Resedaceæ*, Lindl. *Réséda odorant*, Fr.; *Wohlbriechende Reseda*, Ger; and *Reseda odorosa*, Ital.

6484. *The mignonette* is a trailing hardy annual, a native of Africa, and introduced in 1752. It is "the Egyptian bastard-rocket, with most sweet-smelling flowers," of Justice, and the Dutch florists of his day. The flowers are highly odoriferous, and the plant in pots is in universal request, at all seasons of the year, for placing in rooms.

6485. *Varieties*. There is a sub-biennial semi-frutescent variety, rather more odoriferous than the common sort, which forms an elegant winter plant for the drawingroom, but which is not yet in very general cultivation.

6486. *Propagation and culture*. Rishon, who cultivated this plant extensively for the London market, gives the following instructions, as applicable to the common variety: "To obtain fine plants, strong and ready to blow, during the winter, and through the months of January and February, the seed should be sown in the open ground the end of July; by the middle of September, the plants from this sowing will be strong enough to be removed into pots; for a week after this removal, they must be shaded, after which they may be freely exposed to the sun and air, care being taken to protect them by frames from damage by heavy rains, and from injury by early frosts, until the beginning of November, at which time many of them will show their flowers; and they should then be removed to a green-house or conservatory, or to a warm window in a dwellinghouse, where they will branch out, and continue to blow until the spring. The crop for March, April, and May should be sown in small pots, not later than the 25th of August; the plants from this sowing will not suffer by exposure to rain, whilst they are young; they must, however, be protected from early frosts, like the winter crop; they are to be thinned in November, leaving not more than eight or ten plants in each pot; and at the same time, the pots being sunk about three or four inches in some old tan or coal-ashes, should be covered with a frame, which it is best to place fronting the west: for then the lights may be left open in the evening, to catch the sun whenever it sets clear. The third or spring crop should be sown in pots, not later than the 25th of February; these must be placed in a frame, on a gentle heat, and as the heat declines, the pots must be let down three or four inches into the dung-bed, which will keep the roots moist, and prevent their leaves turning brown, from the heat of the sun, in April and May. The plants thus obtained will be in perfection by the end of May, and be ready to succeed those raised by the autumnal sowing." (*Hort. Trans.* ii. 375.)

6487. *The tree-mignonette*, according to Sabine, "is to be propagated from seeds sown in spring; it may also be increased by cuttings, which will readily strike. The young plants should be put singly into small pots, and brought forward by heat, that of a gentle hot-bed being preferable, but they will grow well without artificial heat. As they advance, they must be tied to a stick; taking care to prevent the growth of the smaller side shoots, by pinching them off, but allowing the leaves of the main stem to remain on for a time to support and strengthen it. When they have attained the height of about ten inches, or more, according to the fancy of the cultivator, the shoots must be suffered to extend themselves from the top, but must be occasionally stopped at the ends, to force them to form a bushy head, which, by the autumn, will be eight or nine inches in diameter, and covered with bloom. Whilst the plants are attaining their proper size, they should be shifted progressively into larger pots, and may ultimately be left in those of about six inches in diameter at top." (*Hort. Trans.* iii. 181.)

SECT. II. *Border-Flowers.*

6488. *Border-flowers* are hardy plants, with showy blossoms, of easy culture, and their use in floriculture is to decorate the flower-garden, shrubbery, and other spots or borders considered as ornamental. We shall take them in the order of perennials, bulbs, biennials, hardy annuals, and half-hardy annuals; and arrange each of these subdivisions according to their time of flowering, heights, and colors: indicating by letters those requiring peat-soil (*p*); such as are rather tender (*t*); such as are most showy (*s*); and such as continue in flower for two or more months (*3*). At the end of each subdivision we shall give its general mode of propagation and culture. It may be added, that most of the plants mentioned as flowering in any particular month will often come into flower the month preceding, and continue in bloom during one or more of the following months. Hence the importance of selecting such flowers as are at once the most easy of cultivation, beautiful in appearance, and that continue longest in flower.

6490. *Propagation of perennial herbaceous plants.* All the modes of propagation, excepting such as are applicable only to woody plants, may occasionally be adopted; but the most general practice is by dividing the root, by suckers or offsets, and by seed; the other modes are by cuttings of the stalks, shoots, or roots, and by layers.

6491. *By dividing the root.* This mode is applicable to nine tenths of hardy herbaceous plants. The plant may either be taken up, divided with the knife, and a portion replanted to continue the species in the spot allotted to it; or, the earth may be partially removed, and part of the roots and crown cut off to make new plants. The sections may, if well rooted, be planted at once where they are to remain and flower, or, what is preferable, they may be planted for one season in nursing-beds in the reserve-garden, and prevented from flowering that season by pinching off the flower-buds as they appear. The common season for performing the operation is spring, when the plant is beginning to push, or in summer or autumn immediately after it has flowered. The latter is generally the preferable period, unless the plant flowers very late, in which case the sections will not have sufficient time to form roots for their support during winter.

6492. *By suckers or offsets.* This mode is also applicable to nine tenths of common herbaceous plants; the best time for removing them is in spring, or early in summer, after the plant has begun to grow. Plant them in the nursing-department, and pinch off their flower-buds, that they may flower strongly next season when removed to their final destination.

6493. *By seed.* This mode is applicable to all the single-flowering kinds, but is only adopted with a few species, which are otherwise difficultly multiplied. Collect the seed from the flowers which expanded first, as being generally the strongest. If it is ripe before August, it may be sown the same season, but if otherwise, it will be preferable to defer sowing till the following spring. Sow on beds of light earth, thinly covering according to the size of the seed, and prick out the plants once or twice according to their strength, size, or weakness, so as they may be fit to remove to their final destination in August or September. They will flower strongly the following year, and probably may show some new varieties.

6494. *By cuttings from the side-shoots or flower-stems.* This mode is applicable to a number of the more delicate and double-flowering herbaceous plants, as to scarlet and pink lychnis, double rockets white and yellow, some hollyhocks, and a variety of others; but more to biennials and annuals than to perennials. The cuttings may be taken off at any time when the shoots are tender and properly prepared, and planted in sandy loam in a warm situation, but shaded and covered with a hand-glass. Afterwards transplant them in the nursery-department, and again the same season where they are finally to remain. They will blow freely the summer following.

6495. *By cuttings from the root-shoots.* This is applicable to some sorts which do not multiply fast at the root, or whose rooted stolones or suckers do not make handsome plants; as to some species of alyssum, statice, silene, &c. The early part of summer is, in general, the most fitting season for performing the operation; plant in sandy loam under a hand-glass, and shade in the sunny part of the day; then transplant in the nursery department for a few weeks, when the strongest plants will show themselves, and may be removed in September to their final destination. They will blow strongly next year.

6496. *By cuttings of jointed root-shoots or pipings.* This is chiefly applicable to the dianthus tribe, saponaria, the striped grass, or any other grasses or reedy plants. Proceed as in piping pinks or carnations (6412.); but no bottom heat will be required for the sorts that come under this section.

6497. *By cuttings from the roots.* This is strictly applicable only to such plants as form buds on their roots, as to most of the rubiaceæ, to the mints, epilobiums, &c. About midsummer is the earliest period at which the creeping roots are generally fit for this purpose; but with some others, as galium, osmunda, &c. it may be done in spring

Plant the cuttings in the shade, and afterwards transplant and treat them like cuttings from the flower-stalks or root-shoots.

6498. *By layers.* Such plants as cannot easily be propagated by any of the foregoing modes may be increased by layers; such as the carnation, some species of salvia, sibbaldia, sibthorpia, some silenes, &c. Commence the operation when the plant begins to flower, and when the layers are rooted, treat them as directed for pipings.

6499. *General culture of fibrous-rooted herbaceous flowers.* Autumn, after the plant has done flowering, or spring, when it has begun to grow, as has been already observed (6189.), are the seasons for planting or transplanting. The general culture is, stirring the soil; renewing it according to the kind of plant (6188.); taking up overgrown plants, reducing them, and replanting (6190.); sticking, pruning, trimming, removing all useless, decayed, injured, or diseased parts; and supplying blanks. (6192.) The general management consists in attending to order and neatness. (6201.)

6501. *Propagation of bulbous-rooted flowers.* By offsets or by seed; the whole, with the exception of the cyclamen, and one or two others, are propagated by offsets, which are to be taken off when the plant is in a state of rest, which happens in most sorts after it has done flowering; afterwards they are to be planted in a nursery-bed for one year, and where they are finally to remain the year following. Autumnal-flowering bulbs are not in a state of rest till the beginning of the following summer: as the colchicum, autumnal-flowering crocuses, amaryllis lutea, and a few others. These, therefore, are to be taken up when their leaves begin to decay early in summer, their offsets separated and planted in the nursery-department, and the parent bulbs replaced in a month or six weeks, in order that they may have time to establish themselves and flower before winter.

6502. *General culture and management.* Bulbous-rooted flowers differ from others in requiring in their cultivated state to be frequently taken up and replanted. Fibrous-rooted plants which grow much at the root, require this occasionally; but almost all bulbs frequently. The reasons are, that in deeply comminuted rich ground, most sorts, but especially those which form their new bulbs *beside* the others, multiply so fast that the bulbs become crowded, small, and unfit to send up strong flowers; that many sorts, as in narcissus, tulip, &c. which form their new bulbs *under* the old one, send down their bulbs at last so deep that they at first come up weakly, and afterwards cease to appear at all, as in the bulbous-rooted irises, colchicum, &c.; and that some, on the contrary, which form their new bulbs *over* the old ones, send them up at last above the surface, as in crocus, gladiolus, &c.; and are consequently killed by the frost or drought. Hence the finer bulbs of florists require to be taken up every year, and all the border-bulbs at least every three or four years. The time to do this is when the plant has flowered and the leaves have begun to decay. No bulb should be taken up for any purpose, or injured in its growth in any way while the leaves are green; for it should ever be remembered by gardeners, that it is the leaves which bring the root to maturity and prepare it for flowering the following year. If these are injured or cut off, or if the plant is transplanted, unless with such a ball as not to touch any of its fibres while in a growing state, the bulb will not recover so as to be able to flower for at least one year, and probably two or three. The time for keeping bulbs out of ground depends on their habits as to flowering. The object is to heal the wounds made by removing the offsets, and perhaps by setting the bulb more completely in a state of rest, to render it more excitable when planted. A month will in general be sufficient for this purpose, and more cannot be allowed with safety to the autumnal-flowering bulbs: more than three months is more likely to be injurious than useful to most sorts, though hyacinths, and other bulbs which form articles of general commerce, are frequently kept out of the soil half the year: when planted so late, however, they seldom flower well the first season, and commonly not at all for a year or two afterwards. The taking up, drying, and replanting of border-bulbs must be attended to by the flower-gardener with equal regularity, though not with equal frequency as the finer, select, or florists' bulbs: the offsets may be planted in beds in the reserve-garden, if wanted for stock; and the soil of the spot where the plants stood in the border renewed according to its kind, and the flowering-bulbs replaced. Some bulbs multiply so fast by throwing out offsets, that they soon cease to send up flower-stems. Of these may be mentioned the ornithogalum umbellatum, luteum, and some other species; some species of scilla, muscari, iris, allium, oxalis, and others. These should either be annually taken up, their offsets removed, and the parent bulb replanted; or the offsets, as soon as they send up leaves, should be destroyed. Indeed, whenever strong-blowing bulbs is the principal object, the offsets should never be allowed to attain any size; but as soon as they indicate their existence by showing leaves above ground, they should be removed with a blunt stick, or in any way least injurious to the parent. By this practice a great accession of strength is given to the main plant, both for the display of blossom during the current season, and for invigorating the leaves to prepare and deposit nutriment in the bulb for the next year. In pursuance of the same objects; every flower should be pinched off as soon as it begins to decay, but the flower-stalk may remain till it begins to change color with the leaves. Some bulbs are greedily sought after by vermin: as the crocus and tulip by the mouse and water-rat; the snowdrop and some of the narcissi by the snail and slug; and the hyacinth by a particular sort of grub-worm. We know of no method of mitigating these evils but by catching the mice and rats, gathering the snails, and taking up, drying, and replanting in fresh soil, the roots attacked by worms or insects. The snail is perhaps the worst of these vermin, and, fortunately, it may be most effectually kept under, by scattering leaves of the brassica tribe (of any variety) over the ground, and picking from them, every morning, the snails which have fixed on them during the night.

6503. *Most bulbs force well;* to expedite this, retard the bulbs by keeping them in an ice-house till the autumn of the second summer; put them in water-glasses or pots in September; and they will be in full blow by Christmas.

6505. *Propagation and culture of biennial border-flowers.* They are all raised from seed, but some of the finest double varieties are continued by cuttings. The seed of such sorts as ripen by August may be sown immediately after it is gathered; but the seed of those sorts which ripen later should be preserved till the following spring, and sown in May or the beginning of June. Sow thinly in beds in the reserve-garden, transplant into other beds when the plants are a few inches high, and in September or October remove the plants to their final destination. If this be, as it most generally will in the mingled flower-border, to provide a succession of the same sorts, then it can only be done in the case of those sorts which are done flowering by September or the first of October, and the others must be removed early in March with balls. Great care is requisite in removing some sorts which have large tap-roots, as *cænothra*, holly-hock, *lavatera*, &c., for if materially checked they will not flower strongly. The best mode is to nurse these sorts in large pots, and transplant them in October or February, with their balls entire. The sorts continued by cuttings are chiefly fine double varieties of wallflowers, stocks, rose-campions, &c. The cuttings may be taken from the flower-stalks, or the root-shoots, early in summer, put under hand-glasses, and otherwise treated as cuttings of perennials. If the cuttings of some sorts, as *dahlia*, *chrysanthemum*, *lobelia*, &c. are taken off early in the season, they will flower in the autumn. The plants once placed where they are to remain, their general culture and management is the same as for the perennial border-flowers. (6187.)

SUBJECT. 4. *Species and Varieties of Hardy Annual Border-Flowers.*

6506. **HARDY ANNUAL BORDER-FLOWERS. — JUNE.**

Height from 0 to $\frac{1}{2}$ of a ft.	From $\frac{1}{2}$ of a foot to 1 $\frac{1}{2}$ foot.	From 1 $\frac{1}{2}$ foot to 2 $\frac{1}{2}$ feet.	From 2 $\frac{1}{2}$ feet to 3 $\frac{1}{2}$ feet.	From 3 $\frac{1}{2}$ feet upwards.

6507. *Propagation and culture of hardy annual flowers.* They are all raised from seed, though occasionally some fine varieties of cheiranthus, viola, &c. are preserved by cuttings. The seed is generally sown in March or April, in patches or rings in the borders where the plants are to flower. The ground is previously stirred and made fine; the patch is sown of a circular form of six or eight inches' diameter, or a row only is sown in the circumference of the circle, the seeds covered according to their size, and the plants, when they are an inch high, thinned out to one, three, five, seven, or more, according to their kind. This, and occasionally stirring the soil, with staking, &c. as in perennial flowers, is all the culture they require. Sometimes the whole, or many of the sorts, are sown in the reserve-garden, and transplanted where they are finally to remain. This answers well for such sorts as the lupin, sunflower, and sweetpea; but is rather precarious with such early flowering and short-lived sorts as annual stocks, candytuft, Venus's looking-glass, &c.

6508. *Seed may be saved* either from the top and first-expanded blossoms of plants in the borders, or from patches sown in the reserve-garden. For the sake of neatness and beauty, no more flowers on each plant ought to be allowed to ripen their seeds than are wanted for the supply; but unless for varieties difficult to procure from the seedsmen, the simplest, and indeed the most economical mode, is to procure supplies yearly from them.

6509. *Some very pleasing conceits for arranging annual flowers* are given by Swindon (*Beauties of Flora*, 1778), a Brentford nurseryman. He gives a copious list of annuals, arranged according to their heights and colors; and by affixing a number to each sort, he can readily indicate on his plans the kinds to be employed, and their relative position. Thus he has 89 sorts of common hardy annuals, arranged in six different classes, for six different ranges, in borders, as follow:—

First range, which grow from 8 to 12 or 14 inches high.

1. Cape marigold; purple and white.
2. Large caterpillar; yellow, and singular pod.
3. Venus's looking-glass; light purple.
4. Ram's horns; yellow, the pod its beauty.
5. Venus's navel-wort; clear white.
6. Round snails; yellow, and singular pod.
7. Dwarf variegated lychins; crimson and white.
8. Heart's ease; purple and yellow.
9. Half moons, or moon-trefoil; white, and singular pod.
10. Blue meadow lychins; sky-blue.
11. Dwarf virgin's stock; purple.
12. Small hedgehogs; yellow, and singular pod.
13. Woodroof; light blue.
14. Red hawkweed; pale red.
15. Large hedgehogs; yellow, and singular pod.

Second range, which grow from 12 to 18 or 20 inches high.

16. Oak of Jerusalem; yellowish, with fragrant smell.
17. Small white candytuft; clear white.
18. Long-horned devil in a bush; yellow, and singular pod.
19. Convolvulus minor; bright blue with yellow eye.
20. Large purple candytuft; light purple.
21. White lobel's catchfly; reddish-white.
22. Annual snapdragon; purple and yellow.
23. Large white candytuft; clear white.
24. Scarlet, or wing peas; dark and light red.
25. Striped convolvulus minor; blue and white.
26. Red lobel's catchfly; bright red.
27. Dwarf snapdragon; deep orange.
28. Broad Spanish nigella with brown seed; deep blue.
29. Red flos adonis; dark red.

Third range, which grow from 20 to 24 or 28 inches high.

30. Spanish nigella, with black seed; light blue.
31. Spanish hawkweed; pale yellow, and purple eye.
32. Blue Moldavian balm; deep blue, and fine scent.
33. Annual rest-harrow; pale red.
34. Double Roman nigella; white mixed with blue.
35. Small running nasturtium; dark orange.
36. Nettle-marjoram; yellowish, no smell but to the over-curious.
37. Rocket-larkspur; pink and white.
38. Sweet-scented lupines; bright yellow.
39. Blue Moldavian balm; fair white, and fragrant smell.
40. Dutch lupines; fine blue.
41. Annual hare's ear; pale yellow.
42. Purple jacobea; purplish-red and yellow eye.
43. Dutch ranunculus-marigold; sulphur-color.
44. Red-topped clary; pale-red, and pink leaves.

Fourth range, which grow from 2 to 2½ or 3 feet high.

45. Belvidere; yellowish, a handsome plant.
46. Small variegated corn-poppy; various, red and white, &c.
47. Double upright larkspur; blue, bluish, &c.
48. Cyanus minor; blue, crimson, &c.
49. Thorn-apple; white, and singular pod.
50. Prince's feather; dark crimson.
51. Crown-larkspur; pale pink, spotted, &c.
52. Honey scabious; pale blue, and globular pod.
53. Portugal lychins; pale red.
54. Small blue lupines; bright blue.
55. Loves lies a-bleeding; light red.
56. Ranunculus-marigold; deep orange.
57. Honeysort; dark purple, and singular shape.
58. Strawberry-spinage; bright-red fruit.

Fifth range, which grow from 3 to 4 feet high.

59. Venetian small-flowered mallow; purplish-white.
60. Double crimson jagged-leaf poppy; dark crimson.
61. Tall narrow-leaf wallflower; bright yellow.
62. Arach; deep crimson.
63. Double striped carnation-poppy; red and white.
64. Blue sweet trefoil; lead-color.
65. Red lavatera; light changeable red.
66. Branching larkspur; blue and white, &c.
67. Tall white lupines; clear white.
68. Double black carnation-poppy; rose-color.
69. & 27. Small Peruvian nasturtium; dark orange.
70. Lord Anson's peas; fine blue.
71. White lavatera; snow white.
72. Dwarf double and quilled yellow sunflower; deep yellow.
73. Bladder ketmia; pale-sulphur and purple eye, with singular pod.

Sixth range, which grow from 5 to 7 or 10 feet high.

74. Tall double yellow sunflower, with black seed; deep yellow.
75. Painted lady sweet-scented peas; pale-red, and white.
76. Arach; sulphur-colored.
77. Purple sweet-scented peas; dark and light purple.
78. Tall Indian armist; bright crimson.
79. Painted lady crown-peas; black and white.
80. Convolvulus major; fine purple.
81. White crown-peas; clear white.
82. Large Indian nasturtium; dark and light orange.
83. Tall double brimstone sunflower; sulphur-colored.
84. White sweet-scented peas; clear white.
85. Plain tangier peas; fine crimson.
86. Tall oriental mallow; purple.
87. Painted lady tangier peas; pale-red and white.
88. Scarlet beans; fine scarlet.
89. Curled-leaf upright mallow; white tinged with purple.

6510. *In borders* he sows in six rows, or rather at six different distances from the walk, according to the different ranges, thus:—

74	75	76	77	78	79	80	81	82	83	84	85	86	87	88	89
59	60	61	62	63	64	65	66	67	68	69	70	71	72	73	
45	46	47	48	49	50	51	52	53	54	55	56	57	58		
30	31	32	33	34	35	36	37	38	39	40	41	42	43	44	
16	17	18	19	20	21	22	23	24	25	26	27	28	29		
1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	

6511. *For a circular clump, or cone of flowers*, including all the 89 different sorts, he arranges the six heights in six concentric circles (*fig. 616.*), placing a persicaria and oriental mallow in the centre. The general appearance (*fig. 617.*), he says, is "the same on every side, rising gradually from the edge upwards, the highest plants meeting nearly in a point at the centre, and no two flowers of the same color or shape being seen together." (*Beauties of Flora*, &c. p. ii.) To those who have but a limited space and means, or who have few perennial flowers;—to persons in remote situations in the country;—to residents in the colonies; and to female and infant gardeners, the above list and modes of arrangement afford a source of considerable show and amusement at a very small expense,—little trouble, and, being annuals, little loss of time. Swindon was in the habit of supplying masters of ships with packets of these seeds for all parts of the world.

617

SUBJECT. 5. Species and Varieties of Half-hardy Annual Border-Flowers.

6512. HALF-HARDY ANNUAL BORDER-FLOWERS, FLOWERING IN JULY, AUGUST, AND SEPTEMBER.

Height from 0 to $\frac{1}{2}$ of a ft.	From $\frac{3}{4}$ of a foot to 1 $\frac{1}{2}$ foot.	From 1 $\frac{1}{2}$ foot to 2 $\frac{1}{2}$ feet.	From 2 $\frac{1}{2}$ feet to 3 $\frac{1}{2}$ feet.	From 3 $\frac{1}{2}$ feet upwards.

6513. *Propagation and culture of half-hardy annual flowers.* These are raised from seed, which is sown in March in a hot-bed; and the plants, when an inch or two high, are transplanted into another bed of very moderate temperature. Here they may remain till the middle of May, or till all danger from frosty nights is over, and be then transplanted to where they are to flower in the borders, and treated in all respects as hardy annuals.

6514. *To save seed.* In dry seasons, most sorts will ripen seeds, if permitted, but in wet seasons, unless the plants have been well forwarded in spring, and planted in a dry soil and warm situation, the seed will not be matured. In such cases, a hand-glass supported over the flower is of use; or some may be removed with balls into large pots, and placed in an airy pit, frame, or green-house. In the northern and western counties, where the climate is cold and moist, half-hardy annuals never ripen their seeds in any year; and supplies are therefore annually obtained from the London seedsmen.

SECT. III. Flowers for particular Purposes.

6515. *The particular purposes to which flowers are sometimes applied,* may be either the concealment of local defects, or the production of local beauties. Among the former may be classed, covering naked walls, posts, parts of ruins, or other upright objects; concealing horizontal defects, as naked sub-barned spots, unsightly banks, &c., producing vegetation under the shade and drip of trees; among the latter, ornamenting water with flowering plants; ornamenting rocks, or assemblages of stones formed in imitation of rocks; preserving a green appearance on beds or borders during winter; forming edgings to beds or borders; furnishing odors; and presenting botanical, curious, and scientific assemblages.

SUBJECT. 1. *Flowers which reach from five to seven feet in height, for covering naked Walls, or other upright Deformities, and for shutting out distant Objects which it is desirable to exclude.*

6516. *The flowers suited for covering upright deformities* are the climbers and twining plants: the former to be supported by spray or trellis-work, or nailed in the manner of wall-trees, and the latter by rods. We shall select a few species of each from the plants already enumerated in the foregoing section, to which the botanist will easily be able to add others from the more extensive catalogues.

Climbers, perennial. Astragalus galegiformis, Clematis alpina, viorna, v. purpurea, Lathyrus latifolius, Ficus sylvatica, Bryonia dioica.
Climbers, biennial. Vicia biennis, Fumaria spicata.
Climbers, annual. Lathyrus, or sweet pea,

9 sorts, Momordica elaterium, Tropæolum majus.
Climbers, half-hardy annuals. Cucumis colocyntis, dudaim, flexuosus.
Twining plants, perennial. Convolvulus altheoides, arvensis, Humulus lupulus, Tamus communis (10 feet high).

Twining plants, annuals. Convolvulus tricolor, Phaseolus multiflorus.
Twining plants, half-hardy annuals. Convolvulus discolor, Michauxia, purpurea, p. flo. carneo, p. flo. cær. pallido. Ipomœa coccinea, & phœnicea.

SUBJECT. 2. *Flowers for concealing Defects on horizontal Surfaces: as naked sub-barren Spots, unsightly Banks, &c.*

6517. *The flowers suited for covering horizontal deformities* are creepers and trailers, of which we shall here bring together the names of the most common sorts:—

Creepers and trailers which are perennial. Ajuga reptans, r. flo. albo. Anthemis nobilis, n. flo. pleno. Arenaria montana, saxatilis, Asperula odorata, taurina, tinctoria, Cerastium latifolium, repens, Cirœea alpina, luteiana, Fragaria v. idica, veta fol. var., v. monophylla, Galium boreale, cruciatum, rubioides, verum, Geum rep-

tans, Gypsophila prostrata, repens, Hedysarum obscurum, Hieracium aurantiacum, Lysimachia nummularia, Phaca australis, Polygala major, vulgaris, Potentilla astracantha, aurea, verna, Rubia cordifolia, tinctorum, Sagina procumbens, Saxifraga sarmatensis, Tormentilla reptans, Trifolium repens maculatum

Creepers and trailers, hardy annuals. Medicago intertexta, orbicularis, scutellata, Momordica elaterium, Reseda odorata, Tropæolum majus, minus.
Creepers and trailers, half-hardy annuals. Cucumis, the three species enumerated as climbers, Monopsis scintillaris, conspicua, Nolana prostrata.

SUBJECT. 3. *Flowers which will grow under the Shade and Drip of Trees.*

6518. *Flowers which will thrive under trees* are of particular value. In improving neglected flower-gardens and pleasure-grounds, it is a common complaint that new things cannot be brought forward on account of the shade and drip of trees. This section, and the corresponding one of hardy shrubs, will, it is hoped, aid in removing that complaint, which can only have arisen from ignorance of the native habits of plants. It is proper to observe, however, that there is scarcely any, indeed we may say, no plant, that will thrive under a dense evergreen fir-tree clothed with branches down to near the surface: moss is all that can be there expected; or, if somewhat open, the pyrola, box, and juniper will exist. Where trees are so dense, however, no plant or shrub can be desired under them.

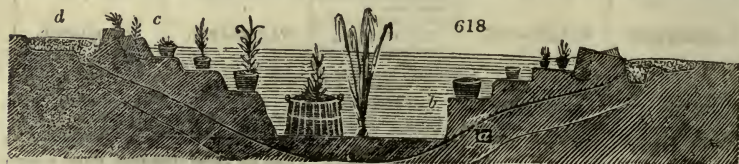

Perennials. Anemone nemorosa, n. flo. pleno, pennsylvanica, ranunculoides, Arum maculatum, Asarum europæum, Asperula laxigata, odorata. Atropa belladonna, Betonica officinalis, Chrysosplenium alternifolium, oppositifolium, Cirœea alpina, luteiana, Clematis recta, Convallaria multiflora, verticillata, Fragaria vesca, v. fol. var. v. monophylla, Geranium sylvaticum, s. flo. pleno, Geum urbinum, Heliborus viridis, Hypericum hirsutum, Imperatoria ostruthium, Lathyrus tuberosus, Lysimachia

ciliata, vulgaris, Mercurialis perennis, Monarda didyma, fistulosa, Origanum vulgare, Orobis angustifolius, lathyroides, tuberosus, nigric, sylvaticus, vernus, Primula acaulis, veris, v. elatior, v. polyanthos, Ranunculus aulcomus, Sálvia sylvestris, Sambucus ebulus, Saponaria officinalis, Saxifraga umbrosa, Scabiosa sylvatica, Spirœa aruncus, Stellaria graminea, nemorum, Teucrium Scordonia, Viola dumetorum, sylvatica, Viola canina. *Bulbs.* Allium lineare, Crocus vernus, Fritillaria imperialis, meleagris, Fu-

maria bulbosa, Galanthus nivalis, Helleborus hyemalis, Scilla non-scripta, Ophrys apifera, muscifera, ovata, Orchis bifolia, maculata, militaris, Oxalis acetosella, Sanguinaria canadensis.
Biennials. Cynoglossum officinale, sylvaticum, Digitalis purpurea, p. flo. albo, Monarda punctata.
Hardy annuals. Antirrhinum orontium, Briza maxima, Impatiens noli tangere.

SUBJECT. 4. *Flowers for ornamenting Pieces of Water, or planting Aquariums.*

6519. *Flowers for water or watering-places* are of two kinds, *aquatics*, to plant in the water, and *marsh plants*, to plant round the margin of the pond, stream, or aquarium. The shape and size of the aquarium (fig. 618.) must depend on the extent and style of the flower-garden, of which it forms a part. In all

cases the bottom, if not naturally retentive, must be rendered so by a stratum of tempered (or puddled) clay (a); the sides should be formed in terraces, or steps descending towards the centre (b), to hold pots of plants which grow in shallow water, while those that require deep water, as the bulrush, typha, &c. may be planted in the ground, or in large tubs placed in deep water. The margin of the aquarium may either be finished with regular masonry or brick-work; or what, in some situations, has a better effect, with rough stones, conglomerated vitrified bricks, or flints (c), in the interstices of which marsh plants will thrive exceedingly. The whole may be surrounded by a drain and gravel-walk (d), raised a few inches above the level of the water. Many of the aquatic plants, as nymphæa, nuphar, menyantbes, villarsia, butomus, and hottonia, &c. are highly beautiful; and, considering that some exotic species, as amaryllis, lobelia, crinum, &c. (6317.) will thrive in water in our climate, the aquarium ought not to be wanting in any flower-garden.

6520. *Propagation and culture.* They are propagated by seeds or dividing the root: the seeds being sown and placed under the water. In other respects they require the same general treatment as other herbaceous plants. Some useful remarks on the treatment of the more rare nymphæas and nuphars by Kent, will be found in the *Horticultural Transactions*, vol. iii. p. 24.

6521.

AQUATIC PLANTS WITH SHOWY FLOWERS.

MAY.	JUNE.	JULY.	AUGUST.
RED. <i>Equisetum fluviatile</i> <i>Hydrocotyle vulgaris</i>	RED. <i>Equisetum palustre</i> <i>Butomus umbellatus</i>	RED. <i>Hippurus vulgaris</i> <i>Polygonum amphibium</i>	RED. <i>Hydropeltis purpurea</i> <i>Polygonum hydropiper</i>
WHITE. <i>Nasturtium officinale</i> <i>Ranunculus aquatilis</i>	WHITE. <i>Hydrocharis morsus-ranae</i> <i>Phellandrium aquaticum</i>	WHITE. <i>Alisma damasonium</i> — <i>natans</i> — <i>plantago</i> <i>Calla palustris</i> <i>Nymphaea alba</i> — <i>odorata</i> <i>Poa fluitans</i> <i>Stratiotes aloides</i>	WHITE. <i>Cerastium aquaticum</i> <i>Poa aquatica</i>

6523. *Propagation and culture.* The same as for herbaceous plants, taking into consideration the difference in the soil and site.

SUBJECT. 5. Flowers for ornamenting Rocks, or Aggregations of Stones, Flints, Scoriae formed in imitation of Rocky Surfaces, &c.

6524. In strict propriety, *mountain or rock plants* only should be introduced on artificial rock-work; but natural mountains and rocks are always moist and cool, and the plants which have their habitations there would not always thrive on dry ridges of earth and stones. On a small scale, therefore, choice is generally made of such plants as are not tall and rampant, and as grow naturally in a dry soil. In the following list, as in the others, the most ornamental of them are distinguished by a letter (s), and those which flower the greater part of the summer by a figure (3), &c.

Perennials. Achillea alpina 3, montana, Ajuga alpina, pyramidalis 3, Alchemilla alpina, pentaphylla, Alyssum montanum, murale, saxatile, Anemone alpina, appennina, baldensis, pulsatilla 3, p. major 3, Anthemis montana, Anthyllis montana, Antirrhinum alpinum, Aquilegia alpina, Arabis alpina 3, bellidifolia 3, lucida 3, sibirica 3, Arenaria montana 3, saxatilis 3, Arnica montana 3, Artemisia rupestris, Astragalus alpinus, hypoglottis, montanus 3, uralensis 3, Athamanta libanotis, Bartsia alpina 3, Betonica alopecurus, Campanula carpatica 3, collina 3, rapunculoides 3, rotundifolia, saxatilis 3, Cardamine petraea 3, Centaurea montana, Cerastium dioicum, Cheiranthus helveticus 3, Chelidonia sedoides, Chrysanthemum montanum, Cochlearia saxatilis, Cucubalus behen, Dianthus collinus,

hyssopifolius, plumarius, virginicus, Draba aizoides, ciliaris, stellata, Epilobium montanum, Epimedium alpinum 3, Geranium pyrenaicum, Geum montanum, m. minor, Gnaphalium margaritaceum 3, Hedysarum saxatile, Hypericum montanum 3, Illecebrum paronychia 3, Physalis alkekengi, Impatiens saxifraga, Podalyria austriaca 3, Potentilla rupestris, Rubus arcticus 3, chamemorus 3, roseifolius 3, saxatilis 3, Saxifraga aizoides, nivalis, oppositifolia, pennsylvanica, petraea, rotundifolia, sarmentosa, Sedum forsterianum, glaucum, hybridum, rupestre, sexangulare, villosum, Silene alyeistris, rupestris, saxatilis, saxifraga, Telephium imperati, Teucrium montanum, Thlaspi alpestre, Thymus vulgaris, Tormentilla reptans, Trifolium alpestre, montanum, repens maculatum, Valeriana montana, pyre-

naica, Veronica montana, saxatilis, Viola lutea, montana.

Bulbs. Allium carinatum, Fritillaria pyrenaica, Ornithogalum pyrenaicum, Oxalis acetosella, violacea 3.

Biennials. Alyssum deltoideum 3, Campanula cervicaria 3, thyrsoidea 3, Carduus marianus, Carlina vulgaris, Cheiranthus cheiri, incanus, Cochlearia glastifolia, Digitalis purpurea, p. flo. albo, Echium vulgare, Gnaphalium luteo-album, Hedysarum coronarium, Marrubium alysion, Teucrium montanum 3, Thlaspi saxatile, Verbena officinalis.

Hardy Annuals. Alyssum caesium 3, Antirrhinum chalcidense 3, Campanula perfoliata, Geranium maculatum, Monarda elatium, Reseda odorata, Scorzonera picroides, tingitana, Silene aetne, behen, Trifolium polonicum, Valeriana tricolor.

6525. The ground-plan and figure of the elevation of the rock-work must, as in the case of the aquarium, be made to harmonise with surrounding objects. Simple outlines and surfaces, not too much broken, show the plants to most advantage, and are not so liable to ridicule as imitations of hills or mountains, or high narrow cones, or peaks of scoriae in the Chinese manner, which are to be seen in some places. A ground-plan, in the form of a crescent, or of any wavy figure widest towards the middle part of its length, and with the surface not steeper than forty-five degrees (fig. 619.) will be found well suited to the

less durable materials, such as bricks, pudding-stone, scoriae, &c. which are found in flat countries. Sometimes one side of such rock-works may be nearly perpendicular, in which case, if facing the north, it affords an excellent situation for ferns and mosses.

6526. In countries abounding with stone, massy and extensive pieces of rock-work may be formed, and shrubs introduced as well as plants, so as to produce a scene of considerable beauty and interest. Its base, and such parts as are near the eye, may be formed of masses of granite or basalt; selecting such for the shady side as are already covered with mosses and lichens, especially the lichen atra-flavus, geographicus, ventosus, stellaris, &c. These vegetables will not grow on sandstone, and but seldom on limestone, therefore stones of these earths should be kept as much as possible in the more distant parts, where they will be partially covered with shrubs and plants, rooted in proper soil, introduced in the crevices. When works of this kind are extensive, a winding walk or stair may be led over them, and wells, or small reservoirs of water, introduced in some places for mountain bog-plants and aquatics, and for keeping the whole mass moist and cool.

SUBJECT. 6. Evergreen-leaved Flowers, or such as are adapted for preserving an Appearance of Vegetation on Beds and Borders during the Winter Months.

6527. A due proportion of evergreen-leaved flowers is very necessary for enlivening borders in the winter time, and more especially in dug compartments on a surface of turf, which, without some evergreen plants, look dreary by contrast with the verdant surface.

Perennials. Achillea millefolium, m. flo. rubro, Alchemilla alpina, pentaphylla, vulgaris, v. pubescens, Anthemis nobilis, n. flo. pleno, Bellis perennis, hortensis, h. variegata, h. alba, h. fistulosa, h. prolifera, Campanula pumila 3, Dianthus barbatus, h. atro-rubens, hortensis, Gentiana acaulis 3, veronica 3, Gnaphalium dioicum 3, Lychnis flosculatus, f. flo. pl. f. flo. albo, viscaria, v. flo. pl. v. flo. albo, Melissa officinalis, Melittis melissophyllum

Primula acanthis, auricula, veris, v. elatior, v. polyanthus, v. flo. pleno, Saxifraga cespitosa, cuneifolia, geranioides, geum, hypnoides, mutata, nivalis, oppositifolia, petraea, umbrosa, Silene acaulis 3, Statice armeria, a. flo. albo, Stipa pennata, Teucrium chamaedrys, montanum, Thymus vulgaris, zygis 3, Veronica hyunda, Viola grandiflora 3, g. flo. luteo 3, g. flo. maculata 3, odorata cocc. 3, o. flo.

pleno cocc. 3, o. flo. albo 3, o. flo. pleno albo 3, o. flo. pl. purp. 3.

Bulbs. Amaryllis lutea, Helleborus hyemalis.

Diennials. Agrostemma coronaria, c. flo. albo, c. flo. pl. rub. Anchusa italica, paniculata 3, Dianthus armeria 3, ferrugineus 3, montpeliculus 3, Hesperis matronalis, Iberis linifolia 3, Lavatera arborea, Silene elscusa.

SUBJECT. 7. *Flowers for Edgings to Beds or Borders*

6528. The principal plants for edgings, next to the dwarf-box, are the statice armeria, bellis perennis, gentiana acaulis, saxifraga umbrosa, oppositifolia, hynoides, festuca ovina, and other low-growing evergreens; but all the following sorts may be used in extensive concerns requiring edgings of flowers. The common and other heaths make very beautiful edgings in parterres of peat soil.

Perennials. Achillea millefolium, m. flo. rubro, Alchemilla alpina, pentaphylla vulgaris, v. pubescens Anthemis nobilis, n. flo. pleno, Bellis perennis, hortensis, h. variegata, h. alba, h. fistulosa, h. prolifera, Campanula pumila 3 s, Dianthus barbatus, b. atro-rubens, hortensis, Festuca glauca, Gentiana acaulis 3, verna 3, Gnaphalium dioicum 3, Lychnis flos cuculi, f. flo. pleno, f. flo. albo, viscaria, v. flo. pleno, v. flo. albo, Melissa officinalis, Melittis me-

lissophyllum, Primula acaulis, auricula, veris, v. elatior, v. polyanthus, v. flo. pleno, Saxifraga cespitosa, cuneifolia, geranioides, geum, hynoides, mutata, nivalis, oppositifolia, petraea, umbrosa, Silene acaulis 3, Statice armeria, a. flo. albo, Stipa pennata, Teucrium, chamaedrys montanum, Thymus montanus 3 s, serpyllum 3 s. citri odoris, vulgaris, zygis s, Veronica hybrida, Viola grandiflora 3, g. flo. luteo 3, g. flo. maculato 3, odorata cor. 3, o. flo. ple-

no cor. 3, o. flo. albo 3, o. flo. pleno albo 3, o. flo. pl. purp. 3.

Annuals. Briza maxima, Calendula officinalis, o. flo. pleno, Cheiranthus annuus rub maritimus, m. flo. alb., Delphinium ajacis, Dianthus, prolifera, 3, Iberis amara, a. major, umbellata alba, u. purpurea, u. rubra, Reseda odorata, Silene armeria rub. a. flo. alb. rubella, Viola tricolor, t. mac. major, t. mac. minor.

SUBJECT. 8. *Highly odorous Flowers.*

6529. *Flowers with sweet smells* are no less desirable than those with fine forms or colors. So little has hitherto been done in the nomenclature and classification of vegetable odors, whether fixed or volatile, that we can hardly submit any thing satisfactory on the subject. No small part, however, of the pleasure derived from flowers depends on their odors; and that these are very different, every one must have remarked who has walked in a wood or a garden after a warm shower, or in a dewy summer's evening. Perhaps the best mode to arrange the odors of plants in our present imperfect state of knowledge on the subject, would be to fix on some generally known smells, as those of the rose, lily, thyme, &c. and group the others under these in the way of natural orders; and thus we should have rosodorea, liliodorea, thymodorea, &c; but in default of some such, or any system, we shall here bring together a few names under commonly received distinctions.

The entire plant aromatic. Agrimonia eupatoria, Hysopus officinalis, Salvia, numerous species, Thymus vulgaris, Acorus calamus.

The flower mellifluous. Symphytum officinale, orientale, tuberosum, Iris persica, Lilium candidum, Hottonia palustris, Cerinth minor.

The flower aromatic and mellifluous. Balsamita vulgaris, Artemisia abrotanum.

Liliaceous smells. Convallaria majalis, Viola odorata, Hyacinthus orientalis, Narcissus, various species, Reseda odorata.

Sweet aromatic smells. Melissa officinalis, Monarda didyma, Origanum basilicum, Thymus citriodorus Cheiranthus cheiri, Calendula officinalis.

The flower smelling like hay. Asperula odorata, taurina, Galium boreale, Stellaria graminea, Tussock fragrans, Anthoxanthum verum, Heliotropium indicum.

Antic smell. Primula veris, elatior, acaulis, Scandix odorata, Anethum graveolens, Angelica archangelica.

Sternutatory smells. Achillea ptarmica, vulgaris, Dictamnus albus.

Soporific smells. Humulus lupulus,

Atropa belladonna, Nicotiana Tabacum.

Night-smelling flowers. Hesperis matronalis, Enothera fruticosa, pumila, Cheiranthus cheiri, annuus, Tropaeolum majus, Reseda odorata.

Volatile smells which perfume the surrounding atmosphere. Lilium candidum, Cheiranthus cheiri, Hesperis matronalis, Reseda odorata.

Stinks. Atrantia major, Cimicifuga foetida, Ferula asafoetida, Helibolus foetida, Allium, various species, Scrophularia aquatica, Anthemis cotula.

SUBJECT. 9. *Other selections of Flowers.*

6530. *Other selections* will readily occur to the florist who is conversant with the ample store of plants at his command; such as double flowers, flowers that continue in bloom the greater part of the year, flowers for peat soils, &c. all which he may select from the indications in the tables already given. He may also select, according to the Linnæan or natural orders, by referring to the tables (558. and 589.) in which the genera are so arranged; or according to the native habitation, native country, year of introduction, or rarity, which circumstances he will find noted in the excellent catalogues of Sweet and Page.

SUBJECT. 10. *Botanical and other Assemblages of Plants.—Dial-Plants, Parasites, Ferns and Mosses, Alpines, and a selection for a small garden.*

6531. *Botanical collections*, as well as cabinets of shells and minerals, have been in vogue by the curious since Solomon's time. In many private families there is a taste for scientific botany; in which case all the hardy plants of the vegetable kingdom, as far as they are introduced into this country, are arranged in their order according to some system; and either in narrow beds, in which one species follows another; or in groups, on lawn or gravel, in which the species most nearly allied according to the system adopted, are placed together, each group containing an order (fig 553.), and all the orders of a class forming a constellation of groups, connected at one point with the preceding order, and at another with that which follows. Sometimes a different arrangement is adopted, and all the plants that can be considered as ornamental are assembled in beds or borders, and all those that are merely curious, as the ferns, mosses, fungi, &c., or useful in agriculture or the arts, as the grasses, garden-plants, plants used in dyeing, tanning, &c. are arranged in beds or groups in compartments by themselves. This is in general the most suitable mode for a private garden. With respect to the species to be introduced in these groups, the gardener will have recourse to the tables already referred to, in which, in the Jusseuean table (589.), under Gramineæ, Cyperaceæ, Juncæ, Rostiacæ, he will find all the grasses; under Filices, all the ferns; under Lycopodiæ, the plant-mosses; under Equisetaceæ, the equisetums, &c. The economical plants he will find under general heads in our view of the distribution of the British Flora (973.), and the species he will find enumerated, and classed, in our *Encyclopædia of Agriculture*.

6532. *Dial-plants.* Among curious collections, it may sometimes be desired to assemble the dial-plants, or such as indicate the hours of the day. An ample list of these has been given by Linnaeus, in the *Philosophica Botanica*; but the following, being plants generally known and easily procured, may be deemed sufficient to complete a botanist's dial in Britain:—

	Opens in the morning.	Shuts from moon to night.		Opens in the morning.	Shuts from moon to night.
	Hou. Min.	Hou. Min.		Hou. Min.	Hou. Min.
Tragopogon luteum	3 5	9 10	Hypochaeris maculata	6 7	4 5
Leontodon serotinum	4 0	12 1	Nymphaea alba	7 0	5 0
Picris echioides	4 5	12 0	Lactuca salvia	7 0	10 0
Crepis alba	4 5	12 0	Tagetes erecta	7 0	5 1
Cichorium intibus	4 5	8 9	Anagallis arvensis	7 8	2 5
Papaver nudiculus	5 0	7 0	Hieracium pilosella	8 0	2 0
Hemerocallis fulva	5 0	7 8	Dianthus prolifera	8 0	1 0
Sonchus oleraceus	5 0	11 12	Calendula arvensis	9 0	5 3
— alpinus	5 0	12 0	Arenaria purpurea	9 10	2 5
Convolvulus arvensis	5 6	4 5	Portulaca hortensis	9 10	11 12
Lapana communis	5 6	10 0	Malva caroliniana	9 10	12 1
Leontodon taraxacum	5 6	8 9	Stellaria media	9 10	9 10

6533. In botanical collections, some peculiarities of culture may be required for parasites, ferns, mosses, fungi, and marine vegetables. The only hardy herbaceous parasite is the cuscuta, or dodder, a twining plant found in hedges, and on hops, furze, thistles, and many weeds, with thread-like reddish stems, a few small membranaceous scales, and balls of white or purplish flowers, which appear in July and August. They propagate themselves by seed, which germinates in the soil, and at first draws its nourishment from thence; but the original root withers away as soon as the young stem has twined round any other plant. In cultivating the cuscuta, it is easy to imitate nature by sowing the seeds at the root of a thistle or whin.

6534. In raising ferns and mosses from seed, these being very small, should be sown on the surface of peat-earth, ground to the finest powder: the seed need not be covered, but the pots should be placed in the shade, or in a vault; and a moist close atmosphere produced by covering with a bell-glass, rendered semi-opaque by a wash of mud. When they come up, they may be transplanted into pots of the smallest size, and placed in situations formed in imitation of their natural sites. The more hardy ferns and mosses, and also some of the fungi, will come up very well, if the entire plants, covered with ripe seed, are strewn over a bed or border of peat-soil, completely shaded from the sun. The parent vegetables in rotting will afford shelter and congenial nourishment to their infant offspring.

6535. Seeds of the fungi, hepaticæ, algæ, and lichens, may be sown in pots of fine earth, like the mosses; but many require to be sown on pieces of decaying bark or wood, or on stones or pieces of lime, or on walls, &c. Portions of these, or of whatever substances are requisite, should be procured and neatly fitted to pots of six or eight inches' diameter; the seed should be sown immediately when gathered, one sort in a pot, and the pots set in a vault; some kept damp and close by means of other pots whelmed over them; and others allowed more air, according to their natures. If it is wished to multiply specimens, it may be done after they come up, by dividing the masses on which they grow.

6536. The culture of hardy marine productions, or submersed algæ, may be attempted by forming a cistern or basin of salt-water with shelves or terraces within, in the manner of the common aquarium. (fig. 618.) Their pots or receptacles, in the form of rough cones or square blocks, may be formed from basalt or compact limestone, and a specimen of the sea-weed, in which the seeds are supposed to be ripe, attached to each receptacle; or some of the receptacles may be placed in the sea near the fuci, which it is desired to introduce to the marine aquarium; and when the young fuci appear, the stones may be removed to the cistern, and placed on a higher or lower terrace, according to the depth of water supposed to be requisite. It has not been proved, that the motion and alternate immersion and exposure to air produced by the tides is essential to the growth of marine vegetables; but if it is, these circumstances can be imitated by pumping the marine aquarium dry once a-day into a cistern above its level, and then allowing the water to return gradually; or the same thing might be effected without the labor of pumping, by two moderate-sized cisterns fixed like scales on the ends of a moving beam, for weights, &c. The lichens of fresh-water are of easy cultivation.

6537. Alpines. A very general assemblage of plants is formed by gardeners under the title of alpines. These ought properly to consist only of such plants as grow on high mountains; but the gardener adds to them all very dwarf small plants that are difficult to preserve in a state of cultivation. Some of these, instead of being alpine, are arenarious, sea-side, or bog plants. Alpine plants are universally very low, bushy, and evergreen. In their native sites, they are covered by snow great part of the year, and consequently never experience either violent cold, violent heat, or intense light. The atmosphere which surrounds them is of light or thin air, almost always highly charged with vapor, and the soil in which they grow is generally soft, black, and peat-like, forming a thin stratum on rock, or filling up the chinks of rocks or stones, and always moist. Art imitates these circumstances, by putting such plants in small pots of peat or bog-earth, well drained by gravel, or scarcely drained at all, or mixed with stones, or with sand, according to the habitation to be imitated. The pots are kept, during winter, under glass in frames, in a situation exposed only to the morning sun; and in summer they are removed to a full northern exposure, or screens placed so as to produce this effect in their winter situation. Care is taken to water three or four times a-day during summer, and to keep the ground around the pots constantly moist; and in winter to protect by mats, in addition to the glass, when the cold is likely to be greater than 25° or 30°. Perhaps an improvement in the management of alpine plants would be to set the pots, in the summer season, on a grating or frame of cast-iron, placed a few inches' distance above a cistern or pond of water, by which means a constant evaporation would take place, and a moist cool atmosphere be produced. In winter they might remain in the same situation, protected by frames; or they might be removed to their usual site; or the pots might be arranged in beds, and a pipe, finely pierced with holes, in Loddige's manner, might pass along the centre of each bed, at such a distance above it as that the shower would just cover the bed. A shower might thus be applied at pleasure, and the plants kept moist by prolonged and gentle rains, instead of being deluged by sudden and heavy rains from the watering-pot. Whatever plan be adopted, it is essential that the site be open to the morning sun only during winter, and to only one or two hours' sun during summer, and that it should not be shaded by trees. Professor Thouin arranged a bank for alpine plants in the Paris garden, and has given an account of it, accompanied by some very judicious reasoning, in the *Annales de Muséum*, (see a translation in *Hort. Trans.* vol. i. App.); but experience shows, that plants of this description never thrive long on beds or banks of any kind; those planted by Professor Thouin never did much good, and in the course of two years, as we were informed on the spot, many of them died off, and the rest became too luxuriant for the situation. Potting is by far the best mode, as each individual plant may then be examined at the root as well as the top, and its soil or situation changed at pleasure. From the rarity of this class of plants, the difficulty of keeping them, their vivid green, neat shapes, small size, and many of them flowering early in spring, they are much prized, and collections made in most flower-gardens of note; we shall, therefore, give a list of the leading species of alpines, most of which will be found in a former table (6489), as plants for the front row of the border:—

Perennials. Achillea alpina 3, Aconitum pyrenaicum, Adoxa moschatellina 3, Ajuga alpina, genevensis, Alchemilla alpina, Alyssum alpestre, Anemone alpina, apennina, baldensis, Antirrhinum triornithophorum 3, A. vulgare alpina, Arabis alpina 3, bellidifolia 3, lucida 3, sibirica 3, Aretia alpina 3, helvetica 3, vitaliana 3, Arnica bellidiastrium 3, montana 3, scorpioides 3, Astragalus alpinus, Bellium bellidioides 3, Calacia alpina, Campanula alpina 3, carpatia 3, Cerastium alpinum, Cheiranthus alpinus 3, helveticus 3, Chieria sedulosa, Chrysoplegium alternifolium, oppositifolium, Cistus tuberosus 3, Cnicus spinosissimus 3, Convolvulus soldanella 3, Cortusa matthioli 3, Coteledon lutea, umbellatus, Crepis rigida, sibirica, Cyrepedium acaule 3, album 3, calceolus 3, c. fol. glabris 3, canadense 3, Dianthus alpinus, glaucus, Draba aizoides,

ciliaris, stellata, Dryas octopetala 3, Erigeron alpinum, Erinus alpinus 3, Frankenia hirsuta, levis, Gentiana adscendens 3, ciliata 3, pneumonanthe 3, punctata 3, purpurea 3, saponaria 3, septemfida 3, verna 3, Glaux maritima, Gnaphalium alpinum 3, Gundelia tournefortii 3, Gunnera perpersa 3, Hypochaeris helvetica, Hypoxis erecta 3, Isopyrum thalictroides 3, lichenis flos-cuculi, quadridentata 3, vespertina, Mörhigia muscosa, Orontium japonicum 3, Panax quinquefolium 3, Parnassia palustris, Peganum harmala 3, Pentstemon sedoides, Phlox pilosa 3, setacea 3, subulata 3, Primula cortusoides 3, farinosa 3, helvetica 3, integrifolia 3, longifolia 3, marginata, nivalis, Ranunculus alpestris, glacialis, parnassifolius, Rubus arcticus 3, chamemorus 3, roseifolius 3, saxatilis 3, Sansevieria carnea 3, Saxifraga aizoides,

aizoon, androsacet, autumnalis, casia, cassinosa, cernua, cordifolia, coteledon, crassifolia, cuneifolia, geranioides, geum, granulata, g. flo. pleno, moschata nivalis, palmata, rivularis, stellaris, viscosa, Sedum, aizoon, album, dasphyllum, difficiens forsterianum, glaucum, hybridum, quadrifidum, sexangulare, villosum, virens, Sempervivum arachnoides 3, cuspidatum 3, globiferum 3, hirtum 3, sediflorum 3, sectorium 3, Sibbaldia procumbens 3, Thlaschia europæa 3, Silene acaulis 3, vallisia, Sisyrinchium bermudiana 3, Thlaspi alpestre, Tiarella cordifolia 3, trifolia 3, Valeriana tuberosa, Veronica alpina, abyssa, Veronica pinnata, Viola cænesia 3, pedata 3.

Biherb. Bulbocodium verum 3, e. flo. clamen coum 3, europæum 3, g. flo. albo, Ixia bulbocodium 3, Ophrys apifera, muscifera, ovata, Orchis bifolia, conopsea, maculata, militaris, pyra-

midalis, Scilla amœna 3, autumnalis 3, bifolia 3, b. flo. albo 3, campanulata 3, italica 3, lilio-hyacinthus, 1. flo. pleno, lustranica 3 s, præcox 3, sibipica 3, verna. [*This is a most beautiful tribe of little early blue-flowering plants, deserving a place in every flower-garden.*] Trillium erectum 3.
Biennials. Campanula sibirica, virgata, Delphinium aconiti, Dianthus armeria, monspeliacus. Digitalis lutea, Gna-

phalum luteo album, sylvaticum, Gypsophila muralis, Linum striatum, Monarda rosea, Phyteuma comosa, Ranunculus pennsylvanicus, Scabiosa columbata, uranica, Scorzonera resedifolia, Teucrium campanulatum, Thlaspi hirtum, saxatile, Thymus alpinus, grandiflorus, patavinus, Tragopogon crucifolius, Trichostema brachiatum, Trigonella platycarpus.
Hardy annuals. Arctotis anthemoides s,

tristis s, Artemisia amara, pectinata. Bellis annua, Bellium bellidifolia, minutum, Biscutella coronopifolia, Campanula erinus, hybrida, Cheiranthus maritimus, m. flo. albo, Cistus guttatus s, Claytonia perfoliata, 33, Dianthus prolier s, Geranium gruinum s, Lychnis leta, quadridentata, Silene actœon, rubella, Viola tricolor, viol. tri. mac. major, v. tri. mac. minor.

6538. *A collection of flowers for a small garden.* Having given a selection of the most rare plants, and such as in a state of cultivation are the most difficult to preserve; we shall conclude with a list of flowers, the most common, hardy, and showy, which flower great part of the year, will thrive in almost any soil and situation, and which are recommended as fit for the commonest description of flower-borders, shrubberies, or parterres.

Flowering from February to May.

Red. Hepatica triloba. Anemone hortensis, Alyssum deltoideum. Bellis perennis. Erinus alpinus. Erythronium dens canis. Fritillaria imperialis, meleagris. Fumaria solida. Hyacinthus orientalis. Orobus vernus. Phlox subulata, setacea. Primula vulgaris, villosa, longiflora, farinosa.
Blue. Hepatica trilob. Anemone pulsatilla, apennina. Cynoglossum omphaloides.

Crocus vernus. Muscari botryoides comosum. Iris pumila. Primula auricula. Pulmonaria officinalis, virginica. Scilla præcox, bifolia, verna. Viola.
Yellow. Adonis vernalis. Alyssum saxatile, minimum. Crocus vernus, sulphureus, susianus. Erythronium americanum. Fritillaria imperialis. Helleborus lyemalis. Narcissus angustissimus, minor, bulbocodium, trian-

drus, jonquilla, pseudo-narcissus, bicolor, tazetta. Primula veris.
White. Anemone nemorosa, hepatica. Arabis alpina. Bellis perennis. Cardamine pratensis. Crocus biflorus. Erythronium dens canis. Galanthus nivalis. Helleborus niger. Lecucorum vernum. Primula nivalis, vulgaris. Ranunculus amplexicaulis. Sanguinaria canadensis. Tiarella cordifolia.

Flowering from May to August.

Red. Antirrhinum majus. Astrantia major, minor. Aquilegia vulgaris, canadensis. Anemone hortensis. Bellis prolifera. Cistus helianthemum. Cheiranthus cheiri, annuus, incanus. Chelone barbata, obliqua. Dianthus barbatus, superbus, cæsius. Dictamnus albus. Dodecatheon meadia. Epilobium angustissimum. Fumaria formosa. Geranium macrorrhizum, sylvaticum, sanguineum, Lancastriense. Gladiolus communis. Iris versicolor. Lathyrus latifolius. Liliun chalcædonicum. Lychnis viscaria, flos-cuculi, chalcædonica. Lythrum salicaria, virgatum. Monarda didyma. Orobus varius. Orthis muscula. Papaver orientale. Pæonia officinalis, tenuifolia. Phlox glaberrima, stolonifera, ovata, amœna, intermedia, pilosa, maculata. Rudbeckia purpurea. Scilla nutans. Tulipa gesneriana, suaveolens suavis. flo. pleno. Thalictrum aquilegifolium.

urn. Valeriana rubra. Veronica carnea.
Blue. Anemone hortensis. Aster alpinus. Aconitum napellus. Campanula persicifolia, pumila, carpatica. Catantæra cœrulea. Cheiranthus incanus, annuus. Centaurea cyaneus. Delphinium grandiflorum, elatum, azureum. Gentiana saponaria, septemfida, asclepiadea, acaulis. Geranium palustre. Hemerocallis cœrulea. Iris cristata, sambucina, germanica, xiphium xiphoides. Linum perenne, pumila. Lupinus perennis, polemonium cœruleum. Phyteuma orbiculare. Scilla campanulata, nutans. Sophora australis. Veronica prostrata, chamædrys, incana, spicata, gentianoides. Vinca major.
Yellow. Allium moly. Antirrhinum spartium. Caltha palustris. Cheiranthus cheiri. Cistus helianthemum. Coreopsis tenuifolia, aurea, verticillata.

Hemerocallis flava, fulva. Liliun canadense, bulbiferum, tigrinum. Oenothera pumila, fruticosa. Papaver cambricum. Tulipa sylvestris, gesneriana. Trollius europæus, asiaticus. Viola tricolor, grandiflora, lutea.
White. Antirrhinum majus. Anthericum liliago, liliastrum. Actæa racemosa. Anemone dichotoma. Bellis perennis. Campanula persicifolia, pumilum. Cheiranthus incanus, annuus. Convolvularia polygonatum. Dictamnus albus. Hesperis matronalis. Iris xiphoides. Liliun candidum. Narcissus poeticus. Ornithogalum pyramidale. Phlox suaveolens. Pancratium maritimum. Polygonum viviparum. Ranunculus acutifolius. Saxifraga granulata. Scilla campanulata, nutans. Stipa pennata. Spirea aruncus, filipendula, ulmaria, trifoliata. Thalictrum aquilegifolium. Tulipa gesneriana. Veronica spicata, pinnata. Vinca minor.

CHAP. IX.

Catalogue of Hardy Trees, with showy Flowers.

6539. *All trees may be considered as ornamental* by adding to the beauty of landscape; but we mean here to confine ourselves to such as are ornamental, by the conspicuousness of their flowers. These are not numerous; they are all of the deciduous kind, and their time of inflorescence is limited to two or three months. The principal are the horse-chestnut, acacia, the fruit-trees in their wild state, some species of mespilus, sorbus, cytisus, robinia, &c.; these, with some others, we have arranged according to their height and time of flowering, in order to admit of a selection for the back rows of the shrubbery. None of the few evergreen trees which we possess, have showy flowers, but we have added the names of these, with their heights, to facilitate a selection for mixing with the deciduous sorts in the mingled or grouped shrubbery. We have omitted all those showy flowering and evergreen trees which do not usually attain the height of twenty feet, deeming it more suitable for our purpose to include them among the shrubs of that size. All the useful and curious species of trees will be found in Page's *Prodromus*, with their heights, time of flowering, soil, mode of propagation, and other circumstances. In the *Arboricultural Catalogue* (Part III. Book III. Chap. VIII.), the most useful timber-trees are described, and the shapes of trees, and their colors, and characteristic expressions, are treated of both under *Arboricultural* and *Landscape Gardening*. (See Part III. Book III. Chap. II. Book IV. Chap. II.) Much less attention has of late been paid to the introduction of new sorts of trees into this country, than to the introduction of fruits and flowers. The French and Germans seem to excel us in this respect. A considerable number of new sorts of

ornamental trees have lately been added to the British Arboretum, by Messrs. Loddiges, and specimens of them are conspicuously arranged in the Hackney nursery, to show their forms and characters.

SECT. I. *Deciduous Trees with showy Flowers.*

6540.

DECIDUOUS TREES. — MARCH AND APRIL.

Height from 20 ft. to 28 ft.	From 28 feet to 36 feet.	From 36 feet to 44 feet.	From 44 feet to 52 feet.	From 52 feet upwa ds.
RED. <i>Pyrus angustifolia, s.</i> <i>Mespilus oxycant, pr. s.</i> WHITE. <i>Prunus cerasus, s.</i> — <i>domestica, s.</i> — <i>nigra, s.</i> <i>Pyrus coronaria, s.</i> — <i>communis, s.</i> — — <i>fl. plen. s.</i> — — <i>fo. var. s.</i> YELLOW. <i>Salisburia adiantifolia</i> GREEN. <i>Taxus baccifera</i> BROWN. <i>Populus candicans</i> — <i>heterophylla</i> — <i>pendula</i> — <i>trifida</i>	RED. SECT. II. *Evergreen Trees.*

6541.

EVERGREEN TREES.

All of these flower in March, April, and May.

Height from 20 ft. to 28 ft.	From 28 feet to 36 feet.	From 36 feet to 44 feet.	From 44 feet to 52 feet.	From 52 feet & upwards.
<i>Cupressus sempervirens</i> <i>Pinus abies alba</i> — <i>cenibra</i> — <i>lanceolata</i> — <i>palustris</i> — <i>pumila</i> <i>Quercus gramuntia</i> — <i>suber</i>	<i>Pinus tæda</i> — <i>picea</i> — <i>abies nigra</i> — <i>rubra</i> — <i>canadensis</i> — <i>cedrus</i> <i>Juniperus virginiana, p.</i> <i>Prunus caroliniana</i>	<i>Pinus pinea</i> — <i>variabilis</i> — <i>sylvest. marit.</i> — <i>pungens</i> <i>Quercus esculus</i> — <i>phellos</i> — — <i>virens</i>	<i>Pinus abies</i> — <i>inops</i> — <i>resinosa</i> — <i>balsamea</i>	<i>Pinus pinaster</i> — <i>rigida</i> — <i>sylvestris</i> — <i>strobus</i>

Propagation and culture. See ARBORICULTURE. Most of the trees enumerated in both the foregoing sections are highly ornamental as single objects on a lawn; and form curious chamber plants when dwarfed and potted in the Chinese manner. (*Hort. Trans.* iv. 289.)

CHAP. X.

Ornamental Shrubs.

6542. *The ornamental shrubs* are a much more numerous tribe than the trees: we shall first notice the more select sorts, as the rose, rhododendron, althæa, &c. and afterwards, in succession, the deciduous kinds, evergreens, creepers, and sorts for particular purposes.

SECT. I. *Select Shrubs.*

6543. The term *select shrubs* we apply to such shrubs as have been much cultivated, and of which numerous varieties are recognised as beautiful.

SUBSECT. 1. *Rose.* — *Rosa, L. Icos. Polyg. L. and Rosaceæ, J. Rosier, Fr. ; Rosenstock, Ger. ; and Rosajo, Ital.*

6544. *The rose* is known by every body at first sight, and has been a favorite flower from time immemorial among the civilised nations of Europe and Asia. The shrub varies in size in different species, from one foot to six or eight, and the colors are red, white, yellow, purple, black, striped; simple, or in almost numberless shades and mixtures; and single, semi-double, and double. It is cultivated in every garden, from that

of the most humble cottager upwards; some species, as *R. centifolia damascena*, &c. are also cultivated by commercial gardeners on a large scale for distilling rose-water, and for making attar, or essential oil of roses. Six pounds of rose-leaves will impregnate by distillation a gallon of water strongly with their odor; but a hundred pounds afford scarcely half an ounce of attar. The rose is also used in medicine. Botanists are not agreed as to the number of original species of this genus, some regard all the European species as originated from one source; others, and especially the moderns, divide them into species, subspecies, and varieties. The most scientific work which has appeared on the roses in England, is the *Rosarum Monographia* of Lindley, 1819, in which above a hundred species or subspecies are described, and some of them figured; and Miss Laurence has published ninety plates of *A Collection of Roses from Nature*, 1810. In France, Guilleméau has published *Histoire Naturelle de la Rose*, 1800; and Redouté and Thory are engaged in a splendid work, in folio, entitled *Les Roses*, containing plates of all the known species and varieties of this flower. Thory has published a separate tract on their culture, entitled *Prodrome de la Monographie du Genre Rosier*, &c. 1820; Pronville, a *Nomenclature Raisonnée*, in 1818; and Vibert, *Observations*, &c. in 1820. A copious and intelligent account of the Scotch roses has been lately given by Sabine (*Hort. Trans.* iv. 231.), and some hundreds of new varieties have flowered from seedling plants, in the nursery of Lee, and will soon be found in his sale-catalogues.

6545. *Species and varieties.* The lists of the London and Paris nurserymen contain upwards of 500 names: that of Calvert and Co., Englishmen, who have established a nursery at Bonne Nouvelle near Rouen, enumerates near 900 sorts. The greater part of these have been raised from seed on the continent, where it ripens better than in this country, within the last thirty years. A number of varieties have also been raised in Britain, especially of the *R. spinosissima*, or Scotch rose, of which above 300 varieties are procurable in the Glasgow nursery. New varieties are raised in France and Italy annually; Villaresi, royal gardener at Monza, has raised upwards of fifty varieties of *Rosa indica*; not one of which have, as far as we know, reached this country. Some of them are quite black, others shaped like a ranunculus, and many of them highly odoriferous. The following table contains nearly 150 species and varieties of single roses, of longest standing, arranged according to their time of flowering, heights, and colors; and of the greater number of which there are double and semi-double varieties of the same colors. The names are chiefly taken from Page's *Prodromus*, and the plants are known by them in the Hammersmith nursery. Ample lists, as already observed, may be had from all the principal nurserymen, and the best mode of making a selection is to view the plants while in flower.

--------------------------------------	---------------------------------------	------	------	--------------------------------

6547. *Propagation.* By seed for new varieties, and chiefly by layers for continuing approved sorts. They are also multiplied by budding, cuttings, and suckers.

6548. *By seed.* Ripe hips containing the seeds are obtained from semi-double and single flowers, and to increase the chance of new varieties, these should be taken from plants that have been planted among, or near to the sorts of which a cross is desired. We are not aware that Knight's mode of extracting the stamina from the one parent, and dusting the stigma with the anthers of the other, has been applied to the rose, but there can be no doubt it might be done in many instances. In France and Italy, the usual mode is to form a plantation of double and semi-double sorts mixed indiscriminately, and take the result of promiscuous impregnation. Guillemeau has given lists of such as are adopted for this purpose: and Villaresi raised most of his beautiful varieties of the *Rosa indica*, by planting them among as many varieties of the European roses as he could procure. Austen nurseryman at Glasgow, and Lee of Hammersmith, mix all the sorts of Scotch roses together in the same plantation. The other mode may be compared to cross-breeding at random; and this to random-in and in-breeding.

6549. *Process.* Few of the hips are ripe before October, but most sorts that come to maturity in this country, will be fit to gather by November. The seeds of the rose require to be one year in the soil before they vegetate; they may either be immediately rubbed or washed out, and preserved among sand or cinder-dust: or the hips entire may be so preserved a full year, when the husks will be perfectly rotten, and the seed being separated and sown in February, will come up in the May or June following. The best place to lay up the hips is the floor of a cellar, such as that used for storing roots; but in whatever way they are preserved, care must be taken that they are not laid together in such masses as to produce fermentation; and that the heap be turned over frequently in course of the twelve months, to promote decay. The seeds should be sown in a soft moist soil, such as that composed of equal parts of sand and vegetable mould, in a shady situation; it may be covered from a fourth to half an inch, according to the size of the seeds, and the surface should be kept moist by watering in the evenings, till the plants have come up and attained a few inches in height. Early in the second spring, they may be transplanted in rows a foot apart every way, and a year afterwards again transplanted to a distance more or less, according to the sorts. Here they are to remain till they flower, which varies in different sorts, from the third to the fifth year, but most commonly they flower the fourth summer.

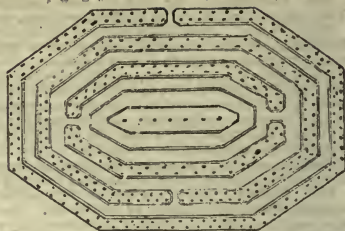

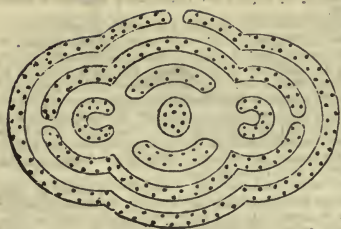

6550. *By layers.* The common mode is to lay down the young shoots of the preceding summer late in autumn, or early in the succeeding spring, and then, with the exception of the moss-rose, and one or two others, they form rooted plants by the next autumn. But it is now found, that if the same shoots are laid down when the plant is beginning to flower in July, they will, with a few exceptions, produce roots and be fit to remove the same autumn, by which a whole year is gained. Such sorts as do not root in one year must be left on the stools till the second autumn; but layers made when the shoots are in a growing state, and furnished with healthy leaves, root much more freely than shoots of ripe wood. After the plants are removed from the stools, they are planted in nursery rows, and in a year, the blossom-buds having been carefully pinched off from the first laying down, they will be fit for removal to their final destination. The stools are then to be pruned, and the soil stirred and enriched on the general principles already laid down. (2004.)

6551. *By suckers and dividing the roots.* Many of the commoner sorts admit of being rapidly multiplied in this way; and the plants obtained may be planted in their final destination at once.

6552. *By cuttings.* Most of the sorts might, no doubt, be propagated from cuttings of the young wood; cut at a joint where it is beginning to ripen, and planted in sand and vegetable mould under a hand-glass. But this mode is only adopted with such sorts as strike easily, as the *R. indica*, and other eastern species.

6553. *By budding.* This mode of propagating roses is adopted chiefly with the rare sorts, and such as are difficult to propagate by layers; for it is found, that plants so originated, even though on stocks of the hardier sorts, are less durable than such as are raised by any of the other modes. But the chief use of budding in the culture of the rose is to produce standard roses, or to produce several sorts from the same stock. Standard roses are a modern invention, it is generally supposed of the Dutch, first carried to Paris, and about twenty years ago to England. They are highly artificial objects, of great beauty, and form magnificent ornaments to parterres and borders. The stocks are either of the tree-rose (*R. villosa*, W.), or of any sorts of woody wild roses, as *R. scabriuscula*, *heterophylla*, or *sarculosa*, Wds. They are budded at different heights from three to seven feet, but commonly between five and six feet from the ground. A stock in the Paris garden, which carries several sorts, has a naked stem of nearly fifteen feet, and there are others at Malmaison and the Grand Trianon, of equal height. These stocks are, both in France and England, procured from woods and copses, and after being planted in nursery lines, are often budded the same summer, sometimes in spring by the scalope mode of budding (2059), *Pœil poussant* of the French; and never later than the succeeding spring or summer by the common mode, *Pœil dormant*, Fr. Generally two buds are inserted on opposite sides of the stock, but often three or four, or a dozen, in alternate positions on the upper six, or twelve inches of the stem. Every stock is supported by a rod, which should reach a foot or eighteen inches higher than the situation of the bud; to this rod the stock is tied, and afterwards the shoots from the buds, which are otherwise liable to be blown off by high winds. The Paris nurserymen being supplied with stronger stocks than can readily be procured in England, and having a better climate, and more experience in the culture of roses, excel us in this department of rose propagation, and their standards afford an article of commerce with other countries. Their common plants, raised by layers, are also in extensive demand, but in these we equal, if not surpass them. Fine collections of standard roses from Paris, may be seen in the Hammersmith nursery, in the Comte de Vandes's garden at Bayswater in the Duchess of Dorset's at Knowle, and at various other places.

6554. *Final situation.* No species of rose, wild or cultivated, thrives well in or very near large towns, on account of the smoke and confined air. The yellow and Austrian roses (*R. lutea* and *L. bicolor*) are difficult to flower in any situation, but seldom or never blow in the suburbs of London: even the monthly rose does not thrive so well there as at some miles' distance in the country. Roses are generally planted in the front of shrubberies, and in borders; they are also planted by themselves in rose-gardens or rosaries (fig. 620.), in groups on lawn or gravel, either with common box or other edgings, or with edgings of wire, in imitation of basket-work. These last are called baskets of roses; the ground enclosed in the basket-margin is made convex, so as to present a greater surface to the eye, and increase the illusion; the shoots of the stronger sorts are layered or kept down by pegs till they strike roots into the ground, so that the points of the shoots furnished with buds appear only above the soil, which is sometimes covered with moss or small shells. Under this treatment, the whole surface of the basket becomes, in two or three years, covered with rose-buds and leaves of one or of various sorts. Where one of the larger free-growing sorts is employed, as the moss, or any of the Provins (*rose de cramoisi*, Fr.) varieties, one plant may be trained so as to cover a surface of many square yards. Where different sorts are introduced in

the same basket, they should be as much as possible assimilated in size of leaves and flowers, and habits of growth, and as different as possible in the colors of their flowers. By mixing small-flowered with large showy sorts, the beauty of the former is lost without adding to the effect of the latter.

6555. In *rosaries* commonly but one plant of a sort is introduced, and the varieties which most resemble each other are placed together, by which their distinctions are better seen. Particular compartments are often devoted to one species, as the Scotch, Chinese, yellow, burnet-leaved, &c. which has an excellent effect; sometimes a piece of rock-work in the centre is covered with the creeping roses, and on other occasions these are trained to trellis-work, which forms a fence or hedge of roses round the whole. In this hedge, standard-roses are sometimes introduced at regular distances; a grove of standards is also frequently formed in the centre of the rosary, and sometimes they are introduced here and there in the beds.

6556. *Standard roses*, however, have certainly the best effect in flower-borders, or when completely detached on a lawn: their sameness of form, and that form being compact and lumpish, prevents them from grouping well, either among themselves or with other objects. Their beauty consists in their singularity as rose-plants, and in their flowers; and, therefore, to display these beauties to the best advantage, they require to be seen singly, or in succession. This is the case where they occur as single objects on a lawn, or in the centre in, and here and there among, groups of flowers; or in lines or avenues, along flower-walks. In the gardens of the Grand Trianon, they are planted profusely in large masses, like plantations of trees and shrubs, and there much of their individual beauty is lost, and no good general effect produced.

6557. *Soil.* Most species of the rose in their wild state grow in sandy and rather poor soil, excepting such as are natives of woods, where the soil is richer, and comparatively moist. But all the cultivated roses, and especially the double-flowering kinds, require a rich loamy soil, inclining to clay rather than sand; and they require also, like most double flowers, plenty of moisture when in a growing state.

6558. *General culture.* To produce strong flowers, roses require some attention to pruning; old wood should be yearly cut out, and the young shoots thinned and shortened according to their strength, and whether number or magnitude of flowers be wanted. Those sorts which throw up numerous suckers should be taken up every three or four years, reduced and replanted; and most sorts, excepting the standards, will be improved by the practice, provided attention be paid to remove a part of the old soil, and replace it by new. The points of the shoots of the more delicate sorts of roses are very apt to die when pruning is performed in winter or spring; to avoid the consequences of this evil, many give a second pruning in June, or do not prune the tender sorts at all till the beginning of that month. A very good time for performing the operation is immediately after the bloom is over; cutting out old exhausted wood, shortening shoots which have flowered to a good bud accompanied with a healthy leaf, but leaving such shoots as are still in a growing state untouched till October. Where very large roses are wanted, all the buds but that on the extreme point of each shoot should be pinched off as soon as they make their appearance, and the plant liberally supplied with water. To lessen evaporation, and keep up a constant moisture at the roots of their roses, the Paris gardeners generally mulch them with half-rotten stable-dung, or partially rotten leaves.

6559. *Forwarding and retarding roses.* The earliest flowering rose is the monthly, which, in mild seasons, and planted against a wall, will sometimes flower in the beginning of April; the roses next in succession are the cinnamon, which flowers in May; the damask, in the end of May or beginning of June; the blush, York and Lancaster, Provence and Dutch hundred-leaved, in June, July, and August. The Virginia and musk roses are the latest European sorts; they flower in September, and in shaded situations will sometimes continue in bloom till the middle of October; but the earliest rose (the monthly) is also the latest, and generally continues flowering till interrupted by frost. The earliest sorts may be materially forwarded by being planted against a south wall, and if portable sashes are placed before them, and the wall is either flued and heated by fires, or a lining of dung placed behind, the plants may be brought to flower in February or March. The monthly rose being protected by glass in autumn, or aided by artificial heat, may be continued in bloom till Christmas. A very common mode of obtaining late roses, and one of the greatest antiquity (48.), is by cutting all the flower-shoots off when the buds begin to appear, or by rubbing off all the rudiments of shoots, of every kind, early in spring; a second crop is in consequence produced, which will not be in a state to bloom before the autumn.

6560. *Forcing the rose.* The best sorts for this purpose are the common and moss Provence; the Indian sorts force well, or rather, in stoves, continue in bloom all the year; but the commoner varieties of these not being fragrant, they are in less repute than the European roses. Rose-plants should be a year in pots previously to the autumn when it is intended to force them; they should be planted in pots of six or eight inches' diameter, in rich loam, and plunged in an open airy situation; their flower-buds pinched off as they appear; and the plants put early into a state of rest, by excluding the sun and rain, but

not a free circulation of air. Abercrombie says, "There is no certainty of attaining a fine blow of roses in the depth of winter by the most expensive artifices of forcing; and yet fine flowers may be produced early in the spring by any ordinary stove put in operation in December. When the plants are first introduced, keep the air of the house at about 50°, never letting it fluctuate to more than two or three degrees below or above. In the second week, aim at 60° as the standard; in the third week at 65°. When a month has nearly elapsed, begin to increase the heat gradually to 70; having brought it to this standard, let it afterwards exceed it from three to five degrees, rather than sink below. A succession may be kept up by introducing some pots every eight or ten days."

6561. *Insects.* All the species of roses are very liable to the attacks of insects, especially of the aphides; some, and especially the briar and Scotch rose, are attacked by the *Cynips rosæ*, which, by puncturing the bark, occasions the production of rose-galls, and of those mossy tufts often seen on wild roses, which were known formerly under the name of *Bedeguar*, and used in medicine. A great number of insects seem fond of the flowers of roses, from the appalling earwig (*Forficula auricularia*) to the seemingly harmless lady-bird (*Coccinella 14-guttata*) (fig. 621.), which deposits its larvæ (a) in the leaves of various species, both wild and cultivated. There seems no remedy for insects on plants in the open air so simple and effectual as gathering them by hand, or removing the leaf, or that part of the shoot which is infested by them. Under cover, tobacco-smoke will prove an effectual remedy for the aphides; but the larvæ of many others, and especially of tipula and the tenthredinidæ, which occasion the wrapping up and shrivelling of the leaves, can only be removed by washing with lime-water or hand-picking.

621

SUBJECT. 2. *Select American and other Peat-Earth Shrubs, viz. of Magnoliaceæ, Magnolia; of Rhodoraceæ, Rhododendron, Azalea, Kalmia; of the genera Cistus, Arbutus, Vaccinium, Andromeda, Erica, Daphne, and various others.*

6562. *Of select American shrubs* there are numerous species and varieties, both deciduous and evergreen, which will be found arranged according to their heights and colors in the two succeeding tables, and those requiring a peat-soil distinguished by a letter (p). They are all highly valued for their flowers, which are large and magnificent in magnolia and rhododendron; odoriferous in azalea and daphne; and beautiful in andromeda, vaccinium, and erica: arbutus is valued both for its flowers and fruit. They are mostly natives of America, and introduced within the latter half of the last century.

6563. *Propagation.* They are all propagated by seed or by layers; though grafting or inarching is resorted to in some cases as more expeditious. The seed is either procured from America, or saved in this country, and, being very small, is sown as early as possible in pans of peat-earth, and placed in the shade. In winter it is placed under a cold-frame, or otherwise protected from the frost, and the plants come up in May or June. In the following autumn, or succeeding spring, they are pricked out into other pots, or into beds of peat-earth in a shady situation. Here they are protected by hoops and mats during winter; and in two years are again transplanted into a similar soil and situation, and at distances corresponding to the size of the leaves, or habits of the plants; here they remain till they flower, or till wanted to be removed to their final destination. They commonly flower from the fourth to the seventh year.

6564. *By layers.* The young shoots only are used for this purpose, either laid down in June and July, when in full growth, or in the following autumn; by the former plan a year is gained, as the shoots will be rooted, and may be removed by the succeeding winter or spring. Some sorts of magnolia, rhododendron, &c. require two years to form a sufficient number of roots. The plants, when removed, may be planted in nursery lines, in proper soil, and kept well watered during summer, and protected the first winter by mats; or, they may be planted in pots, and receive, during winter, the protection of a frame.

6565. *By suckers, and by dividing the root.* Both these modes may occasionally, though but rarely, be resorted to. Some species of azalea and andromeda throw up numerous suckers, and the heaths may often be increased by dividing their roots.

6566. *By cuttings.* Some of the azaleas, heaths, &c. may be multiplied by cuttings of the young shoots, when in a growing state, taken off where the wood is beginning to ripen, and planted in sand and peat, and covered with a hand-glass. If this operation is performed in the end of June, they will be ready to remove into prepared beds, or to plant in small pots by the middle of September.

6567. *By grafting, budding, or inarching.* This is practised with some sorts of magnolia, arbutus, daphne, &c. which are placed on stocks of harder species of the same genus, as on *M. purpurea*, *A. unedo*, *D. laureola*, &c. The stocks are planted in pots a year before wanted, which admits of their being placed in any position with respect to the shoot being inarched. The daphnes and arbutus andrachne, are generally grafted with detached scions.

6568. *Culture.* The culture requisite for American plants, Abercrombie observes, "principally consists in providing some imitation of the original soil, in order that they may flourish in full vigor; and, where there is no factitious soil provided, in making a compensation during the dry part of summer, by plentiful waterings. Most of the exotic shrubs brought from America, were originally found growing on tracts of ground resembling our beds of peat, except that the alluvial soil there extends along a greater surface, and the body of vegetable mould embedded in the swamp is richer and deeper, being on a scale corresponding with the magnitude of the rivers. The native plants found in these situations, vegetate with the highest vigor and luxuriance. The soil in many parts is so pervaded by vegetable substances, that where from any cause a section of the solid ground occurs, as in the bank of a river, or the shaft of a well, a layer of decayed logs, branches, and leaves of trees is uncovered to the spectator. The luxuriance of the vegetables may, however, partly be ascribed to the excessive moisture which is peculiar to the climate of America. In a few places, indeed, on the western coast, rain is not known; but the soil there is, in general, copiously watered by dew, so as to render it highly productive. In the season called *winter* by the natives of South America, lasting from May to November, a continued succession of impetuous rains gives to the plains, in most places, the appearance of an ocean. When the rains have ceased, the humidity

of the climate is kept up by a constant evaporation from swamps, rivers, and lakes, the largest in the world. As we cannot have the mitigated warmth of the climate of South America in plantations, in the full ground, and as the temperature of our winter cannot be expected to coincide in its effects with the corresponding season even of North America, when so many local circumstances are different, it is neither indispensable, nor perhaps advisable, to create an artificial swamp for the cultivation of *many* American plants. It is mostly safer to confine the efforts of imitation to the kind of *earth*, unless the water can be carried off at any time; for the lodgment of wet might cause some kinds of roots to perish in cold weather. Thus the andromeda arborea would be injured by being floated in winter, and must be protected from frost, though it requires a deal of water in summer. The great object is to imitate the American peat. This is a composition of the branches, twigs, leaves, and roots of trees, with small plants, grass, and weeds; by having lain immemorably in water, the whole is formed into a soft mass, and, when the materials are completely decayed and blended so as to be homogeneous in appearance, the compound is the finest vegetable mould: where this description of peat cannot be obtained, recourse must be had to the best that can be procured from marshes, bogs, or heathy commons, which must be well turned and sweetened, and mixed with sand and rotten leaves or dung." The soil being procured, the next thing to be done is to form a stratum of it of sufficient thickness in the site intended for the plants. When they are merely to remain a year or two, this need not be above a foot in depth; but where they are to remain permanently, it should be at least three feet thick. To encourage the roots to penetrate the native soil, the bottom of the excavation should be dug and mixed with peat; unless a bottom of rough gravel were substituted at the depth of four feet, and such an arrangement made, as that water could be introduced to, and withdrawn from, this layer of gravel at pleasure, so as to saturate the whole superstratum of peat. In level situations, and where water was abundant, this plan might be readily adopted, and none could more closely imitate nature, as, by keeping the surface of the peat a few inches below the level of the natural ground, the water might be allowed to rise a few inches above the peat, and inundate the whole surface of the American ground. In peat countries, and where the climate is moist, as in Lancashire and Cheshire, admirable contrivances of this kind might be adopted, and the American and bog-earth plants, herbaceous as well as shrubby, grown to the greatest perfection.

6569. *Final situation.* American and peat-earth shrubs, requiring large masses of their peculiar soil, and frequent artificial waterings, cannot conveniently be introduced in mingled borders or shrubberies. They are therefore generally planted by themselves in beds or compartments of peat-earth; or entire gardens or shrubberies are devoted exclusively to them. This last mode appears decidedly the best, as the general habits and appearance of American peat-earth plants, independently of their culture, do not harmonise remarkably well with European species. An American garden may have a northern or eastern exposure, and if it slopes considerably will be still less affected by the warm dry weather of summer. It may be laid out in any of the different styles of flower-garden (*figs.* 541. to 545.); herbaceous plants introduced as well as shrubs, and the whole surrounded by a sloping phalanx of American trees. The sorts may either be arranged in the mingled manner (6139.), or grouped or classed according to some system. (6141. to 6150.) Many and indeed most of the American shrubs thrive under the partial shade of lofty deciduous trees, and the leaves which fall from these protect their roots both from the frosts of winter and the drought of summer, while they constantly decay into vegetable mould, and thus at the same time afford a supply of nourishment. Hence, in some cases, the hardier sorts of rhododendron, azalea, andromeda, &c. may be introduced as undergrowths in the margins of thin woods, placing under each plant a cubic yard or more of its proper soil. This mode of planting, it would appear (*Mason on Design*, art. Pitt), was first adopted by the great Earl of Chatham; but it has been carried to the greatest extent, not only with American plants, but with roses and other tender shrubs, in the extensive woods of Fonthill, where, as also at King's Weston near Bristol, Kenwood at Hampstead, &c. many of the plants shed their seeds, and young rhododendrons and azaleas spring up in abundance. In the nurseries, it is a general practice to keep American and other peat-earth plants in pots, and to protect them during winter in frames and pits for convenience of deportation. At the Hammersmith nursery, one green-house is exclusively devoted to evergreen magnolias. All the American and peat-earth shrubs may be selected from the three first tables in next section, by observing the indication of peat-soil (letter *p*); and the herbaceous peat-earth plants may be selected from the tables of Border-Flowers in a similar manner.

SECT. II. *General Catalogue of Shrubs.*

6570. In our general catalogue of shrubs we have included several species, which, from their growing with single naked stems, and forming a spreading head at some height from the ground, are correctly denominated low trees. *Amygdalus communis*, and various species of *Cratægus*, L., may be referred to as examples. As our object is to form such arrangements as will afford most facility to the gardener in adjusting his plants as to height, colour of the flower, and time of inflorescence, we have included all woody plants which do not exceed twenty feet in height under shrubs; and all those that exceed that height (excepting the climbers and twiners) we have allowed to retain their places in the tables of trees. Here, as before, the most ornamental species and those which continue longest in bloom are distinguished by appropriate marks (*s* and *3*).

6574. The propagation and culture of shrubs being the same as that for trees, we combine both subjects in the catalogue of arboriculture in the succeeding book.

SECT. III. Selections of Shrubs for particular Purposes.

6575. The particular purposes to which shrubs, like flowers, may be applied, are the concealment of deformities or imperfections, and the production of particular beauties or desirable effects. We shall here select the names of a few for concealing vertical and horizontal deformity; for producing an immediate effect as to bulk; for producing vegetation under the shade and drip of trees; for ornamenting water and rocks; for forming edges and hedges; for diffusing agreeable odors; for being ornamental by their fruit; and for economical or botanical purposes.

SUBJECT. 1. Shrubs for concealing vertical and horizontal Deformities.

6576. Vertical deformities may either be concealed by the rapid and tall growing sorts (Subject. 2.), or by the climbers or twiners, either deciduous or evergreen. The climbers may be nailed to a wall or fence, or tied to a trellis, or allowed to climb on branches and spray; for the twiners, tall sticks or poles are necessary.

6577. Horizontal deformities may be concealed by rapid-growing bushy plants, by allowing climbers and trailers to spread over them, or by the proper trailers and creepers of the hardest kinds, a few of which are these:—

<i>Deciduous.</i> <i>Rosa arvensis</i> , <i>Rubus fruticosus</i> , <i>Cissus hederacea</i> , <i>Cytisus</i> su-	<i>pinus</i> , <i>Genista decumbens</i> , <i>Rhamnus repens</i> .	<i>Evergreens.</i> <i>Rosa sempervirens</i> , <i>Vinca major</i> and <i>minor</i> .
---	---	---

SUBJECT. 2. Shrubs of rapid and bulky Growth.

6578. Shrubs of rapid and bulky growth are often desirable to produce immediate effect in laying out pleasure-grounds, as well as for producing shelter, and concealing objects.

<i>Deciduous.</i> <i>Colutea arborescens</i> , et frutescens, <i>Cornus alba</i> , <i>florida</i> , et sanguinea, <i>Cytisus laburnum</i> , m. flo. albo 3, m. serotina 3 s, <i>Euonymus angustifolius</i> 3, <i>latifolius</i> 3, <i>verrucosus</i> 3 s, <i>Hypericum hircinum</i> , h. minus prolificum, <i>Ligustrum vulgare</i> , <i>Philadelphus coronarius</i> , <i>Rosa villosa</i> , <i>Sambucus</i>	<i>nigra</i> , <i>Spiræa opulifolia</i> , <i>Syringa vulgaris</i> , <i>Viburnum opulus</i> . <i>Evergreens.</i> <i>Cupressus sempervirens</i> , <i>Ilex aquifolium</i> , <i>Juniperus virginiana</i> , <i>Ligustrum vulgare</i> , var. <i>sempervirens</i> ,	<i>Mespilus pyracantha</i> , <i>Pinus palustris</i> , <i>Quercus gramuntia</i> , <i>Prunus laurocerasus</i> , <i>luisitana</i> , <i>Rhamnus alaternus</i> , <i>Spartium junceum</i> , <i>Taxus baccata</i> , <i>Thuja occidentalis</i> , <i>orientalis</i> , <i>Ulex europæa</i> , var. <i>hibernica</i> ,
--	---	--

SUBJECT. 3. Shrubs which thrive under the Shade and Drip of Trees.

6579. Shrubs which grow under the shade of trees are found in practice to be a most valuable class for filling up blanks in old shrubberies, or screen plantations; and thus producing greenness, variety, and a healthy aspect, instead of emptiness, haggard stems of trees, or mere ghosts of plants.

<i>Deciduous.</i> <i>Cornus alba</i> , <i>alternifolia</i> , <i>florida</i> , <i>sanguinea</i> , <i>Corylus avellana</i> , <i>Daphne alpina</i> 3 <i>mezereum</i> , m. flo. albo 3, m. serotina 3 s, <i>Euonymus angustifolius</i> 3, <i>latifolius</i> 3, <i>verrucosus</i> 3 s, <i>Hypericum hircinum</i> , h. minus prolificum, <i>Ligustrum vulgare</i> , v. fruc. flavo, v. fol. variegatis, <i>Lonicera symphoricarpos</i> 3, <i>tartarica</i> , <i>xylosteum</i> , <i>Mespilus tomentosa</i> , <i>Rosa m. sibirica</i> , <i>arvensis</i> , <i>Rubus occiden-</i>	<i>talis</i> , <i>odoratus</i> , <i>trivialis</i> , <i>villosus</i> , <i>Sambucus nigra</i> fol. var. n. alba, n. lacinata, <i>racemosa</i> , <i>Spiræa canadensis</i> 3, <i>thalictroides</i> 3. <i>Evergreens.</i> <i>Aucuba japonica</i> 3, <i>Buxus sempervirens</i> , s. angustifol. s. aur. var. s. arg. var. s. nana, <i>Cistus canadensis</i> , <i>Daphne cneorum</i> 3, c. fol. var. collina 3 s, <i>laureola</i> , l. fol. var. <i>Ephedra distachya</i> , <i>monostachya</i> , <i>Hypericum androseum</i> , <i>calycinum</i> , <i>Ilex</i>	<i>aquifolium</i> , <i>Ligustrum vulg.</i> <i>sempervir.</i> <i>Viburnum tinus</i> , t. fol. arg. t. fol. aur. t. hirtum, t. lucidum. <i>Climbers.</i> <i>Clematis vitalba</i> , v. <i>canadensis</i> , <i>Hedera helix</i> e, b. fol. arg. mac. e, h. fol. aur. mac. e, h. fol. arg. var. e, h. fol. aur. var. e, h. fol. miximix, <i>Lonicera periclymenum</i> , pl. flo. albo, <i>Rosa arvensis</i> e, repanda, <i>Vinca major</i> e, minor e, m. fol. arg. e, m. fol. aur. e, m. flo. pleno.
---	--	---

SUBJECT. 4. Shrubs for planting by the Sides of Pieces of Water, or in Marshy Grounds, and among Rocks.

6580. *Besides aquatic shrubs*, most of the peat-earth species are also suitable for planting in marshy situations.

<i>Deciduous.</i> Alnus pumila, Betula nana, pumila, and sibirica, Dirca palustris,	Myrica cerifera, and gale, Salix, most of the species.	<i>Evergreens.</i> Arbutus unedo, Ledum palustre, Pinus palustris, Salix reticulata.
---	--	--

6581. *Of mountain or rock shrubs* the following are some of the most hardy : —

<i>Deciduous.</i> Atriplex alpina, Daphne alpina, Gerardia decumbens, Lonicera. albigena, Ononis fruticosa, Potentilla fruticosa, Rhamnus saxatilis, Rhododendron dauricum, Ribes alpinum,	Rosa alpina, spinosissima, Rubus cæsius, corylifolius hispidus, Spartium angulatum.	trum nigrum, Erica, all the hardy species, Cistus, all the species, Gaultheria procumbens, Juniperus communis, Rosmarinus officinalis, Ulex europæus, nana.
	<i>Evergreens.</i> Arbutus alpina, Azalea procumbens, Daphne collina, Empe-	

SUBJECT. 5. Shrubs for forming Edgings and Hedges in Gardens.

6582. *Of shrubs for edgings* few are comparable to the box (*Buxus sempervirens* var. *nana*); but some others may be occasionally used, as the

Andromeda polifolia, Arbutus alpina and uva-ursi, Empetrum nigrum, va-	rious species of Erica, especially herbacea, tetralix, vulgaris (Calluna, W.), Laven-	dula spica, Sedum buxifolium, and even Ulex nanus.
--	---	--

6583. *Hedge plants.* The following are a few of the numerous plants which may be used as hedges for shelter in gardens; almost all the free-growing sorts may be planted in rows, and cut in the hedge form; but the following sorts will form compact evergreen shelters : —

Buxus sempervirens, Juniperus communis, Ulex europæus var. hibernicus, Ilex aquifolium, Laurus nobilis, Ligus-	trum vulgare, sempervirens. Olea (Wild.) angustifolia, latifolia, and media, Rhamnus alaternus, Rosmarinus officinalis,	Taxus baccata, Thuja occidentalis and orientalis, Viburnum tinus, Prunus laurocerasus.
--	---	--

The creeping shrubs may be formed into hedges by training on frame-work.

6584. *Flowering hedges* may be formed of the following deciduous sorts : —

Rosa various species, Coronilla emerus, Daphne mezereum, Hibiscus syriacus,	Philadelphus coronarius, Pyrus japonica, Robinia hispida, Spartium multiflorum,	Spiraea hypericifolia, Syringa persica, vulgaris, hybrida, or varin, &c.
---	---	--

SUBJECT. 6. Shrubs whose Flowers or Leaves have volatile Odors, and diffuse them in the surrounding Air.

6585. *Of shrubs whose odors are volatile* only a few have this quality in the leaves as well as the flower; these are marked leav. : —

<i>Deciduous.</i> Azalea most of the species, Betula sibirica, leav. Daphne mezereum, Rosa rubiginosa, leav. Salix most of the species, but espe-	cially S. viminalis, alba, Syringa vulgaris.	<i>Climbers.</i> Clematis flammula, Jasminum officinale, Lonicera caprifolium, periclymenum.
	<i>Evergreens.</i> Lavandula spica, Rosmarinus officinalis.	

SUBJECT. 7. Shrubs ornamental by their Fruit as well as Flowers.

6586. *Ornamental fruit-bearing shrubs* are also serviceable as encouraging singing-birds to resort to the shrubbery.

<i>Deciduous.</i> Berberis vulgaris, Ligustrum vulgare, Ribes alpinum, cynosbati, Rosa spinosissima, et villosa, Sorbus americana, et lanuginosa, most of the species of Vaccinium, Lonicera, Viburnum, and all the species of Cornus, Euonymus, Mespilus, Prunus, Pyrus, and Sambucus. Few shrubs are more ornamental than the sloe (Prunus spinosa, Linn.); it is profusely covered with odoriferous white flowers early in April, and with dark-purple fruit with a fine bloom, from September to February. It is much cultivated in Japan (464.), where its flowers attain the size of a double rose.	<i>Evergreens.</i> Arbutus unedo, alpina, and uva-ursi, Cornus canadensis, Empe-	trum nigrum, Euonymus americanus, Ilex aquifolium, Juniperus communis, and suecia, Mespilus japonica, pyracantha, Prunus all the species, Taxus baccata, Vaccinium all the species, Hedera helix.
		<i>Climbers and Creepers.</i> Lonicera all the species. Rosa canina, Vitis vulpina.

SUBJECT. 8. Selections of Shrubs for botanical or economical Purposes, parasitic Trees, and Shrubs for a small Shrubbery.

6587. *Selections of shrubs* may be arranged in innumerable modes, as well as herba-ceous plants; as, according to soil, climate, habitation, country, rarity, place in botanical systems, uses in agriculture, or the arts, &c. No gardener can make any selection who does not know by inspection the actual plants, and their habits, culture, and history; to him it is needless to repeat the sources to which he may have recourse for forming any classification whatever.

6588. *A selection for botanical purposes* will necessarily include parasitic plants, of which the only hardy genus is *viscum*. This is propagated in February by sticking the berries, which are viscid when bruised, in a slit like that made in budding, on the smooth bark of the apple, pear, thorn, or almost any tree. If these are not washed away by rain, or otherwise rubbed off, they will germinate in the following summer. To make sure of their not falling off, some bore a hole in the bark and insert the seed; or cut a notch in it, or make a slit: the last seems the best mode, and has been successfully adopted by Professor Thouin in the Paris garden, and extensively by Watts, a nurseryman at Acton, on most sorts of trees. Some, as Professor Walker (*Essays on Nat. Hist.*), on the supposition that the seeds will not vegetate till they have passed through the stomach of a bird, recommend causing fowls to eat the seeds, and then sowing them. But this is found not to answer, for though the digestive powers of the stomach do not destroy the vegetative power of seeds which pass rapidly through it, yet in most cases it does. The mistle-toe in nature is propagated by the mistle-toe-thrush (*Turdus viscivorus*), but not, as is generally supposed, by means of its excrement. This bird feeds on the berries of the mistletoe in winter. These, from their viscosity, often stick to the outer part of the bird's beak, and to disengage them he strikes it against the branch of the tree on which he alights, and leaves the seed sticking to the bark; if this should chance to be a smooth part, the seed will adhere to it, and the succeeding spring will grow, the radicle piercing the bark, and the plume unfolding itself in the air. The *viscum* grows best on the pyrus and mespilus tribes, but it will also grow on the ash, poplar, lime, oak, fir, &c., on which trees we have observed it in abundance in Germany. In the pine-forests, near Magdebourg, it is most abundant on pinus sylvestris.

6589. *A selection of trees and shrubs of great beauty and easy culture, proper for introduction in shrubberies of limited extent:—*

Deciduous trees. *Acer pennsylvanicum*, *Asculus hippocastanum*, *Amygdalus communis*, *Quercus disticha*, *Fagus sylvatica purpurea*, *Platanus occidentalis*, *Quercus coccinea*, *Robinia pseud-acacia*, *Sorbus aucuparia*, *Tilia europea*.

Evergreen trees. *Pinus cedrus*, *bal-samea*, *pinex alies*, *Cupressus sempervirens*, *Quercus granuntia* and *suber*, *Juniperus virginiana*.

Deciduous shrubs. *Amygdalus nana*, *Andromeda paniculata*, *Azalea nudiflora*, and *pontica*, *Chionanthus virginica*, *Coletea cruenta*, *Cornus florida*, *Coronilla emeris*, *Cytisus purpureus*, and *sessilifolius*, *Daphne mezereum*, *Genista florida*, *Halesia tetraptera*, *Hibiscus syriacus* and varieties, *Ligustrum vulgare*, *Magnolia purpurea*, *Mespilus chama-mespilus*, *Philadelphus coronarius*, *Prunus cerasifera*,

CHAP. XI.

Frame Exotics.

6590. *Frame exotics* are such plants as are rather hardier than those kept in the greenhouse and of low growth. Some of these enumerated here will also be found among the greenhouse, and a few among the hardy plants. The frames or pits in which they are kept are never artificially heated, but are well covered with mats or other materials during severe frost. The frames are sometimes attached to the front of the greenhouse or stove, and thus derive some heat from the front flue, which, when an outside frame is in contemplation, is generally built in the front wall. When this is not the case, they may be advantageously placed on a border sloping to the east, south, or west, under the shelter of a hedge or wall. The pots should be plunged in scoriæ, ashes, sawdust, or any similar non-conductors, and abundance of air, and little water given in the winter time. Few scenes are more interesting in the spring season than a small oblong flower-garden, surrounded by a holly-hedge enriched with many spikes of coral berries: within the hedge a sloping frame-border all round; on the north side, containing frame exotics; on the west, early-flowering bulbs, as hyacinth, crocus, narcissus, &c.; on the east, choice atriculas; and on the south side (the border facing the north), a collection of alpinæ. The middle of the garden laid out in beds of florists' flowers. In summer the sashes are applied to various useful purposes, as to ripen fruits against walls, to raise late crops of cucumbers, melons, &c.

SECT. I. Frame Woody Plants.

Those marked *cl* are climbers; *tw* are twiners; and *tr* are trailers.

The propagation and culture of frame exotics is the same as for green-house plants.

CHAP. XII.

Green-house Plants.

6597. Of green-house plants we shall first arrange some of the more select tribes, and next class the most showy and easily-flowered sorts, under the head of woody, succulent, climbing, herbaceous, bulbs, annuals, and biennials. Each of these subdivisions will be arranged as before as far as respects time of flowering and color; but considering the limited height which all exotic plants attain in pots, it has been considered unnecessary to attend to size. Such as are trees in their native country will be indicated by the letters *tr*, and also such as are biennials by the letter *b*; the most tender *t*, most showy *s*, and those continuing in flower two or three months *3*, as before.

SECT. I. Select Green-house Plants.

6598. As select green-house plants we shall consider the geraniums, heaths, and camellias; which three tribes united will supply a green-house with flowers of almost all colors, during every month of the year.

SUBSECT. 1. *Geranium*. — *Geranium*, L. *Geranium*, *Erodium*, and *Pelargonium*, of modern authors. *Monadelphia*, L. and *Geraniaceæ*, J. *Géranier*, Fr.; *Geranium*, Ger.; and *Geranio*, Ital.

6599. The *geranium* tribe comprehends numerous species and varieties of herbaceous suffruticose and shrubby plants, generally of a somewhat succulent nature throughout. They are almost all natives of the Cape of Good Hope, and with the exception of three or four species, have been introduced, or originated here from seed, during the present and latter end of the last century. They are chiefly admired for their flowers, which they produce in abundance from May to September, generally in corymbs from the axillæ of the leaves, of every shade of red, scarlet, and purple, mixed with white and yellow. The plants are easily cultivated, and by proper pruning, with the aid of gentle forcing in winter, many of the species, as the *P. zonale*, *cucullatum*, *cordatum*, &c. may be kept in flower all the year. The best collection of this family is in the nursery of Messrs. Colvill, under the care of the botanist Sweet, whose *Geraniaceæ*, now publishing, is the most elegant and complete work of its kind.

6600. *Species and varieties*. Many species and subspecies have been received from the Cape; but the greater number of the admired sorts have been raised in this country from seed; some of these have received systematic appellations, but the greater number have been named by those who raised them after themselves, or their friends, in the manner of florists' flowers. The following table contains some of the old established sorts, arranged according to their habits of growth and time of flowering; the flowers of most of the sorts are so mixed in regard to color, that it is almost impossible to class them in that respect; most of them are variegated with red, purple, scarlet, and white.

6601.

6602. *Propagation*. The ordinary mode of continuing each species, is by cuttings, but almost all the sorts produce ripe seeds in this country, by which they may be multiplied, and also new varieties produced. The seed, if ripe before midsummer, may be sown as soon as gathered, in pots of light rich earth, and placed in a gentle hot-bed and shaded; the plants will soon come up, and if, when they show two proper leaves, they are transplanted singly into pots, and kept under a cold-frame, they will flower the same autumn. No plant grows more readily by cuttings than the shrubby or suffruticose species of this family: the cuttings may be taken off at a joint where the wood is beginning to ripen; laid in the shade for an hour or two till the wound heals; and then planted in sandy loam, and placed in a gentle heat. The harder sorts, as *P. zonale*, *inquilans*, &c. will strike in the open air or in any shady situation, without

being covered with a glass. Cuttings of the roots of such sorts, as *P. triste*, *gibbosum*, &c., strike readily; a small portion of the root being left above ground. The fibrous-rooted herbaceous sorts, as *E. Chamædryoides* and *glandulosum*, may be multiplied by dividing the roots. "From the latter end of March to the middle or end of July," Cushing observes, "cuttings of all the common kinds of geranium may be put in with success: Let a moderate hot-bed be made up, and surfaced with some old tan; when it is of a proper temperature, let the cuttings be made, and put in some nice rich loam; plunge the pots to the rim on the bed, and shade them for a day or two, but no longer. Pick off any damping leaves that may appear, water them occasionally, and observe to pot them off in due time, by which means they will be stout plants by the end of autumn: the more curious kinds are in general done by cuttings of the thick fleshy roots, which they produce in abundance: as many of these as can be spared with safety being taken off carefully from each plant, and a few of the finer fibres attached to them and neatly potted in small pots, leaving the crown of each about one fourth of an inch over the surface, watered and set on a moderate heat, will, in a few weeks, make excellent plants: one, two, or more stems, which they in general produce, being left to form the plant." (*Exotic Gard.* 90.)

6603. *Culture.* The geraniaceæ require a light rich soil; they grow well in equal parts of sandy loam and well rotted dung; or they will grow in leaf-mould and a little sand, without any thing else. As most species are rapid growers, the pots require to be examined in spring and autumn, and the roots and top reduced, or the plant shifted into a larger pot. In general the shrubby sorts should be kept low and bushy by pruning; for when they are allowed to grow tall and straggling, they are very unsightly and do not flower well. Some of the herbaceous sorts may be considered as frame plants; but the greater number require the green-house, and some of the very succulent sorts are best grown in the dry-stove. When an extensive collection of geraniums is kept, it is desirable to devote a house entirely to their culture; in this the roof should be of a construction to admit as much light as possible, the stage should be near the glass, and there should be ample means of giving air and heat. Most of the species require rather more heat during winter than evergreen woody exotics from the same climates; otherwise they are apt to lose their leaves and rot at the points of the shoots. To prevent this, heat should be given in the daytime and air admitted, and whenever any leaf begins to decay, it should be removed. The hardier geraniaceæ, like other green-house plants, are generally placed in the open air from May to September; but as the flowers are much injured by heavy rains and winds, the more delicate sorts, and all those intended to flower in the best manner, should be kept in the house with abundance of air night and day. In warm situations it is customary in April or May, to plant many of the *P. zonale* and other free-growing sorts in the borders of the flower-garden or shrubbery: these have a splendid effect till attacked by frost, when their roots may either be protected where they stand by abundance of litter and mats, or they may be removed into single pots, and placed in a dry part of the green-house till the following spring. The Rev. W. Williamson has found, that if the plants are taken up, deprived of their stalks and fibrous roots; the wounds made in doing this healed by exposure in a dry place; and afterwards the roots deposited in layers in a mass of sand, placed in a cellar, or otherwise excluded from frost, they will retain their vegetative power through the winter, and grow vigorously when replanted in the open air in spring. (*Hort. Trans.* iv. 414.)

6604. *Forcing the geraniaceæ.* The hardier shrubby sorts force well with a very gentle heat, and in this way may be kept in flower during the winter months till April and May, when they will be succeeded by those that have been kept in the common green-house temperature.

SUBJECT. 2. *Exotic Heath.* — *Erica*, L. *Ocandria Monogynia*, L. and *Ericæ*, J. *Bruyère*, Fr.; *Heyde Kraut*, Ger.; and *Macchia*, Ital.

6605. *The heath family* constitute an extensive assemblage of low shrubby evergreen plants, much valued for the beauty of their flowers, and the blossoming of many of them in the winter season. Scarcely any exotic heaths were known in Miller's time, and none of the Cape species. Almost the whole of these have been introduced to Europe during the reign of Geo. III., and the greater part by Masson, a collector, who made two voyages to Africa at that king's expense.

6606. *Species and varieties.* Above 300 species have been introduced, some of which, from the difficulty of propagation, or accidental causes, have been lost; but there are still upwards of 250 sorts, which may be procured from the nurseries. There are also several varieties which have been raised from seed. The Hon. and Rev. W. Herbert has raised several hybrid heaths, which gives reason (*Hort. Trans.* iv. 27.) for thinking that many of the sorts imported from the Cape, and considered as species, are only hybrids produced by promiscuous impregnation. We have here arranged most of the sorts procurable in the nurseries; and, in addition to the time of flowering, height in inches, and color, designated the form of the flower, as bell (*b*), pill or tube shaped (*p*), open (*o*), roundish (*r*), or ventricose (*v*).

6608. *Propagation.* A number of the sorts ripen their seeds in this country, and may be so propagated; but the greater number are struck from cuttings, and some few, as *E. massoni*, *retorta*, *petiolata*, &c., by layers, which require two years to throw out roots. The seeds are often imported from the Cape, and arrive in winter: they should be sown early in the spring following, in frames filled with equal parts of peat and sand, very thinly covered, placed in the shade, and bell-glasses placed over them. The soil must be kept moderately moist by gentle waterings: they will in general come up in six weeks or three months, and may then be kept close to the glass in the heathery, or in a frame or pit till autumn, when they may be potted off. Seeds which are saved in this country may be sown as soon as gathered, if they ripen before September, but after that period it will be better to preserve them till next spring; as the plants produced from them would not be sufficiently advanced to endure the winter. Cushing (*Exotic Gard.* 74.) prefers a September sowing, because he finds the plants will stand the winter in the seed-pot better than those that have been raised early in spring, and transplanted in autumn into single pots. Ample directions for striking heaths will be found in Cushing's *Exotic Gardener*, who observes, that cultivators failed at first by planting large cuttings of ripened wood, instead of taking only the points of the fresh shoot. The true method, he considers, of propagating heaths was first discovered in the Hammersmith nursery, and the following abstract of the practice there is from Page's *Prodromus*. "About the month of June, or as soon as the plant has made fresh shoots, cut off the extreme points about an inch long or less, according as the sort may afford, but always in the fresh shoot; take off the leaves from the lower part, as far as it is to be put in the sand, without injuring the shoot; this is rather a nice operation, and should be done with a sharp penknife, for the least bruise spoils the cutting. Dibble them into a pot, filled with moistened common white house-sand, before they have time to flag; when they are all planted, water the whole to fix them still better; let the moisture a little subside, then cover them with a small bell-glass, fitted within the rim of the pot, and place them in the shade on a spent hot-bed, keeping them close till rooted, which will, with the free sorts, take place in about two months: when rooted, which is known by their shooting, take off the small glass, for about a week, at night, previous to its total removal. They will be fit to pot off in March the ensuing year."

6609. *Henderson of Woodhall's mode of striking ericas* is as follows:—"The month of July is a good time for putting in most of these cuttings; but the cuttings must not be taken off till the young wood be firm. Cuttings of ericas may be put in at any time when the wood is in a proper state. Take the cuttings off the plants about three quarters of an inch long, pulling them off downwards; strip off the leaves nearly half the length of the cuttings; place the cutting on the nail of the thumb, and, with a sharp knife, at right angles, cut off the small end close to the joint, or place where it was pulled off the plant. Having done this, plant them into a pot filled with small pit or river sand, giving them a good watering to settle the sand about them. Set them on a shelf where they are a little shaded; cover them with glasses, and notice to keep the sand always moist. Some of these sorts will be well rooted in three months, and others will require six months." (*Caled. Mem.* iii. 323.) Henderson keeps his ericas, at all times, cool and airy; "opening the glasses in winter when there is no frost, and letting the wind blow on them, and using no fire but in time of frost. Never," he says, "shift any plant till the pot is quite full of roots. When the plants get large, several of them will continue in good health for three or four years without shifting, and flower well. I have plants of erica *retorta* here, in pots seven inches in diameter, which are very bushy, being eighteen inches across, and fourteen inches high above the pot; erica *infundibuliformis*, two and a half feet in diameter, and two feet nine inches high; erica *pilosa*, betwixt five and six feet high, and three feet across, in pots eleven inches in diameter: these have not been shifted for five years, and are in high health, and covered with strong fine flowers from the mouth of the pot to the top of the plant." (*Caled. Mem.* iii. 327.)

6610. *Culture.* "A prejudice," Page observes, "having spread that the culture of these plants is difficult, one of the greatest ornaments of the green-house has hence, of late, been neglected; although the method of culture is as easy, and nearly as certain, as that of the geranium, but requiring a little more delicacy in the execution." The soil for all the species is peat-earth mixed with from one sixth to one fourth of fine white sand. The pots should be well drained and rather small; but large, in proportion to the size of the plants. Heathes thrive best in a house by themselves, and placed as close to the glass as possible, without risk from frosts: they do not require so much heat as most green-house plants, but abundance of air, and, above all, great regularity as to water, so as to preserve, as much as possible, an equable and moderate degree of moisture about their roots. The mass of mould being once thoroughly dried, the plant is irrecoverably lost; and it is equally so, though the operation goes on with less rapidity, if the pot is kept in a pan of water. No kind of plant is more injured by being kept in a chamber than heath, nor will they thrive in a green-house or in the open air, within the influence of the smoke of large towns. In the best situations and under the best management, many of the species are short-lived, and therefore require to be frequently renewed by cuttings or seed.

6611. *The ericas are not subject to insects.* Henderson says "I have never had any insect on them except the green fly. The old *grandiflora* is the only one with me that has been attacked. I destroyed the flies by dipping the plant into an infusion of tobacco. The ericas, I find, do not agree well with being smoked with tobacco-paper in the usual way." (*Id.* iii. 327.)

SUBSECT. 3. *Camellia.* — *Camellia* and *Thea*, W. *Monad. Polyand. L.* and *Aurantiaca*, J.

6612. Of the *camellia* genus there are four species introduced: the *C. bohea*, *viridis*, and *sasanqua*, are the plants whose leaves furnish the tea imported from China; *C. japonica*, introduced in 1739, is an ornamental evergreen shrub, which grows to the size of a low tree in China, with dark-green ovate leaves, on short petioles, and flowers red, white, striped, and variegated, and single, semi-double, and double, without fragrance, but of great splendor and beauty, and peculiarly valuable, as appearing in December, January, and February.

6613. *Varieties.* These are —

White: the single, semi-double, double, double white, waratah, Wellbank's white, finbriated white, and spotted-leaved.
Red: the single, semi-double, double, pale, dark, large, peony, pomponne,

pink, buff, long-leaved, striped-leaved, myrtle-leaved, Lady Hume's, Greville's coronet, six-angled, and waratah.
Red and white: the striped, double, semi-double, variegated, and spotted-leaved.

There are above half a dozen other sorts, procured from seed, which are not yet named, and many hybrids have not yet come into flower.

6614. *Propagation.* The single red *camellia* is propagated by cuttings, layers, and seeds, for stocks; and on these the other sorts are generally inarched, and sometimes budded or grafted. The cuttings are formed of ripened shoots of the preceding summer, which are taken off in August, cut smoothly across at a joint or bud, two or three of the lower leaves only taken off, and the cuttings then planted and made firm with a small dibber, in pans of sand or loam, or, by some cultivators, sand and peat, or sand alone. The pans are kept in a pit or cold-frame, without being covered with glasses, but shaded during powerful sunshine; and in the following spring such as are struck will begin to push, when they are to be placed in a gentle heat. In September or October following, the rooted plants will be fit to pot off; and in the second or third spring they may be used as stocks. Henderson puts in *camellia*-cuttings at any time of the year, excepting when they are making young wood. He puts fifty cuttings in a pot of sand eight inches in diameter, sets them in a cool place in the back of a vinery or peach-house for a month or six weeks, and then plunges

them to the brim in a hot-bed where there is a little bottom heat. A speedy mode of obtaining stocks is by planting stools in a pit devoted to that purpose, and *laying* these in autumn; the following autumn most of the layers will have produced roots, when they may be taken off and potted, and used as stocks in the succeeding spring. Inarching or grafting is performed early in spring, when the plants begin to grow; the chief care requisite is so to place and fix the pot containing the stock, as that it may not be disturbed during the connection of the scion with the parent plant. The graft being clayed over, is then covered with moss, to prevent its cracking. When independent grafting is resorted to, the mode called *side grafting* (2031.) is generally used, as in the case of orange-trees (5910.); but the operation of tonguing is generally omitted, as weakening the stock, and unnecessary, with a view to prevent the scion from being blown off by winds. A few seeds are sometimes obtained from the single red and semi-double camellias, and from the single waratah; these require two years to come up, but make the best stocks of any. The tea-camellias are generally propagated by layers, but will also succeed by cuttings.

6615. *Soil.* Some cultivators grow the camellias chiefly in peat; but Messrs. Loddiges, who have the most numerous collection of this genus, formerly used loam, with a little sand and peat for most of the sorts; and they are grown in a similar soil in the Hammersmith nursery. Of late, Messrs. Loddiges find light loam alone to answer as well or better. In the Count de Vande's garden, at Bayswater, rotten dung is mixed with loam and peat, and the surface of the pots are top-dressed with fresh cow-dung, free from litter. The plants appear to us to grow most luxuriantly in a strong rich loam; but to be most prolific in flower-buds in loam and peat. Henderson, of Woodhall, is one of the most successful growers of the camellia in Scotland; his compost is as follows: Take one part of light-brown mould, one part of river-sand, one part of peat-earth, one half part rotted leaves. Mix them all well together, and when the camellias require shifting, put some broken coal-char in the bottom of the pots, and some dry moss or hyppnum over it. (*Calcd. Mem.* iii. 316.)

6616. *Camellia-house.* Camellias have the best effect, and are grown to most advantage in a house entirely devoted to them. Such a house should be rather lofty, as the plants never look so well as when six or eight feet high, trained in a conic form, and clothed with branches from the root upwards. The plants should be raised near to the glass by means of a stage, which should be so contrived that as they advance in height, it may be lowered in proportion. Only the very best crown or patent glass should be used; because it is found, from experience, that the least inequality of surface, or thickness of material so operates on the sun's rays, as to concentrate them, and burn or produce blotches on the leaves of the plants. Every cultivator must have observed that leathery shining leaves, like those of the orange, myrtle, &c., are more or less obnoxious to this solar injury; but the leaves of the camellia are particularly so. Some nurserymen recommend a roof which will not admit much light; others, the use of green glass; of an opaque roof, with glass in front only; or, of a house facing the north. Our opinion is, that a light house facing the south, or, better still, glass on all sides, is essential to the perfect growth of the plants; and that all solar accidents may be avoided, or at least rendered of no consequence, by using the best glass, and placing the plants as near it as possible.

6617. *To grow the camellia to a high degree of perfection*, considerable care is requisite. The roots are very apt to get matted in the pot, and by the space they occupy, so to compress the ball of mould as after a time to render it impervious to water. Hence frequent attention should be had, to see that the water poured on the pots, moistens all the earth, and does not escape by the sides of the pot, moistening only the web of fibres. The same cause renders examining the roots, and shifting or reducing and replanting them, a necessary measure, at least once a-year. When the plants are in flower, and in a growing state, they require to be liberally watered, and also a degree of heat somewhat more than is usually given to green-house plants. If this heat is not given in November and December, the plants will not expand their blossoms freely; and if both water and heat are not regularly applied after the blossoming season, vigorous shoots will not be produced. To form handsome plants, they should be trained with single stems to rods, and pruned so as to make them throw out side branches from every part of the stem: to encourage these, the plants should not be set close together on the stage. In summer they may either be set out of doors on a stratum of scoriz, or on a pavement, in a sheltered but open situation; or the glass roof may be taken off. The harder sorts, as the double reds, blush pæony, flowered, &c., answer very well when planted in the bed or border of a conservatory, provided the roof or entire superstructure can be removed in summer to admit the full influence of the weather. Where this cannot be done, the camellia and most other plants are better in portable utensils, which admit both of examining their roots, and placing them in the open air, or in a greater degree of heat at pleasure. The single and double red camellia will endure the open air, when trained against a south wall, and protected by mats in winter; and there can be no doubt that in time these and other species will be more perfectly inured to our climate.

6618. *Henderson, of Woodhall*, gives the following account of his mode of treating the camellia. "The best time for a regular shifting of the camellias is the month of February or beginning of March. After shifting all those that require it, put them into the peach-house or vinery, where there is a little heat; if there be no peach-house, vinery, nor pinery, set them in the warmest part of the green-house. They will soon begin to make young wood. From the time they begin to make their young shoots, till they have finished their growth, give them plenty of water. They may be kept in the vinery or peach-house till they have formed their flower-buds at the extremity and sides of the young growths, when a few of them may be removed to a colder place, say behind the stage of the green-house; for the camellias are fond of being shaded during strong sunshine. In three or four weeks after, a few more of the camellias may be brought from the vinery or peach-house, and put into a cooler situation. This may be repeated three or four times, which will make as many different successions of flowering. Those that are wanted to come into flower early, may remain in the warm house till they are beginning to flower, when they should be taken to a cold place, say the coldest place of the green-house; then give them plenty of light only, and they will open their flowers well, and stand long. A camellia cannot stand heat when in flower, indeed they seldom open their flowers fine when in heat, and, at all events, the flowers soon fall off. Those that are kept all the summer in the vinery, will come into flower by the first or middle of October, and a pretty large plant, having perhaps fifty or a hundred flower-buds, will continue in flower till the month of January. Those plants that are removed early from the vinery, will now be in flower, to succeed those that were in flower in October, and have now done flowering. These last should be immediately taken into the heat. They will make their young wood early, and they may remain in heat till they come into flower, which will perhaps be a month earlier next year. By attending to shifting the camellia-plants from the warm house to the cold, a regular succession of flowers may thus be had from the first of October to the middle of July. I have even had them all the summer, but the flowers are best in the winter. Those produced in summer are far from being so fine, and do not stand half the time of those that come into flower in November, December, January, February, March, and April. Camellias delight to be kept damp all the summer months, and a little shaded from the strong sun. Give them plenty of water while they are making their young shoots; they may also get a gentle sprinkling over the leaves once every week during the summer season, except when they are in flower. Camellias will stand a great deal of cold without being much injured, but they will not form many flower-buds without some artificial heat. I find they flower best when kept in rather small pots or tubs. I never shift them but once in two years, or often once in three years. There are several very large camellias here that have not been shifted these five years, and they are still in high health, having always produced above a hundred fine large flowers every year. Six years ago, I shifted a single camellia from a twelve-inch pot into a tub seventeen inches wide by seventeen deep, and grafted it with two different sorts of double red, one double striped, and one double white; it is still in the same tub, and all the four sorts in high health. I have had all the four sorts in flower at once on it, producing a fine contrast

of colors. The plant is large and handsome, being eight feet six inches high, and six feet nine inches wide. There is another plant here, twelve feet high, having upon it all the sorts I possess. They were only grafted last summer, and a number of the sorts are showing flowers; grafts of all of them have taken and are growing well. The plant is growing in a box sixteen inches over by sixteen inches deep." (*Caled. Mem.* iii. 316.)

SUBJECT. 4. *Various Genera which may be considered as select Green-house Plants, showy, fragrant, and of easy culture.*

6619. Of other select green-house plants, the first we shall mention is the citrus tribe, already treated of as fruit-trees (4879.); the beauty and fragrance of which need no encomium. They merit a house by themselves, though they will thrive perfectly in the same climate as the camellia. The myrtle comes next in order: nerium is a well known genus, whose flowers are of great beauty and long duration; fuchsia is universally admired; jasminum, gardenia, and daphne, have flowers of great fragrance; heliotropium is remarkable as smelling like new hay; various species and varieties of rosa indica and semperflorens are both beautiful and odoriferous, and flower throughout the winter. Among the new genera from the Cape and Botany Bay, acacia, mimosa, eucalyptus, melaleuca, metrosideros, and the proteaceæ, are admired for being prolific in showy flowers, which, for the most part, appear early in spring, and being chiefly evergreens and large-growing hardy plants. Diosma, gnidia, and struthiola, are admired for their minute foliage and elegant flowers; those of xeranthemum are prized for their durability. Bignonia, cobæa, dolichos, jasminum, lonicera, and passiflora, are admired climbers; of passiflora some beautiful hybrids have been originated by Milne of the Fulham nursery. (*Hort. Trans.* iv. 258. and v. 70.) Mesembryanthemum, cactus, and yucca, are curious and beautiful succulents; amaryllis, cyclamen, iris, ixia, and gladiolus, lachenalia, babiana, ferraria, and oxalis, are beautiful bulbous-rooted plants; and calla, celsia, cineraria, lobelia, tropæolum, and jacobæa, select herbaceous sorts.

6620. The principal species of these genera will be found arranged in the following sections, with their colors, and other particulars, added to each. They are of easy culture, and, with the genera of the preceding subsections, may be considered as affording the best choice for a small, showy, odoriferous, ever-green, and ever-flowering collection.

6622. *Propagation.* The method universally applicable is that by cuttings; but a few sorts, which are very difficult to strike, are sometimes layered, grafted, or inarched, and a number are raised from seeds.

6623. *Many green-house plants bring their seeds to perfection in this country; at whatever time these ripen, unless before midsummer, it is best to keep them till the following February.* Sown at that season they soon vegetate, and make strong plants before winter. The pots should be well drained, filled with mould suitable to the species to be sown, and the surface covered with mould of the finest quality, as a bed for the seeds. Several kinds may be sown in a pot, where the quantity of seed is not great, or its quality doubtful; cover with the same fine mould, according to the size of the seeds, and then give a

gentle watering with the finest-rose watering-pot. They may now be set in the most dry airy part of the propagation-house, where they can be regularly attended, as to watering and weeding.

6624. *Watering.* Cushing observes, they will require at least once a-day, in a greater or less degree; for if they are not kept properly moist, the seeds will not by any means vegetate freely, if at all; however, the other extreme is to be studiously avoided. The weeds should be regularly pulled out before they attain any size; else, besides their tops smothering the young seedlings which may have started, the roots, in getting them out afterwards, not only disturb them, but also the remaining seeds that may be perhaps on the point of bursting their embryo. As the spring advances, it will be necessary to lay a few sheets of strong paper over the pots, for two or three hours in the middle of the day, if the weather happens to be clear, and the sun acts forcibly on them; particularly those in which the finer seeds are sown, in order to prevent the surface getting over dry and powder-like; or otherwise, if the mould happens to be pretty moist, it is liable to form a mossy crust, which might be particularly injurious, by preventing the young seedling ushering itself into the light, from penetrating through it with that ease which is requisite. In this manner must they be managed until the beginning or middle of June, at which season the larger kinds of seed may be removed to some shady border, where the pots can be plunged nearly up to the rim in coal-ashes or sand; which will greatly assist to keep them in a proper moist state: here, all the care they will require is to be kept clear from weeds, and regularly watered, morning and evening, if requisite: but never when the sun shines strong upon them, lest the tender leaves of the young plants should get scorched; it will be also necessary to have a careful eye daily for slugs, worms, &c. Should there be any fine light-covered seeds, such as heaths, &c. they must be set in such a manner, that they may be covered with a common hot-bed frame, in a moderately exposed situation, so that in case of sudden or heavy showers, which might otherwise wash the seeds out of the pots, they may be occasionally covered to preserve them from such violence; yet they may be exposed to gentle rains at times, but never long together, lest they become over wet, which would soon perish them in this tender state. They will likewise require to be shaded with a mat in clear weather, or even a double mat, in the very hottest season.

6625. *Potting off.* Early in July, many of them will be growing pretty fast, and will require to be potted off into separate pots; as it is much preferable to do this while they are young and small, before their roots become matted together, than it is afterwards; besides, that they have a considerable portion of the growing season before them to establish themselves, before the winter stops their career. In performing this work, care should be taken to match the pot to the size of the plant, and nature of the species to be potted; as overpotting these small seedlings might be of the worst consequence. The largest-sized pots for this use, unless the plants are particularly strong, are what are called No. 60s: but for heaths, and such like very small articles, a still less size, known by the name of thimble pots, are to be preferred. Being provided with a quantity of these, and the different sorts of mould properly prepared, that may be requisite for the kinds to be done, proceed to part the plants; in doing which, let the nicest care be taken to preserve as much roots and earth to each plant as can possibly be done without injuring the others: let them be neatly potted in the proper mould, which must be gently pressed to the roots, that they may the sooner incorporate themselves with it. In this manner, pot as many as may be thought sufficient for the present purpose, at the same time allowing a few for mischances. They must then be well watered, in the manner already directed for seedlings, and set in a cool frame, on coal-ashes well rolled, or any other hard substance that will prevent the worms getting so freely into them, as they otherwise would. The lights must be kept constantly on, and closed, for a few days, more or less as circumstances may require; and it will be also necessary to shade them very secure from the strong rays of the sun at first; however, in a little time, the lights may be taken off at night, if fine, having them on, and shading in the day, until by degrees the plants are so hardened as to be able to withstand the full power of the sun; thus, in the space of a fortnight or so, they will be fit to be set along with the other plants. This business should not be undertaken later than the middle of August, for if executed at a more advanced season, the plants will not have time to establish themselves; therefore, any that may remain in the pots, not strong enough to be parted by that period, should be removed into the propagation-house early in September, and there placed in their proper situation in that department until the spring following. Indeed, there are some seeds which absolutely require to be kept for that term before they will vegetate; whereby it becomes necessary to examine with care whatever pots have not by that time shown any signs of vegetation, and those which are found alive must be saved, and treated in the same manner as fresh-sown seeds.

6626. *The pots set in the house* will require nearly the same treatment as usual, viz. to be kept perfectly clear from weeds, and regularly watered. Water should now be given in the morning only, as any damps it may occasion will have time sufficient to evaporate in the course of the ensuing day; whereas, if given in the evening, it causes a chillness about their tender leaves, and from the necessary closeness of the house at night, not having free exhalation, it may do a material injury, not only to the seedlings themselves, but likewise to the adjacent plants, by tending to increase the general damp of the house. When first housed, if the weather prove clear, they must be shaded for two or three hours at mid-day; but this practice must not be followed too closely, as the influence of the sun is but seldom too powerful for them at this season, and during the winter months the more sun they receive the better: it is also necessary to be particular in observing that no slugs, snails, or any other insect, harbor about them. Those seeds received from New South Wales, in general, as well as many others of the South Sea Islands, and also several of the larger sorts from the interior parts of the Cape of Good Hope, from the warmer countries of temperate America, and in short, any of the climes in, or approaching the same latitudes, although the plants when grown will flourish and come to perfection in the green-house, yet the seeds will require the aid of a hot-bed when first sown, to set them in vegetation, and until they are parted and established in their separate pots, then to be hardened by degrees to the open air; from which time, they may be treated as directed for the more hardy and common sorts of seedlings. (*Exotic Gard.* 84.)

6627. *By cuttings.* This mode of propagation may be commenced about the middle or end of January. As young shoots in a growing state generally strike most freely, where these are wanting on particular specimens, the plants may be forced for a few weeks in the stove, or in any of the pits in the reserve flower-garden, to produce them. All the soft-wooded, tender, pithy kinds, such as indigofera, crotonaria, polygala, houstonia, chironia, &c., as well as some of the more curious gerania, may require this treatment. By the end of February, the heat will have produced shoots of from two to four inches in length, and from that to any time in March, proceed to cut and dress them neatly with a sharp penknife, taking off all the leaves as close to the stem as possible without wounding it, except a few at the top, to be left for the free respiration of the cutting: this observation should be particularly attended to in making cuttings of evergreens in general, whether hardy or tender: let them be cut off at bottom with a clean horizontal cut, at a joint or bud, and immediately inserted in their proper pots. To have these properly prepared is a very necessary part of the business; being well drained, they should be rather more than half filled with the mould or compost best suited to the nature of the plant, and afterwards filled with good loam or sand, whichever may be.

thought more advisable to insert the cutting in : if sand is used, it should be previously well watered, otherwise it cannot be sufficiently tightened to the base of the cutting ; a most essential point to be observed ; however, it should have time to be well drained off from the pot before the cuttings are put in ; as they, being so tender, are extremely liable to damp at this season ; than which nothing is more injurious. The loam will, in general, be found sufficiently moist of itself ; and should it be of a fine, sandy nature, so much the better ; but if not, a third or fourth part of fine sand should be added, and well mixed previous to its being used.

6628. *Being properly planted*, let them be covered immediately with the proper glass, well fitted, and pressed moderately on the mould, so as perfectly to exclude the air. They should then be plunged in the front of the bark-pit of the propagation-house ; or otherwise in a hot-bed frame made up for that purpose. The inside of the glasses should be regularly wiped with a dry cloth every morning ; and any of them that happen to damp, carefully taken away before they contaminate the rest. If the sun happens to be unclouded, they must be shaded for a few days moderately with strong paper, or some such article ; but by no means is it to be left on too late in the afternoon, as the cuttings being so soft and tender, are extremely susceptible of injury by over-shading. In the space of ten days or a fortnight, some of the free-rooting kinds will be making efforts of growth ; as soon as this is noticed, it will be necessary to give them a little air, by taking the glasses off every evening, when the sun is quite receded from them, and putting them on again early the following morning ; until they are by that means hardened, so as to be able to bear the full power of the sun without the glass, when it is to be entirely discontinued. If any of them should droop their heads when this operation is first performed, it is proper to refrain from moving the glasses until they have gained more strength. The shading is also to be decreased by degrees, but not so much as to be entirely done away while there remains any of them under glasses. In this manner is the business to be followed at different intervals, according as the cuttings are ready during the months of March and April.

6629. *May and June is the most proper time for propagating most or all of the woody shrub-like plants ;* such as myrtles, oranges, metrosideros, banksias, &c. and more particularly heaths, as the young wood will by that time be in general pretty far advanced. If this business is begun in June, which is early enough, they must, on account of the increased heat of the season, be plunged in some cool shady situation, where they can be conveniently shaded when requisite : an exhausted hot-bed, with a frame and good lights on it, will answer very well ; or otherwise, the north side of any low wall or hedge, where they will be a little sheltered from the noonday sun, and have the benefit of it morning and evening ; in either place, the pots must be plunged up to the rim in old tan or sawdust ; and in the latter, they will also require to be covered with large cap-glasses over the small ones, as well mixed cuttings as heaths, except a few of the herbaceous sorts, such as arctotis, calendula, &c. and strong, substantial, broad-leaved kinds, as camellia, laurus, &c. which will succeed better without the small glasses at this season, so that they are covered with sound airtight caps. There are many others, indeed all are-growing deciduous, as well as evergreen sorts, as pomegranates, oleas, myrtles, &c. ; which, in general, only form their callosities previous to the ensuing spring, that do better without the small glasses, as their leaves drop off much sooner when too closely covered, than they do when differently managed ; and it is well certified, that the longer the leaves are retained in an active state, the greater the probability of success : this is to be merely understood as relating to late cuttings ; for the same articles, if put in early in spring, *very young*, in a moderate heat, closely covered, properly shaded and dried, will strike astonishingly quick. Cuttings of all the kinds that remain to be propagated should also be made at this season, and managed in the same manner. The whole being thus arranged, they must be carefully shaded whenever the sun acts violently on them, especially when first put in ; but they ought not to be shaded longer than four or five o'clock in the afternoon, according to circumstances, as the mild influence of the sun at that hour will be necessary to dry up any damps that may have arisen within the caps. It will be also requisite to dry the small bell-glasses every morning, as directed for the spring cuttings, and to water occasionally any of the pots which may require it ; for though it is proper to keep the top of the cutting dry, yet the mould in the pot must be kept as near a medium as possible between wet and dry, otherwise they will not freely vegetate.

6630. *Potting off*. Some of the first put in spring cuttings will, in May or June, require to be parted and potted separately in small pots ; in performing which, be careful to avoid breaking the roots, using them much in the same manner as already directed for seedlings. When potted and watered, they must be set in the propagation-house for a few days, and shaded until they have established themselves in the fresh mould : as soon as they have taken to grow freely, let them be removed to a frame ; but observe not to expose them to the open air entirely at first, as it might do them a material injury, on account of which, the lights over them should be kept closer than usual for a few days. About the middle of June, any of the tenderer green-house cuttings that have been left in the propagation-house since spring, should be plunged under the cap-glasses along with the others : where the whole must be carefully attended to every morning, to pick off damps, dry the glasses, and water when wanted ; it is advisable, when fresh watered, to let the glasses stand off for about a quarter or half an hour, to dry the surface a little, except the sun happens to be very clear, and shining direct on them. It has been already remarked, that there are many kinds which do better without the small glasses ; such as the strong-growing, spongy, and succulent kinds ; also those with thick leathery leaves, as the camellia, and some species of ilex, &c. which are very liable to have their leaves scorched by the glasses collecting the rays of the sun. Any time during the months of June or July, cuttings of these sorts may be made with success ; as by that time the young shoots will be sufficiently firm for that purpose, and will strike freely in good loam : but camellias, and such like sorts, should not be cut until the shoots have finished their growth, and the leaves attained their full size, as they are, when taken too young, particularly subject to rotteness and damp. In July and August, there will be many of the earlier cuttings growing ; they should have their glasses taken off, as before directed, and afterwards be set for a few days in a more exposed situation, to harden them by degrees, in which they must be shaded from the mid-day sun, but freely exposed to the air at night.

6631. *Parting and potting* should also be occasionally performed on such as are ready for that operation ; when, if any of them happen to be more backward than others in the same pot, and not rooted, let them be put in again as cuttings, and treated as such ; those potted should be set in a cool frame, as directed for seedlings, where they must be kept close and shaded, except in mild weather, until they are by degrees inured to the free air.

6632. *Removing to the propagation-house*. At the season in which it is judged advisable to house the general collection of green-house plants, it will be also requisite to have the cuttings removed to the propagation-house, to be cleaned, sorted, and regulated, according to their different kinds and stages of growth. The commoner sorts will do to be set in any part of the house where they will have free air and light, and that they can be got at conveniently to water, and pick them when necessary ; the more curious kinds should be set in a dry airy part, where they can be carefully attended, to prevent their getting over dry or dirty, and also to take the glasses occasionally off those that may be growing. All the backward heaths, proteas, or any other hard-wooded kinds, such as are most of the Botany Bay plants, &c. that take a long time to strike, should be set in one of the coolest and driest situations of the hot-house, where they must be watered and cleaned, like the others, throughout the win-

ter. Towards the commencement of the new year, many of them will begin to grow, therefore the glasses must be taken off such as soon as necessary. With the advancing season, these will likewise advance, and soon require to be parted, and potted separately. (*Exotic Gard.* 101.)

6633. *Almost all the woody green-house plants may be propagated by cuttings*; but a few are occasionally layered, inarched, or grafted, as the camellia, citrus, daphne, &c. which have been already treated of.

6634. *General culture of woody green-house plants.* We shall commence with the shifting season, which generally takes place about the end of May, and trace, from Cushing, an outline for their general culture and management throughout the year. Green-house plants, this author observes, for the most part require a considerable share of pot-room, as many of them are very free growers; but still great caution is necessary to avoid over-potting the tenderer weak-growing kinds. When shifted, let them be neatly tied up, if requisite, and well watered. Any dead or ill grown parts can now be, with propriety, cut away, so as to give the heads a regular neat appearance. In bright sunshine it may be also necessary to shade them for a few days from the influence of the sun and winds, until they are perfectly established in the fresh mould.

6635. *Placing in the open air.* By the middle of June, it will be time to think of preparing the out-door departments, in which it is intended the plants should stand during the summer months. The most eligible situations for this purpose are, the north aspect of vacant walls or hedges, where they will be a little shaded from the noonday sun; or between rows of close hedges, particularly planted for, and solely appropriated to this purpose. By no means set them close under the shade or branches of large trees; as the plants are thereby inevitably drawn into a weak state in a few weeks, and those who adopt such situations are not unfrequently under the disagreeable necessity of throwing away many of, perhaps, their most rare plants, every autumn: and even those that remain will have a bad unsightly appearance. Indeed, shelter from the winds is the great desideratum to prevent their being upset, for most green-house plants are fond of the warmth of the sun, except when recently potted, provided their roots are kept moderately moist. The practice of some gardeners is to plunge them amongst the shrubs and flowers of the pleasure-ground; this answers pretty well with the strong-growing-kinds, such as myrtles, geraniums, coronillas, &c. old plants or supernumeraries that will not be wanted to house in the autumn; and even has a very pretty effect when judiciously done; but it will by no means do for the tender species. Therefore, upon the whole, the most unexceptionable situations are such as at the same time afford a moderate portion of shade, and are so situated as to break the force of those strong gales which frequently blow in the summer and early autumn months, and yet allow that free circulation of air so necessary to the well-being of plants in general, and at all seasons. Having fixed on the place where they are to stand, it must be thoroughly cleansed from weeds, and the hedges, if any, neatly clipped. It should then be well rolled, to make it perfectly firm and level, over it a layer of good lime, slacked and made into the consistency of thick white-wash, should be poured, and left to soak into the surface, as a preventive against worms getting into the pots. When this is dry, let about an inch of finely sifted coal-ashes be regularly laid on, and firmly rolled a second time. Being thus prepared, the plants may be brought out and set regularly and level on the surface, in whatever form or arrangement may best suit the situation or the taste of the cultivator.

6636. *Housing in autumn.* As the young tender shoots of the summer's growth are extremely liable to be injured by the frost, as soon as any symptoms of this appear, they should be removed to their winter quarters, where, if the green-house is built on a proper principle, they can still have the benefit of the free air, and at the same time be in a situation to be protected when necessity requires. They should, at all events, be removed in the earlier part of September. Therefore, about a fortnight before that time, they should be regularly examined, and any roots that may have extended themselves through the holes at the bottom of the pots, cleanly cut away: this tends to stop the too luxuriant growth, and being executed at a proper period, before their final removal, they have time to recover themselves from the partial check they may have received by it; which would come doubly severe, if deferred until the time of removing them into the house; the transition from the cool bottom on which they stood, to the dry boards of the green-house stage, being so materially different. Whatever may be the mode of arrangement adopted (6205), the plants must not be set too close when first put in, as it would occasion most of their tender leaves to turn yellow and fall off; neither should they, if the house happens to have been built on a close construction, be by any means taken in when their leaves are wet.

6637. *When they are all housed,* and dirt of every description taken away, let as much free air be given as possible in the daytime; and even at night, should the weather prove moderately mild, and free from any appearance of frost. Frosts, at this early season, are seldom so severe as to injure any green-house plants that were not immediately exposed to its perpendicular effect; therefore the front windows may be kept open continually, unless there is a prospect of its being particularly severe, or accompanied with cold driving winds, in which case it will be necessary to have them pretty close. If air is too sparingly admitted at this season, when many of the plants have not yet finished their summer's growth, it will inevitably cause them to produce weak and tender shoots, which will be extremely liable to damp off at a more advanced season, when the house must be unavoidably kept close on account of the severities of the external air; and besides, it will tend to give them a more general tender habit, and render them less able to resist the winter colds than they otherwise would. Hence it is evident, that they cannot receive too much air, whenever the state of the external air will admit of it, by being free from all appearance of frost, as it will be so much to their advantage to be thus hardened before the winter assumes its greatest severity.

6638. *Water* should also be plentifully administered when they are first taken into the house, as the dry boards on which they now stand, as well as the elevated situation and free circulating air, occasions them to require more than when they stood on the moist earth; however, by no means go to the extreme, giving it only when evidently necessary.

6639. *As the close foggy weather advances,* water must be given more sparingly, else it will conspire with the atmosphere to increase the damps of the house, which will inevitably injure the plants, by rotting their leaves. These, and dead flowers, should be picked off as soon as they are observable, otherwise they will make a very disagreeable appearance.

6640. *The months of November and December* seem to be more noxious to the health of plants than any other season, by reason of their being full of young sappy leaves, and the remains of many of the autumn flowers still on them, when the weather (which at this time generally becomes close and chilly,) renders it necessary to keep the house shut and warm; this occasions a most pernicious damp to exhale from every part of the house, and even from the earth in the pots, which fixes on the leaves, and other parts of the plants, to their inevitable injury, particularly the younger parts, such as were the produce of the preceding summer. If this kind of weather continues for any considerable time, it will be advisable to give a little fire-heat, to help in drying up these baneful exhalations, and also as much air as can be safely admitted by the doors and front windows, more especially when fire is added, otherwise the heat of the flues will, instead of expelling the contaminated air, rather occasion it to exhale more freely, and be of worse consequences. At this season also, the plants should be regularly examined to clear them of all dirt, and

also to scrape off any moss, &c. that may have grown on the surface of the mould, and to renew it with a little fresh loam ; this contributes much to their good appearance, if neatly executed.

6641. *Fire-heat.* Very little fire-heat seems to be requisite for the preservation of green-house plants in this climate ; in fact, the less it is found necessary to use the better. Except in the case of damp, as before mentioned, it need not be used till the frost be so severe as to lower the thermometer several degrees below 48°, and then merely sufficient to raise it again to that point. If this can be done without the assistance of fire, so much the better ; for which purpose, bass mats may be used along the lower parts of the house, where they can be conveniently fastened : these will be of infinite service, even when fire is used, as less of that element will suffice ; but they should be always taken off in the day to admit the light, unless the weather happens to be particularly severe. It may be also proper to remark, that the more dry the mould in the pots is kept at this season the better, as it will be less liable to attract the frost ; therefore, water must be used very sparingly, and only to such as are in actual want of it. Sometimes, in the depth of winter, there is a succession of very clear weather for several days together, wherein warm sunny days succeed the coldest frost, and nights in which fires have been absolutely necessary ; in this case, it will be requisite to give all the air possible in the day, (unless strong harsh winds, or other occasional preventives, happen to prevail,) observing to shut the windows up close early in the afternoon, so as to include part of the natural heat of the atmosphere within the house. Such weather renders an increase of water necessary, especially over the entrance of the flues, where the fires have the greatest force. It should be administered in the morning, and ought to be kept in the house all night, to expel any frosty particles it may have imbibed, and render it nearly equal to the temperature of the air of the house. But unless water becomes actually necessary by the action of the fire, or the extreme drought of the season, (a circumstance not much to be dreaded in our climate at this time of the year,) the less water used the better ; for though the plants in general like to be kept pretty moist in the summer, there is hardly any thing more pernicious to them now than an extreme of moisture.

6642. *Winter and spring treatment, insects, &c.* During the months of January and February, and, indeed, all through the winter and early spring, on account of the necessary closeness of these departments, it may be expected to see a few dead or yellow leaves on the plants ; these, together with the dead flowers, and whatever damps may occasionally appear, should be picked off as soon as discovered.

6643. *The mildew and green fly* will also be paying frequent visits at this season ; particularly on the young shoots of heaths, and such like tender-leaved plants. The best remedy for the first of these is, to procure about equal proportions of sulphur and roach-lime, slacked and finely sifted, the quantity according to the number of plants infected, to be used in the following manner : As soon as the least symptom of this disease is perceived, (for the sooner it is stopped the better,) which makes its appearance like a whitish down around the tops of the tender shoots, or a species of fungus on the back, or under part of the leaves, provide a vessel full of clear water, large enough to immerge the plant in, exclusive of the pot, which must be held in an inverted position, with the hand placed so as to prevent the mould falling out ; in this manner, plunge the plant into the water, and while it is wet, holding it in the same position, let another apply the above preparation with a powder-puff, or some such machine, in such a manner, that every part of the plant may be perfectly covered : one dressing in this way will, in general, be found sufficient. The plants should afterwards be taken to the reserve-department, or placed in some dry airy part of the house, not conspicuous, until it recovers its verdure.

6644. *As to the fly,* fumigation with tobacco will be found adequate to its destruction ; strictly observing to perform it at the proper season, that is, when the air is perfectly calm, and if close foggy weather, so much the better ; every aperture should also be stopped, so as to exclude the external air as much as possible.

6645. *Towards the end of winter,* the plants should be regularly examined, and cleaned from any filth they may have acquired during that dreary season ; such as moss on the surface of the pots, and leaves that have dropped thereon ; also any plants that may have grown into a loose habit should be tied up. The platforms or stages should be clean brushed, whilst the plants are removed, and any worms that may have harbored in the pots dislodged, by turning them upside down, and lifting them carefully off without breaking the ball of roots, at the bottom or sides of which they are generally to be found. It is easily known when they are in the pots, by their casts on the surface. Indeed, this is a thing that should be attended to at every season of the year, as they are to be observed more or less at all times, and considerably disorder the economy of the pot, when suffered to persevere.

6646. *As the spring advances,* it will be found necessary and convenient to admit a more free circulation of fresh air, and on account of the increasing drought and heat of the season, water must be given more plentifully ; but the houses must not yet be left open at night, particularly the top-lights, as the weather is in general so very changeable at this season, that it frequently happens, although the evening may appear mild and serene, the morning ushers in with a severe frost, which, if admitted to the plants, would materially injure them ; and perhaps at once render all the winter's care and attention abortive. Until about the middle or end of May, the weather seldom becomes in any degree settled ; but at that season we may venture to expose the plants both day and night to all the vicissitudes of the weather, should it continue in any degree moderate. Being thus treated, they will require a considerable increase of water, which may now be copiously given to them, particularly the more free-growing kinds ; but let the following be observed as a general maxim not to be departed from ; that it is necessary to the health of plants, especially the tenderer species, to be permitted to become moderately dry before they are again watered ; because, when kept in a continual wet state, the mould becomes entirely destitute of that active quality so indispensably necessary to vegetation ; and the plant, in consequence, will assume a very unhealthy appearance, which many might perhaps not attribute to the proper cause. (*Exotic Gard.* 130.)

6647. *Treatment of green-house plants in a conservatory.* This should resemble the treatment of plants in pots, as far as the difference of circumstances will permit. The plants in the conservatory cannot be set out in the open garden ; but the roof can be removed to produce the same effect, and should be done about the same time. Instead of shifting, the soil can be refreshed by manure and top-dressings, or it may be entirely renewed ; and pruning, training, and attention to cleanliness and neatness are alike applicable to both modes of culture. When the green-house plants are housed, the lights or roof of the conservatory should be replaced. The plants, in the meantime, will require as much air as it is possible to admit on all fine days, and in case rain prevents the letting down of the roof-lights, the front ones, if any, should be as open as possible. This is to prevent the plants being drawn into long naked stems, and weak branches, which, from their free habit of growth, they inevitably otherwise would be. As the cold of winter increases, which it naturally will do in the months of October, November, and December, a proportionate decrease must be observed in giving either air or water ;

and, if necessary, add a little fire-heat, and mats along those parts of the glass nearest the plants, in such manner as to prevent the frost or piercing winds from injuring them. The conservatory, in these particulars, requires to be managed in the same manner as directed for the green-house. As few objects are more desirable than to preserve the gay appearance of the plants, it will be requisite to pay constant attention to the removal of decayed leaves and weeds of every description ; also to tie up or cut short any loose straggling branches that happen to show themselves, to remove those pots which may have been plunged or set on the pit when out of flower, and, if convenient, to have their places supplied with others in a fresher state.

6648. *During November, December, January, and February*, the moisture of the atmosphere in such departments, where there is a great body of damp mould, will occasion several species of the bryum, and other mosses, as also of the fungi, to vegetate; particularly as the mould has had time to settle, and the surface to become of a close firm texture, which would give the house a very unclean appearance. It must be remedied by frequently stirring with a small fork the whole of the pit, to the depth of two or three inches, and raking it over smoothly with a neat close-toothed rake; which, as well as the fork, should be particularly adapted to this purpose, by being furnished with short handles; so as to enable the operator to use them with freedom under the plants, by which means many branches and flowers will escape being broken off, which cannot be well avoided when awkward tools are allowed to be used for this purpose. As soon as raked, let some fine-sifted fresh loam be thinly scattered over the surface, and it will tend to give it a more agreeable appearance; besides, being dry, it will serve to imbibe a good quantity of the superabundant moisture.

6649. *As the spring advances*, they will require considerable attention to keep them in proper order, on account of their great increase of growth, more particularly the climbing plants, trained against the walls or trellis-work; these should be daily attended to, and trained in their proper places; directing their course to those parts of the house which, from their nakedness, appear to want them most: also these species of plants being remarkably free growers in general, it will frequently be found necessary to thin them, by cutting away any unsightly parts, and those branches most destitute of flowers; by which means there will be sufficient room for the young vigorous growth, and these should be trained in regularly as they advance, otherwise they will attach themselves to the first object they meet, and render it difficult to dress them neatly afterwards.

6650. *Slugs, snails, and other vermin*, are very fond of harboring among the leaves of these plants, when permitted to grow crowded; also under any low bushy plants in the pit, whence they make their nightly excursions, to the great injury of the foliage in general, if not seasonably detected. The drought and warmth increasing with the year, will render it convenient to admit more air, and an increase of water: two very essential points, that should never be neglected.

6651. In summer, the lights having been removed, as before directed, the plants should have any necessary pruning, and be all regularly fresh tied up, to secure them against the free action of the wind; they will, if the weather happens to be dry, which is most frequently the case at this season, require an abundant supply of water, particularly the strong free-growing sorts, on account of being thus exposed to the open air. The cause for thus taking off the top-lights every summer is, that the plants may have the benefit of the warm invigorating showers of that season, and the action of the perpendicular air, which will be a great means of their acquiring that strong, healthy, robust growth, so much wished for: indeed, where it is not practised, the plants seldom fail of being drawn into the opposite unsightly extreme. In two or three years from the first planting, many of them will be grown to as large a size as the house will admit. The knife must be then freely used among such, to keep them within bounds, and prevent their injuring each other, which they inevitably would, if permitted to grow too close together. However, in performing this, one must be very careful lest they disfigure the general appearance of the plant, cutting away only the rude and overgrown parts, which should be taken clean off, without leaving any of the stumps behind. The younger parts which are suffered to remain should then be tied neatly up, so as to form a handsome middling-sized bush. It will also be necessary to observe whether any have outgrown their neighbors in the front rows; these may conveniently be moved into more backward situations, any their places supplied with other new varieties, if to be had. This work may be done with safety any time in spring or autumn, when the weather happens to be a little dull; it will be advisable, however, to cut off a few of the most luxuriant shoots, and to run a spade or large trowel down, around the roots, so as to form a ball, some days previous to its final transplanting, which also operates as a partial check on the free growth of the plant. It should be taken up with a good ball of roots and earth, and well watered as soon as replanted: it may also be found requisite to shade such as are thus removed lightly for a few days, if the weather happens to be very clear. (Cushing.)

SECT. III. *Climbing Green-house Plants.*

Those marked *h* have herbaceous stems.

6652.

CLIMBING GREEN-HOUSE PLANTS.

MAY.	JUNE.	JULY.	AUGUST.	SEPT. OCT.
<i>Aristolochia semper. p.</i>	<i>Asclepias carnosae, p.</i> <i>Hibbertia crenata, p.</i> — <i>volubilis</i> <i>Kennedia coccinea</i> <i>Psoralea palestina</i>	<i>Aristolochia glauca, p.</i> <i>Bignonia grandiflora</i> <i>Capparis spinosa</i> <i>Cocoba scandens, h.</i> <i>Dolichos lignosus, p.</i> <i>Kennedia monophylla</i> <i>Convolvulus canariën. h.</i>	<i>Jasminum gracile, f.</i> — <i>grandiflorum</i> — <i>revolutum</i> <i>Kennedia bimaculata, p.</i> <i>Passiflora coerulea</i> — <i>c. race. quin.</i> — <i>c. r. trilobata</i> — <i>c. r. racemosa</i>	<i>Lonicera japonica, p.</i> <i>Jasminum azoricum</i>

6653. *The propagation and culture* of this tribe is the same as for woody plants. The situation proper for planting climbers and creepers has already been considered. (6204.) To cultivate them to perfection, a house should be entirely devoted to them, in which they should be planted in prepared soil, and trained on poles, like hops, or on arcades, or on single rods running from the front or sides of the house to the back or centre; but sufficiently distant from the glass to show the beauty of the flowers and foliage to the spectator.

SECT. IV. *Succulent Green-house Plants.*

6654.

SUCCULENT GREEN-HOUSE PLANTS.

MAY.	JUNE.	JULY.	AUGUST.	SEPT. OCT.
<i>Aloe ferox</i> , 3. — <i>glauca</i> — <i>reticulata</i> <i>Anthericum pugionifo.</i> <i>Crassula nudicaulis</i> — <i>obliqua</i> — <i>odoratissima</i> <i>Mesembryanthemum</i> — <i>marginatum</i> — <i>mycrophylum</i> <i>Portulacaria afra</i>	<i>Aloe lingua</i> — <i>margaritifera</i> — <i>media</i> — <i>minor</i> , 3. — <i>pentagona</i> — <i>perfoliata</i> <i>Anthericum aloides</i> <i>Crassula orbicularis</i> <i>Mesembryanthemum</i> — <i>aurantium</i> — <i>capitatum</i> <i>Sempervivum montan.</i> — <i>villosum</i> <i>Tetragonia herbacea</i>	<i>Agave americana</i> <i>Aloe maculata</i> — <i>mitriformis</i> — <i>minor</i> — <i>rigida</i> — <i>spiralis</i> — <i>triangularis</i> — <i>lingueformis</i> — <i>frutescens</i> <i>Cotyledon fascicularis</i> — <i>hemispherica</i> — <i>lingueformis</i> <i>Talinum arachnoides</i> — <i>filamentosum</i>	<i>Aizoon lanceolatum</i> <i>Aloe albicans</i> — <i>cymbiformis</i> , 3. — <i>depressa</i> — <i>dichotoma</i> <i>Cacalia repens</i> , p. <i>Cotyledon oblongata</i> <i>Crassula canescens</i> — <i>ciliata</i> — <i>coccinea</i> <i>Mesembryanthemum</i> — <i>compressum</i> — <i>inclaudens</i> — <i>lingueform. crucia.</i> — <i>depressum</i> — <i>difforme</i> <i>Septs capensis</i> , p. — <i>globiflora</i>	<i>Aloe arborescens</i> — <i>picta</i> — <i>inajor</i> — <i>purpurascens</i> <i>Anthericum revolutum</i> <i>Cacalia articulata</i> , p. — <i>carnea</i> — <i>ficoides</i> — <i>kleinia</i> <i>Mesembryanthemum</i> — <i>compressum</i> — <i>inclaudens</i> — <i>lingueform. crucia.</i> — <i>depressum</i> — <i>difforme</i> <i>Septs capensis</i> , p. — <i>globiflora</i>

6655. *Propagation.* With succulents this is remarkably easy, as cuttings and suckers, where they can be procured, seldom fail to put out roots; however, some sorts of aloe, crassula, &c. do not readily produce shoots of any sort by which they may be multiplied. When the leaves are taken off cuttings or suckers, the latter should be laid in a dry airy place, till the wounds heal; they may then be planted in the proper soil, one in each of the smallest-sized pots, and being kept a few weeks in a dry heat, and shaded from bright sunshine, they will seldom fail to grow. In raising succulents from seeds, proceed as directed for the seeds of woody plants; but observe to be more sparing of water after the plants come up.

6656. *Culture.* A sandy loam is the soil universally allowed as the most proper for these plants; not over finely sifted, in order to let the water pass the more rapidly through it; and for the more succulent and dwarf sorts as stapelia, cactus, &c. about an eighth part of old lime-rubbish may be added. Succulents do not associate well with any other description of plants, neither as to appearance or modes of culture; therefore, wherever they are extensively cultivated, there should be a house or houses on purpose for them. One house would be required for the more hardy sorts included in this section, and another for the dry-stove succulents, given in a succeeding table. They require very little watering, and never over the top during the winter months; in summer, if the pots be well drained, they will bear more water, especially when in flower. The pots in which they are placed should be smaller in proportion than for other plants, as they grow slowly, evaporate little, and apparently derive great part of their sustenance from the air. They need not be shifted oftener than once in two or three years; but the surface earth should be taken off, and fresh compost added every year. They do not require to be set out in the open garden during summer; but as much air as possible should be admitted to them, and the roof of the house should be open at that season, night and day, excepting during heavy rains. "The greatest injury," Page observes, "which these plants have to be guarded against, is damps in winter; therefore they should be frequently looked over, and all decayed parts removed, particularly from those which are stemless, and when the leaves touch the earth." He adds, "few of these plants, either those of the green-house or hot-house, are cultivated in general, but merely to fill up the by-shelves and odd corners of the exotic houses; but if a proper attention was paid to them, and their cultivation better known from a study of their characters, we have no doubt but they might be rendered as ornamental and interesting as those now considered the most select. Most of the forms and growths of these plants are truly curious; and many of their flowers of the greatest beauty and brilliancy. Since the days of Dillenius and the late James Lee, these plants have had few admirers; but the present Emperor of Germany, the Prince of Salm, the Vice-King of Lombardy, and our countrymen Haworth and Anderson, the latter the able curator of Chelsea Botanic Garden, are endeavoring to bring them again into that notice which they so eminently deserve." (*Prodromus*, 220.)

6657. *Mesembryanthemum* plants are planted out by Mowbray, in a pit along the front wall of a hot-house. The soil he uses is rich garden-mould and fresh loam: "the sorts are *M. inclaudens*, *aurantium*, *perfoliatum*, *deltoides*, *barbatum*, and other species of different habits; the strong-growing kinds are put towards the back, and the dwarf ones in the front. They grow vigorously, and flower in a superior manner to what they do in small pots; nothing can surpass the brilliancy of their blossoms in a bright summer's day, and many of them continue flowering all winter. All the culture they require is thinning and protection by mats over the glass in severe weather. In summer the sashes are taken off, and the soil may be covered with stones like rock-work." (*Hort. Trans.* v. 274.)

SECT. V. *Bulbous Green-house Plants.*

6658.

BULBOUS GREEN-HOUSE PLANTS.

MARCH TO MAY.	JUNE.	JULY.	AUGUST.	SEPT. TO OCT.
<i>Antholyza cunonia</i> , p. <i>Cyclamen hederaefol.</i> , p. — <i>persicum</i> — <i>flo. albo</i> — <i>flo. adorata</i> <i>Gladiolus abbreviatus</i> , p. — <i>carinatus</i> — <i>cuspidatus</i> — <i>marginatus</i> — <i>orchidiflorus</i> — <i>præcox</i> , (Marc') — <i>watsonius</i> <i>Iris sisyrinchium</i> <i>Ixia aulica</i> — <i>bulbifera</i> <i>Lachenalia flava</i> , (April) <i>Massonia angustifolia</i> — <i>latifolia</i> , (April) — <i>Massonia scab.</i> (Ma.) — <i>violacea</i> , (March) <i>Oxalis laburnifolia</i> , p. <i>Tulipa clusiana</i>	<i>Amaryllis formosissima</i> <i>Antholyza brevifolia</i> , p. — <i>marginata</i> — <i>meriana</i> — <i>merianella</i> — <i>spicata</i> — <i>pallida</i> — <i>tubulosa</i> <i>Gladiolus angustus</i> — <i>bicolor</i> — <i>blandus</i> — <i>byzantinus major</i> — <i>flo. albo</i> — <i>campanulatus</i> — <i>carneus</i> — <i>galentus</i> — <i>namacensis</i> — <i>pyramidalis</i> — <i>roseus</i> — <i>striatus</i> <i>Iris tricuspid</i> <i>Ixia flexuosa</i>	<i>Amaryllis capensis</i> — <i>Fothergillii</i> — <i>major</i> — <i>glauca</i> — <i>humilis</i> — <i>tabulare</i> — <i>vittata</i> <i>Antholyza æthiopica</i> , p. — <i>iridifolia</i> — <i>fulgens</i> — <i>fusca</i> <i>Gladiolus versicolor</i> — <i>undulatus</i> <i>Ixia columnaris</i> — <i>grandiflora</i> — <i>purpurea</i> — <i>versicolor</i> <i>Scilla hyacinthoides</i>	<i>Amaryllis crispa</i> — <i>Johnsonii</i> — <i>linearis</i> <i>Antholyza ringens</i> , p. <i>Gladiolus cardinalis</i> — <i>polystachius</i> <i>Hyacinthus revolutus</i> <i>Ixia stellata alba</i> , p. — <i>purpurea</i> <i>Ornithogalum niveum</i> <i>Polyanthes tuberosa</i> — <i>flo. pleno</i> <i>Tigridia pavonia</i> , p.	<i>Amaryllis sarniensis</i> — <i>corymbosus</i> <i>Lachenalia angustifolia</i> <i>Ornithogalum altissim.</i> <i>Oxalis rubella</i> , p. — <i>temifolia</i> , p. — <i>tricolor</i> — <i>variabilis</i> <i>Veltheimia viridifolia</i>

6659. *Propagation and culture.* After the ample directions on the subject of propagating and cultivating bulbs, already given (6501.), very little can require to be added here. A mode of propagating such as rarely produce offsets may be mentioned: it applies only to tunicate bulbs, which, if cut over transversely, a little above the middle, will form young bulbs in abundance near the margin of the outer coat. This has been successfully practised with *hemanthus pubescens*, and several of the more rare ornithogaliae. The grand art in cultivating bulbs is, to attend to the proper time for putting them into a state of rest; and when they are in a growing state, to place them so near the light, and afford such a supply of air and water as will enable them to bring their leaves to perfection. The management of exotic bulbs is, in general, very imperfect among gardeners, who cannot be too much impressed with the importance of attending to these two points, — the perfecting the leaves, and the putting the bulbs into, and keeping them during a proper time, in a state of rest. Bulbous-rooted plants associate almost as ill with all others as succulents do; and, therefore, wherever a good collection is kept, there should be a house entirely devoted to their culture. The roof should be low and not very steep, and the pots should be kept on a level stage or platform, raised table high, or about two feet and a half, that the flowers may be near the eye. A house, glass on all sides, with a central platform, six or eight feet wide, and two side ones, or side borders, about three feet wide, would form an excellent house for plants of this description, as all of them would be near the glass, and near the eye of the spectator. Whenever the bulbs, cultivated in such a house, became in a dormant state, they could be removed to a pit or frame of proper temperature in the reserve-garden, and kept there dry, till the growing season. Exotic bulbs require nearly the same degree of heat, when lying dormant, as they do when growing.

SECT. VI. *Herbaceous and stemless Green-house Plants.*

6660. HERBACEOUS AND STEMLESS GREEN-HOUSE PLANTS.

MARCH TO MAY.	JUNE.	JULY.	AUGUST.	SEPT. TO OCT.
	<i>Linum flavum</i> — <i>suffruticosum</i> , p. <i>Lotus creticus</i> <i>Sowerbia juncea</i> , p. <i>Statice mucronata</i>	<i>Campanula mollis</i> , p. <i>Witsenia corymbosa</i> , p.	<i>Achillea aegyptiaca</i> , p. <i>Antirrhinum molle</i> <i>Gnaphalium orientale</i> , p. <i>Oenonis natrix</i> , p. — <i>crispus</i>	<i>Agapanthus umb. maj.</i> — — <i>media</i> — — <i>minor</i>

6661. *Propagation and culture.* A small house, constructed like a bulb-house, should be devoted to these plants; some of which are of considerable beauty: but they do not assort well with woody and ever-green species. All the difference between the culture of hardy, and exotic herbaceous plants, consists in the latter being kept in a different climate and in pots.

SECT. VII. *Of Selections of Green-house Plants for particular Purposes.*

6662. *The particular purposes to which green-house plants are applicable* are few compared with those for which plants which grow in the open air may be selected. The most hardy species will be found arranged as frame plants; the most showy and odoriferous under the first four sections. There are scarcely any green-house aquatics; but a few marsh plants; and no parasites, or air plants, suitable for the green-house, have been introduced hitherto. Collections, however, might be made of such as are grown in their native countries for useful or economical purposes, and whose produce is imported to this country, as of *Laurus camphora*, the camphor-tree; *Pistacia lentiscus*, the tree which affords mastich; of such as are highly odoriferous, as *Verbena*, *Heliotropium*, &c. In a botanical collection, *Dionaea* and *Sarracenia* are plants of great rarity, and difficult to preserve or propagate. They are generally procured from their native countries, and grown in peat-earth, kept moist, and the atmosphere also rendered humid by covering them with a hand-glass. Cresswell has produced very strong plants of *S. purpurea*, by treating it as a stove plant. Under his management, "it is planted in a mixture of the fibrous roots, obtained from peat-earth, with an equal quantity of rotten willow wood, broken into small pieces, by which the soil is kept perfectly drained. The pots in which the plants grow are kept in a shaded part of the stove, and watered occasionally, but they do not require to be placed in pans of water, except they become so dry as not to absorb the water given in the usual way." (*Hort. Trans.* iii. 360.) Some fine specimens of these genera, and also of *Nepenthes distillatoria*, are contained in the collection of Messrs. Loddiges, at Hackney.

CHAP. XIII.

Dry-stove Plants.

6663. *What are called dry-stove plants* are such as from experience have been found to require an intermediate degree of heat between the green-house and bark-stove plants and a more dry atmosphere than the latter. Their propagation and culture is the same as for green-house plants; with this difference, that they are not in general removed to the open air during summer; but where the construction of the house admits, the sashes may be removed in dry weather during the three warmest months, but always replaced on the commencement of heavy or cold rains and boisterous winds. We shall arrange them as woody, climbers, succulent, bulbous, and herbaceous plants. To cultivate them to any degree of perfection, it is essentially necessary that a house be appropriated to each section; and each house so arranged as that the plants may be near the glass, and that heat and air may be supplied at the pleasure of the cultivator, or a long narrow house may be divided so as to keep each class separate.

SECT. I. *Woody Dry-stove Plants.*

CHAP. XIV.

Hot-house, or Bark-stove Plants.

6669. *Bark-stove plants* are such as require the highest degree of heat, which has generally been given by the aid of a bed of bark or other fermenting substance, in which the pots containing the plants are plunged. Sometimes, as before observed (6184.), steam or flues are applied under a vault covered with earth or sand as a substitute for bark; and more recently the pots have not been plunged in any material nor bottom heat applied, but a greater atmospherical heat communicated, and the atmosphere about the pots kept moist by watering, &c. We shall arrange the most ornamental species which flower freely under woody, climbing, bulbous, perennial, annual, aquatic, reedy plants; and add some remarks on palms, air plants, and ferns, which, though they seldom flower in this country, or for the greater part have flowers of little show, yet are grand or interesting specimens of vegetable beings.

SECT. I. *Woody Bark-stove Plants.*

6671. *Propagation.* All the known modes are occasionally adopted, but those by seeds and cuttings are the most general. Few stove plants ripen their seeds in this country, and such as are obtained are therefore generally procured from abroad.

6672. *Tropical seeds in general.* Cushing observes, are very liable to lose their powers of vegetation by reason of the transition from warm to cold climates, combined with the length of time which commonly intervenes between their gathering and arrival with us, especially if they have been exposed to damps; on that account they should be sown as soon as they arrive, at least a part of each parcel. Much depends on the state of the seeds when received. East and West India seeds generally arrive with the regular fleets, as indeed do those from the Cape of Good Hope, and all the South Sea islands, for the most part by the Eastern and China ships; so that one may in general be prepared against their arrival. As early spring is undoubtedly the best time for sowing, a few weeks' delay may in some instances be advisable. If received late in October or November, wait until January, or perhaps February, unless it evidently appears that they will not keep out of the earth so long a time in a vegetative state; such as can be sown before August have a good chance to acquire sufficient strength of growth to carry them through the winter months, so adverse to the general efforts of young vegetable life.

6673. *The pots being well drained* should be filled with the compost suitable to the species of plant of which the seed intended to be sown has been produced (see the table); let it be pressed down to about a third or half an inch below the edge of the rim, according to the size of the seeds; if they are small or light sorts, it will be necessary to press it pretty tight, and to add a little of the very fine-sifted mould on which to deposit the seed, previously smoothing it with a bit of thin flat wood, bent so as to lie on it level. Being thus prepared, let the seed be sown regularly on the surface, and cover it from about an eighth to a quarter of an inch, according to the size of the seed as before, with the same sort of fine mould. But if the seed is of the largest sorts, as, for instance, the nut or stone kind, no more is necessary than to press them into the earth with the finger, and to cover somewhat thicker than is recommended for the others. In either case, the covering should be pressed moderately on the seed with the hand; which is indeed a most necessary caution in sowing seeds of any description whatever. In order to ensure the vegetation

of hard or very tough shelled seeds, some have them soaked in water for a few days, say a week, or even ten days, for such as happen to be very dry, previous to sowing : a shallow pan, placed on the coolest part of the flue in the propagation-stove, is the readiest and safest article to receive them for this purpose ; they should be examined daily, and sown the moment any sign of swelling or growth appears : this process, however, is fraught with danger to many of the lighter and smaller sorts.

6674. *The sowing being finished*, the pots must be set on a level spot, and gently, but thoroughly watered with a pot, the rose of which has been made particularly fine, for this and other such uses ; and immediately plunged in a strong heat, without which they will not be likely to vegetate : if a close dung hot-bed the better. A regular but moderate watering, steady heat, and occasional weeding, should any such appear, is all they will now require until they are fit to be removed into separate pots ; which may be done as soon as they have attained a few inches' growth above their cotyledons, or seed-leaves. There are some fruit, such as nelumbium, whose exterior coat is so very hard that the embryo plants are not able to burst through, at least, with us ; to remedy which, the knife is not unfrequently used to pare them thin, even to making a hole in them, but not too near the eye or part where they sprout, with good effect. If the business of seed-sowing is performed in spring, or early in summer, the smaller sorts may be expected to vegetate in the course of five or six weeks at farthest ; whereas, the larger bony kinds will sometimes remain dormant in the earth for the space perhaps of twelve months : this must be attended to, else one might think them beyond a chance of growing, and perhaps throw them away without examination. Whenever there is any doubt of their vegetating, let some of them be taken up and opened with a knife ; when they will at once discover whether they are sound or not ; if sound, they must be still kept in a strong heat, and regularly watered as before ; for want of this simple precaution, valuable seeds are often carelessly thrown on the rubbish-heap, when just bursting their shell or embryo ; and not unfrequently, by that accidental check, are so materially injured as to prevent more than one half of them vegetating again ; if they have been at all so fortunate as to be noticed and resowed. (*Exotic Gard.* p. 8.)

6675. *By cuttings*. Besides the usual supply of the different sorts of earth, &c. there is another article necessary to be provided before we begin the business of making cuttings ; which is, a few dozen of small bell-glasses, (the white glass is best,) of as many different sizes as are the pots in which the cuttings are intended to be planted : they should be fitted to the pot, so as to rest on the inner side of it, about an inch below the rim ; by observing which circumstance, when the pot is filled with earth, the glass will have room sufficient to sink a little into it, so as to perfectly exclude the external air ; of very essential importance to the cutting while in a dormant state, that is, from the time they are put in until they begin to grow.

6676. *The cuttings may be made almost every season* of the year ; yet the months of April, May, and June are certainly the most proper ; as the plants are at that season plentifully supplied with young wood, which, in most species, produce roots when made into cuttings, much sooner than the old wood will if used in the same manner. When the day is fixed upon for this business, let a quantity of pots of the proper size be selected, and prepared by covering their bottoms to the depth of one or two inches with potsherds ; and then, as wanted, about half filled with the compost best suited to the plant intended to be propagated, to grow in for a few weeks, when first struck, and the remaining part with the best loam that can be procured, to insert the cutting in when ready. On the purity and clearness of the loam depends in a great measure the success of many of the tenderer kinds of cuttings, particularly those which are obliged to be kept in moist heat, as it is, when contaminated with other composts, very liable in these situations to cause damp and rotteness, by the particles of putrefying matter generally contained in mixed earths ; and the properties of which are put in motion, by the application of heat. As an exception to this rule, may be adduced sand ; which is of very great utility to mix with the loam, should it happen to be rather stiff for the nature of the cutting : but then, the sand proper for this use is of so pure a nature in itself, that it is evident it cannot have the effect noticed above in regard to mixed soils.

6677. *In the choice of cuttings*, preference should be given to the firmest wood of the same year's growth ; and of these, only such whose leaves have attained their full size and proper color, which are generally to be selected from the lateral shoots ; as the upright leading ones are mostly too luxuriant to make good cuttings. The cuttings of many plants, if taken from the lateral shoots, never become proper erect stems ; but are inclined at all times to form an irregular, bushy, weak head : this is not of small importance to such collectors as cultivate plants merely for the flower ; as such heads generally produce them sooner than luxuriant leaders. The lovers of handsome erect plants, however, choose their cuttings from the upright shoots, early in the season, before they acquire that luxuriance of growth so unfit for the purposes of propagation. The tops of the shoots are to be preferred, unless they happen to flag before used. To prepare them for insertion, most of the leaves must be trimmed off close to the stem, leaving only a few at the top, to allow a free respiration of the air necessary to the life of the plant. This is a most essential article in the art of making cuttings, particularly those of evergreens ; for if they are deprived entirely of their leaves, or that they otherwise flag, or occasionally fall off soon after they are put in, there will be little or no chance of their growing. The reason is obvious, because the inherent sap of the cutting, being deprived of these organs of respiration that kept it in motion, and the cutting having no roots by the efforts of which to produce new leaves, the sap, consequently, becomes stagnated in the pores of the wood ; which, like the stagnation of the blood in animals, will in all likelihood prove mortal, by occasioning an immediate mortification.

6678. *In shortening each cutting* to the most convenient length, care must be taken to do it with a clean cut, in a transverse direction at a joint ; and by no means should they be left exposed, or to lie any considerable time before planted. In planting, a small dibble or other convenient instrument should be used to press the loam sufficiently tight to the base of the cutting, as that is the principal part to be made fast ; as soon as the whole are inserted and the surface of the mould made level and a little firm, give them a gentle watering to settle them ; they should be left to soak about a quarter of an hour, and then covered with a bell-glass, which should be pressed pretty tight, so as perfectly to exclude the outward air. The atmospheric air being prevented by the glass from exhaling any of the juices of the plant, all its powers are forced downward to produce roots, and these will soon prove their existence by producing young leaves and branches. If there are several cuttings of the same sort, they may be all put in one pot, unless they happen to be very large or curious sorts ; but in general each species should be kept in a separate one, on account of the difference in time that some of them require to strike roots ; and also, that any scarce or valuable kind should be put only one in a small pot, as they then are not liable to be injured so much by damp ; neither do they require to go through the precarious operation of separate potting, so soon after being struck. Should it be requisite to have a considerable quantity of cuttings made at the same time, it would be proper to have a one-light frame, with close glasses, placed on a moderate hot-bed, ready to receive them. It should be covered with sawdust or clean tan, about a foot deep, in which to plunge the pots : but if there are only a few done, they may be plunged in any frame among other things, provided there is a moderate heat.

6679. *Watering and shading*. They will now require the most particular attention as to watering and shading. The water must be given twice or thrice very moderately until the earth becomes sufficiently moist, which, if once so, will retain the moisture for a length of time, by being covered with the glass : but the shading is the principal care whenever the sun's rays fall on the glasses, as nothing will create rot.

tenness sooner than letting the leaves flag, and lie upon each other, which will be the positive consequence of a neglect of shade. The most advisable method to do it is, to have a few large sheets of strong paper to lay over the glasses within a frame; which, at the same time that it shades the cuttings, does not prevent the sun's rays from entering the frame and clearing off any damps that may be accumulated therein; whereas, if mats are laid on the outside of the frame-light, it is evident they will tend to have the direct contrary effect. However, in the course of a week or fortnight, they will be able to withstand a little of the rays of the morning and evening sun.

6680. *While in an inactive state*, they should be kept rather dry, but not let to an extreme; else the bark will become shrivelled, and occasion a very smart falling off amongst them; on the other hand, should they be kept in an over-moist state, the consequence would not be less disagreeable, on account of the damp occasioned by the air being so closely confined under the glasses; in this case it would be of infinite service to have the glasses wiped with a dry cloth about once a-week, which is quite sufficient for hot-house cuttings, as they are not so liable to suffer from this cause as those of green-house plants.

6681. *As the heat of the bed declines*, it will be necessary to have another, properly tempered, ready, in which to plunge them when requisite; or otherwise, let the old one be renovated with linings of fresh warm dung; but in such manner as to avoid creating any violent degree of heat or strong rank steam in the bed; as it is better to do it often and but slightly at a time, it being but a trifling increase of labor compared with the probable consequences. By this management one may expect to have some of the free-growing kinds well rooted, and making rapid progress, in the course of a very few weeks; when such is the case, it will be necessary to give them a little air by taking off the bell-glasses at night, and to keep them a little moister than before. If they endure this pretty well for a few days, the glasses may be left off entirely; which will harden and prepare them by the time in which it may be thought convenient to part and pot them separately.

6682. *In taking the bell-glasses off at night*, it is necessary to observe that from their closeness they sometimes occasion the cuttings, more frequently the harder sorts, to produce young leaves and even shoots, before they have sufficient roots: if at any time these should be mistaken for well rooted plants, and their glasses taken off accordingly, in a few hours they may be perceived by their leaves beginning to flag; in which case the glasses must be immediately replaced; otherwise, if neglected, these tender shoots will be utterly spoiled, and it will be a very great chance whether the cutting will ever produce more or not. Should the above circumstance happen, they will be observed to be more impatient of damp afterwards; as indeed will all those be which are growing; the glasses should therefore be more frequently dried, and kept off until the leaves, &c. which were under them, become dry by evaporation; lest we risk their success, I may say, perhaps, their existence, by rotting the first weak efforts towards active life.

6683. *The rooted cuttings* being thus prepared, they may be occasionally taken out of the frame, and set in more exposed airy situations in the hot-house: but as some kinds require a much longer time to produce roots than others, it will be necessary to keep such still in the frame, shading and watering them when requisite, as already directed. Thus may they be treated until the autumn; when, if any yet remain in the cutting state, it will be advisable to have them taken to the propagation-stove, and plunged in the bark-pit; previously clearing them from any damps, moss, or weeds that may have grown amongst them, and renewing the surface with a little fresh loam. Here they will require the same care as when in the frame, except that as the influence of the sun decreases, so must the shading in proportion; using it only for two or three hours in the middle of the day, if at all requisite: and indeed it is necessary here to observe, that in the winter, and early spring months, they must not be shaded on any account, nor watered except when absolute necessity requires it; neither should the cuttings that may be occasionally made at these seasons, receive any water when first put in, as directed for those made in summer, as the mould will be found in general sufficiently moist, in itself; and as there is not that quick principle of vegetation at this season, the water might prove materially injurious, by promoting damp and rottenness. It is even necessary in some instances, should the cutting be of a succulent plant, or in any degree approaching that nature, to provide loam rather dry, than moist; in which they must be planted and left without water, until they have completely formed their callosities, and the wounds are healed; however, in either case, those fresh put in must be partially shaded for a few days, should the weather happen to be clear and sunny. It will be also necessary to dry the inside of the bell-glasses more frequently in the winter months; as there is generally a stronger heat kept in the tan-pit, which gives rise to an increased evaporation; and damp at this season should be more particularly avoided than at any other. In the ensuing spring those put in early, as well as what have remained since the preceding summer, will in general make an effort to grow; as soon as they are observed in this state, let them be managed in the same manner as those already rooted have been.

6684. *In regard to parting and potting* the rooted cuttings or seedlings separately, the greatest nicety should be observed; first, in turning them out of the pots without lacerating the roots; and secondly, in shaking and working the earth from amongst them, until they can be readily parted without breaking; if any of the mould can be conveniently preserved to them, so much the better; but the preservation of the roots should be the principal object. They must be immediately potted in their proper soil, in pots suited to the size of the cuttings, and neatly tied up, if necessary; let them be then well watered with a rose-pot moderately fine, but by no means should they be flooded, or slushed with it, as too many are apt to do, but let it be given gently, and time allowed for it to soak regularly into the mould. They will require a brisk heat and close shading for a few days, until they have established themselves in the fresh mould. (*Exotic Gardener*, 26.)

6685. *Laying and inarching* are rarely practised on hot-house plants. However, there are some that do not produce roots freely by cuttings, which may be multiplied successfully by these methods.

6686. *In laying*, choice should be made of the young tender shoots of the present year; the soft bark of which will sooner form a callosity, and produce roots, than that of any of the preceding year's growth. It is particularly necessary to observe whether the plant intended to be laid is of a brittle nature or not; for if it is, it will be necessary that the shoots be pegged gently down to the surface previous to laying, and thus left until their tops naturally acquire a perpendicular direction, which they will do in a few days; without this precaution, it would be extremely difficult to cut or tongue them without cracking, or breaking them off; but if treated in this manner, the most brittle may be laid without danger. It is a conclusion drawn from several experiments, that the layer, which is inserted to a proper depth, roots sooner and better than that which is laid near the surface; the reason of which is, at a certain depth the air is better excluded, and there is a more regular degree of moisture for the nourishment of the young fibres, when they make their appearance. No part of the shoot should on any pretence be covered with the mould, except that which is meant to produce roots, as the covering the whole renders it extremely liable to rot; and therefore, if any particularly tender plant should happen to be thus treated, it would evidently endanger the whole stool.

6687. *Inarching* is much preferable to the common grafting, for evergreens in particular; it is principally practised as the best means of multiplying all the double varieties of camellia and plants of similar habits; because their strong leaves, if only for a few days deprived of their regular support, by being cut clear from the mother stock, if not covered closely with a glass, will be certain to wither and fall off; after which there will be but very slender chance of the scion's completing a union: it is performed as follows: having provided a stock, which should always be some of the coarser free kinds of the same genus of plants, and nearly of the same diameter as the shoot which is intended for inarching; cut a

thin slip from two to three inches long, about one third or something better of the whole thickness, smoothly off from each of them, in the clearest part of the stem, with a small sharp knife; a most necessary instrument for this business; the bark of each must then be fitted together in the exactest manner, at least on one side, and tied perfectly tight with good matting: they must be clayed in the same manner as grafts; and as being within doors in a warm house will occasion the clay to become over dry, and in consequence liable to crack, they should, at least in dry weather, receive two or three times a-week some water from the rose of a waterpot or by means of a syringe, to preserve it in a moist proper state, observing to do it in the evening, lest the leaves should get scorched by the rays of the sun: a little moss tied neatly round each ball of clay will prevent the water being so frequently necessary; eight or ten weeks will in general be found sufficient time for them to unite; at all events, by that time they may be partially separated from the parent plant, by cutting the inarched shoots better than half-way through; and if on trial, they are found to be united, and bear that operation well, they may in a few days afterwards be entirely cut off and placed in a shady part of the house, where they must be kept moderately syringed as before, and some additional shade given, according to the state of the weather, for two or three weeks; during which time they may be untied, and the top of the stock cut off in a neat manner; and also any unnecessary part of the bottom of the scion that may remain: let a little clay be again applied that these fresh wounds may have sufficient time to become properly healed, which they will in a few weeks. In this manner, Cushing succeeded with myrtus pimento; and other plants allied to it may be propagated on the common myrtle, which are particularly difficult to multiply by any other means; and also many other plants of the same description upon their kind.

6688. *General culture.* To attain a respectable degree of perfection in the culture of tropical plants, Cushing observes, the principal objects to which one should direct his attention, are assiduity in keeping up the stock by propagation; a careful nicety in potting, and shifting in the proper season; a regularity in watering when requisite; a thorough knowledge of the temperature necessary to be kept in the house; and a steady attention to the cleanliness and habits of the plants in general. The business of shifting, or refreshing the roots of plants with earth properly prepared for that purpose, and transplanting them into larger pots than they before occupied, is one of the most necessary operations required to keep them in a good state of growth. The quantity of earth contained in a flowerpot being in comparison so small to that which is requisite to the support of the generality of plants, it must be supposed that unless it is changed or augmented in due season, they will soon exhaust every particle of vegetative matter contained therein, though frequently assisted by proper water, which doubtless contains a large portion of the food of vegetables; the consequence of which is, to the weaker-growing and tender kinds, that its salts being dissolved, and the sandy particles which kept it in a free open state washed away by the frequent and long continued ablutions, it becomes, in the case of ill drained pots for seeds, sour and coagulated; and the plant being no longer able to draw its proper nourishment from it, must inevitably decline, and at last becomes a nuisance to the collection, by breeding insects and filthiness: to the stronger sorts, though in a different manner, it will be no less pernicious, by starving them, and thereby occasioning them to dwindle into naked stems, and awkward unsightly forms.

6689. *The season most proper for shifting hot-house plants* is about the middle or end of April; if done earlier (though some hot-house plants may be said to be in a state of growth for the greater part of the year) the generality of them will be found dormant; and therefore will not have the power to establish themselves sufficiently in the fresh earth to prevent a great part of their leaves falling off, and the whole plant acquiring a sickly appearance; and on the other hand, if done much later, most of them will be in a vigorous state, and it will require infinite care, and increase of labor to keep them properly shaded, else the intense influence of the sun on them, at an advanced season, will have, though a different cause, nearly the same effect; and reduce them to fully as disagreeable a state as in the former case. But if taken soon after they have made the first effort for the season's growth, the fibres being set in motion, and not having a top full of young tender leaves to support, they soon find their way into the fresh mould; and the plants, by being thus taken in time, and when done, placed in a brisk bottom heat to assist them, will in the space of three or four days at farthest be well recovered, and in general, able to support themselves against the strongest rays we may reasonably expect at that season, without much danger to their leaves.

6690. *Operation of shifting.* Being fully prepared for the removal of the plants, let a part of them be taken to the potting-shed together, that they may be no longer than necessary out of the stove; and while these are shifting, the remainder may be taken out of the tan, and set on any of the shelves or benches that are over the flues, so as to allow sufficient room to have it forked up and turned; and should it be sunk considerably below the desired height, some fresh well dried tan should be added, and mixed well with the old in turning; when done, let it be made pretty level with a rake that the plants may be conveniently and regularly set on the surface when shifted. In shifting the plant, the greatest nicety should be used not to injure the roots; because, if the roots, from a multiplicity of wounds, (which are more frequently lacerated than cleanly cut,) once become cankered, or contaminated in any manner, the branches must also be expected to suffer and decay.

6691. *An old but erroneous practice* followed by many, is that of paring off the best part of the roots with a knife; that is, the tips or ends of the fibres, which are undoubtedly the active agents in collecting the food for the stem, &c.; then, without ever loosening the remaining part of the ball, set in the new pot with a little fresh earth thrown loosely about it: as a matter of course, they think it must then be completely drenched or flooded from the waterpot; and lastly, to crown the whole, perhaps set it immediately in a pan of water; when, if they only took time to consider the mutilated state, to which they have reduced the roots, it is impossible they could ever conceive them to be in a state fit to undergo such treatment with any kind of advantage: but it is the misfortune of many, who will not for a moment hesitate to undertake the care of tender and curious plants, as a matter easily understood, yet will not take the trouble of judging for themselves, to follow the old track of cutting and watering, the same as they may have before seen practised on the hardest geraniums or myrtles. Though the method may not seem to hurt some few kinds of strong free-growing plants; yet it never can be allowed as a proper mode of treatment for all plants indiscriminately, because they may happen to have a good portion of roots: indeed, more plants have been destroyed by this practice than by any other particular part of the system of mismanagement which some so blindly follow. There are instances, however, wherein a knife is necessary to the roots as well as the branches, viz. when they become rotten or otherwise contaminated; and also to such as are propagated by cuttings of the roots, as most species of geranium may be, some mimosa also, and indeed any that are observed to produce suckers: in all which cases they should be taken off with precision, and a sufficiency left to support the parent, if considered worth preserving.

6692. *In turning the plant carefully out of its pot, observe if the roots have perforated it in any part, so as to render it impossible to part them without breaking the one, or lacerating the other; in which case prefer the former as the slightest damage: however, when the ball of roots is divested of its pot, let the broken tiles, or whatever substance may have been used as draining, be carefully picked out without tearing off the roots that may have grown amongst them: also any caked or mossy substance on the surface, which will come easily off with the fingers. Then proceed to loosen the earth and matted roots, by gently patting them on the side of the ball with the hand; or otherwise, by pressing it so as to open the pores of the earth without cracking the roots; shake off any loose earth, and having a proper sized pot, ready prepared, put in a quantity of the fresh mould sufficient to raise the crown of the roots to about half an inch below the rim of the pot, on which set the plant; and add more earth, lightly shaking it in among the fibres; let the whole be pressed moderately light, but not so as to render it hard in the least degree, nor by any means using a stick for this purpose, another never-failing attendant on the former practice, by which the roots are extremely liable to be torn or bruised; add mould sufficient to raise the surface level with the rim, as it will settle to a proper depth with watering, and smooth the whole off neatly with the hand.*

6693. *Two or three assistants will be found necessary, where there is much of this work to be done; one of those should be employed in supplying pots and other necessities; the others in washing and cleaning from insects, &c. any plants that may happen to stand in need before shifted; and in tying them up properly to their sticks afterwards: new sticks should be had at least once a-year, to hot-house plants in particular; as the old ones very often harbor more or less of the several pestiferous insects which infest these departments. This done, let the plants be set on a level spot together, and moderately watered with a fine-rose pot, held at a distance above their tops so as to give the leaves a good rinsing; but observe to give no more water than is sufficient to settle the fresh mould to the roots, and by no means to slush or give the surface that puddled appearance, so very disagreeable to be observed in departments where neatness should be the uniform and leading principle. Having thus finished the first division, let them be immediately taken to the stove, to be set on the fresh-turned tan for the present, and those that remained there, taken to the shed to be treated and shifted in the same manner as the others.*

6694. *When the whole are shifted, they may be partially plunged for a few days; setting the pot about half its depth loosely into the tan, to avoid the danger that attends too violent a heat arising in the pit; which is frequently the case, when it has been recently turned or augmented. However, there must be a pretty brisk fire-heat kept up in the house, until the plants recover from their inactive state, the unavoidable consequence of their roots being so recently disturbed. They will be much benefited at this time by a moderate use of the hand-syringe, in the morning before the sun has begun to act upon them with force; also by raising a strong steam in the house, to be done by throwing water on the tops and sides of the warm flues. But when they are freely treated in this manner, they require but little from the water-pot; as over watering is very pernicious to plants in general, and at no time is it more particularly so, than when they have been lately shifted. However this must unavoidably depend on the judgment of him in whose care they are placed; as some of them will require considerably more than others. In a few days, when the danger of a violent heat is over, the plants may be plunged neatly in the tan up to the rim; but observe that it is not left scattered on the surface of the pots, as it would give the work an extremely slovenly appearance; a few inches of clean sawdust laid over the tan, gives a clean and neat appearance, which, in most gardens, is a particularly essential part of the curator's conduct. All the plants which require the aid of tan-heat, being properly plunged, and the remaining ones regulated on the different benches or shelves; let the place be well cleaned out, when little more will be necessary for a few weeks than watering when requisite, squirting, steaming, and attention to the degree of heat necessary to be kept in the house at this season. This should in general be about sixty degrees. If it is kept much lower, it will considerably retard the plants in recovering their vigor; and if many degrees higher, the free-growing kinds will soon over-top, and materially injure the weak and more tardy sorts unless prevented; besides themselves becoming unsightly, the consequence of being drawn, or forced into long weak ungainly stems.*

6695. *Insects.* As the heat increases with the advancing season, the different species of insects to which these departments are liable, will multiply incredibly. Those which seem to make the greatest havoc amongst plants in the hot-house, are, the green fly, the thrips, the mealy white bug, the great scaly bug, the small scale, or the pine-bug, and the red spider, which, although the smallest, is by far the most destructive of any of the species that exist in these departments.

6696. *For the fly and thrips, there is no process which seems to take so much effect on them, as a strong fumigation of tobacco; repeated twice or thrice, according to the strength the insects may have attained.*

6697. *For the bugs, there is none of the several expensive methods mentioned in different authors so effectual, as simply picking them off; this may be said to be tedious, but then it has surely to plead in its behalf; besides, that the plants are in no manner disfigured by the operation; but unless regularity be observed in looking for them, examining plant by plant, and leaf by leaf, from top to bottom, and also any incisions or cracks that may be in the bark of the stem, &c. there will be a constant and tiresome employment; on the contrary, if regularly done, one operation will be of more service than five, if executed in a careless inattentive manner. As each individual plant is picked, it should be carefully washed with a strong lixivium of soft soap and water, which will have a powerful effect on their eggs, which are in general sufficiently small to elude the eye, or perhaps so situated within the young buds that they cannot be got at without materially injuring the future growth; the wash will, however, penetrate into these secret holds, and in general be fully adequate to their destruction.*

6698. *When the plants are out of the house in summer, every part of them should be well washed with strong soap-suds, in which a little of the same tobacco, as used for fumigating, has been infused; in particular, all the joints of the wood-work, and also whatever nail-holes or other crevices may happen to be therein; as in these places some of the species, more especially the white mealy bug, is much inclined to secrete itself for breeding. This operation will, however, if performed in spring and autumn, be a great means of their extinction, and will tend in a great degree to check the multiplication of the others.*

6699. *The red spider, the last and most pernicious of the species mentioned, is to be overcome neither by fumigation nor picking; but by the free but well directed use of common water; either by steam or with the hand-syringe. The steam, by creating a fine dew in the house, prevents the insect from extending its slender web from leaf to leaf, and thus checks its progress; while the syringe, by superior force, breaks the ligaments of those already made, and in most instances washes the insects to the ground; where, although it may recover its fall for the first or second application, it is in the end sure to perish. They will sometimes, however, elude the greatest diligence, for a while, by collecting under large horizontal leaves, which serve them as citadels against the attacks of the water; but here they will soon betray themselves, by extracting the fluid substance of the leaf for their support, in consequence of which it loses its verdure and becomes conspicuous; this, when found, should be picked off, and taken out of the house immediately; for if left anywhere among the plants they will in a little time establish themselves on others. If they happen to be discovered before the leaf has lost its beauty, they may be rubbed off with the hand on a sheet of paper, and expelled the premises. If at any time the quantity*

of water necessary to be used in these operations, should occasion the earth to become over-wet, in those pots particularly which are plunged in the bark-bed, the syringing must be omitted, and use made of the steam only, until they again become reasonably dry. Neither should it be performed when the sun acts freely upon the plants, lest their leaves become in consequence disfigured. For the water forms itself into little spherules, the surfaces of which collect the rays of the sun in a greater or less degree according to their convexity; and thereby the leaves are disfigured by being burned in the focus of each spherule.

6700. *Summer treatment.* As the season advances, it will become necessary to admit a reasonable portion of air on all fine sunny days; and also to decrease the strength of the fires at night: but in these particulars, the only criterion to be guided by, are experience and observations on the weather, the variations in which render it utterly impossible to lay down any certain rule to act by, further than the admonitions of the thermometer; observing to keep it pretty near to sixty degrees. About the beginning or middle of May at farthest, fires may be omitted entirely; as the natural heat of the season united to that of the bark-bed, will in general be found sufficient to keep the mercury up to the above-mentioned point.

6701. *Towards the latter end of June*, the plants by this treatment will generally be in a very luxuriant free state of growth; it will be therefore requisite to raise the pots quite out of the tan-bed, to check and harden them a little, so as to be able to bear the air of the green-house for a few weeks, which will be of considerable advantage to them the ensuing winter. Should any of them remain of a sickly appearance, (and that a few may be in that state, in large collections, must be reasonably expected,) or any particular tender sorts among them, they must be removed to a separate house, as already hinted, where the tan being previously forked up, and otherwise properly prepared for their reception, they must be immediately replunged: if no such house is convenient, a large deep hot-bed frame, set on a good bed of well-prepared dung, will answer nearly as well for this purpose; having nine or ten inches of rotten tan or sawdust spread regularly over the bed within the frame, in which the pots are to be plunged.

6702. *When the bed has been got ready*, a few days should elapse before the plants are set in it, that the steam and violent heat may have sufficient time to evaporate. At the expiration of five or six days, however, the plants in their pots may be set on the surface; where they should remain a little time longer without being plunged; but particular care is necessary that the frame at this time may not be kept too close, which would occasion the heat to ascend more rapidly than the plants could well bear; to avoid this, give plenty of air in the daytime, and also a little at night, with a mat hung before it to prevent the sharp air entering into the frame. When the heat of the bed has attained a proper temperature, so that there may be no danger of the roots being burned or otherwise injured, let the plants be plunged, and afterwards treated in the same manner as if they were still in the hot-house: only observing to keep those that are in a weak state rather dry; as nothing can be more injurious to a sickly plant than too much moisture, by reason of its inability to imbibe the usual quantity through want of vigor. The plants which remain, intended to be set in the green-house, must now have a considerable increase of fresh air on all fine days; and also (the pots being quite out of the tan) they will require a greater portion of water than has been usually given them when plunged.

6703. *As soon as the weather becomes settled*, and the night perfectly free from all chilliness and frost, which is seldom much before the middle of July, the plants may with safety be removed from the stove to the green-house; and set regularly on the benches lately occupied by the green-house plants; which they will ornament very much, during the time the latter are set in clumps in the open air. The stove may in this interval be furnished with a few of each of the different tender annuals, to give it something of a gay lively appearance. They will likewise in some measure serve as a kind of natural trap for the spider, &c.; as they will, should there be any of them left in the house, immediately attack the soft tender leaves of these plants, in which case, as soon as they are observed to be collected in force upon any individual plant, it should be removed to the open air, without loss of time, and another substituted in its room; this practice will contribute towards subduing this formidable enemy, so that, combined with other exertions, by the time it becomes necessary to have the hot-house plants reinstated in the bark-bed, the house should be pretty free from them. These being now in the green-house, will require a little attention to preserve their verdure, such as keeping the glasses close at night and admitting air only on fine days; thus to exclude any chilling or strong winds that may happen to prevail, which would occasion the leaves to contract a languid yellowish appearance; however, in course of a week or ten days, they will be able to withstand any weather that may in reason be expected at this season; unless it happens to be unusually violent, in which case it must be guarded against accordingly.

6704. *The removal of insects, weeds, and dead leaves* is the principal care they will require now for about a month or so, also casually tying up any that may want it, and watering; in which last article, it must be observed, that as they now stand upon dry boards, and the air acting freely on every side of the pot, they must consequently be allowed an increase of water, to counterbalance its effect. The evening is the most proper time for watering at this season, as well as syringing, particularly when dry and warm; for if administered in the morning, the rising heat of the sun exhales it, before it has time to descend to the lower roots; and unless replenished frequently in course of the succeeding day, they are liable to much injury, by being left in an exhausted state until the following morning, and which, it is probable, may not prove more fortunate; whereas, if administered in the evening, it refreshes them after the preceding day's drought, and having sufficient time to penetrate to the roots, they have the night to recruit themselves against the following day. Besides, in syringing, there is much more danger of having the leaves scorched by the sun's rays, if done in the morning, than if done as here recommended: but as either extreme is dangerous, care must be taken to use no more water than is evidently necessary for the health of the plants: for if used to that degree that the earth becomes sour and deprived of its vegetative powers, the consequences may be rather unpleasant.

6705. *By thus setting the plants in the green-house*, it tends to prevent the increase of insects; also their too luxuriant growth during the summer months; and by hardening and ripening the wood, renders them strong and firm, and therefore more likely to bloom; which is, in these ornamental plants, the principal object of the cultivator, besides that they are not so liable to be injured by the severities of the succeeding winter.

6706. *Autumn treatment.* Towards the latter end of August the natural heat of the atmosphere will be on the decline; therefore, except on particular fine days, when a small portion of air may be given, the lights must be kept perfectly close; but more especially so at night: as we have frequently at this season heavy chilling dews, and are also often surprised with unexpected showers of rain or hail; to admit either of which might be very injurious to the plants; however, by shutting up the house before the sun has withdrawn its influence entirely from it, and thereby warming the enclosed air, they may safely stand here some days longer.

6707. *As soon as the month of September commences*, it is time to think of getting the stoves ready for their reception; first, a quantity of fresh tan should be provided, sufficient to raise the bed at least six inches above the kirk or wall of the pit, in conjunction with the best of the old already there, which is to be extracted by shifting. Let the new tan be spread out to dry in ridges, upon some clean airy spot, or convenient yard, for two or three days, where it should be regularly turned twice or thrice a-day, and covered with mats at night; while this is preparing, let the flues of the house be well cleaned and the walls white-washed; an operation necessary to be done every year in these departments, where strong fires are kept for such a length of time; likewise, let the old tan be sifted in the common way, with a pretty coarse sieve or riddle: some gardeners throw it entirely away, but the part sifted being mixed with the new, prevents its heating so violently as it otherwise would when first put in; it also tends to preserve a more regular heat in the other longer than it naturally would if used by itself; as it would be very violent at first, and consequently, like most other things that are worked up above their pitch, liable to be sooner exhausted in proportion to the first foundation.

6708. *Having sifted and got away all the refuse of the old tan*, let the fresh, if well dried, be immediately carried in, and both well mixed together in the pit; still adding, until the bed is raised to the proper height; this done, let the wood and glass-work, kirks, passages, &c., in short, every part of the house be diligently washed; for the twofold purpose of endeavoring to clear it as much as possible from insects, as well as to give it a cleanly appearance: being thus prepared, the plants may be removed from the greenhouse, observing to examine each of them diligently lest any of those plagues so often mentioned, should find their way back to the stove.

6709. *The pots must not be plunged in the tan at first*; as well on account of the danger of the violent heat injuring the roots, as because this early plunging might start them into a fresh growth; which, at this late season, would not be at all to their advantage. They must, therefore, be set on the surface of the tan in regular order, where they may stand twelve or fifteen days, or perhaps longer; being guided in this particular by the state of the atmosphere abroad, as well as the internal temperature of the heat in the pit: by the first week in October, the heat of the external air will be considerably abated, and that in the pit sufficiently moderate. The time for plunging being fixed on, observe to have it done in the most exact manner, placing the tall plants towards the back or centre, and the lower ones to the front or sides of the pit in regular order; according to the form of the house, and the mode of arrangement adopted. If sawdust is used, it will contribute much to their cleanliness, and also make a more agreeable appearance than the tan. All being set to rights, and the passages, &c. swept clean, give the plants a good syringing to wash off whatever dust they may have acquired during their removal, which will complete the business for this time. The principal care afterwards for a few weeks, is to give them a reasonable share of fresh air and water, according to the temperature of the weather; but it is more proper to perform the watering, syringing, and steaming, from this time to the beginning or middle of May, in the forenoon; observing to do it while the rays of the sun fall so obliquely as to ensure the plants from being injured by it: should it be done in the evening, the air in the house would unavoidably get chilled, especially in frosty weather. It is even necessary that the water used for this purpose should be nearly of the same temperature as the air in the house.

6710. *About the middle of October*, it will be necessary to add a little fire-heat at night, beginning with slow fires at first, and regularly increasing them as the severities of the weather increase. Although a circulation of fresh air is at all times requisite to the health of plants, yet the heat of the external atmosphere will at this season be so much diminished that it will not be found convenient to admit it in any considerable quantity; in fact, none should be given, except on particular fine days, when the front or end lights may be opened a few inches. They should be shut early in the day, seldom permitting them to remain open longer than one o'clock; thereby giving the sun time to warm the fresh-admitted air before the chill of the night commences; even this little indulgence cannot be allowed from about the end of October until the beginning of April: as the strong cold winds which generally blow during the winter months find of themselves but too many entrances.

6711. *As to watering in the autumn*, discontinue it to those plants plunged in the pit, as the moisture of the tan, added to that which proceeds from the syringe, will be found quite sufficient for most of them; on the contrary, those over the flues, or on the shelves or kirks near the fires, will require an additional portion on account of the strong fires necessary to be kept when the weather happens to be severe. The use of the syringe and steam must also be stopped in the severest frosts, lest by that means the house should get over chilled; however, they may both be used freely, when the weather proves moderately mild and fine; but by no means is it to be understood, that the house at this time is to be kept in a continual mist; or, on the other hand, that the plants are not to be carefully examined as usual, and watered liberally when in want of it. It is necessary to notice that those plants which are inclined to be deciduous, and also some of the more tender ones, will be occasionally dropping part of their leaves; these should be picked off as soon as they appear, otherwise they will have rather a disagreeable appearance among the plants.

6712. *Winter treatment.* About the middle or end of December, it will be necessary to have the tan in the pit turned, and renovated with a little fresh well-dried bark to enliven the heat, as the severest part of the season is still to be expected; however, in performing this work, great care is required that the plants are not chilled or injured by being removed out of the tan-bed at this cold season: therefore, the mildest weather must be chosen for performing this operation. The pit being cleared, immediately proceed to turn over and mix the old and new tan well together, in which, as soon as it is completed and levelled fit to receive the pots, they may be plunged without delay; as there is not that certain danger of a burning heat ascending now as in the summer months, in which season the powerful action of the sun occasions it to ascend more violently.

6713. *Plunging the pots.* Should it not be convenient to have the whole plunged the same day, those left will require to be set on the surface of the tan during night; lest by being left near the glass, or extreme parts of the house, they might be severely injured ere the morning by the cold air; as it is therefore advisable to keep them as short a time as possible out of the tan at this season, they should without fail be plunged the next or following day at farthest: it will be also requisite to keep a pretty brisk fire-heat in the house, while the plants are out of the tan, and until the bottom heat in the pit becomes sufficiently strong; else they will be liable thereby to droop, and lose many of their leaves in consequence of being checked at this season. Should it happen that a series of clear fine weather follows this operation, the action of the sun may possibly occasion the heat to rise rather violent in course of a few days after being renewed: to this particular attention must be paid, and if any such symptom should appear, it must be immediately remedied by lifting the pots out of their places, and throwing into the holes a small quantity of the surface tan; on which the pots may be again set in a loose manner; thus, by permitting the heat to pass freely off by the sides of the pots, it prevents its burning the earth or roots, which would be certain death to the plants: when its violence has subsided, let the pit be levelled, and pots properly replunged; but unless the weather, as already noticed, happens to be particularly clear, in all likelihood this labor will not be encountered.

6714. *Watering and cleaning.* They will require from this time until about the beginning of March, nothing more than the usual care of watering when necessary, and cleaning them from all dirt or insects as soon as they appear; also to keep the temperature of the enclosed air as near to its regular pitch as possible: to assist in compassing this object, when the weather sets in severe, it will be proper to use either shutters of canvass or bass mats to cover all the lowest parts of the house; and in particular those at the greatest distance from the entrance of the fires every night; otherwise the frost will easily enter these remote parts, and chill the air through the whole house; the consequence of which may be very injurious: on the other hand, if these precautions are not attended to, there will be a necessity of keeping up a very strong fire-heat, which will likewise be attended with pernicious effects.

6715. *Insects.* It is in these intervals that that destructive insect the red spider makes the most rapid progress, on account of the necessity there exists of keeping the houses close, and supporting a dry warm air, both of which circumstances are particularly congenial to its nature; therefore on all fine mild mornings, observe to raise a powerful steam in the house as already directed; by the frequent repetition of which there will be a possibility of keeping them under control.

6716. *Refreshing the bark-bed.* As the internal strength and heat of the tan will now be much on the decline, in consequence of the length of time it has been in use, it will be requisite to turn it more frequently, so that about the beginning of March, it should be again stirred to at least half its depth; which will afford a temperate heat, until the time in which the plants are usually shifted, when it is generally renewed. Some gardeners make it a practice to have merely the upper half of their tan-pits stirred at any time throughout the year, when the heat happens to be on the decline; this is certainly a very proper method where there is plenty of time and hands to perform it; as there is no danger of a burning heat arising; but it requires to be done so much the oftener, such heat seldom lasting above a month or six weeks; it consequently will not answer where these conveniences are not to be had. The plants being regulated in proper order as before, let them have the usual treatment until the time of shifting. (*Exotic Gard.* p. 70.)

SECT. II. Climbing Bark-stove Plants.

6717.

CLIMBING BARK-STOVE PLANTS.

6722. *The propagation and culture* of these need not be entered on, being essentially the same as for hardy or green-house herbaceous plants, the difference of temperature being taken into consideration. Such as have tuberous roots must be treated on the same principle as tubers in the open garden, as, for example, those of *fumaria cava*, *erythronium*, &c. which have their regular seasons of rest.

6723. *The gloriosa superba*, that grand, beautiful tuberous-rooted stove plant, for want of attention to the nature of its roots and its habits of growth, seldom produces flowers in this country. "Its failure," John Sweet observes, "arises chiefly from the defective method in which its roots are preserved during their inaction, and from the want of proper treatment, when they first vegetate in the spring. Injured at these periods, the plants generally continue through the summer, weak and unpromising, throwing up only a few small stems, which do not flower in sufficient strength and beauty." Under the following management, Sweet has had perfect success, and has known a single root grow ten feet in the course of a season, with numerous blossoms upon it. When the stalks and foliage have decayed in the autumn, and left the root, like a well ripened potatoe, in a dormant state, the pot containing it must be removed from the bark-bed to the top of the hot-house flue, at some distance from the fire, all the warmth at this time necessary being merely what is sufficient to keep the earth in the pot free from damp; and to prevent the waterings of the house, or other moisture, falling on the earth in the pot, it should be covered, by inverting upon it another pot of the same size; or if larger, it will hang over its edges and more effectually exclude the wet. If the roots are small, two or three may be placed together in the same pot, whilst in their dormant state; but if they are thus shifted, the mould must be well shaken down in the pot, in order to prevent the access of air to them; the old mould in which they grew must also be used; for fresh earth or sand would stimulate them to move too early. About the second week in March, the roots must be planted, putting one or two, according to their size, into pots measuring six inches over. The best compost for them is fresh loam, mixed with an equal quantity of bog-earth of good quality: the loam should be good, not over rich with dung, nor too heavy. The roots are to be covered about two inches deep, and care must be taken not to break them, unless nature has shown where it is practicable to divide them easily. The pots, when filled, must be plunged into the bark-bed, where the heat should be equal to ninety-five degrees of Fahrenheit's scale. Water is to be given very sparingly at first, and though, as they grow, they will require a more liberal supply, yet it is necessary, at all times, to be very moderate in giving it. The heat must be well kept up, and as the shoots extend they must be supported by sticks, or trained in any direction on wire or cords. (*Hort. Trans.* vol. iii. 23.)

SECT. V. Annual Herbaceous Bark-stove Plants.

6724.

BARK-STOVE ANNUALS.

		— <i>fruct. purp.</i>		

6725. *Propagation and culture.* They are all propagated from seeds, most of which ripen in this country; but some few sorts are continued by cuttings for the sake of preserving particular variations. Sow in February or March in pots, to be plunged in a hot-bed; prick out the plants into the smallest-sized pots, when they have attained one or two proper leaves, and shift them once or twice into pots a size larger in the manner recommended for the balsam (1653.); keeping the plants in hot-beds or pits till ready to blossom, when they may either be removed to such of the houses as are empty at the time, as the bulb-house, green-house, &c. or assembled in a house devoted to annuals. Some few of them, as the ice-plant (*Mesembryanthemum crystallinum*) and egg-plant (*Solanum melongenum*), may be plunged in a warm situation in the open garden.

SECT. VI. Aquatic Stove Plants.

6726.

HOT-HOUSE AQUATIC PLANTS.

MARCH.	JUNE.	JULY.	AUGUST.	SEPTEMBER.
<i>Arum venosum</i> <i>Cyperus alternifolius</i>	<i>Menyanthes indica</i> — <i>ovata</i> <i>Nymphaea pubescens</i> — <i>pygmaea</i> <i>Pontederia dilatata</i>	<i>Aponogeton angustifol.</i> — <i>distachyon</i> <i>Euryale ferox</i> <i>Nelumbium speciosum</i> <i>Nymphaea cœrulea</i> — <i>rubra</i> — <i>stellata</i> — <i>versicolor</i> <i>Philydram lanuginosum</i> <i>Sagittaria lancifolia</i>	<i>Aponogeton monostachyon</i> <i>Damasonium indicum</i> <i>Nymphaea lotus</i> <i>Pontederia cordata</i> <i>Sagittaria obtusifolia</i>	<i>Cyperus papyrus</i> <i>Thalia dealbata</i>

orders of such rare sorts as have not yet flowered. The following are some of the most remarkable of the economical tropical plants used either in their native countries or imported into this country.

FOOD.

Bengal quince (*Egle marmelos*)
Sour-sop (*Annona muricata*)
Alligator-apple (*Annona palustris*)
Cabbage-tree (*Arca delruca*)
Bread-fruit-tree (*Artocarpus incisa*)
Jaca-tree (*Artocarpus integrifolia*)
Akee-tree (*Ehigia sapida*)
Bread-nut-tree (*Brosimum alicastrum*)
Cocoa-plum-tree (*Chrysalidius icaci*)
Star-apple (*Chrysophyllum cainito*)
Cocoa-nut-tree (*Cocca nucifera*)
Coffee-tree (*Coffea arabica*)
Garlic-pear (*Croton tupa*)
Calabash-tree (*Crescentia cucurbitina*)
Sago-palm (*Cycas revoluta*)
Lee-chee (*Diospyros litchi*)
Smooth-fruited lee-chee (*Diosc. longan*)
Date-plum (*Diospyros kaki*)
Malay apple (*Eugenia jambos*)
Mangosteen (*Garcinia mangostana*)
Anchovy-pear (*Grias cauliflora*)
Eatable okro (*Hibiscus esculentus*)
Otaheite chestnut (*Inocarpus edulis*)
Barbadoes cherry (*Malpighia angustifolia*)
Mammoe-tree (*Mammoe americana*)
Mango-tree (*Mangifera indica*)
Saffron-fruit (*Mimosa dulcis*)
Date-palm (*Phoenix dactylifera*)
Guava (*Psidium pyrifolium*, pomif. &c.)
Lotus-tree (*Rhamnus lotus*)
Tamarind-tree (*Tamarindus indica*)
Chocolate-nut-tree (*Theobroma cacao*)
Sweet potatoe (*Convolv. batatas*); climb.

Granadilla (*Passiflora quadrang.*); climb.
Melon-thistle (*Cactus mammillaria*); suc.
Barbadoes gooseberry (*Cactus persea*); suc.
Black pepper (*Piper nigrum*); suc.
Salsilla (*Alatrameria salsilla*); herb.
Eatable arum (*Arum esculentum*); herb.
Otaheite arum (*Tacca integrifolia*); herb.
Sacred Indian bean (*Nedunbium speciosum*); aquatic
Cardamom (*Annonum cardamomum*); reedy
Grains of Paradise (*Annonum granum paradisi*); reedy
Arrow-root (*Maranta arundinacea*); reedy
Plantain-tree (*Musa paradisiaca*); reedy
Banana-tree (*Musa sapientum*); reedy
Sugar-cane (*Saccharum officin.*); reedy
Ginger (*Zingiber officin.*)
MADICINE
Cashew-nut (*Anacardium occidentale*)
Areca-nut-tree (*Arecha catechu*)
Ipecacuanha (*Euphorbia ipecacuanha*)
Papaw-tree (*Carica papaya*); remarkable for its property of intenerating raw meat.
Jesuits'-bark (*Cinchona officinalis*)
Balsam of Capivi (*Copaifera officinalis*)
Gum-guainum (*Guaiacum officinalis*)
Cassava (*Jatropha manihot*)
Cinnamon (*Laurus cinnamomum*)
Cassia (*Laurus cassia*)
Medicinal mimosa (*Mimosa catechu*)
Gum-Arabic-tree (*Mimosa nilotica*)
Pimento-tree (*Myrtus pimento*)
Bitter of porter (*Quassia amara*)

Poison-nut (*Strychnos nux vomica*)
Wild licorice (*Abrus precatorius*); climb.
Jalap-root (*Convolvulus Jalapa*); climb.
Gum-elastic (*Echites elastica*); climb.
Vanilla (*Vanilla aromatica*); climb.
Contrajerva-root (*Dorstenia contrajerva*); herbaceous
Balsam-plant (*Justicia comata*); herb.
ARTS
Jamaica ebony (*Amerium ebenum*)
Bambu (*Bambusa arundinacea*)
Silk-cotton-tree (*Bombax ceiba*)
Tallow-tree (*Croton seiferum*)
Oily palm-tree (*Elais guineensis*)
Olive-wood (*Eleodendron orientale*)
Indian rubber-tree (*Ficus elastica* and *Echites elastica*); climb.
Cotton-tree (*Gossypium arboreum*)
Logwood (*Hematoxylon campechianum*)
Manchineel tree (*Hippomane mancinella*)
Sandbox-tree (*Hura crepitans*)
St. Helena red-wood (*Melania erythroxylon*)
St. Helena ebony (*Melania melanoxylon*)
Sponge-tree (*Mimosa farneana*)
Supple-jack (*Paullinia polyphylla*)
Ground ratan (*Rhynchosium formica*)
Japan sumach (*Rhus succedanea*)
Soapberry (*Sapindus saponaria*)
Mahogany-tree (*Swietenia mahogani*)
Indian oak (*Tectona grandis*)
Lance-wood (*Uvaria lanceolata*)
Indian madder (*Oldenlandia umbellata*); herb.

Some minds relish nothing that is not either immediately useful, or has some relation to utility: to such the foregoing list will be of some value as pointing out plants of great importance to mankind in other countries. From our connection with these countries, and the number of young persons that annually leave Britain to pass great part of their lives in them, it is desirable those plants should be known here also; and hence a rational object for the patriot, who has wealth and leisure, to display them in a conservatory attached to his castle, or palace, (fig. 623.) of suitable elevation and extent.

623

6733. In selections of rare or curious plants, or such as are sought after chiefly by botanists, the palms, the air plants, and the exotic ferns will be included; and on the culture of these, we shall select some remarks from the *Horticultural Transactions*.

6734. The *palme* is a natural order of plants of great interest by their utility, both as fruit-trees, and as supplying other products; and of much grandeur of appearance. The cocoa, sago, and date palms are well known; upwards of fifty other species have been introduced into this country, and are to be found chiefly at Messrs. Loddiges. A number more remain to be procured, of which the doom-palm (fig. 624.) is one of the most remarkable, being the only palm known to have a branched trunk like other trees.

6735. The culture of palms is less a matter of nicety, than expense. They require a powerful moist heat, a large mass of rich earth in the pot, tub, or bed, and ample space for the leaves. As they are of remarkably slow growth, a stove devoted to their culture does not require to exceed the common height at first, but to admit the tree-palms to display their character, it would require to have the roof elevated by degrees to 60, 80, or 100 feet. It is much to be wished that some spirited man of wealth would, in these times of peace and leisure, distinguish himself by palm culture, of which Messrs. Loddiges, much to their honor, have set the first example. It is a common opinion, that their growth is so slow, that little effect would be produced during a life-time: but this every gardener that has supplied his palms with abundance of space for the roots, and adequate heat in their atmosphere, can witness against.

6736. Parasitic stove plants. Maria Graham (Letters from India) remarks, that she saw many of these flourishing in great luxuriance on the rough trunks of palms in the Calcutta botanic garden. At Kew, Spring Grove, and in the garden of the Horticultural Society, they have been

generally grown in rough tan, closely pressed together in small pots or baskets, and suspended from the roof of the hot-house. Messrs. Loddiges have established some specimens on the trunks of palms in the Indian or natural manner, and the Honorable and Rev. W. Herbert appears to have been equally successful. "I am informed," he says, "by a friend at Calcutta, that he cultivated with great ease, all the *dendrobia acerides*, and other parasitical plants, by tying them, with twine, to the stem of a tree, or to the under-side of a branch, and placing above them a pot of water with a hole at the bottom, through which a string passed, nearly as large as the aperture, by which the water was gradually and continually conducted to the upper part of the parasitical plant, which requires to be constantly moist and shaded; and that a tree with smooth bark answered the purpose best. He mentions that *dendrobium pieradii*, fastened to a tree and irrigated in this manner, will, in a little more than a year's time, produce pendulous racemes of flowers, from two to six feet long, and it appears likely to thrive with me under the same treatment. I had previously found no difficulty in establishing *epidendra* on the stems of trees in the stove, by cutting a notch in the bark and inserting the plant like a graft, and tying moss about it to support it, till the young roots had attached themselves to the bark; but from want of sufficient moisture, they have not made much progress, or flowered with me. I have now adopted the above-mentioned mode of irrigating them, with full confidence that it will succeed in our stoves, as well as it does at Calcutta; and very soon after its application to a sickly *epidendron*, growing on the stem of *sterculia balanghas*, vigorous young fibres began to sprout from it on all sides. I am very much inclined to think, that most of such plants would attach themselves to the sides of a porous stone or vessel, or of a dead root, if constantly irrigated, and thrive upon them as well as upon a living tree, especially if the stone or root were covered with growing moss, for I have observed the fibres of more than one sort attach themselves strongly to the outside of the pot in which they are planted; and I conceive that they might be beautifully cultivated, upon an ornamental cone of porous pottery, filled with water and furnished, on the outside, with niches, in which the plants might be fixed, with a little moss or peat to promote their growth in the first instance. I have found the parasitical plants in danger of perishing, from want of moisture, on a deciduous tree, during its season of inactivity, but that deficiency would probably be removed by constant irrigation. The neatest and most convenient vessels for that purpose, perhaps, would be little tubs, such as are sold at toyshops, which might be easily tied to a branch, and perforated with a small gimlet. A short string, of which one end is twisted round, or at least in contact with the plant, and the other inserted into a phial of water, will also be found to convey a regular, though less plentiful supply of moisture, acting in manner of a siphon. I have used it advantageously to nourish a graft, and promote its union with the stock. For the cultivation of parasitical plants in pots, I recommend placing the pots on a back flue, in a tin tray, about two inches deep, and half filled with wet sand, giving an abundant supply of water, but not sufficient to produce rottenness by its stagnation. I find the growth of *crinum*s, which also like a moist heat, to be prodigiously rapid with that treatment; I should suggest a mixture of porous stones, or bits of broken pots, with old tan, or such peat as contains a portion of half-decayed wood, and a garnish of moss to the pot, as preferable, for parasitical plants, to the loam which some of our books have recommended." (*Hort. Trans.* iv. 243.) All these parasites are included under the natural order of *Orchideæ* are of herbaceous habits, and readily propagated by suckers or cuttings.

6737. *The Rafflesia Arnoldi* is the most extraordinary parasite known to botanists. It was discovered by the late Dr. Arnold, in Sumatra, in 1818, in a jungle or thicket, growing close to the ground under the bushes, and attached to the roots of a species of *cissus* or *vites*. The plant consists of the flower only, having neither leaves, branches, or roots; the flower is a yard across; the petals, which are subrotund, being twelve inches from the base to the apex, and it being about a foot from the insertion of the one petal to the opposite one; the petals are from a fourth to three fourths of an inch thick, and the nectarium, it is supposed, would hold twelve pints. It appears to take its origin in some crack or hollow of the stem, and soon shows itself in the form of a round knob, which, when cut through, exhibits the infant flower enveloped in numerous bracteal sheaths, which successively open and wither away as the flower enlarges. A singular change takes place in the vessels of the root or stem on which it grows; their ramifications are multiplied, and they take a direction so as to unite with and accommodate themselves to the base of the parasite to which they convey nourishment. The general appearance of the flower is that of *Stapelia*, and its smell is also fetid. It is diœcious, and supposed by Brown to belong to the natural order of *Asarineæ*. There is another species *R. horsfieldii* with the flowers not above three inches in diameter. Both, it is probable, may in time be introduced in our stoves. (*See Lin. Trans.* xiii. 201.)

6738. *Exotic ferns.* The tree-ferns, Humboldt informs us, are of singular beauty in their native sites. Only a few species of these, as *dicksonia arborescens*, *davallia pyxidata*, *pteris aculeata*, &c. have been introduced; but the number of herbaceous ferns which are stove plants is considerable. They are propagated from seeds which generally ripen freely in this country, and such as are received from abroad generally grow, however long kept; they are also multiplied by dividing the roots. The best collection of exotic ferns is considered to be in the Liverpool garden: many of these have been raised from seed by Shepherd, the assistant curator; and the following are his directions for this purpose: Having provided a common garden-pot, four and a half inches in depth, and three and a half wide, let the bottom part, to the height of one inch, be filled with fragments of broken pots by way of drain. Over these should be spread a stratum of such soil as is commonly used for potting green-house plants, of the depth of two inches; the remaining half inch should be filled with brown loamy earth sifted through a hair sieve, the surface being made perfectly smooth, and on this the seeds are to be scattered as evenly as possible. Care must be taken that the wind be not suffered to blow the seeds away, leaving nothing but empty capsules. The seeds being sown, no other covering is requisite than a bell-glass, which should just fit within the rim of the pot, so as to exclude all air. The pot is then to be kept in a pan always half full of water, and set in a shady part of the stove or hot-house, being always regularly watered as above directed. When the young plants have acquired their second leaf, it is proper to give them a little air by placing a small piece of wood under the edge of the glass, at one side. In a short time afterwards the glass may be entirely removed. (*Hort. Trans.* iii. 338.)

6739. *The seeds come up in two or three months*, and the plants flower the following year. It is not known how long these seeds retain their vegetative quality, but two plants of *acrostichum calomelanus* were raised from seeds brushed from a specimen of that fern in the herbarium of Foster, supposed to be near fifty years old. But the same success did not attend similar attempts with any other specimens from this herbarium. The soil for ferns should be of a soft fine texture to suit the very small fibres of their roots; it requires also to be kept constantly moist in imitation of the native habitations of these plants; which is generally under the shade of trees or rocks. Hence also they may be set in dark parts of the stoves where nothing else will thrive.

SECT. IX. Selection of Dry and Bark-stove Plants, for such as have only one Hot-house to contain them.

6740.

Woody plants. Bambusa arundinacea, Barringtonia speciosa, Carica papaya, Catesbaea spinosa, Clerodendrum fragrans, Coccothraex cerifera, Cocos nucifera, Corypha umbraculifera, Chamærops humilis, Cycas revoluta, Phoenix dactylifera, Coffea arabica, Crotolaria pulchra, Datura arborea, Dillenia speciosa, Dracena draco, Ficus indica, Hibiscus rosa-sinensis, Ixora coccinea, Lagerstroemia reginae, Mimosa nilotica, odoratissima, Myrtus pimenta, Nerium coronarium, odorum, Nyctanthes arbor-tristis, Portulandia grandiflora, Robinia violacea, Solandra grandiflora, Sterculia plantaginifolia,

Tectona grandis, Vinca rosea, Volkameria aculeata.

Climbing. Convolvulus speciosus, Crataeva fragrans, Dolichos urens, Ipomoea digitata, Jasminum sambac, Passiflora coccinea, alata, racemosa.

Seculent. Agave vivipara, Aloe pelucens, Cactus grandiflorus, melocactus, speciosus, Euphorbia clava, Pandanus odoratissimus, Piper nigrum, Stapelia grandiflora.

Bulbs. Amaryllis reginae, josephine, Crinum amabile, erubescens, latifolium, Haemanthus coccineus, Pancratium amoenum.

Herbaceous. Erides odoratum, Arum

bicolor, Epidendrum cochleatum, Gloriosa superba, Gloxinia maculata, Limodorum tankervillei, Phytolacca octandra, Polypodium aureum, Pteris grandiflora.

Aquatics. Cyperus papyrus, Euryale ferox, Menianthes indica, Nelumbium speciosum, Nymphaea lotus, pubescens, rubra, Thalia dealbata.

Reedy. Alpina racemosa, Canna glauca, indica, Heliconia bihai, Maranta arundinacea, Musa paradisiaca, sapientum, Saccharum officinarum, Strelitzia reginae, Zingiber officinale.

CHAP. XV.

Monthly Catalogue of the leading Productions of Ornamental Horticulture.

6741. Our catalogue of monthly ornamental productions extends only to a few of the more generally known flowering plants and trees; what respects the hot-house department is to be understood as referring to flower-gardens, which contain at least a bark-stove, a dry-stove, one or more green-houses, and an adequate number of reserve-pits and frames. Those plants are marked (*) which may be produced from a small garden, where there is a green-house, flued-pit, and hot-beds; not in any quantity, but sufficiently to keep up a hope and a fear for every month. The keeping up of this sort of hope and fear is much more conducive to the sort of happiness or interest which those who have small gardens expect to derive from them, than a grand display of two or three species of flowers, occurring only once or twice in the year.

JANUARY.

FLOWER-GARDEN.	SHRUBBERY.	HOT-HOUSE DEPARTMENT.
The crocus, tulip, and some alliums, beginning to emerge from the ground. If mild weather, perhaps some choice plant in flower, also the primrose*, rose, daisy*, but generally no flower is to be seen at this season.	Evergreens display themselves to advantage, especially the holly* with its coral berries. Calycanthus precox, and white, and laurustinus* in flower.	In the <i>green-house</i> , the camellias* in full bloom, and some heaths and australasian plants. In the <i>stove</i> , streptolizia*, seven species, and some other plants. From the <i>pits</i> and <i>hot-beds</i> in the reserve-garden, forced roses, hyacinths, and other bulbs, mignonette, &c. placed in the conservatory, plant-cabinet, or drawingroom.

FEBRUARY.

The snowdrop*, Christmas rose*, and winter aconite*, in flower; the crocus, crown-imperial, and other bulbs, fast advancing, if the weather be favorable.	The male flowers of the hazel*, yew-tree*; those of Erica carnea, and some shrubs, appear. The lark sings about the beginning of the month, and the thrush about the middle.	In the <i>green-house</i> , camellias* and heaths in great beauty, and also some species of oxalis, protea, &c. In the <i>stove</i> , streptolizia*, and some bulbs and succulents. Forced articles from the <i>pits</i> as before.
---	---	---

MARCH.

Among florists' flowers, the crocus*, scilla*, some hyacinths* and crown-imperials*, and also the primrose* and polyanthus* are in bloom in the latter half of the month; saxifraga oppositifolia* among the alpine; and viola odorata* in a warm border, or on rock-work.	Some pines, poplars, and willows*, show their catkins; the sloe*, cornelian cherry*, mezerion* different varieties, daphne pontica and collina, the loniceria nigra*, and rosemary in flower. The ring-dove begins to coo in the first week.	In the <i>green-house</i> , some camellias* still in flower; numerous heaths* in great beauty; also aletis*, lachenalia*, oxalis*, some geranium*, and above a dozen other genera. In the <i>stove</i> , some scitaminee and bulbs; solandra grandiflora, plinia, eugenia, and justicia. Forced articles as before.
--	---	---

APRIL.

The hyacinth*, narcissus*, auricula*, and polyanthus*, four of the most valued florists' flowers are in perfection in the course of this month. Also, the scilla, fritillaria*, wallflower*, daisy*; pulmonaria officinalis, cynoglossum, orphaloides* various saxifragas, and other alpine.	Most of the wild fruit-trees, as crabs*, pears*, cherries*, and their allied species, are now in flower: most of the willows, birches, elms, and oaks, show their catkins. Among shrubs, the honeysuckle, some robinias*, andromedas*, daphnes, ericas*, and zanthorrhiza, are in flower.	In the <i>green-house</i> , above thirty species of erica*, and nearly as many of the ixia* family, with lachenalia, oxalis, acacia, and various other genera in perfection. In the <i>stove</i> , dracena*, bromelia*, kampeferia, stapelia, and some bulbs in flower. Abundance of forced articles, including annuals, as sweet peas, larkspurs, &c. in flower.
--	---	---

MAY.

The auricula-stage still a fine object in the first week; and the polyanthi narcissi not yet over. The collections of tulips*, anemones*, and pæonies*, in full beauty from the middle of the month. Many showy herbaceous plants, as statice*, lychnis*, phlox*, &c. coming into flower. Among the aquatics, hottonia palustris, and ranunculus aquatilis*.	The horse-chestnut*, hawthorn*, sorbus*, mespilus*, and snowdrop-tree*, in great beauty. Among the American shrubs, several species of magnolia*, azalea*; kalmia*, andromeda*, &c. and among common shrubs, the lilac*, spiraea*, guelder-rose*, honeysuckle*, the cinnamon, Scotch, burnt-leaved, and monthly roses. Most of the singing birds in full note.	In the <i>green-house</i> , a fine display of erica*, ixia*, and gladioli*. Also several geranium, salvia, protea, &c. In the <i>stove</i> , phytolacca decandra, passiflora racemosa*, and other species, justicia, heliconia, and various genera. From the <i>forcing-department</i> , geraniums and other green-house plants, hydrangeas*, balsams* and other tender annuals.
--	---	--

JUNE.

FLOWER-GARDEN.	SHRUBBERY.	HOT-HOUSE DEPARTMENT.
The collections of peonies and anemones not yet faded; those of ranunculus*, iris xiphium* and xiphoides; and of the hardy gladioli* and ixie, in full beauty. Assortments of pink* and sweetwilliam*, in flower towards the end of the month; he-merocallis*, aquilegia*, campanula*, veronica*, and many showy herbaceous perennials; some biennials, as agrostemma, alyssum*, &c.; annuals, as crepis, cucubalus; aquatics, as butomus*, hydrocharis, potamogeton; viola, saxifraga*, and various alpinas.	The lime, laburnum, and fringe-tree*, in flower; towards the middle of the month a number of the roses*; of Americans*, andromeda, magnolia, rhododendron maximum and ponticum, azalea, &c. Of common shrubs, cistus*, helianthemum, erica, dogwood, elder, cytissus, spiraea, loni-cera, &c. The goat-sucker, or fern-owl (<i>Caprimulgus europæus</i>), heard in the evening of the first week. Most singing birds leave off singing about the end of the month.	In the green-house, chiefly tender annuals from the reserve-garden; the proper inhabitants being in the open garden, and there the heaths, gerania, citrus tribe*, diosme, protea, &c. in great beauty. In the store, amaryllis*, and other bulbs, aloe, piper, and other succulents; eugenias, epidendrums, cassia, castrum, &c. The pits filled with tender annuals, or other plants, in the course of propagation and rearing.

JULY.

The florists' flowers of this month are, the pink*, and carnation*; the white marigold* and tyger lilies*; the Brompton stock*, larkspurs*, lupines, and other biennials and annuals. More herbaceous plants are now in flower than in any other month, as chelone*, delphinium*, dictamnus*, gentiana*, statice*, phlox*, silene*, salvia, veronica, saxifraga, &c. The most showy of the aquatics, as nymphæa*, nuphar*, villarsia*, alisma, calla, stratiotes, myosotis*, &c. are now in flower, and various alpinas.	The tulip-tree*, magnolia*, kalmia*, andromeda*, azalea*, erica*, several sorts, and some rhododendrons*, and other American or peat-earth shrubs in flower. Among the commoner sort, the roses* are now in full splendor. The white jasmine*, honeysuckles*, clematis*, spartium, gleitschia triacanthos, cistus, lycium, and a great variety of others of less note. Showy butterflies and moths appear in the beginning, and the dragon-fly towards the end of the month.	The green-house is now filled with tender annuals, as balsams, globe-amaranthus, cockscombs, ice-plants, sensitive mimosa, &c. and probably with some of the stove plants. In the open air, the gerania will be in great beauty, and also erica*, mesembryanthemum*, melaleuca*, metrosideros*, protea, and numerous other genera. There are numerous stove plants now in flower, as cannas*, nelumbium, gloriosa*, amaryllis* pancratium, cactus, euphorbia, myrtus, ipomœa*, justicia, &c. The reserve hot-houses as before.
--	---	---

AUGUST.

The florists' flowers of this month are, the hollyhocks*, pyramidal bell-flowers*, lobelias, annual stocks*, and the poppies*, with liliun canadense* and four other American species. Numerous herbaceous plants are now in flower that first appear in July, and others, as aster* various species, astrantia, helianthus, anthericum*, osifragum, and numerous others first bloom in this month. Among the aquatics may be mentioned belobia dortmanna*, polygonum hydropiper, and several species of potamogeton.	Scarcely any trees are now in bloom; but of American shrubs there are various sorts of azalea*, clethra*, and magnolia*, in perfection; and of select common shrubs, the hibiscus*, with its numerous and beautiful varieties. The rose*, the honeysuckle*, yellow jasmine*, clematis*, spiræa*, and dwarf aculeus, form a greater show in the shrubbery and rosary than in any other month. Robin-red-breast (<i>Molucilla rubicula</i>) sings about the last week, and butterflies, moths, and dragon-flies abound during the whole month.	The green-house as before. In the open air the plants growing vigorously; but excepting gerania*, erica*, and some succulents not many species in flower. In the store, asclepias, convolvulus*, pancratium, lagerstroemia*, passiflora*, plumbago, and numerous other genera in flower. Tender annuals from the reserve-hot-houses as before.
---	---	--

SEPTEMBER.

The florists' flowers of this month are the dahlia*, which flowers also when excited by artificial heat previously to planting in the open ground in July and August; but planted in the usual way, it is now in perfection. Among the bulbs there are only leucopium autumnale*, narcissus autumnalis*, and scilla autumnale*; the china aster, in all its varieties, is now in perfection. Among the herbaceous perennials, aster*, solidago, helianthus, gentiana*, phlox*, and asphodelus, are the chief sorts.	Aralia spinosa, some azaleas*, and kalmia*, Lord Macartney's rose, and one or two other roses are in flower during the greater part of this month. But the chief ornament of the shrubbery is the fruits of the mountain ash*, viburnum*, mespilus*, oxycantha*, Siberian crab*, sorb*, lonicea*, apple, rose*, elder, &c. Spiders, flies, and insects of all kinds, very numerous; few birds in song; but the fieldfare appears about the end of the month.	The green-house plants generally returned to their winter habitation in course of this month; some heaths*, and pelargoniums*, and a few other species in flower. There are not many stove plants in flower at this season; amaryllis*, passiflora, and some succulents may be mentioned. Tender annuals supplied from the forcing-department of the reserve-garden, for decorating the plant-cabinet, conservatory, or drawingroom.
---	---	--

OCTOBER.

The florists' flowers of this month are the Chinese chrysanthemums*, some of the hardier of which will now flower in the open air, and the others under a glass case or in the green-house; the colchicum*, autumn crocus, cyclamen europeum*, and amaryllis lutea*. The principal herbaceous plants are, aster and solidago*, with asphodelus altissimus*, helianthus, gentiana*, and some other genera.	Arbutus unedo* is the only beautiful shrub in flower, and also in fruit, at this season, gordonia, rhamnus, baccharis, clematis, and the common ivy are also in flower.	Any spare room in the green-house is now occupied with chrysanthemums*, and some dahlias* raised in pots, and placed out of the reach of frost, to prolong their bloom. A few ericas*, statice*, and gerania, still in bloom. In the store, vinca*, stapelia*, and a few others. The reserve-pits in preparation for forcing bulbs and roses.
---	---	---

NOVEMBER AND DECEMBER.

The remains of last month in greater or less beauty, according to the weather, and, perhaps, a few plants unnaturally in bloom. In the present mild and humid winter, there are now (December 31. 1821) in bloom in many gardens about London, stocks of several sorts, larkspurs, violets, Indian pinks, pot-marigolds, polyanthus, primroses, gentians, monthly roses, yellow amaryllis, daisies, and various other plants. By a letter we have just received from a horticultural friend at Gottingen, (H. Herring), we find many of the same kinds of flowers were (Dec. 10th) in bloom in his garden.	The remains of last month, according to the weather. Clematis calycina* and, perhaps, a few plants unnaturally in bloom.	Dryandra*, erica*, lantana*, and camellias*, about the middle of December, in the green-house. In the store, all the species of streptitiza*, also stapelia, amaryllis*, alstrick*, and one or two other bulbs. From the forcing-department, hyacinths*, Persian iris*, and other bulbs; monthly roses*, and, about Christmas, the Provence rose*, and other shrubs and flowers, such as sweet briar, Persian lilac, varina lilac, crabs of different sorts, pinks, sweet williams, &c.
---	--	--

BOOK III.

ARBORICULTURE, OR PLANTING.

6742. A TREE is an object which has at all periods been held in a certain degree of admiration by mankind, from its grandeur, its beauty, and its use: a few trees have accordingly been associated with the dwellings of civilised nations in every country. The Persians, Greeks, and Romans were particularly attached to trees: some of their greatest men were proud to acknowledge that they had made plantations with their own hands; and fine specimens, whether planted by nature or art, were held sacred, or specially protected. (37.) The Romans, besides the ornamental plantations of their villas, planted occasionally for useful purposes; they had live hedges, osier plantations, and rows of poplars and elms as props for their vines. (57.) The planting of extensive tracts for timber or fuel, however, does not appear to have been practised by them, or any other people, till the beginning of the sixteenth century, when the insufficiency of the natural forests, which had hitherto supplied civilised society in England with timber and fuel, rendered planting a matter of necessity and profit. In the century succeeding, the improved practice of agriculture created a demand for hedges and strips for shelter; and the fashion of removing from castles in towns and villages, to isolated dwellings surrounded by verdant scenery, led to the extensive employment of trees both as objects of distinction and value. For these combined purposes planting is now universally practised: what relates to the effect of plantations, as parts of rural scenery, belongs to landscape-gardening; and what relates to their use and culture is the subject at present under consideration. We must however keep both objects in view, as well in contriving what shall be most profitable, as in designing what shall be most ornamental or picturesque. We shall therefore consider the uses of trees and plantations with a view both to profit and ornament; the kinds of plantations, their formation, their management, the formation of a tree-nursery, the surveying and valuing of trees and plantations, and the catalogue of timber-trees and hedge plants.

CHAP. I.

Of the Uses of Trees and Plantations, and the Profits attending their Culture.

6743. The purposes for which plantations are made, may be reduced to those which respect the actual consumption or employment of the tree or shrub individually; and those which respect their collective influence relative to surrounding objects. The first considers trees as affording timber, fuel, bark, and other products; and the second views plantations of trees as affording shelter, shade, fences, ornament, or otherwise conferring value on territory.

SECT. I. *Of the Uses of Trees individually, as Objects of Consumption.*

6744. A tree is employed after it has attained a certain age, bulk, or dimension, either in civil, military, or naval architecture; in the construction of machines, implements, and utensils; as fuel; or as affording tannin or dyeing matter; food or medicine for men or animals; or poison for vermin.

6745. For civil architecture the matured timber of the pine and fir tribes is in greatest demand, and foreign deal is generally preferred to British produce, as being of larger growth, and more resinous and durable in quality and texture. That which approaches the nearest to the pine and fir timber of the north is the Scotch pine (*Pinus sylvestris*), when grown in the north highlands, and the larch fir (*Pinus larix*), when grown in hilly or poor districts; resinous timber of the species indigenous in cold countries, when grown on rich soils, and in warm climates, being found deficient in durability. Oak and elm are also used in buildings, especially the former, as being of great durability and suitable for wooden bridges, break-waters, joists in damp situations or on ground-floors, sills, wall-plates, staircases, door and window frames, sashes, &c. Elm is not much used in buildings of magnitude, as being apt to twist, and not very durable; but it makes curiously variegated floors and steps of stairs, and very good weather-boarding for sheds and agricultural buildings. Besides timber and timber-like trees for the general purposes of civil architecture, there are some departments of rural construction, as the formation of fences, drains, embankments, trellis-work, arbors, and the supporting of plants in gardens, which consume branches, spray, thinnings of young plantations, and shoots even of a year's growth. Almost any species of tree may be used for these purposes; but the branches and spray of the oak, elm, and beech, the *weavings* of ash or larch plantations, the shoots of a few years' growth of the oak, sweet chestnut, ash, and hazel, and of one year's growth of certain species of willow are greatly preferred.

6746. For military architecture, by which we mean chiefly the outworks of fortifications, any tree is taken; but the pine and fir tribes are greatly preferred, as requiring less labor in cutting and preparing. Besides those of a timber size for constructing bridges, portals, and others of less dimensions for palisades, chevaux de frise, &c.; branches, spray, and shoots are used for fascines, and fixed works *en haie*, *en corbeille*, &c.

6747. In naval architecture the oak is chiefly used. According to Marshall, "the keels are now pretty generally laid with elm or beech; and part of the upper decks of

men of war is deal : but these woods bear no proportion, in respect of the quantity used, to the oak. The timbers of a ship are principally crooked, but the planking is cut out of straight pieces. In a seventy-four gun ship, the crooked and straight pieces used are nearly equal, but the planking under water is of foreign oak : therefore, of English oak, the proportion of crooked to straight pieces is almost two to one. Masts and yards are of deal. The blockmakers use elm, lignum vitæ, box, and other hard woods. Upon the whole, it may be said, that, in the construction of a ship, oak is the only English wood made use of ; and that of this English oak nearly two thirds are requisite to be more or less crooked." (*Planting and Rural Ornament*, i. 49.)

6748. *In the construction of merchant-vessels*, Monteath, in 1820, states, that "the out-keel commonly used is of beech or elm, and made generally of two or three trees or pieces joined together to whatever length is required ; these require to be nearly straight. The keel-stone, or inner keel, requires trees of nearly the same description, but chiefly oak. Floor timbers are sometimes used of elm and beech, and are a little crooked. First crooks are a good deal crooked towards the one end, as they begin to ascend up the vessel, and are more valuable than the floor timbers, but are also used sometimes of elm and beech. Upright timbers are always made of oak, and are considerably crooked, for elm or beech is seldom put into a good vessel, except the lower part, where the vessel is always under water when light. Top timbers are also of oak, but not so valuable, as they are mostly straight. Beams go under the deck of the vessel, and are also all oak, and have but a small crook, but require trees of considerable length. Knees are always of oak, and are the most principal crooks in the vessel. The stem-piece is a very particular crook. Breast-hooks also have particular crooks. Stern-posts and windlass are straight pieces. Trees that will cut up for planking are used of as great a length as they can be got, and are the better for having a considerable crook or curve one way ; these are used of elm or beech for planking under water, but four planks of oak are required for one of beech or elm for this purpose." (*Forester's Guide*, p. 111.)

6749. *Straight timber is bent to any form* by the use of steam, and other improvements in ship-building ; and thus the larch or any sound resinous timber may be employed, and is so to a certain extent for commercial ships. Sir A. Grant, an experienced planter, is of opinion, that "the larch will, in a short period, instead of the oak, bear the thunder of Britain on her element, the ocean." (*Gen. Rep. of Scot. ii. 270.*) In a communication to the President of the Board of Agriculture, by Wilson, of London, dated in 1797, the idea is suggested of combining small timbers for all the purposes of ship-building. He suggests, that oak of only thirty-three years' growth, by this mode of combining, may be employed where trees of a hundred years old would be requisite by the old method : and he maintains, that ships so built sail faster, and are less liable to accident. (*Gen. Rep. ii. 199.*) The use of timber of small growth has been already introduced in the construction of masts for the largest vessels, either by splicing pieces properly adapted together ; or, by forming hollow masts from small timber, which, uniting strength with lightness, have advantages which solid ones do not possess. (*Perring and Money on Ship-building.*)

6750. *In the construction of machines*, the millwright's chief material is oak, beech, and crab-tree for cogs ; alder, and sometimes willow, for float-boards ; and fir and oak for shafts and frame-work. The waggon and cartwright uses oak and ash for bodies, axles, and spokes ; elm for naves, fellies, and linings ; sometimes also the softer woods for linings, as poplar, willow, lime, and horse-chestnut. The coachmaker and ploughwright use more ash than any other sort of timber. Gates are made of oak and deal, and their posts of oak or larch ; the soft woods are sometimes used, but are far from being durable. Ladders are formed chiefly of deal, or of poplar and willow, as being light ; pumps and water-pipes generally of elm and alder ; beech and sycamore are used in making calendars and cheese-presses, &c. For all these purposes the timber must be full-grown, with some exceptions, as young or root-cut oak and ash for spokes and shafts.

6751. *For implements*, root-cut ash is in general use for the handles of such as require to bear great stress, as of the spade, fork, mattock, forge-hammers, &c. ; willow or deal, of the lighter tools, as the hoe, rake, scythe ; beech and sycamore for the common tools and instruments of carpenters ; box, holly, elder, &c. for the more select tools of artisans, and for mathematical and gaugers' instruments.

6752. *For utensils*, under which is included household furniture, the chief British wood used by the cabinet-maker is beech for bed-frames, chairs, and sofas ; next, birch and broad-leaved elm for the same purposes ; oak for gothic furniture ; the cherry, plum, holly, yew, box, walnut, lime, poplar, and a great variety of woods for occasional purposes ; and deal enters more or less into the construction of almost every thing he makes. The musical instrument-maker uses lime, box, yew, holly, plum-tree, and poplar. The carver uses chiefly lime, and next, pine-deal ; the cooper uses oak, and some chestnut for large casks and vessels, corn-measures, &c. ; birch and alder for herring-barrel staves, sycamore for herring-barrel ends ; these, since a law passed authorising herrings to be put into barrels made from British timber, have been in great demand (*Monteath*) ; ash for dairy utensils, butter-firkins, flour-barrels, &c. ; oak for well-buckets and water-pails, and, in some places, for milk-pails and other dairy utensils ; beech is occasionally used for the same purpose, and for soap-firkins, and willow, oak, ash, and hazel for hoops. The brush-maker uses beech, sycamore, birch, and some holly and box, and also poplar and lime-tree ; locksmiths, the soundest oak, from the root-cut or butt-end of the trunk ; the block-maker, for printing and bleaching-works, uses sycamore ; the turner, beech, sycamore, box, and holly ; trunk and packing-case makers, deal, poplar, elm, or whatever soft wood may be cheapest at the time ; coffin-makers use chiefly elm, sometimes oak ; basket-makers the root-shoots of the willow, and sometimes of the hazel ; bee-hive and straw utensil makers use the bramble and willow ; besom-makers the spray of the birch, broom, heath ; last and patten makers, alder and birch ; the toy-maker, lime, and other soft woods, and also box, holly, and yew. For most of these purposes, the trees must have attained a timber size, and for some of them, they should be full-grown.

6753. *For fuel*, any ligneous vegetable may be used at any age, and either the body or trunk and root of the plant, or its branches and spray. Resinous trees, excepting the larch, afford most flame, and may be used the soonest after being cut ; the ash next in order, then the birch, whose oily bark burns clear ; oak and elm burn the slowest ; and the roots of trees are generally of more slow combustion than their tops. To produce fuel in a short time, the most rapid-growing tree is the common tree-acacia (*Robinia*

pseudacacia). Charcoal, as fuel, is prepared by subjecting roots, or the more ligneous parts of branches, to a smothering combustion.

6754. For affording the tannin principle, the bark of the oak is chiefly used; but that of the Huntingdon willow (*Salix alba*), larch, black poplar, birch, chestnut, hazel, thorn, and some other trees, is found to afford it in such quantities as renders it worth while to disbark them for that purpose. (*Agr. Chem.* 89. and *Com. to Board of Agr.*) The bark is most powerful when taken from the tree at an early age, and hence the oak is cut down before it attains a timber size, for that purpose, as in copse-woods; but the bark of old trees is also used.

6755. For dyeing, the bark of several trees was formerly in use, as of the crab-apple, pear, ash, alder, &c. The bark of the quercitron (*Quercus tinctoria*) is used for dyeing yellow in North America; but in this country, foreign materials, as indigo, logwood, madder, &c. have superseded the use of indigenous, or home-grown vegetables. The berries of some trees, as of the elder, and berry-bearing alder; and the leaves of others, as of the walnut and sloe, have also been used as dye-stuffs.

6756. In various arts and manufactures some of the products of trees are used, as the charcoal (of the dogwood principally) in that of gunpowder; the pitch of the pine, the resin of the spruce fir, and the turpentine of the larch, for a great variety of purposes. The ashes of the burnt branches of all trees, but especially of the ash, afford alkali for the laundress; the spray of the beech and other trees affords, on distillation, the pyroligneous acid, an excellent preservative of timber, and, when purified, a substitute for salt in preserving butcher-meat; the bark of the holly affords birdlime; and the leaves of all trees, excepting the resinous kinds, rot into excellent manure for the field, and highly prized vegetable mould for the garden.

6757. For food to man, in his present state, the timber-trees afford but little resource; but nuts of the sweet chestnut, walnut, and hazel are still esteemed, and our ancestors used the acorn, beech-mast, haw, roan, hip, and bramble. A very agreeable drink is made from the sap of the birch-tree in Sweden, Russia, and some parts of Britain; and, in America, sugar is obtained from the sugar-maple (*Acer saccharinum*) in sufficient quantities to be used in domestic economy. Mast and acorns are esteemed excellent food for swine, haws for deer, and the leaves and spray of many sorts of trees are, or may be, eaten during winter both by domestic and wild animals. Game, which, in every cultivated country, is one of the greatest luxuries of the table, is localised by plantations, in which both birds and quadrupeds find at once shelter, security from their enemies, and food.

6758. For medicine, the products of scarcely any British tree is in use; but the bark, blossoms, and berries of the elder; the fruit of the sloe and crab, and the leaves of the walnut were formerly in considerable repute, and are occasionally used.

6759. As poisons for vermin, the leaves of the walnut, elder, and ash are used by infusion for destroying, or rather annoying, worms by their bitter acrid quality; a glutinous snare for entrapping birds is obtained from the holly and mistletoe.

6760. General result. From the above outline it may be inferred, that the timber-trees in most general demand as such, are the oak, pine, and fir tribes; and next the ash, elm, beech, poplar, willow, birch, sycamore, &c. In the greater number of cases, *ceteris paribus*, the oak, larch, Scotch pine, ash, abele, poplar, and willow, will be found the most profitable trees that can be planted with a view to timber or bark produce.

SECT. II. Of the Uses of Trees collectively as Plantations.

6761. Trees collectively in a growing state may be useful by affording shelter and improving the local climate, improving bad soils, producing shade, by separation, seclusion, distinction, appropriation, concealment of disagreeable objects, heightening the effect of agreeable objects, creating beauty, and adding value prospectively.

6762. Shelter and climate. The umbrageous roof of the forest afforded shelter, and a secure retreat to our savage forefathers; and their civilised descendants still resort to the nearest tree as a place of shelter during a casual storm; to the thick forest as a place of security, when they set the laws of their country at defiance, or have committed crime. Considered agriculturally, "the advantages to be derived from subdividing extensive tracts of barren country by plantations, are evidently great, whether considered in the light of affording immediate shelter to the lands, or in that of improving the local climate. The fact that the climate may be thus improved, has, in very many instances, been sufficiently established. It is, indeed, astonishing how much better cattle thrive in fields even but moderately sheltered than they do in an open exposed country. In the breeding of cattle, a sheltered farm, or a sheltered corner in a farm, is a thing much prized; and, in instances where fields are taken by the season for the purpose of fattening them, those most sheltered never fail to bring the highest rents, provided the soil be equal with that of the neighboring fields which are not sheltered by trees. If we enquire into the cause, we shall find that it does not altogether depend on an early rise of grass, on account of the shelter afforded to the lands by the plantations; but, likewise, that cattle which have it in their power, in cold seasons, to indulge in the kindly shelter afforded them by the trees, feed better; because their bodies are not pierced by the keen winds of spring and autumn; neither is the tender grass destroyed by the frosty blasts of March and April." (*Plant. Kal.* p. 121.) In gardening, as we have already seen (2400.), shelter is not less important than in general economy.

6763. Climate. An Italian author (G. Gautieri) has enumerated and illustrated the advantages, in point of climate, which entire tracts of country derive from extensive woods and forests. "These," he says, "are the arresting the progress of impetuous and dangerous winds; maintaining the temperature of the air; regulating the seasons; lessening intense cold; opposing the formation and increase of ice; moderating intense heats; producing abundance of rain and snow; giving origin to springs, and producing abundance of water in the rivers; discharging the electricity of the atmosphere; dispersing hail, snow, and watery clouds; preserving from inundations; lessening the width and depth of torrents; opposing a barrier to the undermining of banks, and the formation of precipices; preserving the soil on mountains, by which their external figure is maintained; and, finally, retaining within bounds, or disturbing the formation of avalanches, or accumulations of snow." He illustrates each of these propositions by references to what has taken place in Italy and Germany, in consequence of alterations that have been made in the woody surfaces of these countries. (*Dello Influsso de' Boschi*, &c. Milano, 1817.) Williams, an English author (1292.), has endeavored to show that the climate of Britain is deteriorating by the increase

of plantations. These, whether in masses or even in hedge-rows, increase the evaporating surface, and consequently render the atmosphere more humid; an open country, he says, would be more dry, airy, and wholesome. This is, no doubt, correct; and, perhaps, some valleys and plains are more thickly studded with hedge-rows and strips, than a strict regard to the culture of corn, or the salubrity of the atmosphere, would justify; but the same objection will not apply to elevated situations and bleak hilly tracts, which every one allows are greatly improved by planting, both in climate, agricultural produce, and general effect.

6764. *Improving bad soils.* "It certainly is not one of the least recommendations of planting," observes Pontey, "that it may be made to contribute essentially to the improvement of a bad soil, as is the case on sterile heaths and commons, where *three means*, the consequences of the planting, act together in promoting such improvement. The first is, the shade of the trees, which, by decomposing the vegetable matter on the surface soil, renders it at once more fertile, and easily penetrable by the roots. The second is, that by the decomposition of the annual fall of leaves, an addition is made to the vegetable soil, and that of the very best description. The third circumstance is, that as the roots collect a great deal of their support from a depth much lower than field vegetables are used to reach, they hence convert the *useless* into *useful*. In short, instances are not wanting, where land previously producing little besides heath, has, after producing a crop of trees, more especially firs, proved without further means very tolerable pasture." (*Profitable Planter*, p. 231.) In the *Agricultural Report for Perthshire* (p. 243.) a heathy tract is referred to, between Cupar and Perth, containing 2000 acres, which, after being twenty years under a crop of Scotch firs, was profitably subjected to aration.

6765. *The shade of trees* is highly grateful to man, whether reposing under a single tree, or in a state of recreation under the shadow of a row, or in an avenue, grove, or woodland path. "Shelter," Sang observes, "is not more useful in cold seasons, than the shade of trees is gratifying to cattle in hot ones. In an exposed open field, under a burning sun, the torture which cattle often endure is truly distressing." (*Plant. Kal.* 122.) In garden culture, shade is of great value; but walls are occasionally preferred to trees for this purpose; and next to walls, hedges or trees cut in the hedge manner.

6766. *The separation* produced by ligneous vegetables, in the form of hedges, is of long use in gardening, and of great and acknowledged importance in agriculture. In the latter art it may be considered as a criterion of improved culture; for when land lies intermixed, and is cultivated in what is called the common-field manner, the want of sufficient individual interest precludes all extraordinary exertion, and the country so cultivated has the same appearance now, that it had many centuries ago. Even on entire properties lying open, the want of the power of separating and classing cattle, and regulating their mode of grazing, and protecting particular fields for particular purposes, &c. is found so great a disadvantage as to be quite incompatible with the practice of improved farming.

6767. *The seclusion* afforded by trees, either as hedges, rows, strips, or groups to dwellings of limited surrounding territory may be desired from taste, or rendered necessary by personal infirmity, political, local, or pecuniary circumstances. Trees, by their elevation and foliage, shut out external objects, obstruct the gaze of the over-curious, and do not invite the visits of any one; while they leave the occupant in the centre of a little world of his own, in which he may enjoy himself in his own way.

6768. *The distinction* any sort of trees afford to a dwelling in a naked solitary country, or exotic species in one already wooded, is often desirable, as conveying cheerful and social ideas to the passing stranger, and procuring for the owner that applause for improvement which he feels to be his due. In extensive demesnes the outlines or prominent parts of them, may be indicated by particular sorts of trees; so as, from the house, or from a prospect-tower, in a central part of the estate, to render the contour of the whole distinguishable. Where common, or any one kind of trees abound, uncommon or exotic kinds may be made use of; or a common tree, pruned in a particular way, will have an adequate effect.

6769. *To appropriate*, harmonise, or render apparently a part of a near estate, distant woody territory which does not belong to it, may be considered as a selfish principle under the disguise of a social one; but it is, at all events, harmless in a moral point of view, and is valuable as a device in improving the beauty of real landscape. Whatever may be the kinds of trees, or the forms in which they are planted in the distant or adjoining property, which we may wish to appropriate (*fig. 625. a a*); the principle is, to plant the same sorts of trees in corresponding forms (*b b*), in the property which we can call our own.

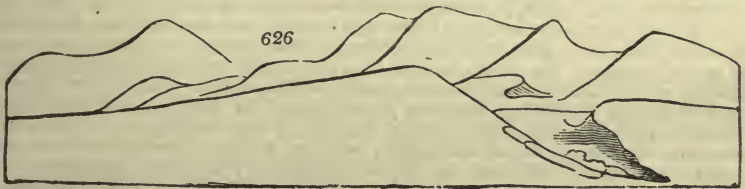

6770. *The concealment of disagreeable objects* by trees is too obvious, useful, and universal an improvement to require being enlarged on. This is one of the most important uses to which they are applied in small demesnes in a populous country, or near large towns. The desire of shutting out the houses of others, and especially of our poorer neighbors, does not so much arise from dislike either to the objects or the inhabitants, as from love of verdant scenery, and from a wish to have a country-seat as much like the country as possible. The desire of shutting out manufactories, steam-engines, coal-works, work-houses, &c. is still greater, because these objects excite ideas by no means in harmony with rural quiet; but no one ever thinks of shutting out a distant farm-house, solitary cottage, church, water-mill, bridge, monument, or ruin; for these are all interesting and agreeable objects, which are either characteristic of the country, or very generally occur there.

6771. *Trees heighten the effect of agreeable objects* by associating or grouping with them; and thereby forming a more perfect whole. Every whole consists of a number of parts, and the more varied the parts, provided they are allied among themselves, and not confused or redundant, the greater must be the effect of the whole. Trees contribute to the beauty of objects already beautiful; by lending new forms, new colors, varied light and shade; by their own motion, by inviting birds, and even by their smell. All these qualities are interesting to the moral and picturesque observer, and of great

importance to the improver, whether he displays water, or erects buildings, or harmonises rocks and mountains. A country-house without trees is felt by every one to be but a part of a whole.

6772. Trees may direct the eye to objects that would otherwise escape notice, or whose beauties would be lost in a general view. By employing them in the foreground of a scene to shut out uninteresting distance or mere sky, the eye may be led to repose on some agreeable near, or interesting distant object, which it had before wandered over unnoticed. By this sort of indication, accompanied by a seat, the dome of St. Paul's at London, of St. Peter's at Rome, and the cupola of the Iwar Wilika of Moscow, are seen from the grounds of residences at twenty or thirty miles' distance from these capitals; and in this way the worthy and amiable Shenstone, pointed out the Wrekin, and church-spire of Halesowen, from the rustic path of the Leasowes.

6773. Trees render indifferent objects interesting when judiciously grouped with them, so as to seem to conceal, by accident, that which we should desire or imagine to be there. Thus, a fragment of a wall, or of a tower, emerging from a thicket, may, by imagination be considered as an index to the main body of the ruined mansion or castle concealed by the wood. A broken gothic arch emerging from a thick wood may seem the commencement of a cloister or the aisles of a ruined abbey. A large stone lying on a naked surface is an object of little interest in a picturesque point of view, but surrounded by a few trees and bushes, it may be taken for part of a stratum of rock. A few yards of brick wall, standing naked and bare in a field would be considered as a deformity; partially cover it with ivy, which may first ascend and then mantle over its top, and add a holly or thorn, a briar, and an oak or ash, and a beautiful group is produced. In scenery, where great deformities or featureless extent is mixed with beauty or grandeur, trees will conceal the latter, and display the former to advantage. Ranges of naked mountains often present this kind of mixture of feature, dulness and want of grouping (*fig. 626.*), which no improvement

but planting could ameliorate and render tolerable. Gilpin, in his *Tours to the Lakes and Highlands*, &c. has some excellent observations on this subject; and there are various instances in the Pentland and Grampian ranges of hills where improvements of this sort have been executed with the happiest effect. (*fig. 627.*)

6774. Beauty may even be created by trees independently of all other objects. A dull flat surface will be rendered more interesting by scattering a few trees over it, of any sort, and in almost any manner: but it may be grouped or massed by one, a few, or by many sorts; or laid out in avenues, stars, platoons, and other modern or ancient forms of planting, so as to become a scene of positive beauty. Every species of trees has its particular form, bulk, mode of growth, flowering, &c. which constitute its character; this character varies with the age of the tree, and its situation, relative to other trees, or to soil, climate, &c. Now, as every tree may be grouped, or combined with those of its own species, or with any or all of the others, in an endless variety of ways, the beauty that may thus be created by trees alone, can only be limited by the extent of surface on which they are to be grown.

6775. The value of landed property containing plantations is enhanced prospectively by the various properties of trees. "It is very generally known," Sang observes, "that such estates as have a quantity of well arranged, healthy timber upon them, when brought to sale, bring an extra price, according to the quality and value of the wood, not only at the time of sale, but, counting forward on its value, to the period of its perfection. Thus, supposing the half-grown timber on an estate to be valued at ten thousand pounds at the time of the sale, instances are to be found where thirty thousand pounds have been given, over and above the valuation of the lands. The purchasers of such estates wisely foresee the increase of value which will arise from healthy timber growing where it may not only be cherished till of full maturity, but where, probably, it can then be turned to the best advantage by reason of its local situation. But, besides the real value of grown timber, there is most generally an ideal value attached to it, namely, that of its ornamental appearance." (*Plant. Kal. 124.*) A landed proprietor, who is a parent, looks on a thriving plantation as capital laid out at compound interest, and on the most undoubted security, for the benefit of his offspring; and he values it in this respect the more, because no man can determine the ratio in which, from the progress of the trees, and the future prosperity of the country, it may increase in value. It does not happen to many to plant trees and cut them down at a mature age; but this only renders planting a more interesting performance to the man who is in secure enjoyment of an estate; for in his full-grown trees he finds a link which connects him with his ancestors, and in his young plantations another which carries him down with his posterity to the next age. In this way he may imagine himself a being "having neither beginning of days nor end of life."

SECT. III. *Of the Profits of Planting.*

6776. From the seemingly distant advantages of planting has arisen the practice, by authors, of presenting statements of the profits, pleasures, and honors attending it, with a view to excite the selfish or patriotic feelings of their readers. "The profits of planting," says Marshall, "are great, when properly executed, and this idea adds solidity to the enjoyment. Pleasure alone may satiate; but profit and pleasure united seldom fail of producing a lasting gratification." Every one who has the least taste for country matters, must be alive to the agreeable and satisfactory feelings with which plantations are formed; and certainly there is something disinterested and respectable in incurring a present expense for what in most cases is to benefit a future generation; but as to the extraordinary profits, either of a near or far distant period, they are by no means to be depended on. With respect to the absolute profit to be derived from trees or plantations, considered independently, it is easy, by a calculation founded on a seemingly very moderate data, to make the clear gain attending the raising of any crop appear considerable; and, accordingly almost every speculative cultivator, whether of corn or trees, calculates on making a fortune in a very few years, as soon as he can get possession of a farm or a tract of waste. The truth is, however, that though accidental circumstances may render it more profitable to cultivate one kind of crop, either of trees or corn, at one time and place rather than another; yet, on the whole, the profits of capital employed in any way in agriculture or planting must, on the general average, be nearly the same. The certain lapse of time which must ever intervene between the planting of trees and their attaining a disposable size, must alone render any calculation made at the time of planting, extremely problematical. In planting, as in every other branch of culture, extraordinary profit is attended by extraordinary production, which soon sinks the market value of the article; add also, that in a commercial, free and highly taxed country, whenever any article attains a very high price, substitutes are found at home, or imported from abroad; so that no particular crop should be considered as exclusively the best to cultivate, and no extraordinary profits ever calculated on from any crop. Plantations should be made with a joint view to all or part of the advantages which we have shown to be attendant on them; but no more ultimate profit calculated on, from the disposal of the trees, than what is expected from capital laid out on any other territorial improvement; indeed, the safest principle on which to act, is to consider capital employed in planting, as on a par with that laid out in the purchase of landed property.

6777. *With respect to the value of trees as plantations*, or in masses, that is entirely relative; and must be sought for in the additional value conferred on the adjoining lands by the improvement of their climate, or their beauty. This sort of value cannot easily be subjected to any general rules of estimation; but unquestionably capital employed in planting and cultivating trees for such purposes, especially for the former, or when they are both united, may be considered as likely in the end to yield a greater interest than that employed in the ordinary routine of tree or corn culture. In bleak exposed situations, the advantages which have arisen from screen plantations have in some cases been so great as to be estimated at a third of the value of the land, and in every case where shelter is wanted they must be considerable. These, however, should be looked on by the prudent man rather in the light of extraordinary cases, attended by unforeseen risks, and though depending chiefly on skill, yet in some degree also on chance.

CHAP. II.

Of the different kinds of Trees and Plantations.

6778. Having considered the different objects for which trees and plantations are cultivated, our next step shall be to arrange *trees and plantations, according to their qualities*, for fulfilling these objects.

SECT. I. *Of the Classification of Trees relatively to their use and effect in Landscape.*

6779. *Timber* is the grand object for which trees are cultivated, and it is either straight or crooked in form, large or small in dimension, hard, soft, or resinous in quality, brittle or flexible in texture, smooth or rough grained, and plain-colored or variegated in appearance.

6780. *Straight timber* is chiefly produced by the pine and fir tribes, and such other trees whose lateral branches do not generally acquire a timber size, as the Lombardy poplar, hornbeam, deciduous cypress.

6781. *Crooked timber* may be produced by any branching tree; but chiefly by the oak, sweet chestnut, broad-leaved elm, walnut, &c.

6782. *Timber of large dimension*, in regard to *length*, is produced by the spruce fir, larch, Lombardy poplar, ash, narrow-leaved elm; in regard to *diameter* by the oak, sweet chestnut, and elm; magnitude in both dimensions is united in the narrow-leaved elm, beech, oak, and larch fir.

6783. *Timber of small dimensions* is produced by the yew, holly, thorn, ash, maple, laburnum, &c.

6784. *Timbers, hard in quality*, or, what are called the hard woods, are the oak, chestnut, sycamore, ash, beech, plane, walnut, box, holly, yew, &c. *Softer timbers*, or the soft woods, are the poplar, willow, lime,

horse-chestnut. *Resinous timbers* are the pine and fir tribes. *Brittle timber* is exemplified in acacia, hornbeam, and spindle-tree; *flexible*, in the ash, broad-leaved elm, and chestnut; *smooth-grained*, in the lime, poplar, willow, hornbeam; *coarse-grained*, in the ash, oak, and chestnut; *plain-colored*, in the willow, lime, holly; and *variegated*, in the yew, thorn, walnut, elm, plum, and many others.

6785. *Bark*, which contains the tannin principle, is an important product of trees. That which affords it in greatest quantity is the oak; and next, as far as chemists have yet ascertained, the Leicester willow (*Salix alba*, var.), Spanish chestnut, ash, sloe, Lombardy poplar, hazel, elm, common willow, sycamore, beech, horse-chestnut, birch, and larch. (659. & *Agr. Chem.* 89.)

6786. *Charcoal*, which is made from either branches, trunk, or roots, has been afforded by different trees at the following rates per cent.; laburnum, 24.5; chestnut, 23.2; oak, 22.6; walnut, 20.6; holly, beech, maple, 19.9; elm, 19.5; Norway pine, 19.2; sawall, 18.4; ash, 17.9; birch, 17.4; Scotch pine, 16.4. (*Agr. Chem.* 105.) Proust found the greatest proportion of charcoal to be afforded by the ash. (698.)

6787. *Ashes* have been afforded by the oak at the rate of 15; elm, 39; beech, 12; and poplar, 7 parts in ten thousand. (*Agr. Chem.* 113.) The result of Saussure's experiments, on procuring ashes from trees, have been already related. (703.)

6788. *For fuel and fencing*. The tendency of trees to produce lateral branches, and renew them when lopped off, is an important quality, and exists in an eminent degree in the ash, elm, oak, willow, poplar, lime, &c.; but not at all in the pine and fir tribes, and but slightly in the plane, walnut, and some others. Those which grow most rapidly are also to be desired as fuel-trees, as the acacia, poplar, willow, in moist soils; and the larch fir, Scotch pine, and birch, on such as are dry. The *ailantus glandulosus* may also be mentioned as a bulky and rapid-growing tree. On the chalky hills at Mereville (before the revolution one of the most extensive parks and magnificent seats in France), this tree thrives, and attains a considerable size, where few others will grow.

6789. *For hoops, basket-willows, besom-spray, implement-handles, poles, &c.* the renewal of trees or shrubs which have been cut down, or technically, their tendency to *stole* or shoot out from the collar, is an important consideration. This quality does not belong to the pine and fir tribes; and only slightly to the beech, sycamore, alder, plane, &c.; but liberally to all those mentioned above, as renewing their branches, and indeed to most trees not resinous. For the same objects, the tendency of trees to *send up suckers* or root-shoots deserves also the attention of the planter. This never takes place with the resinous trees, and seldom with the oak, beech, chestnut, ash, plane, &c.; but it is general with the elm, poplar, acacia, prunus, pyrus, mespilus, lime, and several willows.

6790. *For shelter*, rapid-growing and evergreen trees are desirable, as the Scotch pine; and such as are at the same time clothed with branches from the ground upwards, as the spruce fir; the best of all trees for shelter, unless the situation is very elevated. Among the deciduous trees, the fast-growing branchy sorts are most desirable, as the larch, birch, poplar, willow; in very elevated situations, the birch, mountain ash, and Scotch fir; exposed to the sea-breeze, the elder and sycamore. To maintain a branchy leafy screen from the ground upwards, intermix trees and shrubs which *stole*; or such as grow under the shade and drip of others, as the holly, hazel, dogwood, box, yew, &c. To produce shelter, and yet admit of the growth of grass below the trees, prune any sort to single stems, and use chiefly deciduous sorts.

6791. *For shade*, close plantations are seldom desirable, a free circulation of air being necessary to coolness; therefore use trees with lofty stems and large heads, and prune them to single stems a certain height, as the oak, elm, chestnut, beech, for thick shade; the plane, acacia, poplar, for lighter shade; the birch, balm of Gilead fir, and lime, for odoriferous shade; and avoid the walnut, elder, and laburnum, the atmosphere under which is reckoned deleterious.

6792. *For improving bad soils*, and for all the purposes of planting, the soil and situation, affected by or natural to trees, is an important study for the planter. Some are aquatics, or delight in moist situations near water, as most of the willow and poplar tribes, the alder and elder; others are mountain trees, as the Scotch pine, larch fir, mountain ash, sorb; some delight in valleys or plains, as the narrow-leaved elm, horse-chestnut, plane, lime, oak; others, in craggy steepes and dells, as the ash, silver and spruce firs, most of the pines, and many more; some on chalky soils, as the beech; others on clays, as the oak; on sand, as the Scotch pine; and a few trees will grow in the most opposite situations and soils, as the elder, which is found on mountain tops and on the sea-shore; the birch on the highest mountains, on dry rocks, and on marshes. For the poorest soils, whether high or low, choose the birch, larch, and Scotch pine; and for the richest, the ash, elm, oak, chestnuts, limes, poplars, and willows.

6793. *For the purposes of the separation of, or defence from, the inferior animals*, the plantations called hedges, or close rows of shrubs, are adopted; when these are to be low, such shrubs as send out numerous branches from the root upwards, and are of great durability, are most desirable; as the holly among evergreens; and the hawthorn, sloe, crab, beech, buckthorn, and hornbeam, among deciduous sorts. For moist situations, the alder, elder, birch, and willow, are to be preferred; and for dry upland sites, the juniper, whin, birch, and elder: avoid poisonous trees, as the yew. For tall or tree hedges, such trees as the elm, beech, hornbeam, lime, birch, and spruce fir, are desirable; but the holly excels all other plants for a hedge, whether low or tall, and is liable to no other objection than its slow growth, which occasions a considerable expense in protecting it till it is able to serve for defence.

6794. *For seclusion and concealment*, branchy leafy trees, a number of which have been mentioned (6790.), are obviously desirable; and, for distinction, either sorts different from what are already there, or ordinary sorts pruned and made to assume extraordinary forms.

6795. For the various purposes of *ornament, beauty, or effect*, in landscape, the hardy trees may be arranged as to magnitude, form, mode of growth, duration, and expression.

6796. *Magnitude*. Trees of great height are, the English elm, ash, larch, Polish and Carolina poplars, &c.; but the laburnum, mountain ash, and evergreen oak, are very low trees. A medium in height may be found in the maple, pine, and birch. Some trees exceed in breadth, as the oak, Spanish chestnut, and Scotch elm; others of different heights are very slender, as the Lombardy poplar, cypress, and bird-cherry.

6797. *Form*. The oak and Spanish chestnut afford the most irregular and picturesque

shapes, with round heads; the English elm and ash have long narrow forms, and round heads; the beech and horse-chestnut, compact ovate forms, with obtuse heads; the spruce and pine tribes, in general, have conical shapes, and pointed spiry tops; the Lombardy poplar, cypress, and most willows, have long narrow shapes, and oblong tops.

6798. *Color.* The Scotch pine, yew, and horse-chestnut, are dark-green; the larch and elm, a yellow-green; the abele, Huntingdon willow, a silvery-green, &c.

6799. *Mode and time of growth.* The nature of some trees is to lose their lower branches as they increase in height, as the fir tribe; and others have a tendency to retain them, as the wych elm. In some the branches descend, and often recline on the ground, as the lime-tree and platanus. Some are very compact in their foliage, as the horse-chestnut; others very open, as the ash and acacia. Some have drooping spray, as the weeping-willow; that of others tend upwards, as in the Lombardy poplar; horizontally, as in the oak; and obliquely, as in the Scotch pine. Some grow with rapidity, as the Carolina and Athenian poplars; others very slowly, as the oak and the stone pine.

6800. *Duration.* The most durable of trees is the oak; the least so, some of the poplar and fir tribes. A medium is to be found in the elm and lime.

6801. *Expression.* Some trees convey ideas of utility in the arts, and mark the attention and industry of man, as having planted them for this purpose, as the oak, ash, elm, &c. Others are known, or supposed to be of little use, and convey ideas of neglect or of wildness, as the hornbeam, sorb, trembling poplar, &c. Some indicate general improvement and artificial plantations, as the larch, and spruce fir; others, garden-scenery or plantations near a house, as the cedar, stone pine, and platanus. Some indicate rich deep soil, as the oak; and rich thin soil, as the elm; others, chalk or gravel, as the beech; rocky ground, as the ash; marshy ground, as the alder; the proximity of water, as the willow. There are also natural expressions belonging to trees, partly from general, and partly from accidental association; as strength and stability to the oak, ease and elegance to the birch, sweetness to the lime, gloom to the cypress and yew, melancholy to the weeping-willow, &c.

6802. *The common hardy shrubs* may be similarly arranged; but it will be sufficient to class them according to magnitude, mode of growth, evergreen, deciduous, native, naturalised, and exotic.

6803. *Magnitude.* Some shrubs are high, approaching to the character of trees, as the mespilus and common holly; others very low, as the butcher's broom and dwarf-birch.

6804. *Mode of growth.* Some are creepers, as the ivy; climbers, as the virgin's bower; trailers, as the bramble; compact forms, as that of the arbor vitæ; open airy branches, as in the tamarisk; and singular branches, as those of the stagshorn-sunach. Some, as shrubs, soon acquire picturesque shapes, as the thorn, holly, and elder. Some are evergreens, as the holly, laurel, yew, laurustinus, arbutus, &c.

6805. *Deciduous*, as the guelder-rose, lilac, syringa, &c.

6806. *Native*, as the holly, privet, hazel, thorn, briar, &c.

6807. *Naturalised*, as the rose, syringa, lilac, laburnum, &c.

6808. *Exotic*, or foreign, as the rhododendron, azalea, &c.

6809. These arrangements as to the effect of trees and shrubs in landscape, as far as form, magnitude, mode of growth, and expression are concerned, refer to plants growing detached from other trees, and as nearly full-grown. It is less intended to comprehend every characteristic distinction than to suggest to the artist the principal light in which he ought to view trees and shrubs. Nor could he with confidence attempt planting, with even such a knowledge as could be obtained from the above arrangement, completed by inserting all the names under their proper heads; for unless he has seen the majority of the full-grown trees himself, both singly and connected in groups and masses, and is acquainted with the comparative rapidity of their growth in different climates and soils, he cannot well foresee the result of his labors, or look forward "with the prophetic eye of taste" to certain beauty. Of this there are numerous proofs, arising from the unjust preference given to exotics of unknown shapes and duration, in situations where the general form and situation of the tree, or even of one or two trees, is of the utmost consequence to the effect of a whole. How frequently on a lawn, or in a plantation near a house, do we see acacias, cut-leaved elders, variegated sycamores, &c. where the oak, cedar, beech, lime, or Spanish chestnut would have produced a much more impressive general effect!

SECT. II. Of the Classification of Plantations, or Assemblages of Trees.

6810. *Assemblages of trees*, whether natural or artificial, differ in extent, outline, disposition of the trees, and kind of tree.

6811. In regard to *extent*, the least is a group (fig. 628. *c* and *d*), which must consist at least of two plants; larger, it is called a thicket (*b c*); round and compact, it is called a clump (*a*); still larger, a mass; and all above a mass is denominated a wood or forest, and characterised by comparative degrees of largeness. The term *wood* may be applied to a large assemblage of trees, either natural or artificial; *forest*, exclusively to the most extensive or natural assemblages.

6812. *With respect to the outline, or ground-plan of a plantation*, the simplest disposition is that of a row or line, which may be either straight or crooked, as in hedges, or lines of trees; next that of any determinate shape, as round, exemplified in the clump; square, in the platoon; oblong, in either clump or platoon, and in stripes, screens, or belts; irregular or indeterminate, in thickets, masses, and all larger plantations.

6813. *With respect to the disposition of the trees within the plantation*, they may be placed regularly in rows, squares, parallelograms, or quincunx; irregularly in the manner of groups; without undergrowths, as in groves (fig. 629. *a, b*); with undergrowths, as in woods (*c*); all undergrowths, as in copse-

woods (d). Or they may form avenues (fig. 630. a); double avenues (b); avenues intersecting in the manner of a Greek cross (c); of a martyr's cross (d); of a star (e); or of a cross patée, or duck's foot (*patée d'oie*) (f).

They may form regular glades (fig. 631. a, b); or irregular glades (c); glades, as niches or cabinets (d); as open squares; glades, as squares, *en berceau* (e); or as squares, *en saïons* and *en allée* (f).

6814. With respect to the character of tree-plantations, they may be as various as there are species; but for general effect and designation, woody plants are classed as large or small, trees or undergrowths, deciduous or evergreen, round-headed or spiry-topped; and plantations of every form and disposition may be planted with these, either separately or mixed. Thus we have groups of shrubs, groups of high and low growths, and of trees; plantations of round-headed and spiry-topped trees mixed; of trees and undergrowths; or of low growths only, as in copse-woods and osier-plantations.

CHAP. III.

Of the Formation of Plantations, in which Utility is the principal Object.

6815. The formation of useful plantations embraces the situation, soil, form, species of tree, fencing, and other considerations.

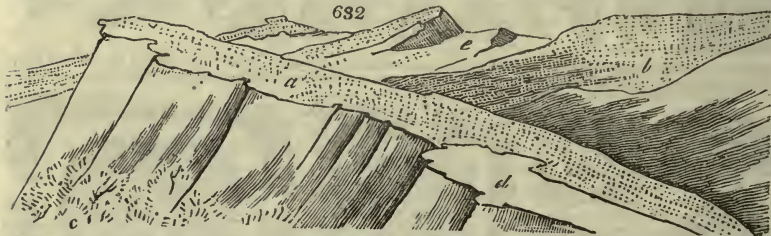

6816. A sheltered situation and deep rich soil would be the most proper if the object of the planter was to obtain the greatest bulk of timber in the shortest time; but this would not be profitable planting, for such a soil would, in all probability, have made greater returns under common farming. The profits of planting do not depend on the absolute quantity of timber produced, but on that quantity relatively to the value of the soil for agricultural purposes. Such situations and soils as can be profitably subjected to aration or permanent pasture, will rarely be found to yield an equal profit, if planted with trees. Suppose a piece of ground to let at 20s. per acre for pasture or arable, to be planted at an expense of only 10l. per acre; then, in order to return the rent, and 5l. per cent. for the money expended, it ought to yield 30s. a year; but as the returns are not yearly, but say at the end of every fifteen years, when the whole may be cut down as copse, then the amount of 30s. per annum, at 5l. per cent. compound interest, being 32l. 8s. every fall of copse made at the interval of fifteen years, ought to produce that sum per acre clear of all expenses. Hence, with a view to profit from the fall of timber or copse-wood, no situation capable of much agricultural improvement should be planted, unless a certain part with a view to sheltering the rest; or for the purposes of separation and fencing.

6817. *Whatever may be the nature of the soil, the sub-soil ought to be rendered dry* if the plants are intended to thrive. Large open drains may be used, where the ground is not to undergo much preparation; but where it is to be fallowed or trenched, under-drains become requisite. It is true, these will in time be choked up by the roots of the trees; but by that period, as no more culture will be requisite, they may be opened, and left open. Many situations, as steep sides of hills and rocky irregular surfaces, do not admit of preparing the soil by comminution previously to planting; but wherever that can be done, either by trenching, digging, or a year's subjection to the plough, it will be found amply to repay the trouble. This is more especially requisite for strips for shelter or hedge-rows, as the quick growth of the plants in these cases is a matter of the utmost consequence. The general mode of planting hedges by the side of an open drain, renders preparation for them, in many cases, less necessary: but for strips, wherever it is practicable, and there is at the same time no danger of the soil being washed away by rains or thaws, as in some chalky hilly districts; or blown about by the wind, as in some parts of Norfolk, and other sandy tracts, preparation by a year's fallow, or by trenching two spits deep, cannot be admitted without real loss, by retarding the attainment of the object desired. There are instances stated of promising oak-plantations from oaks dibbled into soil altogether unimproved; and of plantations of Scotch pine, raised by merely sowing the seeds on a heath or common, and excluding cattle (*Gen. Rep. of Scot.* ii. 269.); but these are rare cases, and the time required, and the instances of failure, are not mentioned. The practise is obviously too rude to be recommended as one of art. The best situations for planting, without any other culture but inserting the seeds or plants, are surfaces partially covered with low woody growths, as broom, furze, &c. "The ground which is covered, or rather half covered, with juniper and heath," says Buffon, "is already a wood half made."

6818. *Osier-plantations* are an exception to these remarks, as to the value of the situation and soil; they require a deep, strong, moist soil, but one not springy, or continually saturated with water; and it will be in vain to plant them without trenching it two or more feet deep.

6819. *The form of plantation for profit or shelter must be determined jointly by the situation and the objects in view.* In rocky abrupt sites (*fig. 632.*), the plantation will consist of a number of masses (*a, b, c*), of forms determined by the rocks and precipices, among which some of the most valuable pasture may be left as glades (*d, e*), for use, effect, and for the sake of game. Strips and hedges for sheltering or separating arable lands, should be formed as much as possible in straight and parallel lines, in order not to increase the expense of tillage by short and irregular turnings. Straight parallel strips, on irregular surfaces, have a more varied appearance at a distance, than strips ever so much varied on a flat surface; for, in the former case, the outline against the sky is varied as much as that on the earth. In extensive hilly pastures, in which it is often

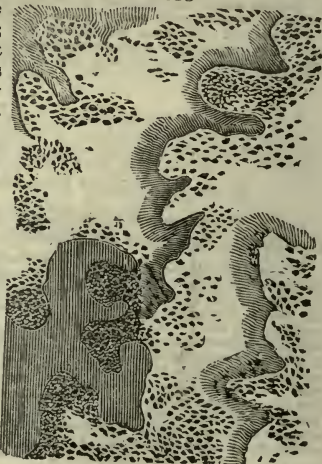

632

desirable to produce shelter, and at the same time to plant only the most rocky and unproductive spots, the forms may be of the most irregular description; and by planting chiefly on the eminences and slopes (*fig. 633.*), shelter will be most effectually produced, the pasture improved, the least valuable ground rendered productive in copse or timber, and the greatest richness and picturesque beauty conferred on the landscape. There are some fine examples of this on the hilly districts of Fifeshire; there, on many estates where nothing was sought for but profit and shelter, the greatest beauty has been produced; and the picturesque tourist now passes through glades and valleys, pastured by well-fed cattle and sheep, enlivened by rocks, thickets, hanging woods, and occasional rills and lakes. Fifty years ago, scarcely a tree was to be seen, and only the most inferior descriptions of live stock.

633

6820. *The enclosing of plantations is too essential a part of their formation to require enlarging on.* In all those of small extent, as hedges and strips, it is the principal part of the expense; but to plant in these forms, or any other, without enclosing, would be merely a waste of labor and property. The sole object of fencing being to exclude the domestic quadrupeds, it is obvious, that whatever, in the given situation, is calculated to effect this at the least expense, the first cost and future repairs or management being taken into consideration, must be the best. Where stones abound on the

spot, a wall is the best and cheapest of all fences as such ; but, in the great majority of cases, recourse is obliged to be had to a verdant fence of some sort, and generally to one of hawthorn. This being itself a plantation, requires to be defended by some temporary barrier, till it arrives at maturity ; and here the remark just made will again apply, that whatever temporary barrier is found cheapest in the given situation will be the best. Hedge fences are in general accompanied by an open drain, which, besides, acting in its proper capacity, furnishes, at its formation, a quantity of soil to increase the pasturage of the hedge plants ; and an excavation (*fig. 634. a*), and an elevation (*f*), to aid in the formation of a temporary fence. A hedge enclosing a plantation, requires

only to be guarded on the exterior side, and of the various ways in which this is done, the following may be reckoned among the best and most generally applicable. By an open drain and paling, or line of posts and rails (*a*), the plants inserted in a facing of stone, or in a facing of sub-soil from the bottom of the drain, backed by the earth of the drain (*b*) ; an excellent mode, as the plants generally thrive, and almost never require cleaning from weeds ; an open drain and paling, and the hedge on the top of the elevation (*c*) ; no open drains, but the soil being a loam, the surface-turves formed into a narrow ridge, to serve as a paling, a temporary hedge of furze sown on its summit, and the permanent hedge of thorn or holly within (*d*) ; and an open drain, but on the inside, the exterior being protected by a steep bank sown with furze (*e*). The first of these modes is the most general, the second the best, and the fourth the cheapest, where timber is not abundant. Separation fences are commonly formed in the first, second, or third manner, but with a paling on both sides.

6821. *Shelter.* Many situations are so exposed that it is extremely difficult to rear trees without some mode of procuring shelter for them during their early growth. This is obtained either by walls, the extent of whose influence is only limited ; by thick planting, or by planting the more hardy and rapid-growing species, to nurse up and protect such as are more tender, but ultimately more valuable. The proportion of nurses to principals is increased according to the bleakness of the site. Pontey says, "both authors and planters are in the habit of erring egregiously, in regard to the proportion of principals and nurses ; as they generally use as many, or more of the former than the latter ; though it is very easy to show, that they ought to use three times as many of the latter as the former. For instance, when trees are planted at four feet apart, each occupies a surface of sixteen feet ; of course four of them will occupy sixty-four, or a square of eight feet ; and therefore, if we plant three nurses to one principal tree, all the former might be displaced gradually, and the latter would still stand only eight feet apart. Nurse-plants should, in every possible case, be such as are most valuable at an early period of growth. The larch and spruce fir should be used liberally, in every case where they will grow freely ; still it is not intended that they should exclude all others, more particularly the birch, which has most of the properties of a good nurse, such as numerous branches and quick growth, on any tolerable soil or situation. It is not, however, like the others, a wood of general application." (*Profitable Planter*, p. 113.) Sang also adopts the proportion of three nurses to one principal, and employs chiefly the resinous tribe, and looks to them for reimbursement till the hard timber has attained to a foot in diameter, under which size hard timber is seldom of much value. His principals are planted at from six to ten feet apart, according to the soil and situation. (*Plant. Kal.* p. 166.)

6822. In procuring shelter much depends on the mode of commencing and continuing plantations on bleak sites. Sang, who has had extensive experience on this subject, observes, that "every plain, and most fields and situations for planting, in this country, have what may be called a windward side, which is more exposed to the destructive blast than any other. It is of very great importance to be apprised of this circumstance ; and to be able to fix upon the most exposed side of the proposed forest plantation. Fix, then, upon the windward side of the plain which is to be converted into a forest ; mark off a horizontal stripe, or belt, at least a hundred yards in breadth. Let this portion of ground be planted thick, say at the distance of thirty inches, or at the most three feet, with a mixture of larch, sycamore, and elder, in equal quantities, or nearly so, if the soil be adapted for rearing these ; but if it be better adapted for Scots pines, then let it be planted with them at the distances prescribed for the above mixture. We have no other kinds that will thrive better, or rise more quickly in bleak situations, than those just mentioned. When the trees in this belt, or zone, have risen to the height of two feet, such hard-wood trees as are intended ultimately to fill the ground should be introduced, at the distance of eight or ten feet from each other, as circumstances may admit. At this period, or perhaps a year or two afterwards, according to the bleak or exposed situation of the grounds, let another parallel belt, or zone, of nearly equal breadth, be added to the one already so far grown up, and so on, till the whole grounds be covered. It is not easy here to determine on the exact breadth of the subsequent belts or zones : this matter must be regulated by the degree of exposure of the grounds, by the shelter afforded by the zone previously planted, and by such like circumstances." (*Plant. Kal.* p. 29.)

6823. In situations exposed to the sea-breeze a similar plan may be successfully followed, and aided in effect, by beginning with a wall ; the first belt having reached the height of the wall, plant a second, a third, and fourth, and so on till you cover the whole tract to be wooded. In this way the plantations on the east coast of Mid-Lothian, round Gossford House, were reared ; and in Sang's manner, the mountains of Blair and Dunkeld were clothed ; and examples, we are informed, might be drawn even from the Orkney and Shetland islands.

6824. The species of tree to be planted must ever depend chiefly on the situation and soil, but partly also on the sort of product desired as the most profitable, and on the importance attached to shelter. As a general principle it may be observed, that the tree which will thrive the best, will turn out the most profitable : for, though its timber may not be of the highest-priced kind, yet there will be quantity as compensation for inferior quality. In rocky irregular surfaces there is generally great variety of situation and depth of soil ; and here a corresponding variety of trees may be introduced, and the more valuable sorts, as the oak, ash, elm, poplar, &c. will no where thrive better than at the foot of precipices, and in narrow dells and other sinuosities, where there is at once shelter and a good depth of dry soil. The thriving of trees and plants of every kind, indeed, depends much more on the quantity of available

soils, and its state in respect to water and climate, than on its constituent principles; moderately sheltered and on a dry sub-soil, it signifies little whether the surface strata be a clayey, sandy, or calcareous loam; all the principal trees will thrive nearly equally well in either so circumstanced; but no tree whatever in these, or in any other soil saturated with water, and in a bleak exposed site. For hedge-row timber, those kinds which grow with lofty stems, which draw their nourishment from the sub-soil, and do least injury by their shade, are to be preferred. These, according to Blakie, are oaks, narrow-leaved elm, and black Italian poplar; beech, ash, and firs, he says, are ruinous to fences, and otherwise injurious to farmers. (*On Hedges and Hedge-row Timber*, p. 10.)

6825. The common practice in planting is to mix different species of trees together, which is unavoidable where nurse or shelter plants are introduced; where these are not wanted, the opinions of planters are divided on the subject. Mixing different sorts is most generally approved of. Marshall advises mixing the ash with the oak, because the latter draws its nourishment chiefly from the sub-soil, and the former from the surface. Nicol is an advocate for indiscriminate mixture (*Practical Planter*, p. 77.); and Pontey says, "both reason and experience will fully warrant the conclusion, that the greatest possible quantity of timber is to be obtained by planting mixtures." (*Prof. Planter*, p. 119.)

6826. Sang is "clearly of opinion, that the best method is to plant each sort in distinct masses or groups, provided the situation and quality of the soil be properly kept in view. There has hitherto been too much random work carried on with respect to the mixture of different kinds. A longer practice, and more experience, will discover better methods in any science. That of planting is now widely extended; and improvements in all its branches are introduced. We, therefore, having a better knowledge of soils, perhaps, than our forefathers had, can, with greater certainty, assign to each tree its proper station. We can, perhaps, at sight, decide, that here the oak will grow to perfection, there the ash, and here again the beech; and the same with respect to the others. If, however, there happen to be a piece of land of such a quality, that it may be said to be equally adapted for the oak, the walnut, or the Spanish chestnut, it will be proper to place such in it, in a mixed way, as the principals; because each sort will extract its own proper nourishment, and will have an enlarged range of pasturage for its roots, and consequently may make better timber-trees. Although by indiscriminately mixing different kinds of hard-wood plants in a plantation, there is hardly a doubt that the ground will be fully cropped with one kind or other, yet it very often happens, in cases where the soil is evidently well adapted to the most valuable sorts, as the oak perhaps, that there is hardly one oak in the ground for a hundred that ought to have been planted. We have known this imperfection in several instances severely felt. It not unfrequently happens, too, that even what oaks, or other hard-wood trees, are to be met with, are overtopped by less valuable kinds, or perhaps such, all things considered, as hardly deserve a place. Such evils may be prevented by planting with attention to the soil, and in distinct masses. In these masses are ensured a full crop, by being properly nursed, for a time, with kinds more hardy, or which afford more shelter than such hard-wood plants. There is no rule by which to fix the size or extent of any of these masses. Indeed, the more various they be made in size, the better will they, when grown up, please the eye of a person of taste. They may be extended from one acre to fifty or a hundred acres, according to the circumstances of soil and situation: their shapes will accordingly be as various as their dimensions. In the same manner ought all the resinous kinds to be planted, which are intended for timber-trees; nor should these be intermixed with any other sort, but be in distinct masses by themselves. The massing of larch, the pine, and the fir of all sorts, is the least laborious and surest means of producing good, straight, and clean timber. It is by planting, or rather by sowing them in masses, by placing them thick, by a timeous pruning and gradual thinning, that we can, with certainty, attain to this object." (*Plant. Kal.* 162. 166.)

6827. Our opinion is in perfect consonance with that of Sang, and for the same reasons; and we may add as an additional one, that in the most vigorous natural forests one species of tree will generally be found occupying almost exclusively one soil and situation, while in forests less vigorous on inferior and on watery soils, mixtures of sorts are more prevalent. This may be observed in comparing New Forest with the natural woods round Lochlomond, and it is very strikingly exemplified in the great forests of Poland and Russia.

6828. Whether extensive plantations should be sown or planted, is a question about which planters are at variance. Miller says, transplanted oaks will never arrive at the size of those raised where they are to remain from the acorn. (*Dict. Quercus.*) Marshall prefers sowing when the ground can be cultivated with the plough. (*Plant. and Rur. Orn.* i. 123.) Evelyn, Emmerich, and Speechly are of the same opinion; Pontey and Nicol practise planting, but offer no arguments against sowing where circumstances are suitable. Sang says, "It is an opinion very generally entertained, that planted timber can never, in any case, be equal in durability and value to that which is sown. We certainly feel ourselves inclined to support this opinion, although we readily admit, that the matter has not been so fully established, from experiment, as to amount to positive proof. But although we have not met with decided evidence, to enable us to determine on the comparative excellence of timber raised from seeds, without being replanted, over such as have been raised from replanted trees, we are left in no doubt as to the preference, in respect of growth, of those trees which are sown, over such as are planted." (*Plant. Kal.* 43.) He particularly prefers this mode for raising extensive tracts of the Scotch pine and larch (p. 430.), and is decidedly of opinion, "that every kind of forest tree will succeed better by being reared from seeds in the place where it is to grow to maturity, than by being raised in any nursery whatever, and from thence transplanted into the forest," (p. 344.) Dr. Yule (*Caled. Hort. Mem.* ii.), in a long paper on trees, strongly recommends sowing where the trees are finally to remain. "It is," says he, "a well ascertained fact, that seedlings allowed to remain in their original station will, in a few seasons, far overtop the common nursed plants several years older."

6829. The opinion of Dr. Yule, and in part also that of Sang, seems to be founded on the idea that the tap-root is of great importance to grown-up trees, and that when this is once cut off by transplanting, the plant has not a power of renewing it. That the tap-root is of the utmost consequence for the first three or four years is obvious from the economy of nature at that age of the plant; perhaps for a longer period;

but that it can be of no great consequence to full-grown trees, appears highly probable from the fact, that when such trees are cut down, the tap-root is seldom to be distinguished from the others. The opinion that young plants have not the power of renewing their tap-root, will, we believe, be found inconsistent with fact; and we may appeal to Sang and other nurserymen, who raise the oak and horse-chestnut from seed. It is customary when these are sown in drills, to cut off their tap-roots without removing the plants at the end of the second year's growth, and when at the end of the third or fourth year they are taken up, they will be found to have acquired others, not indeed so strong as the first would have been had they remained, but sufficient to establish the fact of the power of renewal. We may also refer to the experiment recorded by Forsyth, which at once proves that trees have a power of renewing their tap-roots, and the great advantages from cutting down trees after two or three years' planting. Forsyth "transplanted a bed of oak-plants, cutting the tap-roots near to some of the side-roots or fibres springing from them. In the second year after, he headed one half of the plants down, and left the other half to nature. In the first season, those headed down made shoots six feet long and upwards, and completely covered the head of the old stem, leaving only a faint cicatrix, and produced new tap-roots upwards of two feet and a half long. The other half of the plants that were not headed, were not one fourth the size of the others. One of the former is now eighteen feet high, and fifteen inches in circumference, at six inches from the ground: one of the largest of the latter measures only five feet and half in height, and three inches and three quarters in circumference, at six inches from the ground." (*Tr. on Fruit Trees*, 4to edit. 144.) The pine and fir tribes receive most check by transplanting; and when removed at the age of four or five years, they seldom arrive at trees afterwards; those we should, on most occasions, prefer to sow, especially on mountainous tracts. But for all trees which stole, and in tolerable soils and situations, planting strong plants, and cutting them down two or three years afterwards, will, we think, all circumstances considered, be proved preferable to sowing.

6830. *On the subject of disposing the plants in plantations, there are different opinions; some advising rows, others quincunx, but the greater number planting irregularly.* According to Marshall, "the preference to be given to the row, or the random culture, rests in some measure upon the nature and situation of the land to be stocked with plants. Against steep hangs, where the plough cannot be conveniently used in cleaning and cultivating the interspaces, during the infancy of the wood, either method may be adopted; and if plants are to be put in, the quincunx manner will be found preferable to any. But in more level situations, we cannot allow any liberty of choice; the drill or row manner is undoubtedly the most eligible." (*Plant. and Rur. Orn.* p. 123.) Pontey considers it of much less consequence than most people imagine, whether trees are planted regularly or irregularly, as in either case the whole of the soil will be occupied by the roots and the surface by the shoots. Sang and Nicol only plant in rows where culture with the horse-hoe is to be adopted. In sowing for woods and copses, the former places the patches six feet asunder and in the quincunx order. "It has been demonstrated (*Farmer's Mag.* vii. 409.), that the closest order in which it is possible to place a number of points, upon a plain surface, not nearer than a given distance from each other, is in the angles of hexagons with a plant in the centre of each hexagon. Hence it is argued, that this order of trees is the most economical; as the same quantity of ground will contain a greater quantity of trees, by 15 per cent. when planted in this form than in any other." (*Gen. Rep.* ii. 287.) It is almost needless to observe, that hedge plants should be placed at regular distances in the lines, and also the trees, when those are introduced in hedges. Osier-plantations, and all such as like them require the soil to be dug every year, or every two years, during their existence, should also be planted in regular rows.

6831. *The distances at which the plants are placed must depend on different circumstances, but chiefly on the situation and soil.* Planting thick, according to Nicol, is the safer side to err on, because a number of plants will fail, and the superfluous ones can be easily removed by thinning. "For bleak situations," he observes, "that from thirty to forty inches is a good medium, varying the distance according to circumstances. For less exposed situations, and where the soil is above six inches in depth, he recommends a distance from four to five feet. For belts, clumps, and strips, of a diameter of about one hundred feet; the margin to be planted about the distance of two feet, and the interior at three feet. In sheltered situations of a deep good soil, he recommends a distance of six feet, and no more." (*Pract. Plant.*)

6832. *According to Sang, "the distances at which hard-timber trees ought to be planted are from six to ten feet, according to the quality of the soil, and the exposed or sheltered situation.* When the first four oaks are planted, supposing them at right angles, and at nine feet apart, the interstices will fall to be filled up with five nurses, the whole standing at four and a half feet asunder. When sixteen oaks are planted, there will necessarily be thirty-three nurses planted; and when thirty-six oaks are planted, eighty-five nurses; but when a hundred principal trees are planted in this manner, in a square of ten on the side, there will be two hundred and sixty-one nurse-plants required. The English acre would require five hundred and thirty-six oaks, and one thousand six hundred and ten nurses." (*Plant. Kal.* 163.) Pontey says, "In general cases, a distance of four feet is certainly close enough; as at that space the trees may all remain till they become saleable as rails, spars, &c."

6833. *The number of plants which may be planted on a statute acre = 160 rods, or poles, = 4840 yards = 43,560 feet, is as follows:—*

Feet apart.	No. of Plants.	Feet apart.	No. of Plants.	Feet apart.	No. of Plants.
1	43,560	6	1,210	15	193
1½	19,360	7	889	16	170
2	10,890	8	680	17	150
2½	6,969	9	537	18	134
3	4,840	10	435	19	120
3½	3,556	11	360	20	108
4	2,722	12	302	25	69
4½	2,151	13	257	30	48
5	1,742	14	222		

6834. *The size of the plants depends jointly on the site and the kind of tree; it is universally allowed that none of the resinous tribe succeed well when removed at four or more years' growth; but if the soil is of tolerable quality, prepared by digging or summer pitting, and the site not bleak, plants of such hard woods as stole may be used whose stems are an inch or more in diameter.*

6835. *Nicol is of opinion, "That generally trees three, or at most four, years old from the seed, and which are from twelve to twenty-four inches high, will, in any situation or soil, outgrow those of any size under eight or ten feet, within the seventh year."* (*Pract. Plant.* 130.)

6836. *Sang observes, "The size of plants for exclusive plantations must, in some measure, depend on their kinds; but it may be said, generally, that the plants being transplanted, they should be from a foot to eighteen inches in height, stiff in the stem, and well rooted. Plants for this purpose should seldom be more than three years from the seed; indeed never, if they have been raised in good soil. Many of*

them may be sufficiently large at two years from the seed; and if so, are to be preferred to those of a greater age, as they will consequently be more vigorous and healthy. The larch, if properly treated, will be very fit for planting out at two years of age. A healthy seedling being removed from the seed-bed at the end of the first year, into good ground, will, by the end of the second, be a fitter plant for the forest, than one nursed a second year. The next best plant for the purpose, is that which has stood two years in the seed-bed, and has been transplanted for one season. This is supposing it to have risen a weakly plant; for, if the larch rise strong from the seed the first season, it should never stand a second in the seed-bed. The ash, the elm, and the sycamore, one year from the seed, nursed in good soil for a second season, will often prove sufficiently strong plants. If they be weakly, they may stand two years in the seed-bed; and then being nursed one season in good soil, will be very fit for planting out in the forest. The oak, the beech, and the chestnut, if raised in rich soil, and well furnished with roots at the end of the first year, and having been nursed in rows for two years, will be very fit to be planted out. But if they be allowed to stand two years in the seed-bed, and be planted one year in good ground, they will be still better, and the roots will be found well feathered with fine small fibres. The silver fir and common spruce should stand two years in the seed-bed. If transplanted into very good soil, they may be fit for being planted out at the end of the first year; but, more generally, they require two years in the lines. The Scots pine should also stand for two years in the seed-bed, and should be nursed in good ground for one year; at the end of which they will be much fitter for being planted, than if they were allowed to stand a second year in the lines. They are very generally taken at once from the seed-bed; and in land bare of heath or herbage, they succeed pretty well; nevertheless, we would prefer them one year nursed. The above are the hardy and most useful forest trees; and from the observations made, whatever respects the age or size of other kinds, may easily be inferred." (*Plant. Kal. 158.*)

6837. According to *Pontley*, "the best general rule is, to proportion the size of the plants to the goodness of the soil; the best of the latter requiring the largest of the former. Still on bleak exposures this rule will not hold good, as there the plants should never be large, for otherwise the greater part would fail from the circumstance of wind-waving, and of those that succeeded, few, if any, would make much progress for several years; firs of a foot, and deciduous trees of eighteen inches, are large enough for such places. As in extensive planting, soils which are good and well sheltered but seldom occur, the most useful sizes of plants, for general purposes, will be firs of a foot, and deciduous trees of eighteen inches, both transplanted. None but good-rooted plants will succeed on a bad soil, while on a good one, sheltered, none but very bad-rooted plants will fail; a large plant never has so good a root, in proportion to its size, as a small one; and hence we see the propriety of using such on good soils only. Small plants lose but few of their roots in removal; therefore, though planted in very moderate-sized holes of pulverised earth, soon find the means of making roots, in proportion to their heads. It should never be forgotten, that, in being removed, a plant of two feet loses a greater proportion of its roots than a tree of one, and one of three feet a greater proportion than one of two, and so on, in proportion to its former strength and height, and thus the larger the plants, so much greater is the degree of languor or weakness into which they are thrown by the operation of transplanting." (*Prof. Plant. 161.*)

6838. *The seasons for planting* are autumn and spring; the former, when the soil and situation are moderately good, and the plants large; and the latter, for bleak situations. Necessity, however, is more frequently the guide here than choice, and in extensive designs, the operation is generally performed in all moderately dry open weather from October to April inclusive. "In an extensive plantation," *Sang* observes, "it will hardly happen but there will be variety of soil, some parts moist and heavy, and others dry and light. The lightest parts may be planted in December or January; and the more moist, or damp parts, in February or March. It must be observed, however, that if the ground be not in a proper case for planting, the operation had better be delayed. The plants will be injured, either by being committed to the ground when it is in a sour and wet, or in a dry parched state. At a time when the soil may be termed neither wet nor dry, the operation of planting is most successfully performed. The mould does not then adhere to the spade, nor does it run in; it divides well, and is made to intermingle with the fibres of the plants with little trouble; and in treading and setting the plant upright, the soil is not worked into mortar, which it necessarily must be, if in a wet state, evidently to the great detriment of the plants. It is therefore improper to plant on a retentive soil in the time of rain, or even perhaps for some days afterwards, or after a fall of snow, until it has for some days disappeared. Whereas, on a dry absorbent soil, it may be proper to plant in the time of gentle showers, immediately after heavy rains, or as soon as the snow is dissolved." (*Plant. Kal. 157.*)

6839. *Pontley* is a decided advocate for autumn preparation of the soil, and spring planting. "Autumn planting," he says, "is advisable only in few cases, while spring planting may properly apply to all."

6840. According to *Sang*, the proper time for planting the pine and fir tribes, and all evergreens, is April, or even the first fortnight in May. "Attention should be paid, that no greater number of plants be lifted from the nursery than can be conveniently planted on the same day. Damp weather is the best. When very dry, and the plants rise destitute of earth at their roots, their roots should be dipped in mud (puddle) so as to be coated over by it. In all cases, care should be taken not to shake off any adhering earth from plants at the time of planting." (*Plant. Kal. 341.*)

6841. *The operation of inserting the plants* in the soil is performed in various ways; the most general mode, and that recommended by *Marshall* and *Nicol*, is pitting; in which two persons are employed, one to operate on the soil with the spade, and the other to insert the plant and hold it till the earth is put round it, and then press down the soil with the foot. Where the plants are three feet high or upwards, this is the best mode; but for smaller plants modes have been adopted in which one person performs the whole operation.

6842. *Sang* describes three kinds of manual operation employed by him in planting, and in part in sowing trees: by pitting; by slitting simply, or by cross, or T slitting; by the diamond dibber; by the planting-mattock; and by the planter. In filling an area with plants, he first plants those intended as the final trees, and afterwards the nurses; or one set of operators plant the former, while another follow with the latter, unless the time for removing the nurses, as in the case of evergreen pines and firs, should be later than that for planting the principals. (6832.) "The plants, if brought from a distance, should be

shoughed, i. e. *earthed*; or they may be supplied daily from the nursery, as circumstances direct. All the people employed ought to be provided with thick aprons, in which to lap up the plants; the spademen, as well as the boys or girls; the latter being supplied by the former as occasion may require. All of them should regularly fill their aprons at one time, to prevent any of the plants being too long retained in any of the planters' aprons. One man cannot possibly set a plant so well with the spade, unless in the case of *laying* as two people can; nor, supposing him to do it as well, can he plant half as many in the same space of time as two can. A boy ten years of age is equal, as a holder, to the best man on the field, and can be generally had for less than half the money. Hence this method is not only the best, but the least expensive." (*Plant. Kal.* 167.)

6843. *By pitting.* "The pit having been dug for several months, the surface will therefore be encrusted by the rains, or probably covered with weeds. The man first strikes the spade downwards to the bottom, two or three times, in order to loosen the soil; then poaches it, as if mixing mortar for the builder; he next lifts out a spadeful of the earth, or, if necessary, two spadefuls, so as to make room for all the fibres, without their being anywise crowded together; he then chops the rotten turf remaining in the bottom, and levels the whole. The boy now places the plant perfectly upright, an inch deeper than when it stood in the nursery, and holds it firm in that position. The man *trindles* in the mould gently; the boy gently moves the plant, not from side to side, but upwards and downwards, until the fibres be covered. The man then fills in all the remaining mould; and immediately proceeds to chop and poach the next pit, leaving the boy to set the plant upright, and to tread the mould about it. This in stiff wet soil he does lightly; but in sandy or gravelly soil he continues to tread until the soil no longer retains the impression of his foot. The man has by this time got the pit ready for the next plant, the boy is also ready with it in his hand, and in this manner the operation goes on. On very steep *hangs* which have been pitted, the following rule ought to be observed in planting: to place the plant in the angle formed by the acclivity and surface of the pit; and in finishing to raise the outer margin of the pit highest, whereby the plant will be made to stand as if on level ground, and the moisture be retained in the hollow of the angle, evidently to its advantage." (*Plant. Kal.* 167.)

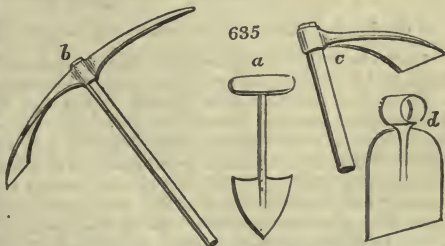

"6844. *The slit method*, either simply (2088.) or by the T method, is not recommended by Sang; but necessity may justify its adoption occasionally. "We would not recommend planting by the slit, unless where there is no more soil than is absolutely occupied by the fibres of the herbage which grows on the place. Excepting on turf, it cannot be performed; nor should it be practised, if the turf be found three or four inches thick. By pitting in summer, turf is capable of being converted into a proper mould in the space of a few months; and the expense of pitting, especially in small plantations, can never counter-balance the risk of success in the eyes of an ardent planter. The most proper time to perform the operation of slitting in the plants, is when the surface is in a moist state. On all steep the plant should be placed towards the declivity, that the moisture may fall to its roots; that is to say, in planting, the spademan should stand highest, and the boy lowest on the bank; by which arrangement the plant will be inserted at the lower angle of the slit." (*Plant. Kal.* 170.)

6845. *Planting with the diamond dibber*, he says, "is the cheapest and most expeditious planting of any we yet know, in cases where the soil is a sand or gravel, and the surface bare of herbage. The plate of the dibber (*fig.* 635. *a*) is made of good steel, and is four inches and a half broad where the iron handle is welded to it; each of the other two sides of the triangle is five inches long; the thickness of the plate is one fifth part of an inch, made thinner from the middle to the sides, till the edges become sharp. The length of the iron handle is seven inches, and so strong as not to bend in working, which will require six eighths of an inch square. The iron handle is furnished with a turned hilt, like the handle of a large gimlet, both in its form and manner of being fixed on. The planter is furnished with a planting-bag, tied round his waist, in which he carries the plants. A stroke is given with the dibber, a little aslant, the point lying inwards; the handle of the dibber is then drawn towards the person, while its plate remains within the ground: by this means a vacuity is formed between the back of the dibber and the ground; into which the planter, with his other hand, introduces the roots of the seedling plants, being careful to put them fully to the bottom of the opening: he then pulls out the dibber, so as not to displace them, and gives the eased turf a smart stroke with the heel; and thus is the plant completely firmed. The greatest error the planter with this instrument can run into, is the imperfect introduction of the roots. Green, or unpractised hands, are apt to double the roots, or sometimes to lay them across the opening, instead of putting them straight down, as above directed. A careful man, however, will become, if not a speedy, at least a good planter in one day; and it is of more importance that he be a sure hand; than a quick one. A person who is of a careless or slovenly disposition, should never be allowed to handle a dibber of this kind."

6846. *Planting with the planting-mattock* (*fig.* 635. *b*) is resorted to in rocky or other spots where pitting is impracticable. "The helve or handle is three feet six inches long; the mouth is five inches broad, and is made sharp; the length from it to the eye, or helve, is sixteen inches; and it is used to pare off the sward, heath, or other brush that may happen to be in the way, previous to casing the soil with the other end. The small end tapers from the eye, and terminates in a point, and is seventeen inches long." By this instrument the surface is skimmed off "for six or eight inches in diameter, and with the pick-end dug down six or eight inches deep, bringing up any loose stones to the surface; by which means a place will be prepared for

the reception of the plant, little inferior to a pit. This instrument may be used in many cases, when the plants to be planted are of small size, such as one-year larch-seedlings, one year nursed; or two-year Scots pines, one year nursed; and the expense is much less than by the spade." (*Plant. Kal.* 385.)

6847. *Planting with the forest-planter.* (*fig.* 635. *c*) "The helve is sixteen inches long, the mouth is four inches and a half broad, and the length of the head is fourteen inches. The instrument is used in planting hilly ground, previously prepared by the hand-mattock. The person who performs the work carries the plants in a close apron; digs out the earth sufficiently to hold the roots of the plant; and sets and firms it

without help from another: It is only useful when small plants are used, and in hilly or rocky situations." (*Plant. Kal. Pref. xxiv.*)

6848. Pontey prefers planting by *pitting*, in general cases; the holes being made during the preceding summer or winter, sufficiently large, but not so deep into a retentive sub-soil as to render them a receptacle for water. When the plants have been brought from a distance he strongly recommends puddling them (6849.) previously to planting; if they seem very much dried, it would be still better to lay them in the ground for eight or ten days, giving them a good soaking of water every second or third day, in order to restore their vegetable powers; for it well deserves notice, that a degree of moisture in soil sufficient to support a plant recently or immediately taken from the nursery, would, in the case of dried ones, prove so far insufficient, that most of them would die in it. The puddling here recommended may also be of great service in all cases of late planting where small plants are used; my method is (after puddling) to tie them in bundles, of two or three hundreds each; and thus send them, by a cart-load at once, to where wanted; where such bundles being set upright, close to each other, and a little straw carefully applied to the outsides of them, may remain without damage in a sheltered situation any reasonable time necessary to plant them. Where loose soil happens to be convenient, that should be substituted in the place of straw.

6849. *A puddle for trees* is made by mixing water with any soil rather tenacious, so intimately as to form a complete puddle, so thick that when the plants are dipped into it enough may remain upon the roots to cover them. The process of puddling is certainly simple, and its expense too trifling to deserve notice: its effects, however, in retaining, if not attracting moisture, are such that, by means of it, late planting is rendered abundantly more safe than it otherwise would be. It is an old invention, and hence it is truly astonishing that it is not more frequently practised. If we could but persuade people to adopt it generally in spring planting, I believe the prejudice in favor of autumn practice would soon be done away. (*Prof. Plant. 167.*)

6850. *Pontey's methods of planting* are in general the same as those of Sang: he uses a mattock and planter of similar shape; and also a two or three pronged instrument, which we have elsewhere denominated the *planter's hack*. (1305. *fig. 90.*) "This instrument," he says, "has been introduced of late years as an improvement on the mattock and planter (*fig. 635. b, c,*), being better adapted to soils full of roots, stones, &c.; they are likewise easier to work, as they penetrate to an equal depth with a stroke less violent than the former: they are also less subject to be clogged up by a wet or tenacious soil. The length of the prongs of both should be about eight inches, and the distances between them, when with three prongs, one and a half, and with two prongs, about two inches; the two-pronged hack should be made somewhat stronger than the other, it being chiefly intended for very stony lands, or where the soil wants breaking, in order to separate it from the herbage, &c. These tools are chiefly applicable to plants of any size up to about two feet, or such as are generally used for great designs, where they are used as a substitute for the spade, in the following manner: The planter being provided with a basket holding the plants required (the holes being supposed prepared, and the earth left in them), he takes a tree in one hand, and the tool in the other, which he strikes into the hole, and then pulls the earth towards him, so as to make a hole large enough to hold all its roots; he then puts in the plant with the other, and pushes the earth to its roots with the back of the planter; after which, he fixes the plant, and levels the soil at the same instant with his foot: so that the operation is performed by one person, with a degree of neatness and expedition which no one can attain to who uses the spade. It is known to all planters, that but few laborers ever learn to plant well and expeditiously in the common method, without an assistant: this method, however, requires neither help nor dexterity; as any laborer of common sagacity, or boy of fifteen, or even a woman, may learn to perform it well in less than half an hour. The facility with which these tools will break clods, clear the holes of stones, or separate the soil from herbage, the roots of heath, &c. (the former being previously mellowed by the frost,) may be easily imagined." (*Prof. Plant. 173.*) The adoption of a small mattock for inserting plants, we recollect to have seen recommended in a tract on planting in the Highlands, by Mac-laurin, a nurseryman, published at Edinburgh upwards of twenty years ago.

6851. *An expeditious mode of slit planting* is described in the *General Report of Scotland*, as having been practised for many years on the Duke of Montrose's estate. It is as follows: "The operator, with his spade, makes three cuts, twelve or fifteen inches long, crossing each other in the centre, at an angle of sixty degrees, the whole having the form of a star. (*fig. 636.*) He inserts his spade across one of the rays (*a*), a few inches from the centre, and on the side next himself; then bending the handle towards himself, and almost to the ground, the earth opening in fissures from the centre in the direction of the cuts which had been made, he, at the same instant, inserts his plant at the point where the spade intersected the ray (*a*), pushing it forward to the centre, and assisting the roots in rambling through the fissures. He then lets down the earth by removing his spade, having pressed it into a compact state with his heel; the operation is finished by adding a little earth, with the grass side down, completely covering the fissures, for the purpose of retaining the moisture at the root, and likewise as a top-dressing, which greatly encourages the plant to push fresh roots between the swards." (*Vol. ii. p. 283.*)

636

CHAP. IV.

On forming Plantations, in which Ornament or Effect is the leading Consideration.

6852. In designing *ornamental plantations*, the situation, form, the disposition of the trees, and the kinds employed, are the principal considerations.

6853. *The situations* to be planted, with a view to effect, necessarily depends on the kind of effect intended; these may reduced to three — to give beauty and variety to general scenery, as in forming plantations here and there throughout a demesne; to give form and character to a country-residence, as in planting a park and pleasure-grounds; and to create a particular and independent beauty or effect, as in planting an extensive area or wood, unconnected with any other object, and disposing of the interior in avenues, glades, and other forms. In the two first cases, the choice of the situation must always be relative to other objects; as, for example, in ornamenting general scenery, to fields and enclosures, buildings, roads, &c.; and to the mansion-garden and other parts of a residence, in laying out a country-seat: but in forming independent plantations the choice may be absolute, and guided by no other consideration than the effect to be produced. One of the greatest beauties produced by planting, either on general scenery, or on the grounds of a residence, is that of varying the form of the surface of the country

or increasing the variations already existing. To do this with most effect, it is an obvious and long established principle, that, other circumstances being the same, the hills are to be more generally planted than the hollows, or even the plains. By planting a hill, or the least rise of ground, that hill or rise is increased in effect; but by planting the low grounds between hills or protuberances, their effect is destroyed. It is to be observed, however, that the latter practice is often what we observe in natural scenery. In hilly tracts in a state of nature, and under the dominion of no other animals than cattle or sheep, the vales or dells (*fig. 637.*) are generally filled with wood and the

tops of the hills bare, which, however agreeable to those who view or study nature chiefly in detail, yet to the general observer it tends to confound form, and introduce monotony of surface. Art, therefore, when planting for general effect, or for heightening the character of surface, adopts a contrary practice (*fig. 638.*) to what is general in

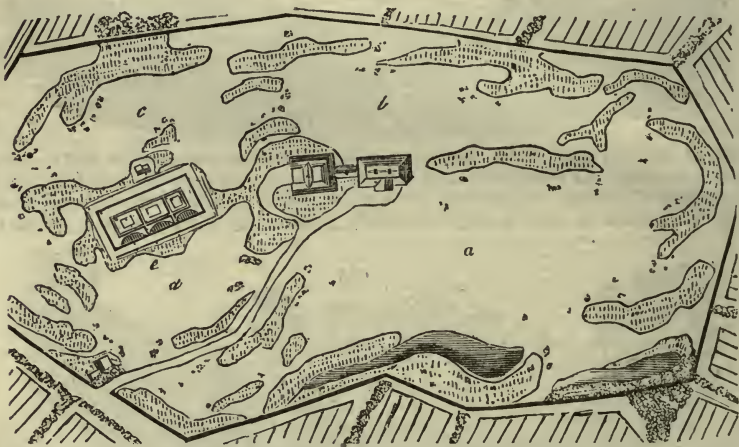

wild nature; for few things in a wild state are suitable to the views of man in a state of civilisation and refinement; and when he admires rude scenery, it is from views of its novelty or rarity in cultivated countries; or with reference to some other art or object, or state of the same object. At the same time, a hill crowned with wood occurs in nature occasionally, both with and without naked hollows or plains at its base, and never fails to excite a superior degree of satisfaction or pleasure in the spectator. To plant hills, therefore, in preference to valleys, may justly be designated an imitation of one of the more interesting features of nature.

6854. *With respect to form,* it may be absolute, or independent of every consideration but the taste of the designer; or it may be relative. It is absolute in plantations intended to create particular beauties within themselves; as in labyrinths, woods pierced with avenues, stars, &c., in the geometric style; or in compositions and groups, thickets and glades in the interior of a wood, laid out in the modern manner. It is relative to the shapes of the ground and to existing objects in the forms adapted for improving general scenery; and to these considerations, and to the situation and form of the mansion, gardens, waters, &c. in laying out the grounds of a country-residence. For either of these objects the general principles of operation are to heighten beauties already existing; to conceal defects; if possible, to create beauty; and to connect detached objects, either in reality or appearance, so as the scenery, from whatever point it may be viewed, may appear a whole; in short, the end is a harmonious and expressive whole, and the means are the grouping and connecting of the parts. Some tracts of country, or those parts of a demesne exterior to the park, may be deficient in woodiness; there trees may be introduced in masses on elevated sites, or the sides of hills; in groups connected with buildings; in thinly scattered trees, in pastures, and by brooks; and in rows in hedges, and by other fences or roads. Where disagreeable objects are to be concealed, the course is evident; and where nothing is interesting, attempts must be made to create interest. A road through a dreary country may often have much of its dulness taken away by one or two rows of trees on each side, the stems of which will break and vary the distant scenery. The lines may vary in form and direction, may swell into strips, or clumps, or thickets; form recesses, or be interrupted, according to circumstances. The route through some of the most dreary tracts in Germany and Russia, and the well-known *Strada di Campagna*, in Italy, are in this way rendered tolerable. In all this, though the main object may be beauty, yet, utility must never be lost sight of. All plantations by arable lands should, as much as possible, be bounded by straight, or at least not very irregular lines, and connected with the hedges or other fences already existing; few single trees or groups should be planted in the area of such fields. In pastures, the worst soils and most exposed situations should be chosen, and such forms adapted as may shelter the stock from all quarters, but especially from the storms and winds which more generally prevail. In planting near cottages and villages, care should be taken not to render the atmosphere unhealthy by stagnating the air, or to lessen the value of their yards and gardens by curtailing their extent, or by excess of shelter and shade. Roads or lanes should on no account be injured, nor the water of streams and ponds rendered dark, discolored by leaves, and unwholesome to men or cattle. In short, the planter, for effect, should never lose sight of utility, or plant in opposition to it; for though he may produce particular sorts of beauty, and especially that lately so fashionable and justly admired disposition of objects, called picturesque, which may be admired by a number for a time; yet there is a much more elevated and universal beauty, that of moral relation, or, in short, refined utility, which, while men

retain their social feelings, must ever be the most interesting to mankind in general, and will therefore finally prevail.

6855. *The outline of plantations*, made with a view to the composition of a country-residence, is guided by the same general principles; whether the trees are to be disposed in regular forms, avowedly artificial; or in irregular forms, in imitation of nature. (*fig. 639.*) The first thing is, in both modes, to compose a principal mass, from which the rest may appear to proceed; or be, or seem to be, connected. In common cases it answers best to include or connect with this mass the house, kitchen and flower-gardens (*e*); from these other masses and groups should proceed, either connected, or better, only seemingly so when viewed horizontally. Their forms should be such

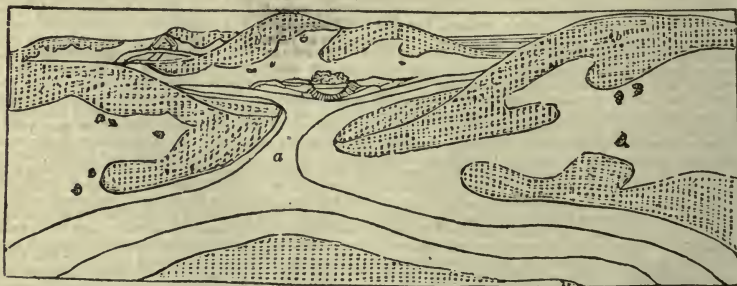

639

and so disposed, relatively to the ground and other objects, and to each other, as to throw the pasture surface into broad masses (*a, b, c, d*), which become wholes in their turn, and their connection and variation is heightened by the variety in the glades between the masses and groups of plantation. Such would be the mode of procedure on a flat to be formed into a modern park; regard being had to exclude or admit the view of certain parts of the distant scenery; never to shut in, or leave without a third distance (as is the term in landscape-painting), any of the scenes within the boundary of the park; and to other laws of perspective, optics, and composition, which will be more fully entered on in treating of landscape-gardening.

6856. *In the pleasure-ground*, which, as far as respects the form or ground outline of plantations, is to be considered as a part of the park, the same principles are applicable. In neither the artificial or natural style, should their width be great; but their form may be varied at pleasure, subject to general principles. Where the ground is irregular (*fig. 640.*), only the modern style can be adopted with good effect; and there, by con-

640

ducting the walks, or forming the water chiefly in the hollows (*a*), and planting the eminences (*b*), varying the manner in which the outlines of these masses embrace the declivities, the happiest effects may be produced. Deviations from these general principles can only be justified by extraordinary circumstances.

6857. *With respect to the extent, or area, occupied by ornamental plantations, as such, that need seldom be great.* They are generally seen only in profile, and therefore a circuitous outline (*fig. 641. a.*) may on most occasions be contrived to have the same effect as planting a solid mass, which will occupy much more ground (*b*), show less exterior variety, and none within. The

641

case is different, however; where the upper surface of a plantation is to be met by the eye, at a large angle, say upwards of 35° . In that case, to produce a grand and imposing effect, real extent is wanting. Examples occur in planting the steep sides of high hills, to be seen from below; or valleys or plains to be seen

from great elevations. It must be confessed that these are among the grandest circumstances in which wood can be viewed; profiles of outlines, varied both as respects the sky and the ground, are beautiful and interesting; and avenues and long rows of trees form imposing perspectives; but the side of a range of mountains clothed with wood, seen at a certain distance, from a plain below or opposite hills, is one of the most magnificent of rural prospects.

6858. *With respect to the disposition of trees in a plantation where art is avowed or purposely displayed, the more regularly the plants are placed the better is the end attained; but, where nature is to be imitated, irregularity will best sustain the character.*

This should be studied in the larger as well as the smaller plantations, in the natural style; but more especially in detached groups, which operate so powerful an effect in laying out the grounds of a residence. The greatest beauty of a group of trees as far as respects their stems, is in the varied direction these take as they grow into trees (*fig. 642.*); but as that is for all practical purposes beyond the influence of art, all we can do is to vary as much as possible the ground-plans of groups, or the relative position which the stems have to each other, where they spring from the earth.

This is considerable, even where a very few trees are used, and of which any person may convince himself by placing a few dots on paper. Thus, two trees (*fig. 643.*), or a tree and shrub, which is the smallest group, may be placed in three different positions with re-

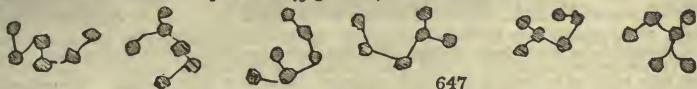

642

ference to a spectator in a fixed point: if he moves round them they will first vary in form separately, and next (at *b*) unite in one or in two groups, according to the position of the spectator. In like manner three trees (*fig. 644.*) may be placed in four different

positions; four trees may be placed in eight different positions (*fig. 645.*); five trees may be grouped in ten different ways as to ground-plan (*fig. 646.*); six may be placed in twelve different positions (*fig. 647.*); and so on.

647

6859. *In planting groups it is not meant to be asserted, that the ground-plan of each should be studiously considered; it will be sufficient if this is done in conspicuous situations, by the sides of walks and roads, and in such places as require for shelter or shade, or to exclude some disagreeable object, a series of groups of nearly the same number of trees. For the ordinary purposes of grouping, such as varying the apparent outline of masses, connecting scattered objects, adding parts to such objects as are incomplete wholes, &c., it will be sufficient to introduce large and small groups; never to put two trees at exactly the same distance from each other; three in the angles of an equilateral triangle; four in those of a square; five in those of an octagon; and so on.*

6860. *Scattered trees.* It has been a very common practice among planters to introduce, in parks, great numbers of detached single trees (in vulgar technology, dotting), with a view of effecting, by them, what can only be done by groups. Excepting the clump, there is not a greater deformity in the grounds of British country-residences. Supposing these trees, planted on a level surface, all of the same sort, and all growing equally well, their insipid sameness of form and position must be evident to the mind's eye of every one. Suppose them on the same character of surface, but all, or chiefly, of different sorts (*fig. 648.*), it is equally evident they will grow with different degrees of vigor, and assume different characters of stem and head; and consequently produce an appearance of the most discordant kind. It is only necessary to analyse a group, to be

convinced of the variety of general form produced, even by trees of one species, but more especially by two kinds, and this, even by specimens that would be unsightly apart; and to observe a portion of the scattered woody scenery, in the openings or glades of a natural forest, to be convinced how much more variety is produced by that manner of planting, than by distributing over a surface great numbers of single trees. It is observed by Uvedale Price, that in the numerous landscapes which compose the *liber veritatis* of Claude, there is not more than one single tree; so highly did this artist value the principle of connection. A single tree, however, is not always to be condemned, even as such, for its form, age, or blossom, or some other accidental circumstance may compensate for its isolated situation; and it may often exist singly as a tree, and yet in connection or grouped with other objects, as buildings, rocks, &c.; and in these cases it is not to be condemned, because the grand object of grouping, connection, is maintained by the co-tangent object.

6861. *Placing the groups.* Another practice in the employment of groups, almost equally reprehensible with that of indiscriminate distribution, is that of placing the groups and thickets in the recesses, instead of chiefly employing them opposite the salient points. The effect of this mode is the very reverse of what is intended; for, instead of varying the outline, it tends to render it more uniform by diminishing the depth of recesses, and approximating the whole more nearly to an even line. The way to vary an even or straight line or lines, is here and there to place constellations of groups against it (*fig. 649. c.*); and a line already varied is to be rendered more so, by placing large groups against the prominences (*a.*) to render them more prominent; and small groups (*b.*), here and there in the recesses, to vary their forms and conceal their real depths.

6862. *In all plantations in the natural style* above the size of a group, the same general principles are to be followed in the disposition of the trees; the plants, whatever be their kinds, and whether the mass is finally to assume the character of a wood, grove, or copse, should be placed irregularly; here thick, and there thin, as if they had sprung up from the accidental semination of birds or winds. "The effect of this arrangement will not be that composition of low and high, oblique and upright stems, and young and old trees, and low growths, which we find in forest scenery; but it is all that can be done in imitation of it at the first planting; and subsequent thinning, pruning, and cutting down, moving, *reversing*, planting, and sowing, must be used from time to time to complete imitation or allusion, unless the owner will rest satisfied with an inferior degree of beauty."

6863. *The general form of tree employed* materially influences the effect of plantations. The capacities of different trees for producing effects in landscape, and the general division of trees into round-headed, oblong-headed, and spiry-topt, have been already pointed out (6795. et seq.) It has also been observed (6857.), that the greater number of plantations are seen chiefly in profile; and hence, that the outline which the tops of the trees form against the sky or the back-ground, is the most conspicuous feature in their aspect. The difference between this outline, when formed of *spiry-topt trees*, as the firs, pines, &c. (*fig. 650.*); of *oblong-headed trees*, as most of the willows, alders, poplars (*fig. 651. b.*); and the *round-headed sorts*, as the oak, ash, elm, and most trees (*fig. 651. a.*).

650

is so considerable, as to merit the particular attention of the planter. Nothing can be more harsh and unvaried than the serrated outline of the fir tribe, whether planted in rows, strips, or masses; whereas the rounded-headed trees, even in single rows, produce some variety of sky outline. The difference is equally great between the face or

651

front surface of a row or mass of spire and round-headed trees; for the great regularity and similarity of the branches of the former, precludes the possibility of breaks in form, or light and shade, and presents one uniform surface of verdure, not unlike the side of a high hedge. The front surface of a row or mass of round-headed trees, on the contrary, from opposite qualities in the branches, produces prominences and recesses of different degrees of magnitude, and of different forms and relative positions. If we look on the upper surface of a plantation of each class, we shall find the difference equally great.

6864. *The situations where spire-topped trees have most effect* is among rocks, and in very irregular surfaces; and especially on the steep sides of high mountains (fig. 652.), where their forms, and the direction of their growth, seem to harmonise with their pointed rocky summits. Fir and pine forests are dull, gloomy, and monotonous in the sandy plains of Poland and Russia, but among the broken rocks, craggy precipices, and otherwise endlessly varied surfaces of Sweden and Norway, they are full of variety. In tame countries they present most variety when planted so thin as barely to touch each other, and when a number of them are kept low, where the whole are of different ages (fig. 653.) But the variety produced, even by this disposition, is still far short of what would be effected by a similar arrangement of round or oval-

653

headed trees (fig. 654.), of different ages, or mixed with shrubs or low growths. The most suitable situation for spire-topped trees, in ornamental scenery, is as single objects

654

or in small groups (fig. 655.), sparingly introduced in the margin of thickets or strips, or sprinkled along the bottoms of dells or dingles. In plantations which comprise masses of all the different species of hardy tree, there they may come in also in their proper place; and in mountain and rocky scenery, they are in the places which nature seems to have intended for them.

655

6865. *The oblong-headed trees* may be introduced much more frequently than the spire-topped sorts; the more obtuse summits blend well with the round-headed trees, and the more acute topped sorts which terminate in flexible flame-like shapes, as the Lombardy poplar, and cypress, form excellent contrasts to the round trees, and serve as transition forms to the spire tribe. The round-headed trees, it need hardly be observed, are the most general in nature, at least in temperate climates, and are the most universally applicable in ornamental planting. These considerations on the forms of trees refer to them chiefly as in independent plantations; in connection with buildings, the choice, as to form, may often be influenced by that of the building, and also by the effect or object intended by planting them.

6866. *With respect to magnitude*, the grand division of woody plants is into trees and shrubs. The bulk and heights of the common trees and shrubs of the country being generally known, the eye estimates the magnitude of other objects by theirs; consequently extraordinary magnitudes, whether large or small, should only be used under extraordinary circumstances. The apparent size, proportion, and distance of objects, might otherwise be deranged, and a discordant effect produced. Shrubs, which have the form of trees; and low trees, as the mountain ash, the apple and pear, often produce this effect, when planted as single objects; and unless their fruit is prized above every thing else, they should, when introduced for the sake of their flowers, either be planted in the margins of plantations, or grouped with trees of the ordinary size. The finest small groups are of this description, or composed of common deciduous timber trees and hardy shrubs, as oaks, chestnuts, hollies, thorns, &c.

6867. *The choice of species* must be made subservient to general effect, and to the particular purposes, for which different species are calculated. These have been already pointed out (chap. ii), as well as their uses (chap. i.), and both should be continually present in the mind of the planter. For the more general purposes of planting, the standard trees of the country, native or naturalised, are mostly to be preferred, as growing freely and preserving harmony; for the purposes of distinction, foreign trees are more likely to answer the end. Foreign trees also contribute greatly to variety and interest, and therefore are indispensable in pleasure-grounds, or other scenes of much resort. "Any number of species may be admitted into improved grounds; commencing with the rare sorts near the house, as the centre of art and refinement, and ending with the common trees of the country, at such distances as the extent and style of the whole may suggest. The proportions of such trees as are only ornamental, and such as are valuable as timber, must be in some degree determined by the character of the place, but chiefly by the taste and view of the owner. Beauty alone, without utility, will not long please; and a few single groups and plants of the rare species, in the grounds more immediately consecrated to man, will generally afford more satisfaction than a lavish display of exotics; the former will always present a more luxuriant and thriving display of scenery than the latter, and sooner attain the maturity of beauty." (*Edin. Encyc. art. Landscape Gardening.*)

6868. *Whatever number of species are used, one only should prevail in one place*; or if there be high or low growths, then one of each kind should prevail. Great attention should be had that the species which compose the groups and thickets, or other scattered woodinesses which border on masses, should consist almost entirely of the species which prevail in the masses: if this precaution is neglected, instead of these appendages producing connection and harmony, they will have a tendency directly the reverse. Thickets may next be considered in regard to their form, that is, the form of their ground-plan; and with groups and single trees in regard to the choice of species. Thickets are produced by nature, by the inroads of cattle, or other animals, grazing or cropping the herbage, and with it the young trees in forest-scenery. On levels and sheltered situations, we find their form comparatively regular, because there appears no permanent or general reason to occasion their encroachment on one side more than on the other. But on varied surfaces and soils a preference is given by depasturing animals to certain natural plants, and the side on which they abound is penetrated more deeply than the other. The plan of the thicket, therefore, varies accordingly. In elevated grounds, exposed to a particular wind, the thickets will exceed in length, which will be found generally to be in the direction of the storm. The cause is too obvious to be pointed out; but this effect, and every other observed in the groups and thickets of natural scenery, always merit study, and most frequently deserve imitation in creations of landscape-scenery. The species of tree ought obviously to be those of the part of the mass to which they belong; for thickets, groups, and single trees, ought to resemble disjointed and broken fragments from those masses. But in particular cases, for rendering a prominence still more prominent, or increasing the depth of a recess, a few plants of similar, or not discordant growths, but of darker or lighter greens, may at a distance add to the effect of each. By the same process, with more contrasted species, where no other mode can be put in execution, the formality of a single row may in some degree be varied in its situation and contour. (*Ed. Encyc. art. Landscape Gardening.*)

6869. *The arrangement of the species* to effect variety must evidently be by grouping or collecting them in masses; for if all the species made use of were intimately mixed together in every part of a plantation, it is evident the eye would meet every where the same species; so that, as far as variation from that source was sought for, it would be entirely wanting. Uvedale Price has treated this subject with much ingenuity; and in reprobating the common practice of mixing as many different sorts as can be procured, in order to produce variety, observes, that "variety, of which the true end is to relieve the eye, not to perplex it, does not consist in the diversity of separate objects, but in the diversity of their effects when combined together in a difference of composition and character. Many think, however, that they have obtained that grand object, when they have exhibited in one body all the hard names of the Linnæan system; but when as many plants as can be well got together are exhibited in every shrubbery, or in every plantation, the result is a sameness of a different kind, but not less truly a sameness that would arise from there being no diversity at all; for there is no having variety of character, without a certain distinctness, without certain marked features on which the eye can dwell." (*Essays on the Picturesque*, vol. i.)

6870. *Repton* observes, "there is more variety in passing from a grove of oaks to a grove of firs than in passing through a wood composed of a hundred different species, as they are usually mixed together. By this indiscriminate mixture of every kind of tree in planting, all variety is destroyed by the excess of variety, whether it is adopted in belts or clumps, as they have been technically called: for example, if ten clumps be composed of ten different sorts of trees in each, they become so many things exactly similar; but if each clump consists of the same sort of trees, they become ten different things, of which one may hereafter furnish a group of oaks, another of elms, another of chestnuts or of thorns, &c. In like manner,

in the modern belt, the recurrence and monotony of the same mixture of trees of all the different kinds, through a long drive, make it the more tedious in proportion as it is long. In part of the drive at Woburn, in which evergreens alone prevail, which is a circumstance of grandeur, of variety, of novelty, and, I may add, of winter comfort, that I never saw adopted in any other place on so magnificent a scale, the contrast of passing from a wood of deciduous trees to a wood of evergreens must be felt by the most heedless observer; and the same sort of pleasure, though in a weaker degree, would be felt in the course of a drive, if the trees of different kinds were collected in small groups or masses by themselves, instead of being blended indiscriminately." (*Inquiry into Changes of Taste*, &c. p. 33.)

6871. *Sir W. Chambers and Price* agree in recommending the imitation of natural forests in the arrangement of the species. In these nature disseminates her plants by scattering their seeds, and the offspring rise round the parent in masses or breadths, depending on a variety of circumstances, but chiefly on the facility which these seeds afford for being carried to a distance by the wind, the rain, and by birds or other animals. So disseminated they spring up, different sorts together, affected by various circumstances of soil and situation; and arrive at maturity, contending with other plants and trees, and with the browsing of animals. At last, that species which had enjoyed a maximum of natural advantages is found to prevail as far as this maximum extended, stretching along in masses and angular portions of surface, till circumstances changing in favor of some other species, that takes the prevalence in its turn. In this way it will generally be found, that the number of species, and the extent and style of the masses in which they prevail, bears a strict analogy to the changes of soil and surface; and this holds good, not only with respect to trees and shrubs, but to plants, grasses, and even the mossy tribe.

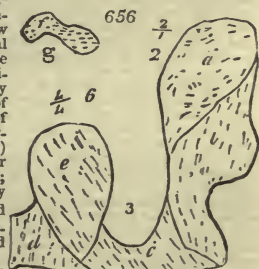

6872. *The most perfect arrangement of species in regard to variety* would be to employ every kind of tree and shrub that will grow freely in the open air, and arrange them according to the natural system. We have already suggested (6144.) that a residence might be wooded in this way, so as in the smallest extent to obtain a maximum of variety and beauty. In most cases, where grouping, or any systematic plan of arranging the species is to be adopted, the form of the groups (fig. 656. *a, b, c, d, e*) should be marked on the plan of the plantation, and the kinds for each form written down in a corresponding list; the small detached masses intended as thickets (*f*) should be similarly marked, the situation of groups indicated either by letters simply (*g*), or by figures (6, 2, 3) referring to a list of kinds; and where shrubs are to be introduced in the groups, two figures may be used ($\frac{2}{3}$, $\frac{4}{4}$), one of which shall indicate the kind of tree, and the other the species of low growth or shrub. This mode we have always adopted in furnishing plans for ornamental planting, and find it enables gardeners to execute them with perfect accuracy.

6873. *The size of the plants used in ornamental planting* should be as great as the soil and situation will admit, for two reasons: first, because an early effect is always desirable; and secondly, because in planting detached groups, large and small plants, and a varied inclination of their stem (fig. 642.) may be introduced in imitation of nature. Small groups on pastured lands, indeed, cannot be formed without trees whose stems are sufficiently high to raise their heads out of the reach of cattle, without enclosing so considerable a space round every tree as to render this mode both tedious, unsightly, and expensive.

6874. *Fences.* Masses, in the ancient style of planting, were generally surrounded by walls or other durable fences. Here the barrier was considered as an object or permanent part of the scene, and for that reason was executed substantially, and even ornamentally. They were generally walls substantially coped, and furnished with handsome gates and piers. The rows of avenues and small clumps, or platoons intended to be finally thrown open, were enclosed by the most convenient temporary fence.

6875. *In planting in the natural style*, a regular fence either of verdant or masonic materials, can never be the final part of perfect imitation, since no such thing is to be found in nature. But in planting in farm-lands, or for the purpose of improving the general scenery, some permanent fence is requisite; and all that can be said is, that which promises in the end to be the most efficient and economical, will almost always be the best. The hedge, sunk fence, common wall, and wide water-course where it will be constantly nearly full of water, here present themselves as the most general kinds. Any fence, however, of which a large excavation, without water, forms a part, as the sunk fence, should be used with great caution; as there are none of this class but what look ill from at least one point of view, that is, when seen lengthways.

6876. *In planting to form a park or residence*, with the exception of the boundary fence, and that which separates the lawn or mown surface from the grazed scenery, no permanent barrier of a formal nature should ever be admitted. In very bleak situations, walls or mounds of earth, however unsightly, may be necessary for a time to shelter and draw up the plants; but the final removal of these and all fences in parks, should be looked to as certain. Light palings, the rails coated over with tar or pyroligneous acid, and the posts charred by burning at the lower end, to render them durable, may be used in the greater number of cases; and in many, where the plants are larger, and the soil and other circumstances favorable to their growth, hurdles or other moveable rails or palings may be used. "The present improved state of the manufacture of iron offers a very desirable accommodation in this respect, affording the best guards for single plants and groups; and iron hurdles, or lines of cast-iron standards and half-inch wires, as rails for masses, have a light and temporary appearance, highly congenial to the idea of their speedy removal. The lines of the fences conforming to the irregular shapes of the masses will not be disagreeable to the eye, if those of the latter are arranged with any regard to apparent connection; for any objects, whether lines or forms, however deficient in beauty of themselves, acquire a degree of interest, and even character, when connected and arranged in such a way as to form a whole. When a plantation is finally to be composed both of trees and undergrowths, thorns, sloes, hollies, berberies, and briars, may, in many cases prevail in the margin; which, when the fence is removed, will form a picturesque phalanx, and protect the whole. Partial inroads, formed by cattle, will only heighten the variety and intricacy of such masses." (*Edin. Encyc. art. Landscape Gardening.*) In this way, as Price observes (*Essays*, vol. i.), the planter may plant as thick as he chooses, and never think of thinning or future management, only taking care to introduce no more trees than what he intends to remain finally as timber. The great majority of the plants being shrubs will soon be overtopped by the timber-trees, which, having abundance of head-room, will grow up in free and unconstrained shapes. The future care of plantations is so generally neglected, that this suggestion, under certain circumstances, well merits adoption; though it certainly can have no pretension to be called a scientific or profitable mode of planting. It is what it pretends to be, a picturesque mode.

CHAP. V.

Of the Culture and Management of Plantations.

6877. *On the management of plantations*, Pontey and Sang observe, that it is too common a case to consider a tree, when once planted, as done with; though, as every one knows, the progress and products of trees, like those of other plants, may be greatly increased or modified by cultivating the soil, pruning and thinning.

6878. With respect to *culture of the soil*, it is evident that young plantations should be kept clear of such weeds as have a tendency to smother the plants; and though this is not likely to take place on heaths and barren sites, yet even these should be looked over once or twice during summer, and at least those weeds removed which are conspicuously injurious. In grounds which have been prepared previously to planting, weeding, hoeing by hand, or by the horse-hoe, and digging or ploughing, become necessary according to circumstances. The hoeings are performed in summer to destroy weeds, and render the soil pervious to the weather; the ploughing and diggings in winter for the same purpose, and sometimes to prepare the soil for spring crops. These, both Pontey and Sang allow, may be occasionally introduced among newly planted trees; though it must not be forgotten that relatively to the trees, the plants composing such crops are weeds, and some of them, as the potatoe, weeds of the most exhausting kind.

6879. *In preparing land for sowing woods*, Sang ploughs in manure, sows in rows six feet apart, and crops the ground between, with low-growing early potatoes, turnip, lettuce, or other green crops. He does not approve of cropping the intervals with young trees, as a sort of nursery, as they prove more scouring crops than esculent vegetables, nor with grain, as not admitting of culture, and being too exhausting for the soil. Marshall, and some other authors, however, approve of sowing the tree-seeds with a crop of grain, and hoeing up the stubble and weeds when the crop is removed.

6880. Pontey observes, "that wherever preparing the soil for planting is thought necessary, that of cultivating it for some years afterwards will generally be thought the same; for where quick growth is essential, cleanliness of appearance is usually of consequence. Slight crops of potatoes, with short tops, or turnips, may be admitted into such plantations with advantage for two or three years, as they create a necessity for annually digging or stirring the surface, and tend very materially to accelerate the growth of the plants. It may be objected, that such crops must impoverish the soil, and no doubt but such is the fact, so far as common vegetables are concerned; but as to the production of wood, its support depends, in a great measure, on a different species of nutriment; and hence, I could never observe that such cropping damaged it materially." (*Profit. Plant.* p. 153.) Osier-plantations for basket-willows and hoops, require digging and cleaning during the whole course of their existence; and so do hedge-rows to a certain extent, and some ornamental plantations.

6881. *Filling up blanks* is one of the first operations that occurs in the culture of plantations next to the general culture of the soil, and the care of the external fences. According to Sang, a forest plantation after pitting, either in the mass form or ordinary mixture, should remain several years after planting, before filling up the vacancies, by the death of the hard-wood plants, takes place. Hard-wood plants, in the first year, and even sometimes in the second year after planting, die down quite to the surface of the ground, and are apparently dead, while their roots, and the wood immediately above them, are quite fresh, and capable of producing very vigorous shoots, which they frequently do produce, if allowed to stand in their places. If a tree, such as that above alluded to, be taken out the first or second year after planting, and the place filled up with a fresh plant of the same kind, what happened to the former may probably happen to the latter; and so the period of raising a plant on the spot may be protracted to a great length of time; or it is possible this object may never be gained.

6882. *The filling up of the hard wood kinds* in a plantation which has been planted after trenching, or summer-fallow which has been kept clean by the hoe, may be done with safety at an earlier period than under the foregoing circumstances; because the trees, in the present case, have greater encouragement to grow vigorously after planting, and may be more easily ascertained to be entirely dead, than where the natural herbage is allowed to grow among them.

6883. *But the filling up of larches and pines* may take place the first spring after the plantation has been made; because such of these trees as have died are more easily distinguished. In many cases when a larch or a fir loses its top, either by dying down, or the biting of hares and rabbits, the most vigorous lateral branch is elected by nature to supply the deficiency, which by degrees assumes the character of an original top. Pines and larches, therefore, which have fresh lateral branches, are not to be displaced, although they have lost their tops. Indeed, no tree in the forest, or other plantation, ought to be removed, until there be no room left to hope for its recovery. If the filling up of plantations be left undone till the trees have risen to fifteen or twenty feet in height, their roots are spread far abroad, and their tops occupy a considerable space. The introduction of two or three plants, from a foot to three feet in height, at a particular deficient place, can never, in the above circumstances, be attended with any advantage. Such plants may indeed become bushes, and may answer well enough in the character of underwood, but they will for ever remain unfit for any other purpose. It is highly improper, then, to commence the filling up of hard-wood plantations before the third year after planting; or to protract it beyond the fifth or the sixth. March is the proper season for this operation. (*Plant. Kalend.* 295.)

6884. *Pruning* is the most important operation of tree culture, since on it, in almost every case, depends the ultimate value, and in most cases, the actual bulk of timber produced. In the purposes of pruning, as for most other practical purposes, the division of trees into resinous or frondose-branched trees, and into non-resinous or branchy-headed sorts, is of use. The main object in pruning frondose-branched trees is to produce a trunk with clean bark and sound timber; that in pruning branchy-stemmed trees, is principally to direct the ligneous matter of the tree into the main stem or trunk, and also to produce a clean stem and sound timber, as in the other case. The branches of frondose trees, unless in extraordinary cases, never acquire a timber size, but rot off from the bottom upwards, as the tree advances in height and age; and, therefore, whether pruned or not, the quantity of timber in the form of trunk is the same. The branches of the other division of trees, however, when left to spread out on every side, often acquire a timber-like size; and as the ligneous matter they contain is in general far from being so valuable as when produced in the form of a straight stem, the loss by not pruning off their side branches, or preventing them from acquiring a timber-like size, is evident. On the other hand, when they are broken off by accident, or rot off by being crowded together, the timber of the trunk, though in these cases increased in quantity, is rendered knotty and rotten in quality.

6885. *With respect to the manner of pruning*, where straight timber is the object, both classes in their infancy, as Sang observes, should be feathered from the bottom upwards, keeping the tops light and spiral, something resembling a young larch. (fig. 637. a) The proportion of their tops should be gradually diminished, year by year, till about their twentieth year, when they should occupy a third part of the height of the plant; that is, if the tree be thirty feet high, the top should be ten feet (b). In all cases in pruning off the branches, the utmost care must be taken not to leave any stumps sticking out, but to cut them in to the quick. It is only by this means that clean timber can be procured for the joiner; or slightly smooth-stemmed trees to please the eye. It is a very general practice to leave snags or stumps (c); before the bole can be enlarged sufficiently to cover these, many years must elapse; the stumps in the meantime become rotten; and the consequence is timber which when sawn up (d) is only fit for fuel.

6886. *Pontey* says, "The sap of a tree may be considered as the raw material furnished by nature; and man, the manufacturer who moulds it into the form most useful for his purpose. A moderate quantity of leaves and small wood is necessary to every tree; but all above that quantity are of no use to the plant, and of little value to its owner." (*Forest Pruner*, 152, 153.)

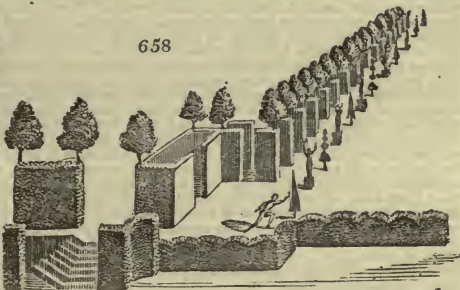

6887. *Pruning for ornament or beauty* must be guided in its operations by what that beauty is. If it is the beauty of art, then the trees may require to be cut or clipped into the shape of animals (fig. 345.); or inanimate natural objects, as mounds of earth, mushrooms; or geometric forms, triangles, globes, cones; or walls, columns, arcades, vases, arbors, temples, theatres, or other architectural or sculptural compositions. (fig. 658.) The dwarfing of trees is also another kind of artificial beauty, much practised by the Chinese; and though the habit be kept up chiefly by withholding nourishment; yet the dwarf is produced by ringing a branch; enveloping it in a ball of loam; amputating it when it has made roots; and then pinching off all exuberance of growth so as to keep it into shape. (*Livingstone*, in *Hort. Trans.* iv. 224.)

6888. *If natural beauty is desired*, then the pruning must be rather negative than positive; the object being to let the tree assume its natural shape, or, as Sang describes it, "express its own nature." All that man can do, therefore, in the way of pruning for this object, is to assist a plant of the tree kind to express the characteristics of a tree; that is, a powerful trunk and ample spreading head, which distinguishes it from a shrub; and this he does by clearing a part of the tree of its side branches; and by avoiding to train up a shrub with a single stem like a diminutive tree. In attending to these instructions the great importance of the use of leaves must never be lost sight of: this is not, as Pontey asserts, to attract the sap, but to elaborate it when propelled to them, and thus form the extract or food taken in by the plant, into a fluid analogous to blood, and which is returned so formed by the leaves into the inner bark and soft wood. It must be a very nice point, therefore, to determine the quantity of branches or leaves that should be left on each tree; and if no more are left than what are necessary, then in the case of accidents to them from insects, the progress of the tree will be doubly retarded. Experience alone can determine these things. Both Pontey and Sang agree that "strength is gained as effectually by a few branches to form a head as by many."

6889. *The general seasons of pruning* are winter and spring, and for the gean midsummer, as it is found to gum very much at any other season. Pontey says, "as to the proper season for pruning, there is only one difficulty; and that is discovering the wrong one, or the particular time when trees will bleed. Only two trees have been found which bleed uniformly at certain seasons, namely, the sycamore and fir, which bleed as soon as the sap begins to move. In spring pruning, desist when this takes place." As a general rule, he thinks "summer preferable to winter pruning; because, in proportion as wounds are made early they heal so much the more in the same season." (*Forest Pruner*, 235.)

6890. *Sang* suspends pruning from the end of February to the middle of July, but carries it on during every other month of the year; the gean, or any other tree very apt to gum, he prunes only in July and August. (*Plant. Kal.* 268.)

6891. *With respect to the implements to be used*, Sang observes, "In every case where the knife is capable of lopping off the branch in question, namely, in the pruning of infant plants, it is the only instrument necessary. All other branches should be taken off by the saw. A hatchet, or a chisel, should never be used. Every wound on the stem, or bole, should be quite into the quick, that is, to the level and depth of the bark; nor should the least protuberance be left. The branch to be lopped off by the saw should, in all cases, be notched or slightly cut on the under side, in order to prevent the bark from being torn in the fall; and when the branch has been removed, the edges of the wound, if anywise ragged, should be pared smooth with the knife. If the tree be vigorous, nature will soon cover the wound over with bark, without the addition of any plaster to exclude the air. In the shortening of a strong branch, the position of which is pretty upright, it should be observed to draw the saw obliquely across it, in such a manner as that the face of the wound shall be incapable of retaining moisture; and afterwards to smooth the edges of the bark with the knife." (*Plant. Kal.* 181.) In every case where

the branches are too large for the knife, Pontey prefers the saw, as the best and most expeditious instrument; and one, the use of which is more easily acquired by a laborer than that of either the bill or axe. In "large work" he uses the common carpenter's saw; for smaller branches, one with somewhat finer teeth, with the plate of steel, and about twenty inches long. Having stated what is general in pruning, the next thing is to submit some particular applications of the art to resinous and non-resinous timber-trees, copse-woods, osier-holts, hedges, and hedge-rows, and trees in parks.

6892. *Resinous trees*, Pontey and Sang agree, should not be pruned at so early an age as the non-resinous kinds. Sang commences about the sixth or eighth year, according to their strength or vigor, and removes no more than one or two tiers of branches at once. Pontey, when the plants are about eight feet high, gives the first pruning by "displacing two or at most three tiers of the lower branches; after which, intervals of three years might elapse between the prunings; never displacing more than two tiers at once, except more shall prove dead." (*Forest Pruner*, 204.) Sang judiciously observes, "Excessive pruning, either of firs, larches, or deciduous trees of any sort, is highly injurious, not only to the health of the plant, but to the perfection of the wood. If a sufficient number of branches are not left on the young plant to produce abundance of leaves, perfectly to concoct its juice, the timber will be loose in its texture, and liable to premature decay." (*Plant. Kal.* 182.) The opinions of Nicol and Monteath are at variance with those of Pontey and Sang, as to pruning resinous trees. Nicol advises leaving snags (*Pract. Plant.* 213.), and Monteath (*For. Guide*, 45.) says, "Never cut off a branch till it has begun to rot, as the bleeding of a live branch will go far to kill the tree."

6893. *Non-resinous trees*, Sang observes, "should be pruned betimes, or rather from their infancy, and thenceforward at intervals of one or at most two years. If the pruning of young forest-trees is performed only at intervals of eight or ten years, the growth is unnecessarily thrown away, and wounds are inflicted which will ever after remain blemishes in the timber; whereas, if the superfluous, or competing branches had been removed annually, and before they attained a large size, the places from which they issued would be imperceptible, or at least not hurtful to the timber, when it came to the hands of the artist. The pruning of all deciduous trees should be begun at the top, or at least those branches which are to be removed from thence should never be lost sight of. Having fixed upon what may be deemed the best shoot for a leader, or that by which the stem is most evidently to be elongated and enlarged, every other branch on the plant should be rendered subservient to it, either by removing them instantly, or by shortening them. Where a plant has branched into two or more rival stems, and there are no other very strong branches upon it, nothing more is required, than simply to lop off the weakest clean by the bole, leaving only the strongest and most promising shoots. If three or four shoots or branches be contending for the ascendancy, they should, in like manner, be lopped off, leaving only the most promising. If any of the branches which have been left further down on the bole of the plant at former prunings have become very strong, or have extended their extremities far, they should either be taken clean off by the bole, or be shortened at a proper distance from it; observing always to shorten at a lateral twig of considerable length. It is of importance that the tree be equally poised; and therefore if it have stronger branches on the one side than the other, they should either be removed or be shortened. Thus, a properly trained tree, under twenty feet in height, should appear light and spiral, from within a yard or two of the ground to the upper extremity; its stem being furnished with a moderate number of twigs and small branches, in order to detain the sap, and circulate it more equally through the plant. Trees of this size, standing in a close plantation, after being properly formed, will require much less attention; indeed, subsequent prunings will mostly consist in keeping their leading shoots single. From the want of air, their lateral branches will not be allowed to extend, but will remain as twigs upon the stem. These, however, frequently become dead branches; and if such were allowed to remain at all on the trees, they would infallibly produce blemishes calculated greatly to diminish the value of the timber: hence the impropriety of allowing any branch to die on the bole of a tree; indeed, all branches should be removed when they are alive; such a method, to our knowledge, being the only sure one to make good timber. From these circumstances, an annual pruning, or at least an annual examination, of all forests, is necessary." (*Plant. Kal.* 180.)

6894. *Heading down such non-resinous trees as stole* we have already (6829.) stated to be an important operation. After the trees have been three or four years planted, Sang directs that such as have not begun to grow freely should be headed down to within three or four inches of the ground. The cut must be made with the pruning-knife in a sloping direction, with one effort. Great care should be taken not to bend over the tree in the act of cutting. By so bending, the root may be split, a thing which too often happens. The operation should be performed in March, and not at an earlier period of the season, because the wounded part might receive much injury from the severe weather in January and February, and the expected shoot be thereby prevented from rising so strong and vigorous. (*Plant. Kalend.* 297.) Buffon, in a memorial on the culture of woods, presented to the French government in 1742, says he has repeated this experiment so often, that he considers it as the most useful practice he knows in the culture of woods.

6895. *For the purpose of producing bends for ship-timber, various modes of pruning have been proposed.* According to Pontey, "little is hazarded by saying, that if plenty of long, clean, straight, free-grown trees could be got, boiling and a screw apparatus would form bends." Monteath, a timber valuator of great experience, and in extensive practice, says, the value of the oak, the broad-leaved elm, and Spanish chestnut, depends a good deal on their being crooked, as they are all used in ship-building. He says he has seen trees successfully trained into crooked shapes of great value, in the following manner: "If you have an oak, an elm, or chestnut, that has two stems, as it were, striving for the superiority, lop or prune off the straightest stem; and if a tree that is not likely to be of such value be standing on that side, to which the stem left seems to incline to a horizontal position, take away the tree, and thus give the other every chance of growing horizontally. At this time it will be necessary to take away a few of the perpendicular shoots off the horizontal branch; and, indeed, if these branches, which is sometimes the case in these trees, seem to contend, take away most of them; but if they do not, it is better at this time not to prune these trees over-much, except the crooked shoots on the horizontal branch, till they arrive at the height of fifteen or even twenty feet. By this time it will be easily seen what kind of tree it is likely to form; and, if it inclines to grow crooked, lighten a little the top of the tree, by taking off a few of the crooked branches on the straighter side, allowing all the branches to remain on the side to which the tree inclines to crook, to give it more weight, and to draw most of the sap or juice that way, and it will naturally incline more to the crook; at the same time clearing away any other tree on the crooked side, that may be apt, with the wind, to whip the side of the tree to which it inclines to crook, also taking away such tree of less value as may prevent it from spreading out to the one side more than to the other." He adds,

"I have myself tried the experiment with several oak-trees at about twelve feet high that were a little inclined to crook, and that had also a main branch inclined to a horizontal position. In the course of less than twenty years I had the pleasure of seeing some of these very trees grow so very crooked that the branch would work in with the main stem or body of the tree, to a complete knee, or square, which is the most valuable of all trees. And as ten trees of crooked oak are required for one straight one, it is of the most essential consequence to have crooked oak-trees; and, besides, an oak-tree, properly crooked, that will answer for a large knee — say the main branch, to be fit to work in with the body or trunk of the tree without much waste of wood, is nearly double in value to the same number of straight trees; and, indeed, knees of oak are extremely scarce, and difficult to be got."

6896. *Pontey* "knows of no way by which bends of tolerable scantlings (knees excepted) can be produced with certainty and little trouble, but from a side branch kept in a bent position by the branches of another tree or trees overhanging its stem." (*Forest Pruner*, 174.)

6897. *Coppice-woods*, in so far as grown for poles or bark, require pruning on the same principle as timber trees, in order to modify the ligneous matter into stem, and produce clean bark. In as far as they are grown for fence-wood, fuel, or besom-spray, no pruning is required.

6898. *Osier-holts* only require the laterals to be pinched off the shoots intended for hoops; those for the basket-maker seldom produce any. The stools also require to be kept free from dead wood and stunted knotty protuberances.

6899. *Hedge-rows* require side pruning, or switching, from their first planting, so as gradually to mould them into "the wedge shape, tapering from bottom to top on both sides equally, till they meet in a point at the top. Two feet at bottom is a sufficient breadth for a five-feet hedge: a greater or a less height should have the bottom wider or narrower accordingly. In dressing young hedges, either of the deciduous or evergreen kinds, the sides only should be cut till the hedge arrive at the proposed height, unless it be necessary, for the sake of shelter, to cut their tops over, in order to make the hedge thicker of branches. Such cutting of the upright shoots, however, is not of any very great use in this respect; because every hawthorn-hedge sends out a number of side shoots, which, if encouraged, by keeping the top narrow as above, will make it abundantly thick." (*Sang*, 447.) In pruning hedges, some use shears; but the hedge-bill (*fig.* 115.) is the most proper instrument, and prunes a smooth unfractured section, not so apt to throw out a number of small useless shoots as generally follow the bruised cut of the shears. (*fig.* 125.)

6900. *Hedge-row trees* require to be pruned to a tall, erect, clean stem, as at once producing more timber and doing least injury to the ground under their drip and shade.

6901. *Trees in strips for shelter, or screens for concealment*, ought to be furnished with branches from the bottom upwards; unless undergrowth supply this deficiency. Where this is not the case, care should be had that the trees be pruned into conical shapes, so as that the lower branches may be as little as possible excluded from the influence of the weather by the upper ones.

6902. *Trees for shade*, where shelter from winds is not wanting, should be pruned to ample spreading heads with naked stems; the stems should be of such a height that the sun's rays, at mid-day, in mid-summer, may not fall within some yards of the base of the trunk; thus leaving, under the tree, as well as on its shady side, a space for the repose of men or cattle.

6903. *Trees in parks* may be considered as chiefly ornamental; and for this purpose should be left with larger heads than such as are grown chiefly for timber. The height to which the stems are cleared of branches should vary according to the kind of tree (*fig.* 659. *a* to *e*); and hollies, thorns, and such shrubs as are left untouched, or that are

protected by enclosure from the cropping of cattle (*f, g*), should be left entirely to themselves. In parks, where no pruning whatever is given to the timber-trees by man, we find they are all pruned or browsed to a certain height by cattle: this adds to their character as trees, but in flat surfaces forms a disagreeable repetition of the horizontal line in which they stand. To break this *browsing line*, pruning is a simple, obvious, and effectual resource.

6904. *Some trees in pleasure-grounds and lawns*, where no cattle ever come, may be allowed to extend their branches so as they may almost recline on the turf; others may be pruned to different heights, according to their natures. Limes, planes, cedars, and firs have a fine effect with their branches depending from their trunks; and give an idea of seclusion and exclusive consecration to man, highly characteristic of what is called pleasure-ground.

6905. *The properly thinning out of plantations*, *Sang* observes, "is a matter of the first importance in their culture. However much attention be paid to the article of pruning, if the plantation be left too thick, it will be inevitably ruined." A circulation of air, neither too great nor too small, is essential to the welfare of the whole. This should not be wanting at any period of the growth of the plantation; but, in cases where it has been prevented by neglect, it should not be admitted all at once, or suddenly. Opening a plantation too much at once, is a sure way to destroy its health and vigor. In

thinning, the consideration which should in all cases predominate, is to cut for the good of the timber left, disregarding the value of the thinnings. For, if we have it in our choice to leave a good, and take away a bad plant or kind, and if it be necessary that one of the two should fall, the only question should be, by leaving which of them shall we do most justice to the laudable intention of raising excellent and full-sized timber for the benefit of ourselves and of posterity? The worst tree should never be left, but with the view of filling up an accidental vacancy."

6906. *In thinning mixed plantations*, the removing of the nurses is the first object which generally claims attention. This, however, should be cautiously performed; otherwise the intention of nursing might, after all, be thwarted. If the situation be much exposed, it will be prudent to retain more nurses, although the plantation itself be rather crowded, than where the situation is sheltered. In no case, however, should the nurses be suffered to overtop or whip the plants intended for a timber crop; and for this reason, in bleak situations, and when perhaps particular nurse-plants can hardly be spared, it may sometimes be necessary to prune off the branches from one side entirely. At subsequent thinnings, such pruned or disfigured plants are first to be removed; and then those which, from their situation, may best be dispensed with. At what period of the age of the plantation all the nurses are to be removed, cannot easily be determined; and, indeed, if the nurses chiefly consist of larches, it may with propriety be said, that they should never be totally removed, while any of the other kinds remain. For, besides that this plant is admirably calculated to compose part of a beautiful mixture, it is excelled by few kinds, perhaps by none, as a timber-tree.

6907. *But when the nurses consist of inferior kinds*, such as the mountain ash and the Scots pine, they should generally be all removed by the time that the plantation arrives at the height of fifteen or twenty feet, in order that the timber-trees may not, by their means, be drawn up too weak and slender. Before this time, it may probably be necessary to thin out a part of the other kinds. The least valuable, and the least thriving plants, should first be condemned, provided their removal occasion no blank or chasin; but where this would happen, they should be allowed to stand till the next, or other subsequent revision. At what distance of time this revision should take place, cannot easily be determined; as the matter must very much depend on the circumstances of soil, shelter, and the state of health in which the plants may be. In general the third season after will be soon enough; and if the plantation be from thirty to forty years old, and in a thriving state, it will require to be revised again, in most cases, within seven years. But one invariable rule ought to prevail in all cases, and in all situations; to allow no plant to overtop or whip another. Respect should be had to the distance of the tops, not to the distance of the roots of the trees; for some kinds require much more head-room than others; and all trees do not rise perpendicular to their roots, even on the most level or sheltered ground.

6908. *With respect to the final distance to which trees standing in a mixed plantation should be thinned*, it is hardly possible to prescribe fixed rules; circumstances of health, vigor, the spreading nature of the tree, and the like, must determine. Whether the trees are to be suffered to stand till full-grown; which of the kinds the soil seems best fitted for; whether the ground be flat or elevated; and whether the situation be exposed or sheltered, are all circumstances which must influence the determination of the ultimate distance at which the trees are to stand. It may, however, be said in general, that if trees be allowed a distance of from twenty-five to thirty feet, according to their kinds and manner of growth, they will have room enough to become larger timber.

6909. *Plantations of Scots pine*, if the plants have been put in at three or three and a half feet apart, will require little care until the trees be ten or twelve feet high. It is necessary to keep such plantations thick in the early stages of their growth, in order that the trees may tower the faster, and push fewer and weaker side branches. Indeed, a fir or soft wood plantation should be kept thicker at any period of its growth than any of those consisting of hard wood and nurses already mentioned; and it may sometimes be proper to prune up certain plants as nurses, as hinted at above for nurses in a mixed plantation. Those pruned up trees are of course to be reckoned temporary plants, and are afterwards to be the first thinned out: next to these, all plants which have lost their leaders by accident should be condemned; because such will never regain them so far as afterwards to become stately timber; provided that the removal of these mutilated trees cause no material blank in the plantation. Care should be taken to prevent whipping; nor should the plantation be thinned much at any one time, lest havoc be made by prevailing winds; an evil which many, through inadvertency, have thus incurred. This precaution seems the more necessary, inasmuch as Scots pine, intended for useful large timber, are presumed never to be planted except in exposed situations and thin soils. At forty years of age, a good medium distance for the trees may be about fifteen feet every way. It may be worthy of remark, however, that after a certain period, perhaps by the time that the plantation arrives at the age of fifty or sixty years, it will be proper to thin more freely, in order to harden the timber; and that, then, this may be done with less risk of danger, from the strength the trees will have acquired, than at an earlier period; but still it should be done gradually.

6910. *Plantations of spruce and silver firs*, intended for large useful timber, should be kept much in the manner above stated, both in their infancy and middle age. As already remarked, planting and keeping them as thick as is consistent with their health, is the best means of producing tall, straight, clean stems, and valuable timber. When planted for screens or for ornament, they require a different treatment; which will be noticed in the proper place.

6911. *To larch-plantations*, the above observations will also apply; and indeed they are applicable to plantations of all kinds of resinous trees. It may be proper here to remark, that the exposed margins of all young plantations should be kept thicker than the interior. The extent to which this rule should be carried, must be regulated according to the degree of exposure of the situation, the age of the plants, the tenderness of the kinds, and other circumstances.

6912. *The proper seasons for thinning* are autumn, or very early in spring, where the trees are to be taken up by the root and replanted elsewhere; and winter for thinning for timber and fuel; but such trees as are valuable for their bark should be left untouched till the sap rises in April or May. Copse-woods require thinning when young, like other plantations, and when once established the stools require to be gone over the second year after cutting, and all superfluous suckers and shoots removed. This operation should be repeated annually, or every two or three years, in connection with pruning, till within three or four years of the general fall of the crop.

6913. *Ornamental plantations* require to be thinned on principles agreeable to the intention with which they were planted. In the artificial forms, the figure must be carefully preserved, as the main object; and in plantations in imitation of nature, the principle of grouping and connection must be kept steadily in view. A thin part is to be rendered thinner, and a thick group, or constellation of plants not opened up, but merely deprived of such trees as are becoming smothered by the rest.

6914. *Improving neglected plantations.* Though it has been more or less fashionable, for upwards of a century, to form plantations; yet it has been also so generally the custom to neglect their future culture, that by far the greater proportion of the surface covered with trees in Britain may be considered as neglected or mismanaged. The artificial strips and masses have generally never been thinned or pruned; and the natural woods and copse-woods improperly thinned, or cut over. It is often a difficult matter to make much of such cases; and always a work of considerable time. "Trees," Sang observes, "however hardy their natures may be, which have been reared in a thick plantation, and consequently have been very much sheltered, have their natures so far changed, that if they be suddenly exposed to a circulation of air, which under different circumstances, would have been salubrious and useful to them, will become sickly, and die. Hence the necessity of admitting the air to circulate freely among trees in a thick plantation, only gradually and with great caution. To prevent a misfortune of this kind, a plantation which has become close and crowded, having been neglected from the time of planting till perhaps its twentieth year, should have only some of the smallest and most unsightly plants removed: one perhaps, in every six or eight, in the first season; in the following season, a like number may be removed; and in two or three years after, it should be gone over again, and so on, till it be sufficiently thinned. It will be proper to commence the thinning, as above, at the interior of the plantation, leaving the skirts thicker till the last; indeed, the thinning of the skirts of such a plantation should be protracted to a great length of time." With thinning, pruning to a certain extent should also be carried on. "If the plantation," Sang observes, "consists of pines and firs, all the rotten stumps, decayed branches, and the like, must be cut off close by the bole. It will be needful, however, to be cautious not to inflict too many wounds upon the tree in one season; the removing of these, therefore, should be the work of two or three years, rather than endanger the health of the plantation. After the removal of these from the boles of the firs and larches, proceed every two or three years, but with a sparing hand, to displace one or perhaps two tiers of the lowermost live branches, as circumstances may direct; being careful to cut close by the trunk, as above noticed. In a plantation of hard wood, under the above circumstances, the trees left for the ultimate crop are not to be pruned so much at first as might otherwise be required; only one or two of their competing branches are to be taken away, and even these with caution. If it be judged too much for the first operation to remove them entirely, they may be shortened, to prevent the progress of the competition; and the remaining parts may be removed in the following season; at which time, as often observed, they must be cut close by the bole." (*Plant. Kal.* 467.)

6915. *The operation of thinning and pruning,* thickening or filling up, or renewing portions that cannot be profitably recovered, should thus go on year after year, as appearances may direct, on the general principles of tree culture. And for this purpose the attentive observation and reflection of a judicious manager will be worth more than directions which must be given with so much latitude. Pontey has noticed various errors in Kennedy's *Treatise on Planting*, and even in Sang's *Kalendar*, on the simple subject of distances, which have originated in their giving directions for anticipated cases, which had never come within their experience. "Most people," he says, "take it for granted, that if trees stand three feet apart, they have only to take out the half, to make the distances six feet, though to do that, they must take down three times as many as they leave. By the same rule again, most people would suppose, that twelve feet distance was only the double of six; but the square of the latter is only thirty-six, and that of the former one hundred and forty-four, or four times the latter; so that to bring six feet distances to twelve, three trees must be removed for every one left." (*Profitable Planter*, 256; *Forest Pruner*, 21.)

6916. *Copse-woods* are sometimes improved by turning them into woods, which requires nothing more than a judicious selection and reservation of those shoots from the stools which are strongest, and which spring more immediately from the collar. But a greater improvement of copse-woods consists in cutting over the overgrown and protuberant stools, by the surface of the soil (*fig.* 660. *a, b, c, d*), which has been found by Monteath completely to regenerate them. The operation is performed with a saw, in a slanting direction, and the young shoots being afterwards properly thinned and pruned, soon establish themselves securely on the circumference of large, and perhaps, rotten-hearted roots. (*Forester's Guide*, 60.)

6917. *Hedge-rows* are often neglected, and, like larger plantations, require renovation by cutting down and filling in vacancies, and by cultivating the soil at their roots. Hedges, Sang observes, which have been long neglected, shoot up to a great height like trees, become naked at bottom, and occupy too much ground, at least for lands in a state of high cultivation. The best method of reducing such to a proper size, and of forming them into an immediate fence, is by plashing.

6918. *Plashing.* This consists in selecting the strongest and straightest shoots. These are to be dressed up and headed down to four feet, and in such a way that the tops of the whole may range in a neat line. These are called the stakes; and, when they are deficient, either in strength or number, recourse must be had to artificial stakes, which must be driven in to stand firm, and supply the deficiency of natural ones. Having proceeded thus far in preparing the hedge for plashing, the hedger is to begin

at one end, and bend down as close as possible the remaining pliable branches, crossing them in the manner of basket-work. Such as are too strong to be bent, may be cut half through with the bill, which will render them pliable enough to be used; and such as are not required for any of the above-mentioned purposes, must be cut off close to the ground. After the plashing is finished, the hedge should be dressed smooth on both sides by the switching-bill or shears. There is another method of plashing, which has been suggested as an improvement upon the foregoing; and that is, by not cutting any of the stems over as stakes, but weaving in the tops along with the other branches. This method will not have so immediate a tendency to bare the lower parts of the hedge by the growth of the top, as when any of the plants are cut over for stakes; but still, at the bendings, the growth will rush out with vigor; besides this plan is attended with more labor. Indeed, the best security against baring the bottom of a plashed hedge, is by cutting over by the surface as many of the plants as can be at all spared; and the shoots arising from these will soon thicken the hedge at bottom. Plashing can only be effectually and handsomely performed, when there is a good portion of long, pliable, and well feathered branches, and where the hedge has, if not youth, at least vigor, on its side. After the plashing is completed, the ditch is to be scoured out, and the bottom of the hedge cleaned and dressed up, in the same neat manner as if all were new work.

6949. *Cutting over old hedges* is a much less expensive method of reclaiming or renewing, than any of the above; and, perhaps, in most cases, may be a more eligible one; saving when an immediate fence is the object. In cutting down an old hedge, there is certainly a very fit opportunity of laying the foundation of a complete and durable fence. The nature of the cutting must be regulated by circumstances, according to the age, the strength, or the closeness of the hedge, and whether it have been planted in single or double rows. If the hedge in question be pretty vigorous and branching towards the bottom, and if the stems stand regularly and closely together, it may be brought into due subjection, without being cut down to the ground. In this case, the sides are first to be switched up with the hook, not altogether close to the stems, but within about a foot of them on each side at bottom, tapering up close at top, which should be four or five feet high, according to the general height of the hedge: but if the hedge be thin at bottom, it will be advisable to cut more in, in order to make it bushy from the ground upwards. If the hedge is not regularly close from end to end, but ragged, and full of gaps, the best method is to cut it over, within eight or ten inches of the ground, and to fill up the gaps with stout well rooted plants of the same kind; or the gaps may be mended by the following method:—Let one of the stoutest thorn-plants next to the gap be reserved uncut, and the space be dugged over, or it may require to be filled up with rich earth to within three inches of the height of the top of the ditch. Then having cleaned the thorn-plant of all side branches or twigs, cut it half through at the height of the earth in the gap, on the side farthest from it, and lay it down upon the earth, securing the most distant end from rising up by a hooked pin; then cover it all over with rich earth, so as to make it the general height of the top of the ditch: and the thorn-plant so laid down and covered, will take root, and send up a profusion of shoots over its whole length. If one plant will not reach the whole extent of the gap, one at each side probably will. The surface of the bank should be pointed up, and the ditch scoured as above directed in plashing.

6920. *In other cases*, when the hedge is getting thin below or too tall, and when the stems are placed regularly within eight or ten inches of one another, and where it is necessary to retain a fence and at the same time to cut so as to have a supply of young shoots from the bottom, the plan to be followed is to cut alternately the one part to within eight or ten inches of the bottom, and the other at four feet high, dressing the bank and scouring the ditch, as directed above. In cases where two rows of quicks have been planted, the front one is to be cut by the surface, and the other at four or five feet high, as circumstances may require.

6921. *Neglected hedge-row timber* may be improved by pruning according to its age. Blakey recommends what he calls foreshortening, or cutting in, as the best method both for young and old hedge-row timber. "This operation is performed by shortening

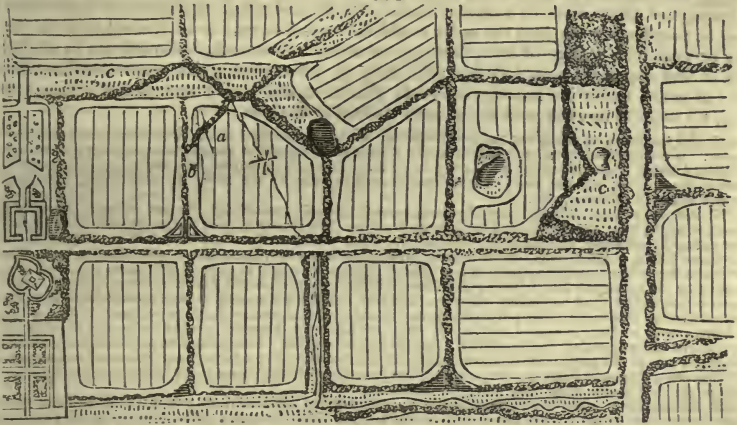

the over-luxuriant side branches (*fig. 661. a*), but not to cut them to a stump, as in snag pruning; on the contrary, the top only of the branch should be cut off, and the amputation effected immediately above where an auxiliary side shoot springs from the branch on which the operation is to be performed (*b*); this may be at the distance of two, four, or any other number of feet from the stem of the tree; and suppose the auxiliary branch which is left (when the top of the branch is cut off) is also over-luxuriant, or looks unsightly, it should also

be shortened at its sub-auxiliary branch, in the same manner as before described. The branches of trees pruned in this manner are always kept within due bounds; they do not extend over the adjoining land to the injury of the occupier, at least, not until the stem of the tree rises to a height out of the reach of pruning, when the top branches can do comparatively little injury to the land. By adopting this system of pruning, the bad effects of close pruning on old trees, and snag pruning on young ones, will be avoided; the country will be ornamented; and the community at large, as well as individuals, benefited."

6922. *Hedge-rows* frequently require to be altered in direction to improve the form, or increase the contents of farm-enclosures. (fig. 662.) Generally, and especially in

662

flat arable lands, this is done by eradicating such as are in unsuitable directions (*a*), and substituting others (*b*) in parallel, or at least in straight lines; but in rising grounds, and where the surface will be improved by shelter, it frequently happens that a crooked hedge is superseded by two straight ones, and the interval (*c*) filled up with plantation. The advantage of straight-lined fields to a farmer is very considerable; and when this object is procured in the latter way, an improvement is produced both useful and ornamental.

6923. *Ornamental plantations* are no less frequently neglected than such as are considered chiefly useful. Clumps, belts, and screens which have become thin, because they have not been thinned, are almost every where to be met with. "In those neglected plantations," says Lord Meadowbank, "where daylight may be seen for miles, through naked stems, chilled and contracted by the cold, the mischief might, perhaps, be partially remedied, by planting young trees round the extremities, which having room to spread luxuriantly, would exclude the winds, and the internal spaces might be thickened up with oak, silver fir, beeches, and such other trees as thrive with a small portion of light. When once the wind is excluded, the weakest of the old trees might be taken out, and the others left to profit by the shelter and space that is afforded." (*Life of Lord Kaimes, by Tytler.*) One of the most hopeless cases of improvement in this department is that of an old clump of Scotch pines (fig. 663.), from which scarcely any trees can be taken without risking the failure of the remainder. The only way is to add to it, either by some scattered groups in one direction, or in various directions. Where a clump consists of hard wood, either entirely or in part, it may sometimes, if effect permits, be reduced to a group, by gradually reducing the number of the trees. The group left should be composed of two or three trees of at least two species, different in bulk, and somewhat in habit, in order that the combined mass may not have the formality of the clump.

663

6924. *Scattered trees in ornamental scenery* otherwise of very good shapes, and very well managed as to pruning, destroying the browsing line, &c. individually, are often, from want of thinning in some places, and thickening in others, deficient in massiness

664

(fig. 664.); the obvious remedy is to thin out some (*a*), and plant others, ^a so as to destroy the straggling non-cooperating appearance which such trees present, and produce something of grouping, massiveness, and character. (fig. 665.)

665

6925. *Wounds, bruises, casualties, and defects of trees.* Small wounds, such as are required to be made by judicious pruning, easily heal up of themselves; large wounds, by amputations of branches, above six inches' diameter, should, if possible, never be made. Even wounds of six inches' diameter, or under, will heal quicker by the application of any material which excludes the air and preserves the wood from corruption; and we agree with Sang, in recommending coal-tar, or the liquor produced from coals

in manufacturing gas. It is, however, less favorable to the progress of the bark over the wound than a coating of clay or cow-dung, covered with moss to keep it moist. Pontey recommends putty and two coats of paint over it. In case the wood, at a *bruised* or amputated place, have by neglect become already corrupted, the rotten or dead wood is to be pared out quite into the quick; and the wound is then to be dressed with tar, or clay covered with a piece of mat, sacking, or moss. A wound, hollowed out as above, may at first appear an unsightly blemish; but, in subsequent years, nature will lay the coats of wood, under the new-formed bark, thicker at that place; and probably may, in time, fill it up to be even with the general surface of the tree.

6926. All *fractures*, by whatever means produced, are to be managed as the circumstances of the case require. If a large branch be broken over at the middle of its length, it should be sawn clear off close by the lateral which is nearest to the bole of the tree: but, if there is no lateral, or branch, capable to carry forward the growth, cut the main or fractured branch in quite to the bole. In both cases, treat the wounds as above recommended.

6927. *Interior rotting*, arising from the dampness of the soil, cannot by the art of man be cured; though it might have been prevented by timely draining. The hearts of trees frequently rot, where there is no excess of moisture, and especially such as have been produced from old roots left in the ground by a previous felling. Such roots, when in good ground, send up very great shoots with few leaves in proportion to their sizes; by the absence of a profusion of these, properly to concoct the juices so abundantly supplied by the roots, the fibre of the wood is loose and imperfect; the next season will supply more leaves in proportion to the supply of juices, yet not a sufficient number for making perfect timber; several years may pass before this event arrive: thus crude and ill digested timber disposed to premature decay, is the foundation over which subsequent coatings of wood are laid: yet, however perfect these may be, they do not prevent the progress of decomposition going on in the interior. Nature teaches how necessary numerous leaves are to the proportion of the solid wood; the cotyledons and subsequent leaves of a one-year-old tree are a thousand times greater, compared to its solid contents, than are the leaves to the solid contents of the first year's shoots from roots like the above.

6928. *Shakes* often arise from the weight and multiplicity of top branches, and might have been prevented by timely pruning. Shakes or rents in the boles of trees, however, often happen where there is no excess of tops. Sometimes the rain running down from the branches, wets one part of the bole, while the rest is comparatively dry. If this circumstance is succeeded by an intense frost, before the wetted side becomes dry, the bole may be rent for a great length, and perhaps to the depth of the core. Shakes or rents, like the above, are difficult to cure. The best method of helping them, is to trace out their upper extremity, caulk it up with oakum, and pitch it over, to prevent the rain descending that way in future. (Sang.)

6929. In cases of *hollowness*, Pontey recommends probing to the bottom, letting out the water, if any, with an auger, drying the cavity with a cloth, filling it with dry sand, plugging it with wood and oakum, and then painting it over.

6930. *Decorticated stems* or branches stripped by lightning, or otherwise, if the soft wood is not much injured, will heal over and become covered with bark; and this the more certainly and rapidly if the air be excluded by a coating of adhesive matter, as cow-dung and quick-lime, or tying on moss or bandages of mat or cloth. Pontey gives an instance in which such treatment was successful in the case of an apple-tree. (Pruner, 230.) We have witnessed it on an extensive scale on the trunk of a pear-tree; and we are informed, on the best authority, of other cases now under progress, in the government garden of the Luxembourg at Paris, as matter of experiment, by Du Thouars, a most ingenious physiologist.

6931. *Withered or decayed tops* may arise from age and incipient decay; but also, as Pontey states, from improper pruning, or the want of it. We often see it from improper pruning of elms, which, after having been close pruned to their summits for many years, are left entirely to nature; in that case they branch out luxuriantly below, and the top withers. By neglecting to thin out the branches on the stems of non-resinous trees, the same effect may be produced.

6932. *Stunted bushy tops* show a deficiency of nourishment; on very tall naked stems it is from these circumstances; and on short stems from defects in the soil. *Obliquely placed misshapen heads*, in detached trees, commonly proceed from the same causes and want of shelter. Stunted growth, both in tops and stems, is also produced by ivy, and by lichens, mosses, the mistletoe, and other parasites. Ivy compresses the bark, precludes its expansion, as well as excludes air and moisture, by which the outer bark becomes rigid and corky. Happily, both men and trees will live a long time under the influence both of deformity and disease.

6933. *Excessive exudations of gum and resins* are peculiar to resinous and some other trees when over-pruned, or pruned at improper times. Mildew, honeydew, and blight, three popular names applied to the effects of certain insects of the *aphis* kind, attack the oak, beech, poplar, and many trees: all that can be said is, if proper regimen has been regularly attended to, trees will overcome these and all other enemies.

6934. *Insects and vermin*. Almost every tree has its particular insect of the hemipterous and dipterous families, and many of the coleoptera family are common to all. The foliage of the small-leaved elm of hedges is often almost entirely destroyed in the early part of the season by tenthrædinidæ; and those of the larch and Scotch pine have suffered materially in some seasons from aphides. The *Aphis laricea*, L. (*Eriosomata* of Leach) increased to an alarming extent from 1800 to 1802, on the larch, on account of three dry seasons following each other; but, though it retarded their growth, it ultimately destroyed very few trees. Sang says he has known it since 1785; that it dirties more than injures the tree, and is now (1819) thought little of. Indeed, almost every species of tree has been known to have suffered in some one or more seasons, and in particular districts from insects; for which, on so large a scale, there seems to be no applicable remedy but patiently waiting till their excess, or the increase of other vermin, their natural enemies, or a change of seasons, cause them to disappear. Trees, properly cultivated and managed, generally overcome such enemies. The hare is well known to be very injurious to young trees, and especially to laburnums, by gnawing off their bark. Coating their stems with dung and urine, fresh from the cow-house, is said to be an effectual remedy. It may be put on with a brush about two feet high; a barrow-load will suffice for a hundred trees, with stems of three or four inches in diameter; and its virtue, after laid on, endures at least two years. (Bull, in *Caled. Hort. Mem.* iv. 190.)

CHAP. VI.

Of appropriating the Products of Trees, preparing them for Use or Sale, and estimating their Value.

6935. *Of the different products afforded by trees*, the first is their leaves, which are or may be collected in close plantations for the sake of the manure they afford; and in open groves, parks, and lawns, for that purpose, and to prevent their injuring the grassy surface. Leaves are also gathered on the continent as food for cattle. Though, at first consideration, leaves would appear to benefit pastures by sheltering the roots of the grass during winter, and afterwards rotting into manure; yet experience proves, that in considerable quantities they impede the growth of the grass plants, by bringing on decay at their roots, in all probability owing to their exclusion of air. For this purpose, in well wooded parks, the leaves are carefully collected in the beginning of winter, and carried to rot-heaps in secluded situations, where in two years from the time of gathering, they become the valuable mould so much in demand by the gardener. A very ingenious machine for sweeping together, and at the same time lifting up leaves into a box or receiver, has been invented by Snowdon, a London machinist, and has been partially in use in Windsor Forest and at Hampton Court; it is also calculated for cutting or wrenching off weeds, (as clean cut weeds are found to grow again, the same season, while the roots of the others often rot,) or mowing and lifting the weeds or swarth into the cart; but it is not yet sufficiently matured to enable us to describe it as completely answering all its intended purposes. Great credit, however, is due to the ingenious inventor, who has been occupied on it for upwards of two years, and who has spared neither time nor money.

6936. *Prunings or spray* are the next product of trees; those which they afford at a very early period, and all clippings of hedges or artificial forms, are only fit to be used as leaves; the larger prunings may be used for some of the various purposes to which copse-wood and the lop of trees are applied. On the continent, and especially in Sweden and Norway, spray of all kinds is carefully faggotted in summer, dried and slacked for the use of cattle in winter. This was also the practice of the Romans, who preferred the spray of the elm, as the Swedes do that of the birch.

6937. *The thinnings*, when not beyond a suitable age, and taken up properly (6905.) and at a proper season, may be replanted in other situations, or as single trees and groups; or they may be used as hoops, hop-poles, poles for garden-training, for fencing, for props in coaleries, and for a great variety of purposes; those whose barks are useful for tannin should not be cut down or rooted up till May, but the others at any time during winter. It is common to sort them into lots, according to their kind or size; and to faggot up the spray for fuel, besom-stuff, or for distilling for bleachers' liquid. See *Copse-woods*, (6941.)

6938. *The seeds of trees* in general cannot be considered of much use beyond that of continuing the species, and therefore, in very particular cases, where it is desired a tree should attain bulk as rapidly as possible, the flowers should be pinched off as they appear. The seeds of the oak, beech, and sweet chestnut, however, are valuable for feeding swine, and where they abound may either be swept together after they drop, and carried away and preserved dry in lofts for that purpose; or if other circumstances are favorable, swine may be driven under the trees to collect them. These, and other seeds, as the haw and holly, are also eaten by deer. The seeds of the trees mentioned, and of all the resinous tribe, are in general demand by the nurserymen for the purposes of propagation. The seeds of almost all other trees and shrubs are also in limited or occasional demand; or may be collected for private sowing. They generally ripen late in the season, and are to be collected in the end of autumn or beginning of winter, with the exception of a few, such as the elm, poplar, willow, and one or two others, which ripen their seeds in May or June.

6939. *In osier-grounds*, willows, whether intended for the basket-maker or cooper, should not be cut till the second season after planting, in order to strengthen the stools; but by the third autumn the crop will be fit for the basket-maker, and the fourth, plantations intended for the cooper (hoops requiring the growth of two years) will be ready. The seasons for cutting are November and March; after the former period the wounds are apt to be injured by frost, and after the latter the sap is too far advanced; some is lost by bleeding, and the buds are developed too suddenly to admit of proper strength in the shoots. The cut should be made within three buds of the point whence the shoot issued, in a sloping direction, and the section on the under-side. (1885.) In cutting hoop-willows, the swell at the bottom of the shoot only should be left, that being furnished with abundance of buds for future growth. After being cut, the hoops are trimmed from any side shoots, and tied up in bundles of a hundred, of six scores each, which, in 1820, sold for from four shillings to five shillings a bundle. The willows are sorted into three sizes, and tied in bundles two feet in circumference, within a foot of the lower ends. When to be peeled, they are immediately after cutting set on their thick ends in standing water, a few inches deep, and there they remain till the growth ascends freely, which is commonly by the end of the succeeding May. "The apparatus for peeling is simply two round rods of iron, nearly half an inch thick, sixteen inches long, and tapering a little upwards, welded together at the one end which is sharpened, so as that it may be easily thrust down into the ground. When thus placed in a piece of firm ground, the peeler sits down opposite to it, and takes the willow in the right hand by the small end, and puts a foot or more of the great end into the instrument, the prongs of which he presses together with the left hand, and with the right draws the willow towards him; by which operation the bark will at once be separated from the wood: the small end is then treated in the same manner, and the peeling is completed. Good willows peeled in the above manner, have been sold for some seasons past, at from six shillings and sixpence to seven shillings the bundle of four feet in circumference. After being peeled, they will keep in good condition for a long time, till a proper market be found."

6940. *Copse-woods* are generally cut over when the shoots of the stools have attained from three to five inches' diameter at their bases; some grown chiefly for hop-poles, and ware or stuff for crates, hampers, or wattled hurdles, are cut over earlier, and others, where small timber for fencing and other country purposes is wanted, are left later. In some parts of Herefordshire, where the oak grows with great rapidity, copse-woods are cut over every twelve years; in the highlands of Scotland, where it grows much slower, the time varies from twenty to twenty-five or thirty years. "The bark is there considered as having arrived at its utmost perfection, and at its highest value, at the age of between twenty and thirty years: under that age, its virtues are weak; above it, the bark becomes coarse and loses its sap. Another important reason for cutting down oak coppice-wood about the above period, is suggested in the *Stirling-*

shire Report, p. 218.; namely, 'that it is a fact established by experience, that it will not renew itself, if it remains uncut, beyond the space of about forty years.' (*Gen. Rep. of Scotland*, 218.) Where there is a considerable tract of copse-wood, it is common to *divide it into portions*, in number according to the period of cutting. These are to be cut in rotation, so that when the last portion is cut over, the first is again ready for cutting.

6941. *The season for cutting* the kinds of trees whose barks are not made use of, is winter and early in spring; but the oak and other trees which are peeled, are left till the middle of April or May. Birch and larch woods will peel nearly a month earlier than the oak. Should there be no frost, birch and larch may be peeled about the beginning of April; but the birch is commonly allowed to stand till July, and the peeling of it is commenced after that of the oak has been completed; and the reason is, there is an outer skin upon birch-bark which requires to be taken off, as it is of no use to the tanner, and renders that part which is of use more difficult to be ground, and the month of July is the only time at which the two barks can be separated with ease, as at this time the juice or sap has made its circulation through the tree and bark, and this circumstance renders the separation more easy. From the beginning of May to the middle of July is the usual time for barking the oak. The earlier in the spring this operation is performed on the oak, both for the growth, if a natural wood, and for the bark, the better. When the sap has begun to rise, the bark will easily be detached from the wood, and it ought then to be taken off without loss of time; and if the whole could be taken off before the leaf is completely developed, the bark would be better. After the sap has arisen to the leaf and new growth, the bark becomes more dry, and requires more beating to separate it from the wood. And when what is called the black sap is descending the tree, the bark taken off is black, and loses its original color; and at this time also the bark begins to throw off a scurf, more especially young bark without much cork on it; this outer skin having less of the proper sap or juice, and being much drier when taken off, will weigh less, and consequently will not be so valuable. If possible, oaks should be barked by the middle of June, as every ton of bark taken off after the first of July will be deficient two cwt. per ton, compared with the same quantity taken off in May or early in June.

6942. *The termination of cutting* is generally fixed for the fifteenth day of July, and after this date there should not be a single stool of oak wood cut that is intended for the growth; and as soon as possible after the fifteenth, the whole of the wood and bark should be carried away, that the young growths may not be disturbed or injured, as at this time they will have made considerable progress; at any rate, there should neither be wood nor bark remaining within the new cut hag after the first of August; nor should either horse or cart be permitted to enter it after that period, for after the beginning of August, oaks make what is termed a lammas growth, and the future prosperity and health of the coppice, in a great measure, depend on the first year's growth, as far as regards form and vigor of the shoots. (*Forester's Guide*, 69.)

6943. *The best mode of cutting* is evidently that of using a saw, and cutting the shoots over in a slanting direction close by the surface. When the stool, after having been cut several times, has acquired considerable diameter, it is customary in the midland counties, Marshall states, to hollow it out in the centre, from a notion that by rotting away the central roots, the circumferential stems will grow more vigorously, and become as it were separate plants. This is in fact the case in very old copses. For several cuttings, however, it must evidently be the safer policy to keep the stool highest in the middle to throw off the rain, and preserve it sound.

6944. *Monteath says*, "It will be found, upon experiment, perfectly evident, that stools dressed down to the surface of the ground, (taking care always not to loosen the bark from the root, or allow it to be peeled off in the smallest degree below the earth, but rounded down level to it,) that these stools will send forth the most vigorous shoots, and stand the weather, and be the stoutest and best throughout the age of the coppice." (*Forester's Guide*, 61.) From the late season at which the trees to be barked are generally cut, they often receive considerable injury, both from that circumstance, and the manner in which the operation is performed. Monteath appears to us to have furnished the best directions for executing the work in a safe manner. He first sends a person furnished with an instrument with a sharp cutting edge (*fig. 140*) through the copse, whose business is "to trample down the long grass or foggage all round the root, and then, to make a circular incision into the bark so deep as to reach the wood, at about an inch above the surface of the earth; thus the bark when taken off, will injure no part of that which is below the circular incision."

6945. *The root of the tree being thus prepared*, the cutters ought to proceed to their part of the work, not with an axe, however, as is most generally recommended, but with a saw, because, in cutting with the axe unless the root of the tree be so small in diameter as to be severed in one or two strokes at most, the axe loosens the root to such a degree, that it not only loses the present year's growth, but often fails altogether to grow. Therefore if the diameter of the root be six inches, or upwards, it should always be cut with a cross-cut saw; entering the saw about half an inch above where the circular incision has been made into the bark, if a small tree; but if the tree be ten or twelve, or more inches in diameter, the saw ought to be entered two inches above it.

6946. *There are two advantages to be derived from cutting with the saw*; it has no tendency to loosen the root of the tree, but leaves it in such a condition as to be more easily and properly dressed; it also saves a portion of the wood that would otherwise be destroyed by the axe. On no pretence should oaks of six inches' diameter be cut with an axe, but always with a saw. Having cut through the tree with a saw, take a sharp adze, and round the edges of the stool or root, going close down to the surface of the earth, taking with the adze both bark and wood, sloping it up towards the centre of the stool, taking particular care always that the bark and wood both slope alike, as if they formed one solid body, being sure always that the bark be not detached from the root. An objection has been made to this mode of cutting with the saw, as taking up too much time; but I have found that two men with a cross-cut saw, kept in good order, will cut as much as two men will with an axe. (*Forester's Guide*, 58.)

6947. *The disbarbed timber* is prepared for sale by being sorted into straight poles of the largest size, stakes and other pieces fit for palings, faggots, fuel, &c. The unbarbed wood is similarly sorted, and affords, where there is much hazel or ash, cord-wood or bundles of clean shoots for making packing crates, hampers, &c., poles for hops, larger poles for fences, rails, paling-stakes, stakes and shoots for hurdles, besom-stuff, spray for distillation, and a variety of other objects according to the local demand, or the opportunity of supplying a distant market by land-carriage. The brush or spray of non-resinous trees is called in some places ton-wood, and is used for distilling the pyrolignous acid used in bleach-fields and calico print-works. "When wood of this description is sent to Glasgow, where there are extensive works for the purpose of distilling it, it sells readily at from 11. 2s. to 11. 10s. per ton; but when there are large cuttings, particularly of young woods, it is worth while to erect boilers near the wood to distil it, as these boilers can be erected at no great expense, and in this case the liquid is easily carried in casks to where it is consumed, at less expense than the rough timber could be; of course it will pay much better. Small wood of this description is also used for charcoal: but in distilling it, there is part of it made into charcoal, which will supply the demand of that article, so that it is by far the most profitable way, when there is any great quantity to dispose of, to erect boilers and distil it; unless where the local situation of the wood will admit of its being shipped at a small expense, and carried to where the works mentioned are carried on. All kinds of wood will give the extract in question, excepting fir; but oak, ash, Spanish chestnut, and birch, are the best." (*Forester's Guide*, 155.) Where the oak grows slow, as in the highlands, the butt-ends of the poles are used for spokes for chaise-wheels. "Long spokes are from thirty to thirty-two inches by three inches and a half broad, and one inch and a half thick, and the short ones for the same purpose, from twenty-two to twenty-four inches long, and the same sizes otherwise. Cart-

wheel spokes, from twenty-six to twenty-eight inches long, four inches broad by two inches thick. These are the sizes they require to stand when rough-blocked from the axe. Small wood when sold for this purpose, brought, in 1820, 2s. a cubic foot, measured down to three inches square." (*Monteath*.)

6948. *In some cases cope-woods are sown with grass-seeds, and pastured by sheep, horses, and cattle. Some admit the animals the fifth year after the last cutting, others not till the eighth; but Monteath thinks this should never be done till the fifteenth year. If the ground is properly covered with trees, it can seldom be advantageous to admit any species of stock unless during a month or two in winter.*

6949. *In the operation of barking trees, "the barkers are each furnished with light short-handled mallets, made of hard wood, about eight or nine inches long, three inches square at the face, and the other end sharpened like a wedge, in order the more easily to make an incision in the bark, which is done all along the side of the tree which happens to be uppermost, in a straight line: and as two barkers are generally employed at one tree, it is proper, that whilst the one is employed in making an incision with the mallet, as above, the other being furnished with the barking-bill (fig. 140.), cuts the bark across the tree, in lengths of from two feet six inches to three feet. Having thus made the incision in the bark, both ways, the barkers being also each furnished with peeling-irons (figs. 136. to 139.), if the tree or piece of timber to be barked is such as the two barkers can easily lift one end of it, this is placed on two pieces of wood, three feet long, and called horses; these are about the thickness of a paling-stake, and have a forked end on each about six inches long, the other end sharpened to go into the ground; two of these horses are placed in a triangular form against one another, one end of the piece to be peeled being raised on the horses, the two barkers standing opposite to each other, and entering the peeling-irons into the incision made by the mallet, and pressing the iron downwards between the bark and the timber. In this way it will be found very easy to take the bark off in one whole piece round the tree; and, if possible, let these pieces be as long as the incisions made in the bark. In some cases, where there is not much sap, the bark may require a little beating with the square end of the mallet, to cause it to separate easily from the wood; but the less beating with the mallet the better, as it has a tendency to blacken the bark in the inside, or fleshy part of it, so that when the tanner sees it, he supposes it to be damaged, and undervalues it. The branches of the tree being previously all lopped off with the axe, the persons, in number according to the extent of the work, with the bill smooth all the branches, cutting them in lengths of from two feet six inches to three feet, down as small as one inch in circumference. The barkers, principally women, are each provided with a smooth hard stone of about six or eight pounds weight, beside which they sit down, and having collected a quantity of saplings, branches, or twigs, they hold it on the stone with one hand, and with the mallet in the other, they beat the piece till the bark be split from the wood, from the one end to the other, and taking it off all the length of the piece, if possible, then lay it regularly aside, till a bundle of considerable size is formed."*

6950. *Drying the bark. "The point most particularly to be observed in this art is, putting the bark up to dry; which is done by putting the bark upon what is called the lofts or ranges. These are erected by taking forked pieces of the loppings, called horses, the one three feet long, the other two feet six inches, and driving each about four inches into the ground, opposite one another, about two feet asunder in the breadth, and as much betwixt them, lengthways, as will admit long small pieces of wood to be put upon them, and as many of these must be put together as will hold the bark of every day's peeling. These ought to be erected in as dry and elevated a spot as can be found in the margin of the wood or better outside of it. The bark being carried and laid on this loft, with the thick ends of it all laid to the high side of the range, and the small bark laid on to the thickness of about six inches; and the bark taken off the largest of the wood laid regularly on the top, which serves for a covering, and the lofts or ranges having a declivity of about six inches, the rain will run off them readily, and if properly put up in this manner, they will keep out a great deal of rain. After it has lain in this state for three days, if the weather is good and dry, it ought to be all turned over, and the small bark spread out, so as not to allow it to sit together, which, if much pressed, it is apt to do; and if it does so with the natural sap in it, it has a chance of moulding, which is extremely hurtful to the bark, and both lessens it in weight and in value. After the bark has stood on the ranges about eight or ten days, if the weather be good, it may either be put into a house or a shed, or if intended to be put up into a stack, it may now be done." A stack of bark ought never to exceed eight feet in width, and twelve or fifteen feet in height, raised in the middle like a haystack. If it is to stand any length of time in the stack, it ought to be thatched, and in that state may remain all winter. The greatest care ought to be taken to preserve the color of the inner parts of the bark, because the color of it is generally looked to as a principal criterion of its value, and the merchant or tanner judges of its value chiefly by its color. Before being put into the stack, the natural sap ought to be dried out of it, in order to prevent its fermenting; because if a fermentation takes place in one part of the stack, it generally goes through and spoils the whole. The same mode of treatment will do for all kinds of bark as well as the oak; but the birch has an outer or shedy skin upon it, that is of no use, and rejected by the tanner, and, as already observed, must be peeled off.*

6951. *Chopping the bark. "When the bark is ready for the tanner, it has to undergo the work of chopping, which is done by driving in two or more stakes into the ground, with a fork on the upper end of each, leaving them about two feet six inches from the ground, and laying a long small piece of wood across between the two, where a number of people stand, and the bark is carried and laid down behind them, which they take up in their hands and lay on the cross tree, and then, with a sharp whittle or bill in the other hand, they cut it into small pieces, about three inches in length; when this is done, it is trampled into bags, which hold about two hundred weight each, and in these bags it is weighed when sold by the ton, in tons, hundred weights, quarters, and pounds, and in the above manner delivered to the merchant or tanner." (*Forester's Guide*, 199.)*

6952. *Pollard-trees, which may be considered in most cases as injurious deformities, are lopped at stated periods like cope-woods, and the lop, whether to be barked or otherwise, is to be treated in all respects like that of cope.*

6953. *The period at which trees are felled, for the sake of their timber, is determined by various causes. By maturity of growth, or where the annual increase is so trifling as*

to render their standing no longer worth while in point of profit: when wanted for private use or sale; or when defects in the tree, or new arrangements, in its situation, point out the necessity of its removal. "A timbered estate," Marshall observes, "should frequently be gone over by some person of judgment; who, let the price and demand for timber be what they may, ought to mark every tree which wears the appearance of decay. If the demand be brisk and the price high, he ought to go two steps farther, and mark not only such as are full-grown, but such also as are near perfection." In trees, as in the human species, there are three stages, youth, manhood, and old age. In the period of youth, the growth is rapid; in manhood, that growth is matured; and in old age, it begins to decay.

6954. *The most profitable season for felling timber* is at what may thus be termed the beginning of manhood. After that time, though the tree may appear sound and healthy, its annual increase is so little, that it would be more profitable to cut it down and replant. The number of years that a tree may stand, before it arrives at this period, must vary in different soils and situations; but the period itself may easily be ascertained — by the annual shoots — the state of the bark — and by taking the circumference of the tree at the same place for two or three successive seasons, and comparing the difference. In the view of profiting from timber produce, it is of great consequence to cut down plantations at maturity. Many trees will stand half, others a whole century, after they are full-grown, appear quite healthy, and, at the same time, make little or no increase of timber. But there are particular cases, arising from the nature and state of the markets, where it may even be more profitable to cut timber before it is arrived at a full growth. (*Treat. on Countr. Res. ii. 577.*)

6955. *Preparations for felling* It has been strongly recommended to disbark trees a year or more before they are taken down in consequence of the result of certain experiments commenced by Buffon in 1737. In May of that year, he disbarked three oak-trees, forty feet in height, where they stood. In the course of three years they died, and, on cutting them down, the outer wood was found hard and dry, and the internal wood moist and softer. After trying its strength, &c. he concludes, that "timber which has been disbarked and dried while standing, will weigh heavier, and prove stronger than timber cut in its bark." Bosc, and other French authors, (in *Cours Compl. d'Agr. &c. art. Aubier, Bois, Quercus*, &c.) strongly recommend this practice, which is followed in some places on the continent, and in this country with the oak and larch; but not, as far as we have learned, with any other tree. Monteaith finds it by far the most efficient way of seasoning larch-timber. He barked some trees in spring, and did not cut them down till autumn, and others stood in the peeled state for two years. After various and extensive trials, he is "decidedly of opinion, that the larch treated in this way at thirty years of age will be found equally durable with a tree cut down at the age of fifty years, and treated in the ordinary way." (*Forester's Guide*, 152.)

6956. *As the dry rot (Merulius destruens, Sow.)* is found to arise in a great measure from want of seasoning, or at least to proceed with the greatest rapidity in timber not well seasoned, this practice seems to deserve adoption in that point of view. (*Encyc. Brit. Suppl. art. Dry Rot.*) In some parts of the north of Europe, the trees are divested of their bark for one or two feet in height from the ground a year or more previous to that on which they are to be felled. We saw this done in Poland and Lithuania; but though we made diligent enquiry in Sweden, we could not learn distinctly the extent to which it was practised in that country and Norway. It is occasionally practised in both for the ostensible purpose of hardening the soft wood: but also accompanied by a deep incision made for the purpose of extracting tar; a practice obviously injurious to the timber, and therefore generally in these countries kept out of view. When trees stand close together, a very obvious preparation to felling is lightening the tops of such branches as would do injury in falling to the trees that are to be left, or to other adjoining objects.

6957. *The season of felling* is commonly winter, for timber not to be disbarked; but some for the resinous tribe recommend summer as being the season in which it is generally felled in the north of Europe and in the Alps. But the summer season is there adopted from necessity, as in winter the woods are so filled up with snow that felling is hardly practicable. As the timber of these countries is generally squared for the market; the soft wood is chiefly removed, so that the season of felling does not seem as to them to be of much consequence. Besides, the timber is never so full of sap in summer as it is in spring and autumn, and therefore, next to mid-winter, midsummer may be the next best time for felling all kinds of timber-trees. Where the trees are disbarked at the base a year or more before felling, the soft wood will be partially hardened; but this practice is by no means general in the north.

6958. Knowles, in a recent work on preserving the British navy, the dry rot, &c. after collecting the opinions of all the ancient and modern authors who have written on felling timber, concludes, that the common notion that trees felled in winter contain less of sap or of the vegetable juices than those cut down at any other season of the year, is not true; and that the method of barking standing trees in spring, and not felling them till the succeeding winter, has not in any way realised the expectations formed of the plan. After describing all the different modes that have been adopted for seasoning timber, he concludes, that the best mode of seasoning is to "keep it in air, neither very dry nor very moist; and to protect it from the sun and rain by a roof raised sufficiently high over it so as to prevent by this and other means, a rapid rush of air." (*Inquiry into the Means of preserving the British Navy from Dry rot, &c. by Knowles, Sec. to the Com. of Surveyors*, chap. iii.)

6959. *The operation of felling* is performed either by digging an excavation round the stem, and cutting the roots at two or three feet distant from it, or by cutting over the stem at the surface. By the former mode the root is obtained for use, and the ground more effectually cleared and prepared for the roots of other adjoining trees, or whatever crop is to follow. Where the tree is intended to stole, which can very seldom be advisable in the case of cutting full-grown timber, or where there is some nicety in taking it down so as not to injure other trees or adjoining objects, it is cut or sawn over, and the root, if to be removed, dug out afterwards. "In cutting large trees, in order to make the tree fall the way required, enter the cross-cut saw on that side of the tree it is intended to fall, and cut it about a third part through; then enter the saw at the other side, and when it is cut so far as to admit a wedge, place the wedge exactly opposite the way you

want the tree to fall, and keep driving it slowly till the tree is nearly cut through." (*Monteath.*)

6960. *Disbranching.* The tree being felled, is next divested of its branches, which are sorted into fence-wood, fuel, ton-wood, &c. according to the kind of tree; and the trunk is generally preserved as entire as possible for the purchaser. Sometimes it is cut in two, and the root-cut, or but-end, being the most valuable, sold for one class of purposes at a higher price, and the top-cuts for others somewhat lower. Sometimes timber is purchased by private contract by the foot or load in a growing state, or after being cut down; in other cases regular sales are made annually, and the produce exposed for sale by auction. It is measured by the cubic foot, fifty of which are a load; and the calculated tables and *Measurer's Guide* generally resorted to, are those of Hoppus.

6961. *The roots of trees* are the last product we shall mention. These should, in almost every case, be effectually eradicated; to aid in which, in the case of very large roots, splitting by wedges, refting by gunpowder (1941.), tearing up by the hydrostatic press (*fig. 211.*), or by a common lever and triangle (*fig. 666.*), may be resorted to. Some compact ash or oak roots are occasionally in demand by smiths, leather-cutters, and others; but in general roots should be reduced to pieces not exceeding three feet long, and six inches in diameter, and put up in stacks not less than three feet every way, but commonly containing two cubic yards. These, when dry, are sold for fuel, or reduced to charcoal on the spot. In eradicating and stacking up coppice-woods, it is common to allow a certain sum per sack, something for every acre of ground cleared; and if there are no trees to bark, the allowances are also made for the poles, faggots, &c. so that no part of the operation is performed by day-work.

6962. *The usual method of charring wood* is as follows:—

6963. *The wood being collected* near the place intended for the operation, and cut into billets, generally about three feet in length, the pits or stacks are usually formed in this manner: A spot, adapted to the purpose, of from about fifteen or twenty feet in diameter, of a conical form, is selected, and after being properly levelled, a large billet of wood split across at one end, and pointed at the other, is fixed in the centre of the area, with its pointed extremity in the earth, and two pieces of wood, inserted through the clefts of the other end, forming four right angles; against these cross-pieces, four other billets of wood are placed, one end on the ground, and the other leaning against the angles. A number of large and straight billets are afterwards laid on the ground, to form a floor, each being, as it were, the radius of the circular area; on this floor, a proper quantity of brush or small wood is strewed, to fill up the interstices, when the floor will be complete: and in order to keep the billets in the same position in which they were first arranged, pegs or stumps are driven into the ground, in the circumference of the circle, about a foot distant from one another; upon this floor a stage is built, with billets set upon one end, somewhat inclining towards the central billet, and on the tops of these another floor is laid, in a horizontal direction, but of shorter billets, as the whole is intended, when finished, to form a cone. The whole is then coated over with turf, and the surface generally plastered with a mixture of earth and charcoal-dust.

6964. *Previous to the operation of setting fire to the pile*, the central billet in the upper stage is drawn out, and pieces of dry combustible wood substituted in its place, to which the fire is applied. Great attention is necessary during the process, in the proper management of the fire, and in immediately covering up the apertures through which the flame obtrudes itself, until the operation be concluded; which is generally effected in the space of two or three days according to circumstances. When the charcoal is thought to be sufficiently burnt, which is easily known from the appearance of the smoke, and the flames no longer issuing with impetuosity through the vents; all the apertures are to be closed up very carefully, with a mixture of earth and charcoal-dust, which, by excluding all access of the external air, prevents the coal from being any further consumed, and the fire goes out of itself. In this condition it is suffered to remain, till the whole is sufficiently cooled; when the cover is removed, and the charcoal is taken away. If the whole process is skilfully managed, the coals will exactly retain the figure of the pieces of wood: some are said to have been so dexterous, as to char an arrow, without altering even the figure of the feather. (*Encyc. Brit. vol. v. art. Charcoal.*)

6965. *The method of charring wood, for the making of gunpowder*, according to an improved system, adopted not many years ago, is however a much more costly operation, though the expense attending it is amply compensated by the superior excellence of the article when manufactured. It is done in iron cylinders, and in so complete a manner, that every particle of the wood is charred. The oily or tarry matter is also preserved, and may, so far as the quantity goes, be made use of instead of foreign tar or pitch. This mode of charring wood for making gunpowder, is carried to the greatest perfection, near Petworth in Sussex, and there is a manufacture of a similar nature near Chester. (*Gen. Rep. for Scotland, vol. ii. p. 332.*)

6966. *The valuation of trees* forms a distinct profession, and can only be acquired after much experience; like other valuations of property, it depends on a great variety of considerations, some of a general, but the greater part of a local nature. All we shall here attempt, is to give a few general ideas which may be of use to the private cultivator or forester.

6967. *In valuing any plantation*, the first thing is to know its contents in acres; if this cannot be done, the number of plants must be counted. If a young plantation, the trees of which are unfit for present use as timber, is to be valued, then its value at any distant period, not exceeding twenty or twenty-five years, must be estimated; and whatever sum that estimate amounts to, the present value of that sum will give an idea of the value of the plantation, allowing liberally for accidents to the trees and other unforeseen circumstances. Thus, suppose a plantation of oaks, intended as copse, or actually established as

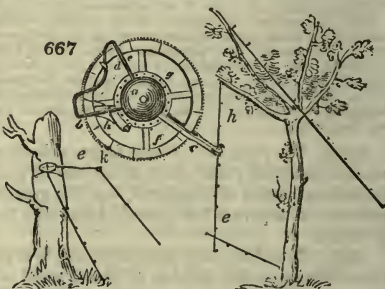

such, to have grown four years, its present value would be next to nothing; but if arrived at its twentieth year, it would fetch fifty pounds per acre. Then the question is, required the present value of fifty pounds, due sixteen years hence, the market price of money being five per cent. ? and this, according to any of the modern annuity tables (say *Bailey's*, 4to. 1808. tab. iv.) is 22l. 18s. This principle is applicable to all kinds of valuing by anticipation; and there is no other mode of valuing applicable to young plantations. The benefits derived from the trees in the way of shelter and ornament, are to be estimated in valuing the territory, and are foreign to the present purpose, which has for its object tree-produce only.

6968. *In valuing saleable trees of any kind, their number per acre, or their total number by enumeration being ascertained, and the kinds and sizes classed, then each class is to be estimated according to its worth as timber, fence-wood, fuel, bark, &c.* "In a coppice-wood which cannot readily be measured, the readiest method of counting the stools is, to cause two men to take a line, say about a hundred feet long, or more, and passing the line round as many of the stools as it will enclose, the one man standing still while the other moves round a new number of stools, and count always the stools betwixt the two lines, causing the one man to move the one time with the line, whilst the other man stands still, and so on alternately. The valuator at the same time taking care to average every twenty stools as they go on, before losing sight of the counted stools. This way, too, is a very speedy and sure method of counting the number of trees in any plantation. Or, the stools of a coppice-wood may be counted and averaged by two men going parallel to each other, and the person valuing going betwixt them; the two men putting up marks with moss, or pieces of white paper, on a branch of the stools; the one man going always back by the last laid marks, and the valuator always counting and averaging the stools betwixt the newly-laid and the late-laid marks; counting and averaging the stools always as the men go on, taking only twenty, or even ten stools at a time. To those who have been in the practice of doing this frequently, it will be found very easy, and will be done very speedily, and with a very considerable degree of accuracy. The proper method of learning to do this correctly is, when a person cuts an oak wood for the first time (or, even were the work repeated several times), he should then, in order to make himself perfectly acquainted with ascertaining the average quantity of bark that a stool, or even a stem of a stool will produce, go before the peelers, and select a stool or stem: after having examined it narrowly, he supposes it to produce a certain quantity of bark, and marks this down in his memorandum-book. He then causes a person to peel it by itself, dry it, and carefully tie it up, and weigh it, and compare it with the weight he supposed it to produce, and he will at once see how near his calculation comes to the truth. A stem of oak from a natural stool, suppose it to measure in girth two inches, by seven feet long, will contain two solid inches and one third of an inch, according to the measurement of Hoppus. This stem or shoot will produce two pounds two ounces of bark. Again, a stem or shoot of natural oak, measuring four inches in girth, by nine feet in length, will be found to contain one solid foot of wood, and will produce thirteen pounds and a half of bark." (*Forester's Guide*, 170.)

6969. *When growing trees are valued, an allowance is made from their cubic contents for the bark.* The rule given by Monteath is, "when the girth or circumference is any thing from twelve inches up to twenty-four inches, then deduct two inches; from twenty-four to thirty-six, three inches; from thirty-six to forty-eight, four inches; from forty-eight to seventy-two, five inches; and above seventy-two, six inches." These deductions, he says, "will be found to answer in almost all trees; unless in such as are very old, and have rough and corky barks or barks covered with moss, when an extra allowance is to be made." (*Forester's Guide*, 180.) "Many persons," the same author observes, "in valuing measurable oak-trees, proceed on the data that every cubic foot of timber will produce a stone (sixteen pounds) of bark. This," he says, "is not always correct;" and he states the following facts from his own experience, with a view to assist beginners in ascertaining the quantity of bark from various trees. "An oak-tree, about forty years old, measured down to four inches and a half side of the square, and weighing only the bark peeled off the timber that is measured, without including any of the bark of the spray, &c. every foot of measured timber will produce from nine to eleven pounds of bark. An oak-tree, of eighty years old, weighing only the bark peeled off the measurable timber, as above, every foot will produce from ten to thirteen pounds of bark. Every foot of large birch-timber, peeled as above, will produce fourteen pounds of bark. Every foot of mountain ash, as above, will produce eleven pounds and a half of bark. Every foot of the willow, unless a very old tree, will produce from nine to eleven pounds. Every foot of larch fir, not exceeding thirty years old, will produce from seven to nine pounds of bark. The timber of trees, particularly the oak, is peeled out, every branch and shoot, down as small as an inch in circumference." (*Forester's Guide*, 189.) The price of timber, like that of every other article in general use, varies with the supply and demand; and is easily ascertained from the timber-merchants at the different sea-ports; as is that of bark, charcoal, and fire-wood from the tanners and coal-merchants.

6970. *To facilitate the measuring of standing timber, Monteath has invented a very ingenious machine.* (fig. 667.) It consists of a wheel, or perambulator, about eight inches

in diameter, with a bell (a) on the end of its axle; at the end of every foot gone over by the serrated circumference of the perambulator, this bell is struck by means of a spring (b); the sound of this bell will be heard from the top of the highest tree. A forked handle (c) works on the top of the main axle on each side of the wheel; one of a set of connecting rods (e, h) goes into it, and is fixed with a screw making a swivel joint, and by screwing the nut firm, the wheel can be set to any position, and it will work equally well any way. A small hand (d), in the circle of the triangular spring, points to the inches or quarters of an inch on the wheel, and tells what exceeds the inch after a lesser spring (e), which strikes at every inch, has struck the bell. The circumference of the wheel (f) measures two feet. The rods for working the measuring machine are each three feet long, and one inch in diameter, with connecting screws of brass on each end of them; so that as many as are

required for any length or height, can be easily screwed into each other. The other small rods for taking the length of the tree, as also of its branches, are only five eighths of an inch in diameter: each rod is three feet long, and goes together with connecting screws of brass. The rods are painted black, and divided into feet and inches, with white letters; so that by connecting any number of the rods together that may be required, and by applying them to the tree or branches (*k*), you can take the exact length in a speedy, accurate, and simple manner. (*Forester's Guide*, 207.)

6971. *The value of the invention turns on the use of the wheel, in taking the girth of the tree. Thus, "after having taken the length of the tree in feet and inches, which length may be taken by the rods as already described, the girth is most generally taken at half the length, which girth we are enabled to take with the measuring wheel: this is easily done, by putting up the wheel, with as many of the connecting rods together as will put it up to the height required; then, suppose there are no branches in the way, and having before made a mark on the bark of the tree with the small rods, the uppermost one having a small marking-iron in its end for that purpose; this mark is made where the girth is to be taken, and from where you are to take your departure with the wheel, which being done, press the wheel round the tree, following it, and keeping it as level as possible, which the wheel will in a great measure do of itself, by its having teeth like a saw in the hem of the wheel, unless carelessly attended to. As the wheel goes round the tree, be sure to count the number of times the bell strikes, which it does at every foot; and when you see you have not another twelve inches or one foot more to run, to arrive at the place where you took your departure from, count the number of inches that it strikes over and above the last foot, and thus you will at once have the feet and inches that the tree is in circumference; of which take the fourth, and this gives you the side of the square: but when there are branches in the way of getting round the tree, you must have a spare handle for the machine (*e, k*), about two feet, or two feet six inches in length, and by altering the swivel-joint at the top of the first rod to any position required, the person working the wheel by the rods can stand in the same place, and put the wheel, say half way round the tree, if it is very large, and by turning the swivel-joint, and reversing the wheel, at the same time sending it round the other side of the tree till it meet where it left off, and by counting the feet and inches as above, and adding the two together, you will at once have the extreme girth of the tree. When branches are to measure, or when branches are in the way of getting round the tree with the rods, the person with the small rods stands on the opposite side of the tree, and directs the person when to stop with the wheel. Thus, by a little practice in working the wheel, and paying attention to count the feet and inches as they strike, two men will measure growing or standing trees equally as accurately and expeditiously as if the trees were lying on the ground. In taking the girth with a line, you have first to put it round the tree, then you double it, and apply it to a foot-rule; you then take the half for the side of the square, whereas this machine gives you the exact feet and inches from the top of the highest tree, without the help of any other rule." (*Forester's Guide*, 208.) Neither this machine, nor a mechanical dendrometer, invented about twenty years ago, though both of considerable merit, appear to us so well calculated for general use as the *Timber Measurer of Broad*. (fig. 154.)*

6972. *The books of accounts for trees and plantations have already been mentioned. (2340.) Some have proposed measuring the whole of, or at least all the detached and hedge-row trees on an estate periodically; numbering each tree, and keeping a corresponding register, by which the proprietor, when at a distance, might give directions for cutting down particular trees, &c.; but this appears rather too much in the mercantile style for the dignified enjoyment of landed property, and does not promise any very great advantages.*

CHAP. VII.

Of the Formation of a Nursery-Garden for the Propagation and Rearing of Trees and Shrubs.

6973. *Nurseries for rearing trees are commonly left to commercial gardeners, as the plantations of few private landowners are so extensive, or continued through a sufficient number of years to render it worth their while to originate and nurse up their own tree and hedge plants. Exceptions, however, occur in the case of remote situations, and where there are tracts so extensive as to require many years in planting. Besides, as Sang observes, "some are of opinion, that trees, in order to their being rendered sufficiently hardy, should be reared on the soil and situation where they are ultimately to be planted; and if the design be extensive, and such as may require many years for its completion; a conveniently situated nursery is, in that case, highly desirable, not only as saving the carriage of plants, and facilitating the business of transplanting, but as increasing the chance of success, on account of the plants remaining a much shorter time out of the ground than if brought from a distance. If the situation, however, ultimately destined for the trees be cold, high, and bleak, and the soil of course various, some good, and much of it bad, or of an indifferent quality, there it would by no means be advisable to attempt the establishment of a nursery, and especially a nursery to raise plants from seeds. The chief properties of nursery plants intended for transplanting, consist in their strength and cleanness of stem, and in their roots having a multiplicity of healthy fibres; and in order to obtain plants possessing these qualities, it is necessary to sow, and plant out to nurse, if not in rich, at least in mellow earth, and in a moderately sheltered situation." (*Plant. Kal.* 20.) The following directions by Sang as to the soil, shelter, aspect, and fencing of a nursery-garden are equally applicable to such as are intended for private or commercial purposes:—*

6974. *In order to have a complete nursery, it should contain soils of various qualities, and not less than eighteen inches or two feet deep; the generality of it should be light friable earth; a part of it should be*

of a clayey nature; and another part should be mossy. Each of these will be found peculiarly useful in the raising of the different kinds of young plants. The whole should be well drained, and trenched, and cropped with vegetables for one or even two years previously to sowing tree-seeds. For transplanting, it may be used the first year. A nursery may certainly be over-sheltered; "but this is likely to happen only in the case of its being very small; for, if it extend to several acres, unless it be surrounded by very tall trees, the area will be considerably exposed. No part should be either too much exposed, or too much sheltered. Any aspect from east to west, following the course of the sun, will answer. Ground of an unequal surface is most likely to contain the various soils above mentioned. A nursery should, therefore, in general, rise from a level to a pretty smart acclivity; yet no part of it should be too steep, because it is in that case very troublesome to labor. The nursery-ground may be sufficiently fenced by a stone wall, or even a hedge six feet high; and if it be of small size, an acre or thereabouts, it will require no other shelter; but if it extend to four or five acres, it must have dividing hedges properly situated, to afford shelter over all the space. The fence, whether of thorns or stone, should be made proof against the admission of hares or rabbits. It should be subdivided into compartments and borders, of proportionate size to the contents of the area, by walks. The compartments should never be encumbered with large trees, as apples, pears, or the like; because, being already established in the ground, they never fail to rob the young trees of their food, and to cause them to be poor and stunted, unworthy of being planted in the forest. It would be very convenient to have a rill of water passing through the ground, or to have a small pond, fed by a spring or a pipe, for the purpose of watering." (*Plant. Kal. 22.*)

6975. In preparing the soil for the culture of trees it will be advisable to trench it to its full depth, and "necessary," the same author continues, "to give it a good dressing of lime or marl and dung in compost. Rank manure, such as stable-litter, should not be applied to nursery-ground, at the time of cropping, with nursery articles; but if it be necessary to enrich it, this should be done by a manured crop of onions, turnips, lettuces, or the like. Potatoes should never go before a crop of seedlings, even of the coarser sorts, as ash, oak, or chestnuts; because potatoes never can be taken clean out of the ground; and it being indispensable to pull up those which rise among the tree-seedlings, many of these unavoidably come up along with them. Hence, crops of lettuces, turnips, cabbages, or the like, should rather precede the crop of seedlings. The best kind of management in this particular case, is to interchange the crops of timber-trees and esculents occasionally; perhaps, with respect to most sorts of seedling-plants, alternately observing to sow all small seeds, in particular, if not in a rich, at least in a fine tilth." (*Plant. Kal. 24.*)

6976. For a private nursery, he continues, "no place, certainly, can be more eligible than a field, which may also be occupied as a kitchen-garden. If, for instance, three acres were required for the purposes of nursery, and one or two acres were also required for extra kitchen-ground, or for green crops for cattle-feeding, it would be proper to enclose five or six acres, less or more, according to circumstances; by which means two important objects might be obtained, viz. land of a good quality, and fine tilth, for the raising of seedlings; and an opportunity of effectually changing crops at pleasure. Carrots are peculiarly scouring for a nursery, and, indeed, rather severe for most lands: but we have very seldom found a good crop of trees following one of carrots; while we have found peas, beans, and especially lettuces, easy and enriching crops, well adapted as preparers for succeeding crops of nursery articles."

6977. In so far as respects public nurseries, "we have long remarked, that those which are as much market-gardens as nurseries, generally produce the best seedlings, and young articles, for sale; provided that their ground be any thing more than of a middling quality. This fact, if one were wanting, is a sufficient proof of the utility of occupying the ground as above advised, in the double character of a kitchen-garden and nursery."

6978. In a cold climate, or bleak situation, "with a poor barren soil, we would by no means advise the raising of seedlings, either in public or private nurseries. It will be found a cheaper, as well as a more satisfactory method, to purchase seedlings, transplant them, and nurse them till fit for final planting; and, even, in this case, a piece of the best, and most sheltered land in the situation, will be necessary for the purpose." (*Plant. Kal. 26.*)

6979. A rotting-ground will be required for the preparation of certain seeds, by mixing them with sand, ashes, or soil, and leaving them there for different periods, from six months to two years, to rot off their interior coverings. On a small scale, a portion of the compost-ground of the kitchen-garden may be used for this purpose. If the scale is large, an area of a few square poles should be set apart for bedding in plants taken up for replanting, or what is called laying in by the heels, or shoughing: this is generally called the bedding-ground or (in Scotland) the shoughing-ground.

6980. Buildings. If the situation of the nursery be near to the kitchen-garden, and the latter have the proper office-buildings (1701.), no other erection will be required for the nursery than a working-shed for ordinary purposes, occasional shelter, and protection to newly taken up plants; and for packing or tying them up properly before sending them to their final situation, &c. Frames and hand-glasses may be required for some of the more tender seeds and seedlings; and, on a large scale, a seed-loft and its appendages, as well as an office for writing, &c. may require to be erected apart from those belonging to the kitchen-garden.

6981. Stocking with plants. The ground being arranged, and prepared by one or more vegetable crops, the next thing is to stock it with stools, or stock plants, to propagate from by layers, and to procure stools for grafting or budding, but especially in a private forest-tree nursery with tree-seeds. In the tables of ornamental trees and shrubs (6540. to 6571.), given in the preceding book; and in the general index at the end of the work will be found the particular mode of propagation, and the requisite soil for each tree and shrub: by inspecting these sources it will be seen what plants must be procured for stools. If the object is merely forest culture, few, excepting some of limes, poplars, and planes, will be required; but, if tender trees and shrubs are to be reared, the number will be more considerable. Plant the tenderer sorts in the sheltered borders, and the more hardy in the open compartments: the tree kinds may be placed from six to eight feet every way, and the more delicate shrubs from three to six feet apart in suitable soils. Stocks for grafting, whether for fruit or barren trees, are to be planted in nursery rows, according to their kinds; those for inarching round the parent plant (2007.) or in pots.

CHAP. VIII.

Of the Culture and Management of a Nursery for Trees and Shrubs.

6982. The principal objects of culture in a private tree-nursery are the hardy trees and shrubs of the country, which produce seeds; and the great object of the private nursery-gardener must be to collect or procure these seeds, prepare them for sowing, sow them in their proper seasons, and transplant and nurse them till fit for final planting. We shall arrange the principal trees and shrubs which ripen their seeds in this country; as cones, nuts, berried stones, berries with small seeds, leguminous seeds, and small soft seeds.

Before treating of the gathering, storing, separating the seeds, sowing, and nursery culture, of each of these general divisions, it is essential to remark, that in collecting every kind of tree-seed, preference should be given to that produced by trees the largest and most perfect of their kind, and to the fullest and best-ripened seeds on these trees. The reasons have been too frequently given in this work to require repetition.

SECT. I. *Coniferous Trees and Shrubs, their Seeds, Sowing, and Rearing.*

6983. *The principal hardy coniferous trees and shrubs are as follow : —*

Juniperus virginiana, December
Cupressus thuyoides, January
 — *sempervirens*, January
Pinus balsamea, September
 — *larix*, December
 — *canadensis*, November

Pinus sylvestris, November
 — *picea*, October
 — *abies*, November
 — *nigra*, November
 — *pinea*, December

Pinus strobus, October
 — *pinaster*, December
 — *cedrus*, March.
Shrubs.
Thuja occidentalis, November
 — *orientalis*, November.

6984. *Cones may be gathered any time between the ripening season and the following April ; but the sooner they are gathered the better, as they supply work for the regular hands of the establishment in bad weather during the winter months ; or admit of giving industrious money-making persons work by the job in the winter evenings. The general mode of separating the seeds is by kiln-drying, in the same way as in drying malt, but applying a more gentle heat.*

6985. *The cone-kiln is constructed after the manner of a common malt-kiln : the bearers should be about nine feet distant from the fire, and two inches apart. A wire cloth is spread over them from side to side of the kiln, and the cones are laid on it to the thickness of twelve or fourteen inches. A gentle fire is then applied, and regularly kept up till the cones become opened. During the time of drying, the cones must be frequently turned upon the kiln ; and when the seeds begin to drop out, they must be removed to the seed-loft, and sifted till all the seeds which are loose fall out, and be taken from among the cones. The cones are afterwards to be thrashed severely with flails, or passed through a hand-threshing machine, and sifted as before, and so on, till the seeds are taken out as completely as possible. It is, however, a safer method to split the larch-cones before putting them into the kiln. This operation is performed by a small flat triangular spatula, sharpened at the point and cutting-angles, and helved like a shoemaker's awl. The cone is held by the fore-finger and thumb of the one hand, upon a flat piece of wood, while, with the other, by the splitter, it is split up from the great end ; and afterwards each half is split up the middle, which parts the cone into four divisions. This is by far the best and least destructive to the seeds of any method we know ; because the cones so split, when exposed to the heat, are suddenly opened, and readily discharge the seeds ; which, consequently, are less injured by the fire-heat. Besides the above method of splitting, there are others. Some people use a cone-mill, which has large sharp teeth in a concave cylinder, and others fixed in a corresponding roller. The mill is wrought by turning the roller by a handle resembling that of common fanners. The cones are let into the mill by a hopper. This instrument is very difficult to work, and bruises the seeds very much ; many of which are of course destroyed. We have several times made use of the common improved bark-mill, for separating the seeds from larch fir cones ; but the cones are thus so much compressed and bruised, that the seeds suffer exceedingly ; and we would by no means advise it : indeed, among all the methods which we have known adopted, to perform the painful and laborious work of extracting the seeds of the larch, the plan of splitting them singly is much the best and safest for the seeds, and ought to be adopted by every one who has occasion to use only small quantities of seed. None of the other kinds of cones require so much labor as the larch, excepting, perhaps, those of the cedar of Lebanon, and black American spruce. Cones, which have given out all their seeds, are generally, and very properly, used as fuel for drying other cones. This sort of fuel requires the attention of a very steady feeder ; indeed, the most careful and attentive are apt to set the full or drying cones on fire, from the resinous nature, and tendency to flame, of the empty cones used as fuel. Such kilns should, therefore, be erected in situations far removed from a dangerous neighborhood.*

6986. *The cones of Scotch pine, the larch and the spruce, " are the principal kinds which are opened by kiln-heat. The cones of the silver fir, the balm of Gilead fir, and the Weymouth pine, give out their seeds with very little trouble : indeed, if they be not gathered soon in autumn, and kept from severe drought, they will fall to pieces of their own accord. Seeds of the white American spruce are only procured from warm situations, and from America, and are generally sold in a clean state, or separated from the cones. Cones of the black and red spruce are brought from America, and sold in the state of cones. These should be split, and exposed in a sieve tilted before a gentle fire, with a sheet of paper below the sieve to receive the seeds as they fall out. The seeds should be removed every quarter of an hour ; because they are small, and are very easily injured by the heat."*

6987. *The cones of cedar of Lebanon " should be kept for one year at least, after they are taken from the tree, before the seed be attempted to be taken out. This is necessary, on account of the soft nature of the seeds, and the great quantity of resinous matter which the cones contain when growing, and which is discharged by the keeping. The best way to take out the seeds of the cedar, is to split the cones, by driving a sharp conical piece of iron through the heart of them. This work, as well as the taking out of the seeds is greatly facilitated, by steeping the cones in water for a day or two, previous to splitting them. The coats of the leaves should be opened with the hand, and the seeds carefully taken out. The cones of the cedar are brought from the Levant, and may be purchased with safety for seed, although it be several years since they were taken from the tree." (Plant. Kal. 325.)*

6988. *Sowing. April is the best season for all the species ; the soil should be in excellent condition, well mellowed by the preceding winter's frost and snow, carefully dug and raked as fine as possible. All the sorts are sown in beds, excepting the cedar of Lebanon and some pines ; and the manner of sowing is by cuffling or bedding in, already described. (1875.)*

6989. *The soil for the Scotch pine, before being dug over in February, should be thickly coated with rotted hot-bed dung : the seeds should be sown so as to rise at the distance of a quarter of an inch from one another ; and the covering should be half an inch thick. The best preparation for larch-seeds is a previous crop of two-years' seedling Scotch pines, and next, a similar crop of the larch. The soil should be dunged and prepared as for the Scotch pine ; after sowing the seeds, both of this tree and the Scotch pine, previous to covering them, draw a light roller along the bed, to press the seeds firmly into the earth ; then cover a quarter of an inch thick. The larch should rise at the same distance as the Scotch pine ; but the seeds being generally more or less injured in separating, many do not come up, and they are therefore sown thicker than the other.*

6990. *The seeds of the spruce fir are to be treated like those of the Scotch pine ; and the balm of Gilead*

fir-seeds, like those of the larch, only the covering should not be less than half, nor more than three quarters of an inch.

6991. *The seeds of the silver fir and pinaster* require the same sort of treatment as those of the larch. "They must not be sown to rise nearer one another than three in an inch. The covering should be a full inch thick, and performed with great accuracy: for if any of the seeds be left too lightly covered, or if any of them be too deeply covered, they will alike be destroyed." (*Plant. Kal. 332.*)

6992. *The seed of the Weymouth and stone pines* may be treated like those of the Scotch pine, but the former covered three quarters of an inch thick, and the latter an inch and a quarter. Sang states, that the only way to get stately trees of these, as of most of the pine tribe, is to sow them where they are to rise into timber.

6993. *The white American spruce-seeds* "are smaller than those of any of the preceding kinds, and therefore require a lighter covering than any of them. One fifth of an inch is quite sufficient. They should be sown on a piece of fine dry sandy loam, and be covered with earth of rotten leaves of trees to the above thickness, by sifting it upon them." (*Plant. Kal. 333.*)

6994. *The seeds of black and red American spruce fir* "are very small and tender. They are still smaller than the seeds of the white American spruce, and therefore require a covering still lighter than mentioned for it. The black and red American spruce should be sown on rich boggy earth, which has been made very fine; and should be covered as lightly as possible. Rich mossy earth, containing a good portion of white sand answers best. This should be sifted over the seeds with a fine sieve. Neither of these American spruces will allow the roller to pass over them previous to covering. The whole of them should be shaded from the mid-day sun in the time of coming up, and for some time after, by means of hoops and matting, or spruce fir branches stuck in the opposite alleys, so as to form an arch over the beds." (*Plant. Kalen. 334.*)

6995. *Cedar of Lebanon seeds* should be sown in boxes of light sandy loam; or on a spot of properly prepared well sheltered soil, and covered half an inch: the red and white cedar-seeds may be similarly treated, covering a quarter of an inch thick. *Arbor-vitæ* seeds will come up best under a frame or hand-glass: they should be sown on light sandy soil, and covered a quarter of an inch.

6996. *The strictest attention should be paid to the foregoing directions*, both in regard to quality of soil, and thickness of covering the seed; for, though resinous trees are extremely hardy when grown up, yet they are all very tender in infancy. The raising regular crops of this tribe is, therefore, justly reckoned the masterpiece of nursery culture in the open ground; and is supposed to be best understood in the northern counties.

6997. *Transplanting.* This tribe benefit less by transplanting than the non-resinous trees; and therefore where circumstances admit, the better plan is, after the seedlings have stood two years in the seed-bed, to remove them where they are finally to remain. The exceptions are those sorts which are transplanted into pots, as the cedars and cypresses, and some of the more delicate pines, which may be kept in the nursing state, in pots, several years, as their roots can be turned out entire. About the middle of April is the proper time for transplanting all the resinous tribe, excepting the larch; for, as this tree pushes earlier than the others, it should be transplanted in February and March. The first operation common to all seedlings is to loosen the roots of the plants in the seed-bed with a fork, so as, when drawn out by the hand, they may come up with all their fibres entire. The ground, which must be mellow, need not be so rich as for sowing the seeds; being previously prepared, they should be immediately planted in the trench manner. (2085.) The Scotch pine is generally planted in lines twelve inches apart, and the plants a foot distant in the lines; if intended to remain two years in the lines, they should be placed six inches apart in the line; but they always rise with the best roots, after being only one year transplanted. The spruce and balm of Gilead firs should generally be transplanted at two years; but, if weak in the seed-bed, may remain till the third year. They should be planted at the same distances as the Scotch pine, in humid rich earth. The silver fir may be treated in the same manner, but it requires rather more space. If to be nursed only one year, they may be planted in lines nine inches apart, and at six inches' distance in the lines; but if to remain two years, then fifteen inches between the lines, and eighteen inches in the line will be necessary. The Weymouth pine should be transplanted at two years into a well pulverised, rich, and sub-humid soil, where it should remain two years before final planting; distance between the lines twelve inches, and from plant to plant eight inches.

6998. *The pinaster and stone pine* generally rise to well sized plants the first season after sowing, and should then be transplanted into a rich well comminuted soil, rather sandy and dry, at nine inches between the lines, and four inches apart in the lines. After remaining there one year, they should be removed to their final situation. Great care is requisite in moving these plants, especially the stone pine, which sends down very long roots.

6999. *The white American spruce*, after remaining two years in the seed-bed, should be nursed two years in rich sandy and rather dry soil, in lines distant twelve inches, and the plants six inches apart in the lines. The black and red American spruce are much more delicate than the white. After being two years in the seed-bed, they should be planted out in beds of sandy or subpeaty soil, at six inches apart, to stand for one year; at the end of this period, they should be lifted and planted in rows at the same distances as the white American spruce.

7000. *The cedar of Lebanon*, when one year old, should be lifted and planted in pots of the finest soil; or in lines, at the same distance as the silver fir; after being two years nursed, it should be removed to its final situation, as it never does much good if planted finally at a greater age, unless in pots, which is much the best method. The red and white cedars and cypress may remain two years in the seed-bed, and then be treated like the cedar of Lebanon.

7001. *The larch* may be moved from the seed-bed into the nursing lines, at one or two years. The soil to receive them should be soft, tender, and prepared by a crop of esculent vegetables with dung the preceding season; but they should never be planted in land newly manured with fresh dung. One year's seedlings, to be nursed one year, should be planted four inches apart in the lines; but if to stand for two years, five inches, and fifteen inches between the lines. The two years' seedlings should be sized, as in the seed-bed they never all rise to the same height; the larger size may be placed six inches apart in the lines, and twelve or fourteen inches between the lines, to stand one year; the smaller, at five inches, and a foot, for standing the same period: they should then be removed to their final situation.

7002. *Care of the roots.* No description of tree-plants receive so much injury from the loss of roots;

from the roots being exposed to the air by being kept long out of the soil ; or from compression and exclusion of air and moisture by being kept in close bundles, or thick layers, as those of the resinous tribe ; they should therefore be finally planted as soon as possible after removal from the nursery ; and, indeed, whenever it is practicable, no more should be taken up in one day than can be planted that day or the next. Nor are any plants more easily deprived of the vital principle, by packing and carriage either by sea or land ; though, being all evergreens, excepting the larch, they do not readily show it. This has been stated to us, by experienced planters in Wales and other parts of England, as the reason why so few trees are finally produced from the immense numbers of Scotch pine and larch fir annually sent there by the Scotch nurserymen.

7003. *Pruning* is not required by any of the resinous tribe in the nursery, unless to pinch off a contending leader, or amputate a bruised part of the root or top.

SECT. II. *Trees and Shrubs bearing Nuts, Acorns, Masts, Keys, &c. their Sowing and Rearing.*

7004. *The principal hardy trees bearing nuts, acorns, masts, &c. are the following : —*

Fraxinus excelsior, November	Quercus prinus, November	
Fagus sylvatica, September, October	— alba, November	<i>Shrubs.</i>
Castanea vesca, November	Platanus occidentalis, December	Amygdalus communis, September
Asculus hippo-castanum, October	Acer pseudo-platanus, October	Staphylea pinnata, October
Carpinus betulus, November	Juglans regia, September.	— virginiana, October
Quercus robur, November		Acer communis, & various species, Sept.
		Corylus avellana, October.

7005. *Gathering and keeping.* These being gathered, if circumstances permit, should be immediately sown ; but where this cannot be done, or where they are to be sent to a distance, they should be thinly spread in an airy loft till thoroughly dried, when they may be preserved till spring in bags or barrels, or sent off to any distance in these or other packages. When the seeds of the ash, sycamore, platanus, and hornbeam, are only to be kept for the purpose of spring sowing, the best plan is to take them to the rotting-ground (6979.), mix them with their bulk of dry sand or ashes, spread them in a stratum of ten inches in thickness, in the form of beds, cover with sand to the same thickness, and leave them in that state till wanted for spring sowing.

7006. *Sowing.* The bedding-in manner (2091.), or by drills, may be adopted for all the kinds. Acorns, horse and Spanish chestnuts, almonds, and hazel-nuts, should be sown in February, in strong loam, in good heart and well comminuted : the seeds should be placed half an inch apart, and covered two inches thick. Walnuts require a similar soil and covering, but should be placed two inches nut from nut. Ash-seeds will come up in soil of middling quality, but it should be well dug, and in an open situation, that the plants may not be drawn. Place the seeds half an inch apart, and cover one inch. Sycamore-plants when young being liable to be killed by the frost, the seeds should not be sown till the end of March or beginning of April ; they should be sown in exposed, dry, sandy soil, an inch apart, and covered one inch in thickness. On rich moist land they will rise so tall and soft, that the extremities of their shoots will not ripen in autumn, and the plants will in consequence be unfit for use. Beech-plants, when newly risen, are still more tender than those of the sycamore kind, and therefore should generally be sown in April, but not later than the middle of the month ; for if very dry weather set in, they will not rise till the following spring, and so have a great chance of them perishing by the frost. The soil should be tender and rich, previously under a culinary crop with dung ; and it should receive a small dressing of well rotted manure previously to digging for semination. The seeds should lie an inch apart, and be covered a full inch. The best time for sowing the hornbeam is in October ; but it may also be sown in February : the soil should be light, but not very rich : the bed form answers best : the seeds should lie half an inch apart, and be covered half an inch in thickness. The plant is seldom raised from seeds ; but when this is done, a soft peat-earth soil is the best, and the covering should not be more than a quarter of an inch. The seeds of the bladder-nut, if sown as soon as gathered, will come up the following spring ; if not, a part will not rise till the second year : sow in light rich soil, and cover an inch and a half deep.

7007. *Transplanting.* The operation of loosening the plants, sorting them into sizes, and pruning their roots and tops, require to be first performed. As these plants have generally long and strong tap-roots, these require to be cut in the operation of loosening ; which, for this purpose, must be performed with a sharp spade, and care taken in thrusting it down, that the root is not cut too high ; care should also be taken to preserve uninjured all the lateral fibres. In sorting the plants into two or three sizes, the fractured tap-root of each must be cut smoothly off with a sharp knife, and any side shoots on the stem cut close off. If the plants cannot be immediately planted, they may be laid in by the heels, or shoughed ; that is, thickly bedded in the bedding-ground (6979.) till wanted. Here they may remain in layers not more than three or four inches thick, for a month or two in the winter season ; and for a week or two even in February and March. None of the kinds should remain in the seed-bed longer than two years ; but in drills they may remain three years ; and more especially if the operation of tapping be performed ; that is, cutting through their tap-roots about eight inches below the surface. " This is most effectually and readily done by two men with

sharp spades; *rutting* or cutting the ground obliquely with their spades, on each side the line at once, and exactly opposite to each other. After this operation has been performed, the plants should be made firm, by a person treading the rows with a foot on each side. These kinds, so tapped, will, in the course of the following season, in consequence of being thus root-pruned, push many more fibres on the upper part of their roots, than they otherwise would have done; and thus will the plants be better fitted for being transplanted into shallow soils, or indeed into any soil, than they would have been by being allowed to remain in the ground untapped till the time of lifting.” (*Plant. Kal.* 135.)

7008. *Trench-planting* is decidedly the best for all plants to be placed in lines; but more especially for ligneous sorts. Dibbing in is an easier and more rapid mode; but by trench-planting the fibres are spread out and regularly disposed on each side of the main root; whereas, by dibbing, as Sang observes, they are “huddled together into a hole probably not more than an inch and half in diameter.” Dibbing, however, may be adopted in the case of such seedling trees as have been robbed of most of their fibrous roots, by being pulled out in thinning beds intended to stand for two years.

7009. *The age at which most of these sorts should be transplanted* is one year; and the soil most desirable for removing them to, is the same as recommended for the seed-bed. The distances between the lines and the plants in the line depend partly on their kinds, but principally on the length of time they are to stand before retransplanting or final removal. The larger-growing broad-leaved sorts, as the chestnuts and walnuts, to stand only one year, should not be nearer than eighteen inches by six inches; and the oak, ash, beech, &c. not nearer than fourteen inches by three inches; if to stand for three years, the interspaces may be two or three inches more: something depends on the openness of the situation, and a good deal on the soil. The judicious nursery-gardener will consider all the circumstances, and adopt such variations of the ordinary distances as shall produce plants with well ripened shoots, and numerous fibrous roots.

7010. *Pruning, culture, and taking up for final planting.* When the plants are to remain two or more years in the nursery lines without removal, dig the ground between the rows in winter. At midsummer cut close off the lower side shoots; some defer this work till winter; but, besides the loss of sap avoided by midsummer pruning, the wounds heal the same season. In taking up for final planting, such plants as have been trench-planted must be loosened on the side which was solid at planting; if they have been in training for several years they should be lifted by throwing out a trench on one side, fully to the depth of the roots, and then putting in the spade on the opposite side, so as to get below all the roots.

SECT. III. *Trees and Shrubs with berried Stones, their Sowing and Rearing.*

7011. *The principal hardy trees with berried stones* are the following:—

Sorbus aucuparia, August	Rhamnus frangula, September	Hedera helix, April
— domestica, November	— communis, November	Daphne laureola, June
Ilex aquifolium, November	Laurus nobilis, November	— mezereum, June
Pyrus torminalis, November	Rosa, various species, October	Viburnum tinus, June
— aria, September	Prunus padus, August	Phillyrea angustifolia, February
Taxus baccata, November	— lusitanica, September	Mespilus oxyacantha, October
Prunus cerasus, July	— virginiana, August	— azarolus, October
— domestica, October.	— spinosa, October	— pyracantha, November
Shrubs.	— canadensis, August	— amelanchier, November
Rhamnus alaternus, October	— laurocerasus, September	Juniperus communis, October.

7012. *Rotting.* The whole of these when gathered, require to be taken to the rotting-ground; mixed with their bulk of dry sand or ashes, laid in beds of ten inches in thickness, and then covered with ten inches of sand, light sandy earth, or ashes. Here some sorts, as the holly, will require to remain two years; the haw, mountain ash, and yew, one year; and the other sorts, one winter, or till the following February. During this time the beds of each kind should be uncovered, carefully turned over, and the covering replaced. The advantage of rotting off their exterior covering in heaps rather than in the soil, where they are to germinate, is the saving of ground; for though some of the holly and haw, for example, will come up the next or the second season after sowing, yet, by keeping them one or two years in the rot-heap, we are sure all the seeds will germinate the same spring in which they are committed to the soil. To the above general remarks, the gean forms an exception; for if sown immediately after being gathered in July, it will come up the following spring; but it will keep in the rot-heap a year. When any of these seeds are to be sent to a distance, instead of being carried to the rot-heap, they are spread thin in lofts, dried and packed in barrels; great care must be taken that they are sufficiently dried, otherwise putrescent fermentation will commence, and the vegetative principle will be destroyed by the heat evolved.

7013. *Sowing.* The season is generally February, and the manner by *bedding in*, as before. The haw, the most important of this class, should be sown in the lightest richest land in the nursery; and if not very rich, some dung may be added. Sow in beds three feet four, or three feet six inches apart; the seeds should lie within a fourth of an inch of each other, and be rolled with a roller of fifty or sixty pounds' weight, and exactly the breadth of the bed, previously to covering, which should be one inch deep. If the seeds are too moist to admit of drawing a roller over them, beat in the seeds with the back of the spade. This operation of rolling in seeds not only fixes them in their places, so as to admit of applying the covering with greater freedom, but by consolidation is calculated to retain moisture, exclude too much air, and thereby promote germination. Holly and yew seeds should be sown on rich friable soil, shaded by a wall or by wattled

hurdles, or other means, from the mid-day sun. The distance is the same as for laws; they should be rolled, or beat in, and covered not more than half an inch. If previously rotted for two years, they will all come up the following May; but if only one year in the rotting-bed, a part will not come up till the second year: in this case they should be sown thin, as the growing plants will impede the others in breaking through the soil. Mountain ash seeds require a fine and rather rich soil; the seeds should not lie nearer than an inch, and the covering should be only a quarter of an inch. The gean should be sown, as soon as gathered, in deep sandy loam, the pulp being previously bruised; it need not be very rich, but must be dug deep before sowing: place the seeds an inch apart, and cover three quarters of an inch thick. Gean-stones, which have been preserved in the rotting-ground for spring sowing, will not come up regularly the summer following, but a part will lie till the second spring. The advantage of sowing as soon as gathered, is therefore obvious. * Great care should be taken not to sow the cherry for the gean, as the former is not nearly so well calculated for a timber-tree. The seeds of the common and Portugal laurel, laurel-bay, mezereon, spurge-laurel, phillyrea, and the like, should be sown as soon as gathered, in rich soft soil, on a dry bottom: the seeds should be an inch apart, and be covered an inch. During the severest weather of winter, it will be advisable to protect them by hoops and mats. The seeds of the service, buckthorn, bird-cherry, and other species of prunus, rhamnus, and mespilus, may be treated like those of the laurel, but will not at all require so deep a covering, nor will any of them require protection in winter.

7014. *Transplanting.* What has been advanced on transplanting plants from nuts, keys, &c. will apply here. Most of these species being smaller, will not require so great distances between the rows and plants. All the deciduous sorts may be transplanted in February or early in March; and all the evergreen species from the middle of April to the middle of May, and during the month of August. The greatest care will be requisite in lifting evergreens from the seed-bed, where they have been already once moved, so as not to injure their fibres; and on no account should more be taken up at a time than what can be planted the same day. Select for them the soils most suitable to their natures (6974.), as far as the limits of the nursery will permit; and in general, rather prefer a shady situation, especially for the holly, yew, and all the laurels. Hollies having few fibrous roots should be frequently transplanted; but this is not necessary with the yew, which has fibres in greater quantity. In transplanting the deciduous sorts, prefer narrow spaces between the lines, and wider intervals in the rows, to wide rows, and plants crowded in the row. One year's seedling thorns, for instance, to be nursed one year, may stand nine or ten inches by two inches; if for two years, twelve or fourteen inches by three or three and a half inches.

7015. *For pruning, culture, and lifting for final planting, see nut-bearing trees, &c. (7004.)*

SECT. IV. *Trees and Shrubs bearing Berries and Capsules with small Seeds.*

7016. *The principal hardy berry and capsule bearing trees are the following: —*

Tilia europea, November
Pyrus communis, October
— *malus*, October.

Shrubs.

Berberis vulgaris, September
Buxus sempervirens, September

Cornus mascula, October
— *virginiana*, October
Sambucus nigra, September
— *racemosa*, September
— *canadensis*, September
Lonicera, various species, August
Jasminum fruticans, October

Ligustrum vulgare, October
Eucynmus latifolius, November
— *europeus*, November
Viburnum lantana, September
— *opulus*, October
Ribes grossularioides, September.

7017. *Gathering and keeping.* As this class of seeds are only wanted in small quantities, the most convenient way of preserving them is in the seed-loft or root-cellar in dry sand. They should be frequently turned over to separate the seeds from the pulp and husks, and cleaned by sifting and fanning early in February. For sending to a distance, they are to be treated like berried stones; or they may be separated and cleaned previously to deportation.

7018. *Sowing.* All of them require a soft and rather moist soil, with the exception of the box, which should have a soil rather sandy and dry. They may be sown in February, in beds, and covered not more than a quarter of an inch; and when the seeds first begin to vegetate, it will be an advantage to shade them from the sun, by wattled hurdles; place them across beds which lie north and south, and along those lying in a direction east and west.

7019. *Their transplanting and future culture are the same as for the foreign division.*

SECT. V. *Trees and Shrubs bearing leguminous Seeds, their Sowing and Rearing.*

7020. *The principal hardy leguminous trees are as follow: —*

Cytisus alpinus, October
Robinia pseud-acacia, November.

Shrubs.

Robinia caragana, November

Colutea arborescens, October
— *cruenta*, October
— *pocockii*, November
— *media*, October
Coronilla emerus, October

Cytisus nigricans, September
— *sessilifolius*, October
— *austriacus*, September
— *tomentosus*, September
— *laburnum*, October.

7021. *Gathering and keeping.* These being collected are to be dried thoroughly in an

airy loft, and the pods being afterwards threshed or opened, the seeds may be preserved in bags or boxes till spring, or sent to any distance.

7022. *Sowing.* The season for sowing all of them is February; the soil should be light, deep, and sandy, and the seeds placed an inch apart, and covered three quarters of an inch thick. This should be particularly attended to in the case of the laburnum, the seeds of which, being generally sure growers, if they rise thick, they lose their leaves about midsummer, become mildewed, and die. Attention should be paid not to inter-mix the tree-laburnum (*C. alpinus*, 'W. en.) with the shrubby sort.

SECT. VI. *Trees and Shrubs bearing small soft Seeds, their Sowing and Rearing.*

7023. *The principal hardy trees with small seeds are as under:—*

Alnus glutinosa, November
Betula alba, October
Ulmus campestris, June
— *glabra*, June
Populus nigra, May
— *tremula*, May

Populus alba, May
— *balsamifera*, May
Salix alba, June.

Shrubs.
Syringa vulgaris, October

Cistus, various species, September
Philadelphus coronarius, October
Salix pentandra, August
— *babylonica*, June
Rhus cotinus, and other species, July.

7024. *Gathering and keeping.* All these require to be gathered as soon as ripe, otherwise some are apt to drop out of their capsules, as the alder, birch, and lilac; and others to be blown away and lost, as the elm, poplar, willow, and sumach. They should be gathered perfectly dry, and spread thin in a airy loft, till fit to put up in bags or boxes, for keeping or deportation.

7025. *Sowing.* Most of the sorts may be sown immediately after being gathered, in which case they will be more certain of germinating; and a number of elms, poplars, and willows, will come up the same autumn. But as protection during winter will, in that case, become requisite, the better way, in general, is to defer sowing till March or April, when all the sorts may be sown in light rich earth, rather moist, and covered not more than half an inch. The principal tree of this class is the broad-leaved elm, which, where intended for two-year seedlings, which, in most cases, is the preferable age for transplanting, should be sown to rise at least two inches apart, as the plants grow with great vigor even the first year.

7026. Their *transplanting and future culture* are the same as directed for berried stones, keys, &c.

SECT. VII. *Culture common to all the Classes of Tree-seeds.*

7027. *Insects and vermin.* New-sown seeds of most kinds are greedily devoured by various descriptions of vermin. Mice attack "acorns, sweet chestnuts, hazel-nuts, walnuts, and holly-seeds. They not only eat them on the spot, but they carry to their retreats great numbers of the seeds of which they are most fond. The cheapest, and perhaps the most effectual trap for their destruction, is the well known but neglected fourth figure trap. (fig. 668.) The new-sown haws and mountain ash berries are a prey to the chaffinches, green linnets, and other birds. If the quantity sown be not great, the beds may be hooped over and covered with small-meshed nets. But if a great breadth of ground be sown, it must be constantly watched after sowing. If the watching be vigilantly attended to, for a few days immediately after sowing, the seed will not need much more attention till they begin to break the ground; at which period the watching should be closely and regularly continued. As they are always the strongest and best-ripened seeds which rise first; it is therefore of much importance to prevent these from being picked up." (*Plant. Kalend.* 250.)

668

7028. *Weeds.* Before the tree-seeds come up a crop of weeds will probably have made their appearance; these are to be removed when young, otherwise drawing out their roots will materially disturb the vegetating seeds. "It not unfrequently happens, that the land in which fir and larch seeds have been sown, becomes battered by heavy rains. This will certainly happen if rain fall immediately after sowing before the surface become dry; but if it once be fully dried after sowing, and before the rain fall, it will seldom or never batter. Suppose, however, the seed-beds are battered, so that the tender seeds cannot rise with freedom, the best way to relieve them is to draw over them a wooden roller, stuck over with lath-nails at half an inch distance, and driven in so as to remain half an inch beyond the wood of the roller. The roller should not be more than thirty inches long and not more than thirty pounds weight. By drawing this roller along the one side of the battered bed, while walking in the alley, and returning with it over the other, an ordinary-sized bed will be completely relieved. Some people *rake* their battered beds, in order to enable the seeds to rise. This is a most dangerous and destructive method of relieving vegetating plants. From their tender state, the smallest twist breaks them over, and consequently destroys them. We have experienced much advantage from using

the light armed roller, here recommended. It is, however, much better when no such are required. The surest way to guard against the need of such means, is to work the land when it is in a proper condition, and to sow the seeds in such weather as that the surface after sowing will be fully dry before rain come on. There is no dispensing with this precaution, when it is wished to secure an equal and good crop of seedlings." (*Plant. Kal.* 367.)

7029. *Birds.* In May the pines and firs will begin to pierce the ground with the husks of the seeds still on their tops, and then watching the birds becomes of the utmost importance; not one ought to be allowed to light on the beds; to prevent which will require unremitting attention from break of day till sunset, for five or six weeks, till the plants are all up, and have thrown off their husks. After the nuts, mast, and haws have come up, they are no longer in danger from mice, but they may be attacked by snails, and grubs of beetles and cockchafers at their roots. These are to be hand-picked.

7030. *Watering and shading.* In June severe droughts very often set in, and these are very prejudicial to small seeds, especially those of the resinous tribe, when rising through the soil. At this time watering and shading may be applied with great advantage, provided the former is accompanied by the latter, and daily attended to from the time it is commenced till rain falls. The best mode of shading is by the wattled hurdle. By the end of July the seedling plants of most sorts will be out of danger, and excepting a few of the tender sorts specified as requiring protection in winter, or by a hand-glass or cold-frame, will require no other care but weeding till fit to be transplanted.

SECT. VIII. *Of propagating Trees by Layers, Cuttings, Suckers, Grafting, &c.*

7031. *Layering* is next to rearing from seeds the most general mode of propagating hardy trees and shrubs. The more common species of forest trees to which this mode is applicable, are the *Acer Platanoides*, *pseudo-platanus*, *tartaricum*, *dasy carpum*, *opalus*, *negundo*, and other species; *Betula lenta*, *populifolia*, and *rubra*; *Fagus ferruginea*; *Platanus occidentalis* and *orientalis*; *Populus græca*, *monolifera*, and *cane-scens*; *Tilia alba*, *americana*, *europæa*, and *pubescens*; and *Ulmus campestris*, *ne-moralis*, and *suberosa*. Some of these, as the poplars and planes, are also propagated by cuttings; but layers make the strongest plants. Whenever seeds can be procured, however, it is best to propagate in that way, as likely to produce the largest trees. The other trees propagated by layers, will be found in our *Encyclopædia of Plants*, and in the *arboricultural catalogue*; and also all the shrubs so propagated. The situations and distances for planting stools in the nursery have been already mentioned (6981.); and, as there is nothing peculiar in the operation of layering timber-trees or shrubs, we have merely to refer to the general directions as to layers and stools. (1993.) The young or preceding year's shoots of all the sorts above enumerated, if layered in autumn or winter, will be fit for being detached and planted in nursery lines by that time twelve months. They should be transplanted into well comminuted soil, as far as practicable, suitable to the nature of each; the distances should be regulated by the size of the layers and the time they are to be nursed. For ordinary purposes layers need not be nursed more than two years; but for single trees and ornamental plantations, they should be several times removed, and close pruned, till they have attained six or eight feet in height. Evergreen trees and shrubs, as being more tender than the others, should be layered in March and April, and from August to October. Some sorts root most freely when the wood is in a succulent state; and of such the current year's shoots are laid about midsummer. This is practised with *Stuartia*, *Arbutus*, *Andromeda*, *Kalmia*, *Azalea*, *Magnolia*, *Alaternus*, *Phillyrea*, *Laurus nobilis* and *sassafras*, *Zanthoxylum*, *Pyrus japonica*, &c. The same practice is adopted with other free-growing sorts that it is wished to multiply as rapidly as possible; as the *Rosa* (6546.), *Hibiscus*, *Lonicera*, *Aristolelia*, *Mespilus*, &c. Layers of the last sorts made during summer from the same year's shoots, will be fit to detach by the winter or the following spring; of the other sorts seldom sooner than the second August or autumn; but even then a season is gained, as the layers of those plants made in autumn, generally require to remain two years before they have made sufficient roots. The layers of all evergreens should be removed at the proper seasons for pruning, laying, or transplanting that tribe; that is, in April and May, and in August and September.

7032. *By cutting* is the next most general mode of propagating trees and shrubs, and the common forest trees generally so multiplied are as follow: *Platanus occidentalis* and *orientalis*; *Populus angulata*, *balsamifera*, *dilatata*, *græca*, *monolifera*, *nigra*, *pendula*, and *trepida*; *Salix* all the tree species; and *Sambucus nigra*. These are also propagated by layers, and a few of them by seeds; which last, it should never be forgotten, is by far the best mode where timber-trees is the object. The numerous tribe of shrubs propagated by cuttings, will be found in the *Encyclopædia of Plants* already referred to.

7033. *The manner of forming and planting cuttings* has been already described. (2063.) The season for deciduous and evergreen woody plants are the same as for layering; and as in the latter mode of

propagation, so in multiplying by cuttings, some sorts succeed best when the current year's wood is taken at midsummer; as for example, *Laurus æstivalis*, benzoin, and sassafras, *Bignonia*, *Euphorbia*, *Phlomis*, *Rosa*, *Santolina*, &c. Cuttings of some of these sorts, made of year-old wood in spring or autumn, require to stand two seasons before they have made sufficient roots to admit of their removal; by midsummer cuttings one year is gained. The same practice may be applied to deciduous sorts; but the plants produced are not so strong as by cuttings of ripened wood. All cuttings require to be planted in a shady situation, and sandy soil, dry at bottom; but kept somewhat moist by occasional watering in dry weather; their lengths are generally made in proportion to the length of the year-old wood, but seldom exceeding six or eight inches. The shoots of some sorts, as poplar, willow, honeysuckle, &c., are divided into several cuttings of this length. An inch of the former year's wood is often preserved in autumn-made cuttings; but this is not essential; as more important points are, making a smooth horizontal section at a bud, and in planting, pressing the earth very firmly to the lower extremity of the cutting. Midsummer cuttings should in almost all cases be covered with hand or bell glasses. The alder, most willows, the Lombardy, and some other poplars, will grow from cuttings or truncheons of several feet long, and of several inches in diameter. "This method is occasionally adopted, when it is requisite to form expeditiously some rough plantation, to serve as a hedge or screen along an outward boundary. Cuttings for this purpose may consist of long slender rods of one or two years' growth, or as well of large truncheons or stakes from three to six feet in length. Further, the willow, in particular, will increase from large pole-cuttings of from six to ten feet, planted out at once to form either pollard-stems, or be trained into full standards." (*Abercrombie*.)

7034. The season for transplanting struck cuttings into nursery lines, are those already mentioned as the most fit for moving deciduous and evergreen trees, originated by other modes. (6983. to 7023.)

7035. *By suckers.* A few common trees, and a number of shrubs are propagated by suckers. The timber-trees are the *Ailantus glandulosa*, *Robinia pseud-acacia*, *Populus canescens*, *alba*, and *tremula*, and *Ulmus campestris*. Of hedge plants, the common sloe and other wild plums, crabs, and pears, are, or may be so propagated. Various shrubs are propagated by suckers. Suckers make better trees than plants raised from cuttings, and also very good hedge plants. To induce a tree to send up suckers, the horizontal roots may be laid bare, notched in different places, and the earth mixed with sand and replaced; a powerful co-operative would be to cut the tree over by the surface, by which means all the sap would be employed in root-shoots. At the end of one, but sometimes not till the end of the second season, the suckers will be fit to slip off, or to separate by the knife with a part of the parent root attached; they may then be pruned as required, and planted in nursery lines.

7036. *Grafting, budding, and inarching*, are modes applicable to a few hardy trees and shrubs. The common forest trees are the *Fraxinus americana*, *Populus canadensis*, *heterophylla*, and *lævigata*, *Pyrus Aria*, *Quercus exoniensis*, and *Ulmus campestris* and *suberosa*. These, and the ornamental trees and shrubs so propagated, are worked on stocks of the more hardy species of the same or of the next allied genus; and, probably, make as durable plants for timber-trees as layers; by which mode the above enumerated sorts are also propagated. The stocks should be at least one year established, previously either to grafting or inarching: the operation for deciduous sorts is performed in spring at the rise of the sap. (2010.) Evergreens are almost always inarched either in April, or May, or August. Budding is performed in June and July, and is chiefly used in propagating the rose. (6553.) Some inarched sorts require two seasons before the scion can be detached from the parent plant.

7037. *General culture and management of a private nursery.* There is nothing material to be advanced on this head, but what has been already recurred to in this chapter, or in treating of the general management of the kitchen-garden. The first grand point is so to arrange the rotation of crops, that a crop of culinary vegetables shall intervene between every crop of trees, where that crop remains on the same soil two or more years; and between every two or three crops, where the crop of trees is lifted annually or the second year. The next thing is changing the surface of the soil, as in horticulture (2557.), weeding, stirring the surface, watering, shading, pruning, training, staking, and protecting. The important points of management are to procure the proper quantities of seeds or stools requisite to produce the quantity of trees to be annually furnished; to proportion the number of plants taken up daily to the number replanted in the nursery or forest the same day, and to attend to general order and neatness.

CHAP. IX.

Arboricultural Catalogue.

7038. In our *arboricultural catalogue* we mean to enumerate, and shortly describe, the principal timber-trees which may be cultivated with advantage as such, in the climate of Britain, and also the most useful plants for hedges. We shall arrange the whole as resinous, hard-wooded, and soft-wooded trees; including in each section the hedge plants belonging to it, and in the last, the willows proper for osier-plantations; the general culture of the trees contained in each of these sections, has been given in chapters III. IV. VII. and VIII.

SECT. I. *Resinous or Coniferous Trees.*

7039. *The resinous forest trees* are comprised in three genera belonging to the natural order of *Coniferae*, J.; viz. *Pinus* and *Cupressus*, *Monac. Monad. L.*, and *Juniperus*, *Diac. Monad. L.* The trees which are valuable as timber are comprehended under the genus *Pinus*, which comprises the three subdivisions of pines, larches, and firs. The first is distinguished by fasciculated leaves in different sheaths, but proceeding from the same sheathing base; the second by fasciculated leaves from solitary sheaths; and the third by solitary leaves. The branches of the whole genus are frondose or spreading, and caducous: those of the pine tribe spread the least; those of the larch tribe rather droop; and those of the firs are thin and much spread, and are peculiarly frondlike.

7040. *The wild or Scotch pine*, erroneously denominated Scots fir, is the *Pinus sylvestris*, L. (*Lam. pin. 1. t. 1.*) *Pin*, Fr.; *Keifer* or *Föhre*, Ger.; and *Pino*, Ital. (fig. 669. a) It is an evergreen sub-conical tree; the foliage inclining to dark-blue or grey; shorter and broader than those of the stone pine (b); it is common in most parts of Europe, particularly the northern countries, and is the only species of the genus indigenous to Britain, being a native of Scotland, and naturalised in England and Wales. Under favorable circumstances it attains the height of seventy or eighty feet: it flowers in May, and the cones are fit to gather in December. The finest pine-woods in Britain are at Invercauld, in Invernesshire, and Gordon Castle, in Aberdeenshire.

7041. *Use.* The timber of this tree is the red or yellow deal of the north of Europe, and is the most durable and valuable of any of the genus, unless we except the common larch. The universality of its application is known to every one. The Highland pine, Sang states to be not inferior to any imported, either in cleanness or durability, when it has been grown on a proper soil, and to a sufficient age. "But the planted Lowland pine," he adds, "is seldom applied to offices higher than that of roofing sheds or huts, lining of carts, lathing, or making of packing-boxes; while the natural or self-sown is fit for the finest purposes." Pontey considers the English-grown wild pine, if properly pruned and grown to a sufficient age, as likely to equal that of foreign growth. The tree is of great value as a nurse-plant; being next to the common birch and bastard mountain ash, or mountain sorb (*Pyrus hybrida*), the most hardy timber-tree. Among its minor uses we shall only mention the production of tar by incision.

7042. *Varieties.* Of these, several have been noticed by botanists, and some consider the *P. maritima* (Willden.) as nothing more. According to Sang, the variety commonly cultivated is least worth the trouble. "The *P. sylvestris*, var. *montana*," he says, "is the variety which yields the red wood; even young trees of this sort are said to become red in their wood, and full of resin very soon. The late distinguished Don, of Forfar, exhibited specimens of cones of each variety to the Highland Society of Scotland, and likewise to the Caledonian Horticultural Society. The variety preferred by Don, is distinguished by the disposition of its branches, which are remarkable for their horizontal direction, and for a tendency to bend downwards close to the trunk. The leaves are broader and shorter than in the common kind, and are distinguishable at a distance by their much lighter and beautiful glaucous appearance. The bark of the trunk is smoother than in the common kind. The cones are thicker, and not so much pointed. The plant is more hardy than the common sort, grows freely in almost any soil or situation, and quickly arrives at a considerable size." Sang says, he has seen trees of this variety at Caristoun and Brechin Castle: and it is much to be wished that he or some other competent nurseryman, in that quarter, would collect the seeds, and propagate it extensively. Thouin (*Notes sur la Culture de Pins*, 8vo. 1819.) mentions a variety, which he calls *P. syl. var. pin de riga*, as affording the best timber. Whether the pine which forms the extensive plantations along the sea-coast at Bourdeaux, and is called by foreign authors, *Pinus maritima*, be a variety of *P. sylvestris* or a distinct species, does not appear to be ascertained. The plant is tender, and easily killed by frost when young; but its timber is said to be of excellent quality. (*Radclyff's Flanders*, 250.)

7043. *Soil and native site.* "This tree is naturally the inhabitant of mountainous districts, and of rocky, gravelly, or poor sandy soils, where its timber becomes most valuable and durable. On the sides of mountains, in dells and hollows, among stones and rocks, beside rapid rivulets or mountain torrents, it is found in high perfection; and if it stand single, it is of great beauty. In many parts of the Scots Highlands, where the soils are extremely various, and much mixed, the Scots pine has arrived at a good size, and often attained remarkable dimensions. In any kind of soil from a sandy to a clay, provided the substratum be rubble or rock, it will grow and flourish; but in wet tilly soils, it ought never to be planted; because whenever the roots have exhausted the turf or upper soil, and begin to perforate the sub-soil, the tree languishes and dies." (*Plant. Kal.* 65.)

7044. *Insects.* The larvæ of *Noctua Pinastri*, L. (*Xylena*, Hüb.) are deposited in the leading buds, and often perforate the young shoots, and leave the tree without a leader. The *aphis pini* infests the tender shoots; and various *dermestidae* live in the bark, and perforate the soft wood.

7045. *The Corsican pine* (*P. laricio*, P. S.) is a native of the mountains of Corsica and is nearly allied to the Scotch pine. There is a specimen in the Paris gardens, planted in 1784 and 56 feet high in 1821, thus described by David Don. "*P. laricio* is a much handsome and finer tree than *P. sylvestris* with which however it in some respects agrees. It is of a more pyramidal habit, and its branches are shorter and more regularly verticillated. Its leaves are a third longer, and of a lively green, with their sheaths nearly entire." Its cones are shorter, ovate and quite straight, with depressed scales: and its bark is finer and much more entire. The enlightened Professor of Agriculture informed us, that it is equally hardy with *P. sylvestris*, and that its wood is much more weighty and resinous, and consequently more compact, stronger, and more flexible. It grows wild on the summits of the highest mountains in Corsica. It seems to bear cones very freely, which ripen nearly about the same time as those of *P. sylvestris*.

7046. *The pitch or red Canadian pine* (*P. resinosa*) (*Lam. pin. 20. t. 4.*) is an Ameri-

can tree, introduced in 1756, not unlike the Scotch pine, and "receives its name from the color of the bark. From the high geographical range of this pine, it is well adapted to associate with the *P. sylvestris*. It has been imported in the form of masts into this country. Like the *P. sylvestris*, it affords an inferior timber on a damp and unsuitable soil." (*Caled. Hort. Mem.* ii. 367.)

7047. *The pinaster or cluster-pine* (*P. pinaster*, L.) (*Lam. pin.* 9. t. 5.) (*fig.* 669. *b*) grows to the height of fifty or sixty feet, with broader, thicker, and longer leaves than the common pine (*a*): the branches are also farther apart, and grow more horizontal than in that tree. As the tree advances in age it becomes naked and unsightly below; but the top grows highly picturesque, and may readily be distinguished in the landscapes of the Roman and Florentine painters. It grows naturally on the mountains of Italy and the south of France; in Switzerland it is cut into shingles for covering their houses, and also for making pitch. It flowers in April and May, and the cones are fit to be gathered in December. It was introduced in 1596, but never much cultivated, being less hardy and much less valuable as a timber-tree than the common pine. It is very picturesque, and well merits culture in that point of view. There are some large specimens at Culzean Castle, on the sea-coast of Ayrshire.

7048. *The stone pine* (*P. pinea*) (*Lam. pin.* 11. t. 6, 7, 8.) (*fig.* 669. *c*) grows to a considerable height, with a straight stem and rough bark. The leaves are not quite so long as those of the pinaster, and are of a greyish or sea-green color. The cones are five inches in length, round, thick, and obtuse; the kernels are large, and frequently served up in desserts during the winter season in Italy and the south of France, and they are also much relished by the Chinese, for the same purpose. It is a native of the south of Europe; very common about Ravenna, and forming a distinguishing ornament of the villas of Rome and Florence. It was introduced here in 1570; but as the wood is not so resinous as most of the other sorts, it has been only cultivated for ornament.

7049. *The swamp, Georgia, pitch, or long-leaved pine* (*P. palustris*) (*Lam. pin.* 27. t. 20.) (*fig.* 669. *d*) is a valuable and a lofty tree in America, affording planks, which, imported in this country, are valued 20 per cent. higher than any other American timber excepting the black larch. The leaves are a foot or more in length, produced in tufts at the ends of the branches, and having a singular appearance. It grows in a warmer climate than most other pines; and if it were found to produce equally valuable timber in the low warm situations of England, which it does in America, it would be a most valuable tree. It was introduced in 1730, but has been very little cultivated.

7050. *The Weymouth or New England larch*, commonly called Weymouth pine, (*P. Strob*) (*Lam. pin.* 31. t. 22.) (*fig.* 670.) forms the connecting link between the pine and larch tribe. It is one of the tallest of the genus, attaining in America the height of 100 feet and upwards. The bark is smooth and delicate, and the leaves soft and of a bluish green. Vast quantities of the timber, under the name of the white pine, are imported from America; but the tree seems to be of so delicate a habit, as to prevent our expecting it ever to become a large or valuable tree with us, especially in exposed situations. It was introduced in 1705, and has been a good deal cultivated, having formerly been supposed the most valuable tree of the genus, next to the common pine. The largest specimens are at Mersham-hatch, Sir E. Knatchbull's seat in Kent, and at Whitton Park in Middlesex.

670

7051. *The cedar-larch, or cedar of Lebanon*, is the *P. cedrus*, L. (*Lam. pin.* 59. t. 37.) *Cèdre*, Fr.; *Cederbaum*, Ger.; and *Cedro*, Ital. It is distinguished from all other trees of the genus by its strong ramose branches, which, in some cases, deviate from the common character, and become irregular in shape, and permanent in duration. The general character of the shoot, even when the tree is young, is singularly bold and picturesque, and quite peculiar to the species. The tree is a native of the coldest part of the mountains of Libanus, Amanus and Taurus; but it is not now to be found in those places in great numbers. Maundrell, in his journey from Aleppo to Jerusalem in 1696, could reckon only sixteen large trees, though many small ones: one of the largest was twelve yards six inches in girth, and yet sound; and thirty seven yards in the spread of its boughs. The forest of Libanus never seems to have recovered the havoc made by Solomon's forty score thousand hewers: so that we have now, as Professor Martyn observes, probably more cedars in England than there are in Palestine. The tree is supposed to have been introduced here in 1683. The oldest specimens are

two in Chelsea-garden; but there are more magnificent ones at Whitton Park, Zion House, Pains-hill, Warwick Castle, and other places.

7052. *Use.* The tree has been very generally planted for ornament, and from its branchy head, and its aversion to pruning, it is not likely ever to become a valuable timber-tree in this country. When planted for that purpose, it should, as Sang recommends, be sown in groves, and thus by proximity drawn up with few branches. Much has been said of the timber which borders on the miraculous; as far as experience has gone, it is greatly inferior to that of the common larch, or the wild pine. Its great use is as a single tree in lawns, where it combines beauty and singularity in a degree not to be found in any other tree. It has also an excellent effect in the margin of plantations, and one or two plants will give force and character to the dulllest front of round-headed trees, and effect a great deal even in the fronts and sky outlines of plantations with spiry tops. (fig. 560.)

7053. *The common larch* is the *P. larix*, L. (*Lam. pin.* 53. 35.) *Larix* or *Mélèze*, Fr.; *Gerchenbaum*, Ger.; and *Laricio*, Ital. It is the only species of the genus, the leaves of which are deciduous; it rises to eighty or a hundred feet high, forming a narrow cone of small white-barked caducous, pendulous branches, with delicate drooping spray. It is a native of the Alpine mountains, on the north sides of which, in hollows and chasms, it attains to its greatest height and thickness, and most durable timber. In returning from Italy, by the Simplon, the silver fir will be found in great perfection in the hollows on the south side, the common Scotch pine on the summit, and the larch in descending to the Vallais. It appears to have been cultivated by Parkinson in 1629; and Evelyn, in 1664, speaks of a tree of good stature, "not long since to be seen at Chelmsford, in Essex, (also mentioned by Harte,) which sufficiently reproaches our not cultivating so useful a material for many purposes." Harte, in his excellent essays, published in 1715, gives a figure of the larch, and strongly recommends its culture. It was first introduced into Scotland by Lord Kames in 1734 (*Lam. pin.* t. 35.), and afterwards in 1741, planted by the Duke of Athol at Dunkeld, and these last trees have prospered so astonishingly, and the timber produced from such as have been cut down, has so fully answered all the eulogiums that have been bestowed on it, that the larch is now considered on the whole, as decidedly the most valuable timber-tree, not even excepting the oak. Some of the first-planted larches in the low grounds, near Dunkeld, have grown to the height of one hundred and twenty feet in fifty years, which gives an average of two feet four and a quarter inches a-year. It is stated by the Duke of Athol, in a communication to the Horticultural Society, made in June, 1820, that on mountainous tracts, at an elevation of fifteen or sixteen hundred feet, the larch, at eighty years of age, has arrived at a size to produce six loads (300 cubic feet) of timber, appearing in durability and every other quality, to be likely to answer every purpose, both by sea and land. (*Hort. Trans.* iv. 416.) Professor Martyn (*Miller's Dict.* in loco) has brought together a mass of valuable information respecting the history of the larch in this country, and its uses in others. That singularly accomplished agricultural writer, Dr. Anderson, did much to promote its increase by his essays and other works from 1750 to 1790; and subsequently the Bishop of Llandaff, Marshall, Nicol, Pontey, and Sang, have each, in practice, and by their popular publications, contributed to spread the tree; and now several millions are annually planted in the mountainous districts of the empire. The larch, Sang observes, passes all other timber-trees, for the first ten or twenty years after planting, and will arrive at a timber size in almost any situation or soil. It bears, he says, "the ascendancy over the Scots pine in the following important circumstances: that it brings double the price, at least, per measurable foot; that it will arrive at a useful timber size in one half or a third part of the time, in general, which the fir requires; and, above all, that the timber of the larch, at thirty or forty years old, when placed in soil and climate adapted to the production of perfect timber, is in every respect superior in quality to that of the fir at a hundred years old. In short, it is probable that the larch will supersede the Scots pine in most situations in this island, at no very distant period." The finest specimens of this tree are at Dunkeld, Blair, and Monzie, in Perthshire.

7054. *Use.* Much has been said of the durability of larch-timber in Italy: its resistance to fire, according to some (Matthiolus), and its great combustibility, according to others (Du Hamel); its durability under water (at Venice), and its not being liable to warp (Harte). We shall confine ourselves to its uses as experimentally proved in Britain; and perhaps we shall do this with most effect by stating that it may be used for all the purposes for which the best foreign deal is applied; for many of those of the oak; and that it is more durable than any other timber when placed in a situation between wet and dry, especially if the bark be not removed, it being still more incorruptible than the wood. The bark is also of considerable value in tanning; a circumstance of great importance, since it is found that disbarking a year or more previously to felling is the best mode of seasoning the timber (6955.), and preventing it from warping, or being attacked by the dry or wet rot. (5927. and 6926.) One property almost peculiar to the larch is, that the timber is exceedingly valuable at every period of its growth; so that a dead hedge of larch-boughs, or a hurdle watted with larch-spray, will last longer than dead hedges or watted hurdles of any other species of tree. Planted in rows in exposed gardens it forms a useful hedge plant in point of shelter; but in this respect is deficient as a fence, and gets soon naked below. It is, stakes, pales, rails, posts, and especially gate-posts, of this tree, are therefore more valuable than of any other; the spruce fir approaching the nearest to it in these respects. Turpentine is extracted from it in the Tyrol; but that being always injurious to the timber, can never be recommended for adoption in this country: it is also peculiarly valuable as a nursing-tree.

7055. *Varieties or species.* Of the *P. larix*, there is a variety with red and another with white flowers, one with cinereous bark, called the Russian larch, and one with pendulous branches. There are also the

black larch (*P. pendula*) and red larch (*P. microcarpa*), natives of America, by some considered distinct species; the timber of both of which is said to be harder than that of the common white larch. As these trees are only to be met with in the nurseries, originated by layers, they cannot be recommended to be planted as timber-trees. There are, however, a few large specimens at Dunkeld and other places; and from these the trees will probably soon be propagated by seed, and a practical estimate be formed of their merits. There are some trees of the red larch on the Athol estates, but they do not contain one third as many cubic feet of timber as the white larch at the same age. The wood is so ponderous that it will scarcely swim on water. (*Hort. Trans.* iv. 416.)

7056. *Soil and site.* The larch will grow and attain a large size in every soil and situation, excepting in standing water; but a certain elevation of surface, or coldness of climate and inferiority of soil, is absolutely necessary to produce the timber in perfection. The quality of the timber of all trees is more or less affected by climate and soil; but that of the resinous tribe particularly so. We pointed out several instances in 1806. (*Treatise on Country Residences*, ii.) Sang mentions a number as having occurred since 1812 (*Plant. Kal.* 59.), and observes generally that he has "known it in many places make the most rapid progress for 30 or 35 years, and though there was no external signs of disorder, yet, when it was felled, the wood had begun to rot in the hearts of the trees; so that there was scarcely a sound tree over a large extent of ground; yet here, the oak, the chestnut, the elm, and the ash, amongst which the larch had been used as a nurse, are not only in the utmost vigor, but their wood is perfectly sound. Some larches in a similar soil and situation had attained seven feet each, and were quite hollow a good way upwards."

7057. *Insects.* The *Coccus laricea*, and the others mentioned as inhabiting the common pine.

7058. *The Norway fir, or common spruce fir, (P. Abies, L. (Lam. pin. 73. t. 25.) Sapin, Fr.; Fichte, or Tanne, Ger.; Abiete, Ital.)* is the first species of that section of pinus in which the leaves are solitary. It is one of the tallest of European trees, attains from 100 to 150 feet in height, with a very straight but not thick trunk, and throwing out its spreading frond-like branches so as to form an elegant narrow cone of vivid green. It is a native of the north of Europe, and particularly abundant, as the name imports, in Norway: its timber being the white deal received from that country and the Baltic. It is supposed to have been introduced about 1548, and has been, and still is, more cultivated than any species of the genus, excepting the common pine and the larch. Some of the finest specimens are in Harefield Park, at Blenheim, and at Temple Newsham.

7059. *Use.* The timber is inferior to that of the common pine in durability and bulk; and being often knotty, is not proportionably strong for horizontal bearings with that timber. White Norway deal, however, is used for a great variety of purposes in building; and the entire trees are more prized than any other for masts for small crafts, for spars both for marine purposes and on land. What constitutes the value of this fir is, that its timber is equally durable at any age, like that of the larch; and what renders it peculiarly adapted for masts, spars, scaffolding, poles, &c. is its habit of almost in every case, whether standing single or detached, growing perfectly erect and straight. The tree may be cut for rods, stakes, and scythe or other implement handles, when the trunk at the base is not more than two inches in diameter, and the bark being kept on it, it will prove almost as durable as the larch. Pontey says, that poles of spruce are so far inferior to those of the larch, that they are more apt to crack when exposed whole to the influence of the sun and air; but in all other respects it is nearly equal to it, and in straightness surpasses it. The tree is peculiarly valuable as a nurse, from being evergreen, and closely covered with branches, by which radiating heat is retained; from its conical shape and rigid stem, by which it does not suffocate or whip the adjoining trees; from its being valuable at whatever age it is thinned out; and from its being an excellent shelter for the most valuable game. It will not, however, grow in situations where the common pine and larch will flourish. It is also an excellent hedge plant for shelter, but is deficient in point of defence and durability. By incision, it yields a resin, from which, by various preparations, turpentine and Burgundy pitch are formed. The tops or sprouts (*spruytsen*, Ger.) give the flavor to what is called spruce-beer.

7060. *Varieties and species.* Linnæus has five varieties of *P. abies*; but the principal are, the white (*P. alba*) (*Lam. pin.* 39. t. 26.), the red (*P. rubra*) (*Lam. pin.* 43. t. 28.), and the black (*P. nigra*) (*Lam. pin.* 41. t. 27.) These are all natives of N. America, and their timber, which is white, possesses nearly the same properties as that of the European species. The white spruce rises only to 40 or 45 feet, with pale bluish-green leaves. The black spruce is reckoned the most durable of the tribe. "In America, the black spruce is used for knees in ship-building, where neither oak nor black larch can be easily obtained: these knees are not prepared from two diverging branches, as in the oak; but from a portion of the base of the trunk connected with one of the largest diverging roots. The timber of the red is universally preferred throughout the United States for sail-yards, and indeed imported for this purpose into Liverpool from Nova Scotia, where it is also used for constructing casks for salted fish. It is chiefly from the decoction in water of young shoots of the black, and not exclusively from those of the white spruce, as supposed by Lambert, that the celebrated beer is prepared by fermentation, with a due proportion of sugar or molasses. The essence of spruce of the dealers is prepared by evaporating this decoction to the consistence of honey."

7061. *Soil and site.* Pontey says it grows rapidly on every description of soil, from a very stiff loam, and such as possess a very considerable degree of humidity, to a very dry sand, provided the situation be not very much exposed. Sang says it luxuriates much in deep low situations: in shallow soils and exposed places it never succeeds. It "should never be planted for the sake of its wood, excepting in masses or groves by itself; otherwise its timber is so coarse and knotty, that it is hardly worth working: but in the mass way, if planted thick, and properly pruned and thinned afterwards, it may be trained to tall clean timber."

7062. *Insects.* The *Coccus abietis*, and occasionally the others which infest the common pine.

7063. *The silver fir (P. Picea) (Lam. pin. 46. t. 30.) (fig. 671. a)* is a lofty evergreen tree, forming a cone broader at the base, in proportion to its height, than the spruce, and displaying a more stable and majestic figure than any of the other firs. It is more thinly covered with frond-like branches than the spruce, and differs from it also in regard to the frondlets, which, when they grow old, and begin to decay, do not droop down as in that tree, but remain rigid till the last. The upper surface of the leaves is of a fine vivid green, and their under surface has two white lines running lengthwise on each side of the midrib, giving the leaves that silvery look, whence has arisen the name. It flowers in May, and the cones are ripe in December. It is a native of the Alps and Germany, was known here in 1603, and has been a good deal planted

as an ornamental tree. It grows faster for the first twenty or thirty years of its growth than any other tree of the genus, excepting the larch. Some of the finest specimens in England are at Woburn, in the evergreen-drive, planted by Miller. The tree called the grand silver fir there, measured, in 1810, nine feet ten inches in diameter, at four feet from the ground; it has a clean-pruned stem of seventy-five feet, and the estimated height is upwards of 110 feet.

7064. *Use.* The timber is reckoned inferior to that of the common pine, and is not of much value till of forty or fifty years' growth. According to Sang, though till of late years planted only as an ornamental tree, "yet there is, perhaps, none of the genus more worthy of cultivation for the sake of its timber." It is more prolific in resinous matter than any of the fir kind.

7065. *Its soil and site* are nearly similar to those most desirable for the common spruce; but it requires a climate rather milder, and a more loamy earth. On poor sands, where the common pine and larch will thrive, it dies off in a year or two after planting. None of the genus are more majestic on a lawn; but its characteristic or natural situation, is in dells, and on the sides of sheltered rocky steepes.

7066. *The balm of Gilead fir (P. Balsamea) (Lam. pin. 48. t. 31.) (fig. 671. b)* is an American tree of much smaller stature, and more delicate habits than the silver fir. Its timber is of little value; nor can the tree be reckoned very ornamental, though frequently planted for the sake of variety. The balm or resin procured from it possesses no medical properties superior to those of common turpentine; but the tree during summer sends out a pleasing terebinthinate odor.

7067. *The hemlock-spruce, or hemlock-fir, (P. Canadensis) (Lam. pin. 50. t. 32.) (fig. 671. c)* is a drooping, low, evergreen tree, which may be considered as entirely ornamental.

SECT. II. Hard-wooded non-resinous Trees.

7068. *Of hard-wooded trees* we shall give a few descriptive traits of the principal species; the most important of which are the oak, ash, elm, chestnut, and beech.

7069. *The oak* is the *Quercus*, L. *Monac. Polyan. L. and Amentaceæ, J. Chêne, Fr.; Eich, Ger.; and Quercia, Ital.* The following species and varieties are planted for their timber.

7070. *The common oak (Q. robur) (Eng. Bot. 1845.)* is a native of Britain. It grows to the height of fifty or sixty feet when in a heavy loam; flowers in April, and ripens its acorns in October and November. The most valuable variety of the common oak is said (*Caled. Hort. Mem. iii. 376.*) to be the pedunculata (*Eng. Bot. 1342.*), or the stalk-fruited; by some considered a distinct species. It is distinguished from *Q. robur* by the marked circumstance of the acorns being placed on long fruit-stalks, whilst those of the *robur* are nearly sessile. Besides, the superior utility and hardness of the timber, the pedunculata oak is, in fact, the more magnificent of the two British sorts. Miller says, this variety of the *Q. robur* (and which he calls the *femina*), is more rare than the sessile-fruited; but Professor Martyn says, this is not the case, and that the pedunculata is equally general as the other. It is observed by Du Hamel, that oaks in forests being propagated from the acorn, there are so many varieties that it is difficult to find two resembling each other in every respect. Professor Martyn observes, that the figures in ancient authors have the fruit uniformly on foot-stalks, which shows that that variety had been most common; and Ray considers it as the common oak of England. Du Roi affirms, that the timber of the sessile-fruited is reddish, and brittle, whilst that of the stalk-fruited is whitish and hard. From these and various accounts, as well as our own observation, we consider ourselves justified in recommending to nurserymen and others, who gather acorns for seeds, to take effectual precautions that only the stalked sort be gathered.

7071. *The Turkey oak (Q. cerris) (Du Roi, 2. t. 5. f. 1.)*, a native of the south of Europe, introduced in 1735. This species is distinguished by oblong, pointed, and frequently lyrate leaves, jagged, and a little hoary on the under side. The acorns are small, and have rough prickly cups. The tree grows from forty to sixty feet high. There are several varieties, but the best is that called the Devonshire or Lucombe, from the name of the person who raised it from seeds, saved from a tree of the Turkey oak grown in Devonshire.

7072. *Other oaks.* There are about forty species of exotic oaks introduced in this country, which may be considered as timber-trees, and are such in effect, in their native countries. Of these the greater part are natives of America; and it has been recommended (*Caled. Mem. iii. 378.*) to cultivate the *Q. tinctoria* or Quercitron on account of its bark, which affords a valuable yellow dye; all these species, however, are either too tender, or too scarce, or too dwarfish, and slow-growing, to warrant us in considering any other than the common and Lucombe oaks, as fit for the purposes of profitable planting.

7073. *Use.* The oak cannot be considered so valuable a tree for general purposes as the common pine and larch; but its great strength and durability will probably long maintain its superiority in Europe, and the other temperate regions of the globe, as a material for naval architecture. The timber is useful at every age, and more durable when of small diameter than that of any other of the hard woods; the value of the bark of young trees is greater than that of such as are old.

7074. *Soil and site.* It grows best in a deep clayey loam, not beyond a moderate elevation above the sea; but it will grow in any soil not marshy, not attaining, however, a large size in poor sands or at a considerable elevation.

7075. *Insects.* The egger moth (*Phalæna Quercus*, L.; *Lasiocampa*, Leach) (fig. 672.) inhabits all the species, and its larvæ sometimes denude entire branches. The small gnât (*Cynips Quercus folii*, L. *Diplolepis*, Leach) (fig. 673.) pierces the leaves with its sting, and deposits its eggs in the wound; the extravasated juices rise round it, and form a gall, which becomes hard, and in this the larva lives and feeds, and changes to a pupa. The oak-galls of commerce are so formed: the best are imported from Turkey and Greece.

673

7076. The ash is the *Fraxinus*, L. *Polygam. Diœc.* L. and *Oleina*, B. P. *Frêne*, Fr.; *Asche*, Ger.; and *Frassino*, Ital. There are two species which may be considered as forest trees.

7077. The common ash (*F. excelsior*, L.) (*Eng. Bot.* 1692.) is a native of Britain, and grows from sixty to eighty feet in height, with a straight stem. It has pinnate leaves, which come out late in spring, generally from April 22d to May the 15th, and fall early in autumn; it flowers in April and May, and the female and hermaphrodite plants ripen their seeds or keys in November. Of this there is a variety, the simple-leaved (*simplicifolia*), possessing no advantages as a timber-tree, and rather to be avoided by the profitable planter, as generally propagated in the nurseries by layers. Raised from seeds it produces pinnate leaves.

7078. The white or American ash, *F. Americana*, W. (*Mich. Arb.*) This is a lofty tree like the other, distinguished by the whiteness of its bark, narrow leaves, and smaller seeds. It is found in Jersey and Pennsylvania, where it attains the height of eighty feet, with about three feet in diameter at the base. It is patient of cold, thrives in deep fresh soil, by the banks of rivers, and unites all the good properties of the common ash. There are two varieties, the red and blue: by some accounted distinct species. They are smaller trees, and present no advantages to the profitable planter over the two species mentioned.

7079. *Use.* The ash is unquestionably the most valuable indigenous timber next to the oak; and in some places, as copse, is more valuable than that tree. It is more especially used by the coachmaker and agricultural carpenter. The wood is useful when the stem is only three inches in diameter. Toughness and elasticity seems to be its characteristics, and for this purpose, the faster the tree grows the better. Timber from a tree of slow growth, and considerable age, is uniformly found to be more or less brittle, and therefore more or less unfitted for the purposes to which this tree is applied, especially shafts or poles of carriages. As underwood, it is fit to cut every seven years for crate-ware for the potteries, hoops, and hop-poles, requiring for those products little or no thinning or culture, but merely periodical cutting. It forms excellent fuel, burning when green or new better than any other tree. "A few ash-pollards," Professor Martyn observes, "will produce many loads of lop, which makes the sweetest of all fires." The ashes afford more potash than those of most trees; and the bark is used occasionally for tanning, and will dye yellow.

7080. *Soil and site.* It will not thrive on thin soils, where the bottom is wet, nor in mossy earth or gravel; but in most others it will do well: and above all, in a hollow, where a friable loam has accumulated from the *débris* of surrounding rocky heights, and is drained by a rivulet. Such rocky dells and dingles abound in Perthshire and Fifeshire, and in them the ash is to be found in great perfection. It will not thrive at a great height above the sea, nor in bleak situations anywhere.

7081. The elm is the *Ulmus*, L. *Pentand. Dig.* L. and *Amentaceæ*, J. Orme, Fr.; *Ulmebaum*, Ger.; and *Olmo*, Ital. There are two species which may be regarded as timber-trees.

7082. The English or narrow-leaved elm, *U. Campestri*. (*Eng. Bot.* 1886.) (fig. 674. a) It is considered a native, or naturalised in England, by Sir J. E. Smith and others; but Dr. Walker considers it as brought originally from the Holy Land. It would be difficult to point out any situation where it has the appearance of having sprung up from seeds; though it is said to be common in the woods of the north-west of England. It is certainly the loftiest of the deciduous trees of this country, being often found upwards of eighty feet high. It flowers in April and May, and ripens its seed in a fortnight or three weeks after the decay of the flower. This species requires a dry soil, rather good than indifferent, and also a good climate. It does not thrive in the north of England or in Scotland, unless in good soils and moderately sheltered places. Professor Martyn says, it is not found north of Newark on Trent. It grows to a great size in a short time. Evelyn says, in little more than forty years it will arrive to a load of timber. Marshall says, the largest narrow-leaved elms he has seen, are in the Vale of Gloucester, and of these, the best is Piffé's elm, near the Baddington oak. At five feet high it girths sixteen feet; at ten feet it throws out large arms, which rise seventy or eighty feet. Some of the elms in the mall of St. James's Park are upwards of 200 years old. Boucher says, that he sold a line of English elms, above sixty in number, which at twenty-four year's growth were about eighteen inches in diameter, a foot above ground, and forty feet high.

674

7083. The Dutch elm (introduced with King William), *U. major* (E. B. 2161.), *U. suberosa*, W. It is chiefly remarkable for its fungous rough bark, large rugose leaves, and rapid growth. The timber is of little use.

7084. The Scotch or smooth-barked elm (*U. glabra*) (E. B. 2248) (fig. 674. b) is readily distinguished by its smooth dark lead-colored bark, and by its leaves, which are nearly smooth on the upper surface. It is the most useful timber-tree of the genus, and is almost the only tree of the elm kind planted in Scotland, where it also forms stocks for grafting the Dutch and English elm. A new variety of this species has attracted notice at Downton, which Sabine (*Hort. Trans.* vi. 146.) proposes calling the Downton elm. A very rapid-growing variety, called the Scampston elm, is in vogue in Durham and Northumberland. (*Agr. Surv. of Durham*, ch. x.)

7085. *Other species.* The genus *Ulmus*, like *salix*, is one of those whose species are so nearly related as to be often confounded. Linnaeus considered all the European elms as forming only one species. At present botanists make five British species, besides an equal number from America. The *U. campestris* and *glabra*, however, are the only sorts worth cultivating for their timber. (*Don*, in *Hort. Tour*, 539.)

7086. *Use.* Elm-timber is used in all works where it may be continually dry or wet; as, for water-pipes, pumps, water-wheels, &c. It is also very generally used for weather-boarding, and for common cabinet-work. The knotty parts like those of the ash, are used for naves and hubs. The lop and top make good fuel and charcoal.

7087. *Soil and site.* The narrow-leaved elm requires a light dry soil and warm situation, and will do little good in sand or gravel, in exposed places; but the smooth-barked sort is a very hardy tree, and will grow in thin clayey soil on retentive substrata better than most others. It will also thrive in situations elevated and exposed on all sides.

7088. *The beech is the Fagus sylvatica, L. (Eng. Bot. 1846.) Monac. Polyan. L. and Amentaceæ, J. Hêtre, Fr.; Büche, Ger; and Faggio, Ital.* It is a native of England, and grows in its natural soil and situation to sixty or eighty feet high. It is found congregated in forests, in chalky flinty soils, thrives well in sheltered bottoms: but not where it is exposed to the west. There are fine specimens of this tree at Castle Howard, Woburn, Newbottle, and Dalkeith Park. It is not so long-lived as the elm, nor will it grow in situations so much elevated as will the Scotch elms.

7089. *Use.* The timber is brittle, and decays soon in the air; but under water it is more durable. It is used by the millwright, turner, carver, last and wheel maker, chair and cabinet maker, and more or less in other branches. It is much used by bakers and in glass-houses as billet-wood; and the stack-wood forms an excellent charcoal.

7090. *Soil and site.* Dryness and some degree of calcareous matter are the characteristics of the soil in which the beech delights; and the declivities of hills facing the east or south are its favorite situations.

7091. *The common hornbeam is the Carpinus Betulus, L. (Eng. Bot. 2032.) Monac. Polyan. L. and Amentaceæ, J.* It is a native tree, nearly allied in habits and appearance to the beech, but is less lofty, and thrives in colder stiffer soils, and in rather more elevated situations. It flowers in April, and ripens its seeds in November. "Although Evelyn is perhaps too partial to the hornbeam, yet, raised from seed, it forms a tree of the first rate, equalling the common beech in magnificence; but unfortunately the hornbeam, like several of our best forest trees, may with ease, almost at any period of the year, be propagated from layers, and the usual consequences of this practice, follow, — a stunted, bushy, dwarf-like progeny. This tree, however, retaining its decayed, shrivelled, pale-russet leaves during winter, like the common beech, forms most valuable shelter planted in hedges." (*Cal. Mem. ii. 397.*)

7092. *Use.* Chiefly in turnery, being white and tough as the name imports. It is frequently used as a substitute for the beech.

7093. *Soil and situation.* A dry soil is essential, whether cold or chalky. It is a social tree, and found in natural copse-woods, as in Hertfordshire; but never at any great height above the level of the sea.

7094. *The Spanish chestnut is the Castanea vesca, W.; Fagus Castanea, L. (Eng. Bot. 886.) Monac. Polyan. L. and Amentaceæ, J.* It is the *Châtaignier* of the French; *Castanienbaum* of the Germans; and *Castagno* of the Italians. It is one of the most magnificent of European trees, exceeding the oak in height, and equalling it in bulk and extent. It is doubtful whether it be a native of Britain, though it ripens its fruit in sheltered valleys even in Scotland. It seems a very long-lived tree, of which the best proof is the specimen on Mount Etna, two hundred and four feet in circumference. Boucher says, the shade of the chestnut, like that of the ash, is injurious to other plants. The leaves which continue late in autumn are not liable to be eaten by insects like those of the oak. The Spanish chestnut has been already described as a fruit-tree. (4745.) As a timber-tree it is used for the same purposes as the oak; though by some considered as more brittle when old. The roof of Westminster Abbey, and that of the Parliament House in Edinburgh, with many other antient works, are said to be constructed of it; but considering that it is not a native tree, this is extremely improbable; and it is much more rational to suppose, with Professor Martyn and Daines Barrington, that what is by many taken for chestnut, is only oak of a different grain. It is used by the cabinet-maker and cooper; makes an excellent coppice-tree for poles and hoops; the bark is equal in astringency to that of the larch and mountain-ash for tanning; and the leaves and nuts afford food both for men and deer.

7095. *Soil and situation.* The soil in which it thrives best is a deep sandy loam, and the situation one somewhat sheltered. In Calabria, and on the Apennines between Florence and Bologna, where we have seen it in abundance, it does not attain a great size on the higher and more exposed parts of those mountains, but is, as Sang observes, a surprisingly magnificent tree in the hollows. Pontey says, "on sandy soils, where the oak would make but slow progress, I have seen the chestnut grow extremely quick, and therefore, in such cases, the latter should be used instead of the former."

7096. *The walnut (Juglans regia) has been already treated of as a fruit-tree. (473.)* Its timber, when of mature age, is valuable as a cabinet wood, and for gun-stocks, being light, hard, and durable.

7097. *The common sycamore is the Acer Pseudo-platanus, L. (Eng. Bot. 303.) Polyg. Monac. L. and Acereæ, J.* It is one of our hardiest native trees, and equal in magnitude with, though more tame in its outline and form than, the oak. It flowers in April and May, and ripens its keys or seeds in November. Its foliage is earlier than that of most trees, and its decadence is next to that of the ash. It is a quick grower, will endure the sea-breeze better than most trees, and is not liable to grow to one side when exposed to winds that blow chiefly in one direction.

7098. *Use.* The timber is chiefly used by the turner and millwright, and formerly, when earthenware was less common, it was in great request for trenchers and other table and household utensils. It affords a saccharine juice, like the sugar and other American maples, from which a wine may be made.

7099. *The Norway maple (A. platanoides) is a tree common in the native woods of Lithuania; and in Norway it clothes the hills from the sea-shore to their summits. It grows to a large size, and its leaves die to a golden color. Its timber does not differ materially from that of the sycamore.*

7100. *Soil and situation.* Both thrive best in a soil similar to that preferred by the ash, but will grow in all inferior soils, and exposed to the sea-breeze as well as at a great height above the level of the sea.

7101. *The mountain ash* is the *Pyrus aucuparia*, E. B. (*Eng. Bot.* 337.) *Icos. Di-Pentag.* L. and *Rosaceæ*, J. It is a low and very hardy native tree, attaining the height of twenty or thirty feet, with a straight, clean, erect stem, and globular compact head. It flowers abundantly in April and May, and ripens its berries in August or October, according to the situation.

7102. *Use.* In profitable planting it is chiefly valuable as a nurse-tree, growing very fast when young, and enduring the most severe exposures. The timber is used by wheelwrights, and for other common country purposes: the bark is used by tanners; and the berries afford a dye. As an undergrowth it affords tolerable poles and hoops.

7103. *Soil and site.* It will grow in any soil, dry or wet; and as to situation, it is found on the sea-shore, and near the tops of the highest mountains. It seems to thrive best on the sides of most rocky dells and dingles.

7104. *The whitebeam-tree* (*Pyrus aria*) (*Eng. Bot.* 1858.) is a very hardy native tree, growing to the height of thirty or forty feet, with an erect stem. Its uses and culture are the same as those of the mountain-ash. Its white leaves, and coral berries mealy to the taste like those of *Pyrus torminalis* (4768.), have a fine effect in autumn.

7105. *The acacia, or locust-tree.* — *Robinia pseud-acacia*, L. (*Schmidt. arb.* 1. t. 32.) *Diadelph. Decan.* L., and *Leguminosæ*, J. This is a thorny fast-growing tree, of middling stature, a native of America, of no great beauty as a tree, but ornamental when young, and very well adapted for copse-wood and rough timber. It flowers in June and July, and ripens its seeds in September. The leaves come out late in spring, and fall off early in autumn like those of the ash.

7106. *Use.* The timber is much valued in North America, and said to be superior to that of the laburnum; "being close-grained, hard, and finely veined; and in America more valued by the cabinet-maker than any other native timber whatever. Pursh, in his late valuable *Flora*, asserts, that being nearly incorruptible, it is equally useful for posts and gates. We are informed by a friend, that gate-posts of this timber, on a property near Baltimore, have remained fresh for nearly a century. The finely pinated leaves, and pendulous white odoriferous flowers, add greatly to its beauty. Its value is scarcely known in this country." (*Caled. Mem.* ii. 414.)

7107. *Soil and site.* It prefers a deep sandy soil, and rather sheltered situation; being very apt to throw up suckers from the running roots, and as it stoles freely, it seems peculiarly calculated for copice-woods. Beatson (*Com. to Board of Agr.*) has cultivated it in this way to great advantage.

7108. *The birch* is the *Betula*, L. *Monæc. Poly. L.* and *Amentaceæ*, J. *Bouleau*, Fr.; *Birichenbaum*, Ger.; and *Betulla*, Ital. There are two species which may be considered valuable as timber-trees. The common birch (*B. alba*, var. *pendula*) (*Eng. Bot.* 2198.) is a middle-sized native-forest tree, distinguished by its white bark, fragrant leaves, and graceful pensile form. It grows in the coldest regions of the north, and farther up the sides of the British mountains than any other timber-tree. In the swampy grounds of Sweden and Russia it grows to a much greater size than in the more temperate climate of this country. It is of importance to cultivate the pendulous variety as a taller and more rapid-growing tree independently of its variety.

7109. *The American birch, mahogany-birch, mountain mahogany, or cherry-birch of Canada*, is the *B. lenta*. (*Mich. arb.* 2. p. 145. t. 4.) (*fig.* 675.) This is a more lofty tree than the common birch, with a brown-colored bark spotted with white. "It abounds most in the middle states of Pennsylvania, New York, and the Jerseys, where it attains a height of seventy feet; but disappears altogether in the higher latitudes of the northern states, and is scarcely to be found in Nova Scotia. It is therefore likely to succeed with us in the moist and deeper soils of our Highland valleys, especially when closely associated with other trees. The probability of this is heightened by various facts already ascertained. The value of the timber is well known to our cabinet-makers; and we have seen tables, bed-posts, and other articles of furniture made of it, equalling in beauty those of mahogany, which it resembles, when some time exposed to the light, the newly wrought boards being of a rose-color. Although of an exceeding quick growth, the grain being naturally close, it takes a fine polish in cabinet-work. We add to this, that the leaves, which appear early in spring, are said to possess a peculiar fragrance, which they retain when dried by means of a stove, affording, on infusion of boiling water, an agreeable diluent, superior to some of the common teas of commerce." (*Caled. Mem.* ii. 380.)

7110. *The poplar-leaved birch* (*B. populifolia*) (*fig.* 676. a) and *Hudson's birch* (*P. Hudsonii*) (*fig.* 676. b) are elegant rapid-growing trees, and when once they are so common as to be propagated from seed, will deserve culture as timber-trees.

7111. *Use.* The timber of the common birch in England is chiefly used as fence-wood, fuel, and occasionally for harrows, &c. and other agricultural implements, the tree being most frequently planted as a nurse to others for coppice or variety. This tree, like the mountain ash, will grow in almost every kind of soil and situation.

7112. *The wild cherry* is the *Prunus avium*, L. (*Blackw.* t. 425.) *Icos. Di-Pentag.* L. and *Rosaceæ*, J. *Guigne*, Fr.; *Wild Kirschen*, Ger.; and *Ciriegio Silvatico*, Ital. It is a native tree above the middle size, the timber of which is of considerable value. It thrives best in dry sandy loams; and in such situations, Sang observes, its timber becomes of most value. It is of peculiar beauty in spring when in flower, in August

when in fruit, and in autumn when its leaves change to a beautiful red and yellow. Its timber is chiefly used by the cabinet-maker and chair-maker.

7113. *The tree-laburnum.* — *Cytisus alpinus*, W. en. (*Bot. Mag.* 176.) *Diadelph. Decan.* L. and *Leguminosæ*, J. It is a low tree, a native of Switzerland, cultivated chiefly for ornament, but affording also a valuable timber. For this purpose the variety or species (*C. alpinus*), with broad leaves and long racemes, is decidedly to be preferred, as being much more of a tree than the other. Sang says, it has a full claim to the characters of useful and ornamental; is beautiful when in flower, and may, in a grove, be trained to a fine stem of very considerable size.

7114. *Use.* The timber (the false ebony of the French) is much prized by cabinet-makers and turners, for its hardness, beauty of grain, and durability. The tree is frequently sown in plantations infested with hares and rabbits, who will touch no other tree as long as a twig of laburnum remains. "Though eaten to the ground in winter," as Boucher observes, "it will spring again next season, and thus afford a constant supply for these animals, so as to save the other trees till of a size to resist their attacks. The timber has been sold for upwards of half a sovereign per foot." It becomes most valuable in light loams and sandy soils.

7115. *The holly* is the *Ilex aquifolium*, L. (*Eng. Bot.* 496.) *Pent. Monog.* L. and *Rhamn.* J. *Houx*, Fr.; *Schbaum*, Ger.; *Agrioglio*, Ital. It is an elegant, shining, evergreen tree, rising from twenty to thirty feet high, affording a timber of considerable value, and much in use as an ornamental hedge plant. It is a native of Britain, of great longevity, and found growing in woods and forests, as an undergrowth to the oak, beech, ash, and fir. It thrives best in a free deep loam, rather light, as in Needwood Forest, in Staffordshire, and the fir-forest of Blackhall, near Aberdeen. It is a cheerful-looking tree from its shining leaves and coral berries, and peculiarly fit for ornament.

7116. *Use.* The timber, which is as white as ivory, is chiefly used in inlaying and veneering, and by turners and mathematical-instrument-makers. The straight shoots, of five and six feet in length, make excellent coachmen's whips. Birdlime is made from the bark by washing and separation of the woody fibre. Sheep and deer eat the croppings. It is the best of all hedge plants. It thrives best in cold loamy soils, and rather sheltered situations.

7117. *The hazel* (*Corylus avellana*), already treated of as a fruit-shrub (4752.), forms a hardy useful undergrowth in most situations, supplying hoops, crate-ware, basket-stuff, walking-sticks, rods, poles, withies, fence-wood, fuel, &c.; besides the fruit, where the soil is tolerable, is worth something, and an excellent charcoal is made from the stack-wood.

7118. *The box-tree* (*Buxus sempervirens*, L. (*Eng. Bot.* 1341.) *Monac. Tetr.* L. and *Euphorbiacæ*, J. *Buis*, Fr.; *Buchsbaum*, Ger.; and *Bosobo*, Ital.) has some claims to attention as a valuable timber, being in considerable demand for inlaying, turnery, mathematical instruments, and wood-engravers' blocks. It thrives in any light soil and under the drip of trees. Raised from the seed it will attain the height of twenty or twenty-five feet, and be fit to cut down in thirty years. (*Miller's Dict.* in loco.) As an ornamental undergrowth and edging plant, it is of the greatest value.

7119. *The elder-tree* (*Sambucus nigra*), already treated of as a fruit-tree (4627.), forms an excellent nurse-plant in exposed situations, and a rapid hedge in most places. The wood is very hard, and used by the toy-makers and turners. When grown as a nurse, or for timber, it should always be raised from the seed.

7120. *The hawthorn.* — *Crataegus oxyacantha*, E.B. (*Eng. Bot.* c. ic.) *Icos. Di-Pentag.* L. and *Rosacæ*, J. *Aubépine*, Fr.; *Hagedorn*, Ger.; *Branco spino*, Ital. It is a native shrub, of great importance as a hedge plant, and is also frequently introduced into narrow plantations as an undergrowth. It will not grow, however, under the drip of trees, and therefore, in a profitable point of view, is only to be considered as affording the impermeable, close, durable, and easily raised fences, called quickset-hedges. The timber of such plants as grow singly, and attain a tolerable size, is valued by the millwright and turner, and the roots by the cabinet-maker. It is often spoiled, Sang observes, through inattention after cutting; if it be allowed to lie in entire logs or trunks, it soon heats, and becomes quite brittle and worthless; it therefore ought to be instantly cut up into planks, and laid to dry. The haws and foliage afford excellent food for deer.

7121. *Soil and site.* It will not thrive in a wet soil, nor one very dry and poor, much elevated or much shaded; a free deep loam in an airy situation suits it best. For hedges it may be raised from cuttings of the roots, planted where they are finally to remain. Such cuttings are only to be procured in quantities

where an old hedge is to be removed, and the labor of selecting and preparing them falls little short of the price of good two-year seedling plants; so that unless in a season when thorn-plants are scarce and dear, few advantages attend this practice.

7122. *The yew* is the *Taxus baccata*, L. (*Eng. Bot.* 746.) *Polyg. Monœc. L.* and *Conifera*, J. If, Fr.; *Eichenbaum*, Ger.; and *Tasso*, Ital. It is a low, bush-like, dark, evergreen tree, of great longevity, slow in growth, and affording a hard, white, valuable timber. It flowers in April and May, and its berries are ripe in November. It is found in a wild state in bleak situations, and on a variety of soils, dry and moist. It is very common in ancient churchyards, in many of which it has attained a great size and age. Evelyn, and after him, Professor Martyn, have referred to a great number of examples of notable trees of this species.

7123. *Use.* The timber is used by the cabinet-maker for inlaying, and by the mathematical-instrument-maker, and whipmaker. It is sometimes used as a substitute for box and other hard woods, and every one knows it was formerly used for bows, and the spray as palm-leaves by the ancient Christians. It forms one of the best hedge plants for gardens, topiary work, &c. and for this purpose was much employed when the geometric style of gardening prevailed.

7124. *Soil and situation.* Almost any soil, not over-wet, will suit the yew, and it will grow on the bleak sides of mountains, and under the drip of trees.

SECT. III. Soft-wooded Trees.

7125. *The soft-wooded timber-trees* may be considered as characterised by great rapidity of growth, comparatively limited duration, and timber of inferior value.

7126. *The horse-chestnut* (*Æsculus hippocastanum*, L. (*Schmidt. arb.* 1. t. 38.) *Hep-tand. Monog. L.* and *Aceres*, J. *Marroniers*, Fr.; *Marronienbaum*, Ger.; and *Marrone*, Ital.) is a magnificent and beautiful tree, when in May it is covered with its digitate foliage, and fine large spikes of white flowers. It is of rapid growth, and speedily produces a considerable bulk of timber, which, however, is of no great value. Being highly ornamental as a single tree, and in the outskirts of plantations, it need never be planted in masses for timber. It was brought from the northern parts of Asia into Europe, about the year 1550, and was cultivated by Gerrard and Tradescant. As Gilpin observes, it is far from being a picturesque tree, its outline being that of a parabola: but all beauty is not picturesque beauty, and the foliage and flowers will ever advocate the cause of this tree, (which the Hon. D. Barrington compares to a giant's nosegay,) though "its leaves begin to drop early in summer, and make a litter around the trees during the remainder of the season."

7127. *Soil and situation.* It requires a good, rather dry soil, and suffers materially from storms of every kind when planted in exposed situations. It used formerly to be much used as an avenue tree, especially by the French, and is particularly adapted for this purpose, and the margins of plantations.

7128. *The lime.* — *Tilia Europæa*, L. (*Eng. Bot.* 610.) *Polyand. Monog. L.* and *Tiliaceæ*, J. *Tilleul*, Fr.; *Lindenbaum*, Ger.; and *Tiglio*, Ital. This is one of the most beautiful, graceful, and fragrant of our native trees, rising to the height of seventy or eighty feet, and finely clothed with pendulous recurved branches, from the ground or the browsing line formed by cattle upwards. It is found wild in woods and grassy declivities, sends out its leaves in April, flowers in May, and ripens its seeds, though sparingly, unless under favorable circumstances, in October.

7129. *Use.* It was much valued by the Romans for its shade, and the multiplicity of purposes to which the timber was applied. It is now more a tree of ornament than of profit, but the timber is still used for various common purposes in general economy, and by the carver; turner, and musical-instrument-maker. It forms an excellent charcoal for gunpowder; and of its inner bark, macerated in water, is formed, in the north of Europe, the bass mats of commerce. This bark is called in Sweden and Russia, *bast*, whence, by corruption, *bass*. It is the fittest of all trees for avenues, and forms good tree-hedges. The famous Kowno honey is made exclusively from the blossom of this tree.

7130. *Varieties and species.* There are several sorts noticed in our *Encyclopædia of Plants*, but the best, both for effect and timber, is the red-twigged (*T. Eu. var. corallina*), and the broad-leaved American (*T. Americana*), which is a distinct species, distinguished by the larger size of the leaves, and elegant pendulous flowers.

7131. *Soil and situation.* All the sorts prefer a deep loam, and rather sheltered situation, for though patient of cold, they are much injured by storms. In Sweden, the common species abound among the *débris* of granite and trap rocks; and in Russia it covers extensive tracts of deep, soft, black earth. In bleak situations, where it is not covered by snow in winter at the roots, or sheltered by other trees, it will not thrive.

7132. *The alder* (*Alnus glutinosa*, W. (*Eng. Bot.* 1505.) *Monœc. Tetrand. L.* and *Amentaceæ*, J.) is a middle-sized native aquatic tree of no great value, either as timber or ornament farther than that it will grow where few other trees will thrive, excepting the birch, poplar, and willow. It flowers in May, and ripens its seeds in September and October.

7133. *Use.* The timber is used in water-works, and by the turner, millwright, lastmakers, and others, as well as for common country purposes, and charcoal.

7134. *The poplar.* — *Populus*, W. *Diœc. Dodec. L.* and *Amentaceæ*, J. *Peuplier*, Fr.; *Poppelbaum*, Ger.; and *Poppio*, Ital. There are several species which may be reckoned timber-trees.

7135. *The abele-tree, P. alba.* (Eng. Bot. 1618.) (fig. 677. a) The variety called the hoary poplar is distinguished from the common wild abele by its larger three, four, or five lobed leaves, dark above and downy under, and by the young shoots having a purple bark covered with white down. It is a rapid-growing tree, speedily attaining great bulk of timber, a height of 60 or 70 feet, and great extent of branches. The *P. vistulensis* seems a variety of this tree; and on the banks of the Vistula, particularly at Villeneuve, near Warsaw, grows to upwards of 100 feet high, with a clean trunk and ample head.

7136. *The common black poplar (P. nigra)* (Eng. Bot. 1910.) (fig. 677. b) is a native tree, of lofty growth, distinguished by its light-green leaves, lightly notched on the edges, and ash-colored bark. It is, by some, considered a mere variety of the alba, and for the purposes of profit may be so considered.

7137. *The trembling poplar (P. tremula)* (fig. 677. c) and *the common poplar (P. canescens)* (d) are hardy natives; but being of less rapid growth than the species mentioned, are little cultivated as timber-trees. The common poplar in the northern counties may be frequently seen in a pollard state in hedges, where it furnishes lop for fuel, and sometimes for handles to hay-rakes, &c.

7138. *The Lombardy poplar (P. dilatata)* grows to a lofty tree, occupies little space, and is not very injurious by its shade. It will not thrive, however, in exposed situations, or in very indifferent soils. Some of the largest trees of this species are at Blenheim. Sang and Nicol say it seldom thrives in Scotland.

7139. *The black Italian poplar (P. dilatata, var.)* of the northern nurseries, so strongly recommended by Pontey, is thus described by him, by comparison with a Lombardy poplar. "The leaves of both are very much alike in color, shape, and turn, the only difference being in the latter producing them somewhat larger than the former, though not near so large as the other poplars, whose leaves are of similar shape. The branches of the latter grow much less erect, and likewise much thinner upon the stem. The only other distinction necessary is the bark, which, on a stem or branch of from two to four or five years' growth, is always found smoother, and of a much darker color than any of the poplars that are at all like it in other respects." He says it was first sent to Scotland from America, and disseminated by Dicksons and Co. of Hassendean-burn. Sang says, "many have ventured to assert, that it is merely a play on the vanity of possessing new sorts, and that it is not really distinct from those formerly cultivated." Pontey says, he measured, in December, 1813, "a tree growing in the garden of Richard Atkinson, of Huddersfield, which has been planted twenty-five years, being then about six feet high; the height is now about sixty feet, and contains forty-six feet of good timber. It grows on the side of a garden where the soil is light, and about a foot deep, upon a very coarse gravel, having been formerly a water-course." We could never find any poplar in general cultivation, or wild, in Italy, but the Lombardy and alba, and occasionally in elevated moist places in the Alps and Apennines, the tremula.

7140. *The black Athenian (P. græca), black American or birch-leaved (P. betulifolia), the Canadian (P. monilifera), and Carolina poplars (P. angulata),* are all rapid-growing lofty trees, which, in favorable soils and sheltered situations, speedily produce great bulk of head and timber; but the hoary and the black Italian appear the best for the general purposes of the profitable planter. They are all short-lived trees; flower in March and April, and ripen their seeds from a fortnight to a month afterwards.

7141. *Use.* The wood being soft is used by the sculptor, tanner, and toymaker, and also occasionally by the cabinet and musical-instrument maker, as a substitute for that of the lime. But no limited application of poplar-timber, like the above, can be depended on by the profitable planter, and, therefore, the safest way is to consider it as useful for the common purposes of domestic and rural economy, and more likely to afford profit from bulk than quality. The bark of the black is so astringent, Sang states, as to be used for tan. Alluding to the black Italian sort, Pontey says, "In that sort of planting which perhaps may be considered as most of all profitable, namely, that which adds to the comfort and consequence, and, of course, the value of a place, previously scantily furnished with that important appendage, wood, this tree is excellent; as, in judicious hands, it may be made to produce very considerable effects, while many others (highly esteemed) would produce them in prospect only. In short, for distant scenery, where wood, not species, is the immediate object, this plant, hitherto in many places a stranger, is clearly superior to all the family of the forest." Of the timber of the hoary poplar, he says, Lord Sheffield "has lately made some floors, which, in appearance, are superior to any floor I have seen, whether of deal or oak; and, as to durability, I see no reason to doubt of that, if the density and weight of the article be considered, in connection with such testimonies as books afford relative to the point. Floors, however, are only one of the many inferior purposes for which it is applicable; as it is certainly proper for almost every article of furniture usually made of mahogany. For the lighter descriptions of it, now so fashionable, it may be made a very good substitute, without any other addition to the natural color of its heart than the means cabinet-makers generally resort to, in order to heighten the color of such wood; and with respect to the sap, and where more of color is required, the aquafortis stain will instantaneously produce it, so far as that it would be difficult to distinguish it from real mahogany. Indeed, it is equal to the best in color and smoothness of surface, and much superior to the plain or inferior sorts in those respects, as well as in transparency and variety; and it has the further advantage over mahogany, and most other woods, that it takes but little of either oil or rubbing, to produce upon it the sort of mellow shining surface, so much admired in furniture that has been some years subjected to proper attention." Of poplars and willows in general, he observes, "were we but half as well apprised of the various purposes to which their timber might be properly applied, as we are of the quickness of their growth, I am persuaded they would then be considered as subjects worthy of general attention."

7142. *Natural soil and situation.* None of the sorts mentioned are ever found wild in very poor soils, but generally in such as are deep and moist, but not springy; by rivers and in bottoms, where the soil has accumulated from the surrounding heights, or alluvial deposits have taken place, for ages, poplars are found in the greatest perfection.

7143. *The willow.* — *Salix*, L. *Diæc. Monan.* L. and *Amentaceæ*, J. *Saule*, Fr.; *Weidenbaum*, Ger.; *Salici*, Ital. There are two species which seem more immediately to merit cultivation as timber-trees, and several as fit for cultivating in osier-grounds.

7144. *The Huntingdon or common white Lincolnshire swallow-tailed willow (S. alba)* (Eng. Bot. 2490.) (fig. 678.) grows to a lofty tree, with a branchy stem, and tapering flame-shaped head. It seems common to Europe, being found pollarded by way-sides in Sweden, the south of Russia, and Italy. As a timber-tree it produces a great bulk in a short time; and as a pollard or coppice wood, on suitable soils, it is prolific in fuel, poles, and bark for the tanner.

7145. *The Upland, or red-twigged willow of Pontey (Profit. Plant. 72.)*, appears to be a variety of the *S. alba*, being distinguished from it by its hoary or silver-like leaves, and deep red shoots. The timber and mode of growth appear to be the same as those of the Huntingdon willow, but being of slower growth, the former is to be preferred. Of the red-twigged willow of Sang, there are large trees near Dunfermline, upwards of 60 feet high.

7146. *The Bedford willow (S. Russelliana)* (Eng. Bot. 1808.) (fig. 679.) is also a lofty bulky-headed tree, in general appearance and habits very much resembling the *S. alba*.
